Introduction

Chapter 1

Introduction to the DS2 Language .......................... 3
Chapter 1
Introduction to the DS2 Language

Introduction to the DS2 Language
DS2 is a new SAS proprietary programming language that is appropriate for advanced data manipulation. DS2 is included with SAS Visual Data Mining and Machine Learning and intersects with the SAS DATA step. It also includes additional data types, ANSI SQL types, programming structure elements, and user-defined methods and packages.

In addition, DATA step logic can be transformed to run in the SAS Embedded Process where DS2 is supported and the DATA step is not.

The DS2 procedure enables you to submit DS2 language statements from a SAS Studio session. For more information about PROC DS2, see SAS Viya Data Management and Utility Procedures Guide. In addition, you can use the runDS2 action to prepare and execute a DS2 program. For more information about the runDS2 action, see SAS Cloud Analytic Services: System Programming Guide.

Note: Because the DS2 language can be used with many data sources, the terms row, column, and table are used to describe the data elements. When you compare this to SAS DATA step terminology, a row corresponds to an observation, a column corresponds to a variable, and a table corresponds to a data set.

Running DS2 Programs
You can submit DS2 programs in one of the following ways.
• In SAS Studio using the DS2 procedure. The DS2 procedure can be used to run DS2 code in Viya or in the CAS server. A single PROC DS2 step can contain several DS2 programs.

For more information, see “DS2” in SAS Viya Data Management and Utility Procedures Guide.

• In SAS Studio using the runDS2 action in the CAS server. The runDS2 action is used in conjunction with the CAS procedure.

Note: Unless you are using Python or Lua, it is recommended that you use PROC DS2 to submit DS2 code to the CAS server.

For more information, see “Run program” in SAS Cloud Analytic Services: System Programming Guide and “DS2 in CAS” in SAS Viya: DS2 Programmer’s Guide.

### Supported Data Sources

DS2 can access the following data sources:

• Hadoop (Hive)
• Impala
• ODBC-compliant databases (such as Microsoft SQL Server)
• Oracle
• PC Files
• PostgreSQL
• SAS data sets
• Teradata

Note: The following data sources are not supported:

• Aster
• DB2 for UNIX and PC operating environments
• Greenplum
• Informix
• Memory Data Store (MDS)
• MySQL
• Netezza
• OLEDB
• SAP (Read-only)
• SAP HANA
• SAS Scalable Performance Data Engine (SPD Engine) data set
• SQL Server
• Sybase
• Sybase IQ
• Vertica
Intended Audience

The information in this document is intended for the following users who perform in these roles:

- **Application developers** who write the client applications. They write applications that create tables, bulk load tables, manipulate tables, and query data.

- **Database administrators** who design and implement the client/server environment. They administer the data by designing the databases and setting up the data source metadata. That is, database administrators build the data model.

- **SAS programmers** who want or need to take advantage of the features of the DS2 language.

When to Use DS2

You do not necessarily have to convert your DATA step programs to DS2. Typically, DS2 programs are written for applications that carry out the following actions:

- require the precision that results from using the new supported data types
- benefit from using the new expressions or write methods or packages available in the DS2 syntax
- take advantage of threaded processing

Syntax Conventions for the DS2 Language

**Typographical Conventions**

Type styles have special meanings when used in the documentation of the DS2 language syntax.

**UPPERCASE BOLD**
identifies DS2 keywords such the names of statements and functions (for example, PUT).

**UPPERCASE ROMAN**
identifies arguments and values that are literals (for example, FROM).

**italic**
identifies arguments or values that you supply. Items in italic can represent user-supplied values that are either one of the following.

- nonliteral values assigned to an argument (for example, ALTER=alter-password).
- nonliteral arguments (for example, KEEP=(column-list)).

If more than one of an item in italics can be used, the items are expressed as item [, … item].
identifies examples of SAS code.

### Syntax Conventions

*SAS Viya: DS2 Language Reference* uses the Backus-Naur Form (BNF), specifically the same syntax notation used by Jim Melton in *SQL:1999 Understanding Relational Language Components*.

The main difference between traditional SAS syntax and the syntax that is used in the DS2 language reference documentation is in how optional syntax arguments are displayed. In traditional SAS syntax, angle brackets (<> ) are used to denote optional syntax. In DS2 language syntax, square brackets ([ ]) are used to denote optional syntax and angle brackets are used to denote non-terminal components.

The following symbols are used in the DS2 language syntax.

- `::=` This symbol can be interpreted as “consists of” or “is defined as”.
- `<>` Angle brackets identify a non-terminal component (that is, a syntax component that can be further resolved into lower level syntax grammar).
- `[ ]` Square brackets identify optional arguments. Any argument that is not enclosed in square brackets is a required argument. Do not enter square brackets unless they are preceded by a backward slash (\), which denotes that they are literal.
- `{ }` Braces provide a method to distinguish required multi-word arguments. Do not enter braces unless they are preceded by a backward slash (\), which denotes that they are literal.
- `|` A vertical bar indicates that you can choose one value from a group. Values that are separated by bars are mutually exclusive.
- `…` An ellipsis indicates that the argument or group of arguments that follow the ellipsis can be repeated any number of times. If the ellipsis and the following arguments are enclosed in square brackets, they are optional.
- `\` A backward slash indicates that the next character is a literal.

The following examples illustrate the syntax conventions that are described in this section. These examples contain selected syntax elements, not the complete syntax.

1. `SET <table-reference> [INDSNAME=variable];`  
   - SET is in uppercase bold because it is the name of the statement.
   - `<table-reference>` is in angle brackets because it is a non-terminal argument that is further resolved into lower level syntax grammar. You must supply at least one `<table-reference>`.
   - BY and DESCENDING are in uppercase roman because they are literal arguments. DESCENDING is in square brackets because it is an optional argument.

2. `|table-reference| ::= {table (table-options)} | sql-text |`  
   - `|` A vertical bar indicates that you can choose one value from a group. Values that are separated by bars are mutually exclusive.

3. `<table-reference>`...
column is in italics because it is an argument that you can supply.

The square brackets and ellipsis around the second instance of column indicate that you can repeat this argument any number of times as long as the arguments are separated by commas.

The <table-reference>::= non-terminal argument syntax is read as follows: A <table-reference> consists of a table name and table options or embedded SQL text.

The vertical bar (|) indicates you can supply either table [table-options] or sql-text, but not both.

The backslash (\) before the braces around sql-text indicate that those braces are literals and must be entered.

Chapter 2
DS2 and the DATA Step

What Is DS2?

DS2 is a SAS proprietary programming language that is used for data manipulation and data modeling applications. The DS2 language shares core features with the DATA step. However, DS2 capabilities extend far beyond those of the DATA step.

DS2 is a procedural language that has variables and scope, methods, packages, control flow statements, table I/O statements, and parallel programming statements. Methods and packages give DS2 modularity and data encapsulation. DS2 enables you to insert SQL directly into the SET statement, thus blending the power of two powerful data manipulation languages.

Similarities between DS2 and the DATA Step

DS2 and the DATA step share many language elements, and those elements behave in the same way:

- SAS formats.
- SAS functions.
- SAS statements such as DATA, SET, KEEP, DROP, RUN, BY, RETAIN, PUT, OUTPUT, DO, IF-THEN/ELSE, Sum, and others.
- DATA step keywords are included in the list of DS2 keywords.

You can perform most DATA step tasks using DS2:

- process variable arrays, multi-dimensional arrays, and hash tables
- convert between data types
- work with expressions
- calculate date and time values
• process missing values

Note: All supported DS2 syntax is covered in this document. Any syntax appearing in other SAS documentation is not part of the supported DS2 syntax unless it is also documented here.

## Differences between DS2 and the DATA Step

### Table 2.1  Comparison by Topic

<table>
<thead>
<tr>
<th>Topic</th>
<th>DATA Step</th>
<th>DS2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Programming paradigm</td>
<td>Executable code resides in the DATA step and PROC step.</td>
<td>Executable code resides in methods.</td>
</tr>
<tr>
<td>Scope</td>
<td>No concept of scope. All variables are global.</td>
<td>Variables that are declared in a method have local scope. All other identifiers have global scope.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>There are three types of global scope:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• data program</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• thread program</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• package</td>
</tr>
<tr>
<td>Declaring variables</td>
<td>Variables are not explicitly declared. Variables are created by assignment. The data type of a variable is determined by the context of how it is first used. All variables have global scope. Variables are also defined when the SET statement is used.</td>
<td>Variables are declared using the DECLARE statement, which also determines the data type and scope attributes of the variable. Variables can be declared by assignment, but a best practice is to enforce variable declaration strict mode by setting the system option DS2COND=ERROR or the PROC DS2 option SCOND=ERROR. Global variables are also defined when the SET or SET FROM statement is used.</td>
</tr>
<tr>
<td>Keywords and reserved words</td>
<td>No reserved keywords.</td>
<td>Keywords are reserved words.</td>
</tr>
<tr>
<td>Quotation marks</td>
<td>Single or double quotation marks can delimit a character constant. Here are two examples that are equivalent: &quot;Tom&quot;</td>
<td>ANSI SQL quoting standards are followed:</td>
</tr>
<tr>
<td></td>
<td>'Tom'</td>
<td>• Single quotation marks delimit a character constant.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Double quotation marks delimit an identifier.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, &quot;Tom&quot; is a delimited identifier, and 'Tom' is a character constant.</td>
</tr>
<tr>
<td>Topic</td>
<td>DATA Step</td>
<td>DS2</td>
</tr>
<tr>
<td>-------</td>
<td>-----------</td>
<td>-----</td>
</tr>
<tr>
<td>PUT statement</td>
<td>Supports column and line parameters.</td>
<td>Column and line parameters are not supported. Dot notation parameters are not supported.</td>
</tr>
<tr>
<td>Variable attributes</td>
<td>Establishing the attributes of a variable requires the use of the LENGTH, FORMAT, INFORMAT, LABEL, and ATTRIB statements.</td>
<td>Establishing the attributes of a variable requires only the DECLARE statement and its HAVING clause.</td>
</tr>
<tr>
<td>Text that is resolved from macro variable references</td>
<td>Double quotation marks are required to reference the resolved value of a macro variable. Here is an example: my_host = &quot;&amp;syshostname&quot;;</td>
<td>Because ANSI SQL quoting standards are followed, double quotation marks denote delimited identifiers. To reference a macro variable in a literal string, use the %TSLIT macro function. Here is an example: my_host = %tslit(&amp;syshostname);</td>
</tr>
<tr>
<td>Data types</td>
<td>Two data types are supported: numeric and character. Numeric data is signed, fractional, limited to 8 bytes, and has approximate precision. Character data is fixed length.</td>
<td>Most ANSI SQL data types are supported. Numeric types of varying sizes and precision. Character data types can be fixed length and variable length. DS2 supports ANSI date, time, and timestamp data types, but can also process SAS date, time, and datetime values using conversion functions.</td>
</tr>
<tr>
<td>Missing and null values</td>
<td>Supports only missing values. No concept of a null value.</td>
<td>Supports both missing and null values. Nulls, from a database, can be processed in ANSI mode or in SAS mode.</td>
</tr>
<tr>
<td>Automatic data type conversion</td>
<td>SAS tries to convert between character and numeric data types when one data type is assigned to a variable of the other data type.</td>
<td>Has many more rules because of many more data types. Most data types are coercible. DATE, TIME, TIMESTAMP, BINARY, and VARBINARY data types are not coercible.</td>
</tr>
<tr>
<td>SQL language statements</td>
<td>Available in PROC SQL, not in the DATA step. Operates only on SAS data sets as tables.</td>
<td>SQL SELECT statements can be written directly in and used as input for a DS2 SET statement. In addition, the SQLSTMT predefined package provides a way to pass SQL statements to a DBMS for execution and to access the result set returned by the DBMS.</td>
</tr>
</tbody>
</table>
The DATA step can interact with a macro at run time (for example, CALL EXECUTE, SYMGET, and CALL SYMPUT).

When DS2 runs inside a Base SAS session (for example, in PROC DS2), SAS macros are available. SAS macro support is not available when DS2 runs in the SAS Federation Server and in grid computing environments such as the in-database SAS Embedded Process, the High-Performance Analytics grid, and the In-Database Code Accelerator.

The DATA step, like SAS procedures, overwrites an existing data set.

In keeping with SQL and database standards, DS2 does not automatically overwrite existing data sets. You must use the `overwrite` option. Here is an example.

```sas
proc ds2;
  data one;
    method run();
    set two;
    end;
  enddata;
  run;
  data one / overwrite=yes;
    method run();
    set three;
    end;
  enddata;
  run;
quit;
```
<table>
<thead>
<tr>
<th>Topic</th>
<th>DATA Step</th>
<th>DS2</th>
</tr>
</thead>
</table>
| Reading from and writing to the same data set | Permits reading from and writing to the same data set name in a DATA or PROC step.  
*data one;  
  *set one;  
  *s = s + 1;  
  *run;* | DS2 does not allow reading from or writing to the same table in a single data program. In database fashion, the user must create a temporary table, drop the original table, and then rename the temporary table. This example is equivalent to what the SAS System does to implement the appearance of reading from and writing to the same data set at the successful conclusion of a DATA or PROC step.  
*proc ds2;  
  *data temp001;  
    *method run();  
    *set one;  
    *s = s * 1;  
    end;  
    *enddata;  
    *run;  
    *quit;*  
*proc fedsql;  
  *drop table one;  
  *alter table temp001 rename to one;  
  *run;  
  *quit;* |

About the Getting Started Sample Programs

How to Run the Sample Programs

You can run all of the getting started sample programs in this chapter from a SAS session using the DS2 procedure. Each is a complete program; simply copy a program into your SAS session and submit it.

The getting started sample programs do not rely on a pre-existing data source, nor do they require a connection to a database. When data is needed, the program creates it.

Note: To submit the getting started sample programs, you must have access to SAS 9.4 or later. Some features might not be available if you do not have the latest release.

Recommended Options

All of the getting started sample programs run correctly with the following SAS system option global statement:

options DS2SCOND=ERROR;
You can also override the default DS2SCOND option setting, WARNING, by specifying the following DS2 procedure option:

```sas
proc ds2 SCOND=ERROR;
```

The ERROR setting enforces variable declaration strict mode. In strict mode, a compilation error occurs if you do not explicitly declare a variable.

**T I P** Variable declaration strict mode is the recommended best practice when writing DS2 programs.

Unlike Base SAS, DS2 protects existing tables from being overwritten. However, if you are developing or changing a table, package, or thread, you need the ability to overwrite these tables.

The OVERWRITE=YES table option enables you to overwrite the table. Here are some examples:

```sas
package foo /overwrite=yes;
thread work.foo(int x) /overwrite=yes;
data foo (overwrite=yes);
data my_data /overwrite=yes;
```

**T I P** The OVERWRITE= option requires the forward slash ( / ) syntax with the PACKAGE and THREAD statements. You can use either the / syntax or the parentheses syntax with the DATA statement.

By default, the value of the OVERWRITE= table option is NO.

### Using the DS2 Procedure

When you use the DS2 procedure to write a program, place your code within the following framework:

```sas
options ds2scond=error;
proc ds2;
... DS2 statements ... 
run;
quit;
```

For more information, see “DS2” in SAS Viya Data Management and Utility Procedures Guide.

### Verifying Access to DS2

In a SAS session, run the following program:

```sas
proc ds2;
quit;
```

The following is written to the log:

```
3317  proc ds2;
3318  quit;
NOTE: PROCEDURE DS2 used (Total process time):
  real time          0.08 seconds
  cpu time           0.04 seconds
```

If you see an error message, such as **ERROR: Procedure DS2 not found**, see your system administrator.
Your First Sample Programs

Overview of the Sample Programs

Because many programmers prefer to learn by reading code, this chapter presents several sample programs before explaining the language constructs that the programs use. The sample programs will help you quickly learn DS2 syntax and concepts so that you avoid common pitfalls.

The first sample program is the “Hello World!” program. Subsequent sample programs are variations on this program. Some variations might seem needlessly complex. The point is to demonstrate common structural programming elements of the DS2 language, not the best way to write the “Hello World!” program.

Note: Although the sample programs introduce syntax and concepts in order of increasing complexity, they do not rely on a particular order to be fully understood.

Example 1: “Hello World!” Program – In a System Method

Here is one way to code the "Hello World!" program. This program writes "Hello World!" to the SAS log from the INIT( ) system method.

What to Notice

• The variable MESSAGE has local scope because it is declared in the INIT( ) method.
• The INIT( ) system method automatically runs first in a DS2 data program.
• Single quotation marks delimit the character constant.
• The libs=work option limits the connection string to use only the SAS Work library. For more information, see the “PROC DS2 Statement” in SAS Viya Data Management and Utility Procedures Guide.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2 libs=work;
data _null_
    /* init() - system method */
    method init();
    declare varchar(16) message; /* method (local) scope */
    message = 'Hello World!';
    put message;
    end;
enddata;
run;
quit;
```

The following is written to the log:

```
Hello World!
```
Example 2: “Hello World!” Program – In a User-defined Method

This variation of the program writes "Hello World!" to the SAS log from a user-defined method.

What to Notice

- Because the variable MESSAGE has global scope in the data program, all methods can access it.
- The INIT( ) system method calls the user-defined GREET( ) method to write the message to the log.

  Note: The GREET( ) method is defined before the method that references it. Otherwise, a compilation error would occur.

In a SAS session, copy or enter the following program. Then, submit it.

```sas
proc ds2 lib=work;
data _null_;  
dcl varchar(16) message; /* data program (global) scope */  
/* greet() - user-defined method */  
method greet();  
  put message;  
end;  
/* init() - automatically runs first in the data program. */  
method init();  
  message = 'Hello World';  
  message = cat(message, '!');  
  greet();  
end;  
enddata;  
run;  
quit;  
```

The following is written to the log:

```
Hello World!
```

Example 3: “Hello World!” Program – In a User-defined Package

This variation of the program writes “Hello World!” and other messages to the SAS log through a user-defined package.
What to Notice

- The PACKAGE statement uses the OVERWRITE=YES table option so that you can run the program more than once without error. By default, DS2 protects existing packages from being overwritten.
- The variable MESSAGE is declared inside the package, not in the data program.
- The package contains a constructor and two package methods to manipulate the greeting string.

The FORWARD statement enables the SETMESSAGE() method to be defined after methods that reference it. Otherwise, a compilation error would occur.

The SETMESSAGE() method uses the THIS operator to distinguish the global variable MESSAGE from the parameter that is named MESSAGE.
- In the data program, the DECLARE PACKAGE statement simultaneously declares a package variable and constructs an instance of the package using the package constructor.
- Dot notation provides access to package methods from the data program.

In a SAS session, copy or enter the following program. Then, submit it.

```sas
proc ds2 libs=work;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
   dcl varchar(100) message;   /* package (global) scope */
   FORWARD setMessage;

   /* greeting(MESSAGE) - constructor */
   method greeting(varchar(100) message);
      setMessage(message);
   end;

   method greet();
      put message;
   end;

   method setMessage(varchar(100) message);
      /* Must use THIS. to distinguish global */
      /* variable MESSAGE from parameter named MESSAGE. */
      this.message = message;
   end;
endpackage;
run;

/* data program */
data _null_;
   /* declares and instantiates an instance of the GREETING package */
   dcl package greeting g('Hello World!');   /* data program (global) scope */

   /* init() - automatically runs first in the data program. */
   method init();
      g.greet();
      g.setMessage('What''s new?');   /* change greeting */
      g.greet();
   end;
enddata;
run;
```
The following is written to the log:

Hello World!
What's new?

Example 4: “Hello World!” Program – In the Implicit Loop

This variation contains two data programs: one to create a table of greetings and one to process the table.

What to Notice

- In the first data program, the DATA statement uses the OVERWRITE=YES table option so that you can run the program more than once without error. By default, DS2 protects existing packages from being overwritten.
- The GREETING package has two constructors: a default constructor and one that accepts an argument.
- The second data program uses the two-step method for instantiating a package:
  1. The DECLARE PACKAGE statement declares a global package variable.
  2. The INIT() method uses the _NEW_ operator to create the package instance. By using the [THIS] operator, the instance is also global.
- In the second data program, the RUN() method uses the implicit loop of the SET statement to read and process the MESSAGE variable from each row in the table.

In a SAS session, copy or enter the following program. Then, submit it.

```sas
proc ds2 libs=work;
/* data program # 1 - Creates a table of greetings */
data work.greetings /overwrite=yes;
dcl char(100) message; /* data program (global) scope */
method init();
  message = 'Hello World!'; output;
  message = 'What''s new?'; output;
  message = 'Good-bye World!'; output;
end;
enddata;
run;
quit;

proc ds2;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
dcl varchar(100) message; /* package (global) scope */
forward setMessage;

/* greeting() - default constructor */
method greeting();
  setMessage('This is the default greeting.');
end;
```
/* greeting(MESSAGE) - constructor */
method greeting(varchar(100) message);
    setMessage(message);
end;

method greet();
    put message;
end;

method setMessage(varchar(100) message);
    /* Must use THIS. to distinguish global */
    /* variable MESSAGE from parameter named MESSAGE. */
    this.message = message;
end;
endpackage;
run;

/* data program #2 */
data _null_;
dcl package greeting g; /* package (global) scope */

/* init() - automatically runs first in the data program. */
method init();
    /* package instance has global scope in the data program */
    g = _NEW_ [this] greeting();
    g.greet();
end;

/* run() - automatically runs after INIT() completes. */
method run();
    /* Implicit loop reads each row from the table */
    set work.greetings;
    g.setMessage(message); /* MESSAGE is read from row by SET statement */
    g.greet();
end;
enddate;
run;
quit;

The following is written to the log:

This is the default greeting.
Hello World!
What's new?
Good-bye World!

Example 5: “Hello World!” Program – In Multiple Package Instances

This version of the program uses multiple instantiation of packages to obtain the same results as Example 4, without creating a table.
What to Notice

- The GREETING package is identical to the GREETING package in the previous example. Because the package already exists, the package block could have been omitted from this program.
- You can use different constructors in the same DECLARE PACKAGE statement.

In a SAS session, copy or enter the following program. Then, submit it.

```sas
proc ds2 libs=work;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
dcl varchar(100) message;  /* package (global) scope */
FORWARD setMessage;

/* greeting() - default constructor */
method greeting();
    setMessage('This is the default greeting.');
end;

/* greeting(MESSAGE) - constructor */
method greeting(varchar(100) message);
    setMessage(message);
end;

method greet();
    put message;
end;

method setMessage(varchar(100) message);
    /* Must use THIS. to distinguish global */
    /* variable MESSAGE from parameter named MESSAGE. */
    this.message = message;
end;
endpackage;
run;

/* data program */
data _null_; /* All package instances have global scope in the data program. */
dcl package greeting
g0() g1('Hello World!') g2('What''s new?') g3('Good-bye World!');

/* init() - automatically runs first in the data program. */
method init();
g0.greet();
g1.greet();
g2.greet();
g3.greet();
end;
enddata;
run;
quit;
```
The following is written to the log:

This is the default greeting.
Hello World!
What's new?
Good-bye World!

**Example 6: “Hello World!” Program – Using a Thread**

This version of the program uses a thread to read a table and pass variables to the data program.

**What to Notice**

- This single DS2 program includes two data programs, a package, and a thread program.
- The data program specifies two threads in the SET FROM statement.
- In the thread program, the RUN() method uses the implicit loop of the SET statement to read and process each MESSAGE variable from the table.
- In the data program, the RUN() method uses the implicit loop of the SET FROM statement to read and process each MESSAGE variable from the thread program.
- In the log, the thread program’s TERM( ) output shows that the thread program ran twice, once per thread. In addition, the value of _N_ indicates the number of times that the RUN( ) method executed on behalf of each thread.

In a SAS session, copy or enter the following program. Then, submit it.

```sas
proc ds2 libs=work;
/* data program #1 - Creates a table of greetings */
data work.greetings /overwrite=yes;
dcl char(100) message; /* data program (global) scope */
method init();
    message = 'Hello World!'; output;
    message = 'What''s new?'; output;
    message = 'Good-bye World!'; output;
end;
enddata;
run;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
dcl varchar(100) message; /* package (global) scope */
forward setMessage;
/* greeting() - default constructor */
method greeting();
    setMessage('This is the default greeting.');
end;
/* greeting(MESSAGE) - constructor */
method greeting(varchar(100) message);
    setMessage(message);
```
method greet();
    put message;
end;

method setMessage(varchar(100) message);
   /* Must use THIS. to distinguish global */
   /* variable MESSAGE from parameter named MESSAGE. */
   this.message = message;
end;
endpackage;
run;

/* thread program - Read the table */
thread work.t /overwrite=yes;

/* run() - system method */
method run();
   set work.greetings;
   output; /* output variables to calling program */
end;

/* term() - system method */
method term();
   put _all_
end;
endthread;
run;

/* data program #2 */
data _null_;  
dcl package greeting g; /* data program (global) scope */
dcl thread work.t t; /* data program (global) scope */

/* init() - automatically runs first in the data program. */
method init();  
/* package instance has global scope in the data program */
g = _NEW_ [this] greeting();
g.greet();
end;

/* run() - automatically runs after INIT() completes. */
method run();
   /* Implicit loop reads each row from the table */
   set from t threads=2;
   g.setMessage(message); /* MESSAGE read from row by SET FROM statement */
   g.greet();
end;
enddata;
run;
quit;
The following is written to the log:

<table>
<thead>
<tr>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hello World!</td>
</tr>
<tr>
<td>What's new?</td>
</tr>
<tr>
<td>Good-bye World!</td>
</tr>
</tbody>
</table>

Basic DS2 Language Concepts

Introducing DS2 Data Types

Unlike Base SAS, DS2 supports many of the ANSI SQL data types that are native to the data sources that SAS supports. Thus, you can declare DS2 variables that do not require data type conversions to access data that is stored in a data source. The ability to avoid data type conversions enables you to move data efficiently to and from a database or other data source.

Note: The types of data that you can store depend on the native types that your data source supports.

For more information, see “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide.

The following table summarizes factors to consider when choosing DS2 data types.
### Table 4.1 DS2 Data Types: Quick Reference

<table>
<thead>
<tr>
<th>DS2 Data Type Category</th>
<th>Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Character</td>
<td>CHAR(n) and VARCHAR(n) use one byte per character. NCHAR(n) and NVARCHAR(n), which handle Unicode national language character sets, use two or four bytes per multi-byte character. When you specify the length of a variable, n, the length determines the size of a fixed-length variable or the maximum size of a variable-length variable. Note: Fixed-length CHAR(n) is the equivalent of a DATA step character variable, where n is the number of characters. It is also the default type for an undeclared DS2 character variable.</td>
</tr>
<tr>
<td>Fractional numeric</td>
<td>DECIMAL(p,s) (alias: NUMERIC) has exact precision. Other fractional numeric types include DOUBLE, FLOAT(p), and REAL (single-precision floating point) and are considered approximate. Note: DOUBLE is the equivalent of a DATA step numeric variable. It is also the default type for an undeclared DS2 numeric variable.</td>
</tr>
<tr>
<td>Integer numeric</td>
<td>Signed, exact whole numbers with varying storage sizes: TINYINT (-128 to 127) – 1 byte SMALLINT (-32,768 to 32,767) – 2 bytes INTEGER (-2,147,483,648 to 2,147,483,647) – 4 bytes BIGINT (-9,223,372,036,854,775,808 to 9,223,372,036,854,775,807) – 8 bytes</td>
</tr>
<tr>
<td>Binary</td>
<td>BINARY(n) is fixed length. VARBINARY(n) is variable length.</td>
</tr>
<tr>
<td>Date and time</td>
<td>DS2 supports ANSI date, time, and timestamp data types, but can also process SAS date, time, and datetime values using these conversion functions: • TO_DATE casts a SAS numeric date to a DS2 DATE • TO_TIME casts a SAS numeric time to a DS2 TIME • TO_TIMESTAMP casts a SAS numeric datetime to a DS2 TIMESTAMP • TO_DOUBLE casts a DS2 DATE, TIME, or TIMESTAMP to a SAS numeric date, time, or datetime</td>
</tr>
</tbody>
</table>
Automatic Conversions of Data Types

About Automatic Conversions

To avoid unintended results, you must understand the DS2 rules for automatic data type conversion.

CAUTION:

A type conversion can lead to the loss of data or precision, or both. Data type conversions are especially critical if you save DS2 data types in SAS data sets, because SAS data sets support only two data types. That is, DS2 variables might be automatically converted to either fixed-length character or numeric double.

An automatic type conversion occurs under the following circumstances:

- A character type is used in a numeric expression.
- A numeric type is used in a character expression.
- A call to a method supplies an argument value that does not exactly match the signature of the method.
- The types of the operands differ in a logical, arithmetic, relational, or concatenation expression.
- A DS2 data type is saved to a data source that does not support the type.

Coercion and Precedence

DS2 uses type coercion and precedence rules to determine the resulting data type for a conversion:

- Coercible data types can automatically convert to multiple data types.
- Non-coercible data types automatically convert to only character data types.
- Precedence determines the conversion type when an expression contains more than one data type.

For more information, see “DS2 Type Conversions” in SAS Viya: DS2 Programmer’s Guide.

Conversion of Nulls and Missing Values

The mode that you use to process null and missing values can affect your data. The default mode for processing nulls and missing values, either SAS mode or ANSI mode, depends on the environment in which you submit your DS2 program and the options that you choose. For example, by default, the DS2 procedure processes data in SAS mode. The SAS Federation Server processes data in ANSI mode.

CAUTION:

During multiple conversions, it is possible to lose the original meaning of data. This is particularly true in the values of SAS special missing values (., .A-.Z).

DS2 Programming Blocks and Scope

A programming block defines a section of a DS2 program that encapsulates variables and code. Programming blocks encourage the creation of modular, reusable code. In
addition, a programming block defines the scope of identifiers within that block. In DS2, it is possible for variables to have the same name and data type, as long as they have different scope.

The following table summarizes the characteristics of DS2 programming blocks and scope.

<table>
<thead>
<tr>
<th>Block</th>
<th>Delimiters</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data program</td>
<td>DATA...ENDDATA</td>
<td>Variables that are declared at the top of this programming block have global scope within the data program. In addition, variables that the SET statement references have global scope. Unless explicitly dropped, global variables in a data program are included in the program data vector (PDV). Note: Global variables exist for the duration of the data program.</td>
</tr>
<tr>
<td>Package</td>
<td>PACKAGE...ENDPACKAGE</td>
<td>Variables that are declared at the top of this programming block have global scope within the package. Package-scope variables are not included in the PDV of a data program that is using an instance of the package. Note: Package-scope global variables exist for the duration of the package instance.</td>
</tr>
<tr>
<td>Thread program</td>
<td>THREAD...ENDTHREAD</td>
<td>Variables that are declared at the top of this programming block have global scope within the thread program. In addition, variables that the SET statement references have global scope. Unless explicitly dropped, global variables in a thread program are included in the thread output set. Note: Thread-scope global variables exist for the duration of the thread program instance, but they can be passed to the SET FROM statement in the data program.</td>
</tr>
<tr>
<td>Method</td>
<td>METHOD...END</td>
<td>A method is a subblock of a data program, package, or thread program. Method names have global scope within the enclosing block. Variables that are declared at the top of this programming block have local scope. Local variables are not included in the PDV. Note: Local variables exist for the duration of the method call.</td>
</tr>
<tr>
<td>DO loop</td>
<td>DO...END</td>
<td>Not applicable.</td>
</tr>
</tbody>
</table>

**Tip** Although method names have global scope, to forward reference a method, use the FORWARD statement at the top of the outer programming block. For more information, see “FORWARD Statement” on page 727.

As the preceding table shows, there are three types of global scope:

- Data program
- Package
- Thread program
Variable Declaration in DS2

Implicit Declaration of Variables
As in Base SAS, DS2 enables you to implicitly create global variables by assignment. However, this is not recommended for these reasons:

- Subtle errors can occur (for example, if a variable name is misspelled).
- The data types of such variables are limited to DOUBLE and CHAR(n).
- Undeclared variables might make your program difficult for others to read and understand.

Variable Declaration with the DECLARE Statement
Unlike Base SAS, DS2 enables you to explicitly declare variables using the DECLARE statement. You can control all attributes of a variable in a single DECLARE statement.

The DECLARE statement takes this form:

```
DECLARE [PRIVATE] data-type variable-list [HAVING having-clause];
```

*Note:* A DECLARE statement is allowed only at the top of the programming block in which it is used. Otherwise, a compilation error occurs.

For more information, see “DECLARE Statement” on page 705.

Variable Declaration Strict Mode
A best practice is to always run your DS2 programs using variable declaration strict mode. This enforces the explicit declaration of all program variables.

For more information about controlling variable declaration strict mode, see “DS2SCOND= System Option” on page 800.

DECLARE Statement and Scope
When you use a DECLARE statement to define a variable, the variable assumes the scope of the programming block in which the variable is declared. A method is a subblock of another programming block. Therefore, a variable that is declared in a method has local scope and exists only when the method executes. A variable that is declared outside a method has global scope within that programming block.

For a sample program that demonstrates scope, see “Example: Block Scope” on page 34.

Declaring a Package Instance
Although a package instance is simply a type of variable, it is a special case that is worth mentioning because it has two parts:

- package variable
  - a variable whose data type is a reference to a type of package.

- package instance
  - an instance of a type of package. Ideally, a package instance is always referenced by at least one package variable.

*Tip:* The scope of each part is determined by the programming block in which the part is declared. Therefore, a package variable can have a different scope than the package instance that it refers to.
For more information, see “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*.

**DS2 Methods and Packages**

Methods and packages are explained in greater detail in Chapter 5, “Understanding DS2 Methods and Packages,” on page 39.

**Parallel Processing in DS2**

DS2 supports parallel execution of a single program that can operate on different parts of a table. This type of parallelism is classified as Single Program, Multiple Data (SPMD) parallelism. In DS2, it is the responsibility of the programmer to identify the program statements that can operate in parallel.

- **TIP** For programs that are CPU bound, using a thread program on Symmetric Multiprocessing (SMP) hardware can improve performance. For programs that are either CPU or I/O bound, Massively Parallel Processing (MPP) hardware can improve performance.

For more information, see “Threaded Processing” in *SAS Viya: DS2 Programmer’s Guide*.

For a sample program that demonstrates a simple use of threads, see “Example: A Simple Thread Program” on page 36.

**What Is a DS2 Program?**

For the purposes of getting started with DS2, a DS2 program is a set of DS2 statements that runs in the DS2 procedure. The getting started sample programs demonstrate that a DS2 program can serve many purposes, including but not limited to the following:

- to define and store one or more packages or threads, in permanent or temporary locations.
- to create one or more data sets or tables, in permanent or temporary locations.
- to run one or more data programs, using any, all, or none of the above components.
- any combination of the above. That is, you can create data, packages, and threads, plus run one or more data programs within a single DS2 program.

The order and number of programming blocks in a DS2 program does not matter, as long as the program compiles and contains enough RUN statements to execute the program.

- **TIP** Always check the log for compilation errors.

In addition, in a SAS session, you can alternate between the DS2 procedure and Base SAS to test your code and to achieve your programming goals.

**Example: Block Scope**

The following program demonstrates how scope determines the visibility of program identifiers.
What to Notice

- This program has six INTEGER variables that have the name \texttt{i}.
- This program has three user-defined methods named SHOWME().

```
options ds2scond=error;
proc ds2;
/* INNERPKG */
package innerPkg /overwrite=yes;
  dcl int i; /* i is global in this package */
  dcl varchar(100) str;

  /* init() - initializes package variables */
  method init();
    i = 5; /* global i */
    str = 'I am INNERPKG!';
  end;

  /* showMe() - displays values that INNERPKG can "see" */
  method showMe() returns int;
    dcl int i; /* local i */
    i = 10; /* local i */
    put str;
    put 'Local i=' i;
    put 'Global i=' this.i;
    return 1;
  end;
endpackage;
run;

/* OUTERPKG */
package outerPkg /overwrite=yes;
  dcl int i; /* i is global in this package */
  dcl package innerPkg ip();
  dcl varchar(100) str;

  /* init() - initializes package variables */
  method init();
    i = 15; /* global i */
    str = 'I am OUTERPKG!';
    ip.init(); /* tell INNERPKG to initialize itself */
  end;

  /* showMe() - displays values that OUTERPKG can "see" */
  method showMe();
    dcl int i; /* local i */
    i = 20; /* local i */
    put str;
    put 'Local i=' i; /* local i */
    put 'Global i=' this.i; /* global i */
    ip.showMe(); /* tell INNERPKG to show what it can "see" */
  end;
endpackage;
run;
```
/* data program */
data _null_

dcl int i; /* i is global in this data program */
dcl package outerPkg op(); /* instantiate with default constructor */
dcl varchar(100) str;
FORWARD showMe;

/* init() - automatically runs as the first method in the program */
method init()

dcl int rc;
i = 25; /* global i */
str = 'I am the data program!';
op.init(); /* tell OUTERPKG to initialize itself */
showMe(); /* show what the data program can "see" */
end;

/* showMe() - displays values that the data program can "see" */
method showMe()

dcl int i; /* local i */
i = 30; /* local i */
put str;
put 'Local i=' i; /* local i */
put 'Global i=' this.i; /* global i */
op.showMe(); /* tell OUTERPKG instance to show what it can "see" */
end;
enddata;
run;
quit;

The following is written to the log:

```
I am the data program!
Local i= 30
Global i= 25
I am OUTERPKG!
Local i= 20
Global i= 15
I am INNERPKG!
Local i= 10
Global i= 5
```

---

**Example: A Simple Thread Program**

The following program demonstrates how a thread creates data and passes variables to the data program.
What to Notice

- The parameterized thread accepts a value that must be initialized by the data program using the \texttt{SETPARMS(\ )} system method.

- The \texttt{OVERWRITE=YES} table option enables the thread program to be overwritten. 
\textit{Note:} The \texttt{THREAD} statement syntax requires the ‘/’ (slash character) syntax.

- Because the data program specifies two threads, the thread program runs in two separate threads in a single process. 
\textit{Note:} This thread program produces one set of output variables per thread.

- Because threads run asynchronously, the order of processing is unpredictable, as the log shows.

- In the data program, the global accumulator variable \texttt{TOTAL} is implicitly retained because of the \texttt{total+answer;} \texttt{Sum} statement syntax.

```plaintext
options DS2SCOND=ERROR;
proc ds2;
  /* thread program - Creates data in a loop */
  thread work.t (double d) /overwrite=yes;
    dcl int x;
    dcl double y;

    method init();
      dcl int i; /* local - not included in the output table */
      do i = 1 to 9;
        x = i;
        y = i * 2.5 + d;
        put 'THREAD: i=' i ' x= ' x ' y= ' y;
        output; /* output variables include X and Y */
      end;
    end;

    method term();
      put 'THREAD TERM (_ALL_):';
      put _all_; 
    end;
  endthread;
run;

  /* data program - Reads data from a thread program */
data;
  dcl thread work.t t;
  dcl double answer total;

  method init();
    t.setparms(1.25); /* initialize parameter of thread */
    put 'INIT (_ALL_):';
    put _all_; 
  end;

  method run();
    set from t threads=2; /* input variables include X and Y */
    answer = x + y;
```

\textit{Example: A Simple Thread Program}
The following is written to the log:

```plaintext
INIT (_ALL_):
  total=0 answer=. x= y= _N_=1
THREAD: i= 1  x= 1  y= 3.75
THREAD: i= 2  x= 2  y= 6.25
THREAD: i= 3  x= 3  y= 8.75
THREAD: i= 4  x= 4  y= 11.25
THREAD: i= 5  x= 5  y= 13.75
THREAD: i= 6  x= 6  y= 16.25
THREAD: i= 7  x= 7  y= 18.75
THREAD: i= 8  x= 8  y= 21.25
THREAD: i= 9  x= 9  y= 23.75
THREAD TERM (_ALL_):
  d=1.25 x= y= _N_=1
  x= 1  y= 3.75  answer= 4.75  total= 4.75
THREAD: i= 7  x= 7  y= 18.75
THREAD: i= 8  x= 8  y= 21.25
THREAD: i= 9  x= 9  y= 23.75
THREAD TERM (_ALL_):
  d=1.25 x= y= _N_=1
  x= 2  y= 6.25  answer= 8.25  total= 13
  x= 3  y= 8.75  answer= 11.75  total= 24.75
  x= 4  y= 11.25  answer= 15.25  total= 40
  x= 5  y= 13.75  answer= 18.75  total= 58.75
  x= 6  y= 16.25  answer= 22.25  total= 81
  x= 7  y= 18.75  answer= 25.75  total= 106.75
  x= 8  y= 21.25  answer= 29.25  total= 136
  x= 9  y= 23.75  answer= 32.75  total= 168.75
  x= 1  y= 3.75  answer= 4.75  total= 173.5
  x= 2  y= 6.25  answer= 8.25  total= 181.75
  x= 3  y= 8.75  answer= 11.75  total= 193.5
  x= 4  y= 11.25  answer= 15.25  total= 208.75
  x= 5  y= 13.75  answer= 18.75  total= 227.5
  x= 6  y= 16.25  answer= 22.25  total= 249.75
  x= 7  y= 18.75  answer= 25.75  total= 275.5
  x= 8  y= 21.25  answer= 29.25  total= 304.75
  x= 9  y= 23.75  answer= 32.75  total= 337.5
TERM: (_ALL_)
  total=337.5 answer=. x=9 y=23.75 _N_=19
```

Chapter 5
Understanding DS2 Methods and Packages

Modularity, Encapsulation, and Abstraction in DS2

Getting Started with DS2 Methods
What Are DS2 Methods? What Are DS2 System Methods? What Are DS2 User-defined Methods?

Getting Started with DS2 Packages
What Are DS2 Packages? What Are DS2 Predefined Packages?

Example: Introduction to DS2 Methods
Example: Introduction to DS2 Packages

Modularity, Encapsulation, and Abstraction in DS2

When you use DS2 methods and packages, you approach writing SAS programs differently than you do when programming in Base SAS. These DS2 language constructs follow a more structured-programming and object-oriented approach.

In general, DS2 methods are like functions, procedures, subroutines, and the methods of object-oriented languages such as Java. A method can be thought of as a module that contains a sequence of instructions to perform a specific task. DS2 methods can exist only within a data program, thread program, or package.

Thus, methods enable you to break up a complex problem into smaller modules. Such modules are easier to design, implement, and test. Code reuse can shorten development time and help standardize often-repeated or business-specific programming tasks. Also, modular programming enhances readability and understandability by testers and other programmers.

DS2 packages enable encapsulation and abstraction of behavior. DS2 packages are similar to classes in object-oriented languages. However, a DS2 package can also be used as a bucket of useful but unrelated methods and variables, if that meets your needs.

A DS2 package bundles data and methods into a named object that can be stored and reused by other DS2 programs. Although DS2 packages do not hide their data or methods (there is no concept of public and private), packages can be designed to abstract
behavioral details. In such a package, the methods define the object and enable controlled manipulation of package data.

Getting Started with DS2 Methods

What Are DS2 Methods?

Because executable code can reside only in methods, methods are the structural building blocks of DS2 programs.

There are two types of methods:

System Methods

Also known as predefined, these methods provide the structural and functional framework for your program to execute.

User-defined Methods

Similar to functions, procedures, and subroutines in other languages, these are the methods that you create or that someone else created for reuse.

All methods are subblocks of other programming blocks. Each method creates a method scope in which local variables can be defined.

A method programming block begins with the METHOD keyword and ends with the END keyword, as the following example shows.

```
method foo();
...DS2 variables and statements...
end;
```

For more information, see “Methods” in SAS Viya: DS2 Programmer’s Guide.

What Are DS2 System Methods?

System methods provide the structural framework that runs your code. That is, to create a program, simply add DS2 statements to one or more of these system methods: INIT( ), RUN( ), TERM( ).

System methods also provide special functionality that SAS programmers need and expect for their data and thread programs, such as implicit looping. In addition, system methods enable the semantic grouping of code, which helps make DS2 programs easier to organize, understand, and maintain.

Here are basic facts about system methods:

- Every DS2 program contains—and executes—all three of the main system methods. If you do not explicitly code a system method, the system executes a default version.
- You can explicitly code any, all, or none of the system methods.
  
  *Note:* A program that contains no system methods is syntactically correct, but performs no useful function.
- You cannot change the signature of a system method, and you cannot overload a system method.
- You cannot directly call a system method, with the exception of SETPARMS( ), which applies only to thread programs.

For more information, see “Overview of System Methods” on page 791.
The following table summarizes the execution details of each DS2 system method.

**Table 5.1 DS2 System Methods: Execution Details**

<table>
<thead>
<tr>
<th>System Method</th>
<th>Execution Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>INIT( )</td>
<td>Automatically executes one time, as the first method of a program. For more information, see “INIT Method” on page 792.</td>
</tr>
<tr>
<td>RUN( )</td>
<td>Automatically executes after INIT( ) completes. The RUN( ) method is the functional equivalent of the DATA step, running as an implicit loop if the method contains a SET or SET FROM statement. For more information, see “RUN Method” on page 793.</td>
</tr>
<tr>
<td>TERM( )</td>
<td>Automatically executes one time, as the last method of a program. For more information, see “TERM Method” on page 797.</td>
</tr>
<tr>
<td>SETPARMS( )</td>
<td>Executes one time, when called from a data program, to initialize the values of a parameterized thread. For more information, see “SETPARMS Method” on page 795.</td>
</tr>
</tbody>
</table>

**What Are DS2 User-defined Methods?**

Similar to functions, procedures, and subroutines in other languages, these are the methods that you create or that someone else created for reuse. Because methods are subblocks of other programming blocks, user-defined methods can exist in data programs, packages, and thread programs.

The following table summarizes basic concepts of user-defined methods.

**Table 5.2 DS2 User-defined Methods: Basic Concepts**

<table>
<thead>
<tr>
<th>User-defined Method Topic</th>
<th>Description</th>
</tr>
</thead>
</table>
| Scope                     | The name of a user-defined method has global scope within the programming block in which it is defined. In addition, each method creates a method scope in which local variables can be defined.  
  **Note:** You can call a user-defined method from wherever the method is in scope, and you can do it as many times as needed. |
| Method parameters         | A user-defined method can accept arguments in the following ways:  
  • by value. The argument value is copied to the method.  
  • by reference (IN_OUT parameter). The method modifies the value of the argument variable. |
| Return values             | Like a function, a user-defined method can return a value, but only if the signature contains no IN_OUT parameters. |
### Method overloading

User-defined methods that have the same name can exist in the same scope if their argument signatures are unique. That is, if only the return type differs, then the overloading is ambiguous.

The following examples show an overloaded method with three unique argument signatures:

```plaintext
method squareIt(int value) returns int;
   return value**2;
end;

method squareIt(decimal(6,2) value) returns decimal(8,4);
   return value**2;
end;

method squareIt(int value, IN_OUT int square);
   square = value**2;
end;
```

**Calling**

Unlike system methods, which automatically run, user-defined methods must be called. You can call a user-defined method as many times as needed.

For more information, see “METHOD Statement” on page 740.

---

### Getting Started with DS2 Packages

#### What Are DS2 Packages?

DS2 packages are language constructs that bundle variables and methods into named objects that can be stored and reused by other DS2 programs. The main benefit of a package derives from the reusability of a set of useful methods. However, DS2 packages are capable of much more.

A DS2 package is similar to a class in object-oriented languages. Thus, you can write packages that approximate the encapsulation and abstraction of object-oriented classes.

*Note:* A DS2 package is not a program. A DS2 package is a template for instantiating an object that can be used in a program.

There are two types of packages:

- **Predefined Packages**
  - These packages encapsulate common functionality that is useful to many customer solutions (for example, manipulating hash and matrix data structures). Predefined packages are part of DS2.

- **User-defined Packages**
  - These are the packages that you create or that someone else created for reuse.

A package is defined by a package programming block. A package begins with the PACKAGE keyword and ends with the ENDPACKAGE keyword, as the following example shows.

```plaintext
package foo;
```
The following table summarizes basic concepts of both user-defined and predefined packages.

### Table 5.3 DS2 Packages: Basic Concepts

<table>
<thead>
<tr>
<th>Package Topic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>The names of package methods and variables have global scope within the package.</td>
</tr>
<tr>
<td></td>
<td><em>Note:</em> You can access a package’s methods and variables from wherever the package instance is in scope.</td>
</tr>
<tr>
<td>Package methods</td>
<td>Because packages are not programs, they do not have system methods that run automatically. Thus, to execute a package method, your program must call it.</td>
</tr>
<tr>
<td></td>
<td>After you instantiate a package, use dot notation to access a method of the package instance, as the following example shows.</td>
</tr>
</tbody>
</table>
|                       | ```
|                       | method run();
|                       | dcl package matrix m([2, 3]);
|                       | dcl double mr mc;
|                       | mr=m.rows();
|                       | mc=m.cols();
|                       | put mr=;
|                       | put mc=;
|                       | end;
| Preparing packages for use | A package must be compiled and stored before it can be used in a program. You can use the DS2 procedure to define and store a user-defined package.  |
|                       | For more information, see “PACKAGE Statement” on page 753.                     |
| Overwriting packages  | Unlike Base SAS, DS2 protects existing tables from being overwritten. However, if you are developing or changing a package, you need the ability to overwrite the package. To overwrite an existing package, use the OVERWRITE=YES table option, as the following example shows.  |
|                       | ```
|                       | package greeting /overwrite=yes;
|                       | ...DS2 variables, statements, and methods...
|                       | endpackage;
|                       | run;
```
## Instantiating packages

To use a package, you create an instance of the package (a package instance) and a variable that references the instance (a package variable). You can instantiate a package in two ways:

- in a single `DECLARE PACKAGE` statement that simultaneously declares a package variable and constructs one or more package instances:
  ```
  dcl package matrix m0() m1(3, 3) m2(5, 4);
  ```
- by first declaring the package variable and then assigning a package instance, using the `_NEW_` operator:
  ```
  data _null_;
  dcl package matrix m1 m2; /* package (global) scope */
  method init();
  dcl package matrix m3; /* method (local) scope */
  m1 = _NEW_ [THIS] matrix(3, 2); /* package (global) scope */
  m3 = _NEW_ matrix(5, 4); /* method (local) scope */
  m2 = _NEW_ [m1] matrix(); /* same scope as m1 instance */
  end;
  ```

Note: If you declare a package variable without simultaneously declaring an instance of the package, the value of the package variable is NULL.

### What Are DS2 Predefined Packages?

Predefined packages encapsulate common functionality that is useful to many customer solutions.

For a list of the predefined packages that are available with DS2, see “Predefined DS2 Packages” in *SAS Viya: DS2 Programmer’s Guide*.

You can find many example programs that use predefined packages in Appendix 2, “DS2 Example Programs,” on page 1109.

## Example: Introduction to DS2 Methods

The following program demonstrates many characteristics of both system and user-defined DS2 methods.

### What to Notice

- This program has three overloaded user-defined methods named SQUAREIT().
- This program contains three system methods.
/* data program */
data _null_
   dcl int root1 result1;
   dcl decimal(6,2) root2;
   dcl decimal(8,4) result2;

   /* overloaded user-defined method */
   method squareIt(int value) returns int
     return value**2;
   end;

   /* overloaded user-defined method */
   method squareIt(decimal(6,2) value) returns decimal(8,4);
     return value**2;
   end;

   /* overloaded user-defined method with IN_OUT parameter */
   method squareIt(int value, IN_OUT int square);
     square = value**2;
   end;

   /* system method */
   method init();
     root1 = 3.01;
     root2 = 3.01;
   end;

   /* system method */
   method run();
     result1 = squareIt(root1);
     put 'The square of INTEGER ' root1 ' is ' result1;

     result2 = squareIt(root2);
     put 'The square of DECIMAL ' root2 ' is ' result2;

     root1 = 4.99;
     squareIt(root1, result1);
     put 'The square of INTEGER ' root1 ' is ' result1;
   end;

   /* system method */
   method term();
     put _all_; /* final values of global variables */
   end;
enddata;
run; quit;

The following is written to the log:

| The square of INTEGER 3 is 9 |
| The square of DECIMAL 3.01 is 9.0601 |
| The square of INTEGER 4 is 16 |
| root1= root2= result1= result2= _N_=1 |
Example: Introduction to DS2 Packages

The following program demonstrates some basic concepts of packages. This is a version of the “Hello World!” program that uses a package to write messages to the SAS log.

What to Notice

• The PACKAGE statement uses the OVERWRITE=YES table option so that you can run the program more than once without error. By default, DS2 protects existing packages from being overwritten.

• In the data program, the DECLARE PACKAGE statement simultaneously declares package variables and constructs two separate instances of the package using the package constructor.

• Dot notation provides access to package methods and package-global variables from the data program.

Note: Although this sample program shows that you can directly access package-global variables, the recommended best practice is to avoid this practice unless you have a valid reason to do so.

```sas
options DS2SCOND=ERROR;
proc ds2;
   /* GREETING - User-defined package that writes a message to the SAS log */
   package greeting /overwrite=yes;
      dcl varchar(100) message; /* package (global) scope */

   /* greeting(MESSAGE) - constructor that accepts an argument */
   method greeting(varchar(100) message);
      THIS.message = message;
   end;

   /* greeting() - default constructor */
   method greeting();
   end;

   /* package method */
   method greet();
      if not missing(message) then
         put message;
      else put 'Message is null or missing.';
   end;
run;

   /* data program */
   data _null_;
      /* declares and instantiates two instances of the GREETING package */
      dcl package greeting g1('Hello World!') g2(); /* data program (global) scope */

      /* init() - system method */
      method init();
         g1.greet();
```
g2.greet();
g2.message = 'Good-bye World!';
g2.greet();
end;
enddata;
run;
quit;

The following is written to the log:

```
Hello World!
Message is null or missing.
Good-bye World!
```

Overview of Formats

A **format** is an instruction that DS2 uses to write data values. You use formats to control the written appearance of data values, or, in some cases, to group data values together for analysis. For example, the ROMANw. format, which converts numeric values to roman numerals, writes the numeric value 2006 as **MMVI**.

General Format Syntax

DS2 formats have the following form:

```
[ $ ] format [ w ] . [ d ]
```

Here is an explanation of the syntax:

- **$**
  - indicates a character format; its absence indicates a numeric format.

- **format**
  - names the format. The format is a DS2 format or a user-defined format that was previously defined with the INVALUE statement in PROC FORMAT. For more information about user-defined formats, see the **SAS Viya Data Management and Utility Procedures Guide**.

- **Restriction**
  - To create and access user-defined formats, a Base SAS session must be available in order to access the SAS catalog file that stores the SAS format definitions.

- **w**
  - specifies the format width, which for most formats is the number of columns in the input data.

- **d**
  - specifies an optional decimal scaling factor in the numeric formats. DS2 divides the input data by 10 to the power of **d**.

- **Tip**
  - When the value of **d** is greater than 15, the precision of the decimal value after the 15th decimal place might not be accurate.

Formats always contain a period (.) as a part of the name. If you omit the **w** and the **d** values from the format, DS2 uses default values. The **d** value that you specify with a format tells DS2 to display that many decimal places, regardless of how many decimal places are in the data. Formats never change or truncate the internally stored data values.

For example, in DOLLAR10.2, the **w** value of 10 specifies a maximum of 10 columns for the value. The **d** value of 2 specifies that two of these columns are for the decimal part of the value, which leaves eight columns for all the remaining characters in the value. This includes the decimal point, the remaining numeric value, a minus sign if the value is negative, the dollar sign, and commas, if any.

If the format width is too narrow to represent a value, DS2 tries to squeeze the value into the space available. Character formats truncate values on the right. Numeric formats sometimes revert to the BESTw.d format. DS2 prints asterisks if you do not specify an adequate width. In the following example, the result is **x=******.
If you use an incompatible format, such as using a numeric format to write character values, DS2 first attempts to use an analogous format of the other type. If this is not feasible, an error message that describes the problem appears in the SAS log.

---

### Using Formats in DS2

#### How to Specify Formats

In DS2, specify formats as an attribute of the HAVING clause of the DECLARE statement. The HAVING clause provides equivalent functionality to the Base SAS FORMAT and LABEL statements, except that now the attribute must be specified in the declaration statement of the variable.

For example, in the following statement, the columns `profit` and `loss` are declared with the EURO13.2 format.

```sas
dcl double profit loss having format euro13.2;
```

**Note:** In DS2, a format for a column cannot be changed or removed. However, you can use formats as arguments in the PUT function to write data in a different format. For more information, see “Write Formatted Data in DS2” on page 54.

#### Write Formatted Data in DS2

You can use formats as arguments in the PUT function to write formatted data. If no format is specified in the PUT function, the variable's default format is used.

For example, in this case, the PUT function returns the formatted value of 99 using the BEST12. format.

```sas
x=99;
y=put(x, best12.);
```

If the PUT function is used without a format, all data is written without formatting.

Any type conversions of the value that is formatted are done based on the format name. Any value that is passed to the PUT function with a numeric format is converted, if necessary, to DOUBLE. Any value that is passed to the PUT function with a character format is converted to NCHAR. For more information, see the “PUT Function” on page 553.

DS2 supports SAS formats as follows.

- Both SAS-supplied and user-defined formats can be used. For information about how to create your own format in SAS, see PROC FORMAT in the SAS Viya Data Management and Utility Procedures Guide.

  **Note:** To create and access user-defined formats, a Base SAS session must be available in order to access the SAS catalog file that stores the SAS format definitions.

- Only the SAS data set and SPD data sets support storing and retrieving a format with a column.
• Formats can be associated with all data types, but all data types are converted to either CHAR or DOUBLE.

• You associate SAS formats with a column by using the HAVING clause of the DS2 DECLARE statement. For more information, see “How to Specify Formats” on page 54.

---

**Validation of DS2 Formats**

Formats are not validated by a data source or applied to a column until execution time. When metadata for a column is requested, the format name is returned without validation.

---

**DS2 Format Examples**

```plaintext
declare datetime shipdate having format dateampm22.2;
x = put (name, $char8.);
x = put (price, myformat. -c);
```

---

**Format Categories**

Formats can be categorized by the types of values that they operate on. Each DS2 format belongs to one of the following categories:

- **Character**
  - writes character data values from character variables.

- **Date and time**
  - writes character data values from character variables.

- **Numeric**
  - writes numeric data values from numeric variables.

The following table provides brief descriptions of DS2 formats. For more detailed information, see the individual formats.

<table>
<thead>

<td>Writes standard numeric data with leading 0s.</td>
</tr>
</tbody>
</table>

**Dictionary**

**$BASE64X Format**

Converts character data into ASCII text by using Base 64 encoding.

<table>
<thead>
<tr>
<th>Category</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment</td>
<td>Left</td>
</tr>
</tbody>
</table>

**Syntax**

$BASE64X_{w}$

**Arguments**

$w$

Specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1–32767</td>
</tr>
</tbody>
</table>

**Details**

Base 64 is an industry encoding method whose encoded characters are determined by using a positional scheme that uses only ASCII characters. Several Base 64 encoding schemes have been defined by the industry for specific uses, such as email or content masking. SAS maps positions 0 – 61 to the characters A – Z, a – z, and 0 – 9. Position 62 maps to the character +, and position 63 maps to the character /.

Here are some uses of Base 64 encoding:
• embed binary data in an XML file
• encode passwords
• encode URLs

The '=' character in the encoded results indicates that the results have been padded with zero bits. In order for the encoded characters to be decoded, the '=' must be included in the value to be decoded.

Example

```plaintext
a=put {'x', $base64x64.};
```

<table>
<thead>
<tr>
<th>Value of x</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;FCA01A793BC&quot;</td>
<td>RkNMDFENzk5M0JD</td>
</tr>
<tr>
<td>&quot;MyPassword&quot;</td>
<td>TX1QYXNd29yZA==</td>
</tr>
<tr>
<td>&quot;www.mydomain.com/myhiddenURL&quot;</td>
<td>d3d3Lm15ZG9tYWluLnNvbi9teWhpZGRlblVSTA==</td>
</tr>
</tbody>
</table>

$BINARY Format

Converts character data to binary representation.

**Category:** Character

**Alignment:** Left

**Syntax**

```plaintext
$BINARYw
```

**Arguments**

`w`

specifies the width of the output field.

**Default**

The default width is calculated based on the length of the variable to be printed.

**Range**

1–32767

**Comparisons**

The $BINARYw. format converts character values to binary representation. The BINARYw. format converts numeric values to binary representation.

**Example**

```plaintext
a = put {'name', $binary16.};
```
<table>
<thead>
<tr>
<th>Value of name</th>
<th>ASCII</th>
<th>EBCDIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB</td>
<td>0100000101000010</td>
<td>1100000111000010</td>
</tr>
</tbody>
</table>

### See Also

**Formats:**
- “BINARY Format” on page 74

### $CHAR Format

Writes standard character data.

**Category:** Character

**Alignment:** Left

**Alias:** $w. and $Fw.

### Syntax

```
$CHAR
```

### Arguments

`w`

specifies the width of the output field. You can specify a number or a column range.

**Default**

8 if the length of variable is undefined; otherwise, the length of the variable.

**Range**

1–32767

### Comparisons

- The $CHARw. format is identical to the $w. and $Fw. formats.
- The $CHARw., $Fw., and $w. formats do not trim leading blanks. To trim leading blanks, use the LEFT function to left align character data before output.

### Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--------</td>
</tr>
</tbody>
</table>
$HEX Format

Converts character data to hexadecimal representation.

**Category:** Character

**Alignment:** Left

---

**Syntax**

$HEX_w$

**Arguments**

\( w \)

specifies the width of the output field.

**Default**
The default width is calculated based on the length of the variable to be printed.

**Range**

1–32767

**Tips**

To ensure that SAS writes the full hexadecimal equivalent of your data, make \( w \) twice the length of the variable or field that you want to represent.

If \( w \) is greater than twice the length of the variable that you want to represent, $HEX_w$ pads it with blanks.

---

**Details**

The $HEX_w$ format converts each character into two hexadecimal characters. Each blank counts as one character, including trailing blanks.

**Comparisons**

The HEX\( w \) format converts real binary numbers to their hexadecimal equivalent.

---

**Example**

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put ('bank', $hex.);</td>
<td>62616E6B</td>
</tr>
</tbody>
</table>

---

**See Also**

Formats:
$OCTAL Format

 Converts character data to octal representation.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment:</td>
<td>Left</td>
</tr>
</tbody>
</table>

**Syntax**

$OCTAL w$

**Arguments**

- `w` specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>The default width is calculated based on the length of the variable to be printed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>1–32767</td>
</tr>
<tr>
<td>Tip</td>
<td>Because each character value generates three octal characters, increase the value of <code>w</code> by three times the length of the character value.</td>
</tr>
</tbody>
</table>

**Comparisons**

The $OCTAL w$ format converts character values to the octal representation of their character codes. The $OCTAL w$ format converts numeric values to octal representation.

**Example**

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-----------------</td>
</tr>
<tr>
<td>a=put('art', $octal15.);</td>
<td>141162164</td>
</tr>
<tr>
<td>a=put('rice', $octal15.);</td>
<td>162151143145</td>
</tr>
<tr>
<td>ba=put('bank', $octal15.);</td>
<td>142141156153</td>
</tr>
</tbody>
</table>

**See Also**

Formats:

- “OCTAL Format” on page 123
$QUOTE Format

Writes data values that are enclosed in double quotation marks.

**Category:** Character  
**Alignment:** Left

## Syntax

$QUOTEw.$

### Arguments

\(w\)

specifies the width of the output field.

**Default**

8 if the length of the variable is undefined; otherwise, the length of the variable + 2

**Range**

2–32767

**Tip**

Make \(w\) wide enough to include the left and right quotation marks.

## Details

The following list describes the output that SAS produces when you use the $QUOTEw.$ format.

- When your data value is not enclosed in quotation marks, SAS encloses the output in double quotation marks.

- When your data value is not enclosed in quotation marks, but the value contains a single quotation mark, SAS takes the following action:
  - encloses the data value in double quotation marks
  - does not change the single quotation mark.

- When your data value begins and ends with single quotation marks, and the value contains double quotation marks, SAS takes the following action:
  - encloses the data value in double quotation marks
  - duplicates the double quotation marks that are found in the data value
  - does not change the single quotation marks.

- When your data value begins and ends with single quotation marks, and contains two single contiguous quotation marks, SAS takes the following actions:
  - encloses the value in double quotation marks
  - does not change the single quotation marks.

- When your data value begins and ends with single quotation marks, and contains both double quotation marks and single, contiguous quotation marks, SAS takes the following actions:
  - encloses the value in double quotation marks
• duplicates the double quotation marks that are found in the data value
• does not change the single quotation marks.
• When the length of the target field is not large enough to contain the string and its quotation marks, SAS returns all blanks.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put('SAS',quote.);</td>
<td>&quot;SAS&quot;</td>
</tr>
<tr>
<td>a=put('SAS''s',quote.);</td>
<td>&quot;SAS's&quot;</td>
</tr>
<tr>
<td>a=put('ad''verb',quote16.);</td>
<td>&quot;ad'verb&quot;</td>
</tr>
<tr>
<td>a=put('&quot;ad &quot;verb&quot;',quote16.);</td>
<td>&quot;&quot;&quot;ad&quot;&quot;&quot;verb&quot;&quot;&quot;</td>
</tr>
<tr>
<td>a=put('&quot;ad&quot;&quot;verb&quot;',quote20);</td>
<td>&quot;&quot;&quot;ad&quot;&quot;&quot;verb&quot;&quot;</td>
</tr>
</tbody>
</table>

$REVERJ Format

Writes character data in reverse order and preserves blanks.

**Category:** Character  
**Alignment:** Right

**Syntax**  
$REVERJw.$

**Arguments**

w  
specifies the width of the output field.

**Default**  
1 if w is not specified

**Range**  
1–32767

**Comparisons**

The $REVERJw.$ format is similar to the $REVERSw.$ format except that $REVERSw.$ left aligns the result by trimming all leading blanks.
Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>a=put('ABCD###','$reverj7.);</td>
<td>###DCBA</td>
</tr>
<tr>
<td>a=put('###ABCD','$reverj7.);</td>
<td>DCBA###</td>
</tr>
</tbody>
</table>

Note: The character # represents a blank space.

See Also

Formats:

- “$REVERS Format” on page 67

$REVERS Format

Writes character data in reverse order and left aligns.

**Category:** Character

**Alignment:** Left

Syntax

$REVERS w.

**Arguments**

w

specifies the width of the output field.

**Default**

1 if w is specified

**Range**

1–32767

Comparisons

The $REVERS w. format is similar to the $REVERJ w. format except that $REVERJ w. does not left align the result.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
Statements and Results

```
a=put('ABCD###',$revers7);       DCBA

a=put('###ABCD',$revers7.);      DCBA
```

**Note:** The character # represents a blank space.

### See Also

**Formats:**

- “$REVERJ Format” on page 66

---

**$UPCASE Format**

Converts character data to uppercase.

**Category:** Character

**Alignment:** Left

### Syntax

$UPCASEw.

### Arguments

**w**

- Specifies the width of the output field.

  **Default:** 8 if the length of the variable is undefined; otherwise, the length of the variable.

  **Range:** 1–32767

### Details

Special characters, such as hyphens and other symbols, are not altered.

### Example

```
Statements                Results

a=put('coxe-ryan',$upcase9.);         COXE-RYAN
```

$ Format

Writes standard character data.

- **Category:** Character
- **Alignment:** Left
- **Alias:** $Fw.$ and $CHARw.$

---

**Syntax**

$w$

**Arguments**

\(w\)

Specifies the width of the output field. You can specify a number or a column range.

- **Default**: 8 if the length of the identifier is undefined; otherwise, the length of the identifier
- **Range**: 1–32767

**Comparisons**

The $w$, $Fw.$, and the $CHARw.$ formats are identical, and they do not trim leading blanks. To trim leading blanks, use the LEFT function to left align character data before output.

**Example**

<table>
<thead>
<tr>
<th>Statements†</th>
<th>Results†</th>
</tr>
</thead>
<tbody>
<tr>
<td>----+----1</td>
<td></td>
</tr>
<tr>
<td>a=put(' Cary',$5.);</td>
<td>#Cary</td>
</tr>
<tr>
<td>a=put('Tokyo',$5.);</td>
<td>Tokyo</td>
</tr>
</tbody>
</table>

† The character # represents a blank space.

**See Also**

**Functions:**
- “LEFT Function” on page 431
BEST Format

SAS chooses the best notation.

**Category:** Numeric  
**Alignment:** Right  
**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

Syntax

```
BESTw.  
```

**Arguments**

`w`  
specifies the width of the output field.

- **Default:** 12  
- **Range:** 1–32  
- **Tip:** If you print numbers between 0 and .01 exclusively, then use a field width of at least 7 to avoid excessive rounding. If you print numbers between 0 and -.01 exclusively, use a field width of at least 8.

Details

The BESTw. format is the default format for writing numeric values. When there is no format specification, SAS chooses the format that provides the most information about the value according to the available field width. BESTw. rounds the value, and if SAS can display at least one significant digit in the decimal portion, within the width specified, BESTw. produces the result in decimal. Otherwise, it produces the result in scientific notation. SAS always stores the complete value regardless of the format that you use to represent it.

Comparisons

- The BESTw. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.
- The BESTDOTXw format writes as many significant digits as possible in the output field. Integers are printed with a decimal.
- The Dw.p format writes numbers with the desired precision and more alignment than the BESTw. format.
- The w.d format aligns decimal points, if possible, but does not necessarily show the same precision for all numbers.
Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1257000,best6.);</td>
<td>1.26E6</td>
</tr>
<tr>
<td>a=put(1257000,best3.);</td>
<td>1E6</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “BESTD Format” on page 72
- “BESTDOTX Format” on page 71
- “D Format” on page 77
- “w Format” on page 137

BESTDOTX Format

Specifies that SAS choose the best notation and use a dot as a decimal separator.

- **Category:** Numeric
- **Alignment:** Right
- **Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

Syntax

`BESTDOTX.w`

Arguments

- `w`
  - specifies the width of the output field.
  - **Default:** 12
  - **Range:** 1–32
  - **Tip:** If you print numbers between 0 and .01 exclusively, then use a field width of at least 7 to avoid excessive rounding. If you print numbers between 0 and -.01 exclusively, use a field width of at least 8.
Details

If the NLDECSEPARATOR system option is disabled, the BESTw. and BESTDOTXw. formats process data the same way. If the NLDECSEPARATOR system option is enabled, then the results from the BESTw. and BESTDOTXw. formats are different. See the following table to understand the differences:

<table>
<thead>
<tr>
<th>LOCALE option</th>
<th>Default decimal separator character for the locale</th>
<th>NLDECSEPARATOR option</th>
<th>Separator character used by BESTw.</th>
<th>Separator character used by BESTDOTXw.</th>
</tr>
</thead>
<tbody>
<tr>
<td>en_US</td>
<td>Dot</td>
<td>Disabled (default)</td>
<td>Dot</td>
<td>Dot</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Enabled</td>
<td>Dot</td>
<td>Dot</td>
</tr>
<tr>
<td>fr.FR</td>
<td>Comma</td>
<td>Disabled (default)</td>
<td>Dot</td>
<td>Dot</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Enabled</td>
<td>Comma</td>
<td>Dot</td>
</tr>
</tbody>
</table>

For more information about the NLDECSEPARATOR system option, see *SAS Viya National Language Support: Reference Guide*.

Comparisons

The BESTDOTXw format writes as many significant digits as possible in the output field. Integers are printed with a decimal. The BESTw. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.

See Also

Formats:
- “BEST Format” on page 70

BESTD Format

Prints numeric values, lining up decimal places for values of similar magnitude, and prints integers without decimals.

Category: Numeric
Alignment: Right
Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS Viya System Options: Reference*.

Syntax

BESTDw.[p]
**Arguments**

\( w \)

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>1–32</td>
</tr>
</tbody>
</table>

\( p \)

specifies the precision.

<table>
<thead>
<tr>
<th>Default</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0 to ( w-1 )</td>
</tr>
</tbody>
</table>

**Requirement**

must be less than \( w \)

**Tip**

If \( p \) is omitted or is specified as 0, then \( p \) is set to 3.

**Details**

The BESTD\( w,p \) format writes numbers so that the decimal point aligns in groups of values with similar magnitude. Integers are printed without a decimal point. Larger values of \( p \) print the data values with more precision and potentially more shifts in the decimal point alignment. Smaller values of \( p \) print the data values with less precision and a greater chance of decimal point alignment.

The format chooses the number of decimal places to be printed for ranges of values, even when the underlying values can be represented with fewer decimal places.

**Comparisons**

- The BEST\( w \). format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.
- The D\( w,p \) format writes numbers with the desired precision and more alignment than the BEST\( w \) format.
- The BESTD\( w,p \) format is a combination of the BEST\( w \). format and the D\( w,p \) format in that it formats all numeric data, and it does a better job of aligning decimals than the BEST\( w \). format.
- The \( w.d \) format aligns decimal points, if possible, but it does not necessarily show the same precision for all numbers.

**Example**

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>---+---1-----+</td>
</tr>
<tr>
<td>a=put(12345, bestd14.);</td>
<td>12345</td>
</tr>
<tr>
<td>a=put(123.45, bestd14.);</td>
<td>123.4500000</td>
</tr>
<tr>
<td>Statements</td>
<td>Results</td>
</tr>
<tr>
<td>------------</td>
<td>------------</td>
</tr>
<tr>
<td>a = put(1.2345, bestd14.);</td>
<td>1.2345000</td>
</tr>
<tr>
<td>a = put(.12345, bestd14.);</td>
<td>0.1234500</td>
</tr>
<tr>
<td>a = put(1.23456789, bestd14.);</td>
<td>1.23456789</td>
</tr>
</tbody>
</table>

**See Also**

**Formats:**
- “BEST Format” on page 70
- “D Format” on page 77
- “w Format” on page 137

**BINARY Format**

Converts numeric values to binary representation.

- **Category:** Numeric
- **Alignment:** Left

**Syntax**

BINARYw.

**Arguments**

w

specifies the width of the output field.

- **Default:** 8
- **Range:** 1–64

**Comparisons**

BINARYw. converts numeric values to binary representation. The $BINARYw.$ format converts character values to binary representation.

**Example**

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a = put(123.45, binary8.);</td>
<td>01111011</td>
</tr>
<tr>
<td>a = put(123.45, binary8.);</td>
<td>01111011</td>
</tr>
</tbody>
</table>
## COMMA Format

Writes numeric values with a comma that separates every three digits and a period that separates the decimal fraction.

**Category:** Numeric  
**Alignment:** Right  
**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

### Syntax

`COMMA[w].[d]`

### Arguments

- **w**
  - Specifies the width of the output field.
  - **Default:** 6  
  - **Range:** 1–32  
  - **Tip:** Make `w` wide enough to write the numeric values, the commas, and the optional decimal point.

- **d**
  - Specifies the number of digits to the right of the decimal point in the numeric value.
  - **Range:** 0–31  
  - **Requirement:** must be less than `w`

### See Also

**Formats:**
- “$SBINARY Format” on page 61
Comparisons

- The COMMAw.d format is similar to the COMMAXw.d format, but the COMMAXw.d format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The COMMAw.d format is similar to the DOLLARw.d format except that the COMMAw.d format does not print a leading dollar sign.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put (23451.23,comma10.2);</td>
<td>23,451.23</td>
</tr>
<tr>
<td>a=put (123451.234,comma10.2);</td>
<td>123,451.23</td>
</tr>
</tbody>
</table>

Formats:
- “COMMAX Format” on page 76
- “DOLLAR Format” on page 88

COMMAX Format

Writes numeric values with a period that separates every three digits and a comma that separates the decimal fraction.

Category: Numeric
Alignment: Right
Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

Syntax

COMMAX[w.d]

Arguments

w

specifies the width of the output field.

Default: 6

Range: 1–32
D Format

Tip: Make \( w \) wide enough to write the numeric values, the commas, and the optional decimal point.

\( d \)

specifies the number of digits to the right of the decimal point in the numeric value.

<table>
<thead>
<tr>
<th>Range</th>
<th>0–31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirement</td>
<td>must be less than ( w )</td>
</tr>
</tbody>
</table>

Comparisons

The COMMA\( w.d \) format is similar to the COMMAX\( w.d \) format, but the COMMAX\( w.d \) format reverses the roles of the decimal point and the comma. This convention is common in European countries.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ ]</td>
<td>[ ]</td>
</tr>
<tr>
<td>[ ]</td>
<td>[ ]</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “COMMA Format” on page 75

D Format

Prints numeric values, possibly with a great range of values, lining up decimal places for values of similar magnitude.

<table>
<thead>
<tr>
<th>Category</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment</td>
<td>Right</td>
</tr>
<tr>
<td>Interaction</td>
<td>When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.</td>
</tr>
</tbody>
</table>

Syntax

\[ \text{D}[w.p] \]
**Arguments**

`w` specifies the width of the output field.

- Default: 12
- Range: 1–32

`p` specifies the significant digits.

- Default: 3
- Range: 0–16
- Requirement: must be less than `w`

**Details**

The `Dw.p` format writes numbers so that the decimal point aligns in groups of values with similar magnitude. Larger values of `p` print the data values with more precision and potentially more shifts in the decimal point alignment. Smaller values of `p` print the data values with less precision and a greater chance of decimal point alignment.

**Comparisons**

- The BESTw. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up.
- `Dw.p` writes numbers with the desired precision and more alignment than BESTw. format

**Example**

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=put (12345,d10.4);</code></td>
<td>12345.0</td>
</tr>
<tr>
<td><code>a=put (1234.5,d10.4);</code></td>
<td>1234.5</td>
</tr>
<tr>
<td><code>a=put (123.45,d10.4);</code></td>
<td>123.4500</td>
</tr>
<tr>
<td><code>a=put (12.345,d10.4);</code></td>
<td>12.34500</td>
</tr>
<tr>
<td><code>a=put (1.2345,d10.4);</code></td>
<td>1.23450</td>
</tr>
<tr>
<td><code>a=put (.12345,d10.4);</code></td>
<td>0.12345</td>
</tr>
</tbody>
</table>

**See Also**

Formats:
DATE Format

Writes SAS date values in the form \textit{ddmmmyy}, \textit{ddmmmyyyy}, or \textit{dd-mm-m-yyyy}.

\textbf{Syntax}

\texttt{DATEw}.

\textbf{Arguments}

\texttt{w} specifies the width of the output field.

\begin{center}
\begin{tabular}{ll}
\textbf{Default} & 7 \\
\hline
\textbf{Range} & 5–11 \\
\textbf{Tip} & Use a width of 9 to print a 4-digit year without a separator between the day, month, and year. Use a width of 11 to print a 4-digit year using a hyphen as a separator between the day, month, and year.
\end{tabular}
\end{center}

\textbf{Details}

The \texttt{DATEw} format writes SAS date values in the form \textit{ddmmmyy}, \textit{ddmmmyyyy}, or \textit{dd-mm-m-yyyy}. Here is an explanation of the syntax:

\textit{dd} is an integer that represents the day of the month.

\textit{mmm} is the first three letters of the month name.

\textit{yy} or \textit{yyyy} is a two-digit or four-digit integer that represents the year.

\textbf{Example}

The example table uses the input value of 17241, which is the SAS date value that corresponds to March 16, 2007.

\begin{center}
\begin{tabular}{lc}
\textbf{Statements} & \textbf{Results} \\
\hline
a=put (17241, date5.); & 16MAR \\
a=put (17241, date6.); & 16MAR
\end{tabular}
\end{center}
<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put (17241, date7.);</td>
<td>16MAR07</td>
</tr>
<tr>
<td>a=put (17241, date8.);</td>
<td>16MAR07</td>
</tr>
<tr>
<td>a=put (17241, date9.);</td>
<td>16MAR2007</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**

- “DATE Function” on page 293

---

**DATEAMPM Format**

Writes SAS datetime values in the form *ddmmyy:hh:mm:ss.ss* with AM or PM.

**Category:** Date and Time  
**Alignment:** Right  
**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS Viya System Options: Reference*.

**Syntax**

```plaintext
DATEAMPM w[d]
```

**Arguments**

- **w**  
  specifies the width of the output field.  
  - **Default:** 19  
  - **Range:** 7–40

- **d**  
  specifies the number of digits to the right of the decimal point in the seconds value.  
  - **Range:** 0–39  
  - **Requirement:** must be less than *w*  
  - **Note:** If *w−d* < 17, SAS truncates the decimal values.
Details

The DATEAMPMw.d format writes SAS datetime values in the form \texttt{ddmmyy:hh:mm:ss.ss}. Here is an explanation of the syntax:

- \texttt{dd} is an integer that represents the day of the month.

- \texttt{mmm} is the first three letters of the month name.

- \texttt{yy} is a two-digit integer that represents the year.

- \texttt{hh} is an integer that represents the hour.

- \texttt{mm} is an integer that represents the minutes.

- \texttt{ss.ss} is the number of seconds to two decimal places.

Comparisons

The DATEAMPMw.d format is similar to the DATETIMEw.d format except that DATEAMPMw.d prints AM or PM at the end of the time.

Example

The example table uses the input value of 1489955694, which is the SAS datetime value that corresponds to 01:14:54 PM on March 19, 2007.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{a=put (1489955694, dateampm.);}</td>
<td>19MAR07:01:14:54 PM</td>
</tr>
<tr>
<td>\texttt{a=put (1489955694, dateampm7.;)}</td>
<td>19MAR07</td>
</tr>
<tr>
<td>\texttt{a=put (1489955694, dateampm10.);}</td>
<td>19MAR07:13</td>
</tr>
<tr>
<td>\texttt{a=put (1489955694, dateampm13.);}</td>
<td>19MAR07:01 PM</td>
</tr>
<tr>
<td>\texttt{a=put (1489955694, dateampm22.2.;)}</td>
<td>19MAR2007:01:14:54.00 PM</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DATETIME Format” on page 82
DATETIME Format

Writes SAS datetime values in the form `ddmmmyy:hh:mm:ss.ss`.

**Category:** Date and Time  
**Alignment:** Right  
**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

### Syntax

**DATETIME**\(w\.d\)**

#### Arguments

- **\(w\)** specifies the width of the output field.
  - **Default**: 16
  - **Range**: 7–40
  - **Tip**: SAS requires a minimum \(w\) value of 16 to write a SAS datetime value with the date, hour, and seconds. Add an additional two places to \(w\) and a value to \(d\) to return values with optional decimal fractions of seconds.

- **\(d\)** specifies the number of digits to the right of the decimal point in the seconds value.
  - **Range**: 0–39
  - **Requirement**: must be less than \(w\)

### Details

The DATETIME\(w.d\) format writes SAS datetime values in the form `ddmmmyy:hh:mm:ss.ss`. Here is an explanation of the syntax:

- **\(dd\)** is an integer that represents the day of the month.
- **\(mmm\)** is the first three letters of the month name.
- **\(yy\)** is a two-digit integer that represents the year.
- **\(hh\)** is an integer that represents the hour in 24–hour clock time.
- **\(mm\)** is an integer that represents the minutes.
**ss.ss**

is the number of seconds to two decimal places.

*Note:* If \( w=d,17 \), SAS truncates the decimal values.

## Comparisons

The DATEAMPM\( w,d \) format is similar to the DATETIME\( w,d \) format except that DATEAMPM\( w,d \) prints AM or PM at the end of the time.

## Example

The example table uses the input value of 1510285759, which is the SAS datetime value that corresponds to 3:49:19 AM on November 10, 2007.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>---+----1----+----2</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>a=put (1510285759,datetime.);</td>
<td>10NOV07:03:49:19</td>
</tr>
<tr>
<td>a=put (1510285759,datetime7.);</td>
<td>10NOV07</td>
</tr>
<tr>
<td>a=put (1510285759,datetime12.);</td>
<td>10NOV07:03</td>
</tr>
<tr>
<td>a=put (1510285759,datetime18.);</td>
<td>10NOV07:03:49:19</td>
</tr>
<tr>
<td>a=put (1510285759,datetime18.1);</td>
<td>10NOV07:03:49:19.0</td>
</tr>
<tr>
<td>a=put (1510285759,datetime19.);</td>
<td>10NOV2007:03:49:19</td>
</tr>
<tr>
<td>a=put (1510285759,datetime20.1);</td>
<td>10NOV2007:03:49:19.0</td>
</tr>
<tr>
<td>a=put (1510285759,datetime21.2);</td>
<td>10NOV2007:03:49:19.00</td>
</tr>
</tbody>
</table>

## See Also

- “DATEAMPM Format” on page 80
- “TIME Format” on page 131

## Functions:

- “DATETIME Function” on page 295
DAY Format

Writes SAS date values as the day of the month.

Category: Date and Time
Alignment: Right

Syntax

\texttt{DAYw}.

Arguments

\texttt{w}

specifies the width of the output field.

Default: 2
Range: 2–32

Example

The example table uses the input value of 18792, which is the SAS date value that corresponds to June 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{a=put(18792, day2.);}</td>
<td>14</td>
</tr>
</tbody>
</table>

See Also

DDMMYY Format

Writes SAS date values in the form \texttt{ddmm<yy>yy} or \texttt{dd/mml<yy>yy}, where a forward slash is the separator and the year appears as either 2 or 4 digits.

Category: Date and Time
Alignment: Right

Syntax

\texttt{DDMMYYw}.
Arguments

\( w \)

specifies the width of the output field.

- Default: 8
- Range: 2–10

Interaction

When \( w \) has a value from 2 to 5, the date appears with as many digits of the day and the month as possible. When \( w \) is 7, the date appears as a two-digit year without slashes.

Details

The DDMMYYw. format writes SAS date values in the form \( ddmmyy\) or \( dd/mm/<yy>yy \). Here is an explanation of the syntax:

- \( dd \)
  - is an integer that represents the day of the month.
- \( / \)
  - is the separator.
- \( mm \)
  - is an integer that represents the month.
- \( <yy>yy \)
  - is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 18985, which is the SAS date value that corresponds to December 24, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{put}(18985, \text{ddmmyy}.); )</td>
<td>24/12/11</td>
</tr>
<tr>
<td>( \text{put}(18985, \text{ddmmyy5}.); )</td>
<td>24/12</td>
</tr>
<tr>
<td>( \text{put}(18985, \text{ddmmyy6}.); )</td>
<td>241211</td>
</tr>
<tr>
<td>( \text{put}(18985, \text{ddmmyy7}.); )</td>
<td>241211</td>
</tr>
<tr>
<td>( \text{put}(18985, \text{ddmmyy8}.); )</td>
<td>24/12/11</td>
</tr>
<tr>
<td>( \text{put}(18985, \text{ddmmyy10}.); )</td>
<td>24/12/2011</td>
</tr>
</tbody>
</table>

See Also

Formats:
DDMMYYx Format

Writes SAS date values in the form ddmm<yy>yy or dd-mm-yy<yy>, where x in the format name is a character that represents the special character that separates the day, month, and year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

Syntax

DDMMYYxw.

Arguments

x

identifies a separator or specifies that no separator appear between the day, the month, and the year. Here are the valid values:

B
separates with a blank

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a slash.

w

specifies the width of the output field.

Default 8

Range 2–10
Interactions
When \( w \) has a value from 2 to 5, the date appears with as many digits of the day and the month as possible. When \( w \) is 7, the date appears as a two-digit year without separators.

When \( x \) has a value of \( N \), the width range changes to 2–8.

Details
The DDMMYYxw format writes SAS date values in the form \( ddmm<yy>yy \) or \( ddXnmX<yy>yy \). Here is an explanation of the syntax:

- \( dd \)
  - an integer that represents the day of the month.

- \( X \)
  - a specified separator.

- \( mm \)
  - an integer that represents the month.

- \( <yy>yy \)
  - a two-digit or four-digit integer that represents the year.

Example
The following examples use the input value of 18702, which is the SAS date value that corresponds to March 16, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a=put(18702,ddmmyyc5.) );</td>
<td>16:03</td>
</tr>
<tr>
<td>( a=put(18702,ddmmyyd8.) );</td>
<td>16-03-11</td>
</tr>
<tr>
<td>( a=put(18702,ddmmyyn8.) );</td>
<td>16032011</td>
</tr>
<tr>
<td>( a=put(18702,ddmmyyp10.) );</td>
<td>16.03.2011</td>
</tr>
</tbody>
</table>

DOLLAR Format

Writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

**Category:** Numeric

**Alignment:** Right

**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

### Syntax

DOLLAR\(w.d\)

### Arguments

\(w\)

- Specifies the width of the output field.
- **Default:** 6
- **Range:** 2–32

\(d\)

- Specifies the number of digits to the right of the decimal point in the numeric value.
- **Range:** 0–31
- **Requirement:** must be less than \(w\)

### Details

The DOLLAR\(w.d\) format writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

The hexadecimal representation of the code for the dollar sign character ($) is 5B on EBCDIC systems and 24 on ASCII systems. The monetary character that these codes represent might be different in other countries, but DOLLAR\(w.d\) always produces one of these codes.

### Comparisons

- The DOLLAR\(w.d\) format is similar to the DOLLARX\(w.d\) format, but the DOLLARX\(w.d\) format reverses the roles of the decimal point and the comma. This convention is common in European countries.
The DOLLARw.d format is the same as the COMMAw.d format except that the COMMAw.d format does not write a leading dollar sign.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1254.71,dollar10.2);</td>
<td>$1,254.71</td>
</tr>
</tbody>
</table>

- “DOLLAR Format” on page 89

DOLLARX Format

Writes numeric values with a leading dollar sign, a period that separates every three digits, and a comma that separates the decimal fraction.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment:</td>
<td>Right</td>
</tr>
</tbody>
</table>
| Interaction:     | When the DECIMALCONV= system option is set to STDEEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

Syntax

DOLLARXw.[d]

Arguments

w

specifies the width of the output field.

Default 6

Range 2–32

d

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 2–31
Requirement  must be less than \( w \)

Details

The DOLLARX\( w.d \) format writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

The hexadecimal representation of the code for the dollar sign character ($) is 5B on EBCDIC systems and 24 on ASCII systems. The monetary character that these codes represent might be different in other countries, but DOLLARX\( w.d \) always produces one of these codes.

Comparisons

- The DOLLARX\( w.d \) format is similar to the DOLLAR\( w.d \) format, but the DOLLARX\( w.d \) format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The DOLLARX\( w.d \) format is the same as the COMMAX\( w.d \) format except that the COMMA\( w.d \) format does not write a leading dollar sign.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1254.71,dollarx10.2);</td>
<td>$1.254,71</td>
</tr>
</tbody>
</table>

Formats:

- “COMMAX Format” on page 76
- “DOLLAR Format” on page 88

DOWNNAME Format

Writess SAS date values as the name of the day of the week.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment:</td>
<td>Right</td>
</tr>
</tbody>
</table>

Syntax

\[ \text{DOWNNAME}_w \]
Arguments

w
specifies the width of the output field.

Default 9

Range 1–32

Tip If you omit w, SAS prints the entire name of the day.

Details
If necessary, SAS truncates the name of the day to fit the format width. For example, the format DOWNAME2. prints the first two letters of the day name.

Example
The example table uses the input value of 18702, which is the SAS date value that corresponds to March 16, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18702,downame.);</td>
<td>Wednesday</td>
</tr>
</tbody>
</table>

See Also

Formats:
• “WEEKDAY Format” on page 141

DTDATE Format

Expects a SAS datetime value as input and writes the SAS date values in the form ddmmyy or ddmmyyyy.

Category: Date and Time

Alignment: Right

Syntax

DTDATE\textsubscript{w}.

Arguments

\textsubscript{w}
specifies the width of the output field.
Defaults

- Default: 7
- Range: 5–9
- Tip: Use a width of 9 to print a 4-digit year.

Details

The DTDATEw. format writes SAS date values in the form \textit{ddmmmyy} or \textit{ddmmmyyyy}. Here is an explanation of the syntax:

- \textit{dd} is an integer that represents the day of the month.
- \textit{mmm} are the first three letters of the month name.
- \textit{yy} or \textit{yyyy} is a two-digit or four-digit integer that represents the year.

Comparisons

The DTDATEw. format produces the same type of output that the DATEw. format produces. The difference is that the DTDATEw. format requires a SAS datetime value.

Example

The example table uses the input value of 1636516159, which is the SAS datetime value that corresponds to 3:49:19 a.m. on November 10, 2011, and prints both a two-digit and a four-digit year for the DTDATEw. format.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1636516159,dtdate.);</td>
<td>10NOV11</td>
</tr>
<tr>
<td>a=put(1636516159,dtdate9.);</td>
<td>10NOV2011</td>
</tr>
</tbody>
</table>

Formats:

- “DATE Format” on page 79

DTMONYY Format

Writes the date part of a SAS datetime value as the month and year in the form \textit{mmmyy} or \textit{mmmyyyy}.

Category: Date and Time

Alignment: Right
Syntax

**DTMONYY**\(w\).

**Arguments**

\(w\)

specifies the width of the output field.

- Default: 5
- Range: 5–7

**Details**

The DTMONYY\(w\). format writes SAS datetime values in the form *mmm*yy or *mmm*yyyy.

Here is an explanation of the syntax:

*mmm*

is the first three letters of the month name.

*yy* or *yyyy*

is a two-digit or four-digit integer that represents the year.

**Comparisons**

The DTMONYY\(w\). format and the MONYY\(w\). format are similar in that they both write date values. The difference is that DTMONYY\(w\). expects a SAS datetime value as input, and MONYY\(w\). expects a SAS date value.

**Example**

The example table uses as input the value 1634364532, which is the SAS datetime value that corresponds to October 16, 2011, at 06:08:52 a.m.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1634364532,dtmonyy.);</td>
<td>OCT11</td>
</tr>
<tr>
<td>a=put(1634364532,dtmonyy5.);</td>
<td>OCT11</td>
</tr>
<tr>
<td>a=put(1634364532,dtmonyy6.);</td>
<td>OCT11</td>
</tr>
<tr>
<td>a=put(1634364532,dtmonyy7.);</td>
<td>OCT2011</td>
</tr>
</tbody>
</table>

**See Also**

DTWKDATX Format
Writesto the date part of a SAS datetime value as the day of the week and the date in the form day-of-week, dd month-name yy (or yyyy).

Category: Date and Time
Alignment: Right

Syntax
DTWKDATXw.

Arguments
w
specifies the width of the output field.
Default 29
Range 3–37

Details
The DTWKDATXw. format writes SAS date values in the form day-of-week, dd, month-name, yy, or yyyy. Here is an explanation of the syntax:

day-of-week
is either the first three letters of the day name or the entire day name.

dd
is an integer that represents the day of the month.

month-name
is either the first three letters of the month name or the entire month name.

yy or yyyy
is a two-digit or four-digit integer that represents the year.

Comparisons
The DTWKDATXw. format is similar to the WEEKDATXw. format in that they both write date values. The difference is that DTWKDATXw. expects a SAS datetime value as input, and WEEKDATXw. expects a SAS date value.

Example
The example table uses as input the value 1634364532, which is the SAS datetime value that corresponds to October 16, 2011, at 06:08:52 a.m.
DTYEAR Format

Writes the date part of a SAS datetime value as the year in the form yy or yyyy.

**Category:** Date and Time  
**Alignment:** Right

### Syntax

` DTYEARw.`

### Arguments

`w`

specifies the width of the output field.

- **Default:** 4
- **Range:** 2–4

### Comparisons

The `DTYEARw.` format is similar to the `YEARw.` format in that they both write date values. The difference is that `DTYEARw.` expects a SAS datetime value as input, and `YEARw.` expects a SAS date value.

---

**DTYYQC Format**

 Writes the date part of a SAS datetime value as the year and the quarter and separates them with a colon (:).

**Category:** Date and Time

**Alignment:** Right

**Syntax**

\[ \text{DTYYQC}_w \]

**Arguments**

\( w \)

specifies the width of the output field.

**Default:** 4

**Range:** 4–6

**Details**

The DTYYQCw. format writes SAS datetime values in the form yy or yyyy, followed by a colon (:) and the numeric value for the quarter of the year.
Example

The example table uses as input the value 1634364532, which is the SAS datetime value that corresponds to October 16, 2011, at 06:08:52 p.m.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1634364532,dtryyqc.);</td>
<td>11:4</td>
</tr>
<tr>
<td>a=put(1634364532,dtryyqc4.);</td>
<td>11:4</td>
</tr>
<tr>
<td>a=put(1634364532,dtryyqc5.);</td>
<td>11:4</td>
</tr>
<tr>
<td>a=put(1634364532,dtryyqc6.);</td>
<td>2011:4</td>
</tr>
</tbody>
</table>

See Also

• “Dates and Times in DS2” in *SAS Viya: DS2 Programmer’s Guide*

Formats:

• “DATETIME Format” on page 82

---

**E Format**

Writes numeric values in scientific notation.

**Category:** Numeric

**Alignment:** Right

**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS Viya System Options: Reference*.

**Syntax**

\[ Ew. \]

**Arguments**

\[ w \]

specifies the width of the output field.

Default 12

Range 7–32
Details
SAS reserves the first column of the result for a minus sign.

Example
The example table uses the input value of 1257.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1257,e10.);</td>
<td>1.257E+03</td>
</tr>
<tr>
<td>a=put(-1257,e10.);</td>
<td>-1.257E+03</td>
</tr>
</tbody>
</table>

EURO Format
Writes numeric values with a leading euro symbol (E), a comma that separates every three digits, and a period that separates the decimal fraction.

Category: Numeric
Alignment: Right

Syntax
EURO\textit{w.d}

Arguments
\textit{w}
specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>1-32</td>
</tr>
</tbody>
</table>

Tip
If you want the euro symbol to be part of the output, be sure to choose an adequate width.

\textit{d}
specifies the number of digits to the right of the decimal point in the numeric value.

<table>
<thead>
<tr>
<th>Default</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0-31</td>
</tr>
<tr>
<td>Requirement</td>
<td>must be less than \textit{w}</td>
</tr>
</tbody>
</table>
Comparisons

- The EURO\textit{w.d} format is similar to the EUROX\textit{w.d} format, but EUROX\textit{w.d} format reverses the roles of the decimal point and the comma. This convention is common in European countries.

- The EURO\textit{w.d} format is similar to the DOLLAR\textit{w.d} format, except that DOLLAR\textit{w.d} format writes a leading dollar sign instead of the euro symbol.

\textit{Note:} The EUROX\textit{w.d} format uses the euro character (U+20AC). If you use the DBCS version of SAS and an encoding that does not support the euro character, an error occurs. To prevent this error, change your session encoding to an encoding that supports the euro character.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{a=put(1254.71,euro10.2);}</td>
<td>\texttt{E1,254.71}</td>
</tr>
<tr>
<td>\texttt{a=put(1254.71,euro5.)};</td>
<td>\texttt{1,255}</td>
</tr>
<tr>
<td>\texttt{a=put(1254.71,euro9.2);}</td>
<td>\texttt{E1,254.71}</td>
</tr>
<tr>
<td>\texttt{a=put(1254.71,euro15.3);}</td>
<td>\texttt{E1,254.710}</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “EUROX Format” on page 99

EUROX Format

Writes numeric values with a leading euro symbol (E), a period that separates every three digits, and a comma that separates the decimal fraction.

- **Category:** Numeric
- **Alignment:** Right

Syntax

\texttt{EUROXw.d}

Arguments

\texttt{w}

specifies the width of the output field.
Tip
If you want the euro symbol to be part of the output, be sure to choose an adequate width.

\( d \)

specifies the number of digits to the right of the decimal point in the numeric value.

Comparisons

- The EUROXw.d format is similar to the EUROW.d format, but EUROW.d format reverses the roles of the comma and the decimal point. This convention is common in English-speaking countries.
- The EUROXw.d format is similar to the DOLLARXw.d format, except that DOLLARXw.d format writes a leading dollar sign instead of the euro symbol.

Note: The EUROXw.d format uses the euro character (U+20AC). If you use the DBCS version of SAS and an encoding that does not support the euro character, an error occurs. To prevent this error, change your session encoding to an encoding that supports the euro character.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put (1254.71, eurox10.2);</td>
<td>E1.254,71</td>
</tr>
<tr>
<td>a=put (1254.71, eurox5.);</td>
<td>1255</td>
</tr>
<tr>
<td>a=put (1254.71, eurox9.2);</td>
<td>E1.254,71</td>
</tr>
<tr>
<td>a=put (1254.71, eurox15.3);</td>
<td>E1.254,710</td>
</tr>
</tbody>
</table>

Formats:
- “DOLLARX Format” on page 89
- “EURO Format” on page 98
FLOAT Format

Generates a native single-precision, floating-point value by multiplying a number by 10 raised to the \( d \)th power.

**Category:** Numeric

**Alignment:** Left

**Syntax**

FLOAT \( w \).\([d] \)

**Arguments**

\( w \)

specifies the width of the output field.

**Requirement**

width must be 4

\( d \)

specifies the power of 10 by which to multiply the value.

**Default**

0

**Range**

0 – 31

**Details**

Values that are written by FLOAT4 typically are those meant to be read by some other external program that runs in your operating environment and that expects these single-precision values. If the value that is to be formatted is a missing value, or if it is out-of-range for a native single-precision, floating-point value, a single-precision value of zero is generated.

**Example**

In the example below, you use the VARBINARY data type in the DECLARE statement to get a hexadecimal representation of a binary number.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results *</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1,float4.);</td>
<td>0000803F</td>
</tr>
</tbody>
</table>

* The result is a hexadecimal representation of a binary number that is stored in IEEE form.

FRACT Format

Converts numeric values to fractions.

**Category:** Numeric
**Syntax**

\texttt{FRACT w.}

**Arguments**

\( w \)

specifies the width of the output field.

Default: 10

Range: 4\textendash}32

**Details**

Dividing the number 1 by 3 produces the value 0.33333333. To write this value as \(\frac{1}{3}\), use the \texttt{FRACT w.} format. \texttt{FRACT w.} writes fractions in reduced form, that is, \(\frac{1}{2}\) instead of 50/100.

**Example**

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{a=put(0.6666666667,fract8.;)}</td>
<td>(\frac{2}{3})</td>
</tr>
<tr>
<td>\texttt{a=put(0.2784,fract8.;)}</td>
<td>(174/625)</td>
</tr>
</tbody>
</table>

**HEX Format**

Converts real binary (floating-point) values to hexadecimal representation.

**Category:** Numeric

**Alignment:** Left

**Syntax**

\texttt{HEX w.}

**Arguments**

\( w \)

specifies the width of the output field.

Default: 8
Range 1–16

Tip If $w < 16$, the $\text{HEX}_w$ format converts real binary numbers to fixed-point integers before writing them as hexadecimal characters. It also writes negative numbers in two's complement notation, and right aligns digits. If $w$ is 16, $\text{HEX}_w$ displays floating-point values in their hexadecimal form.

Details

In any operating environment, the least significant byte written by $\text{HEX}_w$ is the rightmost byte. Some operating environments store integers with the least significant digit as the first byte. The $\text{HEX}_w$ format produces consistent results in any operating environment regardless of the order of significance by byte.

Note: Different operating environments store floating-point values in different ways. However, the $\text{HEX}_{16}$ format writes hexadecimal representations of floating-point values with consistent results in the same way that your operating environment stores them.

Comparisons

The $\text{HEX}_w$ numeric format and the $\text{HEX}_w$ character format both generate the hexadecimal equivalent of values.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>--------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>$a=\text{put}(35.4, \text{hex}8.);$</td>
<td>00000023</td>
</tr>
<tr>
<td>$a=\text{put}(88, \text{hex}8.);$</td>
<td>00000058</td>
</tr>
<tr>
<td>$a=\text{put}(2.33, \text{hex}8.);$</td>
<td>00000002</td>
</tr>
<tr>
<td>$a=\text{put}(-150, \text{hex}8.);$</td>
<td>FFFFFFF6A</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “$\text{HEX}$ Format” on page 63

HHMM Format

Writes SAS time values as hours and minutes in the form $hh:mm$.

Category: Date and Time

Alignment: Right
Syntax

**HHMMw.[d]**

**Arguments**

- **w**
  - Specifies the width of the output field.
  - Default: 5
  - Range: 2–20

- **d**
  - Specifies the number of digits to the right of the decimal point in the minutes value.
  - The digits to the right of the decimal point specify a fraction of a minute.
  - Default: 0
  - Range: 0–19
  - Requirement: must be less than w

**Details**

The HHMMw.d format writes SAS datetime values in the form *hh:mm*. Here is an explanation of the syntax:

- **hh**
  - Is an integer.

- **mm**
  - Is the number of minutes that range from 00 through 59.

SAS rounds hours and minutes that are based on the value of seconds in a SAS time value.

**Comparisons**

The HHMMw.d format is similar to the TIMEw.d format except that the HHMMw.d format does not print seconds.

The HHMMw.d format and the TIMEw.d format write a leading blank for the single-hour digit. The TODw.d format writes a leading zero for a single-hour digit.

**Example**

The example table uses the input value of 46796, which is the SAS time value that corresponds to 12:59:56 p.m..

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(46796,hhmm.);</td>
<td>13:00</td>
</tr>
<tr>
<td>a=put(46796,hhmm8.2);</td>
<td>12:59.93</td>
</tr>
</tbody>
</table>
In the first example, SAS rounds up the time value four seconds based on the value of seconds in the SAS time value. In the second example, by adding a decimal specification of 2 to the format shows that fifty-six seconds is 93% of a minute.

See Also

- “TIME Function” on page 631

### HOUR Format

Writes SAS time values as hours and decimal fractions of hours.

**Category:** Date and Time

**Alignment:** Right

**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS Viya System Options: Reference*.

**Syntax**

\[ \text{HOUR} w. [d] \]

**Arguments**

\( w \)

specifies the width of the output field.

Default: 2

Range: 2–20

\( d \)

specifies the number of digits to the right of the decimal point in the hour value. Therefore, SAS prints decimal fractions of the hour.
Range: 0-19

Requirement: must be less than \( w \)

**Details**

SAS rounds hours based on the value of minutes in the SAS time value.

**Example**

The example table uses the input value of 41400, which is the SAS time value that corresponds to 11:30 AM.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=put(41400,hour4.1);</code></td>
<td>11.5</td>
</tr>
</tbody>
</table>

- “HOUR Function” on page 359
- “MINUTE Function” on page 457
- “SECOND Function” on page 602
- “TIME Function” on page 631

**IEEE Format**

Generates an IEEE floating-point value by multiplying a number by 10 raised to the \( d \)th power.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment:</td>
<td>Left</td>
</tr>
<tr>
<td><strong>CAUTION:</strong></td>
<td>Large floating-point values and floating-point values that require precision might not be identical to the original SAS value when they are written to an IBM mainframe by using the IEEE format and read back into SAS using the IEEE informat.</td>
</tr>
</tbody>
</table>
Syntax

\texttt{IEEEw.\[d\]}

Arguments

\texttt{w}

specifies the width of the output field.

- **Default**: 8
- **Range**: 1–8
- **Tip**: If \texttt{w} is 8, an IEEE double-precision, floating-point number is written. If \texttt{w} is 5, 6, or 7, an IEEE double-precision, floating-point number is written, which assumes truncation of the appropriate number of bytes. If \texttt{w} is 4, an IEEE single-precision floating-point number is written. If \texttt{w} is 3, an IEEE single-precision, floating-point number is written, which assumes truncation of one byte.

\texttt{d}

specifies to multiply the number by $10^d$.

- **Default**: 0
- **Range**: 0–10

Details

This format is useful in operating environments where IEEE\texttt{w.\[d\]} is the floating-point representation that is used. In addition, you can use the IEEE\texttt{w.\[d\]} format to create files that are used by programs in operating environments that use the IEEE floating-point representation.

Typically, programs generate IEEE values in single-precision (4 bytes) or double-precision (8 bytes). Programs perform truncation solely to save space on output files. Machine instructions require that the floating-point number be one of the two lengths. The IEEE\texttt{w.\[d\]} format allows other lengths, which enables you to write data to files that contain space-saving truncated data.

Example

In the following example, you use the VARBINARY data type in the DECLARE statement to produce results that are hexadecimal representations of binary numbers stored in IEEE form.

\begin{verbatim}
data _null_;  
  method run();  
    dcl varbinary(8) a;  
    a=put(1,ieee4.);  
    put a=;  
    a=put(1,ieee5.);  
    put a=;  
  end;  
enddata;  
\end{verbatim}
run;

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1,ieee4.);</td>
<td>3FF00000</td>
</tr>
<tr>
<td>a=put(1,ieee5.);</td>
<td>3FF0000000</td>
</tr>
</tbody>
</table>

* The results contain a binary value.

### JULIAN Format

Writes SAS date values as Julian dates in the form *yyddd* or *yyyyddd*.

**Category:** Date and Time

**Alignment:** Left

### Syntax

\[ \text{JULIAN}w.\]

### Arguments

\[ w \]

specifies the width of the output field.

**Default** 5

**Range** 5–7

**Tip** If \( w \) is 5, the JULIAN\( w \). format writes the date with a two-digit year. If \( w \) is 7, the JULIAN\( w \). format writes the date with a four-digit year.

### Details

The JULIAN\( w \). format writes SAS date values in the form *yyddd* or *yyyyddd*. Here is an explanation of the syntax:

- \( \text{yy} \) or \( \text{yyyy} \)
  - is a two-digit or four-digit integer that represents the year.
- \( \text{ddd} \)
  - is the number of the day, 1–365 (or 1–366 for leap years), in that year.

### Example

The example table uses the input value of 17524, which is the SAS date value that corresponds to December 24, 2007 (the 358th day of the year).
### Statements

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(17524, julian5.);</td>
<td>07358</td>
</tr>
<tr>
<td>a=put(17524, julian7.);</td>
<td>2007358</td>
</tr>
</tbody>
</table>

### See Also

### Functions:

- “DATEJUL Function” on page 293

---

## MDYAMPM Format

Writing datetime values in the form *mm/dd/yy<yy>* *hh:mm AM|PM*. The year can be either two or four digits.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment:</td>
<td>Right</td>
</tr>
</tbody>
</table>
| Interaction: | When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS Viya System Options: Reference*.
| Note:      | The default time period is AM. |

### Syntax

MDYAMPMw.

### Arguments

w

specifies the width of the output field.

- Default: 19
- Range: 8–40

### Details

The MDYAMPMw.d format writes SAS datetime values in the following form:

*mm/dd/yy[yy]* *hh:mm[AM | PM]*:

- *mm* is an integer between 1 and 12 that represents the month.
- *dd* is an integer between 1 and 31 that represents the day of the month.
- *yy* or *yyyy* specifies a two-digit or four-digit integer that represents the year.
is an integer between 00 and 23 that represents hours.

is an integer between 00 and 59 that represents minutes.

AM | PM
specifies either the time period 00:01−12:00 noon (PM) or the time period 12:01−12:00 midnight (AM). The default is AM.

date and time separator characters
is one of several special characters, such as the slash (/), colon (:), or a blank character that SAS uses to separate date and time components.

Comparisons

The MDYAMPMw. format writes datetime values with separators in the form mm/dd/ yy<yy> hh:mm AM | PM, and requires a space between the date and the time.

The DATETIMEw.d format writes datetime values with separators in the form ddmmyy<yy>: hh:mm:ss.ss.

Example

This example uses the input value of 1694836380, or the SAS datetime value that corresponds to 3:53:00 PM on September 15, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>put dt mdyampm18.</td>
<td>9/15/2013 3:53 PM</td>
</tr>
</tbody>
</table>

See Also

Formats:

• “DATETIME Format” on page 82

**MMDDYY Format**

Writes SAS date values in the form mmdd<yy>yy or mmi/ddl<yy>yy, where a forward slash is the separator and the year appears as either 2 or 4 digits.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment:</td>
<td>Right</td>
</tr>
</tbody>
</table>

**Syntax**

MMDDYYw.
Arguments

\( w \)

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>2–10</td>
</tr>
</tbody>
</table>

Interaction

When \( w \) has a value from 2 to 5, the date appears with as many digits of the month and the day as possible. When \( w \) is 7, the date appears as a two-digit year without slashes.

Details

The MMDDYY\( w \). format writes SAS date values in the form \( mmmdd<yy>yy \) or \( mm/dd/<yy>yy \). Here is an explanation of the syntax:

- \( mm \)
  is an integer that represents the month.

- \( / \)
  is the separator.

- \( dd \)
  is an integer that represents the day of the month.

- \(<yy>yy \)
  is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 18925, which is the SAS date value that corresponds to October 25, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>18925</td>
</tr>
<tr>
<td>a=put(18925, mmddyy2.);</td>
<td>10</td>
</tr>
<tr>
<td>a=put(18925, mmddyy3.);</td>
<td>10</td>
</tr>
<tr>
<td>a=put(18925, mmddyy4.);</td>
<td>10/25</td>
</tr>
<tr>
<td>a=put(18925, mmddyy5.);</td>
<td>10/25</td>
</tr>
<tr>
<td>a=put(18925, mmddyy6.);</td>
<td>102511</td>
</tr>
<tr>
<td>a=put(18925, mmddyy7.);</td>
<td>102511</td>
</tr>
<tr>
<td>a=put(18925, mmddyy8.);</td>
<td>10/25/11</td>
</tr>
<tr>
<td>a=put(18925, mmddyy10.);</td>
<td>10/25/2011</td>
</tr>
</tbody>
</table>

Formats:

- “DATE Format” on page 79
- “DDMMYY Format” on page 84
- “MMDDYYx Format” on page 112
- “YYMMDD Format” on page 147

Functions:

- “DAY Function” on page 296
- “MDY Function” on page 453
- “MONTH Function” on page 464
- “YEAR Function” on page 674

**MMDDYYx Format**

Writes SAS date values in the form *mmdd<yy>yy or mm-dd<yy>yy*, where the *x* in the format name is a character that represents the special character, which separates the month, day, and year. The special character can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

**Category:** Date and Time

**Alignment:** Right

**Syntax**

`MMDDYYxw.`

**Arguments**

*x*

identifies a separator or specifies that no separator appear between the month, the day, and the year. Here are the valid values:

- **B**
  separates with a blank
- **C**
  separates with a colon
- **D**
  separates with a hyphen
- **N**
  indicates no separator
- **P**
  separates with a period
S separates with a slash.

w specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>2–10</td>
</tr>
<tr>
<td>Interactions</td>
<td>When w has a value from 2 to 5, the date appears with as many digits of the month and the day as possible. When w is 7, the date appears as a two-digit year without separators. When x has a value of N, the width range changes to 2–8.</td>
</tr>
</tbody>
</table>

Details

The MMDDYY_{xw} format writes SAS date values in the form \texttt{mmdd<yy>yy} or \texttt{mmXdX<yy>yy}. Here is an explanation of the syntax:

- \texttt{mm} is an integer that represents the month.
- \texttt{X} is a specified separator.
- \texttt{dd} is an integer that represents the day of the month.
- \texttt{<yy>yy} is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 18922, which is the SAS date value that corresponds to October 22, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18922,mmddyyx5.);</td>
<td>10:22</td>
</tr>
<tr>
<td>a=put(18922,mmddyyd8.);</td>
<td>10-22-11</td>
</tr>
<tr>
<td>a=put(18922,mmddyyyn8.);</td>
<td>10222011</td>
</tr>
<tr>
<td>a=put(18922,mmddyyyp10.);</td>
<td>10.22.2011</td>
</tr>
</tbody>
</table>

Formats:

- “DATE Format” on page 79
MMSS Format

Writes SAS time values as the number of minutes and seconds since midnight.

**Category:** Date and Time  
**Alignment:** Right  
**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

**Syntax**

\[ \text{MMSS}^w.\{d\} \]

**Arguments**

\(w\)

specifies the width of the output field.

- **Default:** 5  
- **Range:** 2–20  
- **Tip:** Set \(w\) to a minimum of 5 to write a value that represents minutes and seconds.

\(d\)

specifies the number of digits to the right of the decimal point in the seconds value. Therefore, the SAS time value includes fractional seconds.

- **Range:** 0–19  
- **Restriction:** must be less than \(w\)
MMYY Format

Writes SAS date values in the form mmM<yy>yy, where M is the separator and the year appears as either 2 or 4 digits.

**Category:** Date and Time  
**Alignment:** Right

## Syntax

\texttt{MMYYw}.

### Arguments

\texttt{w}  

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
<th>Interaction</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>5–32</td>
<td>When \texttt{w} has a value of 5 or 6, the date appears with only the last two digits of the year. When \texttt{w} is 7 or more, the date appears with a four-digit year.</td>
</tr>
</tbody>
</table>

---

**Example**

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=put(4530,mmss.);</code></td>
<td>75:30</td>
</tr>
</tbody>
</table>

**Functions:**

- “HMS Function” on page 355
- “MINUTE Function” on page 457
- “SECOND Function” on page 602
Details

The MMYYw format writes SAS date values in the form mmM<yy>yy. Here is an explanation of the syntax:

- **mm** is an integer that represents the month.
- **M** is the character separator.
- **<yy>yy** is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 18925, which is the SAS date value that corresponds to October 25, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18925,mmyy5.);</td>
<td>10M11</td>
</tr>
<tr>
<td>a=put(18925,mmyy6.);</td>
<td>10M11</td>
</tr>
<tr>
<td>a=put(18925,mmyy.);</td>
<td>10M2011</td>
</tr>
<tr>
<td>a=put(18925,mmyy7.);</td>
<td>10M2011</td>
</tr>
<tr>
<td>a=put(18925,mmyy10.);</td>
<td>10M2011</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “MMYYx Format” on page 116
- “YYMM Format” on page 144

MMYYx Format

Writes SAS date values in the form *mm<yy>yy* or *mm-<yy>yy*, where the *x* in the format name is a character that represents the special character that separates the month and the year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

- **Category:** Date and Time
- **Alignment:** Right
Syntax

MMYYw.

Arguments

\( x \)
identifies a separator or specifies that no separator appear between the month and the year. Here are the valid values:

- \( C \) separates with a colon
- \( D \) separates with a hyphen
- \( N \) indicates no separator
- \( P \) separates with a period
- \( S \) separates with a forward slash.

\( w \)
specifies the width of the output field.

Default 7

Range 5–32

Interactions

When \( x \) is set to \( N \), no separator is specified. The width range is then 4–32, and the default changes to 6.

When \( x \) has a value of \( C \), \( D \), \( P \), or \( S \) and \( w \) has a value of 5 or 6, the date appears with only the last two digits of the year. When \( w \) is 7 or more, the date appears with a four-digit year.

When \( x \) has a value of \( N \) and \( w \) has a value of 4 or 5, the date appears with only the last two digits of the year. When \( x \) has a value of \( N \) and \( w \) is 6 or more, the date appears with a four-digit year.

Details

The MMYYw. format writes SAS date values in the form \( mm<yy>yy \) or \( mmX<yy>yy \). Here is an explanation of the syntax:

\( mm \)
is an integer that represents the month.

\( X \)
is a specified separator.

\( <yy>yy \)
is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 18822, which is the SAS date value that corresponds to July 14, 2011.
### Statements

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18822,mmyyc5.);</td>
<td>07:11</td>
</tr>
<tr>
<td>a=put(18822,mmyyd7.);</td>
<td>07-2011</td>
</tr>
<tr>
<td>a=put(18822,mmyyn4.);</td>
<td>0711</td>
</tr>
<tr>
<td>a=put(18822,mmyyp8.);</td>
<td>07.2011</td>
</tr>
<tr>
<td>a=put(18822,mmyys10.);</td>
<td>07/2011</td>
</tr>
</tbody>
</table>

### See Also

### MONNAME Format

*Write* SAS date values as the name of the month.

- **Category:** Date and Time
- **Alignment:** Right

#### Syntax

`MONNAME w.`

#### Arguments

- **w**
  - Specifies the width of the output field.
  - **Default:** 9
  - **Range:** 1–32

#### Details

- Use `MONNAME3.` to print the first three letters of the month name.
- If necessary, SAS truncates the name of the month to fit the format width.
Example

The example table uses the input value of 18691, which is the SAS date value that corresponds to March 5, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18691,monname1.);</td>
<td>M</td>
</tr>
<tr>
<td>a=put(18691,monname3.);</td>
<td>Mar</td>
</tr>
<tr>
<td>a=put(18691,monname5.);</td>
<td>March</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “MONTH Format” on page 119

MONTH Format

Writes SAS date values as the month of the year.

- **Category:** Date and Time
- **Alignment:** Right

**Syntax**

```
MONTHw.
```

**Arguments**

`w`

specifies the width of the output field.

- **Default:** 2
- **Range:** 1–32

**Details**

The MONTHw. format writes the month (1 through 12) of the year from a SAS date value.
Example

The example table uses the input value of 18871, which is the SAS date value that corresponds to September 01, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18871,month.);</td>
<td>9</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “MONNAME Format” on page 118

MONYY Format

Writes SAS date values as the month and the year in the form mmyy or mmyyyy.

**Category:** Date and Time

**Alignment:** Right

**Syntax**

MONYY\_w.

**Arguments**

\_w

specifies the width of the output field.

**Default:** 5

**Range:** 5–7

**Details**

The MONYY\_w. format writes SAS date values in the form mmyy or mmyyyy. Here is an explanation of the syntax:

**mmm**

is the first three letters of the month name.

**yy or yyyy**

is a two-digit or four-digit integer that represents the year.
Comparisons

The MONYYw. format and the DTMONYYw. format are similar in that they both write date values. The difference is that MONYYw. expects a SAS date value as input, and DTMONYYw. expects a datetime value.

Example

The example table uses the input value of 18985, which is the SAS date value that corresponds to December 24, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18985,monyy5.);</td>
<td>DEC11</td>
</tr>
<tr>
<td>a=put(18985,monyy7.);</td>
<td>DEC2011</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DTMONYY Format” on page 92
- “DDMMYY Format” on page 84
- “MMDDYY Format” on page 110
- “YYMMDD Format” on page 147

Functions:

- “MONTH Function” on page 464
- “YEAR Function” on page 674

NEGPAREN Format

Writes negative numeric values in parentheses.

- **Category:** Numeric
- **Alignment:** Right
- **Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

Syntax

NEGPARENw.\([d]\)
Arguments

\( w \)

- specifies the width of the output field.
- Default: 6
- Range: 1–32

\( d \)

- specifies the number of digits to the right of the decimal point in the numeric value.
- Default: 0
- Range: 0–31

Details

The NEGPAREN\( w.d \) format attempts to right align output values. If the input value is negative, NEGPAREN\( w.d \) displays the output by enclosing the value in parentheses, if the field that you specify is wide enough. Otherwise, it uses a minus sign to represent the negative value. If the input value is nonnegative, NEGPAREN\( w.d \) displays the value with a leading and trailing blank to ensure proper column alignment. It reserves the last column for a close parenthesis even when the value is positive.

Comparisons

The NEGPAREN\( w.d \) format is similar to the COMMA\( w.d \) format in that it separates every three digits of the value with a comma.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{a=put(100,negparen6.);}</td>
<td>100</td>
</tr>
<tr>
<td>\texttt{a=put(1000,negparen6.);}</td>
<td>1,000</td>
</tr>
<tr>
<td>\texttt{a=put(-200,negparen6.);}</td>
<td>(200)</td>
</tr>
<tr>
<td>\texttt{a=put(-2000,negparen6.);}</td>
<td>(2,000)</td>
</tr>
</tbody>
</table>

NENGO Format

Writes SAS date values as Japanese dates in the form \texttt{e.ymmd}.  

- **Category:** Date and Time  
- **Alignment:** Left
Syntax
NENGOw.

Arguments
w
specifies the width of the output field.

Default 10
Range 2–10

Details
The NENGOw format writes SAS date values in the form e.yymmdd. Here is an explanation of the syntax:

e
is the first letter of the name of the emperor (Meiji, Taisho, Showa, or Heisei).

yy
is an integer that represents the year.

mm
is an integer that represents the month.

dd
is an integer that represents the day of the month.

If the width is too small, SAS omits the period.

Example
The example table uses the input value of 18702, which is the SAS date value that corresponds to March 16, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18702,nengo3.);</td>
<td>H23</td>
</tr>
<tr>
<td>a=put(18702,nengo6.);</td>
<td>H23/03</td>
</tr>
<tr>
<td>a=put(18702,nengo8.);</td>
<td>H.230316</td>
</tr>
<tr>
<td>a=put(18702,nengo9.);</td>
<td>H23/03/16</td>
</tr>
<tr>
<td>a=put(18702,nengo10.);</td>
<td>H.23/03/16</td>
</tr>
</tbody>
</table>

OCTAL Format
Converts numeric values to octal representation.
Syntax

OCTAL\(w\).

Arguments

\(w\)

specifies the width of the output field.

Default 3

Range 1–24

Details

If necessary, the OCTAL\(w\) format converts numeric values to integers before displaying them in octal representation.

Comparisons

OCTAL\(w\) converts numeric values to octal representation. The $OCTAL\(w\)$ format converts character values to octal representation.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-------</td>
</tr>
<tr>
<td>a=put(3592, octal6.);</td>
<td>007010</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “$OCTAL Format” on page 64

PERCENT Format

Writes numeric values as percentages.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment:</td>
<td>Right</td>
</tr>
</tbody>
</table>

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.
Syntax

PERCENT\(w.[d]\)

Arguments

\(w\)

specifies the width of the output field.

Default 6

Range 4–32

\(d\)

specifies the number of digits to the right of the decimal point in the numeric value.

Range 0–31

Requirement must be less than \(w\)

Details

The PERCENT\(w.d\) format multiplies values by 100, formats them the same as the BEST\(w.d\) format, adds a percent sign (%) to the end of the formatted value, and encloses negative values in parentheses. The PERCENT\(w.d\) format allows room for a percent sign and parentheses, even if the value is not negative.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(0.1,percent10.);</td>
<td>10%</td>
</tr>
<tr>
<td>a=put(1.2,percent10.);</td>
<td>120%</td>
</tr>
<tr>
<td>a=put(-.05,percent10.);</td>
<td>( 5%)</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “PERCENTN Format” on page 125

PERCENTN Format

Produces percentages, using a minus sign for negative values.

Category: Numeric
Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in SAS Viya System Options: Reference.

Syntax

PERCENTNw.[d]

Arguments

\(w\)

specifies the width of the output field.

Default 6

Range 4–32

\(d\)

specifies the number of digits to the right of the decimal point in the numeric value.

Range 0–31

Requirement must be less than \(w\)

Details

The PERCENTNw.d format multiplies negative values by 100, formats them the same as the BESTw.d format, adds a minus sign to the beginning of the value, and adds a percent sign (%) to the end of the formatted value. The PERCENTNw.d format allows room for a percent sign and a minus sign, even if the value is not negative.

Comparisons

The PERCENTNw.d format produces percents by using a minus sign instead of parentheses for negative values. The PERCENTW.d format produces percents by using parentheses for negative values.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(-0.1,percentn.);</td>
<td>-10%</td>
</tr>
<tr>
<td>a=put(.2,percentn.);</td>
<td>20%</td>
</tr>
<tr>
<td>a=put(.8,percentn.);</td>
<td>80%</td>
</tr>
<tr>
<td>a=put(-0.05,percentn.);</td>
<td>-5%</td>
</tr>
</tbody>
</table>
### QTR Format

Writes SAS date values as the quarter of the year.

**Category:** Date and Time  
**Alignment:** Right

#### Syntax

`QTRw.`

#### Arguments

- `w` specifies the width of the output field.  
  - **Default:** 1  
  - **Range:** 1–32

#### Example

The example table uses the input value of 18691, which is the SAS date value that corresponds to March 5, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=put(18691,qtr.);</code></td>
<td>1</td>
</tr>
</tbody>
</table>

#### See Also

**QTRR Format**

Writes SAS date values as the quarter of the year in roman numerals.

**Category:** Date and Time  
**Alignment:** Right

**Syntax**

\[ \text{QTRR}_w. \]

**Arguments**

\( w \)

specifies the width of the output field.

**Default** 3  
**Range** 3–32

**Example**

The example table uses the input value of 18885, which is the SAS date value that corresponds to September 15, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{a=put(18885,qtrr.);} )</td>
<td>III</td>
</tr>
</tbody>
</table>

**See Also**

** Formats:**

- “QTR Format” on page 127

---

**ROMAN Format**

Writes numeric values as roman numerals.

**Category:** Numeric  
**Alignment:** Left
Syntax

ROMAN\(w\).

Arguments

\(w\)

specifies the width of the output field.

Default 6

Range 2–32

Details

The ROMAN\(w\) format truncates a floating-point value to its integer component before the value is written.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{a=put(2006,roman.);}</td>
<td>\texttt{MMVI}</td>
</tr>
</tbody>
</table>

SIZEK Format

Writes a numeric value in the form \(nK\) for kilobytes.

Category: Numeric

Alignment: Right

Syntax

\texttt{SIZEK\(w\)[d]}

Arguments

\(w\)

specifies the width of the output field.

Default 9

Range 2–33

\(d\)

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 0–31
Details
To write a numeric value in the form \( nK \) by using the \( \text{SIZEK}_{w,d} \) format, the value of \( n \) is calculated by dividing the numeric value by 1,024. The symbol \( K \) indicates that the value is a multiple of 1,024.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1024, sizek.);</td>
<td>1K</td>
</tr>
<tr>
<td>a=put(200943, sizek.);</td>
<td>197K</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “SIZEKMG Format” on page 130

SIZEKMG Format
Writes a numeric value in the form \( nKB \) for kilobytes, \( nMB \) for megabytes, or \( nGB \) for gigabytes.

Category: Numeric
Alignment: Right

Syntax
\( \text{SIZEKMG}_{w,[d]} \)

Arguments

\( w \)
- specifies the width of the output field.
- Default: 6
- Range: 4–35

\( d \)
- specifies the number of digits to the right of the decimal point in the numeric value.
- Default: 0
- Range: 0–31
Details
When you specify the SIZEKMGw.d format, SAS determines the best suffix: KB for kilobytes, MB for megabytes, or GB for gigabytes, and divides the SAS numeric value by one of the following values:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>KB</td>
<td>1024</td>
</tr>
<tr>
<td>MB</td>
<td>1048576</td>
</tr>
<tr>
<td>GB</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(3688, sizekmg.);</td>
<td>4KB</td>
</tr>
<tr>
<td>a=put(1048576, sizekmg.);</td>
<td>1MB</td>
</tr>
<tr>
<td>a=put(83409922345, sizekmg.);</td>
<td>80MB</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “SIZEK Format” on page 129

**TIME Format**

Writes SAS time values as hours, minutes, and seconds in the form hh:mm:ss.ss.

- **Category:** Date and Time
- **Alignment:** Right
- **Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

**Syntax**

\[ \text{TIME}w.[d] \]
**Arguments**

\( w \)

specifies the width of the output field.

Default: 8

Range: 2–20

**Tip** Make \( w \) large enough to produce the desired results. To obtain a complete time value with three decimal places, you must allow at least 12 spaces: Eight spaces to the left of the decimal point, one space for the decimal point itself, and three spaces for the decimal fraction of seconds.

\( d \)

specifies the number of digits to the right of the decimal point in the seconds value.

Default: 0

Range: 0–19

Requirement: must be less than \( w \)

**Details**

The \( \text{TIME}w.d \) format writes SAS time values in the form \( hh:mm:ss.ss \). Here is an explanation of the syntax:

\( hh \)

is an integer.

*Note:* If \( hh \) is a single digit, \( \text{TIME}w.d \) places a leading blank before the digit. For example, the \( \text{TIME}w.d \) format writes 9:00 instead of 09:00.

\( mm \)

is the number of minutes, ranging from 00 through 59.

\( ss.ss \)

is the number of seconds, ranging from 00 through 59, with the fraction of a second following the decimal point.

**Comparisons**

The \( \text{TIME}w.d \) format is similar to the \( \text{HHMM}w.d \) format except that \( \text{TIME}w.d \) includes seconds.

The \( \text{TIME}w.d \) format and the \( \text{HHMM}w \) write a leading blank for a single-hour digit. The \( \text{TOD}w.d \) format writes a leading zero for a single-hour digit.

**Example**

The example table uses the input value of 59083, which is the SAS time value that corresponds to 4:24:43 PM.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>132</td>
<td>Chapter 6 • DS2 Formats</td>
</tr>
</tbody>
</table>
TIMEAMPM Format

Writes SAS time values as hours, minutes, and seconds in the form hh:mm:ss.ss with AM or PM.

**Category:** Date and Time
**Alignment:** Right
**Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

**Syntax**

```
TIMEAMPM w.[d]
```

**Arguments**

- `w`
  - specifies the width of the output field.
  - Default: 11
  - Range: 2–20
- `d`
  - specifies the number of digits to the right of the decimal point in the seconds value.

**See Also**

**Formats:**

- “HHMM Format” on page 103
- “HOUR Format” on page 105
- “MMSS Format” on page 114
- “TOD Format” on page 135

**Functions:**

- “HOUR Function” on page 359
- “MINUTE Function” on page 457
- “SECOND Function” on page 602
- “TIME Function” on page 631

---

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=(59083,time.);</code></td>
<td>16:24:43</td>
</tr>
</tbody>
</table>
The TIMEAMPMw.d format writes SAS time values in the form hh:mm:ss:ss with AM or PM. Here is an explanation of the syntax:

- **hh** is an integer that represents the hour.
- **mm** is an integer that represents the minutes.
- **ss.ss** is the number of seconds to two decimal places.

Times greater than 23:59:59 PM appear as the next day. Make \( w \) large enough to produce the desired results. To obtain a complete time value with three decimal places and AM or PM, you must allow at least 11 spaces (\( hh:mm:ss \) PM). If \( w \) is less than 5, SAS writes AM or PM only.

### Comparisons
- The TIMEAMPMMw.d format is similar to the TIMEMw.d format except that TIMEAMPMMw.d prints AM or PM at the end of the time.
- TIMEm.d writes hours greater than 23:59:59 PM, and TIMEAMPMMw.d does not.

### Example
The example table uses the input value of 59083, which is the SAS time value that corresponds to 4:24:43 PM.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(59083, timeampm3.);</td>
<td>PM</td>
</tr>
<tr>
<td>a=put(59083, timeampm5.);</td>
<td>4 PM</td>
</tr>
<tr>
<td>a=put(59083, timeampm7.);</td>
<td>4:24 PM</td>
</tr>
<tr>
<td>a=put(59083, timeampm11.);</td>
<td>4:24:43 PM</td>
</tr>
</tbody>
</table>

### See Also
TOD Format

Writes SAS time values and the time portion of SAS datetime values in the form \textit{hh:mm:ss.ss}.

\begin{itemize}
  \item \textbf{Category:} Date and Time
  \item \textbf{Alignment:} Right
  \item \textbf{Interaction:} When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.
\end{itemize}

\section*{Syntax}

\texttt{TODw:.d}

\subsection*{Arguments}

\textit{w} specifies the width of the output field.

\begin{itemize}
  \item \textbf{Default:} 8
  \item \textbf{Range:} 2–20
  \item \textbf{Tip:} SAS writes a zero for a zero hour if the specified width is sufficient (for example, 02:30 or 00:30).
\end{itemize}

\textit{d} specifies the number of digits to the right of the decimal point in the seconds value.

\begin{itemize}
  \item \textbf{Default:} 0
  \item \textbf{Range:} 0–19
  \item \textbf{Requirement:} must be less than \textit{w}
\end{itemize}

\section*{Details}

The TOD\textit{w}.\textit{d} format writes SAS datetime values in the form \textit{hh:mm:ss.ss}. Here is an explanation of the syntax:

\begin{itemize}
  \item \textit{hh} is an integer that represents the hour.
  \item \textit{mm} is an integer that represents the minutes.
  \item \textit{ss.ss} is the number of seconds to two decimal places.
\end{itemize}

\section*{Comparisons}

The TOD\textit{w}.\textit{d} format writes a leading zero for a single-hour digit. The TIME\textit{w}.\textit{d} format and the HHMM\textit{w}.\textit{d} format write a leading blank for a single-hour digit.
VAXRB Format

Writes real binary (floating-point) data in VMS format.

**Category:** Numeric
**Alignment:** Right

**Syntax**

```
VAXRBw.[d]
```

**Arguments**

- **w**
  - Specifies the width of the output field.
  - **Default:** 8
  - **Range:** 2–8

- **d**
  - Specifies the power of 10 by which to divide the value.
  - **Default:** 0
  - **Range:** 0–31

**Details**

Use the VAXRBw.d format to write data in native VAX/VMS floating-point notation.
Example

In the following example, you use the VARBINARY data type so that the result is the hexadecimal representation for the integer.

```sas
data _null_;  
  method run();  
    dcl varbinary(20) a;  
    a=put(1,vaxrb8.);  
    put a=;  
  end;  
enddate;  
run;
```

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1,vaxrb8.);</td>
<td>804000000000000</td>
</tr>
</tbody>
</table>

* The result is the hexadecimal representation for the integer.

**w Format**

Writes standard numeric data one digit per byte.

- **Category:** Numeric
- **Alignment:** Right
- **Alias:** Fw.d
- **Interaction:** When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

**Syntax**

`w.[d]`

**Arguments**

- **w**
  - Specifies the width of the output field.
    - Default 1
    - Range 1–32
    - Tip Allow enough space to write the value, the decimal point, and a minus sign, if necessary.

- **d**
  - Specifies the number of digits to the right of the decimal point in the numeric value.
Range 0–31
Requirement must be less than w
Tip If d is 0 or you omit d, w.d writes the value without a decimal point.

Details
The w.d format rounds to the nearest number that fits in the output field. If w.d is too small, SAS might shift the decimal to the BESTw. format. The w.d format writes negative numbers with leading minus signs. In addition, w.d right aligns before writing and pads the output with leading blanks.

Comparisons
The Zw.d format is similar to the w.d format except that Zw.d pads right-aligned output with 0s instead of blanks.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>put (23.45, 6.3);</td>
<td>23.450</td>
</tr>
</tbody>
</table>

See Also

Formats:
• “Z Format” on page 160

WEEKDATE Format

Writes SAS date values as the day of the week and the date in the form day-of-week, month-name dd, yy (or yyyy).

Category: Date and Time
Alignment: Right

Syntax

WEEKDATEw.

Arguments

w specifies the width of the output field.

Default 29
Details

The WEEKDATEw. format writes SAS date values in the form day-of-week, month-name dd, yy (or yyyy). Here is an explanation of the syntax:

- \( dd \) is an integer that represents the day of the month.
- \( yy \) or \( yyyy \) is a two-digit or four-digit integer that represents the year.

If \( w \) is too small to write the complete day of the week and month, SAS abbreviates as needed.

Comparisons

The WEEKDATEw. format is the same as the WEEKDATXw. format except that WEEKDATXw. prints \( dd \) before the month's name.

Example

The example table uses the input value of 18792, which is the SAS date value that corresponds to June 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=put(18792,weekdate3.);</code></td>
<td>Tue</td>
</tr>
<tr>
<td><code>a=put(18792,weekdate9.);</code></td>
<td>Tuesday</td>
</tr>
<tr>
<td><code>a=put(18792,weekdate15.);</code></td>
<td>Tue, Jun 14, 11</td>
</tr>
<tr>
<td><code>a=put(18792,weekdate17.);</code></td>
<td>Tue, Jun 14, 2011</td>
</tr>
</tbody>
</table>

- “YYMMDD Format” on page 147
WEEKDATX Format

Writes SAS date values as the day of the week and date in the form day-of-week, dd month-name yy (or yyyy).

**Category:** Date and Time

**Alignment:** Right

**Syntax**

WEEKDATXw.

**Arguments**

w

specifies the width of the output field.

**Default** 29

**Range** 3–37

**Details**

The WEEKDATXw. format writes SAS date values in the form day-of-week, dd month-name, yy (or yyyy). Here is an explanation of the syntax:

*dd*

is an integer that represents the day of the month.

*yy* or *yyyy*

is a two-digit or a four-digit integer that represents the year.

If w is too small to write the complete day of the week and month, then SAS abbreviates as needed.

**Comparisons**

The WEEKDATEw. format is the same as the WEEKDATXw. format, except that WEEKDATEw. prints dd after the month's name.

The DTWKDATXw. format is the same as the WEEKDATXw. format, except that DTWKDATXw. expects a datetime value as input.

**Example**

The example table uses the input value of 18681, which is the SAS date value that corresponds to February 23, 2011.
Statements | Results
---|---

a=put(18681,weekdatx.); | Wednesday, 23 February 2011

---

**WEEKDAY Format**

Writes SAS date values as the day of the week.

**Category:** Date and Time  
**Alignment:** Right

**Syntax**

```
WEEKDAY
```

**Arguments**

`w`

specifies the width of the output field.

**Default** 1

**Range** 1–32
Details

The WEEKDAYw. format writes a SAS date value as the day of the week (where 1=Sunday, 2=Monday, and so on).

Example

The example table uses the input value of 18681, which is the SAS date value that corresponds to February 23, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18681,weekday.);</td>
<td>4</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DOWNAME Format” on page 90

YEAR Format

Writes SAS date values as the year.

Category: Date and Time

Alignment: Right

Syntax

YEARw.

Arguments

w

specifies the width of the output field.

Default 4

Range 2–32

Tip If w is less than 4, the last two digits of the year print. Otherwise, the year value prints as four digits.

Comparisons

The YEARw. format is similar to the DTYEARw. format in that they both write date values. The difference is that YEARw. expects a SAS date value as input, and DTYEARw. expects a SAS datetime value.
Example

The example table uses the input value of 18792, which is the SAS date value that corresponds to June 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18792, year2.);</td>
<td>11</td>
</tr>
<tr>
<td>a=put(18792, year4.);</td>
<td>2011</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DTYEAR Format” on page 95

YEN Format

Writes numeric values with yen signs, commas, and decimal points.

Category: Numeric

Alignment: Right

Syntax

YENw.d

Arguments

w

specifies the width of the output field.

Default: 8

Range: 1–32

d

specifies the number of digits to the right of the decimal point in the numeric value.

Restriction: must be either 0 or 2

Tip: If d is 2, then YENw.d writes a decimal point and two decimal digits. If d is 0, then YENw.d does not write a decimal point or decimal digits.
Details

The YENw.d format writes numeric values with a leading yen sign and with a comma that separates every three digits of each value.

The hexadecimal representation of the code for the yen sign character is 5B on EBCDIC systems and 5C on ASCII systems. The monetary character these codes represent might be different in other countries.

Example

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(1254.71,yen10.2);</td>
<td>¥1,254.71</td>
</tr>
</tbody>
</table>

YYMM Format

Writes SAS date values in the form <yy>yyMmm, where M is a character separator to indicate that the month number follows the M and the year appears as either 2 or 4 digits.

Category: Date and Time
Alignment: Right

Syntax

YYMMw.

Arguments

w

specifies the width of the output field.

Default: 7

Range: 5–32

Interaction: When w has a value of 5 or 6, the date appears with only the last two digits of the year. When w is 7 or more, the date appears with a four-digit year.

Details

The YYMMw. format writes SAS date values in the form <yy>yyMmm. Here is an explanation of the syntax:

<yy>yy

is a two-digit or four-digit integer that represents the year.

M

is the character separator.
*mm* is an integer that represents the month.

**Comparisons**

- The YYMM<code>\text{w}.d</code> format is similar to the YYMM<code>\text{xw}.d</code> format, except the YYMM<code>\text{xw}.d</code> format contains a separator such as a hyphen, colon, slash, or period between the year and month.

**Example**

The following examples use the input value of 18925, which is the SAS date value that corresponds to October 25, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18925, yymm5.);</td>
<td>11M10</td>
</tr>
<tr>
<td>a=put(18925, yymm6.);</td>
<td>11M10</td>
</tr>
<tr>
<td>a=put(18925, yymm.);</td>
<td>2011M10</td>
</tr>
<tr>
<td>a=put(18925, yymm7.);</td>
<td>2011M10</td>
</tr>
<tr>
<td>a=put(18925, yymm10.);</td>
<td>2011M10</td>
</tr>
</tbody>
</table>

**See Also**

**Formats:**

- “MMYY Format” on page 115
- “YYMMx Format” on page 145

---

**YYMMx Format**

Writes SAS date values in the form `<yy>ymm` or `<yy>yy-mm`, where the `x` in the format name is a character that represents the special character that separates the year and the month, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

**Category:** Date and Time

**Alignment:** Right

**Syntax**

YYMM<code>\text{xw}.</code>
Arguments

\(x\)

identifies a separator or specifies that no separator appear between the year and the month. Here are the valid values:

\(C\)

separates with a colon

\(D\)

separates with a hyphen

\(N\)

indicates no separator

\(P\)

separates with a period

\(S\)

separates with a forward slash

\(w\)

specifies the width of the output field.

Default 7

Range 5–32

Interactions

When \(x\) is set to \(N\), no separator is specified. The width range is then 4–32, and the default changes to 6.

When \(x\) has a value of \(C\), \(D\), \(P\), or \(S\) and \(w\) has a value of 5 or 6, the date appears with only the last two digits of the year. When \(w\) is 7 or more, the date appears with a four-digit year.

When \(x\) has a value of \(N\) and \(w\) has a value of 4 or 5, the date appears with only the last two digits of the year. When \(x\) has a value of \(N\) and \(w\) is 6 or more, the date appears with a four-digit year.

Details

The YYMM\(xw\) format writes SAS date values in the form \(<yy>yyymm\) or \(<yy>yyXmm\). Here is an explanation of the syntax:

\(<yy>yy\)

is a two-digit or four-digit integer that represents the year.

\(X\)

is a specified separator.

\(mm\)

is an integer that represents the month.

Comparisons

- The YYMM\(w.d\) format is similar to the YYMM\(xw.d\) format, except the YYMM\(xw.d\) format contains a separator such as a hyphen, colon, slash, or period, between the year and month.
Example

The following examples use the input value of 18822, which is the SAS date value that corresponds to July 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18822,yyymc5.);</td>
<td>11:07</td>
</tr>
<tr>
<td>a=put(18822,,yyymd.);</td>
<td>2011-07</td>
</tr>
<tr>
<td>a=put(18822,,yyymm4.);</td>
<td>1107</td>
</tr>
<tr>
<td>a=put(18822,,yyymmp8.);</td>
<td>2011.07</td>
</tr>
<tr>
<td>a=put(18822,,yyyme10.);</td>
<td>2011/07</td>
</tr>
</tbody>
</table>

Formats:
- “MMYYx Format” on page 116
- “YYMM Format” on page 144

**YYMMDD Format**

Writes SAS date values in the form `<yy>-<ymmd> or <yy>-<mm>-<dd>, where a hyphen is the separator and the year appears as either 2 or 4 digits.

**Category:** Date and Time

**Alignment:** Right

**Syntax**

`YYMMDDw`.  

**Arguments**

`w`

specifies the width of the output field.

- **Default:** 8
- **Range:** 2–10
Interaction

When \( w \) has a value from 2 to 5, the date appears with as many digits of the year and the month as possible. When \( w \) is 7, the date appears as a two-digit year without hyphens.

Details

The YYMMDD\( w \) format writes SAS date values in the form <\( yy \)yyymmdd or <\( yy \)>yy–mm–dd. Here is an explanation of the syntax:

- \( yy \)
  is a two-digit or four-digit integer that represents the year.

- \( - \)
  is the separator.

- \( mm \)
  is an integer that represents the month.

- \( dd \)
  is an integer that represents the day of the month.

Comparisons

- The YYMMDD\( w,d \) format is similar to the YYMMDD\( xw,d \) format, except the YYMMDD\( xw,d \) format contains separators, such as a colon, slash, or period between the year, month, and day.

Example

The following examples use the input value of 18720, which is the SAS date value that corresponds to April 3, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18720,yyymmdd2.);</td>
<td>11</td>
</tr>
<tr>
<td>a=put(18720,yyymmdd3.);</td>
<td>11</td>
</tr>
<tr>
<td>a=put(18720,yyymmdd4.);</td>
<td>1104</td>
</tr>
<tr>
<td>a=put(18720,yyymmdd5.);</td>
<td>11-04</td>
</tr>
<tr>
<td>a=put(18720,yyymmdd6.);</td>
<td>110403</td>
</tr>
<tr>
<td>a=put(18720,yyymmdd7.);</td>
<td>110403</td>
</tr>
<tr>
<td>a=put(18720,yyymmdd8.);</td>
<td>11-04-03</td>
</tr>
<tr>
<td>a=put(18720,yyymmdd10.);</td>
<td>2011-04-03</td>
</tr>
</tbody>
</table>

See Also

YYMMDDx Format

YYMMDDx Format writes SAS date values in the form <yy>yyymmdd or <yy>yy-mm-dd, where the x in the format name is a character that represents the special character that separates the year, month, and day. The special character can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

**Syntax**

YYMMDDxw.

**Arguments**

x

identifies a separator or specifies that no separator appear between the year, the month, and the day. Here are the valid values:

B
separates with a blank

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a slash.

w
specifies the width of the output field.
Default | 8  
---|---
Range | 2–10

**Interactions**

When \( w \) has a value from 2 to 5, the date appears with as many digits of the year and the month as possible. When \( w \) is 7, the date appears as a two-digit year without separators.

When \( x \) has a value of \( N \), the width range is 2–8.

**Details**

The YYMMDD\( _w \). format writes SAS date values in the form \(<yy>yyymmdd\) or \(<yy>yyXmmXdd\). Here is an explanation of the syntax:

\(<yy>yy\)

is a two-digit or four-digit integer that represents the year.

\(X\)

is a specified separator.

\(mm\)

is an integer that represents the month.

\(dd\)

is an integer that represents the day of the month.

**Comparisons**

- The YYMMDD\( _w.d \) format is similar to the YYMMDD\( _xw.d \) format, but YYMMDD\( _xw.d \) format contains a separator between the year and month, such as a colon, slash, or period.

**Example**

The following examples use the input value of 18922, which is the SAS date value that corresponds to October 22, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18922,yymmdc5.);</td>
<td>11:10</td>
</tr>
<tr>
<td>a=put(18922,yymmdd8.);</td>
<td>11-10-22</td>
</tr>
<tr>
<td>a=put(18922,yymmddn8.);</td>
<td>20111022</td>
</tr>
<tr>
<td>a=put(18922,yymmddp10.);</td>
<td>2011.10.22</td>
</tr>
</tbody>
</table>

**See Also**

**Formats:**
YYMON Format

Writes SAS date values in the form *yymm* or *yyyyymm*.

**Category:** Date and Time

**Alignment:** Right

**Syntax**

`YYMONw.`

**Arguments**

`w`

specifies the width of the output field. If the format width is too small to print a four-digit year, only the last two digits of the year are printed.

**Default**

7

**Range**

5–32

**Details**

The `YYMONw.` format abbreviates the month's name to three characters.

**Example**

The example table uses the input value of 18792, which is the SAS date value that corresponds to June 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=put(18792, yymon6.);</code></td>
<td>11JUN</td>
</tr>
<tr>
<td><code>a=put(18792, yymon7.);</code></td>
<td>2011JUN</td>
</tr>
</tbody>
</table>
YYQ Format

Writes SAS date values in the form <yy>yyQq, where Q is the separator, the year appears as either 2 or 4 digits, and q is the quarter of the year.

Syntax

YYQw.

Arguments

w
specifies the width of the output field.

Default 6
Range 4–32

Interaction When w has a value of 4 or 5, the date appears with only the last two digits of the year. When w is 6 or more, the date appears with a four-digit year.

Details

The YYQw. format writes SAS date values in the form <yy>yyQq. Here is an explanation of the syntax:

<yy>yy
is a two-digit or four-digit integer that represents the year.

Q
is the character separator.

q
is an integer (1,2,3, or 4) that represents the quarter of the year.

Comparisons

The YYQw. format is similar to the YYQxw. format, but the YYQxw. format has separators between the YY and Q, such as a hyphen, slash, period, or colon.
Example

The following examples use the input value of 18792, which is the SAS date value that corresponds to June 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>

- “YYQZ Format” on page 158

YYQx Format

Writes SAS date values in the form <yy>yyq or <yy>yy-q, where the x in the format name is a character that represents the special character that separates the year and the quarter of the year, which can be a hyphen (−), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

**Category:** Date and Time  
**Alignment:** Right

**Syntax**

YYQxw.

**Arguments**

x

identifies a separator or specifies that no separator appear between the year and the quarter. Here are the valid values:
C  separates with a colon
D  separates with a hyphen
N  indicates no separator
P  separates with a period
S  separates with a forward slash.

\( w \)
specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>4–32</td>
</tr>
</tbody>
</table>

**Interactions**

When \( x \) is set to \( N \), no separator is specified. The width range is then 3–32, and the default changes to 5.

When \( w \) has a value of 4 or 5, the date appears with only the last two digits of the year. When \( w \) is 6 or more, the date appears with a four-digit year.

When \( x \) has a value of \( N \) and \( w \) has a value of 3 or 4, the date appears with only the last two digits of the year. When \( x \) has a value of \( N \) and \( w \) is 5 or more, the date appears with a four-digit year.

**Details**

The YYQ\( w \). format writes SAS date values in the form \(<yy>yyq\) or \(<yy>yyXq\). Here is an explanation of the syntax:

\(<yy>yy\)

is a two-digit or four-digit integer that represents the year.

\( X \)

is a specified separator.

\( q \)

is an integer (1, 2, 3, or 4) that represents the quarter of the year.

**Comparisons**

The YYQ\( w \). format is similar to the YYQ\( xw \). format, but the YYQ\( xw \). format has separators between the YY and Q, such as a hyphen, slash, period, or colon.

**Example**

The following examples use the input value of 18822, which is the SAS date value that corresponds to July 14, 2011.
### Statements

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=put(18822,yyqc4.);</code></td>
<td>11:3</td>
</tr>
<tr>
<td><code>a=put(18822,yyqd.);</code></td>
<td>2011-3</td>
</tr>
<tr>
<td><code>a=put(18822,yyqn3.);</code></td>
<td>113</td>

- “YYQR Format” on page 155
- “YYQRx Format” on page 157
- “YYQZ Format” on page 158

---

### YYQR Format

Writes SAS date values in the form `<yy>yyQqr`, where Q is the separator, the year appears as either 2 or 4 digits, and qr is the quarter of the year expressed in roman numerals.

#### Category:
Date and Time

#### Alignment:
Right

### Syntax

`YYQRw`.

### Arguments

**w**

specifies the width of the output field.

- **Default**: 8
- **Range**: 6–32
- **Interaction**: When the value of w is too small to write a four-digit year, the date appears with only the last two digits of the year.
Details
The YYQRw. format writes SAS date values in the form <yy>yyQqr. Here is an explanation of the syntax:

<yy>yy
  is a two-digit or four-digit integer that represents the year.

Q
  is the character separator.

qrr
  is a roman numeral (I, II, III, or IV) that represents the quarter of the year.

Comparisons
The YYQRw. format is similar to the YYQRxw. format, but the YYQRxw. format has separators between the YY and QR, such as a hyphen, slash, period, or colon.

Example
The following examples use the input value of 18792, which is the SAS date value that corresponds to June 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18792,yyqr6.);</td>
<td>11QII</td>
</tr>
<tr>
<td>a=put(18792,yyqr7.);</td>
<td>2011QII</td>
</tr>
<tr>
<td>a=put(18792,yyqr.);</td>
<td>2011QII</td>
</tr>
<tr>
<td>a=put(18792,yyqr8.);</td>
<td>2011QII</td>
</tr>
<tr>
<td>a=put(18792,yyqr10.);</td>
<td>2011QII</td>
</tr>
</tbody>
</table>

YYQRx Format

Writes SAS date values in the form <yy>yyqr or <yy>yy-qr, where the x in the format name is a character that represents the special character that separates the year and the quarter of the year, which can be a hyphen (−), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits and qr is the quarter of the year expressed in roman numerals.

Category: Date and Time
Alignment: Right

Syntax

YYQRxw.

Arguments

x
identifies a separator or specifies that no separator appears between the year and the quarter. Here are the valid values:

C
separates with a colon
D
separates with a hyphen
N
indicates no separator
P
separates with a period
S
separates with a forward slash.

w
specifies the width of the output field.

Default 8
Range 6–32

Interactions
When x is set to N, no separator is specified. The width range is then 5–32, and the default changes to 7.
When the value of w is too small to write a four-digit year, the date appears with only the last two digits of the year.

Details

The YYQRxw. format writes SAS date values in the form <yy>yyqr or <yy>yy-Xqr. Here is an explanation of the syntax:

<yy>yy
is a two-digit or four-digit integer that represents the year.
X
is a specified separator.

$qr$

is a roman numeral (I, II, III, or IV) that represents the quarter of the year.

**Comparisons**

The YYQR\(w\) format is similar to the YYQR\(xw\) format, but the YYQR\(xw\) format has separators between the YY and QR, such as a hyphen, slash, period, or colon.

**Example**

The following examples use the input value of 18985, which is the SAS date value that corresponds to December 24, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put(18985,yyqrc6.);</td>
<td>11:IV</td>
</tr>
<tr>
<td>a=put(18985,yyqrd.);</td>
<td>2011-IV</td>
</tr>
<tr>
<td>a=put(18985,yyqrn5.);</td>
<td>11IV</td>
</tr>
<tr>
<td>a=put(18985,yyqrp8.);</td>
<td>2011.IV</td>
</tr>
<tr>
<td>a=put(18985,yyqrs10.);</td>
<td>2011/IV</td>
</tr>
</tbody>
</table>

### YYQZ Format

Writes SAS date values in the form `<yy><qq>`, where the year appears as 2 or 4 digits, and `qq` is the quarter of the year.

- **Category:** Date and Time
- **Alignment:** Right
Syntax

YYQZ_w.

Arguments

Z
specifies that no separator appear between the year and the quarter.

w
specifies the width of the output field.

Default 4

Range 4–6

Details

The YYQZ_w. format writes SAS date values in the form <yy> <qq>. Here is an explanation of the syntax:

<yy>
is a two-digit or four-digit integer that represents the year.

Z
specifies that there is no separator.

<qq>
is an integer (01, 02, 03, or 04) that represents the quarter of the year.

Example

The following examples use the input value of 18822, which is the SAS date value that corresponds to July 14, 2011.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=put (18822,yyqz6.);</td>
<td>201103</td>
</tr>
<tr>
<td>a=put (18822,yyqz4.);</td>
<td>1103</td>
</tr>
</tbody>
</table>

- “YYQR Format” on page 155
- “YYQRx Format” on page 157
Z Format

Writes standard numeric data with leading 0s.

Category: Numeric
Alignment: Right
Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in SAS Viya System Options: Reference.

Syntax

\[ Zw.[d] \]

Arguments

\( w \)
specifies the width of the output field.

- Default 1
- Range 1–32
- Tip Allow enough space to write the value, the decimal point, and a minus sign, if necessary.

\( d \)
specifies the number of digits to the right of the decimal point in the numeric value.

- Default 0
- Range 0–31
- Tip If \( d \) is 0 or you omit \( d \), \( Zw.d \) writes the value without a decimal point.

Details

The \( Zw.d \) format writes standard numeric values one digit per byte and fills in 0s to the left of the data value.

The \( Zw.d \) format rounds to the nearest number that will fit in the output field. If \( w.d \) is too large to fit, SAS might shift the decimal to the BESTw. format. The \( Zw.d \) format writes negative numbers with leading minus signs. In addition, it right aligns before writing and pads the output with leading zeros.

Overview of DS2 Functions

A DS2 function performs a computation or system manipulation on arguments and returns a value. A function expression invokes a function from anywhere in a DS2
program, method, or thread. Most functions use arguments supplied by the user, but a few obtain their arguments from the operating environment.

If the data types of the arguments in the function expression are not what is expected by the DS2 function, DS2 performs a type conversion on the arguments so that they have the appropriate data type. If the type conversion is successful, the function executes. Otherwise, an error is issued. For information, see “DS2 Type Conversions” in SAS Viya: DS2 Programmer’s Guide.

Note: DS2 does not support CALL routines. DS2 functions and methods can alter variable argument values if the return type of the function or method is VOID.

Note: The date and time functions work only with SAS date, time, and datetime values. They do not work with values having the DATE, TIME, and TIMESTAMP data types. For information about working with dates, see “Dates and Times in DS2” in SAS Viya: DS2 Programmer’s Guide.

---

**General Function Syntax**

The syntax of a function is

```
function-name(argument[, ...argument])
```

Here is an explanation of the syntax:

- **function-name** names the function.
- **argument** can be a variable name, constant, or a DS2 expression, including another function. The number and type of arguments that DS2 allows are described with individual functions. Multiple arguments are separated by a comma.

**Tip** If the value of an argument is invalid (for example, missing or outside the prescribed range), an error occurs and the function's return expression is set to a missing or null value.

---

**Using Functions**

**Restrictions on Function Arguments**

If the value of an argument is invalid, an error occurs and the return expression is set to a missing or null value. Here are some common restrictions on function arguments:

- Some functions require that their arguments be restricted within a certain range. For example, the argument of the LOG function must be greater than 0.
- Most functions do not permit missing or null values as arguments. Exceptions include some of the descriptive statistics functions and financial functions.

By default when a function argument contains a missing or null value, an error occurs and a message is printed to the SAS log. You can use the MISSING_NOTE option in the DS2_OPTIONS statement to not produce an error and write a note to
the SAS log when a function argument contains a missing or null value. For more information, see “DS2_OPTIONS Statement” on page 724.

• In general, the allowed range of the arguments is platform-dependent, such as with the EXP function.

Data Type Conversion in Functions

The number of arguments and the argument data types that DS2 expects for a function is called the function signature. When a function executes, the arguments in the function expression are compared to the function signature. If the arguments and the signature match, the function executes. If the number of arguments do not match, an error occurs.

If the number of arguments match but one or more argument data types do not match, DS2 attempts to convert the argument data types to those of the function signature. If the type conversion is successful, the function executes. Otherwise, an error occurs.

The documentation for each of the functions include a valid data type for all function arguments. The valid data type is the argument data type that DS2 uses in executing the function. Because DS2 does type conversion, some argument data types in the function expression do not need to be the same as the valid data types for the function argument. For example, if the function expression contains an argument with a data type of INTEGER and the valid data type for that argument is DOUBLE, DS2 converts the data type to DOUBLE when the function executes. Only four data types, VARBINARY and the date/time data types, DATE, TIME, TIMESTAMP, are non-coercible, meaning that the function expression must contain the valid data type.

VARCHAR Data Type in String Functions

SAS Viya supports a new VARCHAR data type for character data. Variables created using the VARCHAR data type are varying width and use character semantics, rather than being fixed-width and using byte semantics of the original SAS character data type.

When a VARCHAR variable is passed to any string function, including the traditional string functions or the K functions, SAS always assumes that the length represents the number of characters. An offset for a VARCHAR variable always represents a character position. The CHAR data type is most suitable for binary data.

Missing and Null Values in DS2 Numeric Functions

For functions that have an input data type of DOUBLE, if a null is passed to the function, the null value is converted to a missing value.

After the function is processed, if the function returns a DOUBLE and if the function returns a missing value, a missing value is returned in SAS mode and a null value is returned in ANSI mode.

Missing and Null Values in DS2 Character Functions

If you pass a character function a null value and the function should return a null value, a null value is returned regardless of whether you are in ANSI mode or SAS mode.
**Using a System Expression to Execute a Function**

The syntax for a function is similar to the syntax for a method, and when DS2 encounters a method or function expression, it must determine what type of expression it is. If a method expression and a function expression have the same name, DS2 executes the method. The only way to execute a function that has the same name as a method is to use a system expression. A system expression has the following syntax:

```plaintext
system.function-expression
```

When DS2 encounters a system expression, the call to the method of the same name is bypassed and DS2 calls the function.

**Notes on Descriptive Statistic Functions**

DS2 provides functions that return descriptive statistics. Except for the MISSING function, the functions correspond to the statistics produced by the Base SAS MEANS procedure. The computing method for each statistic is discussed in the statistical procedures section of the *SAS Viya Data Management and Utility Procedures Guide*. SAS calculates descriptive statistics for the non-null or nonmissing values of the arguments.

---

**DS2 Function Examples**

```plaintext
x=max(cash,credit);

x=sqrt(1500);

NewCity=left(upcase(City));

x=min(YearTemperature-July,YearTemperature-Dec);

s=repeat('----+',16);

x=min((enroll-drop),(enroll-fail));

if sum(cash,credit)>1000 then
    put 'Goal reached';
```

---

**Function Categories**

Functions can be categorized by the types of values that they operate on. Each DS2 function belongs to one of the following categories:

- **Array**
  - operates on a named aggregate collection of homogenous data

- **Bitwise Logical Operations**
  - operates on one or more bit patterns or binary numbers at the level of their individual bits

- **Character**
  - operates on character data and SQL expressions
Date and Time
  operates on date and time values

Descriptive Statistics
  operates on values that measure central tendency, variation among values, and the shape of distribution values

Distance
  returns the geodetic distance

Financial
  calculates financial values such as interest, periodic payments, depreciation, and prices for European options on stocks.

Hyperbolic
  performs hyperbolic calculations such as sine, cosine, and tangent

Mathematical
  operates on values to perform general mathematical calculations

Numeric
  operates on numeric values

Probability
  returns probability calculations.

Quantile
  returns a quantile from specific distributions

Random Number
  returns random variates from specific distributions

Special
  operates on null values and SAS missing values, suspends execution of a program, specifies numeric informats at run time, and executes a FedSQL statement.

Trigonometric
  operates on values to perform trigonometric calculations

Truncation
  operates on values to limit the number of digits

Variable Information
  operates on variables and returns names, types, lengths, informats, labels, and other variable information

The following table provides brief descriptions of DS2 functions. For more detailed information, see the individual functions.

<table>

## Dictionary

### ABS Function

Returns the absolute value of a numeric value expression.

**Category:** Mathematical  
**Returned data type:** BIGINT, DECIMAL, DOUBLE, NUMERIC

**Syntax**

\[
\text{ABS(expression)}
\]

**Arguments**

- **expression**: specifies any valid expression that evaluates to a numeric value.

**Data type**: BIGINT, DECIMAL, DOUBLE, NUMERIC

**See**

**Details**

If the result is a number that does not fit into the range of the argument's data type, the ABS function fails.

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.
Example

The following statements illustrate the ABS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcl int x; x=abs(-345);</td>
<td>345</td>
</tr>
<tr>
<td>dcl double z; z=abs((3 x 50.5) / 5);</td>
<td>30.3</td>
</tr>
</tbody>
</table>

ANYALNUM Function

Searches a character string for an alphanumeric character, and returns the first position at which the character is found.

- **Category:** Character
- **Returned data type:** DOUBLE

**Syntax**

\[ \text{ANYALNUM('expression'[, start])} \]

**Arguments**

- **expression** specifies any valid expression that evaluates to a character string.
  - **Data type:** CHAR, NCHAR
  - **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

- **start** specifies the position at which the search should start and the direction in which to search.
  - **Data type:** INTEGER

**Details**

The results of the ANYALNUM function depend directly on the translation table that is in effect (see “TRANTAB= Option” in *SAS Viya National Language Support: Reference Guide*) and indirectly on the ENCODING and the LOCALE options.

The ANYALNUM function searches a string for the first occurrence of any character that is a digit or an uppercase or lowercase letter. If such a character is found, ANYALNUM returns the position in the string of that character. If no such character is found, ANYALNUM returns a value of 0.

If you use only one argument, ANYALNUM begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start},
specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of `start` is positive, the search proceeds to the right.
- If the value of `start` is negative, the search proceeds to the left.
- If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

ANYALNUM returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of `start` is greater than the length of the string.
- The value of `start` = 0.

**Comparisons**

The ANYALNUM function searches a character string for an alphanumeric character. The NOTALNUM function searches a character string for a non-alphanumeric character.

**Examples**

**Example 1: Scanning a String from Left to Right**

The following example uses the ANYALNUM function to search a string from left to right for alphanumeric characters.

```sas
data ltrtest;
  dcl char(15) string c;
  dcl double j;
  method run();
    string='Next = Last + 1';
    j=0;
    do until (j=0);
      j=anyalnum(string, j+1);
      if j=0 then put 'The end';
      else do;
        c=substr(string, j, 1);
        put j= c=;
      end;
    end;
  end;
enddata;
run;

SAS writes the following output to the log:
```

<table>
<thead>
<tr>
<th>j</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>N</td>
</tr>
<tr>
<td>2</td>
<td>e</td>
</tr>
<tr>
<td>3</td>
<td>x</td>
</tr>
<tr>
<td>4</td>
<td>t</td>
</tr>
<tr>
<td>8</td>
<td>L</td>
</tr>
<tr>
<td>9</td>
<td>a</td>
</tr>
<tr>
<td>10</td>
<td>s</td>
</tr>
<tr>
<td>11</td>

</tr>
<tr>
<td>15</td>
<td>1</td>
</tr>
<tr>
<td>The end</td>
<td></td>
</tr>
</tbody>
</table>
Example 2: Scanning a String from Right to Left
The following example uses the ANYALNUM function to search a string from right to left for alphanumeric characters.

```sas
data rtltest;
  dcl char(15) string c;
  dcl double j;
  method run();
    string='Next = Last + 1;';
    j=999999;
    do until(j=0);
      j=anyalnum(string, 1-j);
      if j=0 then put 'The end';
      else do;
        c=substr(string, j, 1);
        put j= c=;
      end;
    end;
  end;
enddata;
run;
```

SAS writes the following output to the log:

```
j=15 c=1
j=11 c=t
j=10 c=s
j=9 c=a
j=8 c=L
j=4 c=t
j=3 c=x
j=2 c=e
j=1 c=N
The end
```

ANYALPHA Function

Searches a character string for an alphabetic character, and returns the first position at which the character is found.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

`ANYALPHA('expression'[, start])`
**Arguments**

**expression**

specifies any valid expression that evaluates to a character string.

Data type: CHAR, NCHAR

**start**

specifies the position at which the search should start and the direction in which to search.

Data type: INTEGER

**Details**

The results of the ANYALPHA function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE options.

The ANYALPHA function searches a string for the first occurrence of any character that is an uppercase or lowercase letter. If such a character is found, ANYALPHA returns the position in the string of that character. If no such character is found, ANYALPHA returns a value of 0.

If you use only one argument, ANYALPHA begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

ANYALPHA returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

**Comparisons**

The ANYALPHA function searches a character string for an alphabetic character. The NOTALPHA function searches a character string for a non-alphabetic character.

**Examples**

**Example 1: Searching a String for Alphabetic Characters**

The following example uses the ANYALPHA function to search a string from left to right for alphabetic characters.

```sas
data _null_
  dcl char(18) string c;
  dcl double j i;
```
method run();
  string='Next = _n_ + 12E3;';
  j=0;
  do until(j=0);
    j=anyalpha(string, j+1);
    if j=0 then put 'The end';
    else do;
      c=substr(string, j, 1);
      put j= c=;
    end;
  end;
enddata;
run;

SAS writes the following output to the log:

```
  j=1  c=N
  j=2  c=e
  j=3  c=x
  j=4  c=t
  j=9  c=n
  j=16 c=E
The end
```

**Example 2: Identifying Control Characters By Using the ANYALPHA Function**

You can execute the following program to show the control characters that are identified by the ANYALPHA function.

```sas
data testany;
  dcl nchar(3) byte1 hex1;
  dcl double dec anyalpha1;

  method run();
    do dec=0 to 255;
      byte1=byte(dec);
      hex1=put(dec,hex2.);
      anyalpha1=anyalpha(byte1);
      output;
    end;
  end;
enddata;
run;

proc print data=testany;
run;
```

**See Also**

**Functions:**

- “NOTALPHA Function” on page 474
ANYCNTRL Function

Searches a character string for a control character, and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

`ANYCNTRL('expression' [, start])`

**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

Data type: CHAR, NCHAR

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*start*

specifies the position at which the search should start and the direction in which to search.

Data type: INTEGER

**Details**

The results of the ANYCTRL function depend directly on the translation table that is in effect (see “TRANTAB= Option” in *SAS Viya National Language Support: Reference Guide*) and indirectly on the ENCODING and the LOCALE options.

The ANYCNTRL function searches a string for the first occurrence of a control character. If such a character is found, ANYCNTRL returns the position in the string of that character. If no such character is found, ANYCNTRL returns a value of 0.

If you use only one argument, ANYCNTRL begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYCNTRL returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.
Comparisons

The ANYCNTRL function searches a character string for a control character. The NOTCNTRL function searches a character string for a character that is not a control character.

Example

You can execute the following program to show the control characters that are identified by the ANYCNTRL function.

```plaintext
data testany;
  dcl nchar(3) byte1 hex1;
  dcl double dec anycntrl1;

  method run();
    do dec=0 to 255;
      byte1=byte(dec);
      hex1=put(dec,hex2.);
      anycntrl1=anycntrl(byte1);
      if anycntrl1 then output;
    end;
  end;
enddata;
run;

proc print data=testany;
run;
quit;
```

ANYDIGIT Function

Searches a character string for a digit, and returns the first position at which the digit is found.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

```
ANYDIGIT('expression'[, start])
```

Arguments

- `expression` specifies any valid expression that evaluates to a character string.
ANYDIGIT Function

Data type  CHAR, NCHAR

start

specifies the position at which the search should start and the direction in which to search.

Data type  INTEGER

Details

The ANYDIGIT function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYDIGIT function searches a string for the first occurrence of any character that is a digit. If such a character is found, ANYDIGIT returns the position in the string of that character. If no such character is found, ANYDIGIT returns a value of 0.

If you use only one argument, ANYDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

ANYDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The ANYDIGIT function searches a character string for a digit. The NOTDIGIT function searches a character string for any character that is not a digit.

Example

The following example uses the ANYDIGIT function to search for a character that is a digit.

```sas
   data _null_;  
     dcl char(18) string c;  
     dcl double j i;  
     method run();  
       string='Next = _n_ + 12E3;';  
       j=0;  
       do until(j=0);  
         j=anydigit(string, j+1);  
         if j=0 then put 'The end';  
         else do;  
           c=substr(string, j, 1);  
         end;  
     end;  
```
```sas
put j= c=;
end;
end;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
j=14 c=1
j=15 c=2
j=17 c=3
The end
```

### ANYFIRST Function

Searches a character string for a character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7, and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

#### Syntax

`ANYFIRST('expression'[., start])`

#### Arguments

- **expression**
  - specifies any valid expression that evaluates to a character string.
  - **Data type:** CHAR, NCHAR
  - **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

- **start**
  - specifies the position at which the search should start and the direction in which to search.
  - **Data type:** INTEGER

#### Details

The ANYFIRST function does not depend on the TRANTAB, ENCODING, or LOCALE system options.
The ANYFIRST function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7. These characters are the underscore (_) and uppercase or lowercase English letters. If such a character is found, ANYFIRST returns the position in the string of that character. If no such character is found, ANYFIRST returns a value of 0.

If you use only one argument, ANYFIRST begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

ANYFIRST returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The ANYFIRST function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7. The NOTFIRST function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under VALIDVARNAME=V7.

Example

The following example uses the ANYFIRST function to search a string for any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7.

```sas
data _null_;
  dcl char(18) string c;
  dcl double j i;
  method run();
  string='Next = _n_ + 12E3;';
  j=0;
  do until(j=0);
    j=anyfirst(string, j+1);
    if j=0 then put 'The end';
    else do;
      c=substr(string, j, 1);
      put j= c=;
    end;
  end;
end;
enddata;
run;
```
SAS writes the following output to the log:

\[
\begin{array}{l}
j=1 \ c=N \\
j=2 \ c=e \\
j=3 \ c=x \\
j=4 \ c=t \\
j=8 \ c=_ \\
j=9 \ c=n \\
j=10 \ c=_ \\
j=16 \ c=E \\
\end{array}
\]

**ANYGRAPH Function**

Searches a character string for a graphical character, and returns the first position at which that character is found.

- **Category:** Character
- **Returned data type:** DOUBLE

**Syntax**

\[
\text{ANYGRAPH}(\text{string}[, \text{start}])
\]

**Arguments**

- **expression**
  - specifies any valid expression that evaluates to a character string.
  - **Data type:** CHAR, NCHAR

- **start**
  - specifies the position at which the search should start and the direction in which to search.
  - **Data type:** INTEGER

**Details**

The results of the ANYGRAPH function depend directly on the translation table that is in effect (see “TRANTAB= Option” in *SAS Viya National Language Support: Reference Guide*) and indirectly on the ENCODING and the LOCALE options.

The ANYGRAPH function searches a string for the first occurrence of a graphical character. A graphical character is defined as any printable character other than white
space. If such a character is found, ANYGRAPH returns the position in the string of that character. If no such character is found, ANYGRAPH returns a value of 0.

If you use only one argument, ANYGRAPH begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

ANYGRAPH returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

**Comparisons**

The ANYGRAPH function searches a character string for a graphical character. The NOTGRAPH function searches a character string for a non-graphical character.

**Examples**

**Example 1: Searching a String for Graphical Characters**

The following example uses the ANYGRAPH function to search a string for graphical characters.

```plaintext
data _null_;  
dcl char(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12E3;';  
j=0;  
do until(j=0);  
j=anygraph(string, j+1);  
  if j=0 then put 'The end';  
  else do;  
    c=substr(string, j, 1);  
    put j= c=;  
  end;  
end;  
enddata;  
end;
run;
```
SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=6 c==
j=8 c=_
j=9 c=n
j=10 c=_
j=12 c=
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
j=18 c=;
The end
```

**Example 2: Identifying Control Characters By Using the ANYGRAPH Function**

You can execute the following program to show the control characters that are identified by the ANYGRAPH function.

```sas
data testany (overwrite=yes);
dcl nchar(3) byte1 hex1;
dcl double dec anygraph1;

method run();
do dec=0 to 255;
  byte1=byte(dec);
  hex1=put(dec,hex2.);
  anygraph=anygraph(byte1);
  output;
end;
end;
enddata;
run;

proc print data=testany;
run;
quit;
```

**ANYLOWER Function**

Searches a character string for a lowercase letter, and returns the first position at which the letter is found.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>
Syntax

\texttt{ANYLOWER('expression'[\textbackslash start])}

Arguments

\textit{expression}

specifies any valid expression that evaluates to a character string.

\begin{itemize}
  \item \textbf{Data type} \texttt{CHAR, NCHAR}
  \item \textbf{See} \textquote{DS2 Expressions} in \textit{SAS Viya: DS2 Programmer\'s Guide}
\end{itemize}

\textit{start}

specifies the position at which the search should start and the direction in which to search.

\begin{itemize}
  \item \textbf{Data type} \texttt{INTEGER}
\end{itemize}

Details

The results of the ANYLOWER function depend directly on the translation table that is in effect (see \textquote{TRANTAB= Option} in \textit{SAS Viya National Language Support: Reference Guide} and indirectly on the \texttt{ENCODING} and the \texttt{LOCALE} options.

The ANYLOWER function searches a string for the first occurrence of a lowercase letter. If such a character is found, ANYLOWER returns the position in the string of that character. If no such character is found, ANYLOWER returns a value of 0.

If you use only one argument, ANYLOWER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

\begin{itemize}
  \item If the value of \textit{start} is positive, the search proceeds to the right.
  \item If the value of \textit{start} is negative, the search proceeds to the left.
  \item If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.
\end{itemize}

ANYLOWER returns a value of zero when one of the following is true:

\begin{itemize}
  \item The character that you are searching for is not found.
  \item The value of \textit{start} is greater than the length of the string.
  \item The value of \textit{start} = 0.
\end{itemize}

Comparisons

The ANYLOWER function searches a character string for a lowercase letter. The NOTLOWER function searches a character string for a character that is not a lowercase letter.

Example

The following example uses the ANYLOWER function to search a string for any character that is a lowercase letter.

\begin{verbatim}
data _null_;
\end{verbatim}
dcl char(18) string c;
dcl double j i;
method run();
    string='Next = _n_ + 12E3;';
j=0;
do until(j=0);
    j=anylower(string, j+1);
    if j=0 then put 'The end';
    else do;
        c=substr(string, j, 1);
        put j= c=; 
    end;
end;
enddata;
run;

SAS writes the following output to the log:

j=2 c=e
j=3 c=x
j=4 c=t
j=9 c=n
The end

- “NOTLOWER Function” on page 484

ANYNAME Function

Searches a character string for a character that is valid in a SAS variable name under VALIDVARNAME=V7, and returns the first position at which that character is found.

| Category: | Character |
| Returned data type: | DOUBLE |

Syntax

ANYNAME('expression'[start])

Arguments

expression

specifies any valid expression that evaluates to a character string.

Data type  CHAR, NCHAR

specifies the position at which the search should start and the direction in which to search.

Data type INTEGER

Details

The ANYNAME function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7. These characters are the underscore (_), digits, and uppercase or lowercase English letters. If such a character is found, ANYNAME returns the position in the string of that character. If no such character is found, ANYNAME returns a value of 0.

If you use only one argument, ANYNAME begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \texttt{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

• If the value of \texttt{start} is positive, the search proceeds to the right.
• If the value of \texttt{start} is negative, the search proceeds to the left.
• If the value of \texttt{start} is less than the negative length of the string, the search begins at the end of the string.

ANYNAME returns a value of zero when one of the following is true:

• The character that you are searching for is not found.
• The value of \texttt{start} is greater than the length of the string.
• The value of \texttt{start} = 0.

Comparisons

The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7. The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNAME=V7.

Example

The following example uses the ANYNAME function to search a string for any character that is valid in a SAS variable name under VALIDVARNAME=V7.

```
data _null_;  
dcl char(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12E3;';  
  j=0;  
  do until(j=0);  
    j=anyname(string, j+1);  
    if j=0 then put 'The end';  
    else do;  
      c=substr(string, j, 1);  
      put j= c=;
```
SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=8 c=_
j=9 c=n
j=10 c=_
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
The end
```

Functions:

- “NOTNAME Function” on page 486

ANYPRINT Function

Searches a character string for a printable character, and returns the first position at which that character is found.

**Category:** Character  
**Returned data type:** DOUBLE

**Syntax**

```
ANYPRINT('expression'[, start])
```

**Arguments**

- **expression**
  
  specifies any valid expression that evaluates to a character string.

  **Data type**  
  CHAR, NCHAR

  **See**  

- **start**
  
  specifies the position at which the search should start and the direction in which to search.

  **Data type**  
  INTEGER
Details

The results of the ANYPRINT function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE options.

The ANYPRINT function searches a string for the first occurrence of a printable character. If such a character is found, ANYPRINT returns the position in the string of that character. If no such character is found, ANYPRINT returns a value of 0.

If you use only one argument, ANYPRINT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

ANYPRINT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The ANYPRINT function searches a character string for a printable character. The NOTPRINT function searches a character string for a non-printable character.

Examples

**Example 1: Searching a String for a Printable Character**

The following example uses the ANYPRINT function to search a string for printable characters.

```sas
data _null_;
dcl char(18) string c;
dcl double j i;
method run();
  string='Next = _n_ + 12E3;';
j=0;
do until(j=0);
  j=anyprint(string, j+1);
  if j=0 then put 'The end';
  else do;
    c=substr(string, j, 1);
    put j= c=;
  end;
end;
enddata;
enddate;
run;
```
SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=5 c=
j=6 c==
j=7 c=
j=8 c=_
j=9 c=n
j=10 c=_
j=11 c=
j=12 c=+
j=13 c=
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
j=18 c=;
The end
```

**Example 2: Identifying Control Characters By Using the ANYPRINT Function**

You can execute the following program to show the control characters that are identified by the ANYPRINT function.

```
data testany;
dcl nchar(3) byte1 hex1;
dcl double dec anyprint1;

method run();
   do dec=0 to 255;
      byte1=byte(dec);
      hex1=put(dec,hex2.);
      anyprint1=anyprint(byte1);
      output;
   end;
end;
enddata;
run;

proc print data=testany;
run;
quit;
```

**See Also**

**Functions:**
- “NOTPRINT Function” on page 488

**ANYPUNCT Function**

Searches a character string for a punctuation character, and returns the first position at which that character is found.
Syntax

\texttt{ANYPUNCT(\textit{expression}[, \textit{start}])}

Arguments

\textit{expression}

specifies any valid expression that evaluates to a character string.

Data type \texttt{CHAR, NCHAR}

\textit{start}

specifies the position at which the search should start and the direction in which to search.

Data type \texttt{INTEGER}

Details

The results of the \textit{ANYPUNCT} function depend directly on the translation table that is in effect (see “\texttt{TRANTAB= Option}” in \textit{SAS Viya National Language Support: Reference Guide}) and indirectly on the \texttt{ENCODING} and the \texttt{LOCALE} options.

The \textit{ANYPUNCT} function searches a string for the first occurrence of a punctuation character. If such a character is found, \textit{ANYPUNCT} returns the position in the string of that character. If no such character is found, \textit{ANYPUNCT} returns a value of 0.

If you use only one argument, \textit{ANYPUNCT} begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \textit{start} is positive, the search proceeds to the right.
- If the value of \textit{start} is negative, the search proceeds to the left.
- If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.

\textit{ANYPUNCT} returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \textit{start} is greater than the length of the string.
- The value of \textit{start} = 0.

Comparisons

The \textit{ANYPUNCT} function searches a character string for a punctuation character. The \textit{NOTPUNCT} function searches a character string for a character that is not a punctuation character.
Examples

Example 1: Searching a String for Punctuation Characters

The following example uses the ANYPUNCT function to search a string for punctuation characters.

```sas
data _null_;    
dcl char(18) string c;    
dcl double j i;    
method run();    
    string='Next = _n_ + 12E3;';    
    j=0;    
    do until(j=0);    
        j=anypunct(string, j+1);    
        if j=0 then put 'The end';    
        else do;    
            c=substr(string, j, 1);    
            put j= c=;    
        end;    
    end;    
end;    
enddata;    
run;
```

SAS writes the following output to the log:

```
j=8 c=_
j=10 c=_
j=18 c=;
The end
```

Example 2: Identifying Control Characters By Using the ANYPUNCT Function

You can execute the following program to show the control characters that are identified by the ANYPUNCT function.

```sas
data testany (overwrite=yes);    
dcl nchar(3) byte1 hex1;    
dcl double dec anypunct1;    
method run();    
    do dec=0 to 255;    
        byte1=byte(dec);    
        hex1=put(dec,hex2.);    
        anypunct1=anypunct(byte1);    
        output;    
    end;    
end;    
enddata;    
run;
```

Functions:

- “NOTPUNCT Function” on page 490
ANYSPACE Function

Searches a character string for a whitespace character (blank, horizontal and vertical tab, carriage return, line feed, and form feed), and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

### Syntax

```
ANYSPACE('expression'[, start])
```

### Arguments

**expression**

specifies any valid expression that evaluates to a character string.

*Data type* CHAR, NCHAR

*See* “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**start**

specifies the position at which the search should start and the direction in which to search.

*Data type* INTEGER

### Details

The results of the ANYSPACE function depend directly on the translation table that is in effect (see “TRANTAB= Option” in *SAS Viya National Language Support: Reference Guide*) and indirectly on the ENCODING and the LOCALE options.

The ANYSPACE function searches a string for the first occurrence of any character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. If such a character is found, ANYSPACE returns the position in the string of that character. If no such character is found, ANYSPACE returns a value of 0.

If you use only one argument, ANYSPACE begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYSPACE returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
• The value of \( \text{start} = 0 \).

**Comparisons**

The \textit{ANYSPACE} function searches a character string for the first occurrence of a character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. The \textit{NOTSPACE} function searches a character string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed.

**Examples**

**Example 1: Searching a String for a Whitespace Character**

The following example uses the \textit{ANYSPACE} function to search a string for a character that is a whitespace character.

```sas
data _null_;
dcl char(18) string c;
dcl double j i;
method run();
  string='Next = _n_ + 12E3;';
j=0;
do until(j=0);
  j=anyspace(string, j+1);
  if j=0 then put 'The end';
  else do;
    c=substr(string, j, 1);
    put j= c=;
  end;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
j=5 c=
j=7 c=
j=11 c=
j=13 c=
The end
```

**Example 2: Identifying Control Characters By Using the ANYSPACE Function**

You can execute the following program to show the control characters that are identified by the \textit{ANYSPACE} function.

```sas
data testany (overwrite=yes);
dcl nchar(3) byte1 hex1;
dcl double dec anyspace1;
method run();
do dec=0 to 255;
  byte1=byte(dec);
  hex1=put(dec,hex2.);
  anyspace1=anyspace(byte1);
```

ANYUPPER Function

Searches a character string for an uppercase letter, and returns the first position at which the letter is found.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

ANYUPPER(expression[, start])

**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

Data type CHAR, NCHAR

*start*

specifies the position at which the search should start and the direction in which to search.

Data type INTEGER

**Details**

The results of the ANYUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE options.

The ANYUPPER function searches a string for the first occurrence of an uppercase letter. If such a character is found, ANYUPPER returns the position in the string of that character. If no such character is found, ANYUPPER returns a value of 0.

If you use only one argument, ANYUPPER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, `start`, specifies the position at which to begin the search. The direction in which to search is determined in the following way:
• If the value of \textit{start} is positive, the search proceeds to the right.
• If the value of \textit{start} is negative, the search proceeds to the left.
• If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.

\textit{ANYUPPER} returns a value of zero when one of the following is true:
• The character that you are searching for is not found.
• The value of \textit{start} is greater than the length of the string.
• The value of \textit{start} = 0.

\section*{Comparisons}

The \textit{ANYUPPER} function searches a character string for an uppercase letter. The \textit{NOTUPPER} function searches a character string for a character that is not an uppercase letter.

\section*{Example}

The following example uses the \textit{ANYUPPER} function to search a string for an uppercase letter.

\begin{verbatim}
data _null_;   dcl char(18) string c;   dcl double j i;   method run();   string='Next = _n_ + 12E3;';   j=0;   do until(j=0);     j=anyupper(string, j+1);     if j=0 then put 'The end';     else do;       c=substr(string, j, 1);       put j= c=;     end;   end;   enddata;   run;
\end{verbatim}

SAS writes the following output to the log:

\begin{verbatim}
j=1 c=N
j=16 c=E
The end
\end{verbatim}

\section*{See Also}

\textbf{Functions:}

• “\textit{NOTUPPER} Function” on page 495
ANYXDIGIT Function

Searches a character string for a hexadecimal character that represents a digit, and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

\[ \text{ANYXDIGIT('expression'[,'start'])} \]

**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

**Data type** CHAR, NCHAR

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*start*

specifies the position at which the search should start and the direction in which to search.

**Data type** INTEGER

**Details**

The ANYXDIGIT function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYXDIGIT function searches a string for the first occurrence of any character that is a digit or an uppercase or lowercase A, B, C, D, E, or F. If such a character is found, ANYXDIGIT returns the position in the string of that character. If no such character is found, ANYXDIGIT returns a value of 0.

If you use only one argument, ANYXDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYXDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.
Comparisons

The ANYXDIGIT function searches a character string for a character that is a hexadecimal character. The NOTXDIGIT function searches a character string for a character that is not a hexadecimal character.

Example

The following example uses the ANYXDIGIT function to search a string for a hexadecimal character that represents a digit.

```sas
data _null_;  
dcl char(18) string c;  
dcl double j i;  
method run();  
   string='Next = _n_ + 12E3;';  
   j=0;  
   do until(j=0);  
      j=anyxdigit(string, j+1);  
      if j=0 then put 'The end';  
      else do;  
         c=substr(string, j, 1);  
         put j= c=;  
      end;  
   end;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
j=2 c=e
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
The end
```

Functions:

- “NOTXDIGIT Function” on page 497

**ARCOS Function**

Returns the arccosine in radians.

| Category: | Trigonometric |
| Returned data type: | DOUBLE |
Syntax

**ARCOS**(*expression*)

*Arguments*

*expression*

specifies any valid expression that evaluates to a numeric value.

Range: –1 to 1

Data type: DOUBLE

*Details*

The ARCOS function returns the arccosine (inverse cosine) of the argument. The value that is returned is specified in radians.

*Example*

The following statements illustrate the ARCOS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=arcos(1);</td>
<td>0</td>
</tr>
<tr>
<td>x=arcos(0);</td>
<td>1.57079632679489</td>
</tr>
<tr>
<td>x=arcos(-0.5);</td>
<td>2.094395102339319</td>
</tr>
</tbody>
</table>

**ARCOSH Function**

Returns the inverse hyperbolic cosine.

*Category:* Hyperbolic

*Returned data type:* DOUBLE

*Syntax*

**ARCOSH**(*expression*)

*Arguments*

*expression*

specifies any valid expression that evaluates to a numeric value.

Range: *expression >= 1*
Data type  DOUBLE

See  “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

Details
The ARCOSH function computes the inverse hyperbolic cosine. The ARCOSH function is mathematically defined by the following equation, where $expression \geq 1$. In the equation, $expression$ is represented by $x$.

$$ARCOSH(x) = \log(x + \sqrt{x^2 - 1})$$

Example
The following statements illustrate the ARCOSH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x=\text{arcosh}(5);$</td>
<td>2.29243166956117</td>
</tr>
<tr>
<td>$x=\text{arcosh}(13);$</td>
<td>3.25661395480005</td>
</tr>
</tbody>
</table>

ARSIN Function
Returns the arcsine in radians.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Trigonometric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

ARSIN(*expression*)

Arguments

*expression*
 specifies any valid expression that evaluates to a numeric value.
Details
The ARSIN function returns the arcsine (inverse sine) of the argument. The value that is returned is specified in radians.

Example
The following statements illustrate the ARSIN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=arsin(0);</td>
<td>0</td>
</tr>
<tr>
<td>x=arsin(1);</td>
<td>1.57079632679489</td>
</tr>
<tr>
<td>x= arsin(-0.5);</td>
<td>-0.52359877559829</td>
</tr>
</tbody>
</table>

ARSINH Function
Returns the inverse hyperbolic sine.

Category: Hyperbolic
Returned data type: DOUBLE

Syntax
ARSINH(expression)

Arguments
expression
specifies any valid expression that evaluates to a numeric value.

Range $-\infty < x < \infty$
Data type DOUBLE

Details
The ARSINH function computes the inverse hyperbolic sine. The ARSINH function is mathematically defined by the following equation, where $-\infty < x < \infty$. 
\[
ARSINH(x) = \log\left(x + \sqrt{x^2 + 1}\right)
\]

Replace the infinity symbol with the largest double precision number that is available on your machine. In the equation, \textit{expression} is represented by \(x\).

**Example**

The following statements illustrate the ARSINH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x=\text{arsinh}(5));</td>
<td>2.31243834127275</td>
</tr>
<tr>
<td>(x=\text{arsinh}(-5));</td>
<td>-2.31243834127275</td>
</tr>
</tbody>
</table>

**ARTANH Function**

Returns the inverse hyperbolic tangent.

**Category:** Hyperbolic

**Returned data type:** DOUBLE

**Syntax**

\[
\text{ARTANH}(\text{expression})
\]

**Arguments**

\textit{expression}

specifies any valid expression that evaluates to a numeric value.

**Range**

\(-1 < \text{expression} < 1\)

**Data type** DOUBLE

**See**

Details
The ARTANH function computes the inverse hyperbolic tangent. The ARTANH function is mathematically defined by the following equation, where \(-1 < expression < 1\).

\[
ARTANH(x) = \frac{1}{2} \log\left(\frac{1 + x}{1 - x}\right)
\]

Example
The following statements illustrate the ARTANH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcl double x;</td>
<td></td>
</tr>
<tr>
<td>x=artanh(.5);</td>
<td>0.54930614433405</td>
</tr>
<tr>
<td>dcl double x1;</td>
<td></td>
</tr>
<tr>
<td>x=artanh(-.5);</td>
<td>-0.54930614433405</td>
</tr>
</tbody>
</table>

ATAN Function
Returns the arctangent in radians.

**Category:** Trigonometric

**Alias:** ARTAN

**Returned data type:** DOUBLE

**Syntax**

\[
ATAN(expression)
\]

**Arguments**

\(expression\)

specifies any valid expression that evaluates to a numeric value.
Details

The ATAN function returns the 2-quadrant arctangent (inverse tangent) of the argument. The value that is returned is the angle (in radians) whose tangent is \(x\) and whose value ranges from \(-\frac{\pi}{2}\) to \(\frac{\pi}{2}\).

Comparisons

The ATAN function is similar to the ATAN2 function except that ATAN2 calculates the arctangent of the angle from the ratio of two arguments rather than from one argument.

Example

The following statements illustrate the ATAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x = \text{atan}(0));</td>
<td>0</td>
</tr>
<tr>
<td>(x = \text{atan}(1));</td>
<td>0.78539816339744</td>
</tr>
<tr>
<td>(x = \text{atan}(-9.0));</td>
<td>-1.460139105621</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “ATAN2 Function” on page 220

ATAN2 Function

Returns the arctangent of the \(x\) and \(y\) coordinates of a right triangle, in radians.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Trigonometric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

\[
\text{ATAN2} \ (\text{expression-1}, \text{expression-2})
\]

Arguments

\(\text{expression-1}\)

specifies any valid expression that evaluates to a numeric value. \(\text{expression-1}\) specifies the \(x\) coordinate of the end of the hypotenuse of a right triangle.
**expression-2**
specifies any valid expression that evaluates to a numeric value. *expression-2* specifies the y coordinate of the end of the hypotenuse of a right triangle.

**Details**
The ATAN2 function returns the arctangent (inverse tangent) of two numeric variables. The result of this function is similar to the result of calculating the arc tangent of *expression-1* / *expression-2*, except that the signs of both arguments are used to determine the quadrant of the result.

**Comparisons**
The ATAN2 function is similar to the ATAN function except that ATAN calculates the arctangent of the angle from the value of one argument rather than from two arguments.

**Example**
The following statements illustrate the ATAN2 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=atan2(-1, 0.5);</td>
<td>-1.10714871779409</td>
</tr>
<tr>
<td>x=atan2(6,8);</td>
<td>0.643501108793828</td>
</tr>
<tr>
<td>x=atan2(5,-3);</td>
<td>2.11121582706548</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- “ATAN Function” on page 219
Syntax

BAND(expression-1, expression-2)

Arguments

expression-1, expression-2
specifies any valid expression that evaluates to a numeric value.

Range: between 0 and \(2^{32} - 1\) inclusive

Data type: DOUBLE

Example

The following statements illustrate the BAND function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=band(9,11);</td>
<td>9</td>
</tr>
<tr>
<td>x=band(15,5);</td>
<td>5</td>
</tr>
</tbody>
</table>

BETA Function

Returns the value of the beta function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

BETA(a, b)

Arguments

a
is the first shape parameter.

Range: \(a > 0\)

Data type: DOUBLE

b
is the second shape parameter.
Range  
\( b > 0 \)

Data type  DOUBLE

Details

The BETA function is mathematically given by this equation:

\[
\beta(a, b) = \int_0^1 x^{a-1}(1-x)^{b-1} \, dx
\]

Note the following:

\[
\beta(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}
\]

In the previous equation, \( \Gamma(\cdot) \) is the gamma function.

If the expression cannot be computed, BETA returns a missing value.

Example

The following statements illustrate the BETA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x=\text{beta}(5,3); )</td>
<td>0.0095238095238</td>
</tr>
<tr>
<td>( x=\text{beta}(15,45); )</td>
<td>1.6710294365008E-15</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “LOGBETA Function” on page 439

**BETAINV Function**

Returns a quantile from the beta distribution.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Quantile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

\[
\text{BETAINV}(p, a, b)
\]

Arguments

\( p \)

is a numeric probability.
Range  \(0 \leq p \leq 1\)

Data type DOUBLE

\(a\)

is a numeric shape parameter.

Range  \(a > 0\)

Data type DOUBLE

\(b\)

is a numeric shape parameter.

Range  \(b > 0\)

Data type DOUBLE

Details

The BETAINV function returns the \(p\)th quantile from the beta distribution with shape parameters \(a\) and \(b\). The probability that an observation from a beta distribution is less than or equal to the returned quantile is \(p\).

Note: BETAINV is the inverse of the PROBBETA function.

Example

The following example illustrates the BETAINV function.

data test (overwrite=yes);
  dcl double y z;
  method run();
    y=betainv(0.001, 2, 4);
    put 'y=' y;
  end;
enddata;
run;

The following line is written to the SAS log.

\[y = 0.01010178788373\]

See Also

Functions:

- “PROBBETA Function” on page 512

BLACKCLPRC Function

Calculates call prices for European options on futures, based on the Black model.

Category: Financial
BLACKCLPRC Function

Returned data type: DOUBLE

Syntax

BLACKCLPRC(E, t, F, r, sigma)

Arguments

E
is a nonmissing, positive value that specifies exercise price.

Requirement Specify E and F in the same units.

Data type DOUBLE

T
is a nonmissing value that specifies time to maturity, in years.

Data type DOUBLE

F
is a nonmissing, positive value that specifies future price.

Requirement Specify F and E in the same units.

Data type DOUBLE

r
is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type DOUBLE

sigma
is a nonmissing, positive fraction that specifies the volatility (the square root of the variance of r).

Data type DOUBLE

Details

The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. The function is based on the following relationship:

\[
\text{CALL} = e^{-rt} \left( FN(d_1) - EN(d_2) \right)
\]

Arguments

F
specifies future price.

N
specifies the cumulative normal density function.

E
specifies the exercise price of the option.
\( r \)

specifies the risk-free interest rate, which is an annual rate that is expressed in terms of continuous compounding.

\( t \)

specifies the time to expiration, in years.

\[
d_1 = \frac{\ln(F/E) + \left( \frac{\sigma^2}{2} \right) t}{\sigma\sqrt{t}}
\]

\[
d_2 = d_1 - \sigma\sqrt{t}
\]

The following arguments apply to the preceding equation:

\( \sigma \)

specifies the volatility of the underlying asset.

\( \sigma^2 \)

specifies the variance of the rate of return.

For the special case of \( t=0 \), the following equation is true:

\[
\text{CALL} = \max(F - E, 0)
\]

For information about the basics of pricing, see "Using Pricing Functions".

**Comparisons**

The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. These functions return a scalar value.

**Example**

The following statements illustrate the BLACKCLPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=blackclprc(50, .25, 48, .05, .25);</td>
<td>1.55130142723117</td>
</tr>
<tr>
<td>b=blackclprc(9, 1/12, 10, .05, .2);</td>
<td>1</td>
</tr>
</tbody>
</table>

\(\sigma\)

is a nonmissing, positive fraction that specifies the volatility (the square root of the variance of \(r\)).

**Data type**

DOUBLE

**Details**

The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. The function is based on the following relationship:

\[
PUT = CALL + e^{-rt}(E - F)
\]

**Arguments**

\(E\)

specifies the exercise price of the option.

\(r\)

specifies the risk-free interest rate, which is an annual rate that is expressed in terms of continuous compounding.
\[ t \]
\[ F \]
\[ d_1 = \frac{\ln(F) + \left( \frac{\sigma^2}{2} \right) t}{\sigma\sqrt{t}} \]
\[ d_2 = d_1 - \sigma\sqrt{t} \]

The following arguments apply to the preceding equation:
\[ \sigma \]
\[ \sigma^2 \]

For the special case of \( t=0 \), the following equation is true:
\[ \text{PUT} = \max((E - F), 0) \]

For information about the basics of pricing, see "Using Pricing Functions".

**Comparisons**

The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. These functions return a scalar value.

**Example**

The following statements illustrate the BLACKPTPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a = \text{blackptprc}(298, .25, 350, .06, .25) );</td>
<td>1.85980563934969</td>
</tr>
<tr>
<td>( b = \text{blackptprc}(145, .5, 170, .05, .2) );</td>
<td>1.41234979911583</td>
</tr>
</tbody>
</table>

**BLKSHCLPRC Function**

Calculates call prices for European options on stocks, based on the Black-Scholes model.
Syntax

\texttt{BLKSHCLPRC}(E, t, S, r, \sigma)

Arguments

\(E\)
is a nonmissing, positive value that specifies the exercise price.

Requirement Specify \(E\) and \(S\) in the same units.

Data type \texttt{DOUBLE}

\(t\)
is a nonmissing value that specifies the time to maturity, in years.

Data type \texttt{INTEGER}

\(S\)
is a nonmissing, positive value that specifies the share price.

Requirement Specify \(S\) and \(E\) in the same units.

Data type \texttt{DOUBLE}

\(r\)
is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type \texttt{DOUBLE}

\(\sigma\)
is a nonmissing, positive fraction that specifies the volatility of the underlying asset.

Data type \texttt{DOUBLE}

Details

The BLKSHCLPRC function calculates the call prices for European options on stocks, based on the Black-Scholes model. The function is based on the following relationship:

\[
\text{CALL} = S N(d_1) - E N(d_2)e^{-rt}
\]

Arguments

\(S\)
is a nonmissing, positive value that specifies the share price.

\(N\)
specifies the cumulative normal density function.

\(E\)
is a nonmissing, positive value that specifies the exercise price of the option.
\[ d_1 = \frac{\ln\left(\frac{S}{E}\right) + \left(r + \frac{\sigma^2}{2}\right)t}{\sigma\sqrt{t}} \]
\[ d_2 = d_1 - \sigma\sqrt{t} \]

The following arguments apply to the preceding equation:

- \(t\) specifies the time to expiration, in years.
- \(r\) specifies the risk-free interest rate, which is an annual rate that is expressed in terms of continuous compounding.
- \(\sigma\) specifies the volatility (the square root of the variance).
- \(\sigma^2\) specifies the variance of the rate of return.

For the special case of \(t=0\), the following equation is true:

\[ \text{CALL} = \max(S - E, 0) \]

For information about the basics of pricing, see "Using Pricing Functions".

**Comparisons**

The BLKSHCLPRC function calculates the call prices for European options on stocks, based on the Black-Scholes model. The BLKSHPTPRC function calculates the put prices for European options on stocks, based on the Black-Scholes model. These functions return a scalar value.

**Example**

The following statements illustrate the BLKSHCLPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=blkshclprc(50, .25, 48, .05, .25);</td>
<td>1.79894201954462</td>
</tr>
<tr>
<td>b=blkshclprc(9, 1/12, 10, .05, .2);</td>
<td>1</td>
</tr>
</tbody>
</table>

**BLKSHPTPRC Function**

Calculates put prices for European options on stocks, based on the Black-Scholes model.
Category: Financial  
Returned data type: DOUBLE

### Syntax

**BLKSHPTPRC**(*E*, *t*, *S*, *r*, *sigma*)

### Arguments

**E**  
is a nonmissing, positive value that specifies the exercise price.  
**Requirement** Specify **E** and **S** in the same units.  
**Data type** DOUBLE

**t**  
is a nonmissing value that specifies the time to maturity, in years.  
**Data type** INTEGER

**S**  
is a nonmissing, positive value that specifies the share price.  
**Requirement** Specify **S** and **E** in the same units.  
**Data type** DOUBLE

**r**  
is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.  
**Data type** DOUBLE

**sigma**  
is a nonmissing, positive fraction that specifies the volatility of the underlying asset.  
**Data type** DOUBLE

### Details

The BLKSHPTPRC function calculates the put prices for European options on stocks, based on the Black-Scholes model. The function is based on the following relationship:

\[ \text{PUT} = \text{CALL} - S + E e^{-rt} \]

**Arguments**

**S**  
is a nonmissing, positive value that specifies the share price.  

**E**  
is a nonmissing, positive value that specifies the exercise price of the option.
\[ d_1 = \frac{\ln \left( \frac{S}{E} \right) + (r + \frac{\sigma^2}{2})t}{\sigma \sqrt{t}} \]
\[ d_2 = d_1 - \sigma \sqrt{t} \]

The following arguments apply to the preceding equation:

- \( t \)
  - specifies the time to expiration, in years.

- \( r \)
  - specifies the risk-free interest rate, which is an annual rate that is expressed in terms of continuous compounding.

- \( \sigma \)
  - specifies the volatility (the square root of the variance).

- \( \sigma^2 \)
  - specifies the variance of the rate of return.

For the special case of \( t=0 \), the following equation is true:

\[ \text{PUT} = \max(E - S, 0) \]

For information about the basics of pricing, see "Using Pricing Functions".

**Comparisons**

The BLKSHPTPRC function calculates the put prices for European options on stocks, based on the Black-Scholes model. The BLKSHCLPRC function calculates the call prices for European options on stocks, based on the Black-Scholes model. These functions return a scalar value.

**Example**

The following statements illustrate the BLKSHPTPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>

**BLSHIFT Function**

Returns the bitwise logical left shift of two arguments.
Category: Bitwise Logical Operations
Returned data type: DOUBLE

Syntax
BLSHIFT(expression-1, expression-2)

Arguments
expression-1
specifies any valid expression that evaluates to a numeric value.
Range between 0 and \(2^{32}-1\) inclusive
Data type DOUBLE

expression-2
specifies any valid expression that evaluates to a numeric value.
Range 0 to 31, inclusive
Data type DOUBLE

Example
The following statement illustrates the BLSHIFT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=blshift(7,2);</td>
<td>28</td>
</tr>
</tbody>
</table>

<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=bnot(16);</td>
<td>4294967279</td>
</tr>
</tbody>
</table>

---

**BOR Function**

Returns the bitwise logical OR of two arguments.

**Category:** Bitwise Logical Operations

**Returned data type:** DOUBLE

**Syntax**

**BOR(expression-1, expression-2)**

**Arguments**

*expression-1, expression-2*

 *specifies any valid expression that evaluates to a numeric value.*

<table>
<thead>
<tr>
<th><strong>Range</strong></th>
<th>between 0 and $(2^{32})-1$ inclusive</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data type</strong></td>
<td>DOUBLE</td>
</tr>
<tr>
<td><strong>See</strong></td>
<td>“DS2 Expressions” in <em>SAS Viya: DS2 Programmer’s Guide</em></td>
</tr>
</tbody>
</table>

**Example**

The following statement illustrates the BOR function:
**BRSHIFT Function**

Returns the bitwise logical right shift of two arguments.

**Category:** Bitwise Logical Operations  
**Returned data type:** DOUBLE

---

**Syntax**

BRSHIFT(expression-1, expression-2)

**Arguments**

expression-1  
- Specifies any valid expression that evaluates to a numeric value.  
  - **Range:** between 0 and \(2^{32} - 1\) inclusive  
  - **Data type:** DOUBLE  
  - **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

expression-2  
- Specifies any valid expression that evaluates to a numeric value.  
  - **Range:** 0 to 31, inclusive  
  - **Data type:** DOUBLE  
  - **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

---

**Example**

The following statement illustrates the BRSHIFT function:

<table>
<thead>
<tr>

**BXOR Function**

Returns the bitwise logical EXCLUSIVE OR of two arguments.

**Category:** Bitwise Logical Operations  
**Returned data type:** DOUBLE

**Syntax**

\[
\text{BXOR}(\text{expression-1, expression-2})
\]

**Arguments**

- **expression-1, expression-2**
  - specifies any valid expression that evaluates to a numeric value.
  - Range: between 0 and \(2^{32} - 1\) inclusive
  - Data type: DOUBLE

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Example**

The following statement illustrates the BXOR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=bxor(128,64);</td>
<td>192</td>
</tr>
</tbody>
</table>

**BYTE Function**

Returns one character in the ASCII or the EBCDIC collating sequence.

**Category:** Character  
**Returned data type:** VARCHAR

**Syntax**

\[
\text{BYTE}(n)
\]

**Arguments**

- **n**
  - specifies an integer that represents a specific ASCII or EBCDIC character.
Range 0–255
Data type NCHAR

Details
For EBCDIC collating sequences, \( n \) is between 0 and 255. For ASCII collating sequences, the characters that correspond to values between 0 and 127 represent the standard character set. Other ASCII characters that correspond to values between 128 and 255 are available on certain ASCII operating environments, but the information those characters represent varies with the operating environment.

Example
The following statement illustrates the BYTE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII</td>
<td>EBCDIC</td>
</tr>
<tr>
<td>-----+----1----+----2</td>
<td>-----+----1----+----2</td>
</tr>
<tr>
<td>x=byte(80);</td>
<td>P &amp;</td>
</tr>
</tbody>
</table>

See Also
Functions:
- “RANK Function” on page 574

CAT Function
Does not remove leading or trailing blanks, and returns a concatenated character string.

Category: Character
Restriction: This function is not supported in the CAS server.
Returned data type: CHAR, NCHAR

Syntax
\[
\text{CAT}(\text{item}[, \ldots \text{item}])
\]

Arguments
\textit{item}

specifies a constant, variable, or expression, either character or numeric. If \textit{item} is numeric, then its value is converted to a character string by using the BESTw format. In this case, leading blanks are removed and SAS does not write a note to the log.
Details

Length of Returned Variable
If the CAT function returns a value to a variable that has not previously been assigned a length, then that variable is given a length of 200 bytes. If the | | or the .. concatenation operator returns a value to a variable that has not previously been assigned a length, then that variable is given a length that is the sum of the lengths of the values that are being concatenated.

Length of Returned Variable: Special Cases
The CAT function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CAT function has the following length:

- up to 200 characters in WHERE clauses and in PROC SQL
- up to 32767 characters in PROC DS2, except in WHERE clauses
- up to 65534 characters when CAT is called from the macro processor

If CAT returns a value in a temporary buffer, the length of the buffer depends on the calling environment, and the value in the buffer can be truncated after CAT finishes processing. In this case, SAS does not write a message about the truncation to the log.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS does the following:

- changes the result to a blank line in PROC DS2 and in PROC SQL
- writes a warning message to the log stating that the result was either truncated or set to a blank value, depending on the calling environment
- writes a note to the log that shows the location of the function call and lists the argument that caused the truncation
- sets _ERROR_ to 1

The CAT function removes leading and trailing blanks from numeric arguments after it formats the numeric value with the BESTw. format.

Comparisons
The results of the CAT, CATS, CATT, and CATX functions are usually equivalent to results that are produced by certain combinations of the concatenation operators | | and .., and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operators. For more information, see “Length of Returned Variable” on page 238.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT, and you can use them with the OF syntax for variable lists in calling environments that support variable lists.

Example
The following example shows how the CAT function concatenates strings.

```sas
data _null_;
  dcl varchar(25) x y z a;
  dcl varchar(70) result;
  method init();
```
x=' The 2012 Olym';
y='pic Arts Festi';
z=' val included works by D  ';
a='ale Chihuly.,'
result=cat(x,y,z,a);
put result=;
end;
enddata;
rung;

SAS writes the following output to the log:

result=  The 2012 Olympic Arts Festi  val included works by D  ale Chihuly.

CATS Function

Removes leading and trailing blanks, and returns a concatenated character string.

Category: Character
Restriction: This function is not supported in the CAS server.
Returned data type: CHAR, NCHAR

Syntax

CATS(item[, ...item])

Arguments

item

specifies a constant, variable, or expression, either character or numeric. If item is numeric, then its value is converted to a character string by using the BESTw. format. In this case, leading blanks are removed and SAS does not write a note to the log.

Details

Length of Returned Variable

If the CATS function returns a value to a variable that has not previously been assigned a length, then that variable is given a length of 200 bytes. If the | | or the .. concatenation
operator returns a value to a variable that has not previously been assigned a length, then that variable is given a length that is the sum of the lengths of the values that are being concatenated.

**Length of Returned Variable: Special Cases**
The CATS function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CATS function has the following length:

- up to 200 characters in WHERE clauses and in PROC SQL
- up to 32767 characters in PROC DS2, except in WHERE clauses
- up to 65534 characters when CATS is called from the macro processor

If CATS returns a value in a temporary buffer, the length of the buffer depends on the calling environment, and the value in the buffer can be truncated after CATS finishes processing. In this case, SAS does not write a message about the truncation to the log.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS does the following:

- changes the result to a blank value in PROC DS2 and in PROC SQL
- writes a warning message to the log stating that the result was either truncated or set to a blank value, depending on the calling environment
- writes a note to the log that shows the location of the function call and lists the argument that caused the truncation
- sets _ERROR_ to 1

The CATS function removes leading and trailing blanks from numeric arguments after it formats the numeric value with the BEST\(w\) format.

**Comparisons**
The results of the CAT, CATS, CATT, and CATX functions are *usually* equivalent to results that are produced by certain combinations of the concatenation operators `||` and `..`, and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operators. For more information, see “Length of Returned Variable” on page 239.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT, and you can use them with the OF syntax for variable lists in calling environments that support variable lists.

**Example**
The following example shows how the CATS function concatenates strings.

```sas
   data _null_;
      dcl char(25) x y z a;
      dcl char(70) result;
      method init();
         x='  The   Olym';
         y='pic Arts Festi';
         z='  val includes works by D  ';
         a='ale Chihuly.,'
         result=cats(x,y,z,a);
      put result=;
```

240  Chapter 7  •  DS2 Functions
```sas
end;
enddata;
run;

SAS writes the following output to the log:

result=The Olympic Arts Festival includes works by Dale Chihuly.
```

- “CATX Function” on page 243
- “STRIP Function” on page 617

CATT Function

Removes trailing blanks, and returns a concatenated character string.

**Category:** Character

**Restriction:** This function is not supported in the CAS server.

**Returned data type:** CHAR, NCHAR

### Syntax

```
CATT(item[, …item])
```

### Arguments

**item**  
specifies a constant, variable, or expression, either character or numeric. If *item* is numeric, then its value is converted to a character string by using the BESTw. format. In this case, leading blanks are removed and SAS does not write a note to the log.

### Details

#### Length of Returned Variable

If the CATT function returns a value to a variable that has not previously been assigned a length, then that variable is given a length of 200 bytes. If the **||** or the .. concatenation operator returns a value to a variable that has not previously been assigned a length, then that variable is given a length that is the sum of the lengths of the values that are being concatenated.

#### Length of Returned Variable: Special Cases

The CATT function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CATT function has the following length:
• up to 200 characters in WHERE clauses and in PROC SQL
• up to 32767 characters in PROC DS2, except in WHERE clauses
• up to 65534 characters when CATT is called from the macro processor

If CATT returns a value in a temporary buffer, the length of the buffer depends on the calling environment, and the value in the buffer can be truncated after CATT finishes processing. In this case, SAS does not write a message about the truncation to the log.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS does the following:
• changes the result to a blank value in PROC DS2 and in PROC SQL
• writes a warning message to the log stating that the result was either truncated or set to a blank value, depending on the calling environment
• writes a note to the log that shows the location of the function call and lists the argument that caused the truncation
• sets _ERROR_ to 1

The CATT function removes leading and trailing blanks from numeric arguments after it formats the numeric value with the BESTw. format.

Comparisons

The results of the CAT, CATS, CATT, and CATX functions are usually equivalent to results that are produced by certain combinations of the concatenation operators || and .. , and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operators. For more information, see “Length of Returned Variable” on page 241.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT, and you can use them with the OF syntax for variable lists in calling environments that support variable lists.

Example

The following example shows how the CATT function concatenates strings.

data _null_;  
dcl char(25) x y z a;  
dcl char(70) result;  
method init();  
x=' The 2012 Olym';  
y='pic Arts Festi';  
z=' val included works by D  ' ;  
a='ale Chihuly.';  
result=catt(x,y,z,a);  
put result=;  
end;  
enddata;  
run;

SAS writes the following output to the log:

```
result= The 2012 Olympic Arts Festi  val included works by Dale Chihuly.
```
See Also

Functions:
- “CAT Function” on page 237
- “CATS Function” on page 239
- “CATX Function” on page 243
- “STRIP Function” on page 617

CATX Function

Removes leading and trailing blanks, inserts delimiters, and returns a concatenated character string.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restriction:</td>
<td>This function is not supported in the CAS server.</td>
</tr>
<tr>
<td>Returned data type:</td>
<td>CHAR, NCHAR</td>
</tr>
</tbody>
</table>

Syntax

CATX(delimiter, item-1[, …item-n])

Arguments

delimiter
specifies a character string that is used as a delimiter between concatenated items.

item
specifies a constant, variable, or expression, either character or numeric. If item is numeric, then its value is converted to a character string by using the BESTw.format. In this case, SAS does not write a note to the log. For more information, see “The Basics” on page 243.

Details

The Basics
The CATX function first copies item-1 to the result, omitting leading and trailing blanks. Then, for each subsequent argument item-i, i=2, …, n, if item-i contains at least one non-blank character, then CATX appends delimiter and item-i to the result, omitting leading and trailing blanks from item-i. CATX does not insert the delimiter at the beginning or end of the result. Blank items do not produce delimiters at the beginning or end of the result, nor do blank items produce multiple consecutive delimiters.

Length of Returned Variable
The CATX function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CATX function can be up to 32767 characters, except in WHERE clauses.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS truncates the result.
Comparisons

The results of the CAT, CATS, CATT, and CATX functions are *usually* equivalent to results that are produced by certain combinations of the concatenation operators || and .., and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operator. For more information, see “Length of Returned Variable” on page 243.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT, and you can use them with the OF syntax for variable lists in calling environments that support variable lists.

*Note:* In the case of variables that have missing values, the concatenation produces different results.

Example

The following example shows how the CATX function concatenates strings. The first data program creates the Values table. The second and third data programs use the Values table as input.

```text
/* This data program creates the Values table. */
data values;
dcl char(4) x1 x2 x3 x4;
method init();
    /* simple values */
x1='A'; x2='B'; x3='C'; x4='D';
    output;
x1='XX'; x2='YY'; x3='ZZ'; x4='WW';
    output;

    /* values with leading, trailing, and embedded white space */
x1='XX'; x2='YY '; x3='ZZ'; x4='WW ';
    output;

    /* CHAR set to missing */
x1='E'; x2= . ; x3='F'; x4='G';
    output;
x1='H'; x2= . ; x3= . ; x4='J';
    output;

    /* CHAR set to zero-length strings */
x1='X'; x2=''; x3=''; x4='W';
    output;

    /* CHAR set to the null value */
x1='X'; x2=null; x3='Z'; x4=null;
    output;
end;
run;

/* This data program creates the Concat1 table. */
data concat1;
dcl char(1) sp;
dcl char(4) x1 x2 x3 x4;
dcl char(20) test1 test2 spacey;
```
method run();
  set values;
  SP='^';
  test1 = catx(sp, x1, x2, x3, x4);
  test2 = strip(x1)
    || strip(sp) || strip(x2)
    || strip(sp) || strip(x3)
    || strip(sp) || strip(x4);
  spacey = x1 || sp || x2 || sp || x3 || sp || x4;
end;
run;

/* This data program creates the Concat2 table. */
/* The example shows what happens when the delimiter contains */
/* space characters. */
data concat2;
  dcl char(3) sp;
  dcl char(4) x1 x2 x3 x4;
  dcl char(20) test1 test2 spacey;
method run();
  set values;
  SP = ' ^ ';
  test1 = catx(sp, x1, x2, x3, x4);
  test2 = strip(x1)
    || strip(sp) || strip(x2)
    || strip(sp) || strip(x3)
    || strip(sp) || strip(x4);
  spacey = strip(x1)
    || strip(sp) || strip(x2)
    || strip(sp) || strip(x3)
    || strip(sp) || strip(x4);
end;
run;
quit;

proc print data=concat1;
  title 'The Concat1 table';
run;

proc print data=concat2;
  title 'The Concat2 table';
run;
**Output 7.1** Table Showing Concatenated Characters

<table>

CEIL Function

Returns the smallest integer greater than or equal to a numeric value expression.

Category: Truncation
Returned data type: DECIMAL, DOUBLE, NUMERIC

Syntax

CEIL(expression)

Arguments

expression specifies any valid expression that evaluates to a numeric value.

Data type DECIMAL, DOUBLE, NUMERIC

Details

If the result is a number that does not fit into the range of the argument's data type, the CEIL function fails.

If the argument is DECIMAL, the result is DECIMAL. Otherwise, the argument is converted to DOUBLE (if not so already), and the result is DOUBLE.

Comparisons

Unlike the CEILZ function, the CEIL function fuzzes the result. If the argument is within 1E-12 of an integer, the CEIL function fuzzes the result to be equal to that integer. The CEILZ function does not fuzz the result. Therefore, with the CEILZ function, you might get unexpected results.

Example

The following statements illustrate the CEIL function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=ceil(-2.4);</td>
<td>-2</td>
</tr>
<tr>
<td>b=ceil(1+1.e-11);</td>
<td>2</td>
</tr>
<tr>
<td>c=ceil(-1+1.e-11);</td>
<td>0</td>
</tr>
<tr>
<td>d=ceil(1+1.e-13);</td>
<td>1</td>
</tr>
</tbody>
</table>

- “FLOORZ Function” on page 333

CEILZ Function

Returns the smallest integer that is greater than or equal to the argument, using zero fuzzing.

Category: Truncation
Returned data type: DOUBLE

Syntax

CEILZ(expression)

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

Comparisons

Unlike the CEIL function, the CEILZ function uses zero fuzzing. If the argument is within 1E-12 of an integer, the CEIL function fuzzes the result to be equal to that integer. The CEILZ function does not fuzz the result. Therefore, with the CEILZ function, you might get unexpected results.

Example

The following statements illustrate the CEILZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=ceilz(2.1);</td>
<td>3</td>
</tr>
<tr>
<td>b=ceilz(3);</td>
<td>3</td>
</tr>
<tr>
<td>c=ceilz(1+1.e-11);</td>
<td>2</td>
</tr>
<tr>
<td>d=ceilz(223.456);</td>
<td>224</td>
</tr>
</tbody>
</table>

CHOOSER Function

Returns a character value that represents the results of choosing from a list of arguments.

Category: Character
Returned data type: VARCHAR, NVARCHAR

Syntax

CHOOSER(index-expression, selection[, ...selection])

Arguments

index-expression
specifies any valid expression that evaluates to an integer value.

Data type INTEGER

selection
specifies a character constant, variable, or expression. The value of this argument is returned by the CHOOSER function.

Data type DOUBLE

Details

The CHOOSER function uses the value of index-expression to select from the arguments that follow. For example, if index-expression is 3, CHOOSER returns the value of the third selection listed. If the first argument is negative, the function counts backward from the list of arguments, and returns that value.

Comparisons

The CHOOSER function is similar to the CHOOSE function except that CHOOSER returns a character value while CHOOSE returns a numeric value.
Example

The following example shows how CHOOSEC chooses from a series of values:

```sas
data test (overwrite=yes);
    dcl char fruit color planet sport;
    method init();
        Fruit=choosec(1, 'apple', 'orange', 'pear', 'fig');
        Color=choosec(3, 'red', 'blue', 'green', 'yellow');
        Planet=choosec(2, 'Mars', 'Mercury', 'Uranus');
        Sport=choosec(-3, 'soccer', 'baseball', 'gymnastics', 'skiing');
        put Fruit= Color= Planet= Sport=;
    end;
enddata;
run;
```

SAS writes the following output to the log:

```
fruit=apple    color=green    planet=Mercury  sport=baseball
```

### CHOSEN Function

Returns a numeric value that represents the results of choosing from a list of arguments.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

**Syntax**

`CHOSEN(index-expression, selection[, ...selection])`

**Arguments**

- **index-expression**
  - specifies any valid expression that evaluates to an integer value.
  - Data type: INTEGER
  - See: "DS2 Expressions" in *SAS Viya: DS2 Programmer’s Guide"

- **selection**
  - specifies a numeric constant, variable, or expression. The value of this argument is returned by the CHOSEN function.
  - Data type: DOUBLE
Details
The CHOOSEN function uses the value of index-expression to select from the arguments that follow. For example, if index-expression is 3, CHOOSEN returns the value of the third selection listed. If the first argument is negative, the function counts backward from the list of arguments, and returns that value.

Comparisons
The CHOOSEN function is similar to the CHOOSEC function except that CHOOSEC returns a character value while CHOOSEN returns a numeric value.

Example
The following example shows how CHOOSEN chooses from a series of values:

```sas
data test;
  dcl double itemnumber rank score value;
  method run();
  ItemNumber=chosen(5,100,50,3784,498,679);
  Rank=chosen(-2,1,2,3,4,5);
  Score=chosen(3,193,627,33,290,5);
  Value=chosen(-5,-37,82985,-991,3,1014,-325,3,54,-618);
  put 'ItemNumber= ' ItemNumber;
  put 'Rank= ' Rank;
  put 'Score= ' Score;
  put 'Value= ' Value;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
ItemNumber= 679
Rank= 4
Score= 33
Value= 1014
```

CMP Function
Compares two character strings including trailing blanks.

<table>
<thead>
<tr>
<th>Category</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type</td>
<td>BIGINT</td>
</tr>
</tbody>
</table>

Syntax
CMP \( (\text{string-1}, \text{string-2}) \)

Arguments
\( \text{string-1} \)
specifies a character constant, variable, or expression.
Data type  CHAR, VARCHAR

string-2
specifies a character constant, variable, or expression.

Data type  CHAR, VARCHAR

Details
In the CMP function, if string-1 and string-2 do not differ, CMP returns a value of zero. If the arguments differ, the sign of the result is negative if string-1 precedes string-2 in a sort sequence, and positive if string-1 follows string-2 in a sort sequence.

The CMP function does not remove trailing blanks.

Comparisons
The CMP function compares two strings but does not remove trailing blanks. The CMPT function compares two strings and does remove trailing blanks.

Example
The following example uses the CMP function to compare two different strings.

```
proc ds2;
data test (overwrite=yes);
dcl double nopad pad greaterthan lessthan;
   method run();
      nopad=cmp('abc', 'def');
      pad=cmp('abc', 'abc ');
      greaterthan=cmp('abc', 'abcdef');
      lessthan=cmp('abcdef', 'abc');
      put nopad= pad= greaterthan= lessthan=;
   end;
enddata;
run;
```

nopad=-1 pad=-1 greaterthan=-1 lessthan=1

See Also

Functions:
- “CMPT Function” on page 252

CMPT Function
Compares two character strings excluding trailing blanks.

Category:  Character
Returned data type:  BIGINT
Syntax

CMPT \((\text{string-1, string-2})\)

Arguments

\(\text{string-1}\)

specifies a character constant, variable, or expression.

Data type \(\text{CHAR, VARCHAR}\)

\(\text{string-2}\)

specifies a character constant, variable, or expression.

Data type \(\text{CHAR, VARCHAR}\)

Details

In the CMPT function, if \(\text{string-1}\) and \(\text{string-2}\) do not differ, CMPT returns a value of zero. If the arguments differ, the sign of the result is negative if \(\text{string-1}\) precedes \(\text{string-2}\) in a sort sequence, and positive if \(\text{string-1}\) follows \(\text{string-2}\) in a sort sequence.

The CMPT function removes trailing blanks.

Comparisons

The CMPT function compares two strings and removes trailing blanks. The CMP function compares two strings and does not remove trailing blanks.

Example

The following example uses the CMPT function to compare two different strings.

```
proc ds2;
data test (overwrite=yes);
dcl double nopad pad greaterthan lessthan;
  method run();
    nopad=cmpt('abc', 'def');
    pad=cmpt('abc', 'abc ');
    greaterthan=cmpt('abc', 'abcdef');
    lessthan=cmpt('abcdef', 'abc');
    put nopad= pad= greaterthan= lessthan=;
  end;
enddata;
run;
```

nopad=0 pad=0 greaterthan=-1 lessthan=1

COALESCE Function

Returns the first non-null or nonmissing value from a list of numeric arguments.

Category: Mathematical
Returned data type: DOUBLE

Syntax

`COALESCE(expression[, ...expression])`

Arguments

`expression`
specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

Details

COALESCE accepts one or more numeric expressions. The COALESCE function checks the value of each expression in the order in which they are listed and returns the first non-null or nonmissing value. If only one value is listed, then the COALESCE function returns the value of that argument. If all the values of all expressions are null or missing, then the COALESCE function returns a null or a missing value depending on whether you are in ANSI mode or SAS mode. For more information, see “How DS2 Processes Nulls and SAS Missing Values” in SAS Viya: DS2 Programmer’s Guide.

Comparisons

The COALESCE function searches numeric expressions, whereas the COALESCEC function searches character expressions.

Example

The following statement illustrates the COALESCE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x = COALESCE(., .A, 33, 22, 44, .);</code></td>
<td>33</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “COALESCEC Function” on page 255
COALESCEC Function

Returns the first non-null or nonmissing value from a list of character arguments.

**Category:** Character

**Returned data type:** NCHAR

**Syntax**

```
COALESCEC(expression[, ...expression])
```

**Arguments**

- `expression` specifies any valid expression that evaluates to a character value.

**Data type** NCHAR

**See** “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

**Details**

COALESCEC accepts one or more character expressions. The COALESCEC function checks the value of each expression in the order in which they are listed and returns the first non-null or nonmissing value. If only one value is listed, then the COALESCEC function returns the value of that expression. If all the values of all expressions are null or missing, then the COALESCEC function returns a null or missing value depending on whether you are in ANSI mode or SAS mode. For more information, see “How DS2 Processes Nulls and SAS Missing Values” in SAS Viya: DS2 Programmer’s Guide.

**Comparisons**

The COALESCEC function searches character expressions, whereas the COALESCE function searches numeric expressions.

**Example**

The following statements illustrate the COALESCEC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=COALESCEC('','Hello');</code></td>
<td>Hello</td>
</tr>
<tr>
<td><code>a=COALESCEC('','Goodbye','Hello');</code></td>
<td>Goodbye</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**

- “COALESCE Function” on page 254
COMB Function
Computes the number of combinations of \( n \) elements taken \( r \) at a time.

**Category:** Combinatorial  
**Returned data type:** INTEGER

### Syntax

\[ \text{COMB}(n, r) \]

### Arguments

- \( n \)
  - is a nonnegative integer that represents the total number of elements from which the sample is chosen.  
  - Data type: INTEGER

- \( r \)
  - is a nonnegative integer that represents the number of chosen elements.  
  - Restriction: \( r \leq n \)  
  - Data type: INTEGER

### Details

The mathematical representation of the COMB function is given by the following equation:

\[
\text{COMB}(n, r) = \binom{n}{r} = \frac{n!}{r! \cdot (n-r)!}
\]

In the preceding equation, \( n \geq 0, r \geq 0, \text{ and } n \geq r \).

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the COMB function.

### Example

The following statement illustrates the COMB function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x = \text{comb}(27, 2); )</td>
<td>351</td>
</tr>
</tbody>
</table>
COMPARE Function

Returns the position of the leftmost character by which two strings differ, or returns 0 if there is no difference.

**Category:** Character

**Returned data type:** CHAR, VARCHAR

**Syntax**

```
COMPARE(string-1, string-2[, modifiers])
```

**Arguments**

- **string-1**
  - Specifies a character constant, variable, or expression.
  - **Data type:** CHAR, VARCHAR

- **string-2**
  - Specifies a character constant, variable, or expression.
  - **Data type:** CHAR, VARCHAR

- **modifiers**
  - Specifies a character string that can modify the action of the COMPARE function.
  - You can use one or more of the following characters as a valid modifier:
    - **i or I** ignores the case in string-1 and string-2.
    - **l or L** removes leading blanks in string-1 and string-2 before comparing the values.
    - **n or N** ignores the case of string-1 and string-2. A name literal is a name token that is expressed as a string within quotation marks, followed by the uppercase or lowercase letter n. Name literals enable you to use special characters (including blanks) that are not otherwise allowed in table or variable names. For COMPARE to recognize a string as a name literal, the first character must be a quotation mark.
    - **:** (colon) truncates the longer of string-1 or string-2 to the length of the shorter string, or to one, whichever is greater. If you do not specify this modifier, the shorter string is padded with blanks to the same length as the longer string.
Data type | CHAR, VARCHAR
---|---
Tip | COMPARE ignores blanks that are used as modifiers.

Details

The Basics
The order in which the modifiers appear in the COMPARE function is relevant.

- “LN” first removes leading blanks from each string, and then removes quotation marks from name literals.
- “NL” first removes quotation marks from name literals, and then removes leading blanks from each string.

In the COMPARE function, if string-1 and string-2 do not differ, COMPARE returns a value of zero. If the arguments differ, then the following apply:

- The sign of the result is negative if string-1 precedes string-2 in a sort sequence, and positive if string-1 follows string-2 in a sort sequence.
- The magnitude of the result is equal to the position of the leftmost character at which the strings differ.

DBCS Compatibility
The DBCS equivalent function is KCOMPARE. There are minor differences between the COMPARE and KCOMPARE functions. Both functions accept varying numbers of arguments, but usage of the third argument is not compatible. The following example shows the differences in the syntax:

COMPARE(string-1, string-2[, modifiers])  
KCOMPARE(string-1[, position[, count]], string-2)

For more information, see the “KCOMPARE Function” in SAS Viya National Language Support: Reference Guide.

Examples

Example 1: Understanding the Order of Comparisons When Comparing Two Strings
The following example compares two strings by using the COMPARE function.

data test;
  dc1 char string1 string2 modifiers having informat $char8. format $char8.;
methd init();
  string1='12345678'; string2='12345678'; output;
  string1='123'; string2='abc'; output;
  string1='abc'; string2='abx'; output;
  string1='xyz'; string2='abcdef'; output;
  string1='aBc'; string2='abc'; output;
  string1='aBc'; string2='AbC'; modifiers='i'; output;
  string1='   abc  '; string2='abc'; modifiers=' '; output;
  string1='   abc  '; string2='abc'; modifiers='l'; output;
  string1=' abc    '; string2='   abx  '; modifiers=' '; output;
  string1=' abc    '; string2='   abx  '; modifiers='l'; output;
end;
enddata;
run;

data test_out;
method run();
set test;
result=compare(string1,string2,modifiers);
put 'String 1= ' string1 ' String 2= ' string2 ' Modifier= ' modifiers 
 'Result= ' result;
end;
run;

proc print data=test_out noobs;run;quit;

Output 7.3 Results of Comparing Two Strings By Using the COMPARE Function

<table>
<thead>
<tr>
<th>string1</th>
<th>string2</th>
<th>modifiers</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>12345678</td>
<td>12345678</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>123</td>
<td>abc</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>abc</td>
<td>abx</td>

<tr>
<td>abc</td>
<td>abx</td>
<td>l</td>
<td>-3</td>
</tr>
</tbody>
</table>

Example 2: Truncating Strings Using the COMPARE Function

The following example uses the : (colon) modifier to truncate strings.

data test2;
dcl double pad1 pad2 truncate1 truncate2 blank;
method run();
pad1=compare('abc','abc      ');
pad2=compare('abc','abcdef      ');
truncate1=compare('abc','abcdef',':');
truncate2=compare('abcdef','abc',':');
blank=compare('', 'abc', ':' );
put pad1 pad2 truncate1 truncate2 blank;
end;
enddata;
run;
proc print data=test2 noobs;run;quit;
quit;

Output 7.4  Results from Using the Colon Modifier to Truncate Strings

<table>
<thead>
<tr>
<th>pad1</th>
<th>pad2</th>
<th>truncate1</th>
<th>truncate2</th>
<th>blank</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-4</td>
<td>0</td>
<td>0</td>
<td>-1</td>
</tr>
</tbody>
</table>

COMPBL Function

Removes multiple blanks from a character string.

**Category:** Character  
**Returned data type:** NCHAR

**Syntax**

COMPBL(character-expression)

**Arguments**

`character-expression`  
specifies any valid expression that evaluates to a character string and that specifies the character string to compress.

**Data type** NCHAR

**See**  

**Details**

The COMPBL function removes multiple blanks in a character string by translating each occurrence of two or more consecutive blanks into a single blank.

**Comparisons**

The COMPRESS function removes every occurrence of the specific character from a string. If you specify a blank as the character to remove from the source string, the COMPRESS function is similar to the COMPBL function. However, the COMPRESS function removes all blanks from the source string. The COMPBL function compresses multiple blanks to a single blank and has no effect on a single blank.

**Example**

The following statements illustrate the COMPBL function.
COMPFUZZ Function

Performs a fuzzy comparison of two numeric values.

**Category:** Mathematical  
**Returned data type:** DOUBLE

---

### Syntax

COMPFUZZ(expression-1, expression-2[, fuzz[, scale]])

---

### Arguments

#### expression-1

specifies any valid expression that evaluates to a numeric value.

- **Data type:** DOUBLE
- **See:** “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

#### expression-2

specifies any valid expression that evaluates to a numeric value.

- **Data type:** DOUBLE
- **See:** “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

#### fuzz

is a nonnegative numeric value that specifies the relative threshold for comparisons. Values that are greater than or equal to one are treated as multiples of the machine precision.

- **Default:** 1024
- **Data type:** DOUBLE
scale
specifies the scale factor.

Default:  \( \text{MAX (ABS (expression-1), ABS (expression-2))} \)

Data type:  \text{DOUBLE}

Details
The COMPFUZZ function returns the following values if you specify all four arguments:

-1 if \( \text{expression-1} < \text{expression-2} - \text{threshold} \)

0 if \( \text{ABS(expression-1 - expression-2)} \leq \text{threshold} \)

1 if \( \text{expression-1} > \text{expression-2} + \text{threshold} \)

The following relationships exist:

- \( \text{threshold} = \text{fuzz} \times \text{ABS(scale)} \) if \( 0 \leq \text{fuzz} < 1 \)

- \( \text{threshold} = \text{fuzz} \times \text{ABS(scale)} \times \text{CONSTANT('MACEPS')} \) if \( 1 \leq \text{fuzz} < \frac{1}{\text{CONSTANT('MACEPS')}} \)

COMPFUZZ avoids floating-point underflow or overflow.

Comparisons
The COMPFUZZ function compares two floating-point numbers and returns a value based on the comparison. The ROUND function rounds an argument to a value that is very close to a multiple of a second argument. The result might not be an exact multiple of the second argument.

Example
In floating-point arithmetic, the value of a sum sometimes depends on the order in which the numbers are added. One approximate bound for the floating-point error in the computation of a sum of \( n \) numbers, \( x_1 \) through \( x_n \), is expressed by the following formula:

\[
\text{sum} = n \times \text{machine\_precision} \times \sum (\text{abs}(x_1) + \ldots + \text{abs}(x_n))
\]

To compare sums of \( n \) floating-point numbers with the COMPFUZZ function, you can therefore use \( n \) as the fuzz value and the sum of the absolute values as the scale factor, as shown in the following DATA step:

```
data test (overwrite=yes);
dcl double x1 x2 x3 x4 sum1 sum2 diff compfuzz1 compfuzz2 scale;
method run();
  x1 = -1./3.;
  x2 = 22./7.;
  x3 = -1234567891.;
  x4 = 1234567890.;
  /* Add the numbers in two different orders. */
  sum1 = x1 + x2 + x3 + x4;
  sum2 = x4 + x3 + x2 + x1;
  diff = abs(sum1 - sum2);
  put sum1=;
  put sum2=;
  put diff=;
```
Using only a fuzz value gives the wrong result. The fuzz value is 8 because there are four numbers in each sum, for a total of eight numbers.

```
compfuzz1 = compfuzz(sum1, sum2, 8);
put 'fuzz only (wrong):        ' compfuzz1=
/* Using a fuzz factor and a scale value gives the correct result. */
scale = abs(x1) + abs(x2) + abs(x3) + abs(x4);
compfuzz2 = compfuzz(sum1, sum2, 8, scale);
put 'fuzz and scale (correct): ' compfuzz2=
end;
```

The following lines are written to the SAS log:

```plaintext
sum1=1.80952382087707
sum2=1.8095238095238
diff=1.1353265660929E-8
fuzz only (wrong):         compfuzz1=1
fuzz and scale (correct):  compfuzz2=0
```

**Syntax**

```
COMPOUND(a, f, r, n)
```

**Arguments**

**a**

specifies the initial amount.

Range $a \geq 0$

Data type DOUBLE

**f**

specifies the future amount (at the end of $n$ periods).

Range $f \geq 0$
Data type: DOUBLE

\( r \)

specifies the periodic interest rate expressed as a fraction.

Range: \( r \geq 0 \)

Data type: DOUBLE

\( n \)

specifies the number of compounding periods.

Range: \( n \geq 0 \)

Data type: INTEGER

Details

The COMPOUND function returns the missing argument in the list of four arguments from a compound interest calculation. The arguments are related by the following equation:

\[ f = a(1 + r)^n \]

One missing argument must be provided. A compound interest parameter is then calculated from the remaining three values. No adjustment is made to convert the results to round numbers.

If \( n = 0 \), then

\[ f = a \]

and

\[(1 + r)^n\]

is equal to 1.

Note: If you choose \( r \) as your missing value, then COMPOUND returns an error.

Example

The accumulated value of an investment of $2000 at a nominal annual interest rate of 9\%, compounded monthly after 30 months, can be expressed as follows:

\[
\text{future} = \text{compound}(2000, ., 0.09/12, 30);
\]

The value returned is 2502.544. The second argument has been set to missing, indicating that the future amount is to be calculated. The 9\% nominal annual rate has been converted to a monthly rate of 0.09/12. The rate argument is the fractional (not the percentage) interest rate per compounding period.

COMPRESS Function

Returns a character string with specified characters removed from the original string.

Category: Character
COMPRESS Function

Returned data type: CHAR, NCHAR

Syntax

COMPRESS(character-expression[, character-list-expression])

Arguments

character-expression
specifies any valid expression that evaluates to a character expression and from which specified characters will be removed.

Requirement: Enclose a literal string of characters in single quotation marks.

Data type: CHAR, NCHAR

class-list-expression
specifies a variable or any valid expression that initializes a list of characters.

By default, the characters in this list are removed from character-expression.

Requirement: Enclose a literal string of characters in single quotation marks.

Data type: CHAR, NCHAR

Details

The COMPRESS function allows null arguments. A null argument is treated as a string that has a length of zero.

Based on the number of arguments, the COMPRESS functions works as follows:

<table>
<thead>
<tr>
<th>Number of Arguments</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only the first argument, source</td>
<td>All blanks have been removed. If the argument is completely blank, then the result is a string with a length of zero. If you assign the result to a character variable with a fixed length, then the value of that variable will be padded with blanks to fill its defined length.</td>
</tr>
<tr>
<td>Two arguments, source and chars</td>
<td>All characters that appear in the second argument are removed from the result.</td>
</tr>
</tbody>
</table>

To remove digits and plus or minus signs, you could use the following function call:

COMPRESS(source, "1234567890+-");
Examples

**Example 1: Compressing Blanks**
These examples show how to remove blanks from a character string.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcl char a b;</td>
<td>ABCD</td>
</tr>
<tr>
<td>a='AB C D ';</td>
<td></td>
</tr>
<tr>
<td>b=compress(a);</td>
<td></td>
</tr>
<tr>
<td>dcl char a b;</td>
<td>BCD</td>
</tr>
<tr>
<td>a='AB C D';</td>
<td></td>
</tr>
<tr>
<td>b=compress(a,'A ');</td>
<td></td>
</tr>
</tbody>
</table>

**Example 2: Compressing Vowels**
These examples show how to remove characters from a string.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcl char(32) x;</td>
<td>123-4567-8901 234-5678-9012</td>
</tr>
<tr>
<td>dcl char(32) y;</td>
<td></td>
</tr>
<tr>
<td>x='123-4567-8901 e 234-5678-9012 i';</td>
<td></td>
</tr>
<tr>
<td>y=compress(x,'aeiou');</td>
<td></td>
</tr>
</tbody>
</table>

- “TRIM Function” on page 650

**CONSTANT Function**
Computes machine and mathematical constants.

- **Category:** Mathematical
- **Returned data type:** INTEGER, DOUBLE

**Syntax**

CONSTANT(constant[, parameter])
Arguments

constant

is a character constant, variable, or expression that identifies the constant to be returned. Valid constants are as follows:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E'</td>
<td>The natural base</td>
</tr>
<tr>
<td>'EULER'</td>
<td>Euler constant</td>
</tr>
<tr>
<td>'PI'</td>
<td>Pi</td>
</tr>
<tr>
<td>'EXACTINT',nbytes</td>
<td>Exact integer</td>
</tr>
<tr>
<td>'BIG'</td>
<td>The largest double-precision number</td>
</tr>
<tr>
<td>'LOGBIG',base</td>
<td>The log with respect to base of BIG</td>
</tr>
<tr>
<td>'SQRTBIG'</td>
<td>The square root of BIG</td>
</tr>
<tr>
<td>'SMALL'</td>
<td>The smallest double-precision number</td>
</tr>
<tr>
<td>'LOGSMALL',base</td>
<td>The log with respect to base of SMALL</td>
</tr>
<tr>
<td>'SQRTSMALL'</td>
<td>The square root of SMALL</td>
</tr>
<tr>
<td>'MACEPS'</td>
<td>Machine precision constant</td>
</tr>
<tr>
<td>'LOGMACEPS',base</td>
<td>The log with respect to base of MACEPS</td>
</tr>
<tr>
<td>'SQRTMACEPS'</td>
<td>The square root of MACEPS</td>
</tr>
</tbody>
</table>

parameter

is a numeric parameter that can be used as an optional argument with some of the constants specified in constant. When used, parameter alters the functionality of the CONSTANT function.

Details

Overview

CAUTION:

In some operating environments, the run-time library might have limitations that prevent the use of the full range of floating-point numbers that the hardware provides. In such cases, the CONSTANT function attempts to return values that are compatible with the limitations of the run-time library. For example, if the run-time library cannot compute EXP(LOG(CONSTANT('BIG'))), then CONSTANT('LOGBIG') will not return the same value as LOG(CONSTANT('BIG')), but will return a value such that EXP(CONSTANT('LOGBIG')) can be computed.
The Natural Base
CONSTANT('E')

The natural base is described by the following equation:
\[
\lim_{x \to 0} \left(1 + x\right)^{\frac{1}{x}} \approx 2.718281828459045
\]

Euler Constant
CONSTANT('EULER')

Euler's constant is described by the following equation:
\[
\lim_{n \to \infty} \left\{ \sum_{j=1}^{n} \frac{1}{j} - \log(n) \right\} \approx 0.57721566490153286
\]

Pi
CONSTANT('PI')

Pi is the ratio between the circumference and the diameter of a circle. Many expressions exist for computing this constant. One such expression for the series is described by the following equation:
\[
4 \sum_{j=0}^{\infty} \frac{(-1)^j}{2j+1} \approx 3.14159265358979323846
\]

Exact Integer
CONSTANT('EXACTINT[, nbytes])

Arguments

nbytes

is a numeric value that is the number of bytes.

Range  \[ 2 \leq \text{nbytes} \leq 8 \]

Default  8

The exact integer is the largest integer \( k \) such that all integers less than or equal to \( k \) in absolute value have an exact representation in a SAS numeric variable of length \( \text{nbytes} \). This information can be useful to know before you trim a SAS numeric variable from the default 8 bytes of storage to a lower number of bytes to save storage.

The Largest Double-Precision Number
CONSTANT('BIG')

This case returns the largest double-precision floating-point number (8-bytes) that is representable on your computer.

The Logarithm of BIG
CONSTANT('LOGBIG[, base] )

Arguments

base

is a numeric value that is the base of the logarithm.

Default  the natural base, E
Restriction

The base that you specify must be greater than the value of 1+SQRTMACEPS.

This case returns the logarithm with respect to base of the largest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to exponentiate the given base raised to a power less than or equal to CONSTANT('LOGBIG', base) by using the power operation (**) without causing any overflows.

It is safe to exponentiate any floating-point number less than or equal to CONSTANT('LOGBIG') by using the exponential function, EXP, without causing any overflows.

The Square Root of BIG
CONSTANT('SQRTBIG')

This case returns the square root of the largest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to square any floating-point number less than or equal to CONSTANT('SQRTBIG') without causing any overflows.

The Smallest Double-Precision Number
CONSTANT('SMALL')

This case returns the smallest double-precision floating-point number (8-bytes) that is representable on your computer.

The Logarithm of SMALL
CONSTANT('LOGSMALL', base)

Arguments

base

is a numeric value that is the base of the logarithm.

Default

the natural base, E

Restriction

The base that you specify must be greater than the value of 1+SQRTMACEPS.

This case returns the logarithm with respect to base of the smallest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to exponentiate the given base raised to a power greater than or equal to CONSTANT('LOGSMALL', base) by using the power operation (**) without causing any underflows or 0.

It is safe to exponentiate any floating-point number greater than or equal to CONSTANT('LOGSMALL') by using the exponential function, EXP, without causing any underflows or 0.

The Square Root of SMALL
CONSTANT('SQRTSMALL')

This case returns the square root of the smallest double-precision floating-point number (8-bytes) that is representable on the computer.
It is safe to square any floating-point number greater than or equal to \( \text{CONSTANT('SQRTBIG')} \) without causing any underflows or 0.

**Machine Precision**

\( \text{CONSTANT('MACEPS')} \)

This case returns the smallest double-precision floating-point number (8-bytes) \( \varepsilon = 2^{-j} \) for some integer \( j \), such that \( 1 + \varepsilon > 1 \).

This constant is important in finite precision computations.

**The Logarithm of MACEPS**

\( \text{CONSTANT('LOGMACEPS'[, base])} \)

**Arguments**

- **base**
  - is a numeric value that is the base of the logarithm.

**Default**

- the natural base, \( \text{E} \)

**Restriction**

- The \( base \) that you specify must be greater than the value of \( 1+\text{SQRTMACEPS} \).

This case returns the logarithm with respect to \( base \) of \( \text{CONSTANT('MACEPS')} \).

**The Square Root of MACEPS**

\( \text{CONSTANT('SQRTMACEPS')} \)

This case returns the square root of \( \text{CONSTANT('MACEPS')} \).

**Example**

The following example uses the \( \text{CONSTANT} \) function to return values for various constants.

```plaintext
data test;
/* dcl double a b c d; */
method run();
a=constant('E');
b=constant('EULER');
c=constant('PI');
d=constant('EXACTINT');
e=constant('BIG');
f=constant('LOGBIG');
g=constant('SQRTBIG');
h=constant('SMALL');
i=constant('LOGSMALL');
j=constant('SQRTSMALL');
k=constant('MACEPS');
l=constant('LOGMACEPS');
m=constant('SQRTMACEPS');
put 'a= ' a;
put 'b= ' b;
put 'c= ' c;
put 'd= ' d;
put 'e= ' e;
```

Chapter 7 • DS2 Functions
CONVX Function

Returns the convexity for an enumerated cash flow.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Financial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

CONVX(y, f, c, ..., c)

Arguments

y

specifies the effective per-period yield-to-maturity.

Range  

0 < y < 1

Data type  

DOUBLE

Tip

If you express y as a fraction, the dividend must be written as a decimal value. In DS2, integer division results in a value of zero. Zero is converted to a DOUBLE and is passed as the first argument to the CONVX function. The CONVX function returns missing when a zero is passed as the first parameter.
\( f \) specifies the frequency of cash flows per period.

**Range** \( f > 0 \)

**Data type** DOUBLE

\( c \) specifies a list of cash flows.

**Data type** DOUBLE

### Details

The CONVX function returns the value from the following equation.

\[
C = \sum_{k=1}^{K} \frac{c(k)}{k} \frac{(1+y)^k}{f^2}
\]

The following relationship applies to the preceding equation:

\[
P = \sum_{k=1}^{K} \frac{c(k)}{k} \frac{1}{(1+y)^k}
\]

### Example: Using the CONVX Function

```sas
data test;
  dcl double c;
  method run();
    c=convx(1./20,.1,.33,.44,.55,.49,.50,.22,.4,.8,.01,.36,.2,.4);
    put c;
  end;
enddata;
run;
```

SAS writes the following output to the log:

```
42.377760672321
```

### See Also

#### Functions:
- “CONVXP Function” on page 272

---

**CONVXP Function**

Returns the convexity for a periodic cash flow stream, such as a bond.

**Category:** Financial
Returned data type: DOUBLE

Syntax

CONVXP(A, c, n, K, k₀, y)

Arguments

A
specifies the par value.
Range \( A > 0 \)
Data type DOUBLE

c
specifies the nominal per-period coupon rate, expressed as a decimal.
Range \( 0 \leq c < 1 \)
Data type DOUBLE

n
specifies the number of coupons per period.
Range \( n > 0 \)
Data type INTEGER

K
specifies the number of remaining coupons.
Range \( K > 0 \)
Data type INTEGER

k₀
specifies the time from the present date to the first coupon date, expressed in terms of the number of periods.
Range \( 0 < k₀ \leq \frac{1}{n} \)
Data type DOUBLE

y
specifies the nominal per-period yield-to-maturity.
Range \( y > 0 \)
Data type DOUBLE

Details

The CONVXP function returns the value from the following equation.
\[
C = \frac{1}{n^2} \sum_{k=1}^{K} \left( t_k \left( k + 1 \right) \frac{c(k)}{\left( 1 + \frac{y}{n} \right)^{t_k}} \right)
\]

The following relationships apply to the preceding equation:

\[ t_k = nk_0 + k - 1 \]

\[ c(k) = \frac{\zeta}{n} A \quad \text{for} \quad k = 1, \ldots, K - 1 \]

\[ c(K) = \left( 1 + \frac{\zeta}{n} \right) A \]

The following relationship applies to the preceding equation:

\[ P = \sum_{k=1}^{K} \frac{c(k)}{\left( 1 + \frac{y}{n} \right)^{t_k}} \]

**Example: Computing the Convexity of a Bond**

In the following example, the CONVXP function returns the convexity of a bond that has a face value of 1000, an annual coupon rate of 0.01, 4 coupons per year, and 14 remaining coupons. The time from settlement date to next coupon date is 0.165, and the annual yield-to-maturity is 0.08.

```sas
data test;
  dcl double c;
  method run();
    c=convxp(1000,.01,4,14,.33/2,.08);
    put c;
  end;
enddata;
run;
```

SAS writes the following output to the log:

11.7290019868346

**See Also**

**Functions:**

- “CONVX Function” on page 271

---

**COS Function**

Returns the cosine in radians.

**Category:** Trigonometric
Returned data type: DOUBLE

**Syntax**

\[ \text{COS}(\text{expression}) \]

**Arguments**

*expression* is any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Example**

The following statements illustrate the COS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=cos(0.5);</td>
<td>0.87758256189037</td>
</tr>
<tr>
<td>x=cos(0);</td>
<td>1</td>
</tr>
<tr>
<td>x=cos(3.14159/3);</td>
<td>0.50000076602519</td>
</tr>
</tbody>
</table>

---

**COSH Function**

Returns the hyperbolic cosine in radians.

Category: Trigonometric

Returned data type: DOUBLE

**Syntax**

\[ \text{COSH}(\text{expression}) \]

**Arguments**

*expression* is any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*
Details
The COSH function returns the hyperbolic cosine of the argument, given by the following equation.

\[
\frac{e^{\text{argument}} + e^{-\text{argument}}}{2}
\]

Example
The following statements illustrate the COSH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x = \text{cosh}(0);</td>
<td>1</td>
</tr>
<tr>
<td>x = \text{cosh}(-5.0);</td>
<td>74.2099485247878</td>
</tr>
<tr>
<td>x = \text{cosh}(4.37);</td>
<td>39.5281414700662</td>
</tr>
<tr>
<td>x = \text{cosh}(0.5);</td>
<td>1.12762596520638</td>
</tr>
</tbody>
</table>

COUNT Function
Counts the number of times that a specified substring appears within a character string.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

Syntax
COUNT(string, substring[, modifiers])

Arguments
string
specifies a character constant, variable, or expression in which substrings are to be counted.

- Data type: CHAR, VARCHAR
- Tip: Enclose a literal string of characters in quotation marks.

substring
specifies the character constant, variable, or expression to be counted in string.

- Data type: CHAR, VARCHAR
- Tip: Enclose a literal string of characters in quotation marks.
Modifiers

is a character constant, variable, or expression that specifies one or more modifiers. The following characters, in uppercase or lowercase, can be used as modifiers:

i or I ignores character case during the count. If this modifier is not specified, COUNT counts only character substrings with the same case as the characters in substring.

t or T trims trailing blanks from string and substring.

Data type: CHAR, VARCHAR

Tip

If modifiers is a constant, enclose it in quotation marks. Specify multiple constants in a single set of quotation marks. Modifiers can also be expressed as a variable or an expression.

Details

The Basics

The COUNT function searches string, from left to right, for the number of occurrences of the specified substring, and returns that number of occurrences. If the substring is not found in string, COUNT returns a value of 0.

CAUTION:

If two occurrences of the specified substring overlap in the string, the result is undefined. For example, COUNT('booboboo', 'booboo') might return either a 1 or a 2.

Comparisons

The COUNT function counts substrings of characters in a character string, whereas the COUNTC function counts individual characters in a character string.

Example

The following statements illustrate the COUNT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xyz='This is a thistle? Yes, this is a thistle.';</code></td>
<td>3</td>
</tr>
<tr>
<td><code>howmanythis=count(xyz,'this');</code></td>
<td></td>
</tr>
<tr>
<td><code>put howmanythis;</code></td>
<td></td>
</tr>
<tr>
<td><code>xyz='This is a thistle? Yes, this is a thistle.';</code></td>
<td>6</td>
</tr>
<tr>
<td><code>howmanyis=count(xyz,'is');</code></td>
<td></td>
</tr>
<tr>
<td><code>put howmanyis;</code></td>
<td></td>
</tr>
<tr>
<td>`howmanythis_i=count('This is a thistle? Yes, this is a thistle.'</td>
<td>4</td>
</tr>
<tr>
<td>, 'this', ',1');</td>
<td></td>
</tr>
<tr>
<td><code>put howmanythis_i;</code></td>
<td></td>
</tr>
</tbody>
</table>
### COUNTC Function

Counts the number of characters in a string that appear or do not appear in a list of characters.

**Category:** Character  
**Returned data type:** INTEGER

#### Syntax

```plaintext
COUNTC(string, charlist[, modifiers])
```

#### Arguments

- **string**
  - specifies a character constant, variable, or expression in which characters are counted.
  - **Data type:** CHAR, VARCHAR
  - **Tip:** Enclose a literal string of characters in quotation marks.

- **charlist**
  - specifies a character constant, variable, or expression that initializes a list of characters. COUNTC counts characters in this list, provided that you do not specify the V modifier in the `modifiers` argument. If you specify the V modifier, then all
characters that are not in this list are counted. You can add more characters to the list by using other modifiers.

<table>
<thead>
<tr>
<th>Data type</th>
<th>CHAR, VARCHAR</th>
</tr>
</thead>
</table>

**Tips**

Enclose a literal string of characters in quotation marks.

If there are no characters in the list after processing the modifiers, COUNTC returns 0.

**modifiers**

specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTC function. Blanks are ignored. The following characters, in uppercase or lowercase, can be used as modifiers:

- **blank** is ignored.
- **a or A** adds alphabetic characters to the list of characters.
- **b or B** scans *string* from right to left, instead of from left to right.
- **c or C** adds control characters to the list of characters.
- **d or D** adds digits to the list of characters.
- **f or F** adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.
- **g or G** adds graphic characters to the list of characters.
- **h or H** adds a horizontal tab to the list of characters.
- **i or I** ignores case.
- **l or L** adds lowercase letters to the list of characters.
- **n or N** adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using VALIDVARNAME=V7) to the list of characters.
- **o or O** processes the *charlist* and *modifier* arguments only once, at the first call to this instance of COUNTC. If you change the value of *charlist* or *modifier* in subsequent calls, the change might be ignored by COUNTC.
- **p or P** adds punctuation marks to the list of characters.
- **s or S** adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).
- **t or T** trims trailing blanks from *string* and *charlist*. If you want to remove trailing blanks from only one character argument instead of both (or all) character arguments, use the TRIM function instead of the COUNTC function with the T modifier.
- **u or U** adds uppercase letters to the list of characters.
- **v or V** counts characters that do not appear in the list of characters. If you do not specify this modifier, then COUNTC counts characters that do appear in the list of characters.
- **w or W** adds printable characters to the list of characters.
- **x or X** adds hexadecimal characters to the list of characters.
Data type  CHAR, VARCHAR

Tip  If modifier is a constant, enclose it in quotation marks. Specify multiple constants in a single set of quotation marks.

Details
The COUNTC function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. If there are no characters in the list of characters to be counted, COUNTC returns zero.

Comparisons
The COUNTC function counts individual characters in a character string, whereas the COUNT function counts substrings of characters in a character string.

Example
The following example uses the COUNTC function with and without modifiers to count the number of characters in a string.

data test;
  dcl char(24) string a b_i abc_i abc_iv abc_ivt;
  method run();
  
  string = 'Baboons Eat Bananas';
  a = countc(string, 'a');
  b = countc(string, 'b');
  b_i = countc(string, 'b', 'i');
  abc_i = countc(string, 'abc', 'i');
  abc_i = countc(string, 'abc', 'i');
  abc_iv = countc(string, 'abc', 'iv');
  abc_iv = countc(string, 'abc', 'iv');
  abc_ivt = countc(string, 'abc', 'ivt');
  abc_ivt = countc(string, 'abc', 'ivt');
  end;
enddata;
run;

Output 7.5  Results from Using the COUNTC Function with and without Modifiers

<table>
<thead>
<tr>
<th>string</th>
<th>a</th>
<th>b</th>
<th>b_i</th>
<th>abc_i</th>
<th>abc_iv</th>
<th>abc_ivt</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baboons Eat Bananas</td>
<td>5</td>
<td>1</td>
<td>3</td>
<td>8</td>
<td>22</td>
<td>11</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “ANYALNUM Function” on page 188
- “ANYALPHA Function” on page 190
COUNTW Function

Counts the number of words in a character string.

**Category:** Character

**Returned data type:** INTEGER

**Syntax**

\[
\text{COUNTW}(\text{string[, chars[, modifiers]]})
\]
Arguments

string
specifies a character constant, variable, or expression in which words are counted.

Data type    CHAR, VARCHAR

chars
specifies an optional character constant, variable, or expression that initializes a list of characters. The characters in this list are the delimiters that separate words, provided that you do not use the K modifier in the modifier argument. If you specify the K modifier, then all characters that are not in this list are delimiters. You can add more characters to the list by using other modifiers.

Data type    CHAR, VARCHAR

modifiers
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTW function. The following characters, in uppercase or lowercase, can be used as modifiers:

blank       is ignored.
a or A       adds alphabetic characters to the list of characters.
b or B       counts from right to left instead of from left to right. Right-to-left counting makes a difference only when you use the Q modifier and the string contains unbalanced quotation marks.
c or C       adds control characters to the list of characters.
d or D       adds digits to the list of characters.
f or F       adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.
g or G       adds graphic characters to the list of characters.
h or H       adds a horizontal tab to the list of characters.
i or I       ignores the case of the characters.
k or K       causes all characters that are not in the list of characters to be treated as delimiters. If K is not specified, then all characters that are in the list of characters are treated as delimiters.
l or L       adds lowercase letters to the list of characters.
m or M       specifies that multiple consecutive delimiters, and delimiters at the beginning or end of the string argument, refer to words that have a length of zero. If the M modifier is not specified, then multiple consecutive delimiters are treated as one delimiter, and delimiters at the beginning or end of the string argument are ignored.
n or N       adds digits, an underscore, and English letters (that is, the characters that can appear after the first character in a SAS variable name using VALIDVARNAME=V7) to the list of characters.
o or O       processes the chars and modifier arguments only once, rather than every time the COUNTW function is called. Using the O modifier in the DATA step (excluding WHERE clauses), or in the SQL procedure,
can make COUNTW run faster when you call it in a loop where \textit{chars} and \textit{modifier} arguments do not change.

\begin{itemize}
    \item \texttt{p} or \texttt{P} adds punctuation marks to the list of characters.
    \item \texttt{q} or \texttt{Q} ignores delimiters that are inside substrings that are enclosed in quotation marks. If the value of \textit{string} contains unmatched quotation marks, then scanning from left to right produces different words than scanning from right to left.
    \item \texttt{s} or \texttt{S} adds space characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed) to the list of characters.
    \item \texttt{t} or \texttt{T} trims trailing blanks from the \textit{string} and \textit{chars} arguments.
    \item \texttt{u} or \texttt{U} adds uppercase letters to the list of characters.
    \item \texttt{w} or \texttt{W} adds printable characters to the list of characters.
    \item \texttt{x} or \texttt{X} adds hexadecimal characters to the list of characters.
\end{itemize}

Data type: \texttt{CHAR, VARCHAR}

### Details

**Definition of “Word”**

In the COUNTW function, “word” refers to a substring that has one of the following characteristics:

- is bounded on the left by a delimiter or the beginning of the string
- is bounded on the right by a delimiter or the end of the string
- contains no delimiters, except if you use the \texttt{Q} modifier and the delimiters are within substrings that have quotation marks

Note: The definition of “word” is the same in both the SCAN function and the COUNTW function.

Delimiter refers to any of several characters that you can specify to separate words.

**Using the COUNTW Function in ASCII and EBCDIC Environments**

If you use the COUNTW function with only two arguments, the default delimiters depend on whether your computer uses ASCII or EBCDIC characters.

- If your computer uses ASCII characters, then the default delimiters are as follows:
  \begin{verbatim}
  blank ! $ % & ( ) * + , - ./ ; < ^ |
  \end{verbatim}

  In ASCII environments that do not contain the \texttt{^} character, the SCAN function uses the \texttt{~} character instead.

- If your computer uses EBCDIC characters, then the default delimiters are as follows:
  \begin{verbatim}
  blank ! $ % & ( ) * + , - ./ ; < ¬ | ¢
  \end{verbatim}

**Using Null Arguments**

The COUNTW function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. Numeric arguments cannot be null.
**Using the M Modifier**

If you do not use the M modifier, then a word must contain at least one character. If you use the M modifier, then a word can have a length of zero. In this case, the number of words is one plus the number of delimiters in the string, not counting delimiters inside strings that are enclosed in quotation marks when you use the Q modifier.

**Example**

The following example shows how to use the COUNTW function with the M and P modifiers.

The explanation for the value of `mp` for each string is as follows:

- The period is the delimiter and the m modifier causes the period at the end to refer to a subsequent word with zero length, but never less, a word. So there is one word before the period and one word after the period for a total of two words.
- No delimiters, so there is only one word.
- The p modifier adds punctuation as a delimiter therefore 3 words.
- The p modifier adds punctuation, so `/` is a delimiter. The m modifier causes the leading `/` to refer to a word at beginning with zero length for a total of six words.
- The first `\` is an escape character. The second `\` is a delimiter, so there are six words.

```plaintext
data test;
  dcl char(60) string1 having informat $char60. format $char60.;

  method init();
    string1='The quick brown fox jumps over the lazy dog.'; output;
    string1='        Leading blanks'; output;
    string1='2+2=4'; output;
    string1='/unix/path/names/use/slashes'; output;
    string1='\Windows\Path\Names\Use\Backslashes'; output;
  end;
  enddata;
end;

data test_out;
  dcl double default blanks mp;
  method run();
    set test;
    default = countw(string1);
    blanks = countw(string1, ' ');
    mp = countw(string1, '.', 'mp');
    put 'String= ' string1 'Default= ' default 'Blanks= ' blanks 'MP= ' mp;
  end;
  enddata;
end;
```

284  Chapter 7 • DS2 Functions
CSS Function

Returns the corrected sum of squares.

**Category:** Descriptive Statistics

**Returned data type:** DOUBLE

**Syntax**

```css(expression[, …expression])```

**Arguments**

- `expression`
  - specifies any valid expression that evaluates to a numeric value.

**Requirement**

At least one non-null or nonmissing expression is required.

**Data type**

DOUBLE

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Example**

The following statements illustrate the CSS function:

<table>
<thead>
<tr>
<th>default</th>
<th>blanks</th>
<th>mp</th>
<th>string1</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>9</td>
<td>2</td>
<td>The quick brown fox jumps over the lazy dog.</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>1</td>
<td>Leading blanks</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>3</td>
<td>2+2=4</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>6</td>
<td>/unix/path/names/use slashes</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>6</td>
<td>\Windows\Path\Names\Use\Backslashes</td>
</tr>
</tbody>
</table>
Statements | Results
---|---
\(a = \text{css}(5, 9, 3, 6);\) | 18.75
\(b = \text{css}(5, 8, 9, 6,.);\) | 10
\(c = \text{css}(8, 9, 6,.);\) | 4.66666666666666

CUMIPMT Function

Returns the cumulative interest paid on a loan between the start and end period.

**Category:** Financial

**Returned data type:** DOUBLE

**Syntax**

\[
\text{CUMIPMT}(rate, \text{number-of-periods}, \text{principal-amount}[, \text{start-period}[[, \text{end-period}][[, \text{type}]])
\]

**Arguments**

- **rate**
  - Specifies the interest rate per payment period.
  - Data type: DOUBLE

- **number-of-periods**
  - Specifies the number of payment periods. *Number-of-periods* must be a positive integer value.
  - Data type: INTEGER

- **principal-amount**
  - Specifies the principal amount of the loan. Zero is assumed if a missing value is specified.
  - Data type: DOUBLE

- **start-period**
  - Specifies the start period for the calculation.
  - Data type: INTEGER
end-period
specifies the end period for the calculation.

Data type INTEGER

**type**
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if **type** is omitted or if a missing value is specified.

Data type INTEGER

**Example**

- The cumulative interest that is paid during the second year of a $125,000, 30-year loan with end-of-period monthly payments and a nominal annual interest rate of 9%, is computed as follows:

  ```
  data test;
    dcl double TotalInterest having format dollar10.2;
    method run();
      TotalInterest= CUMIPMT(0.09/12, 360, 125000, 13, 24, 0);
      put 'Total Interest=' TotalInterest;
    end;
  enddata;
  run;
  ```

  This computation returns a value of $11,135.23.

- The interest that is paid on the first period of the same loan is computed in the following way:

  ```
  data test;
    dcl double first_period_interest having format dollar10.2;
    method run();
      first_period_interest= CUMIPMT(0.09/12, 360, 125000, 1, 1, 0);
      put 'Total Interest=' first_period_interest;
    end;
  enddata;
  run;
  ```

  This computation returns a value of $937.50.

**See Also**

**Functions:**

- “CUMPRINC Function” on page 287

---

**CUMPRINC Function**

Returns the cumulative principal paid on a loan between the start and end period.

Category: Financial
Syntax

CUMPRINC(rate, number-of-periods, principal-amount[, start-period][, end-period][, type])

Arguments

rate
specifies the interest rate per payment period.

Data type DOUBLE

number-of-periods
specifies the number of payment periods.

Requirement Number-of-periods must be a positive integer value.

Data type INTEGER

principal-amount
specifies the principal amount of the loan.

Data type DOUBLE

Note Zero is assumed if a missing or null value is specified.

start-period
specifies the start period for the calculation.

Data type INTEGER

end-period
specifies the end period for the calculation.

Data type INTEGER

type
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if type is omitted or if a missing value is specified.

Data type INTEGER

Example

• The cumulative principal that is paid during the second year of a $125,000, 30-year loan with end-of-period monthly payments and a nominal annual interest rate of 9%, is computed as follows:

data test;
  dcl double PrincipalYear2 having format dollar10.2;
  method run();
  PrincipalYear2=CUMPRINC(0.09/12, 360, 125000, 12, 24, 0);
The principal that is paid on the second year of the same loan with beginning-of-period payments is computed as follows:

```sas
data test;
  dcl double PrincipalYear2b having format dollar10.2;
  method run();
    PrincipalYear2b = CUMPRINC(0.09/12, 360, 125000, 12, 24, 1);
    put 'Principal Year 2 BOP=' PrincipalYear2b;
  end;
enddata;
run;
```

This computation returns a value of $1000.73.

Functions:

- “CUMIPMT Function” on page 286

---

**CV Function**

Returns the coefficient of variation.

- **Category:** Descriptive Statistics
- **Returned data type:** DOUBLE

**Syntax**

```
CV(expression-1, expression-2 [, ...expression-n])
```

**Arguments**

- **expression** specifies any valid expression that evaluates to a numeric value.

  - **Requirement** At least two arguments are required.
  - **Data type** DOUBLE

  See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Example**

The following statements illustrate the CV function:
DATDIF Function

Returns the number of days between two dates after computing the difference between the dates according to specified day count conventions.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

Syntax

\[ \text{DATDIF}(sdate, edate, basis) \]

Arguments

\textit{sdate}

specifies a SAS date value that identifies the starting date.

Data type \hspace{1cm} \text{DATE}

Tip \hspace{1cm} If \textit{sdate} falls at the end of a month, then SAS treats the date as if it were the last day of a 30-day month.

\textit{edate}

specifies a SAS date value that identifies the ending date.

Data type \hspace{1cm} \text{DATE}

Tip \hspace{1cm} If \textit{edate} falls at the end of a month, then SAS treats the date as if it were the last day of a 30-day month.

\textit{basis}

specifies a character string that represents the day count basis. The following values for \textit{basis} are valid:

'30/360'

specifies a 30-day month and a 360-day year, regardless of the actual number of calendar days in a month or year.

A security that pays interest on the last day of a month will either always make its interest payments on the last day of the month, or it will always make its payments on the numerically same day of a month, unless that day is not a valid day of the month, such as February 30. For more information, see "Method of Calculation for Day Count Basis (30/360)" in

\[
\begin{array}{|c|c|}
\hline
\text{Statements} & \text{Results} \\
\hline
x1=CV(5,9,3,6); & 43.4782608695652 \\
\hline
x2=CV(5,8,9,6,..); & 26.082026547865 \\
\hline
x3=CV(8,9,6,..); & 19.9242421519819 \\
\hline
\end{array}
\]
Alias '360'

'ACT/ACT'
uses the actual number of days between dates. Each month is considered to have the actual number of calendar days in that month, and each year is considered to have the actual number of calendar days in that year.

Alias 'Actual'

'ACT/360'
uses the actual number of calendar days in a particular month, and 360 days as the number of days in a year, regardless of the actual number of days in a year.

Tip ACT/360 is used for short-term securities.

'ACT/365'
uses the actual number of calendar days in a particular month, and 365 days as the number of days in a year, regardless of the actual number of days in a year.

Tip ACT/365 is used for short-term securities.

Data type CHAR, VARCHAR

Details

The Basics
The DATDIF function has a specific meaning in the securities industry, and the method of calculation is not the same as the actual day count method. Calculations can use months and years that contain the actual number of days. Calculations can also be based on a 30-day month or a 360-day year. For more information about standard securities calculation methods, see the References section at the bottom of this function.

Note: When counting the number of days in a month, DATDIF always includes the starting date and excludes the ending date.

Method of Calculation for Day Count Basis (30/360)
To calculate the number of days between two dates, use the following formula:

\[ \text{Number of days} = [(Y2 - Y1) \times 360] + [(M2 - M1) \times 30] + (D2 - D1) \]

Arguments

Y2
specifies the year of the later date.

Y1
specifies the year of the earlier date.

M2
specifies the month of the later date.

M1
specifies the month of the earlier date.

D2
specifies the day of the later date.
D1 specifies the day of the earlier date.

Because all months can contain only 30 days, you must adjust for the months that do not contain 30 days. Do this before you calculate the number of days between the two dates.

The following rules apply:

- If the security follows the End-of-Month rule, and D2 is the last day of February (28 days in a non-leap year, 29 days in a leap year), and D1 is the last day of February, then change D2 to 30.
- If the security follows the End-of-Month rule, and D1 is the last day of February, then change D1 to 30.
- If the value of D2 is 31 and the value of D1 is 30 or 31, then change D2 to 30.
- If the value of D1 is 31, then change D1 to 30.

Example

In the following example, DATDIF returns the actual number of days between two dates, as well as the number of days based on a 30-day month and a 360-day year.

```sas
data test (overwrite=yes);
  method run();
    dcl date sdate edate;
    dcl double actual days360;
    sdate= date'1978-10-16';
    edate= date'1996-02-16';
    sassdate=to_double(sdate);
    sasedate=to_double(edate);
    actual=datdif(sassdate, sasedate, 'act/act');
    days360=datdif(sassdate, sasedate, '30/360');
    put 'Actual= ' actual;
    put 'Days 360= ' days360;
  end;
enddata;
run;
```

The following lines are written to the SAS log.

```
Actual= 6332
Days 360= 6240
```

References

DATE Function

Returns the current date as a SAS date value.

**Category:** Date and Time  
**Alias:** TODAY  
**Returned data type:** DOUBLE

**Syntax**

```
DATE()
```

**Without Arguments**
The DATE function has no arguments.

**Details**
The SAS date value returned is the number of days from January 1, 1960 to the current date.

For more information about how DS2 handles dates, see “Dates and Times in DS2” in *SAS Viya: DS2 Programmer’s Guide*.

**Example**
The following statement illustrates the DATE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=DATE();</td>
<td>18773</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- “TODAY Function” on page 642

DATEJUL Function

Converts a Julian date to a SAS date value.

**Category:** Date and Time  
**Returned data type:** DOUBLE
Syntax

**DATEJUL(julian-date)**

**Arguments**

`julian-date` specifies any valid expression that evaluates to a numeric value and that represents a Julian date. A Julian date is a date in the form `yyddd` or `yyyyddd`, where `yy` or `yyyy` is a two-digit or four-digit integer that represents the year and `ddd` is the number of the day of the year. The value of `ddd` must be between 1 and 365 (or 366 for a leap year).

Data type: **DOUBLE**

**Details**

A SAS date value is the number of days from January 1, 1960 to a specified date. The DATEJUL function returns the number of days from January 1, 1960 to the Julian date specified in `julian-date`.

For more information about how dates are handled in DS2, see “Dates and Times in DS2” in *SAS Viya: DS2 Programmer’s Guide*.

**Example**

The following statements illustrate the DATEJUL function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x=datejul(11365);</code></td>
<td>18992</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- “JULDATE Function” on page 415

---

**DATEPART Function**

Extracts the date from a SAS datetime value.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

**DATEPART(datetime)**
Arguments

datetime

specifies any valid expression that represents a SAS datetime value.

Data type: DOUBLE

Details

A SAS datetime value is the number of seconds between January 1, 1960 and the hour, minute, and seconds within a specific date. The DATEPART function determines the date portion of the SAS datetime value and returns the date as a SAS date value, which is the number of days from January 1, 1960.

Example

The following statement illustrates the DATEPART function where the variable dtvalue, a SAS datetime value, has a value of 1652165417:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dp=put(datepart(dtvalue),date9.);</td>
<td>09MAY2012</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “DATETIME Function” on page 295
- “TIMEPART Function” on page 632

DATETIME Function

Returns the current date and time of day as a SAS datetime value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

DATETIME()

Without Arguments

The DATETIME function does not take any arguments.
Details

The SAS datetime value returned is the number of seconds from January 1, 1960 to the current date and time.

For more information about DS2 date and time values, see “Dates and Times in DS2” in *SAS Viya: DS2 Programmer’s Guide*.

Example

The following statement illustrates the DATETIME function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt=datetime();</td>
<td>1622021468</td>
</tr>
</tbody>
</table>

---

**DAY Function**

Returns the day of the month from a SAS date value.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

```plaintext
DAY(date)
```

**Arguments**

- `date`
  - specifies any valid expression that represents a SAS date value.
  
  **Data type:** DOUBLE

  **See**
  - “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The DAY function produces an integer from 1 to 31 that represents the day of the month.

A SAS date value is the number of days from January 1, 1960 to a specific date.
Example

The following statement illustrates the DAY function where dayvalue, the SAS date value, has a value of 17531, which is December 31, 2007:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt=day(dayvalue);</td>
<td>dt=31</td>
</tr>
</tbody>
</table>

• “MONTH Function” on page 464
• “YEAR Function” on page 674

DEQUOTE Function

Removes matching single quotation marks from a character string that begins with a single quotation mark, and deletes all characters to the right of the closing quotation mark.

Category: Character

Returned data type: NCHAR

Syntax

DEQUOTE(expression)

Arguments

expression

specifies any valid expression that evaluates to a character string.

Data type NCHAR

See

Details

The value that is returned by the DEQUOTE function depends on the first character or the first two characters in expression:

• If the first character of expression is not a quotation mark, DEQUOTE returns a syntax error.

• If the first character of expression is a single quotation mark, the DEQUOTE function removes that single quotation mark from the result. DEQUOTE then scans expression from left to right, looking for more single quotation marks or double quotation marks.
All paired single quotation marks are reduced to a single quotation mark.

All paired double quotation marks are retained.

If a double quotation mark is the second character, DEQUOTE removes the double quotation mark from the result. DEQUOTE then scans expression from left to right. If a matching double quotation mark is found, the text between the double quotation marks is returned. Any text to the right of the closing double quotation mark, to the end of expression is removed from the result.

The first non-paired single quotation mark in expression is the closing single quotation mark and is removed.

If a close parentheses follows the close single quotation mark, the function returns the dequoted string. If characters exist to the right of the close single quotation mark, the function results in a syntax error and the error is printed in the SAS log.

- If expression is enclosed in double quotation marks, the DEQUOTE function returns a null or missing value.

Note: If expression is a constant enclosed in quotation marks, those quotation marks are not part of the value of expression. Therefore, you do not need to use DEQUOTE to remove the quotation marks that denote a constant.

Example

The following statements illustrate the DEQUOTE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>string=dequote(No quotation marks);</td>
<td>ERROR: [HY000]Parse error. Expecting '}' in statement x:</td>
</tr>
<tr>
<td></td>
<td>char(x) string; string=dequote(no =&gt;quotation. (0x817ff05c)</td>
</tr>
<tr>
<td>string=dequote(No 'leading' quotation marks);</td>
<td>ERROR: [HY000]Parse error. Expecting '}' in statement x:</td>
</tr>
<tr>
<td></td>
<td>char(yyy) string; string=dequote(No =&gt;'leading'. (0x817ff05c)</td>
</tr>
<tr>
<td>string=dequote('Single matched quotation marks are removed');</td>
<td>Single matched quotation marks are removed</td>
</tr>
<tr>
<td>string=dequote(&quot;Matched double quotation marks result in a null or missing value&quot;);</td>
<td>.</td>
</tr>
<tr>
<td>string=dequote('Paired ''single'' quotation marks are reduced');</td>
<td>Paired 'single' quotation marks are reduced</td>
</tr>
<tr>
<td>string=dequote(&quot;Double quotation marks&quot; within &quot;single quotation marks&quot;, with space before open quotation mark&quot;);</td>
<td>&quot;Double quotation marks&quot; within &quot;single quotation marks&quot;, with space before open quotation mark'</td>
</tr>
</tbody>
</table>
### Statements

<table>
<thead>
<tr>
<th>String</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>string=dequote('&quot;Double quotation marks within single quotation marks, without space before open quotation mark');</code></td>
<td>Double quotation marks within single quotation marks, without space before open quotation mark</td>
</tr>
<tr>
<td><code>string=dequote('&quot;Text after closing double quotation mark&quot; is removed')</code></td>
<td>Text after closing double quotation mark</td>
</tr>
<tr>
<td><code>string=dequote('No matching quotation mark');</code></td>
<td>Statement execution does not complete. Submit the following characters to complete the execution: '};'</td>
</tr>
<tr>
<td><code>string=dequote('Identifiers after close quotation mark' results in a syntax error);</code></td>
<td>ERROR: [HY000]Parse error. Expecting ')' in statement x: string=dequote('Identifiers after close quotation mark' ==&gt;results. (0x817ff05c)</td>
</tr>
</tbody>
</table>

### DEVIANCE Function

**Returns the deviance based on a probability distribution.**

**Category:** Mathematical  
**Returned data type:** DOUBLE

### Syntax

```
DEVIANCE(distribution, variable, shape-parameter(s)[, ε])
```

### Arguments

**distribution**

is a character constant, variable, or expression that identifies the distribution. Valid distributions are listed in the following table:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli (p. 300)</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Binomial (p. 300)</td>
<td>'BINOMIAL'</td>
</tr>
<tr>
<td>Gamma (p. 301)</td>
<td>'GAMMA'</td>
</tr>
<tr>
<td>Inverse Gauss (Wald) (p. 301)</td>
<td>'IGAUSS'</td>
</tr>
<tr>
<td>Normal (p. 302)</td>
<td>'NORMAL'</td>
</tr>
<tr>
<td>Distribution</td>
<td>Argument</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>Poisson (p. 302)</td>
<td>'POISSON'</td>
</tr>
</tbody>
</table>

**variable**
- is a numeric constant, variable, or expression.

**shape-parameter(s)**
- are one or more distribution-specific numeric parameters that characterize the shape of the distribution.

**ε**
- is an optional numeric small value used for all of the distributions, except for the normal distribution.

**Details**

**The Bernoulli Distribution**

\[
\text{DEVIANCE}('BERNOULLI', \text{variable}, p[, \epsilon])
\]

**Arguments**

**variable**
- is a binary numeric random variable that has the value of 1 for success and 0 for failure.

**p**
- is a numeric probability of success with \( \epsilon \leq p \leq 1 - \epsilon \).

**ε**
- is an optional positive numeric value that is used to bound \( p \). Any value of \( p \) in the interval \( 0 \leq p \leq \epsilon \) is replaced by \( \epsilon \). Any value of \( p \) in the interval \( 1 - \epsilon \leq p \leq 1 \) is replaced by \( 1 - \epsilon \).

The \text{DEVIANCE} function returns the deviance from a Bernoulli distribution with a probability of success \( p \), where success is defined as a random variable value of 1. The equation follows:

\[
\text{DEVIANCE}(\text{BERT}, \text{variable}, p, \epsilon) = \begin{cases} 
-2\log(1 - p) & x = 0 \\
-2\log(p) & x = 1 \\
\cdot & \text{otherwise}
\end{cases}
\]

**The Binomial Distribution**

\[
\text{DEVIANCE}('BINO', \text{variable}, \mu, n[, \epsilon])
\]

**Arguments**

**variable**
- is a numeric random variable that contains the number of successes.

**Range** \( 0 \leq \text{variable} \leq 1 \)

**μ**
- is a numeric mean parameter.

**Range** \( n\epsilon \leq \mu \leq n(1 - \epsilon) \)
\( n \)

is an integer number of Bernoulli trials parameter

Range \( n \geq 0 \)

\( \varepsilon \)

is an optional positive numeric value that is used to bound \( \mu \). Any value of \( \mu \) in the interval \( 0 \leq \mu \leq ne \) is replaced by \( ne \). Any value of \( \mu \) in the interval \( n(1 - \varepsilon) \leq \mu \leq n \) is replaced by \( n(1 - \varepsilon) \).

The DEVIANCE function returns the deviance from a binomial distribution, with a probability of success \( p \), and a number of independent Bernoulli trials \( n \). The following equation describes the DEVIANCE function for the Binomial distribution, where \( x \) is the random variable:

\[
DEVIANCE('BINO', x, \mu, n) = \begin{cases} 
2\left(x \log\left(\frac{x}{\mu}\right) + (n-x) \log\left(\frac{n-x}{n-\mu}\right)\right) & 0 \leq x \leq n \\
2\left(-\log\left(\frac{x}{\mu}\right) + x - \mu\right) & x > n 
\end{cases}
\]

The Gamma Distribution

DEVIANCE('GAMMA', variable, \( \mu \), \( \varepsilon \))

Arguments

\( variable \)

is a numeric random variable.

Range \( variable \geq \varepsilon \)

\( \mu \)

is a numeric mean parameter.

Range \( \mu \geq \varepsilon \)

\( \varepsilon \)

is an optional positive numeric value that is used to bound \( variable \) and \( \mu \). Any value of \( variable \) in the interval \( 0 \leq variable \leq \varepsilon \) is replaced by \( \varepsilon \). Any value of \( \mu \) in the interval \( 0 \leq \mu \leq \varepsilon \) is replaced by \( \varepsilon \).

The DEVIANCE function returns the deviance from a gamma distribution with a mean parameter \( \mu \). The following equation describes the DEVIANCE function for the gamma distribution, where \( x \) is the random variable:

\[
DEVIANCE('GAMMA', x, \mu) = \begin{cases} 
2\left(-\log\left(\frac{x}{\mu}\right) + \frac{x}{\mu}\right) & x \leq \varepsilon, \mu \geq \varepsilon 
\end{cases}
\]

The Inverse Gauss (Wald) Distribution

DEVIANCE('IGAUSS' | 'WALD', variable, \( \mu \), \( \varepsilon \))

Arguments

\( variable \)

is a numeric random variable.

Range \( variable \geq \varepsilon \)

\( \mu \)

is a numeric mean parameter.
Range $\mu \geq \varepsilon$

$\varepsilon$

is an optional positive numeric value that is used to bound variable and $\mu$. Any value of variable in the interval $0 \leq \text{variable} \leq \varepsilon$ is replaced by $\varepsilon$. Any value of $\mu$ in the interval $0 \leq \mu \leq \varepsilon$ is replaced by $\varepsilon$.

The DEVIANCE function returns the deviance from an inverse Gaussian distribution with a mean parameter $\mu$. The following equation describes the DEVIANCE function for the inverse Gaussian distribution, where $x$ is the random variable:

$$
\text{DEVIANCE('IGAUSS', x, \mu) = }
\begin{cases}
  x < 0 & \frac{(x - \mu)^2}{\mu^2 x} \\
  x \geq \varepsilon, \mu \geq \varepsilon & 0
\end{cases}
$$

The Normal Distribution

$\text{DEVIANCE('NORMAL' | 'GAUSSIAN', variable, \mu)}$

Arguments

variable

is a numeric random variable.

$\mu$

is a numeric mean parameter.

The DEVIANCE function returns the deviance from a normal distribution with a mean parameter $\mu$. The following equation describes the DEVIANCE function for the normal distribution, where $x$ is the random variable:

$$
\text{DEVIANCE('NORMAL', x, \mu) = (x - \mu)^2}
$$

The Poisson Distribution

$\text{DEVIANCE('POISSON', variable, \mu[, \varepsilon])}$

Arguments

variable

is a numeric random variable.

Range $\text{variable} \geq 0$

$\mu$

is a numeric mean parameter.

Range $\mu \geq \varepsilon$

$\varepsilon$

is an optional positive numeric value that is used to bound $\mu$. Any value of $\mu$ in the interval $0 \leq \mu \leq \varepsilon$ is replaced by $\varepsilon$.

The DEVIANCE function returns the deviance from a Poisson distribution with a mean parameter $\mu$. The following equation describes the DEVIANCE function for the Poisson distribution, where $x$ is the random variable:

$$
\text{DEVIANCE('POISSON', x, \mu) = }
\begin{cases}
  x < 0 & x \log x - (x - \mu) \\
  x \geq 0, \mu \geq \varepsilon & 2(x \log x - (x - \mu))
\end{cases}
$$
DHMS Function

Returns a SAS datetime value from date, hour, minute, and second values.

Category: Date and Time
Returned data type: DOUBLE

Syntax

\[ \text{DHMS}(\text{date}, \text{hour}, \text{minute}, \text{second}) \]

Arguments

\textit{date}

specifies any valid expression that represents a SAS date value.

Data type: DOUBLE

\textit{hour}

specifies a numeric expression that represents an integer from 1 through 12.

Data type: DOUBLE

\textit{minute}

specifies a numeric expression that represents an integer from 1 through 59.

Data type: DOUBLE

\textit{second}

specifies a numeric expression that represents an integer from 1 through 59.

Data type: DOUBLE

Details

The DHMS function returns a numeric value that represents a SAS datetime value. This numeric value can be either positive or negative.

Examples

\textbf{Example 1: Using the DHMS Function}

The following statements illustrate the DHMS function:
Example 2: Combining Date and Time Values
The following statements illustrate how to combine a SAS date value with a SAS time value into a SAS datetime value, using the current day and time.

<table>
<thead>
<tr>
<th>Statements</th>

<td>1622021987.6</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “HMS Function” on page 355

DIGAMMA Function
Returns the value of the digamma function.

Category: Mathematical
Returned data type: DOUBLE

Syntax
DIGAMMA(expression)

Arguments
expression
specifies any valid expression that evaluates to a numeric value.

Restriction
Zero and negative integers are not valid.

Data type
DOUBLE

See
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

Details
The DIGAMMA function returns the ratio that is given by the following equation.
\[ \Psi(x) = \Gamma'(x)/\Gamma(x) \]
\( \Gamma(.) \) and \( \Gamma'(.) \) denote the Gamma function and its derivative, respectively. For \( \text{expression} > 0 \), the DIGAMMA function is the derivative of the LGAMMA function.

**Example**

The following statement illustrates the DIGAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x = \text{digamma}(1.0); )</td>
<td>-0.57721566490153</td>
</tr>
</tbody>
</table>

---

**DIM Function**

Returns the number of elements in an array.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Array</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

**Syntax**

\[
\text{DIM}(\text{array-name}[\text{, bound-n}])
\]

**Arguments**

- **array-name**
  - specifies the name of a temporary or a variable array.

- **bound-n**
  - is a numeric constant, variable, or expression that specifies the dimension, in a multidimensional array, for which you want to know the number of elements. If no \( \text{bound-n} \) value is specified, the DIM function returns the number of elements in the first dimension of the array.

  \( \text{Bound-n} \) evaluates to an integral value.

  Data type: INTEGER

**Details**

The DIM function returns the number of elements in a one-dimensional array, or the number of elements in a specified dimension of a multidimensional array.

If the DIM function is called with a \( \text{bound-n} \) dimension value that is outside the dimension of the array, then a run-time error occurs and the function returns a NULL integer value.

**Comparisons**

- DIM returns the number of elements in an array dimension.
- HBOUND returns the value of the upper bound of an array dimension.
• LBOUND returns the value of the lower bound of an array dimension.
• NDIMS returns the number of dimensions in an array.

Example
The following example shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions:

```sas
data _null_;  
method init();  
declare char(15) a1[4];  
declare double   a2[2,3,4] sum;  
   
a1 := ('red' 'yellow' 'green' 'blue');  
a2 := (24*2.0);  
   
do i = 1 to dim(a1);  
   put a1[i];  
end;  
   
numelems = 0;  
do i = 1 to ndims(a2);  
   numelems = numelems + dim(a2, i);  
end;  
   
sum = 0;  
do i = lbound(a2, 1) to hbound(a2, 1);  
do j = lbound(a2, 2) to hbound(a2, 2);  
do k = lbound(a2, 3) to hbound(a2, 3);  
   sum = sum + a2[i,j,k];  
end;  
end;  
   
put sum=;  
end;  
enndata;  
run;  
```

SAS writes the following output to the log:

```
red  
yellow  
green  
blue  
sum=48  
```

Functions:
• “HBOUND Function” on page 353
• “LBOUND Function” on page 429
DIVIDE Function

Returns the result of a division that handles special missing values for ODS output.

Category: Arithmetic
Returned data type: DOUBLE

Syntax

\[
\text{DIVIDE}(x, y)
\]

Arguments

\(x\)

specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

\(y\)

specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

Details

The DIVIDE function divides two numbers and returns a result that is compatible with ODS conventions. The function handles special missing values for ODS output. The following list shows how certain special missing values are interpreted in ODS:

- .I as infinity
- .M as minus infinity
- _ as a blank

The following table shows the values that are returned by the DIVIDE function, based on the values of \(x\) and \(y\).
Figure 7.1 Values That Are Returned by the DIVIDE Function

<table>
<thead>
<tr>
<th>x</th>
<th>positive</th>
<th>zero</th>
<th>negative</th>

<td>y</td>
<td>y</td>
<td>y</td>
<td>__</td>
<td>x</td>
</tr>
</tbody>
</table>

Note: The DIVIDE function never writes a note to the SAS log regarding missing values, division by zero, or overflow.

Example

The following example shows the results of using the DIVIDE function.

```sas
data test (overwrite=yes);
  dcl double a b c d;
  method run();
    a=divide(1, 0);
    put a='(infinity)';
    b=divide(2, .I);
    put b=;
    c=divide(.I, -1);
    put c='(minus infinity)';
    d=divide(constant('big'), constant('small'));
    put d='(infinity because of overflow)';
  end;
enddata;
run;
```

The following lines are written to the SAS log:

```
a=I (infinity)
b=0
c=M (minus infinity)
d=I (infinity because of overflow)
```

DUR Function

Returns the modified duration for an enumerated cash flow.

- **Category:** Financial
- **Returned data type:** DOUBLE
Syntax

\textbf{DUR}(y, f, c \ldots, c)

\textbf{Arguments}

\textit{y}

specifies the effective per-period yield-to-maturity, expressed as a fraction.

Range \quad y > 0

Data type \quad \text{DOUBLE}

\textit{f}

specifies the frequency of cash flows per period.

Range \quad f > 0

Data type \quad \text{DOUBLE}

\textit{c}

specifies a list of cash flows.

Data type \quad \text{DOUBLE}

\textbf{Details}

The DUR function returns the value from the following equation.

\[ C = \sum_{k=1}^{K} \left( \frac{c^{(k)} k}{(1 + y)^{k} P} \right) \]

The following relationship applies to the preceding equation:

\[ P = \sum_{k=1}^{K} \frac{c^{(k)} k}{(1 + y)^{k}} \]

\textbf{Example: Using the DUR Function}

\begin{verbatim}
data test;
dcl double d;
method run();
d=dur(.05,1,.33,.44,.49,.55,.50,.22,.4,.8,.01,.36,.2,.4);
put d;
end;
enddata;
run;
\end{verbatim}

SAS writes the following output to the log:

5.28402498798216
See Also

Functions:
- “DURP Function” on page 310

DURP Function

Returns the modified duration for a periodic cash flow stream, such as a bond.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Financial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

\[ \text{DURP}(A, c, n, K, k_0, y) \]

Arguments

\( A \)

specifies the par value.

- Range: \( A > 0 \)
- Data type: DOUBLE

\( c \)

specifies the nominal per-period coupon rate, expressed as a fraction.

- Range: \( 0 \leq c < 1 \)
- Data type: DOUBLE

\( n \)

specifies the number of coupons per period.

- Range: \( n > 0 \) and an integer
- Data type: DOUBLE

\( K \)

specifies the number of remaining coupons.

- Range: \( K > 0 \) and an integer
- Data type: DOUBLE

\( k_0 \)

specifies the time from the present date to the first coupon date, expressed in terms of the number of periods.

- Range: \( 0 < k_0 \leq 1/n \)
Data type DOUBLE

\( y \)

specifies the nominal per-period yield-to-maturity, expressed as a fraction.

Range \( y > 0 \)

Data type DOUBLE

Details

The DURP function returns the value from the following equation.

\[
D = \frac{\frac{1}{n} \sum_{k=1}^{K} t_k c(k)}{P} \frac{n}{1 + \frac{y}{n} t_k}
\]

The following relationships apply to the preceding equation:

- \( t_k = nk_0 + k - 1 \)
- \( c(k) = \frac{c}{n}A \) for \( k = 1, \ldots, K - 1 \)
- \( c(K) = \left(1 + \frac{c}{n}\right)A \)

The following relationship applies to the preceding equation:

\[
P = \frac{\sum_{k=1}^{K} c(k)}{\sum_{k=1}^{K} \frac{1}{(1 + \frac{y}{n})}}
\]

Example: Using the DURP Function

```sas
data test;
  dcl double d;
  method run();
    d = durp(1000, 1/100, 4, 14, 0.33/2, 0.10);
    put d;
  end;
enddata;
run;
```

SAS writes the following output to the log:

3.33170731707317

See Also

Functions:
- “DUR Function” on page 308
EFFRATE Function

Returns the effective annual interest rate.

**Category:** Financial  
**Returned data type:** DOUBLE

**Syntax**

```
EFFRATE(compounding-interval, rate)
```

**Arguments**

- **compounding-interval**
  - is a SAS interval. This value represents how often rate compounds.
  - Data type: CHAR

- **rate**
  - is numeric. Rate is a nominal annual interest rate (expressed as a percentage) that is compounded at each compounding interval.
  - Data type: DOUBLE

**Details**

The EFFRATE function returns the effective annual interest rate. The function computes the effective annual interest rate that corresponds to a nominal annual interest rate.

The following details apply to the EFFRATE function:

- The values for rates must be at least –99.
- In considering a nominal interest rate and a compounding interval, if `compounding-interval` is 'CONTINUOUS', then the value that is returned by EFFRATE equals $e^{rate/100} - 1$.
  
  If `compounding-interval` is not 'CONTINUOUS', and $m$ compounding intervals occur in a year, the value that is returned by EFFRATE equals $(1+[rate/100/m])^m - 1$.

- The following values are valid for `compounding-interval`:
  - 'CONTINUOUS'
  - 'DAY'
  - 'SEMIMONTH'
  - 'MONTH'
  - 'QUARTER'
  - 'SEMIYEAR'
  - 'YEAR'

  - If the interval is 'DAY', then $m=365$. 

Example

The following examples show how the effective rate is calculated:

- If a nominal rate is 10%, then the corresponding effective rate when interest is compounded monthly can be expressed as
  \[ \text{effective-rate}_1 = \text{EFFRATE('MONTH', 10)}; \]
- If a nominal rate is 10%, then the corresponding effective rate when interest is compounded quarterly can be expressed as
  \[ \text{effective-rate}_2 = \text{EFFRATE('QUARTER', 10)}; \]

**ERF Function**

Returns the value of the (normal) error function.

<table>
<thead>
<tr>
<th>Categories:</th>
<th>Mathematical</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Arithmetic</td>
</tr>
</tbody>
</table>

| Returned data type: | DOUBLE |

**Syntax**

\[ \text{ERF(expression)} \]

**Arguments**

*expression*

specifies any valid expression that evaluates to a numeric value.

| Data type | DOUBLE |

**Details**

The ERF function returns the integral, given by the following:

\[ \text{ERF}(x) = \frac{2}{\sqrt{\pi}} \int_{0}^{x} e^{-z^2} \, dz \]

You can use the ERF function to find the probability (p) that a normally distributed random variable with mean 0 and standard deviation will take on a value less than X. For example, the quantity that is given by the following statement is equivalent to PROBNORM(X):

\[ p = .5 + .5 \cdot \text{erf}(x / \sqrt{2}); \]

**Example**

The following statements illustrate the ERF function:
### ERFC Function

Returns the value of the complementary (normal) error function.

**Categories:** Mathematical, Arithmetic

**Returned data type:** DOUBLE

### Syntax

```
ERFC(expression)
```

### Arguments

*expression*

specifies any valid expression that evaluates to a numeric value.

**Data type** DOUBLE

See

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

### Details

The ERFC function returns the complement to the ERF function (that is, \(1 - \text{ERF}(\text{argument})\)).

### Example

The following statements illustrate the ERFC function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x=\text{erfc}(1.0));</td>
<td>0.157299</td>
</tr>
<tr>
<td>(x=\text{erfc}(-1.0));</td>
<td>1.842701</td>
</tr>
</tbody>
</table>

---

**Statement** | **Result**
---|---
\(y=\text{erf}(1.0)\); & 0.842701  
\(y=\text{erf}(-1.0)\); & -0.8427

Functions:

• “ERF Function” on page 313

EXP Function

Returns the value of the e constant raised to a specified power.

**Category:** Mathematical

**Returned data type:** DOUBLE

**Syntax**

\[ \text{EXP(expression)} \]

**Arguments**

expression

specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

**Details**

The EXP function raises the constant \( e \), which is approximately given by 2.71828, to the power that is supplied by the argument. The result is limited by the maximum value of a double decimal value on the computer.

**Example**

The following statements illustrate the EXP function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=exp(1.0);</td>
<td>2.71828182845904</td>
</tr>
<tr>
<td>a=exp(0);</td>
<td>1</td>
</tr>
</tbody>
</table>

FACT Function

Computes a factorial.

**Category:** Mathematical
Returned data type: DOUBLE

Syntax

FACT(expression)

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Data type INTEGER

Details

The mathematical representation of the FACT function is given by the following equation:

\[ FACT(n) = n! \]

In this equation, \( n \geq 0 \).

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the FACT function.

Example

The following statement illustrates the FACT function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=fact(5);</td>
<td>120</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “COMB Function” on page 256
- “PERM Function” on page 507

FIND Function

Searches for a specific substring of characters within a character string.

Category: Character

Returned data type: CHAR

Syntax

FIND(string, substring[, modifier(s)][, startpos])
FIND(string, substring[, startpos][, modifier(s)])

Arguments

string
specifies a character constant, variable, or expression that will be searched for substrings.
Data type CHAR
Tip Enclose a literal string of characters in quotation marks.

substring
is a character constant, variable, or expression that specifies the substring of characters to search for in string.
Data type CHAR
Tip Enclose a literal string of characters in quotation marks.

modifier(s)
is a character constant, variable, or expression that specifies one or more modifiers. The following characters, in uppercase or lowercase, can be used as modifiers:

i or I
ignores character case during the search. If this modifier is not specified, FIND searches only for character substrings with the same case as the characters in substring.

Data type CHAR
Tip If modifier is a constant, enclose it in quotation marks. Specify multiple constants in a single set of quotation marks. Modifier can also be expressed as a variable or an expression.

Note: If you want to remove trailing blanks from only one character argument instead of both (or all) character arguments, use the TRIM function instead of the FIND function with the T modifier.

startpos
is a numeric constant, variable, or expression with an integer value that specifies the position at which the search should start and the direction of the search.
Data type INTEGER
Details

The FIND function searches string for the first occurrence of the specified substring, and returns the position of that substring. If the substring is not found in string, FIND returns a value of 0.

If startpos is not specified, FIND starts the search at the beginning of the string and searches the string from left to right. If startpos is specified, the absolute value of startpos determines the position at which to start the search. The sign of startpos determines the direction of the search.

<table>
<thead>
<tr>
<th>Value of startpos</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>greater than 0</td>
<td>starts the search at position startpos and the direction of the search is to the right. If startpos is greater than the length of string, FIND returns a value of 0.</td>
</tr>
<tr>
<td>less than 0</td>
<td>starts the search at position –startpos and the direction of the search is to the left. If –startpos is greater than the length of string, the search starts at the end of string.</td>
</tr>
<tr>
<td>equal to 0</td>
<td>returns a value of 0.</td>
</tr>
</tbody>
</table>

Comparisons

- The FIND function searches for substrings of characters in a character string, whereas the FINDC function searches for individual characters in a character string.
- The FIND function and the INDEX function both search for substrings of characters in a character string. However, the INDEX function does not have the modifiers nor the startpos arguments.

Example

The following statements illustrate the FIND function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>whereisshe=find('She sells seashells? Yes, she does.','she '); put whereisshe;</td>
<td>27</td>
</tr>
<tr>
<td>variable1='She sells seashells? Yes, she does.'; variable2='she '; variable3='i'; whereisshe_i=find(variable1,variable2,variable3); put whereisshe_i;</td>
<td>1</td>
</tr>
<tr>
<td>expression1='She sells seashells? '</td>
<td></td>
</tr>
</tbody>
</table>
Statements | Results
--- | ---
xyz='She sells seashells? Yes, she does.'; startposvar=22; whereisshe_22=find(xyz,'she',startposvar); put whereisshe_22; | 27

xyz='She sells seashells? Yes, she does.'; startposexp=1-23; whereisShe_ineg22=find(xyz,'She','i',startposexp); put whereisShe_ineg22; | 14

See Also

Functions:

- “COUNT Function” on page 276

- “FINDW Function” on page 326
- “INDEX Function” on page 360

FINDC Function

Searches a string for any character in a list of characters.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

Syntax

```
FINDC(string[, charlist])
FINDC(string, charlist[, modifier])
FINDC(string, charlist, modifier[, startpos])
FINDC(string, charlist[, startpos][, modifier])
```

Arguments

`string`

is a character constant, variable, or expression that specifies the character string to be searched.

<table>
<thead>
<tr>
<th>Data type</th>
<th>CHAR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tip</td>
<td>Enclose a literal string of characters in quotation marks.</td>
</tr>
</tbody>
</table>
**charlist**

is a constant, variable, or character expression that initializes a list of characters. FINDC searches for the characters in this list provided that you do not specify the K modifier in the **modifier** argument. If you specify the K modifier, FINDC searches for all characters that are not in this list of characters. You can add more characters to the list by using other modifiers.

**Data type**  CHAR

**Tip**  Enclose a literal string of characters in quotation marks.

**modifier**

is a character constant, variable, or expression in which each character modifies the action of the FINDC function. The following characters, in uppercase or lowercase, can be used as modifiers:

- **blank**  is ignored.
- **a** or **A**  adds alphabetic characters to the list of characters.
- **b** or **B**  searches from right to left, instead of from left to right, regardless of the sign of the **startpos** argument.
- **c** or **C**  adds control characters to the list of characters.
- **d** or **D**  adds digits to the list of characters.
- **f** or **F**  adds an underscore and English letters (that is, the characters that can begin a SAS variable name using `VALIDVARNAME=V7`) to the list of characters.
- **g** or **G**  adds graphic characters to the list of characters.
- **h** or **H**  adds a horizontal tab to the list of characters.
- **i** or **I**  ignores character case during the search.
- **k** or **K**  searches for any character that does not appear in the list of characters. If you do not specify this modifier, then FINDC searches for any character that appears in the list of characters. The V and K modifiers perform the same function.
- **l** or **L**  adds lowercase letters to the list of characters.
- **n** or **N**  adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using `VALIDVARNAME=V7`) to the list of characters.
- **o** or **O**  processes the **charlist** and the **modifier** arguments only once, rather than every time the FINDC function is called. Using the O modifier in DS2 (excluding WHERE clauses) can make FINDC run faster when you call it in a loop where the **charlist** and the **modifier** arguments do not change.
- **p** or **P**  adds punctuation marks to the list of characters.
- **s** or **S**  adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).
- **t** or **T**  trims trailing blanks from the **string** and **charlist** arguments. Note that if you want to remove trailing blanks from just one character argument instead of both (or all) character arguments, use the TRIM function instead of the FINDC function with the T modifier.
u or U adds uppercase letters to the list of characters.

v or V causes all characters that are not in the list of characters to be treated as delimiters. If V is not specified, then all characters that are in the list of characters are treated as delimiters. The V and K modifiers perform the same function.

w or W adds printable characters to the list of characters.

x or X adds hexadecimal characters to the list of characters.

Data type CHAR

Tip If modifier is a constant, then enclose it in quotation marks. Specify multiple constants in a single set of quotation marks. Modifier can also be expressed as a variable or an expression.

\textit{startpos} is an optional numeric constant, variable, or expression having an integer value that specifies the position at which the search should start and the direction in which to search.

Data type INTEGER

Details

The FINDC function searches string for the first occurrence of the specified characters, and returns the position of the first character found. If no characters are found in string, then FINDC returns a value of 0.

The FINDC function allows character arguments to be null. Null arguments are treated as character strings that have a length of zero. Numeric arguments cannot be null.

If startpos is not specified, FINDC begins the search at the end of the string if you use the B modifier, or at the beginning of the string if you do not use the B modifier.

If startpos is specified, the absolute value of startpos specifies the position at which to begin the search. If you use the B modifier, the search always proceeds from right to left.

If you do not use the B modifier, the sign of startpos specifies the direction in which to search. The following table summarizes the search directions:

<table>
<thead>
<tr>
<th>Value of startpos</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>greater than 0</td>
<td>search begins at position startpos and proceeds to the right. If startpos is greater than the length of the string, FINDC returns a value of 0.</td>
</tr>
<tr>
<td>less than 0</td>
<td>search begins at position –startpos and proceeds to the left. If startpos is less than the negative of the length of the string, the search begins at the end of the string.</td>
</tr>
<tr>
<td>equal to 0</td>
<td>returns a value of 0.</td>
</tr>
</tbody>
</table>

Comparisons

- The FINDC function searches for individual characters in a character string, whereas the FIND function searches for substrings of characters in a character string.
• The FINDC function and the INDEXC function both search for individual characters in a character string. However, the INDEXC function does not have the modifier nor the startpos arguments.

• The FINDC function searches for individual characters in a character string, whereas the VERIFY function searches for the first character that is unique to an expression. The VERIFY function does not have the modifier nor the startpos arguments.

Examples

Example 1: Searching for Characters in a String
This example searches a character string and returns the characters that are found.

data test;
  method run();
    j=0;
    do until(j=0);
      j = findc('Hi, ho!','hi',j+1);
      if j= 0 then put 'The End';
      else do;
        c = substr('Hi, ho!', j, 1);
        put j= c=;
      end;
    end;
  end;
enddata;
run;

SAS writes the following output to the log:

j=2 c=i
j=5 c=h
The End

Example 2: Searching for Characters in a String and Ignoring Case
This example searches a character string and returns the characters that are found. The I modifier is used to ignore the case of the characters.

data test;
  method run();
    string='Hi, ho!';
    charlist='ho';
    j=0;
    do until(j=0);
      j=findc(string,charlist,j+1,'i');
      if j=0 then put 'The End';
      else do;
        c=substr(string, j, 1);
        put j= c=;
      end;
    end;
  end;
  enddata;
run;
SAS writes the following output to the log:

| j=1  | c=H |
| j=5  | c=h |
| j=6  | c=o |
|      | The End |

**Example 3: Searching for Characters and Using the K Modifier**

This example searches a character string and returns the characters that do not appear in the character list.

```sas
data test;
  method run();
  string='Hi, ho!';
  charlist='hi';
  j=0;
  do until(j = 0);
    j = findc(string,charlist,'k',j+1);
    if j=0 then put 'The End';
    else do;
      c = substr(string,j,1);
      put j= c=;
    end;
  end;
end;
enddata;
run;
```

SAS writes the following output to the log:

| j=1  | c=H |
| j=3  | c=, |
| j=4  | c= |
| j=6  | c=o |
| j=7  | c=! |
|      | The End |

**Example 4: Searching for the Characters h, i, and Blank**

This example searches for the three characters h, i, and blank. The characters h and i are in lowercase. The uppercase characters H and I are ignored in this search.

```sas
data test;
  method run();
  whereishi=0;
  do until(whereishi=0);
    whereishi=findc('Hi there, Ian!','hi ',whereishi+1);
    if whereishi=0 then put 'The End';
    else do;
      whatfound=substr('Hi there, Ian!',whereishi,1);
      put whereishi= whatfound=;
    end;
  end;
end;
enddata;
run;
```
Example 5: Searching for the Characters h and i While Ignoring Case

This example searches for the four characters h, i, H, and I. FINDC with the i modifier ignores character case during the search.

```sas
data test;
  method run();
  whereishi=0;
  do until(whereishi=0);
    whereishi=findc('Hi there, Ian!','hi ',whereishi+1);
    if whereishi=0 then put 'The End';
    else do;
      whatfound=substr('Hi there, Ian!',whereishi,1);
      put whereishi= whatfound=;
    end;
  end;
end;
enddata;
run;
```

SAS writes the following output to the log:

whereishi=2 whatfound=i
whereishi=3 whatfound=
whereishi=5 whatfound=h
whereishi=10 whatfound=
The End

Example 6: Searching for the Characters h and i with Trailing Blanks Trimmed

This example searches for the two characters h and i. FINDC with the t modifier trims trailing blanks from the string argument and the characters argument.

```sas
data test;
  method run();
  whereishi_t=0;
  do until(whereishi_t=0);
    expression1='Hi there, '||'Ian!';
    expression2=kscan('bye or hi',3)||'  ';
    expression3=trim('t   ');
    whereishi_t=findc(expression1,expression2,expression3,whereishi_t+1);
    if whereishi_t=0 then put 'The End';
    else do;
      whatfound=substr(expression1,whereishi_t,1);
      put whereishi_t= whatfound=;
    end;
  end;
end;
enddata;
```

SAS writes the following output to the log:

whereishi_t=1 whatfound=H
whereishi_t=2 whatfound=i
whereishi_t=5 whatfound=h
whereishi_t=11 whatfound=I
The End
Example 7: Searching for All Characters, Excluding h, i, H, and I
This example searches for all of the characters in the string, excluding the characters h, i, H, and I. FINDC with the v modifier counts only the characters that do not appear in the characters argument. This example also includes the i modifier and therefore ignores character case during the search.

```sas
data test (overwrite=yes);
  method run();
  whereishi_iv=0;
  do until(whereishi_iv=0);
    xyz='Hi there, Ian!';
    whereishi_iv=findc(xyz,'hi',whereishi_iv+1,'iv');
    if whereishi_iv=0 then put 'The End';
    else do;
      whatfound=substr(xyz,whereishi_iv,1);
      put whereishi_iv= whatfound=;
    end;
  end;
run;
quit;
```

SAS writes the following output to the log:

```sas
whereishi_t=2 whatfound=l
whereishi_t=5 whatfound=h
The End
```

FINDW Function

Returns the character position of a word in a string, or returns the number of the word in a string.

**Category:** Character

**Returned data type:** INTEGER

**Syntax**

\[\text{FINDW}(\text{string}, \text{word}, \text{chars})\]

\[\text{FINDW}(\text{string}, \text{word}, \text{chars}, \text{modifier(s)}, \text{startpos})\]

\[\text{FINDW}(\text{string}, \text{word}, \text{chars}, \text{startpos}, \text{modifier(s)})\]

\[\text{FINDW}(\text{string}, \text{word}, \text{startpos}, \text{chars}, \text{modifier(s)})\]

**Arguments**

- **string**
  
is a character constant, variable, or expression that specifies the character string to be searched.

  Data type  \(\text{CHAR}\)
Tip
Enclose a literal string of characters in quotation marks.

**word**
is a character constant, variable, or expression that specifies the word to be searched.

Data type  
CHAR

Tip
Enclose a literal string of characters in quotation marks.

**chars**
is an optional character constant, variable, or expression that initializes a list of characters.

The characters in this list are the delimiters that separate words, provided that you do not specify the K modifier in the modifier argument. If you specify the K modifier, then all characters that are not in this list are delimiters. You can add more characters to this list by using other modifiers.

Data type  
CHAR

Tip
Enclose a literal string of characters in quotation marks.

**startpos**
is an optional numeric constant, variable, or expression with an integer value that specifies the position at which the search should begin and the direction in which to search.

Data type  
INTEGER

'**modifier(s)**'
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the FINDW function.

You can use the following characters as modifiers:

- **blank**  
is ignored.
- **a or A**  
adds alphabetic characters to the list of characters.
- **b or B**  
ssearches from right to left, instead of from left to right, regardless of the sign of the startpos argument.
- **c or C**  
adds control characters to the list of characters.
- **d or D**  
adds digits to the list of characters.
- **e or E**  
counts the words that are scanned until the specified word is found, instead of determining the character position of the specified word in the string. Fragments of words are not counted.
- **f or F**  
adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.
- **g or G**  
adds graphic characters to the list of characters.
- **h or H**  
adds a horizontal tab to the list of characters.
- **i or I**  
ignores the case of the characters.
- **k or K**  
causes all character that are not in the list of characters to be treated as delimiters. If K is not specified, then all characters that are in the list
of characters are treated as delimiters. The K and V modifiers perform the same function.

l or L  adds lowercase letters to the list of characters.
m or M  specifies that multiple consecutive delimiters, and delimiters at the beginning or end of the string argument, refer to words that have a length of zero.
n or N  adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using VALIDVARNAME=V7) to the list of characters.
o or O  processes the chars and the modifier arguments only once, rather than every time the FINDW function is called. Using the O modifier in DS2 (excluding WHERE clauses) can make FINDW run faster when you call it in a loop where the chars and the modifier arguments do not change.
p or P  adds punctuation marks to the list of characters.
q or Q  ignores delimiters that are inside substrings that are enclosed in quotation marks. If the value of the string argument contains unmatched quotation marks, then scanning from left to right will produce different words than scanning from right to left.
r or R  removes leading and trailing delimiters from the word argument.
s or S  adds space characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed) to the list of characters.
t or T  trims trailing blanks from the string, word, and chars arguments.
u or U  adds uppercase letters to the list of characters.
v or V  causes all character that are not in the list of characters to be treated as delimiters. If V is not specified, then all characters that are in the list of characters are treated as delimiters. The V and K modifiers perform the same function.
w or W  adds printable characters to the list of characters.
x or X  adds hexadecimal characters to the list of characters.

Data type  CHAR

Tip  If you use the modifier argument, then it must be positioned after the chars argument.

Details

Definition of "Delimiter"
"Delimiter" refers to any of several characters that are used to separate words. You can specify the delimiters by using the chars argument, the modifier argument, or both. If you specify the Q modifier, then the characters inside substrings that are enclosed in quotation marks are not treated as delimiters.

Definition of "Word"
"Word" refers to a substring that has both of the following characteristics:
•  bounded on the left by a delimiter or the beginning of the string
• bounded on the right by a delimiter or the end of the string

Note: A word can contain delimiters. In this case, the FINDW function differs from the SCAN function, in which words are defined as not containing delimiters.

**Searching for a String**

If the FINDW function fails to find a substring that both matches the specified word and satisfies the definition of a word, then FINDW returns a value of 0.

If the FINDW function finds a substring that both matches the specified word and satisfies the definition of a word, the value that is returned by FINDW depends on whether the E modifier is specified:

• If you specify the E modifier, then FINDW returns the number of complete words that were scanned while searching for the specified word. If \texttt{startpos} specifies a position in the middle of a word, then that word is not counted.

• If you do not specify the E modifier, then FINDW returns the character position of the substring that is found.

If you specify the \texttt{startpos} argument, then the absolute value of \texttt{startpos} specifies the position at which to begin the search. The sign of \texttt{startpos} specifies the direction in which to search:

<table>
<thead>
<tr>
<th>Value of \texttt{startpos}</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>greater than 0</td>
<td>search begins at position \texttt{startpos} and proceeds to the right. If \texttt{startpos} is greater than the length of the string, then FINDW returns a value of 0.</td>
</tr>
<tr>
<td>less than 0</td>
<td>search begins at position \texttt{–startpos} and proceeds to the left. If \texttt{startpos} is less than the negative of the length of the string, then the search begins at the end of the string.</td>
</tr>
<tr>
<td>equal to 0</td>
<td>FINDW returns a value of 0.</td>
</tr>
</tbody>
</table>

If you do not specify the \texttt{startpos} argument or the B modifier, then FINDW searches from left to right starting at the beginning of the string. If you specify the B modifier, but do not use the \texttt{startpos} argument, then FINDW searches from right to left starting at the end of the string.

**Using the FINDW Function in ASCII and EBCDIC Environments**

If you use the FINDW function with only two arguments, the default delimiters depend on whether your computer uses ASCII or EBCDIC characters.

• If your computer uses ASCII characters, then the default delimiters are as follows:

  \begin{verbatim}
  blank ! $ % & ( ) * + , . / ; < ^ | 
  \end{verbatim}

  In ASCII environments that do not contain the \texttt{^} character, the FINDW function uses the \texttt{~} character instead.

• If your computer uses EBCDIC characters, then the default delimiters are as follows:

  \begin{verbatim}
  blank ! $ % & ( ) * + , . / ; < \texttt{¬} | \texttt{¢}
  \end{verbatim}
Using Null Arguments

The FINDW function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. Numeric arguments cannot be null.

Examples

Example 1: Searching a Character String for a Word

The following example searches a character string for the word “she”, and returns the position of the beginning of the word.

```sas
data _null_; method run(); whereisshe=findw('She sells sea shells? Yes, she does.','she'); put whereisshe=; end; enddata; run;
SAS writes the following output to the log:

whereisshe=28
```

Example 2: Searching a Character String and Using the Chars and Startpos Arguments

The following example contains two occurrences of the word “rain.” Only the second occurrence is found by FINDW because the search begins in position 25. The chars argument specifies a space as the delimiter.

```sas
data _null_; method run(); result = findw('At least 2.5 meters of rain falls in a rain forest.', 'rain', ' ', 25); put result=; end; enddata; run;
SAS writes the following output to the log:

result=40
```

Example 3: Searching a Character String and Using the I Modifier and the Startpos Argument

The following example uses the I modifier and returns the position of the beginning of the word. The I modifier disregards case, and the startpos argument identifies the starting position from which to search.

```sas
data _null_; method run(); string='Artists from around the country display their art at an art festival.'; result=findw(string, 'Art',' ', 'i', 10); put result=; end; enddata;
```
run;
quit;

SAS writes the following output to the log:

```
result=47
```

**Example 4: Searching a Character String and Using the E Modifier**
The following example uses the E modifier and returns the number of complete words that are scanned while searching for the word "art."

```sas
data _null_;  
method run();  
  string='Artists from around the country display their art at an art festival.';  
  result=findw(string,'art',' ','E');  
  put result=;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
result=8
```

**Example 5: Searching a Character String and Using the E Modifier and the Startpos Argument**
The following example uses the E modifier to count words in a character string. The word count begins at position 50 in the string. The result is 3 because "art" is the third word after the 50th character position.

```sas
data _null_;  
method run();  
  string='Artists from around the country display their art at an art festival.';  
  result=findw(string,'art',' ','E',50);  
  put result=;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
result=3
```

**Example 6: Searching a Character String and Using Two Modifiers**
The following example uses the I and the E modifiers to find a word in a string.

```sas
data _null_;  
method run();  
  string='The Great Himalayan National Park was created in 1984. Because of its terrain and altitude, the park supports a diversity of wildlife and vegetation.';  
  result=findw(string,'park',' ','I E');  
  put result=;  
end;  
enddata;  
run;
```
Example 7: Searching a Character String and Using the R Modifier

The following example uses the R modifier to remove leading and trailing delimiters from a word.

```sas
data _null_; method run();
  string='Artists from around the country display their art at an art festival.';
  word=' art ';
  result=findw(string, word, ' ', 'R');
  put result=;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
result=5
```

FLOOR Function

Returns the largest integer less than or equal to a numeric value expression.

<table>
<thead>
<tr>
<th>Category</th>
<th>Truncation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type</td>
<td>DECIMAL, DOUBLE, NUMERIC</td>
</tr>
</tbody>
</table>

Syntax

FLOOR(expression)
**Arguments**

*expression*

specifies any valid expression that evaluates to a numeric value.

Data type: DECIMAL, DOUBLE, NUMERIC

**Details**

If *expression* is within 1E-12 of an integer, the function returns that integer. If the result is a number that does not fit into the range of a DOUBLE, the FLOOR function fails.

If the argument is DECIMAL, the result is DECIMAL. Otherwise, the argument is converted to DOUBLE (if not so already), and the result is DOUBLE.

**Comparisons**

The FLOOR function fuzzes the results so that if the results are within 1E-12 of an integer, the FLOOR function returns that integer. The FLOORZ function uses zero fuzzing. Therefore, with the FLOORZ function, you might get unexpected results.

**Example**

The following statement illustrates the FLOOR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>floor(1.95);</td>
<td>1</td>
</tr>
</tbody>
</table>

**See Also**

Functions:

- “CEIL Function” on page 247
- “CEILZ Function” on page 248
- “FLOORZ Function” on page 333

---

**FLOORZ Function**

Returns the largest integer that is less than or equal to the argument, using zero fuzzing.

**Category:** Truncation  
**Returned data type:** DOUBLE

**Syntax**

FLOORZ(expression)
**Arguments**

*expression* specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

**Comparisons**

Unlike the FLOOR function, the FLOORZ function uses zero fuzzing. If the argument is within 1E-12 of an integer, the FLOOR function fuzzes the result to be equal to that integer. The FLOORZ function does not fuzz the result. Therefore, with the FLOORZ function, you might get unexpected results.

**Example**

The following statements illustrate the FLOORZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>var1=2.1; a=floorz(var1);</td>
<td>2</td>
</tr>
<tr>
<td>b=floorz(-2.4);</td>
<td>-3</td>
</tr>
<tr>
<td>c=floorz(-1.6);</td>
<td>-2</td>
</tr>
</tbody>
</table>

**See Also**

- “CEILZ Function” on page 248
- “FLOOR Function” on page 332

**FMTINFO Function**

Returns information about a SAS format or informat.

**Restrictions:**

This function is not supported in the CAS server.

This function returns information about formats that are supplied by SAS. It cannot be used for user-defined formats that are created with the FORMAT procedure.

**Syntax**

```
FMTINFO('format-name', 'information-type');
```
Arguments

'format-name'
specifies the name of a SAS format or informat.

Requirement  format-name must be enclosed in single quotation marks.

information-type
specifies the type of information that is returned. format-information can be one of the following values:

'CAT'
  returns the function category.
  See  For a complete list, see “Function Categories” on page 171.

'TYPE'
  indicates whether the format-name is a format, an informat, or both.

'DESC'
  returns a short description of the format or informat.

'MIND'
  returns the minimum number of digits to the right of the decimal place in the format or informat.

'MAXD'
  returns the maximum number of digits to the right of the decimal place in the format or informat.

'DEFD'
  returns the default number of digits to the right of the decimal place in the format or informat.

'MINW'
  returns the minimum width value of the format or informat.

'MAXW'
  returns the maximum width value of the format or informat.

'DEFW'
  returns the default width value of the format or informat.

Restriction  You can specify only one information-type argument.

Requirement  information-type must be enclosed in single quotation marks.

Details

The FMTINFO function returns information about a format or informat. You can return information about a format or informat’s category, the type of language element, a description of the language element, and the minimum, maximum, and default decimal and width values.

You cannot specify multiple arguments with the FMTINFO function.

The FMTINFO function returns a character string for all data values, including the numeric value arguments MIND, MAXD, DEFD, MINW, MAXW, and DEFW.
Example

The following example returns information about the COMMAw. and COMMAw.d informat.

data _null_;  
dcl char(30) fdesc fcat ftype;  
dcl double fmind fmaxd fdefd fminw fmaxw fdefw;  
method run();  
ftype=fmtinfo('date','type');  
fcat= fmtinfo('date','cat');  
fdesc= fmtinfo('date','desc');  
fmind= fmtinfo('date','mind');  
fmaxd= fmtinfo('date','maxd');  
fdefd= fmtinfo('date','defd');  
fminw= fmtinfo('date','minw');  
fmaxw= fmtinfo('date','maxw');  
fdefw= fmtinfo('date','defw');  
put ftype=;  
put fcat=;  
put fdesc= ;  
put fmind= ;  
put fmaxd= ;  
put fdefd= ;  
put fminw= ;  
put fmaxw= ;  
put fdefw= ;  
end;  
enddata;  
run;  

The following lines are written to the SAS log.

ftype=BOTH  
fcat=date  
fdesc=date value  
fmind=0  
fmaxd=8  
fdefd=0  
fminw=5  
fmaxw=11  
fdefw=?

FUZZ Function

Returns the nearest integer if the argument is within 1E-12 of that integer.

**Category:** Truncation  
**Returned data type:** DOUBLE

**Syntax**

FUZZ(expression)
**Arguments**

*expression*

specifies any valid expression that evaluates to a numeric value.

Data type **DOUBLE**

See

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The FUZZ function returns the nearest integer value if the expression is within 1E-12 of the integer (that is, if the absolute difference between the integer and argument is less than 1E-12). Otherwise, the expression is returned.

**Example**

The following statements illustrate the FUZZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>var1=5.99999999999999; x=put(fuzz(var1),16.14);</td>
<td>6</td>
</tr>
<tr>
<td>x=put(fuzz(5.99999999), 16.14);</td>
<td>5.99999999</td>
</tr>
</tbody>
</table>

---

**GAMINV Function**

Returns a quantile from the gamma distribution.

- **Category:** Quantile
- **Returned data type:** **DOUBLE**

**Syntax**

`GAMINV(p, a)`

**Arguments**

*p*

specifies any valid expression that evaluates to a numeric probability.

Range 0 ≤ *p* < 1

Data type **DOUBLE**

See

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*a*

specifies any valid expression that evaluates to a numeric shape parameter.
Range $a > 0$

Data type DOUBLE

Details

The GAMINV function returns the $p$th quantile from the gamma distribution, with shape parameter $a$. The probability that a row from a gamma distribution is less than or equal to the returned quantile is $p$.

*Note:* GAMINV is the inverse of the PROBGAM function.

Example

The following statements illustrate the GAMINV function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>q1=gaminv(0.5, 9);</td>
<td>8.668951</td>
</tr>
<tr>
<td>q2=gaminv(0.1, 2.1);</td>
<td>0.584193</td>
</tr>
</tbody>
</table>

- “PROBGAM Function” on page 523

---

**GAMMA Function**

Returns the value of the gamma function.

- **Category:** Mathematical
- **Returned data type:** DOUBLE

**Syntax**

GAMMA(*expression*)

**Arguments**

*expression*

specifies any valid expression that evaluates to a numeric value.

- **Restriction:** Nonpositive integers are invalid.
- **Data type:** DOUBLE
Details

The GAMMA function returns the integral, which is given by the following equation.

\[
\text{GAMMA}(x) = \int_0^\infty t^{x-1}e^{-t} \, dt.
\]

For positive integers, \(\text{GAMMA}(x)\) is \((x - 1)!\). This function is commonly denoted by \(\Gamma(x)\).

Example

The following statement illustrates the GAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x = \text{gamma}(6);)</td>
<td>120</td>
</tr>
</tbody>
</table>

GARKHCLPRC Function

Calculates call prices for European options on stocks, based on the Garman-Kohlhagen model.

**Category:** Financial

**Returned data type:** DOUBLE

**Syntax**

\[
\text{GARKHCLPRC}(E, t, S, R_d, R_f, \sigma)
\]

**Arguments**

\(E\)

is a nonmissing, positive value that specifies the exercise price.

**Requirement** Specify \(E\) and \(S\) in the same units.

**Data type** DOUBLE

\(t\)

is a nonmissing value that specifies the time to maturity.

**Data type** DOUBLE

\(S\)

is a nonmissing, positive value that specifies the spot currency price.
Requirement Specify $S$ and $E$ in the same units.

Data type DOUBLE

$R_d$

is a nonmissing, positive fraction that specifies the risk-free domestic interest rate for period $t$.

Requirement Specify a value for $R_d$ for the same time period as the unit of $t$.

Data type DOUBLE

$R_f$

is a nonmissing, positive fraction that specifies the risk-free foreign interest rate for period $t$.

Requirement Specify a value for $R_f$ for the same time period as the unit of $t$.

Data type DOUBLE

$\sigma$

is a nonmissing, positive fraction that specifies the volatility of the currency rate.

Requirement Specify a value for $\sigma$ for the same time period as the unit of $t$.

Data type DOUBLE

Details

The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. The function is based on the following relationship:

$$\text{CALL} = SN(d_1) \left( e^{-R_f t} \right) - EN(d_2) \left( e^{-R_d t} \right)$$

Arguments

$S$

specifies the spot currency price.

$N$

specifies the cumulative normal density function.

$E$

specifies the exercise price of the option.

$t$

specifies the time to expiration.

$R_d$

specifies the risk-free domestic interest rate for period $t$.

$R_f$

specifies the risk-free foreign interest rate for period $t$. 
\[ d_1 = \frac{\ln \left( \frac{S}{E} \right) + \left( R_d - R_f + \frac{\sigma^2}{2} \right) t}{\sigma \sqrt{t}} \]

\[ d_2 = d_1 - \sigma \sqrt{t} \]

The following arguments apply to the preceding equation:

\( \sigma \)
- specifies the volatility of the underlying asset.

\( \sigma^2 \)
- specifies the variance of the rate of return.

For the special case of \( t=0 \), the following equation is true:

\[ \text{CALL} = \max((S - E), 0) \]

For information about the basics of pricing, see "Using Pricing Functions".

### Comparisons

The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. These functions return a scalar value.

### Example

The following statements illustrate the GARKHCLPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a = \text{garkhclprc}(40, .5, 38, .06, .04, .2) );</td>
<td>1.44942510595479</td>
</tr>
<tr>
<td>( c = \text{garkhclprc}(19, .25, 20, .05, .03, .09) );</td>
<td>1.13042947635</td>
</tr>
</tbody>
</table>

### See Also

Functions:
- “GARKHPTPRC Function” on page 341
Syntax

GARKHPTPRC(\(E, t, S, R_d, R_f, \sigma\))

Arguments

\(E\)

is a nonmissing, positive value that specifies the exercise price.

**Requirement** Specify \(E\) and \(S\) in the same units.

**Data type** DOUBLE

\(t\)

is a nonmissing value that specifies the time to maturity, in years.

**Data type** DOUBLE

\(S\)

is a nonmissing, positive value that specifies the spot currency price.

**Requirement** Specify \(S\) and \(E\) in the same units.

**Data type** DOUBLE

\(R_d\)

is a nonmissing, positive fraction that specifies the risk-free domestic interest rate for period \(t\).

**Requirement** Specify a value for \(R_d\) for the same time period as the unit of \(t\).

**Data type** DOUBLE

\(R_f\)

is a nonmissing, positive fraction that specifies the risk-free foreign interest rate for period \(t\).

**Requirement** Specify a value for \(R_f\) for the same time period as the unit of \(t\).

**Data type** DOUBLE

\(\sigma\)

is a nonmissing, positive fraction that specifies the volatility of the currency rate.

**Data type** DOUBLE

Details

The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. The function is based on the following relationship:

\[
PUT = CALL - S(e^{-R_f t}) + E(e^{-R_d t})
\]

Arguments
\[ S \]
specifies the spot currency price.

\[ E \]
specifies the exercise price of the option.

\[ t \]
specifies the time to expiration, in years.

\[ R_d \]
specifies the risk-free domestic interest rate for period \( t \).

\[ R_f \]
specifies the risk-free foreign interest rate for period \( t \).

\[
d_1 = \frac{\ln \left( \frac{S}{E} \right) + \left( R_d - R_f + \frac{\sigma^2}{2} \right) t}{\sigma \sqrt{t}}
\]

\[
d_2 = d_1 - \sigma \sqrt{t}
\]

The following arguments apply to the preceding equation:

\[ \sigma \]
specifies the volatility of the underlying asset.

\[ \sigma^2 \]
specifies the variance of the rate of return.

For the special case of \( t=0 \), the following equation is true:

\[ \text{PUT} = \max(E - S, 0) \]

For information about the basics of pricing, see "Using Pricing Functions".

**Comparisons**

The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. These functions return a scalar value.

**Example**

The following statements illustrate the GARKHPTPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=garkhptprc(50, .7, 55, .05, .04, .2);</td>
<td>1.4050880944848</td>
</tr>
<tr>
<td>b=garkhptprc(32, .3, 33, .05, .03, .3);</td>
<td>1.56473205137371</td>
</tr>
</tbody>
</table>

Functions:
GCD Function

Returns the greatest common divisor for a set of integers.

Category: Mathematical
Returned data type: DOUBLE

Syntax

\[ \text{GCD(expression-1, expression-2 [, …expression-n])} \]

Arguments

\textit{expression} specifies any valid expression that evaluates to a numeric value.

Requirement
At least two arguments are required.

Data type
DOUBLE

See

Details

The GCD (greatest common divisor) function returns the greatest common divisor of one or more integers. For example, the greatest common divisor for 30 and 42 is 6. The greatest common divisor is also called the highest common factor.

Example

The following statements illustrate the GCD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=gcd(5,15)</td>
<td>5</td>
</tr>
<tr>
<td>x=gcd(36,45)</td>
<td>9</td>
</tr>
</tbody>
</table>

GEODIST Function

Returns the geodetic distance between two latitude and longitude coordinates.

**Syntax**

```
GEODIST(latitude-1, longitude-1, latitude-2, longitude-2 [option(s)])
```

**Arguments**

- **latitude**
  - is a numeric constant, variable, or expression that specifies the coordinate of a given position north or south of the equator. Coordinates that are located north of the equator have positive values; coordinates that are located south of the equator have negative values.
  - **Restriction**
    - If the value is expressed in degrees, it must be between 90 and –90. If the value is expressed in radians, it must be between pi/2 and –pi/2.
  - **Data type**
    - DOUBLE

- **longitude**
  - is a numeric constant, variable, or expression that specifies the coordinate of a given position east or west of the prime meridian, which runs through Greenwich, England. Coordinates that are located east of the prime meridian have positive values; coordinates that are located west of the prime meridian have negative values.
  - **Restriction**
    - If the value is expressed in degrees, it must be between 180 and –180. If the value is expressed in radians, it must be between pi and –pi.
  - **Data type**
    - DOUBLE

- **option(s)**
  - specifies a character constant, variable, or expression that contains any of the following characters:
    - **M** specifies distance in miles.
    - **K** specifies distance in kilometers. K is the default value for distance.
    - **D** specifies that input values are expressed in degrees. D is the default for input values.
    - **R** specifies that input values are expressed in radians.
  - **Data type**
    - CHAR
Details

The GEODIST function computes the geodetic distance between any two arbitrary latitude and longitude coordinates. Input values can be expressed in degrees or in radians.

Examples

Example 1: Calculating the Geodetic Distance in Kilometers

The following example shows the geodetic distance in kilometers between Mobile, AL (latitude 30.68 N, longitude 88.25 W), and Asheville, NC (latitude 35.43 N, longitude 82.55 W). The program uses the default K option.

```sas
data _null_; 
  method run();
    distance=geodist(30.68, -88.25, 35.43, -82.55);
    put 'Distance= ' distance ' kilometers';
  end;
enddata;
run;
```

SAS writes the following output to the log:

```
Distance= 748.652914703181 kilometers
```

Example 2: Calculating the Geodetic Distance in Miles

The following example uses the M option to compute the geodetic distance in miles between Mobile, AL (latitude 30.68 N, longitude 88.25 W), and Asheville, NC (latitude 35.43 N, longitude 82.55 W).

```sas
data _null_; 
  method run();
    distance=geodist(30.68, -88.25, 35.43, -82.55, 'M');
    put 'Distance = ' distance ' miles';
  end;
enddata;
run;
```

SAS writes the following output to the log:

```
Distance = 465.290810878298 miles
```

Example 3: Calculating the Geodetic Distance with Input Measured in Degrees

The following example uses latitude and longitude values that are expressed in degrees to compute the geodetic distance between two locations. Both the D and the M options are specified in the program.

```sas
data _null_; 
  method run();
    dcl double distance lat1 long1 lat2 long2;
    lat1=35.2;
    long1=-78.1;
    lat2=37.6;
    long2=-79.8;
```
pi = constant('pi');
lat1 = (pi*lat1)/180;
long1 = (pi*long1)/180;
lat2 = (pi*lat2)/180;
long2 = (pi*long2)/180;
Distance = geodist(lat1,long1,lat2,long2,'DM');
put 'Distance= ' Distance 'miles';
end;
enddata;
run;

SAS writes the following output to the log:

Distance = 190.72474281970 miles

**Example 4: Calculating the Geodetic Distance with Input Measured in Radians**

The following example uses latitude and longitude values that are expressed in radians to compute the geodetic distance between two locations. The program converts degrees to radians before executing the GEODIST function. Both the R and the M options are specified in this program.

data _null_; method run();
dcl double distance pi lat1 long1 lat2 long2;
   lat1=35.2;
   long1=-78.1;
   lat2=37.6;
   long2=-79.8;
   pi = constant('pi');
   lat1 = (pi*lat1)/180;
   long1 = (pi*long1)/180;
   lat2 = (pi*lat2)/180;
   long2 = (pi*long2)/180;
   Distance = geodist(lat1,long1,lat2,long2,'RM');
   put 'Distance= ' Distance 'miles';
end;
enddata;
run;

SAS writes the following output to the log:

Distance= 190.724742819706 miles

**References**

Returned data type: DOUBLE

Syntax

GEOMEAN(expression [, …expression])

Arguments

expression

is any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

Details

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If any argument is zero, then the geometric mean is zero. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the geometric mean of the non-null or nonmissing values.

Let n be the number of arguments with non-null or nonmissing values, and let x₁, x₂, …, xₙ be the values of those arguments. The geometric mean is the nᵗʰ root of the product of the values:

\[ \sqrt[n]{x_1 \times x_2 \times \cdots \times x_n} \]

Equivalently, the geometric mean is shown in this equation.

\[ \exp \left( \frac{\log(x_1) + \log(x_2) + \cdots + \log(x_n)}{n} \right) \]

Floating-point arithmetic often produces tiny numerical errors. Some computations that result in zero when exact arithmetic is used might result in a tiny nonzero value when floating-point arithmetic is used. Therefore, GEOMEAN fuzzes the values of arguments that are approximately zero. When the value of one argument is extremely small relative to the largest argument, the former argument is treated as zero. If you do not want SAS to fuzz the extremely small values, then use the GEOMEANZ function.

Comparisons

The MEAN function returns the arithmetic mean (average), and the HARMEAN function returns the harmonic mean, whereas the GEOMEAN function returns the geometric mean of the non-null or nonmissing values. Unlike GEOMEANZ, GEOMEAN fuzzes the values of the arguments that are approximately zero.

Example

The following statements illustrate the GEOMEAN function:
<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x1=geomean(1,2,2,4);</code></td>
<td>2</td>
</tr>
<tr>
<td><code>x2=geomean(.,2,4,8);</code></td>
<td>4</td>
</tr>
</tbody>
</table>

---

**GEOMEANZ Function**

Returns the geometric mean, using zero fuzzing.

**Category:** Descriptive Statistics  
**Returned data type:** DOUBLE

**Syntax**

`GEOMEANZ(expression [,...expression])`

**Arguments**

`expression`

specifies any valid expression that evaluates to a nonnegative numeric value.

**Data type**  
DOUBLE

**See**  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If any argument is zero, then the geometric mean is zero. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the geometric mean of the non-null or nonmissing values.

Let \( n \) be the number of arguments with non-null or nonmissing values, and let \( x_1, x_2, \ldots, x_n \) be the values of those arguments. The geometric mean is the \( n^{th} \) root of the product of the values:

\[
\sqrt[n]{x_1 \cdot x_2 \cdot \ldots \cdot x_n}
\]
Equivalently, the geometric mean is shown in this equation.

\[
\exp \left( \frac{\log(x_1) + \log(x_2) + \ldots + \log(x_n)}{n} \right)
\]

**Comparisons**

The MEAN function returns the arithmetic mean (average), and the HARMEAN function returns the harmonic mean, whereas the GEOMEANZ function returns the geometric mean of the non-null or nonmissing values. Unlike GEOMEAN, GEOMEANZ does not fuzz the values of the arguments that are approximately zero.

**Example**

The following statements illustrate the GEOMEANZ function:

<table>
<thead>
<tr>

**HARMEAN Function**

Returns the harmonic mean.

**Category:** Descriptive Statistics

**Returned data type:** DOUBLE

**Syntax**

\[
\text{HARMEAN}(\text{expression}, \ldots, \text{expression})
\]

**Arguments**

*expression*

specifies any valid expression that evaluates to a nonnegative numeric value.

**Data type** DOUBLE
Details

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the harmonic mean of the non-null or nonmissing values.

If any argument is zero, then the harmonic mean is zero. Otherwise, the harmonic mean is the reciprocal of the arithmetic mean of the reciprocals of the values.

Let \( n \) be the number of arguments with non-null or nonmissing values, and let \( x_1, x_2, \ldots, x_n \) be the values of those arguments. The harmonic mean is shown in this equation.

\[
\frac{n}{\frac{1}{x_1} + \frac{1}{x_2} + \ldots + \frac{1}{x_n}}
\]

Floating-point arithmetic often produces tiny numerical errors. Some computations that result in zero when exact arithmetic is used might result in a tiny nonzero value when floating-point arithmetic is used. Therefore, HARMEAN fuzzes the values of arguments that are approximately zero. When the value of one argument is extremely small relative to the largest argument, the former argument is treated as zero. If you do not want SAS to fuzz the extremely small values, then use the HARMEANZ function.

HBOUND Function

Returns the upper bound of an array.

Category: Array

Returned data type: INTEGER

Syntax

HBOUND(array-name[, bound-n])

Arguments

array-name

specifies the name of a temporary or a variable array.

Data type: CHAR

bound-n

is a numeric constant, variable, or expression that specifies the dimension, in a multidimensional array, for which you want to know the upper bound. If no bound-n value is specified, the HBOUND function returns the upper bound of the first dimension of the array.

Bound-n evaluates to an integral value.

Data type: INTEGER

Details

The HBOUND function returns the upper bound of a one-dimensional array, or the upper bound of a specified dimension of a multidimensional array.

HBOUND and LBOUND can be used together to return the values of the upper and lower bounds of an array dimension.
If the HBOUND function is called with a dimension value that is outside the dimension of the array, then a run-time error occurs and the function returns a NULL integer value.

**Comparisons**

- **DIM** returns the number of elements in an array dimension.
- **HBOUND** returns the value of the upper bound of an array dimension.
- **LBOUND** returns the value of the lower bound of an array dimension.
- **NDIMS** returns the number of dimensions in an array.

**Example**

The following example shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions:

```plaintext
data _null_;  
method init();  
declare char(15) a1[4];  
declare double   a2[2,3,4] sum;  

a1 := ('red' 'yellow' 'green' 'blue');  
a2 := (24*2.0);  

do i = 1 to dim(a1);  
    put a1[i];  
end;  

numelems = 0;  
do i = 1 to ndims(a2);  
    numelems = numelems + dim(a2, i);  
end;  

sum = 0;  
do i = lbound(a2, 1) to hbound(a2, 1);  
    do j = lbound(a2, 2) to hbound(a2, 2);  
        do k = lbound(a2, 3) to hbound(a2, 3);  
            sum = sum + a2[i,j,k];  
        end;  
    end;  
end;  

put sum=;  
end;  
enddata;  
run;```
SAS writes the following output to the log:

```
red
yellow
green
blue
sum=48
```

**HMS Function**

Returns a SAS time value from hour, minute, and second values.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

### Syntax

\[
\text{HMS}(\text{hour}, \text{minute}, \text{second})
\]

### Arguments

- **hour**
  - specifies a numeric expression that represents an integer from 1 through 12.
  - Data type: DOUBLE

- **minute**
  - specifies a numeric expression that represents an integer from 1 through 59.
  - Data type: DOUBLE

- **second**
  - specifies a numeric expression that represents an integer from 1 through 59.
  - Data type: DOUBLE
The HMS function returns a numeric value that represents a SAS time value. A SAS time value is a number that represents the number of seconds since midnight of the current day.

For more information, see “Dates and Times in DS2” in SAS Viya: DS2 Programmer’s Guide.

Example

The following statements illustrate the HMS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=hms(12,45,10);</td>
<td>45910</td>
</tr>
<tr>
<td>b=put(a, time.);</td>
<td>12:45:10</td>
</tr>
</tbody>
</table>

</tbody>
</table>
Data type CHAR

*year*

is a numeric constant, variable, or expression that specifies a four-digit year. If you use a two-digit year, then you must specify the YEARCUTOFF= system option.

Data type INTEGER

Details

The HOLIDAY function computes the date on which a specific holiday occurs in a specified year. Only certain common U.S. and Canadian holidays are defined for use with this function. The definition of many holidays has changed over the years. In the U.S., Executive Order 11582, issued on February 11, 1971, fixed the observance of many U.S. federal holidays.

The current holiday definition is extended indefinitely into the past and future, although many holidays have a fixed date at which they were established. Some holidays have not had a consistent definition in the past.

The HOLIDAY function returns a SAS date value. To convert the SAS date value to a calendar date, use any valid SAS date format, such as the DATE9. format.

Comparisons

In some cases, the HOLIDAY function and the NWKDOM function return the same result. For example, the statement `holiday('thanksgiving', 2012)` returns the same value as `nwkdom(4, 5, 11, 2012)`.

In other cases, the HOLIDAY function and the MDY function return the same result. For example, the statement `holiday('christmas', 2012)` returns the same value as `mdy(12, 25, 2012)`.

Example

The following statements illustrate the HOLIDAY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcl double thanks having format date9.;</td>
<td></td>
</tr>
<tr>
<td>thanks = holiday('thanksgiving', 2013);</td>
<td>28NOV2013</td>
</tr>
<tr>
<td>put thanks;</td>
<td></td>
</tr>
<tr>
<td>dcl double boxing having format date9.;</td>
<td></td>
</tr>
<tr>
<td>boxing = holiday('boxing', 2013);</td>
<td>26DEC2013</td>
</tr>
<tr>
<td>put boxing;</td>
<td></td>
</tr>
<tr>
<td>dcl double easter having format date9.;</td>
<td></td>
</tr>
<tr>
<td>easter = holiday('easter', 2013);</td>
<td>31MAR2013</td>
</tr>
<tr>
<td>put easter;</td>
<td></td>
</tr>
<tr>
<td>dcl double canada having format date9.;</td>
<td></td>
</tr>
<tr>
<td>canada = holiday('canada', 2013);</td>
<td>01JUL2013</td>
</tr>
<tr>
<td>put canada;</td>
<td></td>
</tr>
</tbody>
</table>
HOUR Function

Returns the hour from a SAS time or datetime value.

Syntax

HOUR(time | datetime)

Arguments

time

specifies any valid expression that represents a SAS time value.

Data type: DOUBLE

datetime

specifies any valid expression that represents a SAS datetime value.

Data type: DOUBLE

See Also

Functions:

• “MDY Function” on page 453
• “NWKDOM Function” on page 502
Details
The HOUR function returns a numeric value that represents the hour from a SAS time or datetime value. Numeric values can range from 0 through 23. HOUR always returns a positive number.

Example
The following statement illustrates the HOUR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=hour(time());</td>
<td>10</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “MINUTE Function” on page 457
- “SECOND Function” on page 602

INDEX Function
Searches a character expression for a string of characters, and returns the position of the string’s first character for the first occurrence of the string.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax
INDEX(target-expression, search-expression)

Arguments

**target-expression**
specifies any valid expression that evaluates to a character string.

Data type  NCHAR

**search-expression**
specifies any valid expression that evaluates to a character string to search for in target-expression.

Data type  NCHAR
Tip

Enclose a literal string of characters in single quotation marks.

See

Details

The INDEX function searches target-expression, from left to right, for the first occurrence of the string specified in search-expression, and returns the position in target-expression of the string's first character. If the string is not found in target-expression, INDEX returns a value of 0. If there are multiple occurrences of the string, INDEX returns only the position of the first occurrence.

Comparisons

The VERIFY function returns the position of the first character in target-expression that does not contain search-expression where the INDEX function returns the position of the first occurrence of search-expression that is present in target-expression.

Example

The following statements illustrate the INDEX statement:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a='ABC.DEF (X=Y)'; b='X=Y'; c=index(a,b);</td>
<td>10</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “INDEXC Function” on page 361
- “INDEXW Function” on page 363
- “VERIFY Function” on page 657

INDEXC Function

Searches a character expression for specified characters and returns the position of the first occurrence of any of the characters.

| Category: | Character |
| Returned data type: | DOUBLE |

Syntax

INDEXC(target-expression, search-expression[, ...search-expression])
Arguments

target-expression
specifies any valid expression that evaluates to a character string that is searched.

Data type NCHAR

search-expression
specifies the characters to search for in target-expression.

Data type NCHAR

Details

The INDEXC function searches target-expression, from left to right, for the first occurrence of any character present in the search expressions and returns the position in target-expression of that character. If none of the characters in the search expressions are found in target-expression, INDEXC returns a value of 0.

Comparisons

The INDEXC function searches for the first occurrence of any individual character that is present within the search expression, whereas the INDEX function searches for the first occurrence of the search expression as a pattern.

Example

The following statements illustrate the INDEXC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a='ABC.DEF (X2=Y1)';</td>
<td>4</td>
</tr>
<tr>
<td>b='()';</td>
<td>8</td>
</tr>
<tr>
<td>c='.';</td>
<td>4</td>
</tr>
<tr>
<td>b=indexc(a,'0123',';()=.');</td>
<td></td>
</tr>
<tr>
<td>b=indexc(a,b);</td>
<td></td>
</tr>
<tr>
<td>b=indexc(a,b,c);</td>
<td></td>
</tr>
<tr>
<td>c='have a good day';</td>
<td>2</td>
</tr>
<tr>
<td>d=indexc(c,'pleasant','very');</td>
<td></td>
</tr>
</tbody>
</table>

Functions:

- “INDEX Function” on page 360
- “INDEXW Function” on page 363
INDEXW Function

Searches a character expression for a string that is specified as a word, and returns the position of the first character in the word.

**Category:** Character  
**Returned data type:** DOUBLE

**Syntax**

INDEXW(target-expression, search-expression [, delimiter])

**Arguments**

*target-expression*

specifies any valid expression that evaluates to a character string that is searched.

Data type: NCHAR  

*search-expression*

specifies any valid expression that evaluates to a character string and that is searched for in target-expression. SAS removes the leading and trailing delimiters from search-expression.

Data type: NCHAR  

*delimiter*

specifies a character expression that you want INDEXW to use as a word separator in the character strings. The default delimiter is the blank character.

Data type: NCHAR

**Tip**

If the blank character is a delimiter, order it so that it is not the last character in delimiter. Trailing blanks are ignored because delimiter is trimmed of trailing blanks.

**Details**

The INDEXW function searches target-expression, from left to right, for the first occurrence of search-expression and returns the position in target-expression of the substring's first character. If the substring is not found in target-expression, then INDEXW returns a value of 0. If there are multiple occurrences of the string, then INDEXW returns only the position of the first occurrence.

The substring pattern must begin and end on a word boundary. For INDEXW, word boundaries are delimiters, the beginning of target-expression, and the end of target-expression.
INDEXW has the following behavior when search-expression contains blank spaces or has a length of 0:

- If both target-expression and search-expression contain only blank spaces or have a length of 0, then INDEXW returns a value of 1.
- If search-expression contains only blank spaces or has a length of 0, and target-expression contains character or numeric data, then INDEXW returns a value of 0.

**Comparisons**

The INDEXW function searches for strings that are words, whereas the INDEX function searches for patterns as separate words or as parts of other words. INDEXC searches for any characters that are present in the excerpts.

**Example**

The following statements illustrate the INDEXW function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a='The power to know.'; word='power'; c=indexw(a,word);</td>
<td>5</td>
</tr>
<tr>
<td>a='The power to know.'; b=indexw(a,'know');</td>
<td>0</td>
</tr>
<tr>
<td>a='The power to know.'; b=indexw(a,'know','.');</td>
<td>14</td>
</tr>
<tr>
<td>a='abc,def@ xyz'; b=indexw(a,',','@');</td>
<td>0</td>
</tr>
<tr>
<td>a=&quot;abc,def@ xyz&quot;; b=indexw(a,'def','@');</td>
<td>5</td>
</tr>
<tr>
<td>x=&quot;abc,def@ xyz&quot;; xyz=indexw(x, 'xyz', '@');</td>
<td>10</td>
</tr>
</tbody>
</table>

- “INDEXC Function” on page 361

**INPUTC Function**

Enables you to specify a character informat at run time.

**Category:** Special
Returned data type: CHAR

Syntax

\[
\text{INPUTC}(\text{source}, \text{informat}[, w])
\]

Arguments

**source**

specifies a character constant, variable, or expression to which you want to apply the informat.

Data type CHAR

**informat**

is a character constant, variable, or expression that contains the character informat that you want to apply to source.

Data type CHAR

**w**

specifies any valid expression that evaluates to a numeric width to apply to the informat.

Interaction If you specify a width here, it overrides any width specification in the informat.

Data type INTEGER

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

Details

If the INPUTC function returns a value to a variable that has not yet been assigned a length, by default the variable length is determined by the length of the first argument.

Comparisons

The INPUTN function enables you to specify a numeric informat at run time.

Example

This example shows how to specify character informats.

```sas
data _null_;
dcl char(10) type type2;
method init();
  type=inputc('positive', '$upcase15.');
  type2=inputc('positive', '$upcase15.', 3);
  put type=;
  put type2=;
end;
enddata;
run;
```
The following line is written to the SAS log.

type=POSITIVE
type2=POS

See Also

Functions:
- “INPUTN Function” on page 366
- “PUT Function” on page 553

**INPUTN Function**

Enables you to specify a numeric informat at run time.

**Category:** Special

**Returned data type:** DOUBLE

**Syntax**

```
INPUTN(source, informat[, w[, d]])
```

**Arguments**

**source**

specifies a character constant, variable, or expression to which you want to apply the informat.

Data type: CHAR

**informat**

is a character constant, variable, or expression that contains the numeric informat that you want to apply to source.

Data type: CHAR

**w**

is a numeric constant, variable, or expression that specifies a width to apply to the informat.

Interaction: If you specify a width here, it overrides any width specification in the informat.

Data type: INTEGER

**d**

is a numeric constant, variable, or expression that specifies the number of decimal places to use.

Interaction: If you specify a number here, it overrides any decimal-place specification in the informat.
Comparisons

The INPUTC function enables you to specify a character informat at run time. Using the PUT function is faster because you specify the informat at compile time.

Example

This example shows how to specify numeric informats.

```sas
data _null_;  
  method init();  
  declare double salary;  
  salary = inputn('20,000.00', 'comma10.2');  
  put salary=;  
end;  
enddata;  
run;  
```

SAS writes the following output to the log:

```
20000
```

See Also

Functions:
- “INPUTC Function” on page 364

`INT Function`

Returns the integer value, fuzzed to avoid unexpected floating-point results.

<table>
<thead>
<tr>
<th>Category</th>
<th>Truncation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

```
INT(expression)
```

Arguments

- `expression`
  - specifies any expression that evaluates to a numeric value.

Data type  DOUBLE

See

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*
Details
The INT function returns the integer portion of the argument (truncates the decimal portion). If the argument’s value is within 1E-12 of an integer, the function results in that integer. If the value of expression is positive, the INT function has the same result as the FLOOR function. If the value of expression is negative, the INT function has the same result as the CEIL function.

Comparisons
Unlike the INTZ function, the INT function fuzzes the result. If the argument is within 1E-12 of an integer, the INT function fuzzes the result to be equal to that integer. The INTZ function does not fuzz the result. Therefore, with the INTZ function, you might get unexpected results.

Example
The following statements illustrate the INT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>var1=2.1; a=int(var1);</td>
<td>2</td>
</tr>
<tr>
<td>a=int(-2.4);</td>
<td>-2</td>
</tr>
<tr>
<td>a=int(1+1.e-11);</td>
<td>1</td>
</tr>
<tr>
<td>a=int(-1.6);</td>
<td>-1</td>
</tr>
</tbody>
</table>

See Also
Functions:

- “INTZ Function” on page 410
- “MOD Function” on page 460
- “MODZ Function” on page 462
- “ROUND Function” on page 583

INTCINDEX Function
Returns the cycle index when a date, time, or timestamp interval and value are specified.

Category: Date and Time
Returned data type: INTEGER
Syntax

INTCINDEX(interval[multiple][.shift-index], date-time-value)

Arguments

interval[multiple][.shift-index] specifies a basic or complex interval. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The three parts of the interval name are as follows:

interval specifies a character constant, a variable, or an expression that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR

Note For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Tip Interval can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

multiple specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type INTEGER

See “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type INTEGER

See “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference
YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

date-time-value

specifies a date, time, or timestamp value that represents a time period of a specified interval.

Data type DOUBLE

Details

The INTCINDEX function returns the index of the seasonal cycle when you specify an interval and a DATE, TIME, or TIMESTAMP value. For example, if the interval is MONTH, each observation in the data corresponds to a particular month. Monthly data is considered to be periodic for a one-year period. A year contains 12 months, so the number of intervals (months) in a seasonal cycle (year) is 12. WEEK is the seasonal cycle for an interval that is equal to DAY. This example returns a value of 36 because September 1, 2013, is the sixth day of the 35th week of the year.

```sas
sasdate1=to_double(date'2013-09-01');
cycle_index1 = intcindex('day', sasdate1);
```

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

The INTCINDEX function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant.

Comparisons

The INTCINDEX function returns the cycle index, whereas the INTINDEX function returns the seasonal index.

In this example, the INTCINDEX function returns the week of the year.

```sas
sasdate1=to_double(date'04apr2013');
cycle_index = intcindex('day', sasdate1);
```

In this example, the INTINDEX function returns the day of the week.

```sas
sasdate1=to_double(date'04apr2013');
index = intindex('day', '04APR2013'd);
```

In this example, the INTCINDEX function returns the hour of the day.

```sas
sasts=to_double(timestamp '2012-09-01 00:00:00');
a= intcindex('minute', sasts);
```

In this example, the INTINDEX function returns the minute of the hour.

```sas
sasts=to_double(timestamp '2012-09-01 00:00:00');
a= intindex('minute', sasts);
```

In the example `intseas(intcycle('interval'))`, the INTSEAS function returns the maximum number that could be returned by `intcindex('interval', date)`.

Example

The following statements illustrate the INTCINDEX function:
### Statements

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sasdate1=to_double(date’2013-09-01’);</code></td>
<td>36</td>
</tr>
<tr>
<td><code>cycle_index1 = intcindex(‘day’, sasdate1);</code></td>
<td></td>
</tr>
<tr>
<td><code>put cycle_index1;</code></td>
<td></td>
</tr>
<tr>
<td><code>sascydate=to_double(timestamp ’2013-05-23 05:03:01’);</code></td>
<td>1</td>
</tr>
<tr>
<td><code>cycle_index1 = intcindex(‘dtqtr’, sascydate);</code></td>
<td></td>
</tr>
<tr>
<td><code>put cycle_index1;</code></td>
<td></td>
</tr>
<tr>
<td><code>sascydate=to_double(date’2013-12-13’);</code></td>
<td>1</td>
</tr>
<tr>
<td><code>cycle_index1 = intcindex(‘tenday’, sascydate);</code></td>
<td></td>
</tr>
<tr>
<td><code>put cycle_index1;</code></td>
<td></td>
</tr>
<tr>
<td><code>sascydate=to_double(time ’23:13:02’);</code></td>
<td>24</td>
</tr>
<tr>
<td><code>cycle_index1 = intcindex(‘minute’, sascydate);</code></td>
<td></td>
</tr>
<tr>
<td><code>put cycle_index1;</code></td>
<td></td>
</tr>
<tr>
<td><code>sascydate=to_double(timestamp ’2013-05-05 10:54:03’);</code></td>
<td>1</td>
</tr>
<tr>
<td><code>var1=’semimonth’;</code></td>
<td></td>
</tr>
<tr>
<td><code>cycle_index1 = intcindex(var1, sascydate);</code></td>
<td></td>
</tr>
<tr>
<td><code>put cycle_index1;</code></td>
<td></td>
</tr>
</tbody>
</table>

### INTCK Function

Returns the number of interval boundaries of a given kind that lie between two SAS dates, times, or timestamp values encoded as DOUBLE.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

#### Syntax

```
INTCK(interval[multiple][,shift-index], start-date, end-date[, ’method’])
INTCK(start-date, end-date[, ’method’])
```

---

**INTCK Function**

Returns the number of interval boundaries of a given kind that lie between two SAS dates, times, or timestamp values encoded as DOUBLE.
Arguments

interval[multiple][.shift-index]

specifies a basic or complex interval. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The three parts of the interval name are as follows:

interval

specifies a character constant, a variable, or an expression that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR

Note For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Tip Interval can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

multiple

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type INTEGER

See “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type INTEGER

See “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.
**start-date**

specifies an expression that represents the starting SAS date, time, or timestamp value.

Data type DOUBLE

**end-date**

specifies an expression that represents the ending SAS date, time, or timestamp value.

Data type DOUBLE

'method'

specifies that intervals are counted using either a discrete or a continuous method.

You must enclose method in quotation marks. Method can be one of these values:

CONTINUOUS

specifies that continuous time is measured. The interval is shifted based on the starting date.

For example, the distance in months between January 15, 2013, and February 15, 2013, is one month.

Alias C or CONT

DISCRETE

specifies that discrete time is measured. The discrete method counts interval boundaries (for example, end of month).

The default discrete method is useful to sort time series observations into bins for processing. For example, daily data can be accumulated to monthly data for processing as a monthly series.

For the DISCRETE method, the distance in months between January 31, 2013, and February 1, 2013, is one month.

Alias D or DISC

Default DISCRETE

Data type CHAR

**Details**

(Calendar Interval Calculations)

All values within a discrete time interval are interpreted as being equivalent. This means that the dates of January 1, 2013 and January 15, 2013 are equivalent when you specify a monthly interval. Both of these dates represent the interval that begins on January 1, 2013 and ends on January 31, 2013. You can use the date for the beginning of the interval (January 1, 2013) or the date for the end of the interval (January 31, 2013) to identify the interval. These dates represent all of the dates within the monthly interval.

In the following example, the start-date (Jan. 14, 2013) is equivalent to the first quarter of 2013.

```
sasdate1=to_double(date'2013-01-14');
sasdate2 = to_double(date'2013-09-02');
qtr=intck('qtr', sasdate1, sasdate2);
```
The end-date (September 2, 2013) is equivalent to the third quarter of 2013. The interval count, that is, the number of times the beginning of an interval is reached in moving from the start-date to the end-date is 2.

The INTCK function using the default discrete method counts the number of times the beginning of an interval is reached in moving from the first date to the second. It does not count the number of complete intervals between two dates:

- The following example returns 0, because the two dates are within the same month.
  ```sas
  sasdate1=to_double(date'2013-01-01');
  sasdate2 = to_double(date'2013-01-31');
  month=intck(month, sasdate1, sasdate2);
  put month;
  ```

- The following example returns 1, because the two dates lie in different months that are one month apart.
  ```sas
  sasdate1=to_double(date'2013-01-31');
  sasdate2 = to_double(date'2013-02-01');
  month=intck(month, sasdate1, sasdate2);
  put month;
  ```

- The following example returns –1 because the first date is in a later discrete interval than the second date. (INTCK returns a negative value whenever the first date is later than the second date and the two dates are not in the same discrete interval.)
  ```sas
  sasdate1=to_double(date'2013-02-01');
  sasdate2 = to_double(date'2013-01-31');
  month=intck('month', sasdate1, sasdate2);
  put month;
  ```

Using the discrete method, WEEK intervals are determined by the number of Sundays, the default first day of the week, that occur between the start-date and the end-date, and not by how many seven-day periods fall between those dates. To count the number of seven-day periods between start-date and end-date, use the continuous method.

Both the multiple and the shift-index arguments are optional and default to 1. For example, YEAR, YEAR1, YEAR.1, and YEAR1.1 are all equivalent ways of specifying ordinary calendar years.

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

### Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in *SAS Viya Functions and CALL Routines: Reference*.

### Example

The following statements illustrate the INTCK function:
In the second example, INTCK returns a value of 1 even though only one day has elapsed. This result is returned because the interval from December 31, 2012, to January 1, 2013, contains the starting point for the YEAR interval. However, in the third example, a value of 0 is returned even though 364 days have elapsed. This result is because the period between January 1, 2013, and December 31, 2013, does not contain the starting point for the interval.

In the fourth example, SAS returns a value of 6 because January 1, 2010, through January 1, 2013, contains six semiyearly intervals. (Note that if the ending date were December 31, 2012, SAS would count five intervals.) In the fifth example, SAS returns a value of 6 because there are six two-week intervals beginning on a first Monday during the period of January 7, 2013, through April 1, 2013. In the sixth example, SAS returns the value 27. That indicates that beginning with January 1, 2013, and counting only Saturdays as weekend days through February 1, 2013, the period contains 27 weekdays.

In the seventh example, the use of variables for the arguments is illustrated.

<table>
<thead>

Functions:

- “INTDT Function” on page 381
- “INTNX Function” on page 393
- “INTTS Function” on page 409

INTCYCLE Function

Returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or
datetime interval is specified.

Category: Date and Time

Returned data type: VARCHAR, NVARCHAR

Syntax

```
INTCYCLE(interval[.multiple][.shift-index][, seasonality])
```

Arguments

- `interval[.multiple][.shift-index]`
  specifies a basic or complex interval. Multipliers and shift indexes can be used with
  the basic interval names to construct more complex interval specifications. The three
  parts of the interval name are as follows:
  - `interval`
    specifies a character constant, a variable, or an expression that contains an
    interval name such as WEEK, MONTH, or QTR.
    Data type CHAR
  
  Note
  For more information, see “Date and Time Intervals” in SAS Viya
  Functions and CALL Routines: Reference.

  Tip
  Interval can appear in uppercase or lowercase.

  Example
  YEAR specifies year-based intervals.

- `multiple`
  specifies an optional multiplier that sets the interval equal to a multiple of the
  period of the basic interval type.
  Data type INTEGER

  See
  "Incrementing Dates and Times By Using Multipliers and By
  Shifting Intervals"

  Example
  YEAR2 specifies a two-year, or biennial, interval type.
shift-index

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions

The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type

INTEGER

See

"Incrementing Dates and Times By Using Multipliers and By Shifting Intervals"

Example

YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

seasonality

specifies a numeric value.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

Default

52

Data type

INTEGER, CHAR

Example

The seasonality argument in the following example

\[
\text{INTCYCLE('MONTH', 3)};
\]

causes the function call to return the value QTR. The function call

\[
\text{INTCYCLE('MONTH')};
\]

does not have a seasonality argument and returns the value YEAR.

Details

The Basics

The INTCYCLE function returns the interval of the seasonal cycle, depending on a date, time, or datetime interval. For example, INTCYCLE('MONTH'); returns the value YEAR because the months from January through December constitute a yearly cycle. INTCYCLE('DAY'); returns the value WEEK because the days from Sunday through Saturday constitute a weekly cycle.
For information about multipliers and shift indexes, how intervals are calculated, and working with data and time intervals, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

The INTCYCLE function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

**Seasonality**

Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTCYCLE function uses the concept of seasonality and returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or datetime interval is specified. For more information about seasonality and using the forecasting methods in PROC FORECAST, see the SAS/ETS User’s Guide.

**Example**

The following statements illustrate the INTCYCLE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>cycle_year=intcycle('year'); put cycle_year;</td>
<td>YEAR</td>
</tr>
<tr>
<td>cycle_quarter=intcycle('qtr'); put cycle_quarter;</td>
<td>YEAR</td>
</tr>
<tr>
<td>cycle_3=intcycle('month', 3); put cycle_3;</td>
<td>QTR</td>
</tr>
<tr>
<td>cycle_month=intcycle('month'); put cycle_month;</td>
<td>YEAR</td>
</tr>
<tr>
<td>cycle_weekday=intcycle('weekday'); put cycle_weekday;</td>
<td>WEEK</td>
</tr>
<tr>
<td>cycle_weekday2=intcycle('weekday', 5); put cycle_weekday2;</td>
<td>WEEK</td>
</tr>
<tr>
<td>cycle_day=intcycle('day'); put cycle_day;</td>
<td>WEEK</td>
</tr>
<tr>
<td>cycle_day2=intcycle('day', 10); put cycle_day2;</td>
<td>TENDAY</td>
</tr>
<tr>
<td>var1='second'; cycle_second=intcycle(var1); put cycle_second;</td>
<td>DTMINUTE</td>
</tr>
</tbody>
</table>
INTDT Function

Specifies the number of days to add to a DATE value.

**Category:** Date and Time

**Returned data type:** DATE

**Syntax**

INTDT(expression, increment)

**Arguments**

*expression*  
specifies any valid expression that represents a DATE value.  

Data type: DATE

*increment*  
specifies a negative, positive, or zero integer that represents the number of days to add to the date.  

Data type: INTEGER

**Details**

The INTDT function increments a DATE value by the number of days that you specify.

**Comparisons**

The INTNX function increments a SAS date, time, or datetime value that is encoded as a DOUBLE value.

**Example**

The following statements illustrate the INTDT function:
### INTFIT Function

Returns a time interval that is aligned between two dates.

**Category:** Date and Time  
**Returned data type:** CHAR

**Syntax**

\[
\text{INTFIT}(expression-1, expression-2, 'type')
\]

**Arguments**

*expression*

specifies any valid expression that represents a SAS date or datetime value.  
**Data type** DOUBLE

*type'*

specifies whether the arguments are SAS date values, datetime values, or a row. The following values for type are valid:

- d specifies that expression-1 and expression-2 are date values.  
- dt specifies that expression-1 and expression-2 are datetime values.  
- obs specifies that expression-1 and expression-2 are rows.  

**See**  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*
Details

The INTFIT function returns the most likely time interval based on two dates, datetime values, or rows that have been aligned within an interval. INTFIT assumes that the alignment value is SAME, which specifies that the date is aligned to the same calendar date with the corresponding interval increment. For more information about the alignment argument, see “INTNX Function” on page 393.

If the arguments that are used with INTFIT are rows, you can determine the cycle of an occurrence by using row numbers. In the following example, the first two arguments of INTFIT are row numbers, and the type argument is obs. If Jason used the gym the first time and the 25th time that a researcher recorded data, you could determine the interval by using the following statement: `interval=intfit(1, 25, 'obs');`. In this case, the value of interval is OBS24.2.

For information about time series, see the SAS/ETS 9.3 User’s Guide.

The INTFIT function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Example

The following example shows the interval that is aligned between two dates. The type argument in this example identifies the input as date values.

```sas
data test;
  dcl char(10) c;
  dcl double sasdate1 sasdate2;
  method run();
    sasdate1=to_double(date'2013-08-01');
    sasdate2=to_double(date'2013-09-01');
    c=intfit(sasdate1, sasdate2, 'd');
    put c;
  end;
enddata;
run;
```

The following line is written to the SAS log.

```
MONTH
```

 Functions:

- “INTCK Function” on page 371
- “INTNX Function” on page 393

INTGET Function

Returns a time interval based on three date or datetime values.

**Category:** Date and Time  
**Returned data type:** NCHAR, NVARCHAR
Syntax

INTGET(date-1, date-2, date-3)

Argument
date

specifies any valid expression that evaluates to a SAS date or datetime value.

Data type DOUBLE

Details

**INTGET Function Intervals**

The INTGET function returns a time interval based on three date or datetime values. The function first determines all possible intervals between the first two dates, and then determines all possible intervals between the second and third dates. If the intervals are the same, INTGET returns that interval. If the intervals for the first and second dates differ, and the intervals for the second and third dates differ, INTGET compares the intervals. If one interval is a multiple of the other, then INTGET returns the smaller of the two intervals. Otherwise, INTGET returns a missing value. INTGET works best with dates generated by the INTNX function whose alignment value is BEGIN.

In the following example, INTGET returns the interval DAY2:

```sas
interval=intget('01mar00'd, '03mar00'd, '09mar00'd);
```

The interval between the first and second dates is DAY2, because the number of days between March 1, 2000, and March 3, 2000, is two. The interval between the second and third dates is DAY6, because the number of days between March 3, 2000, and March 9, 2000, is six. DAY6 is a multiple of DAY2. INTGET returns the smaller of the two intervals.

In the following example, INTGET returns the interval MONTH4:

```sas
interval=intget('01jan00'd, '01may00'd, '01may01'd);
```

The interval between the first two dates is MONTH4, because the number of months between January 1, 2000, and May 1, 2000, is four. The interval between the second and third dates is YEAR. INTGET determines that YEAR is a multiple of MONTH4 (there are three MONTH4 intervals in YEAR), and returns the smaller of the two intervals.

In the following example, INTGET returns a missing value:

```sas
interval=intget('01Jan2006'd, '01Apr2006'd, '01Dec2006'd);
```

The interval between the first two dates is MONTH3, and the interval between the second and third dates is MONTH8. INTGET determines that MONTH8 is not a multiple of MONTH3, and returns a missing value.

The intervals that are returned are valid SAS intervals, including multiples of the intervals and shift intervals. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

**Note:** If INTGET cannot determine a matching interval, then the function returns a missing value. No message is written to the SAS log.
Retail Calendar Intervals
The INTGET function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Retail Calendar Intervals: ISO 8601 Compliant" in “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Example
The following statements illustrate the INTGET function:

<table>
<thead>
<tr>

Functions:
- “INTFIT Function” on page 382
- “INTNX Function” on page 393
INTINDEX Function

Returns the seasonal index when a date, time, or timestamp interval and value are specified.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

\[
\text{INTINDEX}(\text{interval}[\text{multiple}][.\text{shift-index}], \text{date-value}[, \text{seasonality}])
\]

**Arguments**

- **interval[.multiple][.shift-index]**
  - specifies a basic or complex interval. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The three parts of the interval name are as follows:

  - **interval** specifies a character constant, a variable, or an expression that contains an interval name such as WEEK, MONTH, or QTR.
    
    **Data type** CHAR

  - **Note** For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

  - **Tip** Interval can appear in uppercase or lowercase.

  - **Example** YEAR specifies year-based intervals.

- **multiple** specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

  **Data type** INTEGER

  **See** “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

  **Example** YEAR2 specifies a two-year, or biennial, interval type.

- **shift-index** specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

  **Restrictions** The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

  If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH
subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

**Data type** INTEGER

**See** “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

**Example** YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

date-value

specifies a date, time, or timestamp value that represents a time period of the given interval.

**Data type** DOUBLE

seasonality

specifies a number or a cycle.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

**Data type** INTEGER, CHAR

**Example** In this example, the following functions produce the same result.

```
INTINDEX('MONTH', sasdate, 3);
INTINDEX('MONTH', sasdate, 'QTR');
```

*Seasonality* in the first example is a number (the number of months), and in the second example *seasonality* is a cycle (QTR).

**Details**

**INTINDEX Function Intervals**

The INTINDEX function returns the seasonal index when you supply an interval and an appropriate date, time, or timestamp value. The seasonal index is a number that represents the position of the date, time, or timestamp value in the seasonal cycle of the specified interval. This example returns a value of 12 because there are 12 months in a yearly cycle and December is the 12th month of the year.

```
sasdate=to_double(date'2012-12-01');
x=intindex('month', sasdate);
put x;
```

In the following examples, INTINDEX returns the same value (1) because both statements have dates that occur in the first quarter of the year 2013.

```
sasdate=to_double(date'2013-01-01');
x=intindex('qtr', sasdate);
put x;
```
Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTINDEX function uses the concept of seasonality and returns the seasonal index when a date, time, or timestamp interval and value are specified. For more information about seasonality and using the forecasting methods in PROC FORECAST, see the SAS/ETS User's Guide.
Comparisons

The INTINDEX function returns the seasonal index whereas the INTCINDEX function returns the cycle index.

In the following example, the INTINDEX function returns 5 because April 4, 2013 is on a Thursday, the fifth day of the week.

```sas
sasdate=to_double(date'2013-04-04');
x = intindex('day', sasdate);
put x;
```

Using the same date, the INTCINDEX function returns 14 because April 4, 2013 is the 14th week of the year.

```sas
sasdate=to_double(date'2013-04-04');
x = intcindex('day', sasdate);
put x;
```

In this example, the INTINDEX function returns the minute of the hour.

```sas
sasdate=to_double(timestamp'2012-09-01 06:05:04');
x = intindex('minute', sasdate);
put x;
```

Using the same date and time, the INTCINDEX function returns the hour of the day.

```sas
sasdate=to_double(timestamp'2012-09-01 06:05:04');
y = intcindex('minute', sasdate);
put y;
```

In the example `intseas('interval')`, INTSEAS returns the maximum number that could be returned by `intindex('interval', date);`.

Example

The following statements illustrate the INTINDEX function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sasdate1=to_double(date'2013-08-14'); interval1 = intindex('qtr', sasdate1); put interval1;</code></td>
<td>3</td>
</tr>
<tr>
<td><code>sastime1=to_double(time'09:05:15'); interval3 = intindex('hour', sastime1); put interval3;</code></td>
<td>10</td>
</tr>
<tr>

<tr>
<td><code>sastime1=to_double(timestamp'2013-05-28 05:15:00'); interval5 = intindex('dtmonth', sastime1); put interval5;</code></td>
<td>5</td>
</tr>
</tbody>
</table>
INTNEST Function

Calculates the number of whole periods of the smaller interval that will fit into the period of the larger interval.

**Category:** Date and Time  
**Returned data type:** DOUBLE

**Syntax**

INTNEST(interval1, interval2)

**Required Arguments**

(interval1)  
specifies the first interval.  
Data type: CHAR

(interval2)  
specifies the second interval.  
Data type: CHAR

---

Details

An interval nests within another interval when a whole number of the first interval spans the same time period as the second interval for all time periods. In order to nest, the two intervals must generate beginning and ending dates that align.

If the first interval, `interval1`, spans a larger time period than the second interval, `interval2`, then the returned number is positive. If the second interval spans a larger period than the first interval, then the returned number is negative.

The following time series tasks are related to the INTNEST function:

accumulation
   if one interval nests into another interval, even with a variable number, accumulation from the smaller time periods into the larger time periods is accomplished with a simple rule. If the intervals do not nest, consider transforming a time series from one frequency to another with a more complex rule (for example, an interpolation).

seasonality
   many seasonal models require that the higher frequency interval nest into the lower frequency seasonal interval with a fixed number of periods.

time reconciliation
   time reconciliation requires that the higher frequency interval nest into the lower frequency interval.

The following table contains the types and descriptions of results that are returned by the INTNEST function:

<table>
<thead>
<tr>
<th>Result</th>
<th>Description</th>
<th>Explanation or Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Same</td>
<td>The two input intervals define the same time periods for all time periods.</td>
</tr>
<tr>
<td>1</td>
<td>Variable Number</td>
<td>The first interval contains a whole number of periods of the second interval, but the number varies over time.</td>
</tr>
<tr>
<td>-1</td>
<td>Variable Number</td>
<td>The second interval contains a whole number of periods of the first interval, but the number varies over time.</td>
</tr>
<tr>
<td>n &gt; 1</td>
<td>Fixed Number</td>
<td>The first interval contains a whole number n periods of the second interval, and that is fixed for all time.</td>
</tr>
<tr>
<td>n &lt; -1</td>
<td>Fixed Number</td>
<td>The second interval contains a whole number n periods of the first interval, and that is fixed for all time.</td>
</tr>
<tr>
<td>Result</td>
<td>Description</td>
<td>Explanation or Example</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------</td>
<td>----------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Missing value of M</td>
<td>Multiple Mismatch</td>
<td>Both intervals cannot nest into the other interval. However, intervals of these types can nest for some multiple values. intnest('semimonth3', 'month')</td>
</tr>
<tr>
<td>Missing value of S</td>
<td>Shift Mismatch</td>
<td>Both intervals cannot nest into the other interval. However, if a shift value is changed, then either the intervals would be the same or one interval would nest into the other. intnest('semimonth2.2', 'month')</td>
</tr>
<tr>
<td>Missing value of B</td>
<td>Base Mismatch</td>
<td>The interval bases define time periods that are so different that nesting is not possible for any multiple or shift. For example, YEAR always begins on January 1 of each year and is shifted by months. However, YEARV always begins on the Monday on or immediately preceding January 4, and YEARV is shifted by ISO 8601 weeks that begin on Monday. Since January 1 is only a Monday for some years, the intervals will not consistently start on the same day. The same problem exists if the YEAR interval is shifted by months, since the first of a month would not be a Monday for all years. intnest('year', 'yearv')</td>
</tr>
</tbody>
</table>

**Example**

The following example illustrates the relationship between two intervals that nest. Both intervals are either date intervals or datetime intervals. For each observation, the value that is calculated for begin1 is the same as begin2, and the value that is calculated for end1 is the same as end2.

```sas
/* interval1 and interval2 are any 2 valid intervals */
nest=INNEST(interval1, interval2);
/* If interval1 and interval2 are date intervals, then start and end are any SAS date values. If interval1 and interval2 are datetime intervals, then start and end are SAS datetime values. This algorithm would need to be modified if a SAS date interval is compared to a SAS datetime interval. */
do date=start to end;
   if ( ( nest = .B ) or
       ( nest = .M ) or
       ( nest = .S ) ) then do;
      /* skip this case as the rule does not apply */
      end;
   else if ( nest = 0 ) then do;
      begin1=INTNX(interval1, date, 0);
      begin2=INTNX(interval2, date, 0);
      end1=INTNX(interval1, date, nest, 'E');
      end2=INTNX(interval2, date, nest, 'E');
      end;
   else if ( nest = 1 ) then do;
```
begin1=INTNX(interval1,date,0);  
end1=INTNX(interval1,date,0,'E');  
n=INTCK(interval2,begin1,end1);  
begin2=INTNX(interval2,begin1,0);  
end2=INTNX(interval2,begin2,n,'E');  
end;
else if ( nest = -1 ) then do;  
begin2=INTNX(interval2,date,0);  
end2=INTNX(interval2,date,0,'E');  
n=INTCK(interval1,begin2,end2);  
begin1=INTNX(interval1,begin2,0);  
end1=INTNX(interval1,begin1,n,'E');  
end;
else if ( nest > 1 ) then do;  
begin1=INTNX(interval1,date,0);  
begin2=INTNX(interval2,begin1,0);  
end1=INTNX(interval1,date,0,'E');  
end2=INTNX(interval2,begin2,nest-1,'E');  
end;
else if ( nest < 1 ) then do;  
begin2=INTNX(interval2,date,0);  
begin1=INTNX(interval1,begin2,0);  
end1=INTNX(interval1,begin1,(-nest)-1,'E');  
end2=INTNX(interval2,date,0,'E');  
end;
output;
end;

INTNX Function

Increments a SAS date, time, or datetime value encoded as a DOUBLE, and returns a SAS date, time, or datetime value encoded as a DOUBLE.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

\[
\text{INTNX}(\text{interval[multiple][.shift-index], start-from, increment[, 'alignment']})
\]

\[
\text{INTNX}(\text{start-from, increment[, 'alignment']})
\]

**Arguments**

*interval[multiple][.shift-index]*

specifies a basic or complex interval. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The three parts of the interval name are as follows:

*interval*

specifies a character constant, a variable, or an expression that contains an interval name such as WEEK, MONTH, or QTR.
Data type CHAR

Note For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Tip Interval can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

multiple

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type INTEGER

See “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type INTEGER

See “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

start-from

specifies an expression that represents a SAS date, time, or datetime value encoded as a DOUBLE and that identifies a starting point.

Data type DOUBLE
**increment**
specifies a negative, positive, or zero integer that represents the number of date, time, or datetime intervals. Increment is the number of intervals to shift the value of start-from.

Data type INTEGER

'**alignment**'
controls the position of SAS dates within the interval. You must enclose alignment in quotation marks. Alignment can be one of these values:

BEGINNING
specifies that the returned date or datetime value is aligned to the beginning of the interval.

Alias B

MIDDLE
specifies that the returned date or datetime value is aligned to the midpoint of the interval, which is the average of the beginning and ending alignment values.

Alias M

END
specifies that the returned date or datetime value is aligned to the end of the interval.

Alias E

SAME
specifies that the date that is returned has the same alignment as the input date.

Alias S

**SAME DAY**

See “SAME Alignment” on page 396

Default BEGINNING

Data type CHAR

See “Aligning SAS Date Output within Its Intervals” on page 396

**Details**

**The Basics**
The INTNX function increments a date, time, or datetime value by intervals such as DAY, WEEK, QTR, and MINUTE, or a custom interval that you define. The increment is based on a starting date, time, or datetime value, and on the number of time intervals that you specify.

The INTNX function returns the SAS date value for the beginning date, time, or datetime value of the interval that you specify in the start-from argument. (To convert the date value to a calendar date, use any valid DS2 date format, such as the DATE9. format.) The following example shows how to determine the date of the start of the week that is six weeks from the week of October 17, 2011.
sasdate=to_double(date'2011-10-17');
x=intnx('week', sasdate, 6);
put x date9.;

INTNX returns the value 27NOV2011.

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Aligning SAS Date Output within Its Intervals

SAS date values are typically aligned with the beginning of the time interval that is specified with the interval argument.

You can use the optional alignment argument to specify the alignment of the date that is returned. The values BEGINNING, MIDDLE, or END align the date to the beginning, middle, or end of the interval, respectively.

SAME Alignment

If you use the SAME value of the alignment argument, then INTNX returns the same calendar date after computing the interval increment that you specified. The same calendar date is aligned based on the interval's shift period, not the interval. To view the valid shift periods, see “Intervals by Category” on page 374.

Most of the values of the shift period are equal to their corresponding intervals. The exceptions are the intervals WEEK, WEEKDAY, QTR, SEMIYEAR, YEAR, and their DT counterparts. WEEK and WEEKDAY intervals have a shift period of DAYS; and QTR, SEMIYEAR, and YEAR intervals have a shift period of MONTH. When you use SAME alignment with YEAR, for example, the result is same-day alignment based on MONTH, the interval's shift period. The result is not aligned to the same day of the YEAR interval. If you specify a multiple interval, then the default shift interval is based on the interval, and not on the multiple interval.

When you use SAME alignment for QTR, SEMIYEAR, and YEAR intervals, the computed date is the same number of months from the beginning of the interval as the input date. The day of the month matches as closely as possible. Because not all months have the same number of days, it is not always possible to match the day of the month.

For more information about shift periods, see “Intervals by Category” on page 374.

Alignment Intervals

Use the SAME value of the alignment argument if you want to base the alignment of the computed date on the alignment of the input date.

```sas
/*** returns 22MAR2011 ****/
dcl double x having format date9.;
sasdate=to_double(date'2011-03-15');
x=intnx('week', sasdate, 1, 'same');
put x;

/*** returns 22MAR11:08:45:00  ****/
dcl double y having format datetime.;
method init();
sasdt=to_double(timestamp'2011-03-15 08:45:00');
y=intnx('dtweek', sasdt, 1, 'same');
put y;

/*** returns 15MAR2016 ****/
```
dcl double z having format date9.;
sasdate=to_double(date'2011-03-15');
z=intnx('year', sasdate, 5, 'same');
put z;

Adjusting Dates
The INTNX function automatically adjusts for the date if the date in the interval that is
incremented does not exist. Here is an example:

/*** returns 15AUG2011 ***/
dcl double a having format date9.;
sasdate=to_double(date'2011-03-15');
a=intnx('month', sasdate, 5, 'same');
put a;

/*** returns 28FEB2014 ***/
dcl double b having format date9.;
sasdate=to_double(date'2012-02-29');
b=intnx('year', sasdate, 2, 'same');
put b;

/*** returns 30SEP2011 ***/
dcl double c having format date9.;
sasdate=to_double(date'2011-08-31');
c=intnx('month', sasdate, 1, 'same');
put c;

/*** returns 01MAR2012 (the 1st day of the 3rd month of the year) ***/
dcl double d having format date9.;
sasdate=to_double(date'2011-03-01');
d=intnx('year', sasdate, 1, 'same');
put d;

/*** returns 29FEB2012 (the 60th day of the year) ***/
dcl double d having format date9.;
sasdate=to_double(date'2011-03-01');
d=intnx('year', sasdate, 1, 'same', 'day');
put d;

In the following example, the INTNX function returns the value 01JAN2014, which is
the beginning of the year two years from the starting date (29FEB2012).

dcl double a having format date9.;
sasdate=to_double(date'2012-02-29');
a=intnx('year', sasdate, 2);
put a;

In this example, the INTNX function returns the value 28FEB2014. In this case, the
starting date begins in the year 2012, the year is two years later (2014), the month is the
same (February), and the date is the 28th, because that is the closest date to the 29th in
February 2014.

dcl double b having format date9.;
sasdate=to_double(date'2012-02-29');
b=intnx('year', sasdate, 2, 'same');
Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Examples

Example 1: Using the INTNX Function

The following statements illustrate the INTNX function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>sasdate1 = to_double(date'2013-02-05'); yr=intnx('year', sasdate1, 3); put yr; put yr date7.;</td>
<td>20454 01Jan16</td>
</tr>
<tr>
<td>sasdate1 = to_double(date'2013-01-05'); x=intnx('month', sasdate1, 0); put x; put x date7.;</td>
<td>19359 01JAN13</td>
</tr>
<tr>
<td>sasdate1 = to_double(date'2013-01-01'); next=intnx('semiyear', sasdate1, 1); put next; put next date7.;</td>
<td>19540 01JUL13</td>
</tr>
<tr>
<td>sasdate1 = to_double(date'2012-08-01'); past=intnx('month2', sasdate1, -1); put past; put past date7.;</td>
<td>19114 01MAY12</td>
</tr>
<tr>
<td>sasdate1 = to_double(date'2013-04-01'); sm=intnx('semimonth2.2', sasdate1, 4); put sm; put sm date7.;</td>
<td>19555 16JUL13</td>
</tr>
<tr>
<td>x='month'; sasdate1 = to_double(date'2013-06-01'); nextmon=intnx(x, sasdate1, 1); put nextmon; put nextmon date7.;</td>
<td>19540 01JUL13</td>
</tr>
<tr>
<td>m1='month     '; m2=trim(m1); sasdate1 = to_double(date'2012-06-15'); x=intnx(m2, sasdate1, 1); put x; put x date7.;</td>
<td>19175 01JUL12</td>
</tr>
</tbody>
</table>
**Example 2: Using the ALIGNMENT Argument**

The following examples show the results of advancing a date by using the optional alignment argument.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sasdate1 = to_double(date'2013-01-01');</code></td>
<td>19510</td>
</tr>
<tr>
<td><code>x=intnx('month', sasdate1, 5, 'beginning');</code></td>
<td>01JUN13</td>
</tr>
<tr>
<td><code>put x;</code></td>
<td></td>
</tr>
<tr>
<td><code>put x date7.;</code></td>
<td></td>
</tr>
<tr>
<td><code>sasdate1 = to_double(date'2013-01-01');</code></td>
<td>19524</td>
</tr>
<tr>
<td><code>x=intnx('month', sasdate1, 5, 'middle');</code></td>
<td>15JUN13</td>
</tr>
<tr>
<td><code>put x;</code></td>
<td></td>
</tr>
<tr>
<td><code>put x date7.;</code></td>
<td></td>
</tr>
<tr>
<td><code>sasdate1 = to_double(date'2013-01-01');</code></td>
<td>19539</td>
</tr>
<tr>
<td><code>x=intnx('month', sasdate1, 5, 'end');</code></td>
<td>30JUN13</td>
</tr>
<tr>
<td><code>put x;</code></td>
<td></td>
</tr>
<tr>
<td><code>put x date7.;</code></td>
<td></td>
</tr>
<tr>
<td><code>sasdate1 = to_double(date'2013-01-01');</code></td>
<td>19510</td>
</tr>
<tr>
<td><code>x=intnx('month', sasdate1, 5, 'sameday');</code></td>
<td>01JUN13</td>
</tr>
<tr>
<td><code>put x;</code></td>
<td></td>
</tr>
<tr>
<td><code>put x date7.;</code></td>
<td></td>
</tr>
<tr>
<td><code>sasdate1 = to_double(date'2013-01-15');</code></td>
<td>19585</td>
</tr>
<tr>
<td><code>x=intnx('month', sasdate1, 5, 'same');</code></td>
<td>15AUG13</td>
</tr>
<tr>
<td><code>put x;</code></td>
<td></td>
</tr>
<tr>
<td><code>put x date7.;</code></td>
<td></td>
</tr>
<tr>
<td>interval='month';</td>
<td>19667</td>
</tr>
<tr>
<td>align='m';</td>
<td>15NOV13</td>
</tr>
<tr>
<td><code>sasdate1 = to_double(date'2013-09-01');</code></td>
<td></td>
</tr>
<tr>
<td><code>x=intnx(interval, sasdate1, 2, align);</code></td>
<td></td>
</tr>
<tr>
<td><code>put x;</code></td>
<td></td>
</tr>
<tr>
<td><code>put x date7.;</code></td>
<td></td>
</tr>
<tr>
<td>m1='month';</td>
<td>19312</td>
</tr>
<tr>
<td>m2=trim(m1);</td>
<td>15NOV12</td>
</tr>
<tr>
<td><code>sasdate1 = to_double(date'2012-09-01');</code></td>
<td></td>
</tr>
<tr>
<td><code>x=intnx(m2, sasdate1, 2, 'm');</code></td>
<td></td>
</tr>
<tr>
<td><code>put x;</code></td>
<td></td>
</tr>
<tr>
<td><code>put x date7.;</code></td>
<td></td>
</tr>
</tbody>
</table>

**See Also**

**Concepts:**

**Functions:**

- “INTCK Function” on page 371
INTRR Function

Returns the internal rate of return as a decimal value.

**Category:** Financial

**Returned data type:** DOUBLE

**Syntax**

\[ \text{INTRR}(freq, c1, c2[, \ldots, cn]) \]

**Arguments**

- **freq**
  - Specifies the number of payments over a specified base period of time that is associated with the desired internal rate of return.
  - **Range**: \( freq > 0 \)
  - **Data type**: DOUBLE
  - **Tip**: The case \( freq = 0 \) is a flag to allow continuous compounding.

- **\( c1, c2, \ldots, cn \)**
  - Specifies the cash payments.
  - **Requirement**: At minimum, two cash payments are required.
  - **Data type**: DOUBLE

**Details**

The INTRR function returns the internal rate of return over a specified base period of time for the set of cash payments \( c0, c1, \ldots, cn \). The time intervals between any two consecutive payments are assumed to be equal. The argument \( freq > 0 \) describes the number of payments that occur over the specified base period of time. The number of notes issued from each instance is limited.

The internal rate of return is the interest rate such that the sequence of payments has a 0 net present value. (See the “NPV Function” on page 498.) It is given by the following equation.

\[
    r = \begin{cases} 
        \frac{1}{freq} - 1 & \text{if } freq > 0 \\
        -\log_x (\text{npv}) & \text{if } freq = 0 
    \end{cases}
\]

In this equation, \( x \) is the real root of the polynomial.
\[ \sum_{i=0}^{n} c_i x^i = 0 \]

In the case of multiple roots, one real root is returned and a warning is issued concerning the non-uniqueness of the returned internal rate of return. Depending on the value of payments, a root for the equation does not always exist. In that case, a missing value is returned.

Missing values in the payments are treated as 0 values. When \( freq > 0 \), the computed rate of return is the effective rate over the specified base period. To compute a quarterly internal rate of return (the base period is three months) with monthly payments, set \( freq \) to 3.

If \( freq \) is 0, continuous compounding is assumed and the base period is the time interval between two consecutive payments. The computed internal rate of return is the nominal rate of return over the base period. To compute with continuous compounding and monthly payments, set \( freq \) to 0. The computed internal rate of return will be a monthly rate.

**Comparisons**

The IRR function is identical to INTRR, except for in the IRR function, the internal rate of return is a percentage.

**Example**

For an initial outlay of $400 and expected payments of $100, $200, and $300 over the following three years, the annual internal rate of return can be expressed as

\[
\text{rate} = \text{intrr}(1, -400, 100, 200, 300);
\]

The value that is returned is 0.19437709962747.

Functions:
- “IRR Function” on page 414

---

**INTSEAS Function**

Returns the length of the seasonal cycle when a date, time, or datetime interval is specified.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

\[
\text{INTSEAS}(\text{interval}[\text{multiple}][\text{shift-index}][, \text{seasonality}])
\]
**Arguments**

\textit{interval}[\textit{multiple}][.\textit{shift-index}]  

specifies a basic or complex interval. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The three parts of the interval name are as follows:

- **interval**
  
specifies a character constant, a variable, or an expression that contains an interval name such as WEEK, MONTH, or QTR.

  Data type: CHAR  

- **multiple**
  
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

  Data type: INTEGER  

  See: “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

- **shift-index**
  
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

  Restrictions: The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

  If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

  Data type: INTEGER  

  See: “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

- **Example**
  
YEAR specifies year-based intervals.

YEAR2 specifies a two-year, or biennial, interval type.

YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.
The INTSEAS function returns the number of intervals in a seasonal cycle. For example, when the interval for a time series is described as monthly, then many procedures use the option INTERVAL=MONTH. Each observation in the data then corresponds to a particular month. Monthly data is considered to be periodic for a one-year period. A year contains 12 months, so the number of intervals (months) in a seasonal cycle (year) is 12.

Quarterly data is also considered to be periodic for a one-year period. A year contains four quarters, so the number of intervals in a seasonal cycle is four.

The periodicity is not always one year. For example, INTERVAL=DAY is considered to have a period of one week. Because there are seven days in a week, the number of intervals in the seasonal cycle is seven.

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Retail Calendar Intervals
The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Seasonality
Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTSEAS function uses the concept of seasonality and returns the length of the seasonal cycle when a date, time, or datetime interval is specified. For more information about seasonality and forecasting, see the SAS/ETS User's Guide.

Example
The following statements illustrate the INTCYCLE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>cycle_years = intseas('year'); put cycle_years;</td>
<td>1</td>
</tr>
<tr>
<td>cycle_smiyears = intseas('semiyear'); put cycle_smiyears;</td>
<td>2</td>
</tr>
<tr>
<td>cycle_quarters = intseas('quarter'); put cycle_quarters;</td>
<td>4</td>
</tr>
<tr>
<td>cycle_number = intseas('month', 'qtr'); put cycle_number;</td>
<td>3</td>
</tr>
<tr>
<td>cycle_months = intseas('month'); put cycle_months;</td>
<td>12</td>
</tr>
<tr>
<td>cycle_smimonths = intseas('semimonth'); put cycle_smimonths;</td>
<td>24</td>
</tr>
<tr>
<td>cycle_tendays = intseas('tenday'); put cycle_tendays;</td>
<td>36</td>
</tr>
<tr>
<td>cycle_weeks = intseas('week'); put cycle_weeks;</td>
<td>52</td>
</tr>
<tr>
<td>cycle_wkdays = intseas('weekday'); put cycle_wkdays;</td>
<td>5</td>
</tr>
<tr>
<td>cycle_hours = intseas('hour'); put cycle_hours;</td>
<td>24</td>
</tr>
<tr>
<td>cycle_minutes = intseas('minute'); put cycle_minutes;</td>
<td>60</td>
</tr>
<tr>
<td>cycle_month2 = intseas('month2.2'); put cycle_month2;</td>
<td>6</td>
</tr>
<tr>
<td>cycle_week2 = intseas('week2'); put cycle_week2;</td>
<td>26</td>
</tr>
<tr>
<td>var1 = 'month4.3'; cycle_var1 = intseas(var1); put cycle_var1;</td>
<td>3</td>
</tr>
<tr>
<td>cycle_day1 = intseas('day1'); put cycle_day1;</td>
<td>7</td>
</tr>
</tbody>
</table>

Functions:
INTSHIFT Function

Returns the shift interval that corresponds to the base interval.

<table>
<thead>
<tr>
<th>Category</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type</td>
<td>NCHAR, NVARCHAR</td>
</tr>
</tbody>
</table>

Syntax

```plaintext
INTSHIFT(interval[multiple][.shift-index])
```

Arguments

*interval[multiple][.shift-index]*

specifies a basic or complex interval. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The three parts of the interval name are as follows:

*interval*

specifies a character constant, a variable, or an expression that contains an interval name such as WEEK, MONTH, or QTR.

Data type: CHAR

Tip: *Interval* can appear in uppercase or lowercase.

Example:

YEAR specifies yearly intervals.

*multiple*

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type: INTEGER

Example:

YEAR2 consists of two-year, or biennial, periods.

*shift-index*

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Note: For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Example:

YEAR specifies yearly intervals.
Restrictions

The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type

INTEGER

See

“Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

Example

YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

Details

The INTSHIFT function returns the shift interval that corresponds to the base interval. For custom intervals, the value that is returned is the base custom interval name. INTSHIFT ignores multiples of the interval and interval shifts.

The INTSHIFT function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

Example

The following statements illustrate the INTSHIFT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>shift1=intshift('year');</code></td>
<td>MONTH</td>
</tr>
<tr>
<td>put shift1;</td>
<td></td>
</tr>
<tr>
<td><code>shift2=intshift('dtyear');</code></td>
<td>DTMONTH</td>
</tr>
<tr>
<td>put shift2;</td>
<td></td>
</tr>
<tr>
<td><code>shift3=intshift('minute');</code></td>
<td>DTMINUTE</td>
</tr>
<tr>
<td>put shift3;</td>
<td></td>
</tr>
<tr>
<td><code>interval='weekdays';</code></td>
<td></td>
</tr>
<tr>
<td><code>shift4 = intshift(interval);</code></td>
<td>WEEKDAY</td>
</tr>
<tr>
<td>put shift4;</td>
<td></td>
</tr>
<tr>
<td>Statements</td>
<td>Results</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>shift5=intshift('weekday5.4');</code></td>
<td>WEEKDAY</td>
</tr>
<tr>
<td><code>put shift5;</code></td>
<td></td>
</tr>
<tr>
<td><code>shift6=intshift('qtr');</code></td>
<td>MONTH</td>
</tr>
<tr>
<td><code>put shift6;</code></td>
<td></td>
</tr>
<tr>
<td><code>shift7=intshift('dttenday');</code></td>
<td>DTTENDAY</td>
</tr>
<tr>
<td><code>put shift7;</code></td>
<td></td>
</tr>
</tbody>
</table>

**INTTEST Function**

Returns 1 if a time interval is valid, and returns 0 if a time interval is invalid.

**Category:** Date and Time

**Returned data type:** INTEGER

**Syntax**

`INTTEST(interval[multiple][.shift-index])`

**Arguments**

**interval[multiple][.shift-index]**

specifies a basic or complex interval. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The three parts of the interval name are as follows:

**interval**

specifies a character constant, a variable, or an expression that contains an interval name such as WEEK, MONTH, or QTR.

- **Data type:** CHAR

**Note**

For more information, see “Date and Time Intervals” in *SAS Viya Functions and CALL Routines: Reference*.

**Tip**

*Interval* can appear in uppercase or lowercase.

**Example**

YEAR specifies year-based intervals.

**multiple**

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

- **Data type:** INTEGER

**See**

“Date and Time Intervals” in *SAS Viya Functions and CALL Routines: Reference*.
Example  YEAR2 specifies a two-year, or biennial, interval type.

**shift-index**

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

**Restrictions**

The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

**Data type**

INTEGER

**See**

“Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference

**Example**

YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

**Details**

The INTTEST function checks for a valid interval name. This function is useful when checking for valid values of `multiple` and `shift-index`.

The INTTEST function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference. These intervals are ISO 8601 compliant. For more information, see “Date and Time Intervals” in SAS Viya Functions and CALL Routines: Reference.

**Example**

In the following examples, SAS returns a value of 1 if the `interval` argument is valid, and 0 if the interval argument is invalid.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>test1 = inttest('month');</td>
<td>1</td>
</tr>
<tr>
<td>put test1;</td>
<td></td>
</tr>
<tr>
<td>test2 = inttest('week6.13');</td>
<td>1</td>
</tr>
<tr>
<td>put test2;</td>
<td></td>
</tr>
</tbody>
</table>
### INTTS Function

Specifies the number of seconds to add to a TIMESTAMP value.

**Category:** Date and Time  
**Returned data type:** TIMESTAMP

#### Syntax

```
INTTS(expression, increment)
```

#### Arguments

- **expression**
  - specifies any valid expression that represents a TIMESTAMP value.  
  - **Data type:** TIMESTAMP
  - **See:** "DS2 Expressions" in SAS Viya: DS2 Programmer’s Guide

- **increment**
  - specifies a negative, positive, or zero integer that represents the number of seconds to add to the time.  
  - **Data type:** INTEGER

#### Details

The INTTS function increments a TIMESTAMP value by the number of seconds that you specify.

#### Comparisons

The INTNX function increments a SAS date, time, or datetime value encoded as a DOUBLE value.
Example

The following statements illustrate the INTDT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>y = timestamp '2011-03-01 16:51:36.00' ;</td>
<td>y = 2011-03-01 16:51:36</td>
</tr>
<tr>
<td>z = intts(y, 43);</td>
<td>z = 2011-03-01 16:52:19</td>
</tr>
<tr>
<td>y = timestamp '2011-05-01 02:58:17.00' ;</td>
<td>y = 2011-05-01 02:58:17</td>
</tr>
<tr>
<td>z = intdt(y, -2500);</td>
<td>z = 2011-05-01 02:16:37</td>
</tr>
</tbody>
</table>

See Also

### INTZ Function

Returns the integer portion of the argument, using zero fuzzing.

**Category:** Truncation

**Returned data type:** DOUBLE

**Syntax**

\[
\text{INTZ}(\text{expression})
\]

**Arguments**

**expression** specifies any valid expression that evaluates to a numeric value.

**Data type** DOUBLE

**See** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The following rules apply:

- If the value of the argument is an exact integer, INTZ returns that integer.
- If the argument is positive and not an integer, INTZ returns the largest integer that is less than the argument.
• If the argument is negative and not an integer, INTZ returns the smallest integer that is greater than the argument.

**Comparisons**

Unlike the INT function, the INTZ function uses zero fuzzing. If the argument is within 1E-12 of an integer, the INT function fuzzes the result to be equal to that integer. The INTZ function does not fuzz the result. Therefore, with the INTZ function, you might get unexpected results.

**Example**

The following statements illustrate the INTZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>var1=2.1;  a=intz(var1);</td>
<td>2</td>
</tr>
<tr>
<td>a=intz(-2.4);</td>
<td>-2</td>
</tr>
<tr>
<td>a=intz(1+1.e11);</td>
<td>1</td>
</tr>
<tr>
<td>a=intz(-1.6);</td>
<td>-1</td>
</tr>
</tbody>
</table>

**IPMT Function**

Returns the interest payment for a given period for a constant payment loan or the periodic savings for a future balance.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Financial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>
Syntax

\texttt{IPMT(rate, period, number-of-periods, principal-amount [, future-amount] [, type])}

Arguments

\textit{rate}

specifies the interest rate per payment period.

Data type \hspace{1em} \texttt{DOUBLE}

\textit{period}

specifies the payment period for which the interest payment is computed.

Requirement \textit{Period} must be a positive integer value that is less than or equal to the value of \textit{number-of-periods}.

Data type \hspace{1em} \texttt{INTEGER}

\textit{number-of-periods}

specifies the number of payment periods.

Requirement \textit{Number-of-periods} must be a positive integer value.

Data type \hspace{1em} \texttt{INTEGER}

\textit{principal-amount}

specifies the principal amount of the loan.

Data type \hspace{1em} \texttt{DOUBLE}

Note \hspace{1em} Zero is assumed if a missing value is specified.

\textit{future-amount}

specifies the future amount.

Data type \hspace{1em} \texttt{DOUBLE}

Notes \hspace{1em} \textit{Future-amount} can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of periodic savings.

\hspace{1em} Zero is assumed if \textit{future-amount} is omitted or if a missing value is specified.

\textit{type}

specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments.

Data type \hspace{1em} \texttt{INTEGER}

Note \hspace{1em} 0 is assumed if \textit{type} is omitted or if a missing value is specified.
Example

The interest payment on the first periodic payment of an $8,000 loan, where the nominal annual interest rate is 10% and the end-of-period monthly payments are 36, is computed as follows:

\[
\text{InterestPaid1} = \text{ipmt}(0.1/12, 1, 36, 8000);
\]

This computation returns a value of 66.6666666666666.

If the same loan has beginning-of-period payments, then the interest payment can be computed as follows:

- \[
\text{InterestPaid2} = \text{ipmt}(0.1/12, 1, 36, 8000, 0, 1);
\]
  This computation returns a value of 0.

- \[
\text{InterestPaid3} = \text{ipmt}(0.1, 3, 3, 8000);
\]
  This computation returns a value of 292.447129909366.

- \[
\text{InterestPaid4} = \text{ipmt}(0.09/12, 359, 360, 125000, 0, 1);
\]
  This computation returns a value of 14.8075736630449.

IQR Function

Returns the interquartile range.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Descriptive Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

\[
\text{IQR(expression [,… expression])}
\]

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

See

Details

If all arguments have null or missing values, the result is a null or missing value depending on whether you are in ANSI mode or SAS mode. For more information, see “How DS2 Processes Nulls and SAS Missing Values” in SAS Viya: DS2 Programmer’s Guide.

Otherwise, the result is the interquartile range of the non-null or nonmissing values. The formula for the interquartile range is the same as the one that is used in the Base SAS UNIVARIATE procedure. For more information, see Base SAS Procedures Guide: Statistical Procedures.
Example

The following statement illustrates the IQR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a = iqr(2, 4, 1, 3, 999999);</td>
<td>2</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “MAD Function” on page 444
- “PCTL Function” on page 505

IRR Function

Returns the internal rate of return as a percentage.

Category: Financial

Returned data type: DOUBLE

Syntax

IRR(freq, c1, c2[...cn])

Arguments

freq

specifies the number of payments over a specified base period of time that is associated with the desired internal rate of return.

Range

freq > 0.

Data type

DOUBLE

Tip

The case freq = 0 is a flag to allow continuous compounding.

c1, c2[...cn]

specifies the optional cash payments.

Requirement

At minimum, two cash payment values are required.

Data type

DOUBLE

Details

The IRR function returns the internal rate of return over a specified base period of time for the set of cash payments c1, c2, ..., cn. The time intervals between any two consecutive payments are assumed to be equal. The argument freq > 0 describes the
number of payments that occur over the specified base period of time. The number of notes issued from each instance is limited.

**Comparisons**

The IRR function is identical to INTRR, except that in the IRR function, the internal rate of return is a percentage.

**Example**

For an initial outlay of $400 and expected payments of $100, $200, and $300 over the following three years, the annual internal rate of return as a percentage can be expressed as

\[
\text{rate} = \text{IRR}(1, -400, 100, 200, 300);
\]

The value that is returned is 19.437709962747.

**See Also**

Functions:

- “INTRR Function” on page 400

---

**JULDATE Function**

Returns the Julian date from a SAS date value.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

\[
\text{JULDATE}(\text{date})
\]

**Arguments**

\[
\text{date}
\]

specifies any valid expression that represents a SAS date value.

**Data type** DOUBLE

**See** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

A SAS date value is a number that represents the number of days from January 1, 1960 to a specific date. The JULDATE function converts a SAS date value to a Julian date. If date falls within the 100-year span defined by the system option YEARCUTOFF=, the result has three, four or five digits: In a five-digit result, the first two digits represent the year, and the next three digits represent the day of the year (1 to 365, or 1 to 366 for leap years). As leading zeros are dropped from the result, the year portion of a Julian date can be omitted (for years ending in 00) or it can have only one digit (for years ending 01-
09). Otherwise, the result has seven digits: the first four digits represent the year, and the next three digits represent the day of the year.

For years that end between 00–09, you can format the five-digit Julian date by using the Z5. format.

For more information about how DS2 handles dates, see “Dates and Times in DS2” in SAS Viya: DS2 Programmer’s Guide.

Comparisons

The function JULDATE7 is similar to JULDATE except that JULDATE7 always returns a four-digit year. Thus, JULDATE7 is year 2000 compliant because it eliminates the need to consider the implications of a two-digit year.

Example

The following statements illustrate the JULDATE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>julian=juldate(mdy(12,31,2013));</td>
<td>7365</td>
</tr>
<tr>
<td>julian=put(juldate(mdy(12,31,2013)),z5.);</td>
<td>07365</td>
</tr>
<tr>
<td>julian=juldate(mdy(9,1,1999));</td>
<td>99244</td>
</tr>
<tr>
<td>julian=juldate(mdy(7,1,1886));</td>
<td>1886182</td>
</tr>
</tbody>
</table>

• “JULDATE7 Function” on page 416

JULDATE7 Function

Returns a seven-digit Julian date from a SAS date value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

JULDATE7(date)
**Arguments**

date

specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

A SAS date value is a number that represents the number of days from January 1, 1960 to a specific date. The JULDATE7 function returns a seven-digit Julian date from a SAS date value. The first four digits represent the year, and the next three digits represent the day of the year.

For more information about how DS2 handles dates, see “Dates and Times in DS2” in *SAS Viya: DS2 Programmer’s Guide*.

**Comparisons**

The function JULDATE7 is similar to JULDATE except that JULDATE7 always returns a four-digit year. Thus, JULDATE7 is year 2000 compliant because it eliminates the need to consider the implications of a two-digit year.

**Example**

The following statements illustrate the JULDATE7 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>julian=juldate7(mdy(12,31,2006));</td>
<td>2007365</td>

---

**KCOUNT Function**

Returns the number of double-byte characters in an expression.

**Category:** DBCS

**Returned data type:** INTEGER

**Syntax**

KCOUNT(['source'])
Arguments
'source'
specifies any valid expression that evaluates to a character string.

Data type: NCHAR

Tip: Enclose a literal string of characters in quotation marks.

Details
For restrictions and more information, see “Internationalization Compatibility for SAS String Functions” in SAS Viya National Language Support: Reference Guide.

Example
The following example uses Japanese characters.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>proc ds2;</td>
<td>c=0</td>
</tr>
<tr>
<td>data <em>null</em>;</td>
<td>c=2</td>
</tr>
<tr>
<td>method run();</td>
<td></td>
</tr>
<tr>
<td>c = kcount('Abc def');</td>
<td></td>
</tr>
<tr>
<td>put c=;</td>
<td></td>
</tr>
<tr>
<td>c = kcount('SAS漢字');</td>
<td></td>
</tr>
<tr>
<td>put c=;</td>
<td></td>
</tr>
<tr>
<td>end;</td>
<td></td>
</tr>
<tr>
<td>enddata;</td>
<td></td>
</tr>
<tr>
<td>run;</td>
<td></td>
</tr>
<tr>
<td>quit;</td>
<td></td>
</tr>
</tbody>
</table>

See Also

Functions:
- “COUNT Function” on page 276

KSTRCAT Function
Concatenates two or more character expressions.

Category: DBCS
Returned data type: NCHAR

Syntax

\[ \text{KSTRCAT}(\text{expression-1}, \text{expression-2}, \ldots, \text{expression-n}) \]
Arguments

expression

specifies any single-byte or double-byte character expression.

Requirement At least two expressions are required.

Data type NCHAR

Details

For restrictions and more information, see “Internationalization Compatibility for SAS String Functions” in SAS Viya National Language Support: Reference Guide.

KSTRCAT concatenates two or more single-byte or double-byte character expressions. It also removes unnecessary shift out and shift in escape code (SO/SI) pairs between the expressions.

Example

The following example uses Japanese characters.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>proc ds2;</td>
<td></td>
</tr>
<tr>
<td>data <em>null</em>;</td>
<td></td>
</tr>
<tr>
<td>method run();</td>
<td></td>
</tr>
<tr>
<td>dcl nchar(8) a;</td>
<td></td>
</tr>
<tr>
<td>a = kstrcat('SAS', '漢字', 'SAS');</td>
<td>a=SAS漢字SAS</td>
</tr>
<tr>
<td>put a=;</td>
<td></td>
</tr>
<tr>
<td>end;</td>
<td></td>
</tr>
<tr>
<td>enddata;</td>
<td></td>
</tr>
<tr>
<td>run;</td>
<td></td>
</tr>
<tr>
<td>quit;</td>
<td></td>
</tr>
</tbody>
</table>

See Also

Functions:

• “CAT Function” on page 237

KSTRIP Function

Returns a character string with all leading and trailing blanks removed.

Category: DBCS

Returned data type: NCHAR
Syntax

KSTRIP(['string'])

Arguments

['string']

specifies any valid expression that evaluates to a character string.

Data type NCHAR

Tip

Enclose a literal string of characters in quotation marks.

See

Details

The KSTRIP function returns the argument with all leading and trailing single-byte character set (SBCS) blanks removed. If the argument is blank, KSTRIP returns a string with a length of zero.

Assigning the results of KSTRIP to a variable does not affect the length of the receiving variable. If the value that is trimmed is shorter than the length of the receiving variable, DS2 pads the value with new trailing blanks.

Example

The following example shows how the KSTRIP function deletes leading and trailing blanks, and how the double-byte character set (DBCS) character is truncated. This example uses the Japanese Shift_JIS encoding.

```
proc ds2;
data _null_;method run();
dcl nchar(8) v;
dcl nchar(10) a b c;
/* 1 leading DBCS blank and 1 trailing DBCS blank */
/* plus a SBCS blank */
v = ' SAS漢字 ';
puit v=;
a = '*'||v'||''';
puit a=;
/* SBCS blank stripped */
b = '*'||kstrip(v)||''';
/* Only 1 DBCS blank, remain */
c = '*'||kstrip(' ')||''';
puit b=; put c=;
end;
enddata;
runt;quit;
```

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>proc ds2;</td>
<td>v= SAS漢字</td>
</tr>
<tr>
<td>data <em>null</em>;</td>
<td>a=* SAS漢字 *</td>
</tr>
<tr>
<td>method run();</td>
<td>b=* SAS漢字 *</td>
</tr>
<tr>
<td>dcl nchar(8) v;</td>
<td>c=* *</td>
</tr>
<tr>
<td>dcl nchar(10) a b c;</td>
<td></td>
</tr>
<tr>
<td>/* 1 leading DBCS blank and 1 trailing DBCS blank */</td>
<td></td>
</tr>
<tr>
<td>/* plus a SBCS blank */</td>
<td></td>
</tr>
<tr>
<td>v = ' SAS漢字 ';</td>
<td></td>
</tr>
<tr>
<td>put v=;</td>
<td></td>
</tr>
<tr>
<td>a = '*'</td>
<td></td>
</tr>
<tr>
<td>put a=;</td>
<td></td>
</tr>
<tr>
<td>/* SBCS blank stripped */</td>
<td></td>
</tr>
<tr>
<td>b = '*'</td>
<td></td>
</tr>
<tr>
<td>/* Only 1 DBCS blank, remain */</td>
<td></td>
</tr>
<tr>
<td>c = '*'</td>
<td></td>
</tr>
<tr>
<td>put b=; put c=;</td>
<td></td>
</tr>
</tbody>
</table>
KUPDATE Function

Inserts, deletes, and replaces character value contents.

Category: DBCS

Returned data type: NCHAR

Syntax

KUPDATE(’expression’, position, n [, ’characters-to-replace’])

Arguments

’expression’

specifies any valid expression that evaluates to a character string.

Data type: NCHAR

Tip: Enclose a literal string of characters in quotation marks.

position

specifies a numeric expression that is the beginning character position.

Data type: INTEGER

n

specifies a numeric expression that is the length of the substring to be replaced.

Restrictions: n cannot be larger than the length of the expression that remains in expression after position.

n is optional, but you cannot omit both n and characters-to-replace from the function.

Data type: INTEGER

Tip: If you omit n, SAS uses all of the characters in characters-to-replace to replace the values of expression.

’characters-to-replace’

specifies an expression that evaluates to a character string that replaces the contents of expression.

Restriction: characters-to-replace is optional, but you cannot omit both characters-to-replace and n from the function.
The KUPDATE function replaces the value of `expression` with the expression in `characters-to-replace`. KUPDATE replaces `n` characters starting at the character that you specify in `position`.

If you omit `characters-to-replace`, `n` characters are removed from the string.

If you specify more `characters-to-replace` than `n`, all characters are used as replacement. `n` is ignored.

If you specify fewer `characters-to-replace` than `n`, only the first `n` characters are replaced. The other characters are deleted.

Here are some examples.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>kupdate(&quot;123456&quot;,2,3);</code></td>
<td>1 56</td>
</tr>
<tr>
<td><code>kupdate(&quot;123456&quot;,2,3,&quot;abcd&quot;);</code></td>
<td>1abc56</td>
</tr>
<tr>
<td><code>kupdate(&quot;123456&quot;,2,3, &quot;ab&quot;);</code></td>
<td>1ab 56</td>
</tr>
</tbody>
</table>

**Comparisons**

The KUPDATE function tries to update the target string (`expression`) using the actual length of the last argument (`characters-to-replace`), in spite of the third argument (`n`). The KUPDATES function tries to update the target string (`expression`) based on the third argument (`n`).

**Example**

The following example uses Japanese characters.
**KUPDATES Function**

Inserts, deletes, and replaces character value contents.

<table>
<thead>
<tr>
<th>Category:</th>
<th>DBCS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>NCHAR</td>
</tr>
</tbody>
</table>

      put r;
      r=kupdate(str, 2, '分析');
   end;
enddata;
run;
quit;
```

**Results**

- r=北軟件
- r=北abcd軟件
- r=北ab軟件
- r=北ab
- r=北軟件
- r=北分析數據軟件
- r=北分析軟件
- r=北分析

---

**KUPDATES Function**

Inserts, deletes, and replaces character value contents.
Syntax

\[
\text{KUPDATE(\textbf{expression}, \textit{position}, n \ [, characters-to-replace])}
\]

Arguments

\[\textbf{expression}\]
  specifies any valid expression that evaluates to a character string.
  - Data type: NCHAR
  - Tip: Enclose a literal string of characters in quotation marks.

\textit{position}
  specifies a numeric expression that is the beginning character position.
  - Data type: INTEGER

\texttt{n}
  specifies a numeric expression that is the length of the substring to be replaced.
  - Restrictions:
    - \texttt{n} cannot be larger than the length of the expression that remains in \textit{expression} after \textit{position}.
    - \texttt{n} is optional, but you cannot omit both \texttt{n} and \textit{characters-to-replace} from the function.
  - Data type: INTEGER
  - Tip: If you omit \texttt{n}, SAS uses all of the characters in \textit{characters-to-replace} to replace the values of \textit{expression}.

\[\textit{characters-to-replace}\]
  specifies an expression that evaluates to a character string that replaces the contents of \textit{expression}.
  - Restriction: \textit{characters-to-replace} is optional, but you cannot omit both \textit{characters-to-replace} and \texttt{n} from the function.
  - Data type: NCHAR
  - Tip: Enclose a literal string of characters in quotation marks.

Details

For restrictions and more information, see “Internationalization Compatibility for SAS String Functions” in \textit{SAS Viya National Language Support: Reference Guide}.

The KUPDATE function replaces the value of \textit{expression} with the expression in \textit{characters-to-replace}. KUPDATE replaces \texttt{n} characters starting at the character that you specify in \textit{position}.

If you omit \textit{characters-to-replace}, \texttt{n} blank characters are used to replace the existing value.
If you specify more characters-to-replace than \( n \), only the first \( n \) characters are used as replacement.

If you specify fewer characters-to-replace than \( n \), blank characters are added at the end until the number of characters replaced is equal to \( n \).

Here are some examples.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>kupdate(&quot;123456&quot;,2,3);</code></td>
<td>1 56</td>
</tr>
<tr>
<td><code>kupdate(&quot;123456&quot;,2,3,&quot;abcd&quot;);</code></td>
<td>labc56</td>
</tr>
<tr>
<td><code>kupdate(&quot;123456&quot;,2,3,&quot;ab&quot;);</code></td>
<td>lab 56</td>
</tr>
</tbody>
</table>

### Comparisons

The KUPDATES function tries to update the target string (expression) based on the third argument (\( n \)). The KUPDATE function tries to update the target string (expression) using the actual length of the last argument (characters-to-replace), in spite of the third argument (\( n \)).

### Example

The following example uses Japanese characters.
KURTOSIS Function

Returns the kurtosis.

Function:

See Also

Function:

- “KUPDATE Function” on page 421
Syntax

`KURTOSIS(expression-1, expression-2, expression-3, expression-4 [,...expression-n])`

**Arguments**

`expression`

specifies any valid expression that evaluates to a numeric value.

**Requirement**

At least four non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

**Data type**

DOUBLE

**See**

**Details**

Kurtosis is primarily a measure of the heaviness of the tails of a distribution. Large kurtosis values indicate that the distribution has heavy tails.

Null values and missing values are ignored and are not included in the computation.

If all non-null or nonmissing arguments have equal values, the kurtosis is mathematically undefined and the KURTOSIS function returns a null or missing value.

**Example**

The following statements illustrate the KURTOSIS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=kurtosis(5,9,3,6);</code></td>
<td>0.92799999999999</td>
</tr>
<tr>
<td><code>b=kurtosis(5,8,9,6.,);</code></td>
<td>-3.3</td>
</tr>
<tr>
<td><code>c=kurtosis(8,9,6,1);</code></td>
<td>1.5</td>
</tr>
<tr>
<td><code>d=kurtosis(8,1,6,1);</code></td>
<td>-4.48337950138504</td>
</tr>
</tbody>
</table>

**LARGEST Function**

Returns the kth largest non-null or nonmissing value.

**Category:** Descriptive Statistics

**Returned data type:** DOUBLE
Syntax

\texttt{LARGEST}(k, \textit{expression}, ..., \textit{expression})

Arguments

\textit{k}

specifies any valid expression that evaluates to a numeric value that represents the largest value to return. For example, if \( k \) is 2, the LARGEST function returns the second largest value from the list of expressions.

Data type \texttt{DOUBLE}

\textit{expression}

specifies any valid expression that evaluates to a numeric value and that is to be searched.

Data type \texttt{DOUBLE}

Details

If \( k \) is null or missing, less than zero, or greater than the number of values, the result is a null or missing value. Otherwise, if \( k \) is greater than the number of non-null or nonmissing values, the result is a null or missing value.

Example

The following statements illustrate the LARGEST function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{k=1;} \texttt{largest1=largest(k, 456, 789, .Q, 123);}</td>
<td>789</td>
</tr>
<tr>
<td>\texttt{k=2;} \texttt{largest2=largest(k, 456, 789, .Q, 123);}</td>
<td>456</td>
</tr>
<tr>
<td>\texttt{k=3;} \texttt{largest3=largest(k, 456, 789, .Q, 123);}</td>
<td>123</td>
</tr>
<tr>
<td>\texttt{k=4;} \texttt{largest4=largest(k, 456, 789, .Q, 123);}</td>
<td>.</td>
</tr>
</tbody>
</table>

Functions:

- “ORDINAL Function” on page 504
- “PCTL Function” on page 505
LBOUND Function

Returns the lower bound of an array.

**Category:** Array

**Returned data type:** INTEGER

**Syntax**

\[
\text{LBOUND}(\text{array-name}[, \text{bound-n}])
\]

**Arguments**

- **array-name**
  - specifies the name of a temporary or a variable array.

- **bound-n**
  - is a numeric constant, variable, or expression that specifies the dimension, in a multidimensional array, for which you want to know the lower bound.
    - If no \( \text{bound-n} \) value is specified, the LBOUND function returns the lower bound of the first dimension of the array.
    - Bound-\( n \) evaluates to an integral value.

**Details**

The LBOUND function returns the lower bound of a one-dimensional array, or the lower bound of a specified dimension of a multidimensional array. LBOUND and HBOUND can be used together to return the values of the lower and upper bounds of an array dimension.

If the LBOUND function is called with a dimension value that is outside the dimension of the array, then a run-time error occurs and the function returns a NULL integer value.

**Comparisons**

- DIM returns the number of elements in an array dimension.
- HBOUND returns the value of the upper bound of an array dimension.
- LBOUND returns the value of the lower bound of an array dimension.
- NDIMS returns the number of dimensions in an array.

**Example**

The following example shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions:

```r
data _null_
  method init()
    declare char[15] a1[4];
    declare double a2[2,3,4] sum;
```

"SMALLEST Function" on page 610
a1 := ('red' 'yellow' 'green' 'blue');
a2 := (24*2.0);

do i = 1 to dim(a1);
    put a1[i];
end;

numelems = 0;
do i = 1 to ndims(a2);
    numelems = numelems + dim(a2, i);
end;

sum = 0;
do i = lbound(a2, 1) to hbound(a2, 1);
do j = lbound(a2, 2) to hbound(a2, 2);
do k = lbound(a2, 3) to hbound(a2, 3);
    sum = sum + a2[i,j,k];
end;
end;

put sum=;

end;
enddata;
run;

SAS writes the following output to the log:

red
yellow
green
blue
sum=48

• “HBOUND Function” on page 353
• “NDIMS Function” on page 467

LCM Function

Returns the least common multiple for a set of integers.

Category: Mathematical
Returned data type: DOUBLE
Syntax

\[ \text{LCM(} \text{expression}-1, \text{expression}-2 [, \ldots \text{expression}-n]) \]

Arguments

\text{expression} specifies any valid expression that evaluates to an integer.

Requirement At least two arguments are required.

Data type DOUBLE

Details

The least common multiple is the smallest number that two or more numbers will divide into evenly.

Example

The following statements illustrate the LCM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a=\text{lcm(1,5,3,0)};)</td>
<td>0</td>
</tr>
<tr>
<td>(b=\text{lcm(25,70,85,130)};)</td>
<td>77350</td>
</tr>
<tr>
<td>(c=\text{lcm(33,78)};)</td>
<td>858</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “GCD Function” on page 344

LEFT Function

Left aligns a character expression.

Category: Character

Returned data type: VARCHAR, NVARCHAR

Syntax

\[ \text{LEFT(} \text{expression} \) \]
**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

**Data type** CHAR, NCHAR

**See** "DS2 Expressions" in *SAS Viya: DS2 Programmer's Guide*

**Details**

LEFT returns a character string with leading blanks moved to the end of the value.

**Example**

The following statements illustrate the LEFT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=' END-OF-YEAR';</td>
<td>END-OF-YEAR</td>
</tr>
<tr>
<td>b=left(a);</td>
<td>END-OF-YEAR</td>
</tr>
</tbody>
</table>

**See Also**

Functions:

- “COMPRESS Function” on page 264
- “RIGHT Function” on page 581
- “STRIP Function” on page 617
- “TRIM Function” on page 650

**LENGTH Function**

Returns the length of a character string, excluding trailing blanks, and returns a 0 for a blank character string.

**Category:** Character

**Alias:** LENGTHN

**Returned data type:** DOUBLE

**Syntax**

`LENGTH(expression)`
Arguments

expression

specifies any valid expression that evaluates to a character string.

Data type

CHAR, NCHAR

See

Details

The LENGTH function returns an integer that represents the position of the rightmost non-blank character or number in expression. If the value of expression is a blank character, LENGTH returns a value of 0. If expression is a numeric expression, LENGTH converts and processes the expression as a character expression.

Comparisons

• The LENGTH function returns the length of a character string, excluding trailing blanks, whereas the LENGTHC function returns the length of a character string, including trailing blanks.

• The LENGTH function returns the length of a character string, excluding trailing blanks, whereas the LENGTHM function returns the amount of memory in bytes that is allocated for a character string.

Example

The following statements illustrate the LENGTH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=length('ABCDEF');</td>
<td>6</td>
</tr>
<tr>
<td>b=date();</td>
<td></td>
</tr>
<tr>
<td>a=length(b);</td>
<td>5</td>
</tr>
<tr>
<td>a=length(' ');</td>
<td>0</td>
</tr>
<tr>
<td>a=length(.);</td>
<td>1</td>
</tr>
</tbody>
</table>

* The data type for b is converted to NCHAR with a value of 16763 whose length is 5.

** The data type for the null or missing value ( . ) is converted from DOUBLE to NCHAR with a value of . whose length is 1.

See Also

Functions:

• “LENGTHC Function” on page 434

• “LENGTHM Function” on page 435

• “LENGTHN Function” on page 436
LENGTHC Function

Returns the length of a character string, including trailing blanks.

Category: Character
Returned data type: DOUBLE

Syntax

LENGTHC(expression)

Arguments

expression

specifies any valid expression that evaluates to a character string.

Data type NCHAR

Details

The LENGTHC function returns an integer that represents the position of the rightmost blank or non-blank character in expression. For fixed-length variables, LENGTHC returns the declared length of the variable. If the value of expression is missing and contains blanks, LENGTHC returns the number of blanks in expression. If expression is a numeric expression, LENGTHC converts and processes the numeric expression as a character expression.

Comparisons

• The LENGTHC function returns the length of a character string, including trailing blanks, whereas the LENGTH function returns the length of a character string, excluding trailing blanks. LENGTHC always returns a value that is greater than or equal to the value returned by LENGTH.

• The LENGTHC function returns the length of a character string, including trailing blanks, whereas the LENGTHM function returns the amount of memory in bytes that is allocated for a character string. For fixed-length character strings, LENGTHC and LENGTHM always return the same value. For varying-length character strings, LENGTHC always returns a value that is less than or equal to the value returned by LENGTHM.

Example

The following statements illustrate the LENGTHC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=lengthc('string with trailing blanks ');</td>
<td>32</td>
</tr>
</tbody>
</table>
Statements | Results
--- | ---
dcl varchar(25) string; string='The power to know. '; a=lengthc(string); 20

dcl char(25) string; string='The power to know. '; a=lengthc(string); 25

a=lengthc(''); 0

See Also

Functions:
- “LENGTH Function” on page 432
- “LENGTHM Function” on page 435
- “LENGTHN Function” on page 436

LENGTHM Function

Returns the amount of memory, in characters, that is allocated for a character string.

Category: Character
Returned data type: DOUBLE

Syntax

LENGTHM(expression)

Arguments

expression
specifies any valid expression that evaluates to a character string.

Data type NCHAR

Details

The LENGTHM function returns an integer that represents the amount of memory in bytes that is allocated for the expression. If expression is a numeric expression (either initialized or uninitialized), SAS automatically converts the numeric value to a right-justified character string by using the BEST12. format. In this case, LENGTHM returns a value of 12 and writes a note in the SAS log stating that the numeric values have been converted to character values.
Comparisons

The LENGTHM function returns the amount of memory in characters that is allocated for a character string, whereas the LENGTH and LENGTHC functions return the length of a character string. LENGTHM always returns a value that is greater than or equal to the values returned by LENGTH and LENGTHC.

Example

The following statements illustrate the LENGTHM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=lengthm('ABCDEF ');</td>
<td>20</td>
</tr>
<tr>
<td>dcl char(30) string;</td>
<td></td>
</tr>
<tr>
<td>string='The Power to Know. ';</td>
<td></td>
</tr>
<tr>
<td>a=lengthm(string);</td>
<td>60</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “LENGTH Function” on page 432
- “LENGTHC Function” on page 434

LENGTHN Function

Returns the length of a character string, excluding trailing blanks.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

Syntax

LENGTHN(string)

Arguments

expression

specifies any valid expression that evaluates to a character string.

Data type: CHAR

See

Details

The LENGTHN function returns an integer that represents the position of the rightmost non-blank character in string. If the value of string is blank, LENGTHN returns a value of 0. If string is a numeric constant, variable, or expression (either initialized or uninitialized), SAS automatically converts the numeric value to a right-justified character string.

Comparisons

- The LENGTHN and LENGTH functions return the same value for non-blank character strings. LENGTHN returns a value of 0 for blank character strings, whereas LENGTH returns a value of 1.
- The LENGTHN function returns the length of a character string, excluding trailing blanks, whereas the LENGTHC function returns the length of a character string, including trailing blanks. LENGTHN always returns a value that is less than or equal to the value returned by LENGTHC.
- The LENGTHN function returns the length of a character string, excluding trailing blanks, whereas the LENGTHM function returns the amount of memory in bytes that is allocated for a character string. LENGTHN always returns a value that is less than or equal to the value returned by LENGTHM.

Example

The following statements illustrate the LENGTHN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>c=lengthn(' abc ') ; put c ;</td>
<td>6</td>
</tr>
<tr>
<td>d=lengthn('abc ') ; put d ;</td>
<td>3</td>
</tr>
<tr>
<td>e=lengthn(18) ; put e ;</td>
<td>2</td>
</tr>
<tr>
<td>f=lengthn(' ') ; put f ;</td>
<td>0</td>
</tr>
</tbody>
</table>

LGAMMA Function

Returns the natural logarithm of the Gamma function.

Category: Mathematical
Returned data type: DOUBLE

Syntax

LGAMMA(expression)

Arguments

expression specifies any valid expression that evaluates to a numeric value.

Requirement Must be a positive number.

Data type DOUBLE

Example

The following statements illustrate the LGAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=lgamma(2);</td>
<td>0</td>
</tr>
<tr>
<td>a=lgamma(1.5);</td>
<td>-0.12078223763524</td>
</tr>
</tbody>
</table>

LOG Function

Returns the natural logarithm (base e) of a numeric value expression.

Category: Mathematical

Returned data type: DOUBLE

Syntax

LOG(expression)

Arguments

expression specifies any valid expression that evaluates to a numeric value.

Requirement Must be a positive number.

Data type DOUBLE

Example

The following statements illustrate the LOG function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=log(1.0);</td>
<td>0</td>
</tr>
<tr>
<td>a=log(10.0);</td>
<td>2.30258509299404</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “LOG10 Function” on page 440
- “LOG2 Function” on page 442

LOGBETA Function

Returns the logarithm of the beta function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

LOGBETA(a, b)

Arguments

\(a\)

- is the first shape parameter, where \(a>0\).

Data type DOUBLE

\(b\)

- is the second shape parameter, where \(b>0\).

Data type DOUBLE

Details

The LOGBETA function is mathematically given by the equation

\[ \log(\beta(a, b)) = \log(\Gamma(a)) + \log(\Gamma(b)) - \log(\Gamma(a + b)) \]

In the equation, \(\Gamma(\cdot)\) is the gamma function.

If the expression cannot be computed, LOGBETA returns a missing value.
Examples

Example 1
The following DS2 statements compute the logarithm of the beta function. The first shape parameter is 5 and the second shape parameter is 3.

```sas
data test;
  method run();
    y=logbeta(5,3);
    put y=;
  end;
enddata;
run;
```

The following line is written to the SAS log.

```
y=-4.65396035015752
```

Example 2
The following statement illustrates the LOGBETA function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select logbeta(5,3);</code></td>
<td><code>-4.6539603501575</code></td>
</tr>
</tbody>
</table>

See Also

Functions:
- “BETA Function” on page 222

LOG10 Function

Returns the base-10 logarithm of a numeric value expression.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Mathematical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

`LOG10(expression)`

Arguments

- `expression` specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Must be a positive number.</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>
Example

The following statements illustrate the LOG10 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=log10(1.0);</td>
<td>0</td>
</tr>
<tr>
<td>a=log10(10.0);</td>
<td>1</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “LOG Function” on page 438
- “LOG2 Function” on page 442
Examples

Example 1: Computing the Log with the LOG1PX Function
The following example computes the log of 1 plus the value 0.5.

```sas
data _null_
   method run();
   x=log1px(0.5);
   put x=;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
x=0.40546510810816
```

Example 2: Comparing the LOG1PX Function with the LOG Function
In the following example, the value of X is computed by using the LOG1PX function. The value of Y is computed by using the LOG function.

```sas
data _null_
   method run();
   x=log1px(1.e-5);
   put x= hex16.;
   y=log(1+1.e-5);
   put y= hex16.;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
x=3EB4F8A9A9AE7317
y=3EB4F8A9A9AF0A25
```

See Also

Functions:
- “LOG Function” on page 438

LOG2 Function

Returns the base 2 logarithm of a numeric value expression.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Mathematical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

```
LOG2(expression)
```
**Arguments**

*expression*

specifies any valid expression that evaluates to a numeric value.

---

**Requirement**  
Must be a positive number.

**Data type**  
DOUBLE

**See**  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

---

**Example**

The following statements illustrate the LOG2 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=log2(8.0);</td>
<td>3</td>
</tr>
<tr>
<td>a=log2(4);</td>
<td>2</td>
</tr>
</tbody>
</table>

---

**See Also**

**Functions:**

- “LOG Function” on page 438
- “LOG10 Function” on page 440

---

**LOWCASE Function**

Converts all letters in a character expression to lowercase.

---

**Category:**  
Character

**Alias:**  
LOWER

**Returned data type:**  
VARCHAR, NVARCHAR

---

**Syntax**

`LOWCASE(expression)`

---

**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

---

**Requirement**  
Literal character expressions must be enclosed in single quotation marks.

**Data type**  
CHAR, NCHAR
Details

The LOWCASE function copies a character expression, converts all uppercase letters to lowercase letters, and returns the altered value as a result.

Comparisons

The UPCASE function converts all letters in an argument to uppercase letters. The LOWCASE function converts all letters in an argument to lowercase letters.

Example

The following statement illustrates the LOWCASE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=lowcase('INTRODUCTION');</td>
<td>introduction</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “UPCASE Function” on page 654

MAD Function

Returns the median absolute deviation from the median.

**Category:** Descriptive Statistics

**Returned data type:** DOUBLE

**Syntax**

\[
\text{MAD}(\text{expression}, \ldots \text{expression})
\]

**Arguments**

- **expression**
  
  specifies any valid expression that evaluates to a numeric value of which the median absolute deviation from the median is to be computed.

  Data type: DOUBLE

**Details**

If all arguments have missing or null values, the result is a missing or null value. Otherwise, the result is the median absolute deviation from the median of the
nonmissing or non-null values. The formula for the median is the same as the one that is used in the UNIVARIATE procedure. For more information, see Base SAS Procedures Guide: Statistical Procedures.

Example

The following statement illustrates the MAD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>c=mad(2, 4, 1, 3, 5, 999999); put c;</td>
<td>1.5</td>
</tr>
</tbody>
</table>

MARGRCLPRC Function

Calculates call prices for European options on stocks, based on the Margrabe model.

Category: Financial

Returned data type: DOUBLE

Syntax

MARGRCLPRC(\(X_1, t, X_2, \sigma_1, \sigma_2, \rho_{12}\))

Arguments

\(X_1\)

is a nonmissing, positive value that specifies the price of the first asset.

Requirement Specify \(X_1\) and \(X_2\) in the same units.

Data type DOUBLE

\(t\)

is a nonmissing value that specifies the time to expiration, in years.

Data type DOUBLE

\(X_2\)

is a nonmissing, positive value that specifies the price of the second asset.
Requirement
Specify $X_2$ and $X_1$ in the same units.

Data type
DOUBLE

$\sigma_1$
is a nonmissing, positive fraction that specifies the volatility of the first asset.

Data type
DOUBLE

$\sigma_2$
is a nonmissing, positive fraction that specifies the volatility of the second asset.

Data type
DOUBLE

$\rho_{12}$
specifies the correlation between the first and second assets, $\rho_{X_1X_2}$.

Range
between –1 and 1

Data type
DOUBLE

Details
The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. The function is based on the following relationship:

$$\text{CALL} = X_1N(d_1) - X_2N(d_2)$$

Arguments

$X_1$
specifies the price of the first asset.

$X_2$
specifies the price of the second asset.

$N$
specifies the cumulative normal density function.

$$d_1 = \frac{\ln\left(\frac{N_1}{N_2}\right) + \frac{\sigma_2^2}{2}t}{\sigma_1\sqrt{t}}$$

$$d_2 = d_1 - \sigma_1\sqrt{t}$$

$$\sigma^2 = \sigma_{X_1}^2 + \sigma_{X_2}^2 - 2\rho_{X_1X_2}\sigma_{X_1}\sigma_{X_2}$$

The following arguments apply to the preceding equation:

$t$
specifies the time to expiration.

$\sigma_{X_1}^2$
specifies the variance of the first asset.

$\sigma_{X_2}^2$
specifies the variance of the second asset.
\( \sigma_{x_1} \)

specifies the volatility of the first asset.

\( \sigma_{x_2} \)

specifies the volatility of the second asset.

\( \rho_{x_1, x_2} \)

specifies the correlation between the first and second assets.

For the special case of \( t = 0 \), the following equation is true:

\[
\text{CALL} = \max(X_1 - X_2, 0)
\]

*Note:* This function assumes that there are no dividends from the two assets.

For information about the basics of pricing, see "Using Pricing Functions".

**Comparisons**

The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. These functions return a scalar value.

**Example**

The following statements illustrate the MARGRCLPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a = margrclprc(15, .5, 13, .06, .05, 1);</code></td>
<td>2</td>
</tr>
<tr>
<td><code>put a;</code></td>
<td></td>
</tr>
<tr>
<td><code>b = margrclprc(2, .25, 1, .3, .2, 1);</code></td>
<td>1</td>
</tr>
<tr>
<td><code>put b;</code></td>
<td></td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- “MARGRPTPRC Function” on page 447

**MARGRPTPRC Function**

Calculates put prices for European options on stocks, based on the Margrabe model.

- **Category:** Financial
- **Returned data type:** DOUBLE
Syntax

MARGRPTPRC($X_1$, $t$, $X_2$, $\sigma_1$, $\sigma_2$, $\rho_{12}$)

**Arguments**

$X_1$

is a nonmissing, positive value that specifies the price of the first asset.

Requirement Specify $X_1$ and $X_2$ in the same units.

Data type DOUBLE

$t$

is a nonmissing value that specifies the time to expiration, in years.

Data type DOUBLE

$X_2$

is a nonmissing, positive value that specifies the price of the second asset.

Requirement Specify $X_2$ and $X_1$ in the same units.

Data type DOUBLE

$\sigma_1$

is a nonmissing, positive fraction that specifies the volatility of the first asset.

Data type DOUBLE

$\sigma_2$

is a nonmissing, positive fraction that specifies the volatility of the second asset.

Data type DOUBLE

$\rho_{12}$

specifies the correlation between the first and second assets, $\rho_{X_1, X_2}$.

Range between –1 and 1

Data type DOUBLE

**Details**

The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. The function is based on the following relationship:

$$\text{PUT} = X_2 N(p_{d1}) - X_1 N(p_{d2})$$

**Arguments**

$X_1$

specifies the price of the first asset.

$X_2$

specifies the price of the second asset.
specifies the cumulative normal density function.

\[ pd_1 = \frac{\ln \left( \frac{N_1}{N_2} \right) + \left( \frac{\sigma^2 t}{2} \right)}{\sigma \sqrt{t}} \]

\[ pd_2 = pd_1 - \sigma \sqrt{t} \]

\[ \sigma^2 = \sigma_{x_1}^2 + \sigma_{x_2}^2 - 2 \rho_{x_1, x_2} \sigma_{x_1} \sigma_{x_2} \]

The following arguments apply to the preceding equation:

- \( t \) is a nonmissing value that specifies the time to expiration, in years.
- \( \sigma_{x_1}^2 \) specifies the variance of the first asset.
- \( \sigma_{x_2}^2 \) specifies the variance of the second asset.
- \( \sigma_{x_1} \) specifies the volatility of the first asset.
- \( \sigma_{x_2} \) specifies the volatility of the second asset.
- \( \rho_{x_1, x_2} \) specifies the correlation between the first and second assets.

To view the corresponding CALL relationship, see the “MARGRCLPRC Function” on page 445.

For the special case of \( t=0 \), the following equation is true:

\[ \text{PUT} = \max(X_2 - X_1, 0) \]

Note: This function assumes that there are no dividends from the two assets.

For information about the basics of pricing, see "Using Pricing Functions".

**Comparisons**

The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. These functions return a scalar value.

**Example**

The following statements illustrate the MARGRPTPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a = \text{margrptprc}(2, .25, 3, .06, .2, 1); )</td>
<td>1.00000000009729</td>
</tr>
<tr>
<td>put a;</td>
<td></td>
</tr>
</tbody>
</table>

Functions:

- “MARGRCLPRC Function” on page 445

MAX Function

Returns the largest value from a list of arguments.

Category: Descriptive Statistics

Returned data type: BIGINT, DECIMAL, DOUBLE, NUMERIC

Syntax

MAX(expression-1, expression-2 [, …expression-n])

Arguments

expression

is any valid expression that evaluates to a numeric value.

Requirement

At least two arguments are required.

Data type

BIGINT, DECIMAL, DOUBLE, NUMERIC

See

Details

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.

Comparisons

The MAX function returns the largest value from a list of arguments. The MAX operator (<> returns the largest of two operands.

The MAX function returns a null or missing value only if all arguments are null or missing. The MAX operator (<> returns a null or missing value only if both operands are null or missing. In this case, it returns the value of the operand that is higher in the sort order for null or missing values.
Example

The following statements illustrate the MAX function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=max(8,3);</td>
<td>8</td>
</tr>
<tr>
<td>x=max(2, 6, .);</td>
<td>6</td>
</tr>
<tr>
<td>x=max(2, -3, 1, -1);</td>
<td>2</td>
</tr>
<tr>
<td>x=max(3, ., -3);</td>
<td>3</td>
</tr>
</tbody>
</table>

Functions:
- “MIN Function” on page 456

MD5 Function

Returns the result of the message digest of a specified string in binary format.

- **Category:** Character
- **Restriction:** Use CHAR character arguments only. MD5 does not accept NCHAR character arguments.
- **Returned data type:** BINARY

Syntax

\texttt{MD5(string)}

**Arguments**

- **string**: specifies a character constant, variable, or expression.

**Data type**: BINARY, CHAR

**Tips**: Enclose a literal string of characters in single quotation marks.

For scalar character variable arguments, the initial character set encoding that is specified in the DECLARE statement is used to transcode the variable before it is passed to the MD5 function. For binary arguments, the binary value is converted to a character string and the session encoding is used to transcode the value it is passed to the MD5 function.
Details

The Basics
The MD5 function converts a string, based on the MD5 algorithm, into a 128-bit hash value. This hash value is referred to as a message digest (digital signature), and it is nearly unique for each string that is passed to the function.

The MD5 function does not format its own output. Use the $BINARYw. or the $HEXw. formats to view readable results.

The Message Digest Algorithm
A message digest results from manipulating and compacting an arbitrarily long stream of binary data. An ideal message digest algorithm never generates the same result for two different sets of input. However, generating such a unique result would require a message digest as long as the input itself. Therefore, MD5 generates a message digest of modest size (16 bytes), created with an algorithm that is designed to make a nearly unique result.

Using the MD5 Function
You can use the MD5 function to track changes in your tables. The MD5 function can generate a digest of a set of column values in a record in a table. This digest could be treated as the signature of the record, and be used to keep track of changes that are made to the record. If the digest from the new record matches the existing digest of a record in a table, then the two records are the same. If the digest is different, then a column value in the record has changed. The new changed record could then be added to the table along with a new surrogate key because it represents a change to an existing keyed value.

The MD5 function can be useful when developing shell scripts or Perl programs for software installation, for file comparison, and for detection of file corruption and tampering.

You can also use the MD5 function to create a unique identifier for observations to be used as the key of a hash package. For more information, see “Using the Hash Package” in SAS Viya: DS2 Programmer’s Guide.

Example
Here is an example of how to generate results that are returned by the MD5 function.

data _null_;  
  method init();  
  dcl char(16) y z having format $hex32.;  
  y = md5('abc');  
  z = md5('access method');  
  put y= ;  
  put z= ;  
end;  
enddata;  
run;

SAS writes the following results to the log:

y=900150983CD24FB0D6963F7D28E17F72  
z=53128C19421A8E0C7F6436D06A026537

y=900150983CD24FB0D6963F7D28E17F72  
z=53128C19421A8E0C7F6436D06A026537

Chapter 7 • DS2 Functions
MDY Function

Returns a SAS date value from month, day, and year values.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

\[
\text{MDY}(\text{month}, \text{day}, \text{year})
\]

**Arguments**

- **month** specifies a numeric expression that represents an integer from 1 through 12.
  
  **Data type:** DOUBLE

  **See**  
  "DS2 Expressions" in SAS Viya: DS2 Programmer’s Guide

- **day** specifies a numeric expression that represents an integer from 1 through 31.
  
  **Data type:** DOUBLE

  **See**  
  "DS2 Expressions" in SAS Viya: DS2 Programmer’s Guide

- **year** specifies a numeric expression that represents a two-digit or four-digit year. The YEARCUTOFF= system option defines the year value for two-digit dates.
  
  **Data type:** DOUBLE

  **See**  
  "DS2 Expressions" in SAS Viya: DS2 Programmer’s Guide

**Example**

The following statements illustrate the MDY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>mn=8; dy=27; yr=12; birthday= mdy(mn,dy,yr); put birthday;</td>
<td>08/27/2012</td>
</tr>
<tr>
<td>mn=7; dy=11; yr=12; anniversary= mdy(mn,dy,yr); put anniversary;</td>
<td>11JUL2012</td>
</tr>
</tbody>
</table>

Functions:
- “DAY Function” on page 296
- “MONTH Function” on page 464
- “YEAR Function” on page 674

MEAN Function

Returns the arithmetic mean (average) of the non-null or nonmissing arguments.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

MEAN(expression[, ...expression])

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Requirement
At least one non-null or nonmissing argument is required. Otherwise, the function returns a null or missing value.

Data type
DOUBLE

See

Comparisons

The GEOMEAN function returns the geometric mean, the HARMEAN function returns the harmonic mean, whereas the MEAN function returns the arithmetic mean (average).

Example

The following statements illustrate the MEAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=mean(2,.,.,6);</td>
<td>4</td>
</tr>
<tr>
<td>a=mean(1,2,3,2);</td>
<td>2</td>
</tr>
</tbody>
</table>
MEDIAN Function

Returns the median value.

**Category:** Descriptive Statistics

**Returned data type:** DOUBLE

**Syntax**

`MEDIAN(expression[, …expression])`

**Arguments**

`expression`

specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

**Details**

The MEDIAN function returns the median of the nonmissing or nonnull values. If all arguments have missing or null values, the result is a missing or null value.

*Note:* The formula that is used in the MEDIAN function is the same as the formula that is used in PROC UNIVARIATE in *Base SAS Procedures Guide: Statistical Procedures*.

**Comparisons**

The MEDIAN function returns the median of nonmissing or nonnull values, whereas the MEAN function returns the arithmetic mean (average).

**Example**
The following statements illustrate the MEDIAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=median(2, 4, 1, 3);</td>
<td>2.5</td>
</tr>
<tr>
<td>y=median(5, 8, 0, 3, 4);</td>
<td>4</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “MEAN Function” on page 454

MIN Function

Returns the smallest value.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Descriptive Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>BIGINT, DECIMAL, DOUBLE, NUMERIC</td>
</tr>
</tbody>
</table>

Syntax

MIN(expression-1, expression-2 [,…expression-n])

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Requirement</th>
<th>At least two arguments are required.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>BIGINT, DECIMAL, DOUBLE, NUMERIC</td>
</tr>
</tbody>
</table>

Details

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.

Comparisons

The MIN function returns the smallest value from a list of values. The MIN operator (<=) returns the smallest value of two operands.

The MIN function returns a null or missing value only if all arguments are null or missing. The MIN operator returns a null or missing value only if either operand is null
or missing. In this case, it returns the value of the operand that is lower in the sort order for null or missing values.

**Example**

The following statements illustrate the MIN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=min(2,.,6);</td>
<td>2</td>
</tr>
<tr>
<td>a=min(2,-3,1,-1);</td>
<td>-3</td>
</tr>
</tbody>
</table>

**MINUTE Function**

Returns the minute from a SAS time or datetime value.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

MINUTE(time | datetime)

**Arguments**

**time**

- specifies any valid expression that represents a SAS time value.
  - **Data type:** DOUBLE
  - **See:** “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

**datetime**

- specifies any valid expression that represents a SAS datetime value.
  - **Data type:** DOUBLE
  - **See:** “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

**Details**

The MINUTE function returns an integer that represents a specific minute of the hour. MINUTE always returns a positive number in the range of 0 through 59. Null or missing values are ignored.

**Example**

The following statement illustrates the MINUTE function:
MISSING Function

Returns a number that indicates whether the argument contains a missing value.

**Syntax**

MISSING(expression)

**Arguments**

*expression* specifies any valid expression that evaluates to a value.

<table>
<thead>
<tr>
<th>Data type</th>
<th>All data types</th>
</tr>
</thead>
</table>

**Note**

If you are using SAS Federation Server, ANSI null values are translated to SAS missing values inFedSQL CALL invocations when the DS2_SASMISSING environment variable is set to TRUE.

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

- The MISSING function checks if a value is a null or missing value and returns a numeric result. If the argument does not contain a missing value, SAS returns a value of 0. If the argument contains a missing value, SAS returns a value of 1.
- In SAS mode, a blank-filled character value is defined to be the SAS missing value. In ANSI mode, a blank-filled character value is defined as nonmissing and non-null.
- In SAS mode, a DOUBLE value could be a SAS missing value (. , .A through .Z). The other numeric types do not support SAS missing values.
- The MISSING function returns a 1 if a package instance does not exist. That is, the package variable is a missing package reference. The MISSING function returns a 0 if the package variable references a package instance.
Comparisons

The MISSING function can have only one argument. The NMISS function requires numeric arguments and returns the number of missing values in the list of arguments.

*Note:* Missing values and null values are treated differently in SAS mode versus ANSI mode. Missing and null values might be converted dependent on mode.

Examples

**Example 1: Using the MISSING Function**
The following example illustrates the MISSING function.

```sas
data _null_; method init();
dcl int a[3];
dcl double i;
a[1]=2;
a[2]=4;
a[3]=.;
do i = 1 to 3;
   if missing(a[i]) then put 'Missing';
   else put 'Not Missing';
end;
end;
enddata;
run;
```

The following lines are written to the SAS log.

```
Not Missing
Not Missing
Missing
```

**Example 2: MISSING Function with SAS Mode and ANSI Mode**
This example illustrates how a DS2 program with a MISSING function can return different results based on mode.

```sas
data _null_; method init();
declare char(1) a[3];
declare double b[3];
declare int c[3];
declare double i;

a := ('a', '', NULL);
b := (1, ., NULL);
c := (1, NULL, NULL);

do i = 1 to 3;
   if (missing(a[i])) then put a[i]= 'missing';
   else put a[i]= 'not missing';
   if (missing(b[i])) then put b[i]= 'missing';
   else put b[i]= 'not missing';
```
if (missing(c[i])) then put c[i] = 'missing';
else put c[i] = 'not missing';
end;
end;
enddata;
run;

In SAS mode, the following lines are written to the SAS log.

```
a[1]=a not missing  
b[1]=1 not missing  
c[1]=1 not missing  
a[2]= missing       
b[2]= missing      
c[2]= missing      
a[3]= missing      
b[3]= missing      
c[3]= missing      
```

In ANSI mode, the following lines are written to the SAS log.

```
a[1]=a not missing  
b[1]=1 not missing  
c[1]=1 not missing  
a[2]= not missing   
b[2]= missing      
c[2]= missing      
a[3]= missing      
b[3]= missing      
c[3]= missing      
```

Functions:

- “NMISS Function” on page 470
- “N Function” on page 466
- “NULL Function” on page 499

MOD Function

Returns the remainder from the division of the first argument by the second argument, fuzzed to avoid most unexpected floating-point results.

**Category:** Mathematical

**Returned data type:** DOUBLE

**Syntax**

```
MOD(dividend-expression, divisor-expression)
```
Arguments

dividend-expression
specifies a dividend that is any valid expression that evaluates to a numeric value.

Data type DOUBLE

divisor-expression
specifies a divisor that is any valid expression that evaluates to a numeric value.

Restriction divisor-expression cannot be 0

Data type DOUBLE

Details

The MOD function returns the remainder from the division of dividend-expression by divisor-expression. When the result is nonzero, the result has the same sign as the first argument. The sign of the second argument is ignored.

The computation that is performed by the MOD function is exact if both of the following conditions are true:

- Both arguments are exact integers.
- All integers that are less than either argument have exact 8-byte floating-point representations.

If either of the above conditions is not true, a small amount of numerical error can occur in the floating-point computation. In this case, the following occurs:

- MOD returns zero if the remainder is very close to zero or very close to the value of the second argument.
- MOD returns a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more. In this case, SAS also writes an error message to the log.

Comparisons

Here are some comparisons between the MOD and MODZ functions:

- The MOD function performs extra computations, called fuzzing, to return an exact zero when the result would otherwise differ from zero because of numerical error.
- The MODZ function performs no fuzzing.
- Both the MOD and MODZ functions return a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more.

Example

The following statements illustrate the MOD function:
<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=mod(10,3);</td>
<td>1</td>
</tr>
<tr>
<td>a=mod(.35,-.1);</td>
<td>0.05</td>
</tr>
<tr>
<td>a=mod(17,3);</td>
<td>2</td>
</tr>
<tr>
<td>a=mod(.3,-.9);</td>
<td>0.3</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “MODZ Function” on page 462
- “INT Function” on page 367
- “INTZ Function” on page 410

MODZ Function

Returns the remainder from the division of the first argument by the second argument, using zero fuzzing.

Category: Mathematical

Returned data type: DOUBLE

Syntax

\[
\text{MODZ}(\text{dividend-expression}, \text{divisor-expression})
\]

Arguments

\textit{dividend-expression}

specifies a dividend that is any valid expression that evaluates to a numeric value.

Data type: DOUBLE

\textit{divisor-expression}

specifies a divisor that is any valid expression that evaluates to a numeric value.

Restriction: \textit{divisor-expression} cannot be 0

Data type: DOUBLE

Details

The MODZ function returns the remainder from the division of \textit{dividend-expression} by \textit{divisor-expression}. When the result is nonzero, the result has the same sign as the first argument. The sign of the second argument is ignored.

The computation that is performed by the MODZ function is exact if both of the following conditions are true:

- Both arguments are exact integers.
- All integers that are less than either argument have exact 8-byte floating-point representation.

If either of the above conditions is not true, a small amount of numerical error can occur in the floating-point computation. For example, when you use exact arithmetic and the result is zero, MODZ might return a very small positive value or a value slightly less than the second argument.

Comparisons

Here are some comparisons between the MODZ and MOD functions:

- The MODZ function performs no fuzzing.
- The MOD function performs fuzzing, to return an exact zero when the result would otherwise differ from zero because of numerical error.
- Both the MODZ and MOD functions return a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more.

Example

The following statements illustrate the differences between the MOD and MODZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=mod(10,3); b=modz(10,3);</td>
<td>1 1</td>
</tr>
<tr>
<td>a=mod(.35,-.1); b=modz(.35,-.1);</td>
<td>0.05 0.49999999999999</td>
</tr>
<tr>
<td>a=mod(17,3); b=modz(17,3)</td>
<td>2 2</td>
</tr>
<tr>
<td>a=mod(.3,-.9); b=modz(.3,-.9);</td>
<td>0.3 0.3</td>
</tr>
</tbody>
</table>

**MONTH Function**

Returns a number that represents the month from a SAS date value.

**Category:** Date and Time  
**Returned data type:** DOUBLE

**Syntax**

```
MONTH(date)
```

**Arguments**

- `date` specifies any valid expression that represents a SAS date value.

**Range**  
1–12

**Data type** DOUBLE

**See** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Example**

The following statement illustrates the MONTH function when the month is November:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=month(date());</code></td>
<td>11</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**

- “DAY Function” on page 296
- “YEAR Function” on page 674

---

**MORT Function**

Returns amortization parameters.

**Category:** Financial  
**Returned data type:** DOUBLE
Syntax

MORT\( (a, p, r, n) \)

Arguments

\( a \)

specifies any valid expression that evaluates to the initial amount.

Data type DOUBLE

\( p \)

specifies any valid expression that evaluates to the periodic payment.

Data type DOUBLE

\( r \)

specifies any valid expression that evaluates to the periodic interest rate that is expressed as a fraction.

Data type DOUBLE

\( n \)

specifies any valid expression that evaluates to the number of compounding periods.

Range \( n \geq 0 \)

Data type INTEGER

Details

Calculating Results

The MORT function returns the missing argument in the list of four arguments from an amortization calculation with a fixed interest rate that is compounded each period. The arguments are related by the following equation:

\[
p = \frac{ar(1 + r)^n}{(1 + r)^n - 1}
\]

One missing argument must be provided. The value is then calculated from the remaining three. No adjustment is made to convert the results to round numbers.

Restrictions in Calculating Results

The MORT function returns an invalid argument note to the SAS log and sets \&_ERROR_\ to 1 if one of the following argument combinations is true:

- \( rate < -1 \) or \( n < 0 \)
- \( principal \leq 0 \) or \( payment \leq 0 \) or \( n \leq 0 \)
• principal <= 0 or payment <= 0 or rate <= –1
• principal * rate > payment
• principal > payment * n

Example

In the following example, an amount of $50,000 is borrowed for 30 years at an annual interest rate of 10% compounded monthly.

data test (overwrite=yes);
  dcl double payment;
  method run();
    payment=mort(50000, . , .10/12, 30*12);
    put payment;
  end;
enddata;
run;

The value that is returned is 438.79 (rounded). The second argument is set to missing, which indicates that the periodic payment is to be calculated. The 10% nominal annual rate has been converted to a monthly rate of 0.10/12. The rate is the fractional (not the percentage) interest rate per compounding period. The 30 years are converted to 360 months.

N Function

Returns the number of non-null or nonmissing numeric values.

Category: Descriptive Statistics

Returned data type: DECIMAL, DOUBLE, NUMERIC

Syntax

N(expression [, …expression])

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Requirement: At least one argument is required.

Data type: DECIMAL, DOUBLE, NUMERIC

Details

Null values are converted to missing values and are counted as missing values.
Comparisons

The N function counts non-null and nonmissing values, whereas the NMISS function counts missing values. The N function requires numeric arguments.

Example

The following statements illustrate the N function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=n(1,0,.,2,5,.);</td>
<td>4</td>
</tr>
<tr>
<td>a=n(1,2);</td>
<td>2</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “NMISS Function” on page 470

NDIMS Function

Returns the number of dimensions in an array.

Category: Array

Returned data type: INTEGER

Syntax

NDIMS(array-name)

Arguments

array-name specifies the name of a temporary or a variable array.

Details

The NDIMS function returns the number of dimensions of a multidimensional array, or returns 1 for a one-dimensional array.

Comparisons

- DIM returns the number of elements in an array dimension.
- HBOUND returns the value of the upper bound of an array dimension.
- LBOUND returns the value of the lower bound of an array dimension.
- NDIMS returns the number of dimensions in an array.
Example: Using Array Functions

The following example shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions:

```sas
data _null_
method init();
    declare char(15) a1[4];
    declare double   a2[2,3,4] sum;

    a1 := ('red' 'yellow' 'green' 'blue');
    a2 := (24*2.0);

    do i = 1 to dim(a1);
        put a1[i];
    end;

    numelems = 0;
    do i = 1 to ndims(a2);
        numelems = numelems + dim(a2, i);
    end;

    sum = 0;
    do i = lbound(a2, 1) to hbound(a2, 1);
        do j = lbound(a2, 2) to hbound(a2, 2);
            do k = lbound(a2, 3) to hbound(a2, 3);
                sum = sum + a2[i,j,k];
            end;
        end;
    end;

    put sum=;
end;
```

SAS writes the following output to the log:

```
red
yellow
green
blue
sum=48
```

- “HBOUND Function” on page 353
- “LBOUND Function” on page 429
NETPV Function

Returns the net present value as a percent.

Category: Financial

Returned data type: DOUBLE

Syntax

\[ \text{NETPV}(r, \text{freq}, c_0, c_1, \ldots, c_n) \]

Arguments

\( r \)

is numeric, the interest rate over a specified base period of time expressed as a fraction.

Range \( r \geq 0 \)

Data type DOUBLE

\( \text{freq} \)

is numeric, the number of payments during the base period of time that is specified with the rate \( r \).

Range \( \text{freq} > 0 \)

Data type DOUBLE

Note

The case \( \text{freq} = 0 \) is a flag to allow continuous discounting.

\( c_0, c_1, \ldots, c_n \)

are numeric cash flows that represent cash outlays (payments) or cash inflows (income) occurring at times 0, 1, ... \( n \). These cash flows are assumed to be equally spaced, beginning-of-period values. Negative values represent payments, positive values represent income, and values of 0 represent no cash flow at a given time. The \( c_0 \) argument and the \( c_1 \) argument are required.

Data type DOUBLE

Details

The NETPV function returns the net present value at time 0 for the set of cash payments \( c_0, c_1, \ldots, c_n \), with a rate \( r \) over a specified base period of time. The argument \( \text{freq} > 0 \) describes the number of payments that occur over the specified base period of time.

The net present value is given by the equation:

\[ \text{NETPV}(r, \text{freq}, c_0, c_1, \ldots, c_n) = \sum_{i=0}^{n} c_i x^i \]

The following relationship applies to the preceding equation:
\[
x = \begin{cases} 
\frac{1}{(1 + r)^{1/freq}} & \text{freq} > 0 \\
\epsilon^{-r} & \text{freq} = 0 
\end{cases}
\]

Missing values in the payments are treated as 0 values. When \(freq > 0\), the rate \(r\) is the effective rate over the specified base period. To compute with a quarterly rate (the base period is three months) of 4% with monthly cash payments, set \(freq\) to 3 and set \(r\) to .04.

If \(freq\) is 0, continuous discounting is assumed. The base period is the time interval between two consecutive payments, and the rate \(r\) is a nominal rate.

To compute with a nominal annual interest rate of 11% discounted continuously with monthly payments, set \(freq\) to 0 and set \(r\) to .11/12.

Example

For an initial investment of $500 that returns biannual payments of $200, $300, and $400 over the succeeding 6 years and an annual discount rate of 10%, the net present value of the investment can be expressed as follows:

```plaintext
data _null_; 
  method run(); 
  value = netpv(.10,.5,-500,200,300,400); 
  put value; 
end; 
enddata; 
run; 
```

The value that is returned is 95.982864829379.

See Also

Functions:

- “NPV Function” on page 498

NMISS Function

Returns the number of null and SAS missing numeric values.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Descriptive Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

Syntax

\[ \text{NMISS}(expression [, \ldots expression]) \]

Arguments

- \(expression\): specifies any valid expression that evaluates to a numeric value.

- Requirement: At least one argument is required.
Details
Null values are converted to SAS missing values and are counted as missing values.

Comparisons
The NMISS function returns the number of null or SAS missing values, whereas the N function returns the number of non-null and nonmissing values. NMISS requires numeric values and works with multiple numeric values, whereas MISSING works with only one value that can be either numeric or character.

Example
The following statements illustrate the NMISS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=nmiss(1,0,.,2,5,.);</td>
<td>2</td>
</tr>
<tr>
<td>a=nmiss(1,0);</td>
<td>0</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “MISSING Function” on page 458
- “N Function” on page 466
- “NULL Function” on page 499

NOMRATE Function
Returns the nominal annual interest rate.

Syntax
NOMRATE(compounding-interval, rate)
**Arguments**

*compounding-interval*

is a SAS interval. This value represents how often the returned value is compounded.

Data type CHAR

*rate*

is numeric. *Rate* is the effective annual interest rate (expressed as a percentage) that is compounded at each interval.

Data type DOUBLE

**Details**

The NOMRATE function returns the nominal annual interest rate. NOMRATE computes the nominal annual interest rate that corresponds to an effective annual interest rate.

The following details apply to the NOMRATE function:

- The values for rates must be at least –99.
- In considering an effective interest rate and a compounding interval, if *compounding-interval* is 'CONTINUOUS', then the value that is returned by NOMRATE equals $\log_e(1+\frac{rate}{100})$.

If *compounding-interval* is not 'CONTINUOUS', and $m$ intervals occur in a year, the value that is returned by NOMRATE equals the following:

$$m \left(1 + \frac{\frac{rate}{100}}{m} \right)^{\frac{1}{m}} - 1$$

- The following values are valid for *compounding-interval*:
  - 'CONTINUOUS'
  - 'DAY'
  - 'SEMIMONTH'
  - 'MONTH'
  - 'QUARTER'
  - 'SEMIYEAR'
  - 'YEAR'
- If the interval is 'DAY', then $m=365$.

**Example**

- If an effective rate is 10% when compounded monthly, the corresponding nominal rate can be expressed as follows:
  $$\text{effective\_rate1} = \text{NOMRATE('MONTH', 10)};$$

- If an effective rate is 10% when compounded quarterly, the corresponding nominal rate can be expressed as follows:
  $$\text{effective\_rate2} = \text{NOMRATE('QUARTER', 10)};$$
NOTALNUM Function

Searches a character string for a non-alphanumeric character, and returns the first position at which the character is found.

**Category:** Character  
**Returned data type:** DOUBLE

**Syntax**

```
NOTALNUM('expression'[, start])
```

**Arguments**

- **expression** specifies any valid expression that evaluates to a character string.
  - **Data type:** CHAR, NCHAR
  - **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*
- **start** is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.
  - **Data type:** INTEGER

**Details**

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in *SAS Viya National Language Support: Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTALNUM function searches a string for the first occurrence of any character that is not a digit or an uppercase or lowercase letter. If such a character is found, NOTALNUM returns the position in the string of that character. If no such character is found, NOTALNUM returns a value of 0.

If you use only one argument, NOTALNUM begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTALNUM returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
• The value of \texttt{start} = 0.

**Comparisons**

The \texttt{NOTALNUM} function searches a character string for a non-alphanumeric character. The \texttt{ANYALNUM} function searches a character string for an alphanumeric character.

**Example**

The following example uses the \texttt{NOTALNUM} function to search a string from left to right for non-alphanumeric characters.

```sas
data _null_;  
dcl nchar(16) string c;  
dcl double j i;  
method run();  
  string='Next = Last + 1;';  
j=0;  
do until(j=0);  
j=notalnum(string, j+1);  
  if j=0 then put 'The end';  
  else do;  
    c=substr(string, j, 1);  
    put j= c=;  
  end;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
j=5 c=  
j=6 c==  
j=7 c=  
j=12 c=  
j=13 c==  
j=14 c=  
j=16 c=;  
The end
```

**See Also**

**Functions:**

• “\texttt{ANYALNUM Function}” on page 188

**NOTALPHA Function**

Searches a character string for a nonalphabetic character, and returns the first position at which the character is found.

- **Category:** Character
- **Returned data type:** DOUBLE
Syntax

\texttt{NOTALPHA(‘expression’[, \textit{start}])}

\textbf{Arguments}

\textit{expression} specifies any valid expression that evaluates to a character string.

Data type \texttt{CHAR, NCHAR}

\textit{start} is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

Data type \texttt{INTEGER}

\textbf{Details}

The results of the \texttt{NOTUPPER} function depend directly on the translation table that is in effect (see “\texttt{TRANTAB= Option}” in \textit{SAS Viya National Language Support: Reference Guide}) and indirectly on the \texttt{ENCODING} and the \texttt{LOCALE} system options.

The \texttt{NOTALPHA} function searches a string for the first occurrence of any character that is not an uppercase or lowercase letter. If such a character is found, \texttt{NOTALPHA} returns the position in the string of that character. If no such character is found, \texttt{NOTALPHA} returns a value of 0.

If you use only one argument, \texttt{NOTALPHA} begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

\begin{itemize}
  \item If the value of \textit{start} is positive, the search proceeds to the right.
  \item If the value of \textit{start} is negative, the search proceeds to the left.
  \item If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.
\end{itemize}

\texttt{NOTALPHA} returns a value of zero when one of the following is true:

\begin{itemize}
  \item The character that you are searching for is not found.
  \item The value of \textit{start} is greater than the length of the string.
  \item The value of \textit{start} = 0.
\end{itemize}

\textbf{Comparisons}

The \texttt{NOTALPHA} function searches a character string for a nonalphabetic character. The \texttt{ANYALPHA} function searches a character string for an alphabetic character.
Examples

Example 1: Searching a String for Nonalphabetic Characters
The following example uses the NOTALPHA function to search a string from left to right for nonalphabetic characters.

```sas
data _null_;  
dcl char(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12E3;';  
  j=0;  
  do until(j=0);  
    j=notalpha(string, j+1);  
    if j=0 then put 'The end';  
    else do;  
      c=substr(string, j, 1);  
      put j= c=;  
    end;  
  end;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
j=5 c= 
j=6 c== 
j=7 c= 
j=8 c=_ 
j=10 c=_ 
j=11 c= 
j=12 c+= 
j=13 c= 
j=14 c=1 
j=15 c=2 
j=17 c=3 
j=18 c=; 
The end
```

Example 2: Identifying Control Characters By Using the NOTALPHA Function
You can execute the following program to show the control characters that are identified by the NOTALPHA function.

```sas
data test;  
dcl nchar(3) byte1 hex1;  
dcl double dec notalpha1;  
method run();  
  do dec=0 to 255;  
    byte1=byte(dec);  
    hex1=put(dec,hex2.);  
    notalpha1=notalpha(byte1);  
    output;  
  end;  
end;  
enddata;
```
run;

Functions:
• “ANYALPHA Function” on page 190

NOTCNTRL Function

Searches a character string for a character that is not a control character, and returns the first position at which that character is found.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

NOTCNTRL(‘expression’, [start])

Arguments

expression
specifies any valid expression that evaluates to a character string.

Data type: CHAR, NCHAR

start
is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

Data type: INTEGER

Details

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTCNTRL function searches a string for the first occurrence of a character that is not a control character. If such a character is found, NOTCNTRL returns the position in the string of that character. If no such character is found, NOTCNTRL returns a value of 0.

If you use only one argument, NOTCNTRL begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

• If the value of start is positive, the search proceeds to the right.
• If the value of start is negative, the search proceeds to the left.
• If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.

\textsc{NOTCNTRL} returns a value of zero when one of the following is true:

• The character that you are searching for is not found.
• The value of \textit{start} is greater than the length of the string.
• The value of \textit{start} = 0.

\textbf{Comparisons}

The \textsc{NOTCNTRL} function searches a character string for a character that is not a control character. The \textsc{ANYCNTRL} function searches a character string for a control character.

\textbf{Example}

You can execute the following program to show the control characters that are identified by the \textsc{NOTCNTRL} function.

\begin{verbatim}
data test (overwrite=yes);
dcl double dec notcntrl1;
dcl char byte1 hex1;
method run();
do dec=0 to 255;
  byte1=byte(dec);
  hex1=put(dec, hex2.);
  notcntrl1=notcntrl(byte1);
  output;
end;
end;
enddata;
run;
\end{verbatim}

\textbf{See Also}

\textbf{Functions:}

• “\textsc{ANYCNTRL Function}” on page 193

\textbf{NOTDIGIT Function}

Searches a character string for any character that is not a digit, and returns the first position at which that character is found.

\textbf{Category:} Character  \hspace{1cm} \textbf{Returned data type:} DOUBLE

\textbf{Syntax}

\texttt{NOTDIGIT('expression'[, \textit{start}])}
Arguments

description

expression

specifies any valid expression that evaluates to a character string.

Data type CHAR, NCHAR

start

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

Data type INTEGER

Details

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTDIGIT function searches a string for the first occurrence of any character that is not a digit. If such a character is found, NOTDIGIT returns the position in the string of that character. If no such character is found, NOTDIGIT returns a value of 0.

If you use only one argument, NOTDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The NOTDIGIT function searches a character string for any character that is not a digit. The ANYDIGIT function searches a character string for a digit.

Example

The following example uses the NOTDIGIT function to search for a character that is not a digit.

```sas
   data _null_;   method run();
      dcl nchar(18) string c;
      dcl double j i;
      string='Next = _n_ + 12E3;';
      j=0;
```
do until(j=0);
    j=notdigit(string, j+1);
    if j=0 then put 'The end';
    else do;
        c=substr(string, j, 1);
        put j= c=;
    end;
end;
enddata;
run;

SAS writes the following output to the log:

 j=1 c=N
 j=2 c=e
 j=3 c=x
 j=4 c=t
 j=5 c=
 j=6 c==
 j=7 c=
 j=8 c=_
 j=9 c=n
 j=10 c=_
 j=11 c=
 j=12 c+=
 j=13 c=
 j=16 c=E
 j=18 c=;
The end

See Also

Functions:

• “ANYDIGIT Function” on page 194

NOTFIRST Function

Searches a character string for an invalid first character in a SAS variable name under
VALIDVARNAME=V7, and returns the first position at which that character is found.

Category: Character
Returned data type: DOUBLE

Syntax

NOTFIRST(expression[, start])

Arguments

expression
    specifies any valid expression that evaluates to a character string.
Data type     CHAR, NCHAR

See        “DS2 Expressions” in  *SAS Viya: DS2 Programmer’s Guide*

\textit{start} is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

Data type     INTEGER

\section*{Details}

The \texttt{NOTFIRST} function does not depend on the \texttt{TRANTAB}, \texttt{ENCODING}, or \texttt{LOCALE} system options.

The \texttt{NOTFIRST} function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under \texttt{VALIDVARNAME=V7}. These characters are any except the underscore (_), and uppercase or lowercase English letters. If such a character is found, \texttt{NOTFIRST} returns the position in the string of that character. If no such character is found, \texttt{NOTFIRST} returns a value of 0.

If you use only one argument, \texttt{NOTFIRST} begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \texttt{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- \textbf{If} the value of \texttt{start} is positive, the search proceeds to the right.
- \textbf{If} the value of \texttt{start} is negative, the search proceeds to the left.
- \textbf{If} the value of \texttt{start} is less than the negative length of the string, the search begins at the end of the string.

\texttt{NOTFIRST} returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \texttt{start} is greater than the length of the string.
- The value of \texttt{start} = 0.

\section*{Comparisons}

The \texttt{NOTFIRST} function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under \texttt{VALIDVARNAME=V7}. The \texttt{ANYFIRST} function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under \texttt{VALIDVARNAME=V7}.

\section*{Example}

The following example uses the \texttt{NOTFIRST} function to search a string for any character that is not valid as the first character in a SAS variable name under \texttt{VALIDVARNAME=V7}.

\begin{verbatim}
data _null_;    
dcl nchar(18) string c;    
dcl double j i;    
method run();    
    string='Next = _n_ + 12E3;';    
j=0;
\end{verbatim}
do until(j=0);
    j=notfirst(string, j+1);
    if j=0 then put 'The end';
    else do;
        c=substr(string, j, 1);
        put j= c=;
    end;
end;
enddata;
run;

SAS writes the following output to the log:

```
  j=5  c=
  j=6  c==
  j=7  c=
  j=11 c=
  j=12 c==
  j=13 c=
  j=14 c=1
  j=15 c=2
  j=17 c=3
  j=18 c=;
  The end
```

See Also

Functions:

- “ANYFIRST Function” on page 196

NOTGRAPH Function

Searches a character string for a non-graphical character, and returns the first position at which that character is found.

**Category:** Character  
**Returned data type:** DOUBLE

**Syntax**

```
NOTGRAPH(expression[, start])
```

**Arguments**

**expression**

specifies any valid expression that evaluates to a character string.

**Data type**  
CHAR, NCHAR

**See**

start

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

Data type INTEGER

Details

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTGRAPH function searches a string for the first occurrence of a non-graphical character. A graphical character is defined as any printable character other than white space. If such a character is found, NOTGRAPH returns the position in the string of that character. If no such character is found, NOTGRAPH returns a value of 0.

If you use only one argument, NOTGRAPH begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

• If the value of start is positive, the search proceeds to the right.
• If the value of start is negative, the search proceeds to the left.
• If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTGRAPH returns a value of zero when one of the following is true:

• The character that you are searching for is not found.
• The value of start is greater than the length of the string.
• The value of start = 0.

Comparisons

The NOTGRAPH function searches a character string for a non-graphical character. The ANYGRAPH function searches a character string for a graphical character.

Examples

Example 1: Searching a String for Non-Graphical Characters

The following example uses the NOTGRAPH function to search a string for a non-graphical character.

```plaintext
data _null_;  
dcl nchar(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12E3;';  
  j=0;  
  do until(j=0);  
    j=notgraph(string, j+1);  
    if j=0 then put 'The end';  
    else do;  
      c=substr(string, j, 1);  
      put j= cs;```
Example 2: Identifying Control Characters By Using the NOTGRAPH Function
You can execute the following program to show the control characters that are identified by the NOTGRAPH function.

```sas
data test (overwrite=yes);
dcl nchar byte1 hex1;
dcl double dec notgraph1;
method run();
do dec=0 to 255;
  byte1=byte(dec);
  hex1=put(dec,hex2.);
  notgraph1=notgraph(byte1);
  output;
end;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
j=5 c=
j=7 c=
j=11 c=
j=13 c=
The end
```

### NOTLOWER Function

Searches a character string for a character that is not a lowercase letter, and returns the first position at which that character is found.

- **Category:** Character
- **Returned data type:** DOUBLE
- **Syntax:**

```
NOTLOWER('expression'[, start])
```
**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

- **Data type**: CHAR, NCHAR

- **See**: “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*start*

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

- **Data type**: INTEGER

**Details**

The results of the NOTLOWER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in *SAS Viya National Language Support: Reference Guide*) and indirectly on the **ENCODING** and the **LOCALE** system options.

The NOTLOWER function searches a string for the first occurrence of any character that is not a lowercase letter. If such a character is found, NOTLOWER returns the position in the string of that character. If no such character is found, NOTLOWER returns a value of 0.

If you use only one argument, NOTLOWER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTLOWER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

**Comparisons**

The NOTLOWER function searches a character string for a character that is not a lowercase letter. The ANYLOWER function searches a character string for a lowercase letter.

**Example**

The following example uses the NOTLOWER function to search a string for any character that is not a lowercase letter.

```sas
data _null_;  
dcl nchar(18) string c;  
dcl double j i;  
method run();
```
string='Next = _n_ + 12E3;';
j=0;
do until(j=0);
j=notlower(string, j+1);
if j=0 then put 'The end';
else do;
c=substr(string, j, 1);
put j= c=;
end;
end;
enddata;
run;

SAS writes the following output to the log:

<table>
<thead>
<tr>
<th>j</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>N</td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>

NOTNAME Function

Searches a character string for an invalid character in a SAS variable name under VALIDVARNAME=V7, and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

```
NOTNAME('expression'[, start])
```

**Arguments**

- `expression` specifies any valid expression that evaluates to a character string.
Data type  CHAR, NCHAR

start

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

Data type  INTEGER

Details

The NOTNAME function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNANE=V7. These characters are any except underscore (_), digits, and uppercase or lowercase English letters. If such a character is found, NOTNAME returns the position in the string of that character. If no such character is found, NOTNAME returns a value of 0.

If you use only one argument, NOTNAME begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTNAME returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNANE=V7. The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNANE=V7.

Example

The following example uses the NOTNAME function to search a string for any character that is not valid in a SAS variable name under VALIDVARNANE=V7.

```plaintext
data _null_;  
dcl nchar(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12E3;';  
j=0;  
do until(j=0);
j=notname(string, j+1);
if j=0 then put 'The end';
else do;
   c=substr(string, j, 1);
   put j= c=;
end;
end;
enddata;
run;

SAS writes the following output to the log:

```
j=5 c=
n=6 c==
j=7 c=
j=11 c=
j=12 c==
j=13 c=
j=18 c=;
The end
```

### NOTPRINT Function

Searches a character string for a nonprintable character, and returns the first position at which that character is found.

**Category:** Character  
**Returned data type:** DOUBLE

#### Syntax

```
NOTPRINT('expression'[, start])
```

#### Arguments

- **expression**  
  specifies any valid expression that evaluates to a character string.
  
  **Data type** CHAR, NCHAR
  
  **See** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

- **start**  
  is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.
Data type INTEGER

Details

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTPRINT function searches a string for the first occurrence of a non-printable character. If such a character is found, NOTPRINT returns the position in the string of that character. If no such character is found, NOTPRINT returns a value of 0.

If you use only one argument, NOTPRINT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTPRINT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The NOTPRINT function searches a character string for a non-printable character. The ANYPRINT function searches a character string for a printable character.

Example

You can execute the following program to show the control characters that are identified by the NOTPRINT function.

```sas
data test (overwrite=yes);
dcl double dec notprint1;
dcl nchar byte1 hex1;
method run();
do dec=0 to 255;
byte1=byte(dec);
hex1=put(dec, hex2.);
notprint1=notprint(byte1);
output;
end;
end;
enddata;
run;
```

Functions:
NOTPUNCT Function

Searches a character string for a character that is not a punctuation character, and returns the first position at which that character is found.

**Category:** Character
**Returned data type:** DOUBLE

**Syntax**

`NOTPUNCT('expression'[, start])`

**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

**Data type** CHAR, NCHAR

**start**

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

**Data type** INTEGER

**Details**

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTPUNCT function searches a string for the first occurrence of a character that is not a punctuation character. If such a character is found, NOTPUNCT returns the position in the string of that character. If no such character is found, NOTPUNCT returns a value of 0.

If you use only one argument, NOTPUNCT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, `start`, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of `start` is positive, the search proceeds to the right.
- If the value of `start` is negative, the search proceeds to the left.
- If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

NOTPUNCT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
• The value of start is greater than the length of the string.
• The value of start = 0.

Comparisons

The NOTPUNCT function searches a character string for a character that is not a punctuation character. The ANYPUNCT function searches a character string for a punctuation character.

Examples

**Example 1: Searching a String for Characters That Are Not Punctuation Characters**

The following example uses the NOTPUNCT function to search a string for characters that are not punctuation characters.

```sas
data _null_;  
dcl char(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12E3;';  
  j=0;  
  do until(j=0);  
    j=notpunct(string, j+1);  
    if j=0 then put 'The end';  
    else do;  
      c=substr(string, j, 1);  
      put j= c=;  
    end;  
  end;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
j=1 c=N  
j=2 c=e  
j=3 c=x  
j=4 c=t  
j=5 c=  
j=6 c==  
j=7 c=  
j=9 c=n  
j=11 c=  
j=12 c=+  
j=13 c=  
j=14 c=1  
j=15 c=2  
j=16 c=E  
j=17 c=3  
The end
```
Example 2: Identifying Control Characters By Using the NOTPUNCT Function

You can execute the following program to show the control characters that are identified by the NOTPUNCT function.

```sas
data test;
  dcl nchar(3) byte1 hex1;
  dcl double dec notpunct1;

  method run();
    do dec=0 to 255;
      byte1=byte(dec);
      hex1=put(dec,hex2.);
      notpunct1=notpunct(byte1);
      output;
    end;
  end;
enddata;
run;
quit;
proc print data=test;
run;
```

NOTSPACE Function

Searches a character string for a character that is not a whitespace character (blank, horizontal and vertical tab, carriage return, line feed, and form feed), and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

```
NOTSPACE('expression'[, start])
```

**Arguments**

**expression**

specifies any valid expression that evaluates to a character string.

**Data type**  CHAR, NCHAR

**See**

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

**Data type**  INTEGER

**Details**

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in SAS Viya National Language Support: Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTSPACE function searches a string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. If such a character is found, NOTSPACE returns the position in the string of that character. If no such character is found, NOTSPACE returns a value of 0.

If you use only one argument, NOTSPACE begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTSPACE returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

**Comparisons**

The NOTSPACE function searches a character string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. The ANYSPACE function searches a character string for the first occurrence of a character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed.

**Examples**

**Example 1: Searching a String for a Character That Is Not a Whitespace Character**

The following example uses the NOTSPACE function to search a string for a character that is not a whitespace character.

```sas
data _null_
  dcl char(18) string c;
  dcl double j i;
  method run();
    string='Next = _n_ + 12E3;';
    j=0;
    do until(j=0);
```
j=notspace(string, j+1);
if j=0 then put 'The end';
else do;
    c=substr(string, j, 1);
    put j= c=;
end;
end;
enddata;
run;

SAS writes the following output to the log:

j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=6 c==
j=8 c=_
j=9 c=n
j=10 c=_
j=12 c=+
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
j=18 c=;
The end

Example 2: Identifying Control Characters By Using the NOTSPACE Function
You can execute the following program to show the control characters that are identified by the NOTSPACE function.

data test (overwrite=yes);
dcl nchar(3) byte1 hex1;
dcl double dec notspace1;

method run();
do dec=0 to 255;
    byte1=byte(dec);
    hex1=put(dec,hex2.);
    notspace1=notspace(byte1);
    output;
end;
end;
enddata;
run;

See Also

Functions:
• “ANYSPACE Function” on page 209
NOTUPPER Function

Searches a character string for a character that is not an uppercase letter, and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

\[
\text{NOTUPPER('expression'[, start])}
\]

**Arguments**

**expression**

specifies any valid expression that evaluates to a character string.

Data type: CHAR, NCHAR

**start**

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

Data type: INTEGER

**Details**

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= Option” in *SAS Viya National Language Support: Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTUPPER function searches a string for the first occurrence of a character that is not an uppercase letter. If such a character is found, NOTUPPER returns the position in the string of that character. If no such character is found, NOTUPPER returns a value of 0.

If you use only one argument, NOTUPPER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \(\text{start}\), specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \(\text{start}\) is positive, the search proceeds to the right.
- If the value of \(\text{start}\) is negative, the search proceeds to the left.
- If the value of \(\text{start}\) is less than the negative length of the string, the search begins at the end of the string.

NOTUPPER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \(\text{start}\) is greater than the length of the string.
• The value of \( \text{start} = 0 \).

Comparisons

The NOTUPPER function searches a character string for a character that is not an uppercase letter. The ANYUPPER function searches a character string for an uppercase letter.

Example

The following example uses the NOTUPPER function to search a string for any character that is not an uppercase letter.

```sas
data _null_;  
dcl char(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12B3;';  
  j=0;  
  do until(j=0);  
    j=notupper(string, j+1);  
    if j=0 then put 'The end';  
    else do;  
      c=substr(string, j, 1);  
      put j= c=;  
    end;  
  end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
j=2 c=e  
j=3 c=x  
j=4 c=t  
j=5 c=  
j=6 c==  
j=7 c=  
j=8 c=_  
j=9 c=n  
j=10 c=_  
j=11 c=  
j=12 c==  
j=13 c=  
j=14 c=1  
j=15 c=2  
j=17 c=3  
j=18 c=;  
The end
```

NOTXDIGIT Function

Searches a character string for a character that is not a hexadecimal character, and returns the first position at which that character is found.

**Category:** Character

**Returned data type:** DOUBLE

### Syntax

NOTXDIGIT(‘expression’, \[start\])

### Arguments

**expression**

specifies any valid expression that evaluates to a character string.

**Data type** CHAR, NCHAR

**See** “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

**start**

is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search.

**Data type** INTEGER

### Details

The NOTXDIGIT function searches a string for the first occurrence of any character that is not a digit or an uppercase or lowercase A, B, C, D, E, or F. If such a character is found, NOTXDIGIT returns the position in the string of that character. If no such character is found, NOTXDIGIT returns a value of 0.

If you use only one argument, NOTXDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \(start\), specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \(start\) is positive, the search proceeds to the right.
- If the value of \(start\) is negative, the search proceeds to the left.
- If the value of \(start\) is less than the negative length of the string, the search begins at the end of the string.

NOTXDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \(start\) is greater than the length of the string.
- The value of \(start = 0\).
Comparisons

The NOTXDIGIT function searches a character string for a character that is not a hexadecimal character. The ANYXDIGIT function searches a character string for a character that is a hexadecimal character.

Example

The following example uses the NOTXDIGIT function to search a string for a character that is not a hexadecimal character.

```sas
data _null_;  
dcl char(18) string c;  
dcl double j i;  
method run();  
  string='Next = _n_ + 12E3;';  
  j=0;  
  do until(j=0);  
    j=notxdigit(string, j+1);  
    if j=0 then put 'The end';  
    else do;  
      c=substr(string, j, 1);  
      put j= c=;  
    end;  
  end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
j=1 c=N  
j=3 c=x  
j=4 c=t  
j=5 c=  
j=6 c=  
j=7 c=  
j=8 c=_  
j=9 c=n  
j=10 c=_  
j=11 c=  
j=12 c=+  
j=13 c=  
j=18 c=;  
The end
```

See Also

Functions:

NPV Function

Returns the net present value with the rate expressed as a percentage.

Category: Financial
Returned data type: DOUBLE

**Syntax**

\( \text{NPV}(r, \text{freq}, c0, c1, \ldots, cn) \)

**Arguments**

- **r**
  - is numeric, the interest rate over a specified base period of time expressed as a percentage.
  - Data type: DOUBLE

- **freq**
  - is numeric, the number of payments during the base period of time specified with the rate \( r \).
  - Range: \( freq > 0 \)
  - Data type: DOUBLE
  - Note: The case \( freq = 0 \) is a flag to allow continuous discounting.

- **c0, c1, \ldots, cn**
  - are numeric cash flows that represent cash outlays (payments) or cash inflows (income) occurring at times 0, 1, \ldots, n. These cash flows are assumed to be equally spaced, beginning-of-period values. Negative values represent payments, positive values represent income, and values of 0 represent no cash flow at a given time. The \( c0 \) argument and the \( c1 \) argument are required.
  - Data type: DOUBLE

**Comparisons**

The NPV function is identical to NETPV, except that the \( r \) argument is provided as a percentage.

**See Also**

Functions:
- “NETPV Function” on page 469

---

**NULL Function**

Returns a 1 if the argument is null and a 0 if the argument is not null.

- **Category:** Special
- **Returned data type:** INTEGER
Syntax

NULL(expression)

Arguments

expression

specifies any valid expression.

Data type All data types

Note If you are using SAS Federation Server, ANSI null values are translated to SAS missing values in FedSQL CALL invocations when the DS2_SASMISSING environment variable is set to TRUE.

Details

The NULL function returns a 1 only for a null value. It returns a 0 for any non-null value, including a SAS missing value.

The NULL function returns a 1 if a package instance does not exist, that is the package variable is a null package reference. The NULL function returns a 0 if the package variable references a package instance.

Note: Missing values and null values are treated differently in SAS mode versus ANSI mode. Missing and null values might be converted dependent on mode.

Example

The following example illustrates how null can differ in SAS mode and in ANSI mode.

```sas
proc ds2;
  data _null_
    method init();
    declare char(1) a[3];
    declare double  b[3];
    declare int c[3];
    declare int i;

    a := ('a', '', NULL);
    b := (1, ., NULL);
    c := (1, NULL, NULL);

    do i = 1 to 3;
      if (null(a[i])) then put a[i]= 'null';
      else put a[i]= 'not null';

      if (null(b[i])) then put b[i]= 'null';
      else put b[i]= 'not null';

      if (null(c[i])) then put c[i]= 'null';
      else put c[i]= 'not null';
    end;
  end;
enddata;
```
run;
quit;

proc ds2 ansimode;
data _null_; method init();
declare char(1) a[3];
declare double  b[3];
declare int  c[3];
declare int i;
a := ('a', '', NULL);
b := (1, ., NULL);
c := (1, NULL, NULL);
do i = 1 to 3;
   if (null(a[i])) then put a[i]= 'null';
      else put a[i]= 'not null';
   if (null(b[i])) then put b[i]= 'null';
      else put b[i]= 'not null';
   if (null(c[i])) then put c[i]= 'null';
      else put c[i]= 'not null';
end;
enddata;
endrun;
quit;

In SAS mode, the following lines are written to the SAS log.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>1</td>
<td>1</td>
<td>not null</td>
<td>not null</td>
<td>null</td>
<td>not null</td>
<td>null</td>
<td>null</td>
</tr>
</tbody>
</table>

In ANSI mode, the following lines are written to the SAS log.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>

NWKDOM Function

Returns the date for the $n$th occurrence of a weekday for the specified month and year.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

NWKDOM($n$, weekday, month, year)

Arguments

$n$

specifies the numeric week of the month that contains the specified day.

<table>
<thead>
<tr>
<th>Range</th>
<th>1–5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>INTEGER</td>
</tr>
<tr>
<td>Tip</td>
<td>$N=5$ indicates that the specified day occurs in the last week of that month. Sometimes $n=4$ and $n=5$ produce the same results.</td>
</tr>
</tbody>
</table>

weekday

specifies the number that corresponds to the day of the week.

<table>
<thead>
<tr>
<th>Range</th>
<th>1–7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>INTEGER</td>
</tr>
<tr>
<td>Tip</td>
<td>Sunday is considered the first day of the week and has a weekday value of 1.</td>
</tr>
</tbody>
</table>

month

specifies the number that corresponds to the month of the year.

| Range | 1–12 |
Data type  INTEGER

*year*

specifies a four-digit calendar year.

Data type  INTEGER

Details

The NWKDOM function returns a SAS date value for the *n*th weekday of the month and year that you specify. Use any valid SAS date format, such as the DATE9. format, to display a calendar date. You can specify *n*=5 for the last occurrence of a particular weekday in the month.

Sometimes *n*=5 and *n*=4 produce the same result. These results occur when there are only four occurrences of the requested weekday in the month. For example, if the month of January begins on a Sunday, there will be five occurrences of Sunday, Monday, and Tuesday, but only four occurrences of Wednesday, Thursday, Friday, and Saturday. In this case, specifying *n*=5 or *n*=4 for Wednesday, Thursday, Friday, or Saturday will produce the same result.

If the year is not a leap year, February has 28 days and there are four occurrences of each day of the week. In this case, *n*=5 and *n*=4 produce the same results for every day.

Comparisons

In the NWKDOM function, the value for *weekday* corresponds to the numeric day of the week beginning on Sunday. This value is the same value that is used in the WEEKDAY function, where Sunday =1, and so on. The value for *month* corresponds to the numeric month of the year beginning in January. This value is the same value that is used in the MONTH function, where January =1, and so on.

You can use the NWKDOM function to calculate events that are not defined by the HOLIDAY function. For example, if a university always schedules graduation on the first Saturday in June, then you can use the following statement to calculate the date:

```
UnivGrad = nwkdom(1, 7, 6, year);
```

Examples

**Example 1: Returning Date Values**

The following example uses the NWKDOM function and returns the date for specific occurrences of a weekday for a specified month and year.

```
data _null_;  
method run();  
  /* Return the date of the third Monday in May 2012. */  
a=nwkdom(3, 2, 5, 2012);  
  /* Return the date of the fourth Wednesday in November 2012. */  
b=nwkdom(4, 4, 11, 2012);  
  /* Return the date of the fourth Saturday in November 2012. */  
c=nwkdom(4, 7, 11, 2012);  
  /* Return the date of the first Sunday in January 2013. */  
d=nwkdom(1, 1, 1, 2013);  
  /* Return the date of the second Tuesday in September 2012. */  
e=nwkdom(2, 3, 9, 2012);  
  /* Return the date of the fifth Thursday in December 2012. */
```
f=nwkdom(5, 5, 12, 2012);
put a= weekdatx.;
put b= weekdatx.;
put c= weekdatx.;
put d= weekdatx.;
put e= weekdatx.;
put f= weekdatx.;
end;
enddata;
run;

SAS writes the following output to the log:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Monday, 21 May 2012</td>
</tr>
<tr>
<td>b</td>
<td>Wednesday, 28 November 2012</td>
</tr>
<tr>
<td>c</td>
<td>Saturday, 24 November 2012</td>
</tr>
<tr>
<td>d</td>
<td>Sunday, 6 January 2013</td>
</tr>
<tr>
<td>e</td>
<td>Tuesday, 11 September 2012</td>
</tr>
<tr>
<td>f</td>
<td>Thursday, 27 December 2012</td>
</tr>
</tbody>
</table>

Example 2: Returning the Date of the Last Monday in May

The following example returns the date that corresponds to the last Monday in the month of May in the year 2012.

data _null_
  method init();
  /* The last Monday in May. */
  x=nwkdom(5,2,5,2012);
  put x date9.;
end;
enddata;
run;

SAS writes the following output to the log:

28MAY2012

**ORDINAL Function**

Orders a list of values, and returns a value that is based on a position in the list.

**Category:** Descriptive Statistics
Returned data type: DOUBLE

### Syntax

`ORDINAL(position, expression-1, expression-2 [, ...expression-n])`

### Arguments

**position**

specifies an integer that is less than or equal to the number of elements in the list of arguments.

- **Requirement**: `position` must be a positive number.
- **Data type**: DOUBLE

**expression**

specifies any valid expression that evaluates to a numeric value.

- **Requirement**: At least two arguments are required.
- **Data type**: DOUBLE

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer's Guide*

### Details

The `ORDINAL` function sorts the list and returns the argument in the list that is specified by `position`. Missing values are sorted low and are placed before any numeric values.

### Comparisons

The `ORDINAL` function counts both null, missing, non-null, and nonmissing values, whereas the `SMALLEST` function counts only non-null and nonmissing values.

### Example

The following statement illustrates the `ORDINAL` function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=ordinal(4,1,..,2,3,-4,5,6,7);</code></td>
<td>2</td>
</tr>
</tbody>
</table>

---

**PCTL Function**

Returns the percentile that corresponds to the percentage.

- **Category**: Descriptive Statistics
- **Returned data type**: DOUBLE
Syntax

\( \text{PCTL}[n](\text{percentage}, \text{expression}[,...\text{expression}]) \)

Arguments

\( n \)

is a digit from 1 to 5 that specifies the definition of the percentile to be computed.

Default  

Data type

See  

\( \text{percentage} \)

specifies the percentile to be computed.

Data type

Tip  

\( \text{percentage} \) is numeric where, \( 0 \leq \text{percentage} \leq 100 \).

\( \text{expression} \)

specifies any valid expression that evaluates to a numeric value, whose value is computed in the percentile calculation.

Data type

See  

Details

The PCTL function returns the percentile of the non-null or nonmissing values corresponding to the percentage. If \( \text{percentage} \) is null or missing, less than zero, or greater than 100, the PCTL function generates an error message.

Example

The following statements illustrate the PCTL function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>lower_quartile=PCTL(25,2,4,1,3);</td>
<td>1.5</td>
</tr>
<tr>
<td>percentile_def2=PCTL2(25,2,4,1,3);</td>
<td>1</td>
</tr>
<tr>
<td>lower_tertile=PCTL(100/3,2,4,1,3);</td>
<td>2</td>
</tr>
<tr>
<td>percentile_def3=PCTL3(100/3,2,4,1,3);</td>
<td>2</td>
</tr>
<tr>
<td>median=PCTL(50,2,4,1,3);</td>
<td>2.5</td>
</tr>
<tr>
<td>upper_tertile=PCTL(200/3,2,4,1,3);</td>
<td>3</td>
</tr>
</tbody>
</table>
PERM Function

Computes the number of permutations of \( n \) items that are taken \( r \) at a time.

**Category:** Combinatorial

**Returned data type:** INTEGER

**Syntax**

\[
\text{PERM}(n[, r])
\]

**Arguments**

\( n \)

specifies any valid expression that represents the total number of elements from which the sample is chosen.

Data type: INTEGER

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

\( r \)

Specifies any valid expression that represents the number of chosen elements.

Restriction: \( r \leq n \)

Data type: INTEGER

Note: If \( r \) is omitted, the function returns the factorial of \( n \).

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The mathematical representation of the PERM function is given by the following equation:

\[
\text{PERM}(n, r) = \frac{n!}{(n-r)!}
\]

with \( n \geq 0, r \geq 0, \) and \( n \geq r \).

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the PERM function.

**Example**
The following statements illustrate the PERM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=perm(5, 1);</td>
<td>5</td>
</tr>
<tr>
<td>x=perm(5);</td>
<td>120</td>
</tr>
<tr>
<td>x=perm(5, 2)</td>
<td>20</td>
</tr>
</tbody>
</table>

PMT Function

Returns the periodic payment for a constant payment loan or the periodic savings for a future balance.

**Category:** Financial  
**Returned data type:** DOUBLE

**Syntax**

\[\text{PMT}(\text{rate}, \text{number-of-periods}, \text{principal-amount}, [\text{future-amount}][, \text{type}])\]

**Arguments**

- **rate**
  - Specifies the interest rate per payment period.  
  - Data type: DOUBLE
- **number-of-periods**
  - Specifies the number of payment periods.  
  - Requirement: *Number-of-periods* must be a positive integer value.  
  - Data type: INTEGER
- **principal-amount**
  - Specifies the principal amount of the loan. Zero is assumed if a null or missing value is specified.  
  - Data type: DOUBLE
- **future-amount**
  - Specifies the future amount. *Future-amount* can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of periodic...
savings. Zero is assumed if future-amount is omitted or if a missing value is specified.

Data type DOUBLE

**type**
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if **type** is omitted or if a null or missing value is specified.

Data type INTEGER

**Example**

- The monthly payment for a $10,000 loan with a nominal annual interest rate of 8% and 10 end-of-month payments can be computed in the following ways:

  \[ \text{Payment1} = \text{PMT}(0.08/12., 10, 10000, 0, 0); \]
  \[ \text{Payment1} = \text{PMT}(0.08/12., 10, 10000); \]

  These computations return a value of 1037.03208935915.

- If the same loan has beginning-of-period payments, then payment can be computed as follows:

  \[ \text{Payment2} = \text{PMT}(0.08/12., 10, 10000, 0, 1); \]

  This computation returns a value of 1030.16432717796.

- The payment for a $5,000 loan earning a 12% nominal annual interest rate, that is to be paid back in five monthly payments, is computed as follows:

  \[ \text{Payment3} = \text{PMT}(0.01/12., 5, 5000); \]

  This computation returns a value of 1002.50138831008.

- The payment for monthly periodic savings that accrue more than 18 years at a 6% nominal annual interest rate, and which accumulates $50,000 at the end of the 18 years, is computed as follows:

  \[ \text{Payment4} = \text{PMT}(0.06/12., 216, 0, 50000, 0); \]

  This computation returns a value of -129.08160867993.

---

**POISSON Function**

Returns the probability from a Poisson distribution.

**Category:** Probability

**Returned data type:** DOUBLE

**Syntax**

\[ \text{POISSON}(m, n) \]
**Arguments**

\( m \)

specifies any valid expression that evaluates to a numeric mean parameter.

Range \( m \geq 0 \)

Data type DOUBLE

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

\( n \)

specifies any valid expression that evaluates to a random variable.

Range \( n \geq 0 \)

Data type INTEGER

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The POISSON function returns the probability that an observation from a Poisson distribution, with mean \( m \), is less than or equal to \( n \). To compute the probability that an observation is equal to a given value, \( n \), compute the difference of two probabilities from the Poisson distribution for \( n \) and \( n-1 \).

**Example**

The following statement illustrates the POISSON function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=poisson(1, 2);</td>
<td>0.9196986029286</td>
</tr>
</tbody>
</table>

**POWER Function**

Returns the value of a numeric value expression raised to a specified power.

**Category:** Mathematical

**Returned data type:** DOUBLE

**Syntax**

\[ \text{POWER}(\text{numeric-expression}, \text{integer-expression}) \]

**Arguments**

\( \text{numeric-expression} \)

specifies any valid expression that evaluates to a numeric value.
integer-expression
 specifies any valid expression that evaluates to an integer value.

Data type: INTEGER, DOUBLE

Details

If numeric-expression is null, then the POWER function returns null. If the result is a number that does not fit into the range of the argument's data type, the POWER function fails.

Example

The following statement illustrates the POWER function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=power(5*3, 2)</td>
<td>225</td>
</tr>
</tbody>
</table>

PPMT Function

Returns the principal payment for a given period for a constant payment loan or the periodic savings for a future balance.

- Category: Financial
- Returned data type: DOUBLE

Syntax

PPMT(rate, period, number-of-periods, principal-amount[, future-amount][, type])

Arguments

rate
 specifies the interest rate per payment period.

Data type: DOUBLE

period
 specifies the payment period for which the principal payment is computed.

Requirement: Period must be a positive integer value that is less than or equal to the value of number-of-periods
Data type INTEGER

*number-of-periods*
  specifies the number of payment periods.

Requirement *Number-of-periods* must be a positive integer value.

Data type INTEGER

*principal-amount*
  specifies the principal amount of the loan. Zero is assumed if a null or missing value is specified.

Data type DOUBLE

*future-amount*
  specifies the future amount. *Future-amount* can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of periodic savings. Zero is assumed if *future-amount* is omitted or if a null or missing value is specified.

Data type DOUBLE

*type*
  specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if *type* is omitted or if a null or missing value is specified.

Data type INTEGER

**Example**

- The principal payment amount of the first monthly periodic payment for a 2-year, $2,000 loan with a nominal annual interest rate of 10%, is computed as follows:
  \[
  \text{PrincipalPayment} = \text{PPMT}(0.1/12., 1, 24, 2000);
  \]
  This computation returns a value of 75.6231860083663.

- The principal payment for a 3-year, $20,000 loan with beginning-of-month payments is computed as follows:
  \[
  \text{PrincipalPayment2} = \text{PPMT}(0.1/12., 1, 36, 20000, 0, 1);
  \]
  This computation returns a value of 640.010324505867 as the principal that was paid with the first payment.

- The principal payment of an end-of-month payment loan with an outstanding balance of $5,000 at the end of three years, is computed as follows:
  \[
  \text{PrincipalPayment3} = \text{PPMT}(0.1/12., 1, 36, 20000, 5000, 0);
  \]
  This computation returns a value of 359.007807907562 as the principal that was paid with the first payment.

**PROBBETA Function**

Returns the probability from a beta distribution.
Syntax

PROBBETA(x, a, b)

Arguments

x
- is a numeric random variable.
- Range: 0 ≤ x ≤ 1
- Data type: DOUBLE

a
- is a numeric shape parameter.
- Range: a > 0
- Data type: DOUBLE

b
- is a numeric shape parameter.
- Range: b > 0
- Data type: DOUBLE

Details

The PROBBETA function returns the probability that an observation from a beta distribution, with shape parameters a and b, is less than or equal to x.

Example

The following statement illustrates the PROBBETA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=probbeta(.2,3,4);</td>
<td>0.09888</td>
</tr>
</tbody>
</table>

PROBNNML Function

Returns the probability from a binomial distribution.

Category: Probability

Returned data type: DOUBLE
Syntax

PROBBNML(p, n, m)

Arguments

p
is a numeric probability of success parameter.

Range \( 0 \leq p \leq 1 \)

Data type DOUBLE

n
is an integer number of independent Bernoulli trials parameter.

Range \( n > 0 \)

Data type INTEGER

m
is an integer number of successes random variable.

Range \( 0 \leq m \leq n \)

Data type INTEGER

Details

The PROBBNML function returns the probability that an observation from a binomial distribution, with probability of success \( p \), number of trials \( n \), and number of successes \( m \), is less than or equal to \( m \). To compute the probability that an observation is equal to a given value \( m \), compute the difference of two probabilities from the binomial distribution for \( m \) and \( m-1 \) successes.

Example

The following statement illustrates the PROBBNML function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=probbnml(0.5,10,4);</td>
<td>0.376953125</td>
</tr>
</tbody>
</table>

PROBBNRM Function

Returns a probability from a bivariate normal distribution.

Category: Probability

Returned data type: DOUBLE
Syntax

PROBBNRM(\(x, y, r\))

Arguments

\(x\)
- specifies a numeric constant, variable, or expression.
- Data type: DOUBLE

\(y\)
- specifies a numeric constant, variable, or expression.
- Data type: DOUBLE

\(r\)
- is a numeric correlation coefficient.
- Range: \(-1 \leq r \leq 1\)
- Data type: DOUBLE

Details

The PROBBNRM function returns the probability that an observation \((X, Y)\) from a standardized bivariate normal distribution with mean 0, variance 1, and a correlation coefficient \(r\), is less than or equal to \((x, y)\). That is, it returns the probability that \(X \leq x\) and \(Y \leq y\). The following equation describes the PROBBNRM function, where \(u\) and \(v\) represent the random variables \(x\) and \(y\), respectively:

\[
\text{PROBBNRM}(x, y, r) = \frac{1}{2 \pi \sqrt{1 - r^2}} \int_{-\infty}^{x} \int_{-\infty}^{y} \exp \left[ -\frac{u^2 - 2ruv + v^2}{2(1 - r^2)} \right] dv du
\]

Example

The following statement illustrates the PROBBNRM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>p=probbnrm(.4, -.3, .2);</td>
<td>0.27831833451901</td>
</tr>
</tbody>
</table>

PROBCHI Function

Returns the probability from a chi-square distribution.

- Category: Probability
- Returned data type: DOUBLE
Syntax
PROBCHI(\(x, df[, nc]\))

Arguments
\(x\)
is a numeric random variable.
Range \(x \geq 0\)
Data type DOUBLE

\(df\)
is a numeric degrees of freedom parameter.
Range \(df > 0\)
Data type DOUBLE

\(nc\)
is an optional numeric noncentrality parameter.
Range \(nc \geq 0\)
Data type DOUBLE

Details
The PROBCHI function returns the probability that an observation from a chi-square distribution, with degrees of freedom \(df\) and noncentrality parameter \(nc\), is less than or equal to \(x\). This function accepts a noninteger degrees of freedom parameter \(df\). If the optional parameter \(nc\) is not specified or has the value 0, the value returned is from the central chi-square distribution.

Example
The following statement illustrates the PROBCHI function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x=\text{probchi}(11.264, 11));</td>
<td>0.5785813293173</td>
</tr>
</tbody>
</table>

PROBDF Function
Calculates significance probabilities for Dickey-Fuller tests for unit roots in time series.

Category: Probability
Returned data type: DOUBLE
Syntax

PROBDF(x, n[, d[, type]])

Arguments

x
is the test statistic.

Data type DOUBLE

n
is the sample size. The minimum value of n that is allowed depends on the value that is specified for the third argument, d. For d in the set (1,2,4,6,12), n must be an integer greater than or equal to max (2d, 5). For other values of d the minimum value of n is 24.

Data type INTEGER

d
is an integer that gives the degree of the unit root that is tested for. For tests of a simple unit root, (1–B), specify d=1. For tests for a seasonal unit root, specify that d is equal to the seasonal cycle length for tests. The default value of d is 1. That is, a test for a simple unit root is assumed if d is not specified. The maximum value of d is 12.

Data type INTEGER

type
is a character argument that specifies the type of test statistic that is used. The values of type are the following:

RSM
specifies the regression test statistic for the single mean (intercept) case.

RTR
specifies the regression test statistic for the deterministic time trend case.

RZM
specifies the regression test statistic for the zero mean (no intercept) case.

SSM
specifies the studentized test statistic for the single mean (intercept) case.

STR
specifies the studentized test statistic for the deterministic time trend case.

SZM
specifies the studentized test statistic for the zero mean (no intercept) case.

Default SZM

Restriction The values STR and RTR are allowed only when d=1.

Data type CHAR
Details

Theoretical Background

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. Dickey (1976) and Dickey and Fuller (1979) studied the limiting distribution of the OLS estimator of autoregressive models for time series with a simple unit root. Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series with seasonal unit roots. This section introduces the nonseasonal tests, and lists references for the nonseasonal tests.

In the Dicky-Fuller regression, the null hypothesis states that there is an autoregressive unit root $H_0: \alpha = 1$, and an alternative, $H_\alpha: |\alpha| < 1$, where $\alpha$ is the autoregressive coefficient of the following time series:

$$y_t = \alpha y_{t-1} + \epsilon_t$$

This model is referred to as the zero mean (ZM) model. The standard Dickey-Fuller (DF) test assumes that errors are white noise. There are two other types of regression models that include a constant or a time trend:

$$y_t = \mu + \alpha y_{t-1} + \epsilon_t$$

$$y_t = \mu + \beta t + \alpha y_{t-1} + \epsilon_t$$

These two models are referred to as the constant mean model (SM) and the trend model (TR), respectively. The constant mean model includes a constant mean $\mu$ of the time series. However, the interpretation of $\mu$ depends on the stationarity in the following sense: the mean in the stationary case when $\alpha < 1$ is the trend in the integrated case when $\alpha = 1$. Therefore, the null hypothesis should be the joint hypothesis that $\alpha = 1$ and $\mu = 0$. However, for the unit root tests, the test statistics are concerned with the null hypothesis of $\alpha = 1$. The joint null hypothesis is not commonly used. This issue is address in Bhargava, A. (1986) with a different nesting model.

Under the null of I(1) of the Dickey-Fuller test, the differenced process is not serially correlated. There is a great need for the generalization of this specification. The augmented Dickey-Fuller (ADF) test, originally proposed in Dickey and Fuller (1979), adjusts for the serial correlation in the time series by adding lagged first differences to the autoregressive model as follows. Consider the $(p+1)$th order autoregressive time series:

$$y_t = \alpha_1 y_{t-1} + \alpha_2 y_{t-2} + \ldots + \alpha_{p+1} y_{t-p} + \epsilon_t$$

The characteristic equation follows:

$$m^{p+1} - \alpha_1 m^p - \alpha_2 m^{p-1} - \ldots - \alpha_{p+1} = 0$$

If all the characteristic roots are less than 1 in absolute value, $y_t$, is stationary. $y_t$ is nonstationary if there is a unit root. If there is a unit root, the sum of the autoregressive parameters is 1, and therefore you can test for a unit root by testing whether the sum of the autoregressive parameters is 1. The no-intercept model is parameterized as follows.

$$\nabla y_t = \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \ldots + \theta_p \nabla y_{t-p} + \epsilon_t$$

In the equation above, the following relationships apply:

$$\nabla y_t = y_t - y_{t-1}$$
and
\[ \delta = a_1 + \ldots + a_{p+1} - 1 \]
\[ \theta_k = -a_{k+1} - \ldots - a_{p+1} \]

The estimators are obtained by regressing \( \nabla y_t \) on \( y_{t-1}, \nabla y_{t-1}, \ldots, \nabla y_{t-p} \). The \( t \) statistic of the ordinary least squares estimator of \( \delta \) is the test statistic for the unit root test.

If the type argument value specifies a test for a nonzero mean (intercept case), the autoregressive model includes a mean term \( \alpha_0 \). If the type argument value specifies a test for a time trend, the model also includes a time trend term and the model is as follows:
\[ \nabla y_t = \alpha_0 + \gamma t + \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \ldots + \theta_p \nabla y_{t-p} + \epsilon_1 \]

For testing for a seasonal unit root, consider the multiplicative model.
\[ (1 - \alpha_d \beta^d)(1 - \theta_1 \beta - \ldots - \theta_p \beta^p)y_t = \epsilon_t \]

Let \( \nabla^d y_t \equiv y_t - y_{t-d} \). The test statistic is calculated in the following steps:

1. Regress \( \nabla^d y_t \) on \( \nabla^d y_{t-1}, \ldots, \nabla^d y_{t-p} \) to obtain the initial estimators \( \hat{\theta}_i \) and compute residuals \( \hat{\epsilon}_i \). Under the null hypothesis that \( \alpha_d = 1, \hat{\theta}_i \) are consistent estimators of \( \theta_i \).
2. Regress \( \hat{\epsilon}_i \) on \( (1 - \hat{\theta}_1 \beta - \ldots - \hat{\theta}_p \beta^p)y_{t-d}, \nabla^d y_{t-1}, \ldots, \nabla^d y_{t-p} \) to obtain estimates of \( \delta = \alpha_d - 1 \) and \( \theta_i - \hat{\theta}_i \).

The \( t \) ratio for the estimates of \( \delta \) that are produced by the second step is used as a test statistic for testing for a seasonal unit root. The estimates of \( \theta_i \) are obtained by adding the estimates of \( \theta_i - \hat{\theta}_i \) from the second step to \( \hat{\theta}_i \) from the first step.

The series \( (1 - \beta^d)y_t \) is assumed to be stationary, where \( d \) is the value of the third argument to the PROBDF function.

If the series is an ARMA process, then a large value of \( p \) might be desirable in order to obtain a reliable test statistic. To determine an appropriate value for \( p \), see Said and Dickey (1984).

**Test Statistics**

The Dickey-Fuller test is used to test the null hypothesis that the time series exhibits a lag \( d \) unit root against the alternative of stationarity. The PROBDF function computes the probability of observing a test statistic more extreme than \( x \) under the assumption that the null hypothesis is true. You should reject the unit root hypothesis when PROBDF returns a small (significant) probability value.

Consider the Dickey-Fuller regression first. There are several versions of the Dickey-Fuller test. The PROBDF function supports six versions, as selected by the type argument. Specify the type value that corresponds to how you calculated the test statistic \( x \).

The last two characters of the type value specify the type of regression model that is used to compute the Dickey-Fuller test statistic. The meaning of the last two characters of the type value are as follows:
SM specifies a single mean or intercept case. The test statistic $x$ is assumed to be computed from the following regression model:

$$y_t = \mu + \alpha y_{t-1} + e_t$$

TR specifies the intercept and deterministic time trend case. The test statistic $x$ is assumed to be computed from the following regression model:

$$y_t = \mu + \gamma t + \alpha y_{t-1} + e_t$$

ZM specifies the zero mean or no-intercept case. The test statistic $x$ is assumed to be computed from the following regression model:

$$y_t = \alpha y_{t-1} + e_t$$

The first character of the type value specifies whether the regression test statistic or the studentized test statistic is used. Let $\hat{\alpha}$ be the estimated regression coefficient for the lag of the series, and let $se_{\hat{\alpha}}$ be the standard error of $\hat{\alpha}$. The meaning of the first character of the type value is as follows:

R specifies the regression-coefficient-based test statistic. The test statistic follows:

$$\rho = n(\hat{\alpha} - 1)$$

S specifies the studentized test statistic. The test statistic follows:

$$DF_t = \frac{(\hat{\alpha} - 1)}{se_{\hat{\alpha}}}$$

The equation for the type value of R is also called $\rho$-test. The equation for the type value of S is also called $\tau$-test. For the zero mean model, the asymptotic distributions of the Dickey-Fuller test statistics follow:

$$n(\hat{\alpha} - 1) \Rightarrow \left(\int_0^1 W(r) dW(r)\right) \left(\int_0^1 W(r)^2 dr\right)^{-1}$$

$$DF_t \Rightarrow (\int_0^1 W(r) dW(r)) \left(\int_0^1 W(r)^2 dr\right)^{-1/2}$$

For the constant mean model, the asymptotic distributions follow:

$$n(\hat{\alpha} - 1) \Rightarrow \left(\int_0^1 W(r) dW(r)\right) \left(\int_0^1 W(r)^2 dr - \left(\int_0^1 W(r) dr\right)^2\right)^{-1}$$

$$DF_t \Rightarrow \left(\int_0^1 W(r) dW(r)\right) \left(\int_0^1 W(r)^2 dr - \left(\int_0^1 W(r) dr\right)^2\right)^{-1/2}$$

For the trend model, the asymptotic distributions follow:
\[ n(\overline{a} - 1) \Rightarrow \left[ W(r) dW + 12 \left( \int_0^1 r W(r) \, dr - \frac{1}{2} \int_0^1 W(r) \, dr \right) \left( \int_0^1 W(r) \, dr - \frac{1}{2} W(1) \right) \right. \]
\[ \left. - W(1) \int_0^1 W(r) \, dr \right] D^1 \]

\[ DF \tau \Rightarrow \left[ W(r) dW + 12 \left( \int_0^1 r W(r) \, dr - \frac{1}{2} \int_0^1 W(r) \, dr \right) \left( \int_0^1 W(r) \, dr - \frac{1}{2} W(1) \right) \right. \]
\[ \left. - W(1) \int_0^1 W(r) \, dr \right] D^{1/2} \]

The following equation applies to the equations that are shown above:

\[ D = \int_0^1 W(r)^2 \, dr - 12 \left( \int_0^1 W(r) \, dr \right)^2 + 12 \int_0^1 W(r) \, dr \int_0^1 r W(r) \, dr - 4 \left( \int_0^1 W(r) \, dr \right)^2 \]

For more information about the Dickey-Fuller test null distribution, see Dickey and Fuller (1979), Dickey, Hasza, and Fuller (1984), and Hamilton (1994). The preceding formulas are for the basic Dickey-Fuller test. The PROBDF function can also be used for the augmented Dickey-Fuller test, in which the error term is modeled as an autoregressive process. However, the test statistic is computed somewhat differently for the augmented Dickey-Fuller test. For the nonseasonal augmented Dickey-Fuller test, the test statistics can have one of the two forms similar to Dickey-Fuller test. One of the forms is the OLS \( t \) value, \( \frac{\overline{a} - 1}{sd(\overline{a})} \), and the other form is \( \frac{n(\overline{a} - 1)}{1 - \overline{a} - \ldots - \overline{a}^p} \).

**Example**

In the following example, the table Test contains 104 observations of the time series variable \( Y \). The program tests the null hypothesis that there exists a lag 4 seasonal unit root in the \( Y \) series. The following statements illustrate how to perform the single-mean Dickey-Fuller regression coefficient test using PROC REG and the PROBDF function.

```plaintext
data test1;
   set test;
   y4 = lag4(y);
run;

proc reg data=test1 outest=alpha;
   model y = y4 / noprint;
run;

proc ds2;
data _null_
   method run();
      set alpha;
      x = 100 * ( y4 - 1 );
      p = probdf( x, 100, 4, "RSM* ");
      put p= pvalue5.3;
   end;
enddata;
run;
quit;
```

To perform the augmented Dickey-Fuller test, regress the differences of the series on lagged differences and on the lagged value of the series, and compute the test statistic.
from the regression coefficient for the lagged series. The following statements illustrate how to perform the single-mean augmented Dickey-Fuller studentized test for a simple unit root using PROC REG and the PROBDF function:

```sas
data test1;
  set test;
  y1  = lag(y);
  yd  = dif(y);
  yd1 = lag1(yd); yd2 = lag2(yd);
  yd3 = lag3(yd); yd4 = lag4(yd);
run;

proc reg data=test1 outest=alpha covout;
  model yd = y1 yd1-yd4 / noprint;
run;

proc ds2;
  data _null_
  method run();
  set alpha;
  retain a;
  if _type_ = 'PARMS' then
    a = y1;
  if _type_ = 'COV' & _NAME_ = 'Y1' then do;
    x = a / sqrt(y1);
    p = probdf( x, 99, 1, "SSM" );
    put p= ;
  end;
  enddata;
run;
quit;
```

The %DFTEST macro provides an easier way to perform the Dickey-Fuller tests. The following statements perform the same tests as the preceding example:

```sas
%dftest(test, y, ar=4);
%put p=&dftest;
```

*Note:* When DS2 runs outside of SAS, such as in the SAS Federation Server and in grid computing environments, the SAS macro facility is not available and DS2 programs with macros fail to compile.

### PROBF Function

Returns the probability from an $F$ distribution.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

**Syntax**

\[
\text{PROBF}(x, ndf, ddf[, nc])
\]
Arguments

\( x \)

is a numeric random variable.

Range \( x \geq 0 \)

Data type DOUBLE

\( ndf \)

is a numeric numerator degrees of freedom parameter.

Range \( ndf > 0 \)

Data type DOUBLE

\( ddf \)

is a numeric denominator degrees of freedom parameter.

Range \( ddf > 0 \)

Data type DOUBLE

\( nc \)

is an optional numeric noncentrality parameter.

Range \( nc \geq 0 \)

Data type DOUBLE

Details

The PROBF function returns the probability that an observation from an \( F \) distribution, with numerator degrees of freedom \( ndf \), denominator degrees of freedom \( ddf \), and noncentrality parameter \( nc \), is less than or equal to \( x \). The PROBF function accepts noninteger degrees of freedom parameters \( ndf \) and \( ddf \). If the optional parameter \( nc \) is not specified or has the value 0, the value returned is from the central \( F \) distribution.

The significance level for an \( F \) test statistic is given by the following equation.

\[ p = 1 - \text{probf} (x, ndf, ddf); \]

Example

The following statement illustrates the PROBF function:

\[
\begin{array}{|c|c|}
\hline
\text{Statements} & \text{Results} \\
\hline
x = \text{probf} (3.32, 2, 3); & 0.82639336022431 \\
\hline
\end{array}
\]

PROBGAM Function

Returns the probability from a gamma distribution.

Category: Probability
Syntax

PROBGAM\((x, a)\)

Arguments

\(x\)

is a numeric random variable.

Range  \(x \geq 0\)

Data type  DOUBLE

\(a\)

is a numeric shape parameter.

Data type  DOUBLE

Details

The PROBGAM function returns the probability that an observation from a gamma distribution, with shape parameter \(a\), is less than or equal to \(x\).

Example

The following statement illustrates the PROBGAM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x = \text{probgam}(1, 3);)</td>
<td>0.08030139707139</td>
</tr>
</tbody>
</table>

PROBHYPYPR Function

Returns the probability from a hypergeometric distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBHYPYPR\((N, K, n, x[, r])\)

Arguments

\(N\)

is an integer population size parameter.
Range $N \geq 1$
Data type INTEGER

$K$
is an integer number of items in the category of interest parameter.
Range $0 \leq K \leq N$
Data type INTEGER

$n$
is an integer sample size parameter.
Range $0 \leq n \leq N$
Data type INTEGER

$x$
is an integer random variable.
Range $\max(0, K + n - N) \leq x \leq \min(K, n)$

$r$
is a numeric odds ratio parameter.
Range $r \geq 0$
Data type DOUBLE

Details
The PROBHYPR function returns the probability that an observation from an extended hypergeometric distribution, with population size $N$, number of items $K$, sample size $n$, and odds ratio $r$, is less than or equal to $x$. If the optional parameter $r$ is not specified or is set to 1, the value returned is from the usual hypergeometric distribution.

Example
The following statement illustrates the PROBHYPR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=probhypr(200,50,10,2);</td>
<td>0.52367340812167</td>
</tr>
</tbody>
</table>

PROBIT Function
Returns a quantile from the standard normal distribution.

Category: Quantile
Returned data type: DOUBLE
Syntax

PROBIT\((p)\)

Arguments

\(p\)

is a numeric probability.

Range \(0 < p < 1\)

Data type DOUBLE

Details

The PROBIT function returns the \(p^{th}\) quantile from the standard normal distribution. The probability that an observation from the standard normal distribution is less than or equal to the returned quantile is \(p\).

**CAUTION:**

The result could be truncated to lie between -8.222 and 7.941.

Note: PROBIT is the inverse of the PROBNORM function.

Example

The following statements illustrate the PROBIT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=probit(.025);</td>
<td>-1.95996398454005</td>
</tr>
<tr>
<td>x=probit(1.e-7);</td>
<td>-5.19933758219281</td>
</tr>
</tbody>
</table>

PROBMC Function

Returns a probability or a quantile from various distributions for multiple comparisons of means.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

PROBMC\((distribution, q, prob, df, nparms[, parameters])\)
Arguments

distribution
is a character constant, variable, or expression that identifies the distribution. The following distributions are valid: F

<table>
<thead>
<tr>
<th>Distribution</th>

</tr>
</tbody>
</table>

Data type: CHAR

q
is the quantile from the distribution.

Restriction: Either q or prob can be specified, but not both.

Data type: DOUBLE

prob
is the left probability from the distribution.

Restriction: Either prob or q can be specified, but not both.

Data type: DOUBLE

df
is the degrees of freedom.

Note: A missing value is interpreted as an infinite value.

nparms
is the number of treatments.

Data type: DOUBLE

Note: For DUNNETT1 and DUNNETT2, the control group is not counted.

parameters
is a set of nparms parameters that must be specified to handle the case of unequal sample sizes. The meaning of parameters depends on the value of distribution. If parameters is not specified, equal sample sizes are assumed, which is usually the case for a null hypothesis.
Overview
The PROBMC function returns the probability or the quantile from various distributions with finite and infinite degrees of freedom for the variance estimate.

The prob argument is the probability that the random variable is less than q. Therefore, p-values can be computed as 1 – prob. For example, to compute the critical value for a 5% significance level, set prob = 0.95. The precision of the computed probability is $O(10^{-8})$ (absolute error); the precision of computed quantile is $O(10^{-5})$.

Note: The studentized range is not computed for finite degrees of freedom and unequal sample sizes.

Note: Williams' test is computed only for equal sample sizes.

Formulas and Parameters
The equations listed here define expressions that are used in equations that relate the probability, prob, and the quantile, q, for different distributions and different situations within each distribution. For these equations, let $\nu$ be the degrees of freedom, df.

\[
d\mu_{\nu}(x) = \frac{\nu^\nu}{\nu^\nu \Gamma\left(\frac{\nu}{2}\right)^2} x^{\nu-1} e^{-\frac{x^2}{2}} dx
\]

\[
\phi(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}
\]

\[
\Phi(x) = \int_{-\infty}^{x} \phi(u)du
\]

Computing the Analysis of Means
Analysis of Means (ANOM) applies to data that is organized as $k$ (Gaussian) samples, the $i^{th}$ sample being of size $n_i$. Let $I = \sqrt{-1}$. The distribution function $[1, 2, 3, 4, 5]$ is the CDF for the maximum absolute of a $k$-dimensional multivariate $T$ vector, with $\nu$ degrees of freedom, and an associated correlation matrix $\rho_{ij} = -\alpha_i \alpha_j$. This equation can be written as follows.

\[
prob = r(\{h_1 \mid h_2 \mid ... \mid h_k \})
\]

\[
= \int_{0}^{\infty} \left\{ \prod_{j=0}^{k} g(sh_i, y, \alpha_i) \phi(y)dy \right\}d\mu_{\nu}(s)
\]

The following relationship applies to the preceding equation:

\[
g(sh_i, y, \alpha_i) = \Phi \left( \frac{sh_i - ya_i}{\sqrt{1 + \alpha_i^2}} \right) - \Phi \left( \frac{-sh_i - ya_i}{\sqrt{1 + \alpha_i^2}} \right)
\]

In this equation, $\Gamma(\cdot)$, $\phi(\cdot)$, and $\Phi(\cdot)$, are the gamma function, the density, and the CDF from the standard normal distribution, respectively.
For \( \nu = \infty \), the distribution reduces to this equation.
\[
r(t_1 < h, t_2 < h, ..., t_k < h) = \int_0^\infty \prod_{j=0}^{k-1} g(h, y, \alpha_j) \phi(y) dy
\]

The following relationship applies to the preceding equation:
\[
g(h, y, \alpha_j) = \Phi\left(\frac{h - y\alpha_j}{\sqrt{1 + \alpha_j^2}}\right) - \Phi\left(\frac{-h - y\alpha_j}{\sqrt{1 + \alpha_j^2}}\right)
\]

For the balanced case, the distribution reduces to the following equation:
\[
r(t_1 < h, t_2 < h, ..., t_n < h) = \int_0^\infty f(h, y, \rho) \phi(y) dy
\]

The following relationships apply to the preceding equation:
\[
f(h, y, \rho) = \Phi\left(\frac{h - y\sqrt{\rho}}{\sqrt{1 + \rho}}\right) - \Phi\left(\frac{-h - y\sqrt{\rho}}{\sqrt{1 + \rho}}\right)
\]

\[\rho = \frac{1}{n-1}\]

Here is the syntax for this distribution:
\[
x = \text{probmc('anom', q, p, nu, n[, alpha_1, ..., alpha_n])};
\]

**Arguments**

\( x \)
- is a numeric value with the returned result.

\( q \)
- is a numeric value that denotes the quantile.

\( p \)
- is a numeric value that denotes the probability. One of \( p \) and \( q \) must be missing.

\( nu \)
- is a numeric value that denotes the degrees of freedom.

\( n \)
- is a numeric value that denotes the number of samples.

\( alpha_i, i = 1, ..., k \)
- are optional numeric values denoting the alpha values from the first equation of this distribution. See “Computing the Analysis of Means” on page 528.

**Many-One t-Statistics: Dunnett’s One-Sided Test**

- This case relates the probability, \( prob \), and the quantile, \( q \), for the unequal case with finite degrees of freedom. The parameters are \( \lambda_1, ..., \lambda_k \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( \nu \). The equation follows:
\[
prob = \int_0^\infty \int_{-\infty}^\infty \prod_{i=1}^{k} \Phi\left(\frac{\lambda_i y + qx}{\sqrt{1 + i^2}}\right) dy du_k(x)
\]

- This case relates the probability, \( prob \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed \( (\lambda = \sqrt{\frac{1}{2}}) \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( \nu \). The equation follows:
\[ prob = \int_{-\infty}^{\infty} \phi(y) \Phi(\sqrt{2qy})^k \, dy \, du(x) \]

- This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with infinite degrees of freedom. The parameters are \( \lambda_1, \ldots, \lambda_k \), the value of \( n\text{parms} \) is set to \( k \), and the value of \( df \) is set to \( \text{missing} \). The equation follows:

\[ prob = \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \Phi \left( \frac{\lambda_i y + q}{\sqrt{1 - \lambda_i^2}} \right) \, dy \]

- This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with infinite degrees of freedom. No parameters are passed \( (\lambda = \sqrt{\frac{n}{2}}) \), the value of \( n\text{parms} \) is set to \( k \), and the value of \( df \) is set to \( \text{missing} \). The equation follows:

\[ prob = \int_{-\infty}^{\infty} \phi(y) [\Phi(y + \sqrt{2q})]^k \, dy \]

**Many-One t-Statistics: Dunnett’s Two-sided Test**

- This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with finite degrees of freedom. The parameters are \( \lambda_1, \ldots, \lambda_k \), the value of \( n\text{parms} \) is set to \( k \), and the value of \( df \) is set to \( \text{missing} \). The equation follows:

\[ prob = \int_{-\infty}^{\infty} \phi(y) [\Phi(y + \sqrt{2q})]^k \, dy \]

- This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed, the value of \( n\text{parms} \) is set to \( k \), and the value of \( df \) is set to \( \text{missing} \). The equation follows:

\[ prob = \int_{-\infty}^{\infty} \phi(y) [\Phi(y + \sqrt{2q})]^k \, dy \]

**Computing the Partitioned Range**

RANGE applies to the distribution of the studentized range for \( n \) group means. PARTRANGE applies to the distribution of the partitioned studentized range. Let the \( n \) groups be partitioned into \( k \) subsets of size \( n_1 + \ldots + n_k = n \). Then the partitioned range is the maximum of the studentized ranges in the respective subsets. The studentization factor is the same in all cases.
Here is the syntax for this distribution:

\[ x=\text{probmc('partrange', q, p, nu, k, n_1, ..., n_k);} \]

**Arguments**

- \( x \)
  - is a numeric value with the returned result (either the probability or the quantile).
- \( q \)
  - is a numeric value that denotes the quantile.
- \( p \)
  - is a numeric value that denotes the probability. One of \( p \) and \( q \) must be missing.
- \( \nu \)
  - is a numeric value that denotes the degrees of freedom.
- \( k \)
  - is a numeric value that denotes the number of groups.
- \( n_i, i=1, ..., k \)
  - are optional numeric values that denote the \( n \) values from the equation in this distribution. See “Computing the Partitioned Range” on page 530.

**The Studentized Range**

- This case relates the probability, \( prob \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed, the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( \nu \). The equation follows:

\[ prob = \int_0^\infty \prod_{i=1}^k \left( \int_{-\infty}^\infty k\phi(y)\left(\Phi(y) - \Phi(y - qx)\right)^k dy \right) d\mu_x(x) \]

- This case relates the probability, \( prob \), and the quantile, \( q \), for the unequal case with infinite degrees of freedom. The parameters are \( \sigma_1, ..., \sigma_k \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[ prob = \int_{-\infty}^\infty \sum_{j=1}^k \left\{ \prod_{i=1}^k \left[ \Phi\left(\frac{y}{\sigma_i}\right) - \Phi\left(\frac{y - q}{\sigma_i}\right)\right] \phi\left(\frac{y}{\sigma_j}\right) \right\} dy \]

- This case relates the probability, \( prob \), and the quantile, \( q \), for the equal case with infinite degrees of freedom. No parameters are passed, the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[ prob = \int_{-\infty}^\infty k\phi(y)\left(\Phi(y) - \Phi(y - q)\right)^k dy \]

**The Studentized Maximum Modulus**

- This case relates the probability, \( prob \), and the quantile, \( q \), for the unequal case with finite degrees of freedom. The parameters are \( \sigma_1, ..., \sigma_k \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( \nu \). The equation follows:

\[ prob = \int_0^\infty \prod_{i=1}^k \left[ 2\phi\left(\frac{qx}{\sigma_i}\right) - 1 \right] d\mu_x(x) \]
• This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed, the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( \nu \). The equation follows:

\[
\text{prob} = \int_{0}^{\infty} \left( 2\Phi(qx) - 1 \right)^k d\mu(x)
\]

• This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with infinite degrees of freedom. The parameters are \( \sigma_1, ..., \sigma_k \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
\text{prob} = \prod_{i=1}^{k} \left[ 2\Phi\left(\frac{q}{\sigma_i}\right) - 1 \right]
\]

• This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with infinite degrees of freedom. No parameters are passed, the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
\text{prob} = \left[ 2\Phi(q) - 1 \right]^k
\]

**Williams' Test**

PROBMC computes the probabilities or quantiles from the distribution defined in Williams (1971, 1972). See “References” in *SAS Viya Functions and CALL Routines: Reference*. The need for the Williams' Test arises when you compare the dose treatment means with a control mean to determine the lowest effective dose of treatment.

**Note:** Williams' Test is computed only for equal sample sizes.

Let \( X_1, X_2, ..., X_k \) be identical independent \( N(0,1) \) random variables. Let \( Y_k \) denote their average given by the following equation.

\[
Y_k = \frac{X_1 + X_2 + ... + X_k}{k}
\]

It is required to compute the distribution of the following value.

\[
(Y_k - Z)/S
\]

**Arguments**

\( Y_k \)

is as defined previously.

\( Z \)

is an \( N(0,1) \) independent random variable.

\( S \)

is such that \( \frac{1}{2}\nu S^2 \) is a \( \chi^2 \) variable with \( \nu \) degrees of freedom.

As described in Williams (1971), the full computation is extremely lengthy, and is carried out in three stages. See “References” in *SAS Viya Functions and CALL Routines: Reference*.

1. Compute the distribution of \( Y_k \). It is the fundamental (expensive) part of this operation and it can be used to find both the density and the probability of \( Y_k \). Let \( U_i \) be defined in this equation.

\[
U_i = \frac{X_1 + X_2 + ... + X_i}{i}, \quad i = 1, 2, ..., k
\]
You can write a recursive expression for the probability of $Y_k > d$. The value of $d$ can be any real number.

$$\Pr(Y_k > d) = \Pr(U_1 > d)$$

$$+ \Pr(U_2 > d, U_1 < d)$$

$$+ \Pr(U_3 > d, U_2 < d, U_1 < d)$$

$$+ \ldots$$

$$+ \Pr(U_k > d, U_{k-1} < d, \ldots, U_1 < d)$$

$$= \Pr(Y_{k-1} > d) + \Pr(X_k + (k-1)U_{k-1} > kd)$$

To compute this probability, start from an $N(0,1)$ density function.

$$D(U_1 = x) = \phi(x)$$

And recursively compute the convolution.

$$D(U_k = x, U_{k-1} < d, \ldots, U_1 < d) =$$

$$\int_{-\infty}^{d} D(U_{k-1} = y, U_k < d, \ldots, U_1 < d) \phi(kx - (k-1)y) dy$$

From this sequential convolution, it is possible to compute all the elements of the recursive equation for $\Pr(Y_k < d)$, shown previously.

2. Compute the distribution of $Y_k - Z$. This computation involves another convolution to compute the probability.

$$\Pr((Y_k - Z) > d) = \int_{-\infty}^{\infty} \Pr(Y_k > \sqrt{2d} + y) \phi(y) dy$$

3. Compute the distribution of $(Y_k - Z)/S$. This computation involves another convolution to compute the probability.

$$\Pr((Y_k - Z) > tS) = \int_{0}^{\infty} \Pr((Y_k - Z) > ty) d\mu_k(y)$$

The third stage is not needed when $\nu = \infty$. Due to the complexity of the operations, this lengthy algorithm is replaced by a much faster one when $k \leq 15$ for both finite and infinite degrees of freedom $\nu$. For $k \geq 16$, the lengthy computation is carried out. It is extremely expensive and very slow due to the complexity of the algorithm.

**Comparisons**

The MEANS statement in the GLM Procedure of SAS/STAT Software computes the following tests:

- Dunnett's one-sided test
- Dunnett's two-sided test
- Studentized Range
Examples

**Example 1: Computing Probabilities By Using PROBMC**

This example shows how to compute probabilities.

```sas
data _null_; method run();
   declare double par[5];
   declare double df q prob;
   declare char(20) test[3];
   declare int i;

   par := (.5 .51 .55 .45 .2);
   df = 40;
   q = 1;
   test := ('dunnett1' 'dunnett2' 'maxmod');
   do i = 1 to dim(test);
      prob=probmc(test[i], q, ., df, 5, par[1], par[2], par[3], par[4],
                   par[5]);
      put test[i] $10. df q e18.13 prob e18.13;
   end;
end;
enddata;
run;
```

SAS writes the following results to the log:

```
dunnett1   40  1.00000000000E+00 4.82992196083E-01
dunnett2   40  1.00000000000E+00 1.64023105316E-01
maxmod     40  1.00000000000E+00 8.02784203408E-01
```

**Example 2: Computing the Analysis of Means**

```sas
proc ds2;
   data _null_; method run();
      q1=probmc('anom',.0.9,.20);
      put q1=;
      q2=probmc('anom',.0.9,.20,5,.1,.0.1,.1,.0.1,.1);
      put q2=;
      q3=probmc('anom',.0.9,.20,5,.5,.5,.5,.5,.5,0.5);
      put q3=;
      q4=probmc('anom',.0.9,.20,5,.1,.0.2,.3,.0.4,.0.5);
      put q4=;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
q1=2.78950610163346
q2=2.45499619666786
q3=2.45499619666786
q4=2.45323199941123
```
Example 3: Computing the Partitioned Range

data _null_;  
    method run();  
    q1=probmc('partrange',.0.9,.0.9,4,3,4,5,6);  
    put q1=;  
    q2=probmc('partrange',.0.9,12,4,3,4,5,6);  
    put q2=;  
end;  
enddata;  
run;

SAS writes the following results to the log:

q1=4.1022397989482
q2=4.7888626337511

Example 4: Computing Williams’ Test

In the following example, a substance has been tested at seven levels in a randomized block design of eight blocks. The observed treatment means are as follows:

<table>
<thead>
<tr>
<th>Treatment</th>
<th>Mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>X₀</td>
<td>10.4</td>
</tr>
<tr>
<td>X₁</td>
<td>9.9</td>
</tr>
<tr>
<td>X₂</td>
<td>10.0</td>
</tr>
<tr>
<td>X₃</td>
<td>10.6</td>
</tr>
<tr>
<td>X₄</td>
<td>11.4</td>
</tr>
<tr>
<td>X₅</td>
<td>11.9</td>
</tr>
<tr>
<td>X₆</td>
<td>11.7</td>
</tr>
</tbody>
</table>

The mean square, with \((7 - 1)(8 - 1) = 42\) degrees of freedom, is \(s^2 = 1.16\).

Determine the maximum likelihood estimates \(M_i\) through the averaging process.

• Because \(X₀ > X₁\), form \(X₀,₁ = (X₀ + X₁)/2 = 10.15\).
• Because \(X₀,₁ > X₂\), form \(X₀,₁,₂ = (X₀ + X₁ + X₂)/3 = (2X₀,₁ + X₂)/3 = 10.1\).
• \(X₀,₁,₂ < X₃ < X₄ < X₅\)
• Because \(X₃ > X₄\), form \(X₃,₆ = (X₃ + X₆)/2 = 11.8\).

Now the order restriction is satisfied.

The maximum likelihood estimates under the alternative hypothesis are:

• \(M₀ = M₁ = M₂ = X₀,₁,₂ = 10.1\)
• \(M₃ = X₄ = 10.6\)
• $M_4 = X_4 = 11.4$
• $M_5 = M_6 = X_{5,6} = 11.8$

Now compute $t = (11.8 - 10.4) / \sqrt{2 \times 5 / 8} = 2.60$, and the probability that corresponds to $k = 6$, $v = 42$, and $t = 2.60$ is .9924467341, which shows strong evidence that there is a response to the substance. You can also compute the quantiles for the upper 5% and 1% tails, as shown in the following table.

```r
data _null_;
  method run();
    prob=probmc('WILLIAMS',2.6,.,42,6);
    put prob=;
    quant5=probmc('WILLIAMS',.,.95,42,6);
    put quant5=;
    quant1=probmc('WILLIAMS',.,.99,42,6);
    put quant1= ;
  end;
enddata;
run;
```

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>prob=probmc('williams',2,6,.,42,6);</td>
<td>0.99244668715827</td>
</tr>
<tr>
<td>quant5=probmc('williams',.,.95,42,6);</td>
<td>1.80656253603889</td>
</tr>
<tr>
<td>quant1=probmc('williams',.,.99,42,6);</td>
<td>2.49090827298686</td>
</tr>
</tbody>
</table>

### References

Computes cumulative probabilities for the sample median.

**Category:** Probability

**Returned data type:** DOUBLE

**Syntax**

\[
\text{PROBMED}(n, x)
\]

**Arguments**

- **n** specifies the sample size.
  - **Data type:** DOUBLE
- **x** is the point of interest. That is, the PROBMED function calculates the probability that the median is less than or equal to \( x \).
  - **Data type:** DOUBLE

**Details**

The PROBMED function computes the probability that the sample median is less than or equal to \( x \) for a sample of \( n \) independent, standard normal random variables (mean 0, variance 1).

Let \( n \) represent the sample size, and \( x_{(i)} \) represents the \( i \)th order statistic. Then, when \( n \) is odd, the function makes the following calculation:

\[
\Pr[X_{((n+1)/2)} \leq x] = I_{\Phi(x)} \left( \frac{n + 1}{2}, \frac{n + 1}{2} \right)
\]

The following equations refer to the preceding equation:

\[
I_p(a, b) = \frac{1}{B(a, b)} \int_0^p t^{a-1}(1-t)^{b-1} dt
\]

In the equation \( B(a, b) = \Gamma(a)\Gamma(b)/\Gamma(a+b) \), \( \Gamma(.) \) is the gamma function. If \( n \) is even, the PROBMED function performs the following calculation:

\[
\Pr[\frac{X_{(n/2)} + X_{((n+1)/2)}}{2} \leq x] =
\]

\[
\frac{2}{B(n/2, n/2)} \int_{-\infty}^{x} \left[ (1 - \Phi(u))^{n/2} - (1 - \Phi(2x-u))^{n/2} \right] \Phi(u)^{n/2} - 1 \phi(u) du
\]

In this equation, \( B(n/2, n/2) = [\Gamma(n/2)]^2/\Gamma(n) \), and \( \Phi(.) \) and \( \phi(.) \) are the standard normal cumulative distribution function and density function, respectively.
Example

data _null_;  
method run();  
b=probmed(5,-0.1);  
put b;  
end;  
enddata;  
run;  

SAS writes the following output to the log:

0.42563808966747

---

**PROBNEGB Function**

Returns the probability from a negative binomial distribution.

**Category:** Probability

**Returned data type:** DOUBLE

**Syntax**

PROBNEGB\((p, n, m)\)

**Arguments**

\(p\)

is a numeric probability of success parameter.

<table>
<thead>
<tr>
<th>Range</th>
<th>0 ≤ (p) ≤ 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

\(n\)

is an integer number of successes parameter.

<table>
<thead>
<tr>
<th>Range</th>
<th>(n \geq 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

\(m\)

is a positive integer random variable, the number of failures.

<table>
<thead>
<tr>
<th>Range</th>
<th>(m \geq 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>
Details

The PROBNEGB function returns the probability that an observation from a negative binomial distribution, with probability of success \( p \) and number of successes \( n \), is less than or equal to \( m \).

To compute the probability that an observation is equal to a given value \( m \), compute the difference of two probabilities from the negative binomial distribution for \( m \) and \( m-1 \).

Example

The following statement illustrates the PROBNEGB function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x = \text{probnegb}(0.5, 2, 1) )</td>
<td>0.5</td>
</tr>
</tbody>
</table>

PROBNORM Function

Returns the probability from the standard normal distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBNORM(\( x \))

Arguments

\( x \)

is a numeric random variable.

Data type: DOUBLE

Details

The PROBNORM function returns the probability that an observation from the standard normal distribution is less than or equal to \( x \).

Note: PROBNORM is the inverse of the PROBIT function.

Example

The following statement illustrates the PROBNORM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x = \text{probnorm}(1.96) )</td>
<td>0.97500210485177</td>
</tr>
</tbody>
</table>
PROBT Function
Returns the probability from a t distribution.

Category: Probability
Returned data type: DOUBLE

Syntax
\[
\text{PROBT}(x, df[, nc])
\]

Arguments
\(x\)
- is a numeric random variable.
- Data type: DOUBLE
\(df\)
- is a numeric degrees of freedom parameter.
- Range: \(df > 0\)
- Data type: DOUBLE
\(nc\)
- is a numeric noncentrality parameter.
- Data type: DOUBLE

Details
The PROBT function returns the probability that an observation from a Student's \(t\) distribution, with degrees of freedom \(df\) and noncentrality parameter \(nc\), is less than or equal to \(x\). This function accepts a noninteger degree of freedom parameter \(df\). If the optional parameter, \(nc\), is not specified or has the value 0, the value that is returned is from the central Student's \(t\) distribution.

The significance level of a two-tailed \(t\) test is given by the following equation.
\[
p = (1 - \text{probt(abs}(x), df)) \times 2;
\]

Example
The following statement illustrates the PROBT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x = \text{probt}(0.9, 5));</td>
<td>0.79531439982768</td>
</tr>
</tbody>
</table>
PRXCHANGE Function

Performs a pattern-matching replacement.

**Category:**  Character String Matching

**Returned data type:**  CHAR

**Note:**  SAS has adopted the International Components for Unicode (ICU) to implement regular expression matching to Unicode string data. For more information, see Regular Expressions.

**Syntax**

```
PRXCHANGE((perl-regular-expression | regular-expression-id, times, source)
```

**Arguments**

- **perl-regular-expression**
  - specifies a character constant, variable, or expression with a value that is a Perl regular expression.
  - Data type:  CHAR

- **regular-expression-id**
  - specifies a numeric variable with a value that is a pattern identifier that is returned from the PRXPARSE function.
  - Restriction:  If you use this argument, you must also use the PRXPARSE function.
  - Data type:  INTEGER

- **times**
  - is a numeric constant, variable, or expression that specifies the number of times to search for a match and replace a matching pattern.
  - Data type:  INTEGER
  - Tip:  If the value of `times` is –1, then matching patterns continue to be replaced until the end of `source` is reached.

- **source**
  - specifies a character constant, variable, or expression that you want to search.
  - Data type:  CHAR

**Details**

**The Basics**

If you use `regular-expression-id`, the PRXCHANGE function searches the `source` with the `regular-expression-id` that is returned by PRXPARSE. It returns the value in `source` with the changes that were specified by the regular expression. If there is no match, PRXCHANGE returns the unchanged value in `source`. 
If you use `perl-regular-expression`, PRXCHANGE searches the `source` with the `perl-regular-expression`, and you do not need to call PRXPARSE. You can use PRXCHANGE with a `perl-regular-expression` in a WHERE clause and in PROC SQL.

**Note:** The following restrictions apply to PRX functions in DS2:

- Only `m, i, s,` and `x` can be used in the PRX form `/.../...` that can be preceded or followed by a single character.
- The matching mode modifiers `p, o, c, a,` and `l` are not supported.
- The matching mode modifier `g` is supported.

For more information about pattern matching, see “Pattern Matching Using Perl Regular Expressions (PRX)” in *SAS Viya Functions and CALL Routines: Reference*.

### Compiling a Perl Regular Expression

If `perl-regular-expression` is a constant or if it uses the `/o` option, then the Perl regular expression is compiled once, and each use of PRXCHANGE reuses the compiled expression. If `perl-regular-expression` is not a constant and if it does not use the `/o` option, then the Perl regular expression is recompiled for each call to PRXCHANGE.

**Note:** The compile-once behavior occurs when you use PRXCHANGE in a DS2 environment, in a WHERE clause, or in PROC SQL. For all other uses, the `perl-regular-expression` is recompiled for each call to PRXCHANGE.

### Performing a Match

Perl regular expressions consist of characters and special characters that are called metacharacters. When performing a match, SAS searches a source string for a substring that matches the Perl regular expression that you specify.

To view a short list of Perl regular expression metacharacters that you can use when you build your code, see the table “Tables of Perl Regular Expression (PRX) Metacharacters” in *SAS Viya Functions and CALL Routines: Reference*. You can find a complete list of metacharacters on the Perl website.

### Examples

#### Example 1: Changing the Order of First and Last Names By Using the DATA Step

The following example changes the order of first and last names.

```sas
/* Create a table that contains a list of names. */
proc ds2;
data names;
dcl char(32) name;
method init();
  name='Jones, Fred'; output;
  name='Kavich, Kate'; output;
  name='Turley, Ron'; output;
  name='Dulix, Yolanda'; output;
end;
enddata;
run;
quit;

/* Reverse last and first names */
```

proc ds2;
data ReversedNames;
   method run();
      set names;
      name=prxchange('s/(\w+), (\w+)/$2 $1/', -1, name);
   end;
enddata;
run;
quit;

proc print data=ReversedNames;
run;

Output 7.7  Results from the PRXCHANGE Function

<table>
<thead>
<tr>
<th>Obs</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Fred Jones</td>
</tr>
<tr>
<td>2</td>
<td>Kate Kavich</td>
</tr>
<tr>
<td>3</td>
<td>Ron Turley</td>
</tr>
<tr>
<td>4</td>
<td>Yolanda Dulix</td>
</tr>
</tbody>
</table>

Example 2: Changing a Matched Pattern to a Fixed Value
This example locates a pattern in a variable and replaces the variable with a predefined value. The example finds the phone numbers and replaces them with an informational message.

    /* Create table that contains confidential information. */
    proc ds2;
    data a;
      dcl char(95) text;
      method run();
      text='The phone number for Ed is (801)443-9876 but not until tonight.,'
          output;
      text='He can be reached at (910)998-8762 tomorrow for testing purposes.';
      output;
    end;
enddata;
run;
quit;
proc print data=a;
run;
quit;

    /* Locate confidential phone numbers and replace them with message indicating that they have been removed. */
    proc ds2;
    data b;
      method run();
      set a;
      text=prxchange('s/(\([2-9]\d\d) ?[2-9]\d\d-\d\d\d\d/*PHONE NUMBER REMOVED*/'
Output 7.8  Results Before Changing a Matched Pattern to a Fixed Value

Output 7.9  Results from Changing a Matched Pattern to a Fixed Value

Functions:

- “PRXMATCH Function” on page 544
- “PRXPARSE Function” on page 547
- “PRXPOSN Function” on page 549

PRXMATCH Function

Searches for a pattern match and returns the position at which the pattern is found.

- **Category:** Character String Matching
- **Returned data type:** INTEGER
- **Note:** SAS has adopted the International Components for Unicode (ICU) to implement regular expression matching to Unicode string data. For more information, see Regular Expressions.

**Syntax**

```
PRXMATCH(perl-regular-expression, source)
```
Arguments

*perl-regular-expression*

specifies a character constant, variable, or expression with a value that is a Perl regular expression.

Data type: CHAR

*source*

specifies a character constant, variable, or expression that you want to search.

Data type: CHAR

Details

The Basics

When you use *perl-regular-expression*, the PRXMATCH function searches *source* with the *perl-regular-expression* and returns the position at which the string begins. If there is no match, PRXMATCH returns a zero.

You can use PRXMATCH with a Perl regular expression in a WHERE clause and in PROC SQL.

Note: The following restrictions apply to PRX functions in DS2:

- Only m, i, s, and x can be used in the PRX form /.../.../ that can be preceded or followed by a single character.
- The matching mode modifiers p, o, c, a, and l are not supported.

For more information about pattern matching, see “Pattern Matching Using Perl Regular Expressions (PRX)” in SAS Viya Functions and CALL Routines: Reference.

Compiling a Perl Regular Expression

If *perl-regular-expression* is a constant or if it uses the /o option, then the Perl regular expression is compiled once and each use of PRXMATCH reuses the compiled expression. If *perl-regular-expression* is not a constant and if it does not use the /o option, then the Perl regular expression is recompiled for each call to PRXMATCH.

Examples

Example 1: Finding the Position of a Substring By Using a Perl Regular Expression

The following example uses a Perl regular expression to search a string (Hello world) for a substring (world) and to return the position of the substring in the string.

```sas
data _null_;  
dcl double position;  
method run();  
   position=prxmatch('/world/', 'Hello world!');  
   put position;  
end;  
enddate;  
run;
```
SAS writes the following output to the log:

7

Example 2: Extracting a ZIP Code
The following example searches each row in a table for a nine-digit ZIP code, and writes those rows to the table ZipPlus4.

Note: The backslash (\) must be preceded by another backslash (\) that acts as an escape character.

data ZipCodes (overwrite=yes);
  dcl char(16) name;
  dcl char(10) zip;
  method run();
    name='Jonathan'; zip='32532-2343'; output;
    name='Seth'; zip='85030'; output;
    name='Kim'; zip='39204'; output;
    name='Samuel'; zip='93849-3843'; output;
  end;
enddata;
run;

proc print data=ZipCodes; run;
quit;

data ZipPlus4 (overwrite=yes);
  method run();
    set zipcodes;
    select;
      when (prxmatch('/\d{5}-\d{4}/', zip))
        output;
    end;
  end;
enddata;
run;
quit;

proc print data=ZipPlus4; run;
quit;

Output 7.10 Original ZipCodes Table Output

<table>
<thead>
<tr>
<th>Obs</th>
<th>name</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Jonathan</td>
<td>32532-2343</td>
</tr>
<tr>
<td>2</td>
<td>Seth</td>
<td>85030</td>
</tr>
<tr>
<td>3</td>
<td>Kim</td>
<td>39204</td>
</tr>
<tr>
<td>4</td>
<td>Samuel</td>
<td>93849-3843</td>

Functions:
- “PRXCHANGE Function” on page 541
- “PRXPARSE Function” on page 547
- “PRXPOSN Function” on page 549

PRXPARSE Function

Compiles a Perl regular expression (PRX) that can be used for pattern matching of a character value.

**Category:** Character String Matching

**Restriction:** Use with other Perl regular expressions.

**Returned data type:** INTEGER

**Note:** SAS has adopted the International Components for Unicode (ICU) to implement regular expression matching to Unicode string data. For more information, see Regular Expressions.

**Syntax**

```
regular-expression-id = PRXPARSE(perl-regular-expression)
```

**Arguments**

- **regular-expression-id**
  - is a numeric pattern identifier that is returned by the PRXPARSE function.
  - Data type: INTEGER

- **perl-regular-expression**
  - specifies a character, constant, variable, or expression with a value that is a Perl regular expression.
  - Data type: CHAR
Details

The Basics
The PRXPARSE function returns a pattern identifier number that is used by other Perl functions to match patterns. If an error occurs in parsing the regular expression, SAS returns a missing value.

PRXPARSE uses metacharacters in constructing a Perl regular expression. To view a table of common metacharacters, see “Tables of Perl Regular Expression (PRX) Metacharacters” in SAS Viya Functions and CALL Routines: Reference.

Note: The following restrictions apply to PRX functions in DS2:
- Only m, i, s, and x can be used in the PRX form /.../... that can be preceded or followed by a single character.
- The matching mode modifiers p, o, c, a, and l are not supported.

For more information about pattern matching, see “Pattern Matching Using Perl Regular Expressions (PRX)” in SAS Viya Functions and CALL Routines: Reference.

Compiling a Perl Regular Expression
If perl-regular-expression is a constant, the Perl regular expression is compiled only once. Successive calls to PRXPARSE will not cause a recompile, but will return the regular-expression-id for the regular expression that was already compiled. This behavior simplifies the code because you do not need to use an initialization block (IF _N_ =1) to initialize Perl regular expressions.

Examples

Example 1: Compiling a Perl Regular Expression
The following example uses PRXPARSE to compile the Perl regular expression.

```sas
data _null_;  
method init();  
declare double patternID position;  

/* Use PRXPARSE to compile the Perl regular expression. */  
patternID=prxparse('/world/');  
/* Use PRXMATCH to find the position of the pattern match. */  
position=prxmatch(patternID, 'Hello world!');  
put position=;  
end;  
enddata; run;
```

Example 2: Using PRXPARSE to Reverse First and Last Names
data _null_;  
method init();  
declare double patternID position;  
declare char(32) names[4];  
declare int i;

names := ('Jones, Fred '  

position=7
/* Reverse last and first names */
do i = 1 to dim(names);
   names[i]=prxchange('s/\w+/,(\w+)/$2 $1/', -1, names[i]);
   put names[i];
end;
end;
enddata; run;

Functions:
• “PRXCHANGE Function” on page 541
• “PRXMATCH Function” on page 544
• “PRXPOSN Function” on page 549

PRXPOSN Function
Returns a character string that contains the value for a capture buffer.

Category:       Character String Matching
Returned data    CHAR
    type:

Note:           SAS has adopted the International Components for Unicode (ICU) to implement
    regular expression matching to Unicode string data. For more information, see
    Regular Expressions.

Syntax
PRXPOSN(regular-expression-id, capture-buffer, source)

Arguments
regular-expression-id
    specifies a numeric variable with a value that is a pattern identifier that is returned by
    the PRXPARSE function.

    Restriction
    Data type    INTEGER
**capture-buffer**

is a numeric constant, variable, or expression that identifies the capture buffer for which to retrieve a value:

- If the value of `capture-buffer` is zero, PRXPOSN returns the entire match.
- If the value of `capture-buffer` is between 1 and the number of open parentheses in the regular expression, then PRXPOSN returns the value for that capture buffer.
- If the value of `capture-buffer` is greater than the number of open parentheses, then PRXPOSN returns a missing value.

**Data type** INTEGER

**source**

specifies the text from which to extract capture buffers.

**Data type** CHAR

**Details**

The PRXPOSN function uses the results of PRXMATCH or PRXCHANGE to return a capture buffer. A match must be found by one of these functions for PRXPOSN to return meaningful information.

**Note:** The following restrictions apply to PRX functions in DS2:

- Only m, i, s, and x can be used in the PRX form /…/…/ that can be preceded or followed by a single character.
- The matching mode modifiers p, o, c, a, and l are not supported.

For more information about pattern matching, see “Pattern Matching Using Perl Regular Expressions (PRX)” in SAS Viya Functions and CALL Routines: Reference.

**Examples**

**Example 1: Extracting First and Last Names**

The following example uses PRXPOSN to extract first and last names from a table.

```sas
proc ds2;
data ReversedNames;
dcl char(32) name;
method init();
   name='Jones, Fred'; output;
   name='Kavich, Kate'; output;
   name='Turley, Ron'; output;
   name='Dulix, Yolanda'; output;
end;
enddata;
run;
quit;

proc ds2;
data FirstLastNames (overwrite=yes);
dcl char(16) first last;
dcl double re;
keep first last;
```

---
retain re;

method init();
  dcl varchar(32) expression;
  expression = '/(\w+), (\w+)/';
  re=prxparse(expression);
  if missing( re ) then do;
    put 'ERROR: Invalid expression ' expression;
    stop;
  end;
end;

method run();
  set ReversedNames;
  if prxmatch(re, name) then 
    do;
      last=prxposn(re, 1, name);
      first=prxposn(re, 2, name);
    end;
  end;
enddata;
run;
quit;

proc print data=FirstLastNames;
run;
quit;

Figure 7.2  Output from PRXPOSN: First and Last Names

Example 2: Extracting Names When Some Names Are Invalid
The following example creates a table that contains a list of names. Rows that have only 
a first name or only a last name are invalid. PRXPOSN extracts the valid names from the 
table, and writes the names to the table NEW.

proc ds2;
data old;
  dcl char(60) name;
  method init();
    name='Judith S Reaveley'; output;
    name='Ralph F. Morgan'; output;
    name='Jess Ennis'; output;
    name='Carol Echols'; output;
    name='Kelly Hansen Huff'; output;
  end;
enddata;
run;
quit;
name='Judith'; output;
name='Nick'; output;
name='Jones'; output;
end;
enddata;
run;
quit;

proc ds2;
data new;
dcl char(40) first middle last;
keep first middle last;
method run();
re=prxparse('/(\S+)\s+([\s]+\s+)?(\S+)/i');
set old;
if prxmatch(re, name) then
do;
    first=prxposn(re, 1, name);
    middle=prxposn(re, 2, name);
    last=prxposn(re, 3, name);
    output;
end;
end;
enddata;
run;
quit;
proc print data=new;
run;
quit;

PUT Function

Returns a value using a specified format.

Category: Special
Returned data type: NVARCHAR

Syntax

PUT(expression, format)

Arguments

expression

specifies any valid expression.

Requirement position must be a positive number.

Data type DOUBLE, DATE, TIME, TIMESTAMP, CHAR, NCHAR

format.

specifies either a DS2 format or a user-defined format that you want applied to expression.

To override the default alignment, you can add an alignment specification to a format:

−L left aligns the value
−C centers the value
−R right aligns the value

Details

If a value is not specified for the format width or decimal specification, DS2 uses the default values for that format.

If expression is not a valid data type for the format type (either numeric or character), DS2 converts expression to a valid data type for format, with these exceptions:

• date and time expressions are converted to a SAS date, time, or datetime DOUBLE value for numeric formats, and converted to NCHAR for character string formats
• when the format is a binary character format such as $BINARY, SHEX or $OCTAL, expressions with a data type of DOUBLE are converted to NCHAR
• an error is issued when an expression with a data type of VARBINARY is used with a numeric format that does not produce a data type of VARBINARY

When DS2 converts an expression's data type in an assignment statement, the result is left-aligned.

You can use the PUT function to convert a numeric value to a character value and to convert a date, time, or timestamp value to a SAS date/time value.
Comparisons

The PUT function and the PUT statement have similar behavior. However, the PUT statement directs its results to the SAS log whereas the PUT function returns an NCHAR value containing the result of formatting its argument.

Example

The following statements illustrate the PUT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>put(17180, date7.);</td>
<td>15JAN07</td>
</tr>
<tr>
<td>put(‘AB’, $binary.);</td>
<td>010000010100010</td>
</tr>
<tr>
<td>a=35436745.3354</td>
<td>35,436,745.3354</td>
</tr>
<tr>
<td>b=put(a, comma20.4 -L);</td>
<td>35,436,745.3354</td>
</tr>
<tr>
<td>proc format;</td>
<td></td>
</tr>
<tr>
<td>value abc 1=&quot;Yes&quot; 2=&quot;No&quot;;</td>
<td>Yes</td>
</tr>
<tr>
<td>run;</td>
<td></td>
</tr>
<tr>
<td>proc ds2;</td>
<td></td>
</tr>
<tr>
<td>data;</td>
<td></td>
</tr>
<tr>
<td>method init();</td>
<td></td>
</tr>
<tr>
<td>dcl double d;</td>
<td></td>
</tr>
<tr>
<td>d=1;</td>
<td></td>
</tr>
<tr>
<td>x=put(d, abc.);</td>
<td></td>
</tr>
<tr>
<td>put x=;</td>
<td></td>
</tr>
<tr>
<td>d=2;</td>
<td></td>
</tr>
<tr>
<td>x=put(d, abc.);</td>
<td></td>
</tr>
<tr>
<td>put x=;</td>
<td></td>
</tr>
<tr>
<td>end;</td>
<td></td>
</tr>
<tr>
<td>enddata;</td>
<td></td>
</tr>
<tr>
<td>run;</td>
<td></td>
</tr>
<tr>
<td>quit;</td>
<td></td>
</tr>
</tbody>
</table>

PVP Function

Returns the present value for a periodic cash flow stream (such as a bond), with repayment of principal at maturity.

Category: Financial

Returned data type: DOUBLE
Syntax

\( \text{PVP}(A, c, n, K, k_0, y) \)

**Arguments**

\( A \)
- Specifies the par value.
- Range: \( A > 0 \)
- Data type: DOUBLE

\( c \)
- Specifies the nominal per-year coupon rate, expressed as a fraction.
- Range: \( 0 \leq c < 1 \)
- Data type: DOUBLE

\( n \)
- Specifies the number of coupons per year.
- Range: \( n > 0 \)
- Data type: INTEGER

\( K \)
- Specifies the number of remaining coupons.
- Range: \( K > 0 \)
- Data type: INTEGER

\( k_0 \)
- Specifies the time from the present date to the first coupon date, expressed in terms of the number of years.
- Range: \( 0 < k_0 \leq \frac{1}{n} \)
- Data type: DOUBLE

\( y \)
- Specifies the nominal per-year yield-to-maturity, expressed as a fraction.
- Range: \( y > 0 \)
- Data type: DOUBLE

**Details**

The PVP function is based on the following relationship:
\[ P = \sum_{k=1}^{K} \frac{c(k)}{(1 + \frac{y}{n})^{t_k}} \]

The following relationships apply to the preceding equation:

- \( t_k = nk_0 + k - 1 \)
- \( c(k) = \frac{c}{n}A \) for \( k = 1, \ldots, K - 1 \)
- \( c(K) = \left(1 + \frac{c}{n}\right)A \)

**Example**

```plaintext
data _null_;  
  method run();  
  dcl double p;  
  p=pvp(1000,.01,4,14,.33/2,.10);  
  put p;  
end;  
enddata;  
run;  
```

The value that is returned is 743.167613519067.

### QTR Function

**Returns the quarter of the year from a SAS date value.**

**Category:** Date and Time  
**Returned data type:** DOUBLE

**Syntax**

\[ \text{QTR}(date) \]

**Arguments**

- **date** specifies any valid expression that represents a SAS date value.
  
  **Data type**: DOUBLE

**See**  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The QTR function returns a value of 1, 2, 3, or 4 from a SAS date value to indicate the quarter of the year in which a date value falls.

For more information about how DS2 handles date and time values, see “Dates and Times in DS2” in *SAS Viya: DS2 Programmer’s Guide.*
Example

The following statements illustrate the QTR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=17180;</td>
<td></td>
</tr>
<tr>
<td>b=put(a,date7.);</td>
<td>14JAN07</td>
</tr>
<tr>
<td>c=qtr(a);</td>
<td>1</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “YYQ Function” on page 679

QUOTE Function

Adds double quotation marks to a character value.

Category: Character

Returned data type: NCHAR

Syntax

QUOTE(expression)

Arguments

expression

specifies any valid expression that evaluates to a character string.

Data type NCHAR

See

Details

The QUOTE function adds double quotation marks, the default character, to a character value. If double quotation marks are found within the argument, they are doubled in the output.

The length of the receiving variable must be long enough to contain the argument (including trailing blanks), leading and trailing quotation marks, and any embedded quotation marks that are doubled. For example, if the argument is ABC followed by three trailing blanks, then the receiving variable must have a length of at least eight to hold “ABC###”. (The character # represents a blank space.) If the receiving field is not long enough, the QUOTE function returns a blank string, and writes an invalid argument note to the SAS log.
A string of characters enclosed in double quotation marks is a DS2 identifier and not a character constant. The double quotation marks become part of the identifier. Quoted identifiers cannot be used to create column names in an output table.

Example

The following statements illustrate the QUOTE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a='A&quot;B';</td>
<td>&quot;A&quot;&quot;B&quot;</td>
</tr>
<tr>
<td>b=quote(a);</td>
<td></td>
</tr>
<tr>
<td>a='A'B';</td>
<td>&quot;A'B&quot;</td>
</tr>
<tr>
<td>b=quote(a);</td>
<td></td>
</tr>
<tr>
<td>a='Paul''s Catering Service</td>
<td>&quot;Paul's Catering Service&quot;</td>
</tr>
<tr>
<td>b=quote(trim(a));</td>
<td></td>
</tr>
</tbody>
</table>

RANBIN Function

Returns a random variate from a binomial distribution.

**Category:** Random Number

**Restriction:** This function is not supported in the CAS server.

**Returned data type:** DOUBLE

**Syntax**

RANBIN(seed, n, p)

**Arguments**

seed

is a numeric constant, variable, or expression. If seed ≤ 0, the time of day is used to initialize the seed stream.

Range  seed < 2^{31}–1

Data type  INTEGER

See  "Seed Values" in “Using Random-Number Functions and CALL Routines” in SAS Viya Functions and CALL Routines: Reference

n

is a numeric constant, variable, or expression that specifies the number of independent Bernoulli trials parameter.

Range  n > 0
**Data type**  INTEGER

$p$  is a numeric constant, variable, or expression that specifies the probability of success.

**Range**  $0 < p < 1$

**Data type**  DOUBLE

**Details**

The RANBIN function returns a variate that is generated from a binomial distribution with mean $np$ and variance $np(1−p)$. If $n ≤ 50$, $np ≤ 5$, or $n(1−p) ≤ 5$, an inverse transform method applied to a RANUNI uniform variate is used. If $n > 50$, $np > 5$, and $n(1−p) > 5$, the normal approximation to the binomial distribution is used. In that case, the Box-Muller transformation of RANUNI uniform variates is used.

**See Also**

**Functions:**

- “RAND Function” on page 560

---

**RANCAU Function**

Returns a random variate from a Cauchy distribution.

**Category:** Random Number

**Restriction:** This function is not supported in the CAS server.

**Returned data type:** DOUBLE

**Syntax**

RANCAU(seed)

**Arguments**

seed  is a numeric constant, variable, or expression.

**Range**  seed $< 2^{31} − 1$

**Data type**  INTEGER

**Note**  If seed ≤ 0, the time of day is used to initialize the seed stream.

**See**  “Seed Values” in “Using Random-Number Functions and CALL Routines” in SAS Viya Functions and CALL Routines: Reference
Details

The RANCAU function returns a variate that is generated from a Cauchy distribution with location parameter 0 and scale parameter 1. An acceptance-rejection procedure applied to RANUNI uniform variates is used. If \( u \) and \( v \) are independent uniform \((-1/2, 1/2)\) variables and \( u^2 + v^2 \leq 1/4 \), then \( u/v \) is a Cauchy variate. A Cauchy variate \( X \) with location parameter \( \text{ALPHA} \) and scale parameter \( \text{BETA} \) can be generated:

\[
x = \text{ALPHA} + \text{BETA} \times \text{RANCAU(seed)}
\]

### Details

#### Generating Pseudo-Random Numbers

The RAND function generates pseudo-random numbers from various continuous and discrete distributions. Wherever possible, the simplest form of the distribution is used.

The RAND function uses the Mersenne-Twister pseudo-random number generator (RNG) that was developed by Matsumoto and Nishimura (1998). The pseudo-random number generator has a very long period \(2^{19937} - 1\) and very good statistical properties. The period is a Mersenne prime, which contributes to the naming of the RNG. The algorithm is a twisted generalized feedback shift register (TGFSR) that explains the latter part of the name. The TGFSR gives the RNG a very high order of equidistribution...
(623-dimensional with 32-bit accuracy), which means that there is a very small correlation between successive vectors of 623 pseudo-random numbers.

The RAND function is started with a single seed. However, the state of the process cannot be captured by a single seed. You cannot stop and restart the generator from its stopping point.

If the initial seed is exactly divisible by 8192, the RAND function uses the 2002 initialization algorithm (Matsumoto and Nishimura, 2002) (See “References” in SAS Viya Functions and CALL Routines: Reference). Otherwise, RAND uses the 1998 initialization algorithm.

**Reproducing a Pseudo-Random Number Stream**

If you want to create reproducible streams of pseudo-random numbers, then use the STREAMINIT function to specify a seed value for pseudo-random number generation. Use the STREAMINIT function once per data program before any invocation of the RAND function. For more information, see the example in “STREAMINIT Function” on page 615.

**Duplicate Values in the Mersenne-Twister RNG Algorithm**

The Mersenne-Twister RNG algorithm has an extremely long period, but this does not imply that large random samples are devoid of duplicate values. The RAND function returns at most $2^{32}$ distinct values. In a random uniform sample of size $10^5$, the chance of drawing at least one duplicate is greater than 50%. The expected number of duplicates in a random uniform sample of size $M$ is approximately $M^2/2^{33}$ when $M$ is much less than $2^{32}$. For example, you should expect about 115 duplicates in a random uniform sample of size $M=10^5$. These results are consequences of the famous “birthday matching problem” in probability theory.

**Bernoulli Distribution**

$x = \text{RAND}(\text{BERNOULLI}', p)$

**Arguments**

$x$

is an observation from the distribution with the following probability density function:

$$f(x) = \begin{cases} 1 & p = 0, x = 0 \\ p^x(1-p)^{1-x} & 0 < p < 1, x = 0, 1 \\ 1 & p = 1, x = 1 \end{cases}$$

**Range** $x=0, 1$

$p$

is a numeric constant, variable, or expression that specifies the probability of success.

**Range** $0 \leq p \leq 1$

**Beta Distribution**

$x = \text{RAND}(\text{BETA}', a, b)$

**Arguments**
\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{\Gamma(a + b)}{\Gamma(a) \Gamma(b)} x^{a-1} (1 - x)^{b-1}
\]

Range \( 0 < x < 1 \)

\( a \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range \( a > 0 \)

\( b \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range \( b > 0 \)

**Binomial Distribution**

\( x = \text{RAND}('\text{BINOMIAL}', p, n) \)

**Arguments**

\( x \)

is an integer observation from the distribution with the following probability density function:

\[
f(x) = \begin{cases} 
1 & p = 0, x = 0 \\
\binom{n}{x} p^x (1 - p)^{n-x} & 0 < p < 1, x = 0, \ldots, n \\
1 & p = 1, x = n 
\end{cases}
\]

Range \( x = 0, 1, \ldots, n \)

\( p \)

is a numeric probability of success.

Range \( 0 \leq p \leq 1 \)

\( n \)

is an integer parameter that counts the number of independent Bernoulli trials.

Range \( n = 1, 2, \ldots \)

**Cauchy Distribution**

\( x = \text{RAND}('\text{CAUCHY}') \)

**Arguments**

\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{1}{\pi (1 + x^2)}
\]
Chi-Square Distribution

\( x = \text{RAND}('\text{CHISQUARE}', \ df) \)

**Arguments**

\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{2^{d_f/2}x^{d_f/2} - 1}{\Gamma(d_f/2)} e^{-x/2}
\]

**Range**  \( x > 0 \)

\( df \)

is a numeric constant, variable, or expression that specifies the degrees of freedom.

**Range**  \( df > 0 \)

Erlang Distribution

\( x = \text{RAND}('\text{ERLANG}', \ a) \)

**Arguments**

\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{1}{f(0)} x^a - 1 \ e^{-x}
\]

**Range**  \( x > 0 \)

\( a \)

is a numeric constant, variable, or expression that specifies a shape parameter.

**Range**  \( a = 1, 2, ... \)

Exponential Distribution

\( x = \text{RAND}('\text{EXPONENTIAL}') \)

**Arguments**

\( x \)

is an observation from the distribution with the following probability density function:

\[f(x) = e^{-x}\]

**Range**  \( x > 0 \)
**F Distribution**

\[ x = \text{RAND}(F', n, d) \]

**Arguments**

\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{1}{\frac{n}{2} \Gamma\left(\frac{n}{2}\right) \frac{d}{2} \Gamma\left(\frac{d}{2}\right)} \frac{n^{n/2} d^{d/2} x^{n-2}}{(n+x)^{(n+d)/2}}
\]

Range \( x > 0 \)

\( n \)

is a numeric constant, variable, or expression that specifies the numerator degrees of freedom.

Range \( n > 0 \)

\( d \)

is a numeric constant, variable, or expression that specifies the denominator degrees of freedom.

Range \( d > 0 \)

**Gamma Distribution**

\[ x = \text{RAND}(\text{GAMMA}', a, [\lambda]) \]

**Arguments**

\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{x^{a-1} e^{-x/\lambda}}{\lambda^a \Gamma(a)}
\]

Range \( x > 0 \)

\( a \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range \( a > 0 \)

\( \lambda \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Default The optional shape parameter \( \lambda > 0 \) has the default value \( \lambda = 1 \).

**Geometric Distribution**

\[ x = \text{RAND}(\text{GEOMETRIC}', p) \]

**Arguments**
$x$ is an integer count that denotes the number of trials that are needed to obtain one success. $x$ is an integer observation from the distribution with the following probability density function:

$$f(x) = \begin{cases} (1 - p)^{x-1} p & 0 < p < 1, x = 1, 2, \ldots \\ 1 & p = 1, x = 1 \end{cases}$$

Range $x = 1, 2, \ldots$

$p$

is a numeric constant, variable, or expression that specifies the probability of success.

Range $0 < p \leq 1$

**Hypergeometric Distribution**

$x = \text{RAND('HYPER', } N, R, n)$

**Arguments**

$x$

is an integer observation from the distribution with the following probability density function:

$$f(x) = \binom{R}{x} \binom{N-R}{n-x} \binom{N}{n}^{-1}$$

Range $x = \max(0, (n - (N - R))), \ldots, \min(n, R)$

$N$

is a numeric constant, variable, or expression that specifies an integer population size.

Range $N = 1, 2, \ldots$

$R$

is a numeric constant, variable, or expression that specifies an integer number of items in the category of interest.

Range $R = 0, 1, \ldots, N$

$n$

is a numeric constant, variable, or expression that specifies an integer sample size parameter.

Range $n = 1, 2, \ldots, N$

The hypergeometric distribution is a mathematical formalization of an experiment in which you draw $n$ balls from an urn that contains $N$ balls, $R$ of which are red. The hypergeometric distribution is the distribution of the number of red balls in the sample of $n$.

**Lognormal Distribution**

$x = \text{RAND('LOGNORMAL', } [\Theta, \lambda])$
Arguments

\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{1}{x^\lambda 2\pi} \exp \left( -\frac{(\ln(x) - \theta)^2}{2\lambda^2} \right)
\]

Range \( x > 0 \)

\( \lambda \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Default The optional log-scale parameter \( \lambda \) has the default value \( \lambda = 1 \).

\( \theta \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Default The optional log-scale parameter \( \theta \) has the default value \( \theta = 0 \).

**Negative Binomial Distribution**

\( x = \text{RAND}('\text{NEGBINOMIAL}', p, k) \)

Arguments

\( x \)

is an integer observation from the distribution with the following probability density function:

\[
f(x) = \begin{cases} 
\binom{x + k - 1}{k - 1} (1 - p)^x p^k & 0 < p < 1, x = 0, 1, \ldots \\
1 & p = 1, x = 0
\end{cases}
\]

Range \( x = 0, 1, \ldots \)

\( k \)

is an integer parameter that is the number of successes. However, non-integer \( k \) values are allowed as well.

Range \( k = 1, 2, \ldots \)

\( p \)

is a numeric constant, variable, or expression that specifies the numeric probability of success.

Range \( 0 < p \leq 1 \)

The negative binomial distribution is the distribution of the number of failures before \( k \) successes occur in sequential independent trials, all with the same probability of success, \( p \).

**Normal Distribution**

\( x = \text{RAND}('\text{NORMAL}', \theta, \lambda) \)

Arguments
\( x \)

is an observation from the normal distribution with a mean of \( \theta \) and a standard deviation of \( \lambda \) that has the following probability density function:

\[
f(x) = \frac{1}{\lambda \sqrt{2\pi}} \exp\left( -\frac{(x-\theta)^2}{2\lambda^2} \right)
\]

Range \( -\infty < x < \infty \)

\( \theta \)

is a numeric constant, variable, or expression that specifies the mean parameter.

Default 0

\( \lambda \)

is a numeric constant, variable, or expression that specifies the standard deviation parameter.

Default 1

Range \( \lambda > 0 \)

**Poisson Distribution**

\( x = \text{RAND('POISSON', } m) \)

**Arguments**

\( x \)

is an integer observation from the distribution with the following probability density function:

\[
f(x) = \frac{m^x e^{-m}}{x!}
\]

Range \( x = 0, 1, ... \)

\( m \)

is a numeric constant, variable, or expression that specifies a mean parameter.

Range \( m > 0 \)

**T Distribution**

\( x = \text{RAND('T', } df) \)

**Arguments**

\( x \)

is an observation from the distribution with the following probability density function:

\[
f(x) = \frac{\Gamma\left(\frac{df+1}{2}\right)}{\sqrt{df\pi \Gamma\left(\frac{df}{2}\right)}} \left(1 + \frac{x^2}{df}\right)^{-\frac{df+1}{2}}
\]

Range \( -\infty < x < \infty \)
**df**

is a numeric constant, variable, or expression that specifies the degrees of freedom parameter.

Range  \( df > 0 \)

**Tabled Distribution**

\( x = \text{RAND}'\text{TABLE}', p1, p2, \ldots \)  

**Arguments**  

\( x \)

is an integer observation from one of the following distributions:

If \( \sum_{i=1}^{n} p_i < 1 \), then \( x \) is an observation from this probability density function:

\( f(i) = p_i, \quad i = 1, 2, \ldots, n \)

and

\( f(n+1) = 1 - \sum_{i=1}^{n} p_i \)

If \( \sum_{i=1}^{n} p_i \geq 1 \) for some index \( n \), then \( x \) is an observation from this probability density function:

\( f(i) = p_i, \quad i = 1, 2, \ldots, n-1 \)

and

\( f(n) = 1 - \sum_{i=1}^{n-1} p_i \)

\( p1, p2, \ldots \)

are numeric probability values.

Range  \( 0 \leq p1, p2, \ldots \leq 1 \)

Restriction  
The maximum number of probability parameters depends on your operating environment, but the maximum number of parameters is at least 32,767.

The tabled distribution takes on the values 1, 2, ..., \( n \) with specified probabilities.

*Note:* By using the FORMAT statement, you can map the set \{1, 2, ..., \( n \)\} to any set of \( n \) or fewer elements.

**Triangular Distribution**

\( x = \text{RAND}'\text{TRIANGLE}', h \)  

**Arguments**  

\( x \)

is an observation from the distribution with the following probability density function:
In this equation, $0 \leq h \leq 1$.

**Uniform Distribution**

$x = \text{RAND}('\text{UNIFORM'} \ [a, b])$

**Arguments**

- $x$ is an observation from the distribution with the following probability density function:
  
  $f(x) = 1$

  **Range** The range of $x$ is $a \leq x \leq b$. The parameters $a$ and $b$ default values are $a=0$ and $b=1$. You must specify values for both $a$ and $b$ if you do not want to use the default values.

- $a$ specifies a value in the probability density function.
  Default 0

- $b$ specifies a value in the probability density function.
  Default 1

The uniform pseudo-random number generator that the RAND function uses is the Mersenne-Twister (Matsumoto and Nishimura 1998). This generator has a period of $2^{19937} - 1$ and 623-dimensional equidistribution up to 32-bit accuracy. This algorithm underlies the generators for the other available distributions in the RAND function.

**Weibull Distribution**

$x = \text{RAND}('\text{WEIBULL'} \ [a, b])$

**Arguments**

- $x$ is an observation from the distribution with the following probability density function:
\[ f(x) = \frac{a}{b^a} x^a - 1 \left(\frac{x}{b}\right)^a \]

Range \( x \geq 0 \)

\( a \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range \( a > 0 \)

\( b \)

is a numeric constant, variable, or expression that specifies scale parameter.

Range \( b > 0 \)

RANEXP Function

Returns a random variate from an exponential distribution.

**Category:** Random Number

**Restriction:** This function is not supported in the CAS server.

**Returned data type:** DOUBLE

**Syntax**

RANEXP(\( seed \))

**Arguments**

\( seed \)

is a numeric constant, variable, or expression with an integer value. If \( seed \leq 0 \), the time of day is used to initialize the seed stream.

Range \( seed < 2^{31} - 1 \)

Data type INTEGER

See "Seed Values" in “Using Random-Number Functions and CALL Routines” in SAS Viya Functions and CALL Routines: Reference

**Details**

The RANEXP function returns a variate that is generated from an exponential distribution with parameter 1. An inverse transform method applied to a RANUNI uniform variate is used.

An exponential variate \( X \) with parameter LAMBDA can be generated:

\[ x = \text{ranexp}(\text{seed}) / \text{lambda}; \]

An extreme value variate \( X \) with location parameter ALPHA and scale parameter BETA can be generated:
x = alpha - beta * \log(ranexp(seed));

A geometric variate X with parameter P can be generated as follows:

x = floor(-ranexp(seed) / log(1 - p));

See Also

Functions:
- “RAND Function” on page 560

---

**RANGAM Function**

Returns a random variate from a gamma distribution.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Random Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restriction:</td>
<td>This function is not supported in the CAS server.</td>
</tr>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

**Syntax**

RANGAM(seed, a)

**Arguments**

*seed*

is a numeric constant, variable, or expression.

Range

<table>
<thead>
<tr>
<th>seed</th>
<th>seed &lt; 2^{31} - 1</th>
</tr>
</thead>
</table>

Data type

INTEGER

Note

If seed ≤ 0, the time of day is used to initialize the seed stream.

See

"Seed Values" in “Using Random-Number Functions and CALL Routines” in SAS Viya Functions and CALL Routines: Reference

*a*

is a numeric constant, variable, or expression that specifies the shape parameter.

Range

a > 0

**Details**

The RANGAM function returns a variate that is generated from a gamma distribution with parameter a. For a > 1, an acceptance-rejection method due to Cheng (1977) is used. (See “References” in SAS Viya Functions and CALL Routines: Reference). For a ≤ 1, an acceptance-rejection method due to Fishman is used (1978, Algorithm G2) (See “References” in SAS Viya Functions and CALL Routines: Reference).

A gamma variate X with shape parameter ALPHA and scale BETA can be generated:

x = beta * rangam(seed, alpha);
If $2\cdot\text{ALPHA}$ is an integer, a chi-square variate $X$ with $2\cdot\text{ALPHA}$ degrees of freedom can be generated:

$$x=2\cdot\text{rangam}(\text{seed}, \text{alpha});$$

If $N$ is a positive integer, an Erlang variate $X$ can be generated:

$$x=\text{beta}\cdot\text{rangam}(\text{seed}, N);$$

It has the distribution of the sum of $N$ independent exponential variates whose means are $\text{BETA}$.

And finally, a beta variate $X$ with parameters $\text{ALPHA}$ and $\text{BETA}$ can be generated:

$$y_1=\text{rangam}(\text{seed}, \text{alpha});$$
$$y_2=\text{rangam}(\text{seed}, \text{beta});$$
$$x=y_1/(y_1+y_2);$$

- “RAND Function” on page 560

**RANGE Function**

Returns the difference between the largest and the smallest values.

- **Category:** Descriptive Statistics
- **Returned data type:** DOUBLE

**Syntax**

```
RANGE(expression [, …expression])
```

**Arguments**

- **expression**
  - specifies any valid expression that evaluates to a numeric value.

  - **Requirement:** At least one non-null or nonmissing argument is required. Otherwise, the function returns a null or missing value.

  - **Data type:** DOUBLE

  - **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The RANGE function returns the difference between the largest and the smallest of the non-null or nonmissing arguments.

**Example**

The following statements illustrate the RANGE function:
RANK Function

Returns the position of a character in the ASCII or EBCDIC collating sequence.

**Category:** Character  
**Returned data type:** DOUBLE

### Syntax

```
RANK(expression)
```

### Arguments

**expression**  
specifies any valid expression that evaluates to a character string.

**Data type**  
NCHAR

**See**  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

### Details

The `RANK` function returns an integer that represents the position of the first character in the character expression.

### Example

The following statement illustrates the `RANK` function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a=rank('A');</code></td>
<td>ASCII 65</td>
</tr>
</tbody>
</table>

Functions:

• “BYTE Function” on page 236

RANNOR Function

Returns a random variate from a normal distribution.

Category: Random Number

Restriction: This function is not supported in the CAS server.

Returned data type: DOUBLE

Syntax

RANNOR(seed)

Arguments

seed

is a numeric constant, variable, or expression.

Range: $seed < 2^{31} – 1$

Data type: INTEGER

Note: If $seed \leq 0$, the time of day is used to initialize the seed stream.

See: "Seed Values" in “Seed Values” in SAS Viya Functions and CALL Routines: Reference

Details

The RANNOR function returns a variate that is generated from a normal distribution with mean 0 and variance 1. The Box-Muller transformation of RANUNI uniform variates is used.

A normal variate $X$ with mean $\mu$ and variance $\sigma^2$ can be generated with this code:

$$x = \mu + \sqrt{\sigma^2} \times \text{rannor}(seed)$$

A lognormal variate $X$ with mean $e^{\mu + \sigma^2/2}$ and variance $e^{2\mu + 2\sigma^2} - e^{2\mu + \sigma^2}$ can be generated with this code:

$$x = e^{\mu + \sqrt{\sigma^2} \times \text{rannor}(seed)}$$

See Also

Functions:

• “RAND Function” on page 560
RANPOI Function

Returns a random variate from a Poisson distribution.

**Category:** Random Number

**Restriction:** This function is not supported in the CAS server.

**Returned data type:** DOUBLE

**Syntax**

RANPOI(seed, m)

**Arguments**

* seed
  is a numeric constant, variable, or expression.
  
  **Range**  
  \( \text{seed} < 2^{31} - 1 \)
  
  **Data type** INTEGER

  **Note**  
  If \( \text{seed} \leq 0 \), the time of day is used to initialize the seed stream.

* m
  is a numeric constant, variable, or expression that specifies the mean of the distribution.
  
  **Range**  
  \( m \geq 0 \)
  
  **Data type** DOUBLE

**Details**

The RANPOI function returns a variate that is generated from a Poisson distribution with mean \( m \). For \( m < 85 \), an inverse transform method applied to a RANUNI uniform variate is used (Fishman 1976). (See “References” in SAS Viya Functions and CALL Routines.) For \( m \geq 85 \), the normal approximation of a Poisson random variable is used. To expedite execution, internal variables are calculated only on initial calls (that is, with each new \( m \)).

**See Also**

Functions:

- “RAND Function” on page 560
RANTBL Function

Returns a random variate from a tabled probability distribution.

Category: Random Number
Restriction: This function is not supported in the CAS server.
Returned data type: DOUBLE

Syntax

RANTBL(seed, p1...pn)

Arguments

seed

is a numeric constant, variable, or expression.

Range seed < 2^{31}−1
Data type INTEGER

Note If seed ≤ 0, the time of day is used to initialize the seed stream.

See "Seed Values" in “Using Random-Number Functions and CALL Routines” in SAS Viya Functions and CALL Routines: Reference.

pi

is a numeric constant, variable, or expression.

Range 0 ≤ pi ≤ 1 for 0 < i ≤ n
Data type DOUBLE

Details

The RANTBL function returns a variate that is generated from the probability mass function defined by p1 through pn. An inverse transform method applied to a RANUNI uniform variate is used. RANTBL returns

1 with probability p1
2 with probability p2
.
.
n with probability pn

n + 1 with probability 1 − \sum_{i=1}^{n} pi if \sum_{i=1}^{n} pi ≤ 1

If, for some index $j < n$, $\sum_{i=1}^{j} p_i \geq 1$, RANTBL returns only the indices 1 through $j$ with the probability of occurrence of the index $j$ equal to $1 - \sum_{i=1}^{j-1} p_i$.

Let $n=3$ and $P_1$, $P_2$, and $P_3$ be three probabilities with $P_1+P_2+P_3=1$, and $M_1$, $M_2$, and $M_3$ be three variables. The variable $X$ in the following statements will be assigned one of the values of $M_1$, $M_2$, or $M_3$ with probabilities of occurrence $P_1$, $P_2$, and $P_3$, respectively.

```plaintext
array m{3} m1-m3;
x=m{rantbl(seed, of p1-p3)};
```

**See Also**

**Functions:**
- “RAND Function” on page 560

---

**RANTRI Function**

Returns a random variate from a triangular distribution.

- **Category:** Random Number
- **Restriction:** This function is not supported in the CAS server.
- **Returned data type:** DOUBLE

**Syntax**

`RANTRI(seed, h)`

**Arguments**

- **seed**
  - is a numeric constant, variable, or expression.
  - **Range** $seed < 2^{31}-1$
  - **Data type** INTEGER
  - **Note** If $seed \leq 0$, the time of day is used to initialize the seed stream.
  - **See** "Seed Values" in “Using Random-Number Functions and CALL Routines” in SAS Viya Functions and CALL Routines: Reference

- **h**
  - is a numeric constant, variable, or expression that specifies the mode of the distribution.
  - **Range** $0 < h < 1$
  - **Data type** DOUBLE
Details

The RANTRI function returns a variate that is generated from the triangular distribution on the interval (0,1) with parameter $h$, which is the modal value of the distribution. An inverse transform method applied to a RANUNI uniform variate is used.

A triangular distribution $X$ on the interval $(A,B)$ with mode $C$, where $A \leq C \leq B$, can be generated:

$$x = (b-a) \text{rantri}(seed, (c-a)/(b-a)) + a;$$

See Also

Functions:

- “RAND Function” on page 560

RANUNI Function

Returns a random variate from a uniform distribution.

- **Category:** Random Number
- **Restriction:** This function is not supported in the CAS server.
- **Returned data type:** DOUBLE

Syntax

RANUNI(seed)

**Required Argument**

- **seed** is a numeric constant, variable, or expression.

  - **Range:** $seed < 2^{31}-1$
  - **Data type:** INTEGER

  **Note:** If $seed \leq 0$, the time of day is used to initialize the seed stream.

  **See:** "Seed Values" in “Using Random-Number Functions and CALL Routines” in SAS Viya Functions and CALL Routines: Reference

Details

The RANUNI function returns a number that is generated from the uniform distribution on the interval (0,1) using a prime modulus multiplicative generator with modulus $2^{31}-1$ and multiplier 397204094 (Fishman and Moore 1982). You can use a multiplier to change the length of the interval and an added constant to move the interval. For example, the following code returns a number that is generated from the uniform distribution on the interval $(b,a+b)$.

```plaintext
x=(b-a)*rantri(seed, (c-a)/(b-a))+a;
```
random_variate=a*ranuni(seed)+b;

See Also

Functions:
• “RAND Function” on page 560

REPEAT Function

Repeats a character expression.

Category: Character

Returned data type: VARCHAR, NVARCHAR

Syntax

REPEAT(expression, n)

Arguments

expression
specifies any valid expression that evaluates to a character string.

Interaction
If expression is a CHAR or NCHAR expression, then the REPEAT function returns a CHAR value. The maximum length of a CHAR value is 32767 bytes. If expression is a VARCHAR expression, then the REPEAT function returns a VARCHAR value. The maximum length of a VARCHAR value is $2^{31}-1$ bytes.

Data type
CHAR, NCHAR, VARCHAR

See

n
specifies the number of times to repeat expression.

Restriction
$n$ must be greater than or equal to 0.

Data type
INTEGER

Details

The REPEAT function returns a character value consisting of the first argument repeated $n$ times. Thus, the first argument appears $n+1$ times in the result.

Example

The following statement illustrates the REPEAT function:
### REVERSE Function

Reverses a character expression.

**Category:** Character  
**Returned data type:** NCHAR

#### Syntax

```plaintext
REVERSE(expression)
```

#### Arguments

**expression**  
specifies any valid expression that evaluates to a character string.

**Data type**  
NCHAR

**See**  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

#### Details

The REVERSE function returns a character value with the last character in the expression is the first character in the result, the next-to-last character in the expression is the second character in the result, and so on.

**Note:** Trailing blanks in the expression become leading blanks in the result.

#### Example

The following statement illustrates the REVERSE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=reverse('xyz ');</td>
<td>zyx</td>
</tr>
</tbody>
</table>

### RIGHT Function

Right aligns a character expression.

**Category:** Character
**Syntax**

\[ \text{RIGHT}(\text{expression}) \]

**Arguments**

- \( \text{expression} \): specifies any valid expression that evaluates to a character string.

**Details**

The RIGHT function returns an argument with trailing blanks moved to the start of the value. The argument's length does not change.

**Example**

The following statements illustrate the RIGHT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a='\text{Due Date }'; ) \n( b=\text{put}(a, $10.); ) \n( c=\text{put}(\text{right}(a),$10.); )</td>
<td>( \text{Due Date} ) \nDue Date \nDue Date</td>
</tr>
</tbody>
</table>

**See Also**

- “COMPRESS Function” on page 264
- “LEFT Function” on page 431
- “TRIM Function” on page 650

### RMS Function

Returns the root mean square.

- **Category:** Descriptive Statistics
- **Returned data type:** DOUBLE
Syntax

RMS(expression [ , ...expression])

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

Details

The root mean square is the square root of the arithmetic mean of the squares of the values. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the root mean square of the non-null or nonmissing values.

Let $n$ be the number of arguments with non-null or nonmissing values, and let $x_1, x_2, ..., x_n$ be the values of those arguments. The root mean square is calculated as follows.

$$\sqrt{\frac{x_1^2 + x_2^2 + ... + x_n^2}{n}}$$

Example

The following statements illustrate the RMS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x1=rms(1,7);</td>
<td>5</td>
</tr>
<tr>
<td>x2=rms(.,1,5,11);</td>
<td>7</td>
</tr>
</tbody>
</table>

ROUND Function

Rounds the first argument to the nearest multiple of the second argument, or to the nearest integer when the second argument is omitted.

Category: Truncation

Returned data type: DOUBLE

Syntax

ROUND(expression [, rounding-unit])
**Arguments**

*expression*

specifies to be rounded any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*rounding-unit*

specifies a positive numeric expression that specifies the rounding unit.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

**Basic Concepts**

The ROUND function rounds the first argument to a value that is very close to a multiple of the second argument. The results might not be an exact multiple of the second argument.

**Differences between Binary and Decimal Arithmetic**

Computers use binary arithmetic with finite precision. If you work with numbers that do not have an exact binary representation, computers often produce results that differ slightly from the results that are produced with decimal arithmetic. For example, the decimal values 0.1 and 0.3 do not have exact binary representations. In decimal arithmetic, 3*0.1 is exactly equal to 0.3, but this equality is not true in binary arithmetic.

As the following example shows, if a is a float and b is a REAL, there is a difference between the two values.

data _null_;  
dcl float a diff;  
dcl real b;  
method run();  
  a=0.3;  
  b=3*0.1;  
  diff=a-b;  
  put a=;  
  put a=;  
  put diff=;  
end;  
enddata;  
run;

The following lines are written to the SAS log:

```
a=0.3
b=0.3
diff=-1.192092896618E-8
```

**Operating Environment Information**

The example above was executed in the Windows environment. If you use other operating environments, the results will be slightly different.
The Effects of Rounding
Rounding by definition finds an exact multiple of the rounding unit that is closest to the value to be rounded. For example, 0.33 rounded to the nearest tenth equals 3*0.1 or 0.3 in decimal arithmetic. In binary arithmetic, 0.33 rounded to the nearest tenth equals 3*0.1, and not 0.3, because 0.3 is not an exact multiple of one tenth in binary arithmetic.

The ROUND function returns the value that is based on decimal arithmetic, even though this value is sometimes not the exact, mathematically correct result. In the example

ROUND(0.33, 0.1)

ROUND returns 0.3 and not 3*0.1.

Expressing Binary Values
If the characters "0.3" appear as a constant in a DS2 program, the value is computed as 3/10. To be consistent with the standard informat, ROUND(0.33, 0.1) computes the result as 3/10, and the following statement produces the results that you would expect.

if round(x, 0.1) = 0.3 then
    ... more DS2 statements ...

However, if you use the variable Y instead of the constant 0.3, as the following statement shows, the results might be unexpected depending on how the variable Y is computed.

if round(x, 0.1) = y then
    ... more DS2 statements ...

If ROUND reads Y as the characters "0.3" using the standard informat, the result is the same as if a constant 0.3 appeared in the IF statement. If ROUND reads Y with a different informat, or if a program other than SAS reads Y, then there is no guarantee that the characters "0.3" would produce a value of exactly 3/10. Imprecision can also be caused by computation involving numbers that do not have exact binary representations, or by porting tables from one operating environment to another that has a different floating-point representation.

If you know that Y is a decimal number with one decimal place, but are not certain that Y has exactly the same value as would be produced by the standard informat, it is better to use the following statement:

if round(x, 0.1) = round(y, 0.1) then
    ... more DS2 statements ...

Testing for Approximate Equality
You should not use the ROUND function as a general method to test for approximate equality. Two numbers that differ only in the least significant bit can round to different values if one number rounds down and the other number rounds up. Testing for approximate equality depends on how the numbers have been computed. If both numbers are computed to high relative precision, you could test for approximate equality by using the ABS and the MAX functions.

Consider the following example shows.

if abs(x-y) <= 1e-12 * max( abs(x), abs(y) ) then
    ... more DS2 statements ...

Producing Expected Results
In general, ROUND(expression, rounding-unit) produces the result that you expect from decimal arithmetic if the result has no more than nine significant digits and any of the following conditions are true:

- The rounding unit is an integer.
The rounding unit is a power of 10 greater than or equal to 1e-15.  

The result that you expect from decimal arithmetic has no more than four decimal places.

For example:

```plaintext
data rounding;
  method run();
    d1 = round(1234.56789,100)     - 1200;
    d2 = round(1234.56789,10)      - 1230;
    d3 = round(1234.56789,1)       - 1235;
    d4 = round(1234.56789,.1)      - 1234.6;
    d5 = round(1234.56789,.01)     - 1234.57;
    d6 = round(1234.56789,.001)    - 1234.568;
    d7 = round(1234.56789,.0001)   - 1234.5679;
    d8 = round(1234.56789,.00001)  - 1234.56789;
    d9 = round(1234.56789,.1111)   - 1234.5432;
    /* d10 has too many decimal places in the value for */
    /* rounding-unit.                                   */
    d10 = round(1234.56789,.11111) - 1234.54321;
  end;
enddata;
run;
```

The following output shows the results.

**Output 7.12  Results of Rounding Based on the Value of the Rounding Unit**

<table>
<thead>
<tr>
<th>Obs</th>

</tr>
</tbody>
</table>

**Operating Environment Information**

The example above was executed in a z/OS environment. If you use other operating environments, the results will be slightly different.

**When the Rounding Unit Is the Reciprocal of an Integer**

When the rounding unit is the reciprocal of an integer, the ROUND function computes the result by dividing by the integer. Therefore, you can safely compare the result from ROUND with the ratio of two integers, but not with a multiple of the rounding unit.

Here is an example:

```plaintext
data rounding2;
  drop pi unit;
  method run();
    pi = arcos(-1);
    unit=1/7.;
    d1=round(pi,unit) - 22/7.;
    d2=round(pi, unit) - 22*unit;
  end;
```

---

1. If the rounding unit is less than one, ROUND treats it as a power of 10 if the reciprocal of the rounding unit differs from a power of 10 in at most the three or four least significant bits.

2. ROUND treats the rounding unit as a reciprocal of an integer if the reciprocal of the rounding unit differs from an integer in at most the three or four least significant bits.
enddata;
run;

The following output shows the results.

**Output 7.13  Results of Rounding by the Reciprocal of an Integer**

<table>
<thead>
<tr>
<th>Obs</th>
<th>d1</th>
<th>d2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1.3323E-15</td>
</tr>
</tbody>
</table>

*Operating Environment Information*

The example above was executed in a z/OS environment. If you use other operating environments, the results will be slightly different.

**Computing Results in Special Cases**

The ROUND function computes the result by multiplying an integer by the rounding unit when all of the following conditions are true:

- The rounding unit is not an integer.
- The rounding unit is not a power of 10.
- The rounding unit is not the reciprocal of an integer.
- The result that you expect from decimal arithmetic has no more than four decimal places.

For example:

```sas
data _null_;  
  method run();  
    difference=round(1234.56789,.11111) - 11111*.11111;  
    put difference=;  
  end;  
enddata;  
run;  
```

The following line is written to the SAS log:

```
difference=0
```

*Operating Environment Information*

The example above was executed in a z/OS environment. If you use other operating environments, the results might be slightly different.

**Computing Results When the Value Is Halfway between Multiples of the Rounding Unit**

When the value to be rounded is approximately halfway between two multiples of the rounding unit, the ROUND function rounds up the absolute value and restores the original sign.

For example:

```sas
data test;  
  method run ();  
    do i=8 to 17;  
```

enddata;
run;
value=0.5 - 10**(-i);
  round=round(value);
  output;
end;
do i=8 to 17;
  value=-0.5 + 10**(-i);
  round=round(value);
  output;
end;
enddata;
run;

The following output shows the results.
Output 7.14  Results of Rounding When Values Are Halfway between Multiples of the Rounding Unit

</tbody>
</table>

Operating Environment Information
The example above was executed in a z/OS environment. If you use other operating environments, the results might be slightly different.

The approximation is relative to the size of the value to be rounded, and is computed in a manner that is shown in the following example. This example code will not always produce results exactly equivalent to the ROUND function.

data testfile;
  method run();
    do i = 1 to 17;
      value = 0.5 - 10**(-i);
  end;
run;
\[ \text{epsilon} = \min(1e-6, \text{value} \times 1e-12); \]
\[ \text{temp} = \text{value} + 0.5 + \text{epsilon}; \]
\[ \text{fraction} = \text{modz}(	ext{temp}, 1); \]
\[ \text{round} = \text{temp} - \text{fraction}; \]
\[ \text{output}; \]
end;
end;
enddata;
run;

proc print data=testfile noobs;
  format value 19.16;
run;

**Comparisons**

The ROUND function is the same as the ROUNDE function except that when the first argument is halfway between the two nearest multiples of the second argument, ROUNDE returns an even multiple. ROUND returns the multiple with the larger absolute value.

The ROUNDZ function returns a multiple of the rounding unit without trying to make the result match the result that is computed with decimal arithmetic.

**Example**

The following example compares the results that are returned by the ROUND function with the results that are returned by the ROUNDE function. The output was generated from the UNIX operating environment.

```plaintext
data results;
  method run();
    do x=0 to 4 by .25;
      Rounde=rounde(x);
      Round=round(x);
      output;
    end;
  end;
enddata;
run;

proc print data=results noobs;
run;
```

The following output shows the results.

ROUND Function

Rounds the first argument to the nearest multiple of the second argument, and returns an even multiple when the first argument is halfway between the two nearest multiples.

**Category:** Truncation

**Returned data type:** DOUBLE

**Syntax**

```
ROUND(expression [, rounding-unit])
```

**Arguments**

**expression**

specifies any valid expression that evaluates to a numeric value and that is to be rounded.

Data type: DOUBLE

**rounding-unit**

is a positive, numeric expression that specifies the rounding unit.

Default: 1

Data type: DOUBLE

**Details**

The ROUND function rounds the first argument to the nearest multiple of the second argument.

**Comparisons**

The ROUND function is the same as the ROUND function except that when the first argument is halfway between the two nearest multiples of the second argument, ROUND returns an even multiple. ROUND returns the multiple with the larger absolute value.

**Example**

The following example compares the results that are returned by the ROUND function with the results that are returned by the ROUND function.

```
data results
   method run();
   do x=0 to 4 by .25;
      rounde=rounde(x);
```
The following output shows the results.

**Output 7.16  Results That Are Returned by the ROUNDE and ROUND Functions**

ROUNDZ Function

Rounds the first argument to the nearest multiple of the second argument, using zero fuzzing.

**Category:** Truncation  
**Returned data type:** DOUBLE

### Syntax

\[
\text{ROUNDZ} \left( \text{expression} \ [, \text{rounding-unit}] \right)
\]

### Arguments

- **expression**
  - Specifies any valid expression that evaluates to a numeric value.
  - **Data type:** DOUBLE  

- **rounding-unit**
  - Specifies any valid expression that evaluates to a numeric expression and that specifies the rounding unit.
  - **Default:** 1  
  - **Requirement:** Only positive values are valid.
  - **Data type:** DOUBLE  

### Details

The `ROUNDZ` function rounds the first argument to the nearest multiple of the second argument.

### Comparisons

The `ROUNDZ` function is the same as the `ROUND` function with these exceptions:

- `ROUNDZ` returns an even multiple when the first argument is exactly halfway between the two nearest multiples of the second argument. `ROUND` returns the multiple with the larger absolute value when the first argument is approximately halfway between the two nearest multiples.
• When the rounding unit is less than one and not the reciprocal of an integer, the result that is returned by ROUNDZ might not agree exactly with the result from decimal arithmetic. ROUNDZ does not fuzz the result. ROUND performs extra computations, called fuzzing, to try to make the result agree with decimal arithmetic.

Examples

Example 1: Comparing Results from the ROUNDZ and ROUND Functions

The following example compares the results that are returned by the ROUNDZ and the ROUND function.

```plaintext
data test;
  method run();
   do i=10 to 17;
     Value=2.5 - 10**(-i);
     Roundz=roundz(value);
     Round=round(value);
     output;
   end;
   do i=16 to 12 by -1;
     value=2.5 + 10**(-i);
     roundz=roundz(value);
     round=round(value);
     output;
   end;
end;
enddata;
run;

proc print data=test;
  format value 19.16;
quit;
```

The following output shows the results.
Example 2: Sample Output from the ROUNDZ Function

The following statements illustrate the ROUNDZ function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=223.456; b=roundz(a,1); c=put(b), 9.5;</td>
<td>223.00000</td>
</tr>
<tr>
<td>var2=223.456; x=roundz(var2,.01); put x 9.5;</td>
<td>223.46000</td>
</tr>
<tr>
<td>x=roundz(223.456,100); put x 9.5;</td>
<td>200.00000</td>
</tr>
<tr>
<td>x=roundz(223.456,.3); put x 9.5;</td>
<td>223.50000</td>
</tr>
</tbody>
</table>
SAVINGS Function

Returns the balance of a periodic savings by using variable interest rates.

**Category:** Financial

**Returned data type:** DOUBLE

**Syntax**

\[
\text{SAVINGS}(\text{base-date}, \text{initial-deposit-date}, \text{deposit-amount}, \text{deposit-number}, \text{deposit-interval}, \text{compounding-interval}, \text{date}, \text{rate}, \ldots [\text{date}, \text{rate}])
\]

**Arguments**

- **base-date**
  
  specifies the value that is returned is the balance of the savings at the base date.

  **Requirement**  
  *Base-date* is a SAS date.

  **Data type**  
  DOUBLE

- **initial-deposit-date**
  
  specifies the date of the first deposit. Subsequent deposits are at the beginning of subsequent deposit intervals.

  **Requirement**  
  *Initial-deposit-date* is a SAS date.

  **Data type**  
  DOUBLE

- **deposit-amount**
  
  specifies the value of each deposit. All deposits are assumed constant.

  **Data type**  
  DOUBLE

- **deposit-number**
  
  specifies the number of deposits.

  **Data type**  
  INTEGER

- **deposit-interval**
  
  specifies the frequency at which deposits are made.

  **Requirement**  
  *Deposit-interval* is a SAS interval.

  **Data type**  
  CHAR

See Also

Functions:

- “ROUND Function” on page 583
- “ROUNDE Function” on page 592
compounding-interval
specifies the compounding interval.

Requirement  Compounding-interval is a SAS interval.

Data type  CHAR

date
specifies the time at which rate takes effect. Each date is paired with a rate.

Requirement  Date is a SAS date.

Data type  DOUBLE

rate
specifies the interest rate as numeric percentage that starts on date. Each rate is
paired with a date.

Data type  DOUBLE

Details
The following details apply to the SAVINGS function:
• The values for rates must be between −99 and 120.
• Deposit-interval cannot be 'CONTINUOUS'.
• The list of date-rate pairs does not need to be in chronological order.
• When multiple rate changes occur on a single date, the SAVINGS function applies
  only the final rate that is listed for that date.
• Simple interest is applied for partial periods.
• There must be a valid date-rate pair whose date is at or prior to both the initial-
  deposit-date and the base-date.

Example
• If you deposit $300 monthly for two years into an account that compounds quarterly
  at an annual rate of 4%, the balance of the account after five years can be expressed
  as follows:

    data _null_;  
      method run();  
        bd=to_double(date'2005-01-01');  
        idd=to_double(date'2000-01-01');  
        d=to_double(date'2000-01-01');  
        amount_base1=savings(bd, idd, 300, 24, 'month', 'qtr', d, 4.00);  
        put amount_base1;  
      end;  
    enddata;  
    run;

    The following line is written to the SAS log.

    8458.79415896917

• If the interest rate increases by a quarter-point each year, then the balance of the
  account could be expressed as follows:
data _null_;  
method run();  
  bd= to_double(date'2005-01-01');  
  idd= to_double(date'2000-01-01');  
  d1= to_double(date'2000-01-01');  
  d2= to_double(date'2001-01-01');  
  d3= to_double(date'2002-01-01');  
  d4= to_double(date'2003-01-01');  
  d5= to_double(date'2004-01-01');  
  amount_base2 = savings(bd, idd, 300, 24, 'month', 'qtr', d1, 4.00, d2, 4.25, d3, 4.50, d4, 4.75, d5, 5.0);  
  put amount_base2;  
end;  
enddata;  
run;  

The following line is written to the SAS log.  
8623.0902486998  

• To determine the balance after one year of deposits, the following statement sets  
  amount_base3 to the desired balance:  

data _null_;  
method run();  
  bd= to_double(date'2001-01-01');  
  idd= to_double(date'2000-01-01');  
  d= to_double(date'2000-01-01');  
  amount_base3 = savings(bd, idd, 300, 24, 'month', 'qtr', d, 4);  
  put amount_base3;  
end;  
enddata;  
run;  

The following line is written to the SAS log.  
3978.69037121739  

The SAVINGS function ignores deposits after the base date, so the deposits after  
the reference date do not affect the value that is returned.

---

**SCAN Function**

Returns the *n*th word from a character expression.

**Category:** Character  
**Returned data type:** CHAR, NCHAR, VARCHAR

**Syntax**

```sas
SCAN(expression, n [ , delimiters])
```

**Arguments**

- **expression**  
specifies any valid expression that evaluates to a character string.
Data type  CHAR, NCHAR, VARCHAR

Note  The SCAN function supports UTF-8 only if the expression argument is a VARCHAR.

$n$

is a nonzero numeric expression that specifies the number of the word in the character expression that you want SCAN to select. The following rules apply:

• If $n$ is positive, SCAN counts words from left to right in the character string.
• If $n$ is negative, SCAN counts words from right to left in the character string.
• If $n$ is greater than the number of words in expression, SCAN returns a blank value.

$delimiters$

specifies any valid expression that evaluates to a character string and that SCAN uses as word separators in the expression.

Default

Requirement  If delimiter is a constant, enclose delimiter in single quotation marks.

Interaction  ASCII default delimiters are: blank ! $ % & ( ) * + , – . / ; < |. In environments without the ^ character, SCAN uses the ~ character instead.

Data type  CHAR, NCHAR, VARCHAR

Details

Leading delimiters before the first word in the expression do not effect SCAN. If there are two or more contiguous delimiters, SCAN treats them as one.

In DS2, if the SCAN function returns a value to a variable that has not yet been given a length, then that variable is given the length of the first argument. If you need the SCAN function to assign to a variable a value that is different from the length of the first argument, then you should use a DECLARE statement for that variable before the statement that uses the SCAN function.

Example

The following statements illustrate the SCAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr='ABC.DEF (X=y)' ';'</td>
<td></td>
</tr>
<tr>
<td>word=scan(expr,3);</td>
<td>X=Y</td>
</tr>
<tr>
<td>scan('ABC.DEF (X=Y)' ', -3);</td>
<td>ABC</td>
</tr>
</tbody>
</table>
SEC Function

Returns the secant.

Category: Trigonometric
Returned data type: DOUBLE

Syntax

SEC(expression)

Arguments

expression

specifies any valid expression that evaluates to a numeric value that expressed in radians.

Restriction

expression cannot be an odd multiple of PI/2.

See

Comparisons

The SEC function is related to the COS function:

sec(x) = 1/cos(x)

Example

The following statements illustrate the SEC function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=sec(0.5);</td>
<td>1.13949392732454</td>
</tr>
<tr>
<td>y=sec(0);</td>
<td>1</td>
</tr>
<tr>
<td>z=sec(3.14159/3);</td>
<td>1.99999693590391</td>
</tr>
</tbody>
</table>

See Also

Functions:

• “COS Function” on page 274
• “SIN Function” on page 607
• “TAN Function” on page 629
SECOND Function

Returns the second from a SAS time or datetime value.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Date and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

**Syntax**

SECOND(time | datetime)

**Arguments**

time

specifies any valid expression that represents a SAS time value.

Data type DOUBLE

datetime

specifies any valid expression that represents a SAS datetime value.

Data type DOUBLE

**Details**

The SECOND function produces a numeric value that represents a specific second of the minute. The result can be any number that is >= 0 and < 60.

**Example**

The following statements illustrate the SECOND function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=hms(3,19,24);</td>
<td>11964</td>
</tr>
<tr>
<td>b=second(a);</td>
<td>24</td>
</tr>
<tr>
<td>a=hms(6,25,65);</td>
<td>23165</td>
</tr>
<tr>
<td>s=second(a);</td>
<td>5</td>
</tr>
<tr>
<td>a=hms(3,19,60);</td>
<td>12000</td>
</tr>
<tr>
<td>b=second(a);</td>
<td>0</td>
</tr>
</tbody>
</table>

SHA256HEX Function

Returns the result of the message digest of a specified string and converts the string to hexadecimal representation.

Category: Character

Notes: The SHA256HEX function verifies the data integrity and authentication of a message. UTF-8 text is recommended for the SHA256HEX function arguments to ensure consistency across encodings.

Syntax

SHA256HEX('string', string_indicator);

Arguments

string
- specifies any valid expression that evaluates to a character string.

Data type: CHAR, NCHAR

string_indicator
- indicates whether the argument string is regular characters or hexadecimal representation characters.

0 indicates that the expression in the argument string is regular characters.

1 indicates that the expression in the argument string is hexadecimal representation characters.

Note: There must be an even number of hexadecimal representation characters, and they must all be between 0–9, a–f, A–F. Blanks in the hexadecimal representation string are ignored.

Details

The Basics
The SHA256HEX function converts a string, based on the SHA256 algorithm, to a 256-bit hash value. Then, the function converts the data to a hexadecimal representation format.

Using the SHA256HEX Function
You can use the SHA256HEX function to track changes in your data sets. The SHA256HEX function can generate a digest of a set of column values in a table record. This digest could be treated as the signature of the record and be used to track changes
that are made to the record. If the digest from the new record matches the existing digest of a table record, then the two records are the same. If the digest is different, then a column value in the record has changed. The new changed record could then be added to the table along with a new surrogate key because the record represents a change to an existing keyed value.

The SHA256HEX function can be useful when you are developing shell scripts or Perl programs for software installation, file comparison, and detection of file corruption and tampering.

**Comparisons**

The SHA256 function does not format its own output, so you must use the $BINARYw. or $HEXw. formats to view readable results. The SHA256HEX function formats its output, so you do not have to use the $BINARY or $HEX formats.

**Example: Generating Results with the SHA256HEX Function**

This example generates results that are returned by the SHA256HEX function.

```sas
data _null_;
  dcl char y z;
  method run();
    y=sha256hex('abc');
    z=sha256hex('access method');
    put y=;
    put z=;
  end;
enddata;
run;
```

For ASCII systems, the following lines are written to the SAS log.

```
y=BA7816BF0F01CPEA414140DE5DAE2223B00363A396177A9CB410FFG1F20015AD
z=F2758E91725621F59FFP0D15DE8824560ECD471EBB40A83B46D1259EB695915
```

For EBCDIC systems, the following lines are written to the SAS log.

```
y=B58EA6D31995A4D8CE092EB718DFA58B6CEF2288B41FAF1DC52FF3D68FA01
z=D7BE088DAF6B029BADDCC2DD01984867F0A3C342D60719DA7B478721E3E778F63
```

**See Also**

**Functions:**

- “SHA256HMACHEX Function” on page 604

**SHA256HMACHEX Function**

Returns the result of the message digest of a specified string by using the Hash-based Message Authentication (HMAC) algorithm.

**Category:** Character
Notes: The SHA256HMACHEX function verifies the data integrity and authentication of a message. See the following article for more information about the Hash-based message authentication code (HMAC). UTF-8 text is recommended for the SHA256HMACHEX function arguments to ensure consistency across encodings.

Syntax

SHA256HMACHEX('key', 'message' [string-indicator]);

Arguments

key
specifies any valid expression that evaluates to a character string.

Data type CHAR, NCHAR

message
specifies a secret key padded to the right with extra zeros to the input block size of the hash function.

Data type CHAR, NCHAR

string_indicator
indicates whether the key and message are provided in hexadecimal representation.

0 the arguments key and message are not represented in hexadecimal representation.
1 the argument message is represented in hexadecimal representation.
2 the argument key is represented in hexadecimal representation.
3 the arguments key and message are represented in hexadecimal representation.

Note: This argument is useful when the SHA256HMACHEX function is being called repeatedly and the result of a previous call is used as the key in a subsequent call. The following code demonstrates this functionality:

length digest $64;
digest = sha256hmachex('mykey', 'mymessage', 0);
digest = sha256hmachex(digest, 'my new message', 2);

Data type INTEGER

Details

The SHA256HMACHEX function converts a string, based on the SHA256 algorithm, to a 256-bit hash value.

See the following article for more information about the Hash-based message authentication code (HMAC).
Example: Generating Results with the SHA256HMACHEX Function

This example generates results that are returned by the SHA256HMACHEX function.

data _null_;  
    method run();  
    digest = SHA256HMACHEX('key',  
        'The quick brown fox jumps over the lazy dog', 0);  
    if digest=  
        upcase('f7bc83f430538424b13298e6aa6fb143ef4d59a14946175997479dbc2d1a3cd8')  
        then  
            put 'matched';  
        else  
            put 'not matched';  
    end;  
enddata;  
run;

matched

SIGN Function

Returns a number that indicates the sign of a numeric value expression.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Mathematical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

**Syntax**

SIGN(expression)

**Arguments**

expression

specifies any valid expression that evaluates to a numeric value.

**Details**

The SIGN function returns the following values:

-1  
    if expression < 0

0  
    if expression = 0

1  
    if expression > 0.

Example

The following statements illustrate the SIGN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=sign(-5);</td>
<td>-1</td>
</tr>
<tr>
<td>a=sign(5);</td>
<td>1</td>
</tr>
<tr>
<td>a=sign(0);</td>
<td>0</td>
</tr>
</tbody>
</table>

SIN Function

Returns the trigonometric sine.

- **Category:** Trigonometric
- **Returned data type:** DOUBLE

Syntax

SIN(expression)

**Arguments**

- expression specifies any valid expression that evaluates to a numeric value.
  - Data type: DOUBLE

Example

The following statements illustrate the SIN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=sin(25.6)</td>
<td>0.45044059427538</td>
</tr>
<tr>
<td>a=sin(5);</td>
<td>-0.95892427466313</td>
</tr>
</tbody>
</table>

SINH Function

Returns the hyperbolic sine.
Syntax

\[ \text{SINH}(\text{expression}) \]

Arguments

\[ \text{expression} \]

Specifies any valid expression that evaluates to a numeric value.

Data type  \( \text{DOUBLE} \)

See  “DS2 Expressions” in \( \text{SAS Viya: DS2 Programmer’s Guide} \)

Details

The SINH function returns the hyperbolic sine of the argument, which is given by the following equation.

\[ e^{\text{argument}} - e^{-\text{argument}} / 2 \]

Example

The following statements illustrate the SINH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>( a = \text{sinh}(0) );</td>
<td>0</td>
</tr>
<tr>
<td>( a = \text{sinh}(1) );</td>
<td>1.1752011936438</td>
</tr>
<tr>
<td>( a = \text{sinh}(-1.0) );</td>
<td>-1.1752011936438</td>
</tr>
</tbody>
</table>

SKEWNESS Function

Returns the skewness.

Syntax

\[ \text{SKEWNESS}(\text{expression-1, expression-2, expression-3 [, …expression-\text{n}]}) \]
Arguments

**expression**
specifies any valid expression that evaluates to a numeric value.

**Requirement**
At least three non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

**Data type**
DOUBLE

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

Details

If all non-null or nonmissing arguments have equal values, the skewness is mathematically undefined and the SKEWNESS function returns a null or missing value.

Example

The following statements illustrate the SKEWNESS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x1=skeuness(0,1,1);</td>
<td>-1.73205080756887</td>
</tr>
<tr>
<td>x2=skeuness(2,4,6,3,1);</td>
<td>0.59012865638436</td>
</tr>
<tr>
<td>x3=skeuness(2,0,0);</td>
<td>1.73205080756887</td>
</tr>
</tbody>
</table>

**SLEEP Function**

For a specified period of time, suspends the execution of a program that invokes this function.

**Category:** Special

**Returned data type:** DOUBLE

**Syntax**

SLEEP(*number-of-time-units*, *[time-unit]*)

**Arguments**

**number-of-time-units**
specifies any valid expression that evaluates to a numeric value and that specifies the number of units of time for which you want to suspend execution of a program.

**Range**

\( n \geq 0 \)

**Data type**
DOUBLE
**Time-unit**

specifies the unit of time, as a power of 10, which is applied to number-of-time-units. For example, 1 corresponds to a second, and .001 to a millisecond.

**Default**

1 in a Windows PC environment, .001 in other environments

**Data type**

DOUBLE

**Details**

The SLEEP function suspends the execution of a program that invokes this function for a period of time that you specify. The maximum sleep period for the SLEEP function is 46 days.

**Examples**

**Example 1: Suspending Execution for a Specified Period of Time**

The following example delays the execution for 20 seconds:

```sas
data payroll;
  ...DS2 statements...
  time_slept=sleep(20,1);
  ...more DS2 statements...
enddata;
```

**Example 2: Suspending Execution Based on a Calculation of Sleep Time**

The following example tells SAS to suspend the execution until June 15, 2011, at midnight. DS2 calculates the length of the suspension based on the target date and the date and time that the code begins to execute.

```sas
data budget;
  ...DS2 statements...
  sleeptime=dhms(mdy(06,15,2011),00,00,00)-datetime();
  time_calc=sleep(sleeptime,1);
  ...more DS2 statements...
enddata;
```

**SMALLEST Function**

Returns the kth smallest non-null or nonmissing value.

**Category:** Descriptive Statistics

**Returned data type:** DOUBLE

**Syntax**

`SMALLEST(k, expression [, ...expression])`
### Arguments

**k**

specifies any valid expression that evaluates to a numeric value to return.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**expression**

specifies any valid expression that evaluates to a numeric value to be processed.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

### Details

If `k` is null or missing, less than zero, or greater than the number of values, the result is a null or missing value.

### Comparisons

The SMALLEST function differs from the ORDINAL function in that SMALLEST ignores null and missing values, but ORDINAL counts null and missing values.

### Example

This example compares the values that are returned by the SMALLEST function with values that are returned by the ORDINAL function.

```hs
proc ds2
   conn="driver=base;
       catalog=mycatalog;
       schema=(name=mylib;primarypath='\my-primary-path')" nolibs;
 data comparison;
   dcl double smallest_num having label 'SMALLEST Function';
   dcl double ordinal_num having label 'ORDINAL Function';
   method run();
   do k = 1 to 4;
      smallest_num = smallest(k, 456, 789, .Q, 123);
      ordinal_num  = ordinal (k, 456, 789, .Q, 123);
      output;
   end;
 enddata;
 run;
quit;
proc print data=mylib.comparison label noobs;
   var k smallest_num ordinal_num;
   title 'Results From the SMALLEST and the ORDINAL Functions';
 run;
```
Output 7.18  Comparison of Values: The SMALLEST and the ORDINAL Functions

<table>
<thead>
<tr>
<th>Obs</th>
<th>K</th>
<th>SMALLEST Function</th>
<th>ORDINAL Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>123</td>
<td>Q</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>456</td>
<td>123</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>789</td>
<td>456</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>.</td>
<td>789</td>
</tr>
</tbody>
</table>

- “ORDINAL Function” on page 504
- “PCTL Function” on page 505

SQLEXEC Function

Executes a FedSQL statement to create, delete, or update a table or to insert rows into a table.

**Category:** Special

**Restriction:** This function is not supported in the CAS server.

**Syntax**

SQLEXEC('sql-text')

**Arguments**

*sql-text* is a valid FedSQL statement that inserts into, updates, creates, or deletes rows from a table.

**Requirement**

The FedSQL statement must be enclosed in single quotation marks (').

**Note**

The statement can be a string literal, a string value generated from an expression, or a string value that is stored in a variable.

**Details**

The following items apply to the SQLEXEC function:
Use the SQLEXEC function when a FedSQL statement is to be executed only once.
Allocate, prepare, execute, and free are performed at run time.
The SQLEXEC function does not support parameters.
The SQLEXEC function does not support the return of a result set. It cannot be used with a SELECT statement.
SQLEXEC is similar to the SQL EXECUTE IMMEDIATE statement or the JDBC Statement.executeUpdate (string) method.

An SQLSTMT package enables you to execute a FedSQL more than one time, to use parameters, and to access a result set. For more information, see “Using the SQLSTMT Package” in SAS Viya: DS2 Programmer’s Guide.

Example
Here is an example of using the SQLEXEC function:

```plaintext
tablename='testdata';
name='Jane Doe';
age=25;

s='create table ' || tablename || '(name char(50), age int)';
sqlexec(s);

s='insert into ' || tablename || ' values(''' || name || ''',' || age ||')';
sqlexec(s);
```

See Also

SQRT Function
Returns the square root of a value.

<table>
<thead>
<tr>
<th>Category</th>
<th>Mathematical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax
```
SQRT(expression)
```

Arguments

**expression**
specifies any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See
Example

The following statements illustrate the SQRT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=sqrt(36);</td>
<td>6</td>
</tr>
<tr>
<td>a=sqrt(25);</td>
<td>5</td>
</tr>
<tr>
<td>a=sqrt(4.4);</td>
<td>2.097617663403</td>
</tr>
</tbody>
</table>

STD Function

Returns the standard deviation.

Categories: Aggregate
Descriptive Statistics

Returned data type: DOUBLE

Syntax

STD(expression-1, expression-2 [, ...expression-n])

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Requirement
At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

Data type
DOUBLE

See

Example

The following statements illustrate the STD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=std(2,6);</td>
<td>2.82842712474619</td>
</tr>
<tr>
<td>a=std(2,6,.)</td>
<td>2.82842712474619</td>
</tr>
<tr>
<td>a=std(2,4,6,3,1);</td>
<td>1.92353840616713</td>
</tr>
</tbody>
</table>
STDERR Function

Returns the standard error of the mean.

Category: Descriptive Statistics
Returned data type: DOUBLE

Syntax

STDERR(expression-1, expression-2 [, ...expression-n])

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Requirement
At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

Data type
DOUBLE

Example

The following examples illustrate the STDERR function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=stderr(2,6);</td>
<td>2</td>
</tr>
<tr>
<td>a=stderr(2,6,..);</td>
<td>2</td>
</tr>
<tr>
<td>a=stderr(2,4,6,3,1);</td>
<td>0.86023252670426</td>
</tr>
</tbody>
</table>

STREAMINIT Function

Specifies a seed value to use for subsequent pseudo-random number generation by the RAND function.

Category: Random Number
Returned data type: DOUBLE

Syntax

STREAMINIT(seed)
Arguments

\textit{seed} is an integer seed value.

<table>
<thead>
<tr>
<th>Range</th>
<th>seed $&lt; 2^{31} – 1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

Tip If you specify a nonpositive seed, then the STREAMINIT function is ignored. Any subsequent pseudo-random number generation seeds itself from the system clock.

Details

If you want to create reproducible streams of pseudo-random numbers, then specify STREAMINIT before any calls to the RAND pseudo-random number function. For DS2, the STREAMINIT function must be called before the RAND function. Each DS2 program honors one STREAMINIT seed. The prevailing seed value is the one that is specified prior to the first RAND function call. "Seed Values" in “Using Random-Number Functions and CALL Routines” in \textit{SAS Viya Functions and CALL Routines: Reference}.

Example

The following example shows how to specify a seed value with the STREAMINIT function to create a reproducible stream of pseudo-random numbers with the RAND function.

```sas
data random (overwrite=yes);
dcl double i x1;
method run();
  streaminit(123);
  do i=1 to 10;
    x1=rand('cauchy');
    output;
  end;
end;
enddata;
run;

proc print data=random;
  id i;
run;
quit;
```
See Also

Functions:
- “RAND Function” on page 560

STRIP Function

Returns a character string with all leading and trailing blanks removed.

**Category:** Character
**Returned data type:** NCHAR

**Syntax**

`STRIP(expression)`

**Arguments**

*expression*

specifies any valid expression that evaluates to a character string.

*Data type* | NCHAR
---|---

**See**

**Details**

The STRIP function returns the argument with all leading and trailing blanks removed. If the argument is blank, STRIP returns a string with a length of zero.
If the value that is trimmed is shorter than the length of the receiving variable, SAS pads the value with new trailing blanks.

**Note:** The STRIP function is useful for concatenation because the concatenation operator does not remove trailing blanks.

**Comparisons**

The following list compares the STRIP function with the TRIM function:

- For blank character strings, the STRIP and TRIM functions both return a string with a length of zero.
- For strings that lack leading blanks, the STRIP and TRIM functions return the same value.

**Example**

The following example shows the results of using the STRIP function to delete leading and trailing blanks.

```sas
data mycatalog.lengthn;
  dcl char(8) string;
  method init();
    string='abcd    '; output;
    string='  abcd  '; output;
    string='    abcd'; output;
    string='abcdefgh'; output;
    string='x y x'; output
  end;
enddata;
run;

data mycatalog.stripstring;
  dcl varchar(10) original;
  dcl varchar(10) stripped;
  method run();
    set lengthn;
    original = '*'||string||'*';
    stripped = '*'||strip(string)||'*';
  end;
enddata;
run;
```

**Output 7.19  Results from the STRIP Function**

<table>
<thead>
<tr>
<th>Obs</th>
<th>ORIGINAL</th>
<th>STRIPPED</th>
<th>STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><em>abcd</em></td>
<td><em>abcd</em></td>
<td>abcd</td>
</tr>
<tr>
<td>2</td>
<td><em>abcd</em></td>
<td><em>abcd</em></td>
<td>abcd</td>
</tr>
<tr>
<td>3</td>
<td><em>abcd</em></td>
<td><em>abcd</em></td>
<td>abcd</td>
</tr>
<tr>
<td>4</td>
<td><em>abcdefg</em></td>
<td><em>abcdefg</em></td>
<td>abcdefg</td>
</tr>
<tr>
<td>5</td>
<td><em>y x y</em></td>
<td><em>y x</em></td>
<td>y x</td>
</tr>
</tbody>
</table>

---

**SUBSTR (right of =) Function**

Returns a substring, allowing a result with a length of zero.

**Category:** Character

**Returned data type:** VARCHAR, NVARCHAR

**Syntax**

\[ \text{SUBSTR(character-expression, position-expression [ , length-expression])} \]

**Arguments**

**character-expression**

specifies any valid expression that evaluates to a character string.

- **Data type:** CHAR, NCHAR
- **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**position-expression**

specifies any valid expression that evaluates to an integer and that specifies the position of the first character in the substring.

- **Requirement:** \( \text{position-expression} \) must be greater than or equal to zero.
- **Data type:** INTEGER
- **See:** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**length-expression**

specifies any valid expression that evaluates to an integer and that specifies the length of the substring. If you do not specify \( \text{length-expression} \), the SUBSTR (right of =) function returns the substring that extends from the position that you specify to the end of the string.

- **Data type:** INTEGER
Details

The following information applies to the SUBSTR function:

- The SUBSTR (right of =) function returns a missing (SAS mode) or null value (ANSI mode) if `character-expression` is a missing or null value.
- The SUBSTR (right of =) function returns a missing (SAS mode) or empty string (ANSI mode) if either of the following is true: `position-expression` is a missing or null value, or `position-expression` is less than 1 or greater than the length of `character-expression`.
- If the value for `length-expression` is not specified, the SUBSTR (right of =) function returns `length-expression`.
- The SUBSTR (right of =) function returns the substring from `position-expression` to the end of the `character-expression` if `length-expression` meets any of the following conditions:
  - is not specified
  - is less than zero
  - is a null value
  - is greater than the length of the substring from `position-expression` to the end of the `character-expression`

Example

The following statements illustrate the SUBSTR (right of =) function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a='chsh234960b3'; substr(a,5);</td>
<td>234960b3</td>
</tr>
<tr>
<td>a='chsh234960b3'; substr(a,5,6);</td>
<td>234960</td>
</tr>
<tr>
<td>a='chsh234960b3'; substr(a,5,15);</td>
<td>234960b3</td>
</tr>
<tr>
<td>a='chsh234960b3'; substr(a,5,-5);</td>
<td>234960b3</td>
</tr>
</tbody>
</table>

Functions:
- “SUBSTR (left of =) Function” on page 621
- “SUBSTRN Function” on page 623
**SUBSTR (left of =) Function**

Replaces character value contents.

**Category:** Character  
**Returned data type:** VARCHAR, NVARCHAR

---

**Syntax**

SUBSTR `character-expression, position-expression [, length-expression]) = characters-to-replace`

**Arguments**

*character-expression*

specifies any valid expression that evaluates to a character string.

**Data type** CHAR, NCHAR

**position-expression**

specifies any valid expression that evaluates to an integer and that specifies the position of the first character in the substring.

**Requirement** `position-expression` must be greater than or equal to zero.

**Data type** INTEGER

**length-expression**

specifies any valid expression that evaluates to an integer and that specifies the length of the substring that is replaced. If you do not specify `length-expression`, the SUBSTR (left of =) function returns the substring that extends from the position that you specify to the end of the string.

**Restriction** `length-expression` cannot be larger than the length of the expression that remains in `character-expression` after `position-expression`.

**Data type** INTEGER

**Tip** If you omit `length-expression` SAS uses all of the characters on the right side of the assignment statement to replace the values of `character-expression`.

**See** “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

---

**Details**

The following information applies to the SUBSTR (left of =) function:
The SUBSTR (left of =) function returns the characters-to-replace if character-expression is a missing or null value.

The SUBSTR (left of =) function returns character-expression if either of the following is true:

• position-expression is a missing (SAS mode) or null value (ANSI mode)
• position-expression is less than 1 or greater than the length of character-expression

If the value for length-expression is not specified, the SUBSTR (left of =) function returns characters-to-replace.

The SUBSTR (left of =) function returns the following values depending on the length-expression:

<table>
<thead>
<tr>
<th>length-expression is not specified</th>
<th>characters-to-replace is returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>length-expression is less than zero</td>
<td>character-expression is returned</td>
</tr>
<tr>
<td>length-expression is a null value</td>
<td>character-expression is returned</td>
</tr>
<tr>
<td>length-expression is greater than the length of the substring from position-expression to the end of character-expression</td>
<td>characters-to-replace is returned</td>
</tr>
</tbody>
</table>

**Example**

The following statements illustrate the SUBSTR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>mystring='kidnap'; substr(mystring, 1, 3)='cat'; put mystring=;</td>
<td>catnap</td>
</tr>
<tr>
<td>mystring='.A'; substr(mystring, 1)='cat'; put mystring=;</td>
<td>cat</td>
</tr>
<tr>
<td>mystring='kidnap'; substr(mystring,.)=''cat''; put mystring=;</td>
<td>kidnap</td>
</tr>
</tbody>
</table>

**Functions:**

• “SUBSTR (right of =) Function” on page 619
• “SUBSTRN Function” on page 623
SUBSTRN Function

Returns a substring, allowing a result with a length of zero.

<table>
<thead>
<tr>
<th>Category</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type</td>
<td>VARCHAR, NVARCHAR</td>
</tr>
</tbody>
</table>

**Syntax**

SUBSTRN(expression, position-expression[, length-expression])

**Arguments**

**expression**

specifies any valid expression that evaluates to a character string or numeric value.

If expression is numeric, then it is converted to a character value that uses the BEST32 format. Leading and trailing blanks are removed, and no message is sent to the SAS log.

**Data type** CHAR, NCHAR, DOUBLE

**position-expression**

specifies any valid expression that evaluates to an integer and that specifies the position of the first character in the substring.

**Data type** INTEGER

**length-expression**

specifies any valid expression that evaluates to an integer and that specifies the length of the substring. If you do not specify length-expression, the SUBSTRN function returns the substring that extends from the position that you specify to the end of the string.

**Data type** INTEGER

**Details**

**The Basics**

The following information applies to the SUBSTRN function:

- The SUBSTRN function returns a string with a length of zero if either position-expression or length-expression has a missing or null value, or if position-expression is a non-positive value.
- If the value for length-expression is non-positive, the SUBSTRN function ignores length-expression.
• If the length that you specify extends beyond the end of the string, the result is truncated at the end, so that the last character of the result is the last character of the string.

Comparisons
The following table lists comparisons between the SUBSTRN and the SUBSTR functions:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Function</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>the value of position-expression is nonpositive</td>
<td>SUBSTRN</td>
<td>returns a result beginning at the first character of the string.</td>
</tr>
<tr>
<td>the value of position-expression is nonpositive</td>
<td>SUBSTR</td>
<td>• writes a note to the log stating that the second argument is invalid.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• sets <em>ERROR</em> =1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• returns the substring that extends from the position that you specified to the end of the string.</td>
</tr>
<tr>
<td>the value of length-expression is nonpositive</td>
<td>SUBSTRN</td>
<td>returns a result with a length of zero.</td>
</tr>
<tr>
<td>the value of length-expression is nonpositive</td>
<td>SUBSTR</td>
<td>• writes a note to the log stating that the third argument is invalid.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• sets <em>ERROR</em> =1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• returns the substring that extends from the position that you specified to the end of the string.</td>
</tr>
<tr>
<td>the substring that you specify extends past the end of the string</td>
<td>SUBSTRN</td>
<td>truncates the result.</td>
</tr>
<tr>
<td>the substring that you specify extends past the end of the string</td>
<td>SUBSTR</td>
<td>• writes a note to the log stating that the third argument is invalid.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• sets <em>ERROR</em> =1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• returns the substring that extends from the position that you specified to the end of the string.</td>
</tr>
</tbody>
</table>

Examples

Example 1: Manipulating Strings with the SUBSTRN Function
The following example shows how to manipulate strings with the SUBSTRN function.

```
proc ds2;
data test;
  dcl char(6) string result;
dcl double position length;
```
retain string 'abcd';
drop string;
method run();
  do position=-1 to 6;
    do length=max(-1,-position) to 7-position;
      result=substrn(string, position, length);
      output;
    end;
  end;
end;
enddata;
enddata;
run;
quit;

proc print data=test;
run;
**Example 2: Comparison between the SUBSTR and SUBSTRN Functions**

The following example compares the results of using the SUBSTR function and the SUBSTRN function when the first argument is numeric.

```sas
data _null_;  
dcl char substr_result substrn_result;  
method run();  
  substr_result='*'|| substr('1234.5678',2,6)||'*';  
  put substr_result=;  
  substrn_result='*'|| substrn('1234.5678',2,6)||'*';  
  put substrn_result=;  
end;
```

<table>
<thead>
<tr>

</tbody>
</table>
SUM Function

Returns the sum of the non-null or nonmissing arguments.

Category: Descriptive Statistics
Returned data type: BIGINT, DECIMAL, DOUBLE, NUMERIC

Syntax

SUM(expression-1, expression-2 [, … expression-n])

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Requirement

At least two arguments are required.

Data type

BIGINT, DECIMAL, DOUBLE, NUMERIC

See

Details

Null and missing values are ignored and not included in the computation. If all of the arguments have missing values, the result is a missing value. If all the arguments have a null value, the result is a null value.

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.

Example

The following statements illustrate the SUM function.
### SUMABS Function

Returns the sum of the absolute values of the nonmissing arguments.

**Category:** Descriptive Statistics  
**Returned data type:** DOUBLE

#### Syntax

\[
\text{SUMABS}(\text{value}[\ldots\text{value}])
\]

#### Arguments

**value**  
specifies any valid expression that evaluates to a numeric value.

**Data type**  
DOUBLE

#### Details

If all arguments have null or missing values, then the result is a null or missing value. Otherwise, the result is the sum of the absolute values of the nonmissing values.

#### Examples

**Example 1: Calculating the Sum of Absolute Values**

The following example returns the sum of the absolute values of the nonmissing arguments.

```sas
data _null_;  
method run();  
x=sumabs(1,.,-2,0,3,.q,-4);  
put x=;  
end;  
enddata;  
run;
```

SAS writes the following results to the log:

\[
x=10
\]
Example 2: Calculating the Sum of Absolute Values When You Use a Variable List

The following example uses a variable list and returns the sum of the absolute value of the nonmissing arguments.

```sas
data _null_;  
  method run();  
  x1 = 1;  
  x2 = 3;  
  x3 = 4;  
  x4 = 3;  
  x5 = 1;  
  x = sumabs(x1, x2, x3, x4, x5);  
  put x=;  
end;  
enddata;  
run;
```

SAS writes the following results to the log:

```
x=12
```

---

**TAN Function**

Returns the tangent.

**Category:** Trigonometric  
**Returned data type:** DOUBLE

**Syntax**

`TAN(expression)`

**Arguments**

`expression`  
specifies any valid expression that evaluates to a numeric value in radians.

**Restriction**  
`expression` cannot be an odd multiple of π/2

**Data type**  
DOUBLE

**See**  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Example**

The following statements illustrate the TAN function:
<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=tan(0.5);</td>
<td>0.54630248984379</td>
</tr>
<tr>
<td>a=tan(0);</td>
<td>0</td>
</tr>
<tr>
<td>a=tan(3.14159/3);</td>
<td>1.73204726945457</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- “TANH Function” on page 630

---

**TANH Function**

Returns the hyperbolic tangent.

**Category:** Trigonometric

**Restriction:** This function is not supported in the CAS server.

**Returned data type:** DOUBLE

**Syntax**

\[ \text{TANH}(\text{expression}) \]

**Arguments**

*expression*

specifies any valid expression that evaluates to a numeric value.

**Restriction** *expression* cannot be an odd multiple of \( \pi/2 \)

**Data type** DOUBLE

**See** “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The TANH function returns the hyperbolic tangent of the argument, which is given by the following equation.

\[
\frac{e^{\text{argument}} - e^{-\text{argument}}}{e^{\text{argument}} + e^{-\text{argument}}}
\]

**Example**

The following statements illustrate the TANH function.
\begin{tabular}{|l|l|}
\hline
\textbf{Statements} & \textbf{Results} \\
\hline
a=tanh(0); & 0 \\
\hline
a=tanh(0.5); & 0.46211715726 \\
\hline
a=tanh(-0.5); & -0.46211715726 \\
\hline
\end{tabular}

\end{itemize}
TIMEPART Function

Extracts a time value from a SAS datetime value.

**Category:** Date and Time

**Returned data type:** DOUBLE

**Syntax**

```
TIMEPART(datetime)
```

**Arguments**

`datetime`

specifies any valid expression that represents a SAS datetime value.

**Data type** DOUBLE

**Example**

The following statements illustrate the TIMEPART function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dttm=datetime();</code></td>
<td><code>1450175146.88599</code></td>
</tr>
<tr>
<td><code>tm=put(timepart(dttm),time.);</code></td>
<td><code>10:25:47</code></td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**

- “DATEPART Function” on page 294

TIMEVALUE Function

Returns the equivalent of a reference amount at a base date by using variable interest rates.

**Category:** Financial

**Returned data type:** DOUBLE
Syntax

\texttt{TIMEVALUE(base-date, reference-date, reference-amount, compounding-interval, date, rate [...date, rate])}

Arguments

\texttt{base-date}

specifies the time value of the \textit{reference-amount} at the \textit{base-date}.

\begin{itemize}
  \item \textbf{Requirement} \textit{Base-date} is a SAS date.
  \item \textbf{Data type} DOUBLE
\end{itemize}

\texttt{reference-date}

specifies the date of \textit{reference-amount}.

\begin{itemize}
  \item \textbf{Requirement} \textit{Reference-date} is a SAS date.
  \item \textbf{Data type} DOUBLE
\end{itemize}

\texttt{reference-amount}

specifies the amount at the \textit{reference-date}.

\begin{itemize}
  \item \textbf{Data type} DOUBLE
\end{itemize}

\texttt{compounding-interval}

specifies the compounding interval.

\begin{itemize}
  \item \textbf{Requirement} \textit{Compounding-interval} is a SAS interval.
  \item \textbf{Data type} CHAR
\end{itemize}

\texttt{date}

specifies the time at which \textit{rate} takes effect. Each date is paired with a rate.

\begin{itemize}
  \item \textbf{Requirement} \textit{Date} is a SAS date.
  \item \textbf{Data type} DOUBLE
\end{itemize}

\texttt{rate}

specifies the interest rate as numeric percentage that starts on \textit{date}. Each rate is paired with a date.

\begin{itemize}
  \item \textbf{Data type} DOUBLE
\end{itemize}

Details

The following details apply to the \texttt{TIMEVALUE} function:

\begin{itemize}
  \item The values for rates must be between –99 and 120.
  \item The list of date-rate pairs does not need to be sorted by date.
  \item When multiple rate changes occur on a single date, the \texttt{TIMEVALUE} function applies only the final rate that is listed for that date.
  \item Simple interest is applied for partial periods.
\end{itemize}
• There must be a valid date-rate pair whose date is at or prior to both the reference-date and the base-date.

Example

• You can express the accumulated value of an investment of $1,000 at a nominal interest rate of 10% compounded monthly for one year as the following:

```sas
data _null_; method run();
   bd= to_double(date'2001-01-01');
   rd= to_double(date'2000-01-01');
   d= to_double(date'2000-01-01');
   amount_base1 = timevalue(bd, rd, 1000, 'month', d, 10);
   put amount_base1;
end;
enddata;
run;
```

• If the interest rate jumps to 20% halfway through the year, the resulting calculation would be as follows:

```sas
data _null_; method run();
   bd= to_double(date'2001-01-01');
   rd= to_double(date'2000-01-01');
   d1= to_double(date'2000-01-01');
   d2= to_double(date'2000-07-01');
   amount_base2 = timevalue(bd, rd, 1000, 'month', d1, 10, d2, 20);
   put amount_base2;
end;
enddata;
run;
```

• The date-rate pairs do not need to be sorted by date. This flexibility allows amount_base2 and amount_base3 to assume the same value:

```sas
data _null_; method run();
   bd= to_double(date'2001-01-01');
   rd= to_double(date'2000-01-01');
   d1= to_double(date'2000-07-01');
   d2= to_double(date'2000-07-01');
   amount_base3 = timevalue(bd, rd, 1000, 'month', d1, 20, d2, 10);
   put amount_base3;
end;
enddata;
run;
```

TINV Function

Returns a quantile from the t distribution.

**Category:** Quantile  
**Returned data type:** DOUBLE
Syntax

\[ \text{TINV}(p, df[, nc]) \]

Arguments

\( p \)

specifies any valid expression that evaluates to a numeric probability.

Range \( 0 < p < 1 \)

Data type DOUBLE

\( df \)

specifies any valid expression that evaluates to a numeric degrees of freedom parameter.

Range \( df > 0 \)

Data type DOUBLE

\( nc \)

specifies any valid expression that evaluates to a numeric noncentrality parameter.

Data type DOUBLE

Details

The TINV function returns the \( p \)th quantile from the Student’s \( t \) distribution with degrees of freedom \( df \) and a noncentrality parameter \( nc \). The probability that an observation from a \( t \) distribution is less than or equal to the returned quantile is \( p \).

TINV accepts a noninteger degree of freedom parameter \( df \). If the optional parameter \( nc \) is not specified or is 0, the quantile from the central \( t \) distribution is returned.

\textbf{CAUTION:}

\textit{For large values of nc, the algorithm can fail.} In that case, a missing value is returned.

Comparisons

TINV is the inverse of the PROBT function.

Example
The following statements illustrate the TINV function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=tinv(.95, 2);</td>
<td>2.91998558035372</td>
</tr>
<tr>
<td>x=tinv(.95, 2.5, 3);</td>
<td>11.033836251942</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “PROBT Function” on page 540

**TO_DATE Function**

Returns a DATE value from a DOUBLE value that specifies a SAS date value.

**Category:** Date and Time

**Returned data type:** DATE

**Syntax**

TO_DATE(date)

**Arguments**

*date*

specifies any valid expression that represents a SAS date value.

**Data type** DOUBLE

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

A DOUBLE value that specifies a SAS date value represents the number of days between January 1, 1960, and a specified date. SAS can perform calculations on dates ranging from A.D. 1582 to A.D. 19,900. Dates before January 1, 1960, are negative numbers; dates after January 1, 1960, are positive numbers.

- SAS date values account for all leap year days, including the leap year day in the year 2000.
- SAS date values can reliably tell you what day of the week a particular day fell on as far back as September 1752, when the calendar was adjusted by dropping several days. SAS day-of-the-week and length-of-time calculations are accurate in the future to A.D. 19,900.
Example

The following example converts a DOUBLE value that specifies a SAS date value, to a DATE value.

```sas
/* SAS date to date */
data _null_
   dcl date da;
   dcl double d;
   method init();
   d = 19358;
   da = to_date(d);
   put d=YYMMDD10. da=;
   end;
enddata;
run;
```

SAS writes the following output to the log:

```
d=2012-12-31 da=2012-12-31
```

See Also

Functions:

- “TO_DOUBLE Function” on page 637
- “TO_TIME Function” on page 640
- “TO_TIMESTAMP Function” on page 641

TO_DOUBLE Function

Returns a DOUBLE value that specifies a SAS date, time, or datetime value, from a DATE, TIME, or TIMESTAMP value.

**Category:** Date and Time  
**Returned data type:** DOUBLE

**Syntax**

```
TO_DOUBLE (date | time | timestamp)
```

**Arguments**

- `date` is a date constant, variable, or expression.
- `time` is a time constant, variable, or expression.
- `timestamp` is a timestamp constant, variable, or expression.
Details

The following list describes the values that can be returned by the TO_DOUBLE function:

- A SAS date value represents the number of days between January 1, 1960, and a specified date. SAS can perform calculations on dates ranging from A.D. 1582 to A.D. 19,900. Dates before January 1, 1960, are negative numbers; dates after January 1, 1960, are positive numbers.
- SAS date values account for all leap year days, including the leap year day in the year 2000.
- SAS date values can reliably tell you what day of the week a particular day fell on as far back as September 1752, when the calendar was adjusted by dropping several days. SAS day-of-the-week and length-of-time calculations are accurate in the future to A.D. 19,900.
- A SAS time value represents the number of seconds since midnight of the current day. SAS time values are between 0 and 86400.
- A timestamp is a record of the date and time at which a certain event occurred.
- A SAS datetime value represents the number of seconds between January 1, 1960, and an hour/minute/second within a specified date.

Examples

Example 1: Converting a TIMESTAMP Value to a DOUBLE Value

The following example converts a TIMESTAMP value to a DOUBLE value that specifies a SAS datetime value.

```sas
/* Timestamp to SAS datetime */
data _null_;  
dcl timestamp ts;  
dcl double d;  
method init();  
  ts = timestamp '2012-10-19 16:51:36.0625';  
  d = to_double(ts);  
  put d=DATETIME28.9 ts=;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
```

Example 2: Converting a Date Value to a SAS Date Value

The following example converts a DATE value to a DOUBLE value that specifies a SAS date value:

```sas
/* Date to SAS date */
data _null_;  
dcl date da;  
dcl double d;  
method init();  
  da = date '2012-10-19';
```
Example 3: Converting a Time Value to a SAS Time Value
The following example converts a TIME value to a SAS time value:

```sas
/* Time to SAS time */
data _null_;  
dcl time t;  
dcl double d;  
method init();  
t = time '16:51:36.0625';  
d = to_double(t);  
put d=TIME18.9 t=;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
d=16:51:36.062500000 t=16:51:36.062500000
```

Example 4: Converting a NULL Timestamp to a SAS Datetime Value
The following example converts a NULL TIMESTAMP to a SAS datetime value:

```sas
/* NULL timestamp to SAS datetime */
data _null_;  
dcl timestamp ts;  
dcl double d;  
method init();  
ts = null;  
d = to_double(ts);  
put d=DATETIME28.9 ts=;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
d=                           . ts=
```

See Also

Functions:
- “TO_DATE Function” on page 636
- “TO_TIME Function” on page 640
- “TO_TIMESTAMP Function” on page 641
**TO_TIME Function**

Returns a TIME value from a DOUBLE value that specifies a SAS time value.

**Category:** Date and Time  
**Returned data type:** TIME

**Syntax**

```
TO_TIME(date)
```

**Arguments**

`date`

specifies any valid expression that represents a SAS time value.

**Data type** DOUBLE

**See**  

**Details**

A SAS time value represents the number of seconds since midnight of the current day. SAS time values are between 0 and 86400.

**Example**

The following program converts a SAS time value to a formatted time value.

```
/* SAS time to time */
data _null_;  
dcl time t;  
dcl double d;  
method init();  
    d = 45911.68;  
    t = to_time(d);  
    put d=TIME18.9 t=;  
end;  
enddata;  
run;
```

SAS writes the following output to the log:

```
d=12:45:11.680000000  t=12:45:11.680000000
```

**See Also**

**Functions:**

- “TO_DATE Function” on page 636
- “TO_DOUBLE Function” on page 637
TO_TIMESTAMP Function

Returns a TIMESTAMP value from a DOUBLE value that specifies a SAS time value.

Category: Date and Time
Returned data type: TIMESTAMP

Syntax

TO_TIMESTAMP(date)

Arguments

date
specifies any valid expression that represents a SAS datetime value.
Data type: DOUBLE

Details

A SAS datetime value is a DOUBLE value that represents the number of seconds between January 1, 1960, and an hour/minute/second within a specified date.

Examples

Example 1: Converting a SAS Datetime Value to a Timestamp Value
The following example converts a SAS datetime value to a timestamp value.

/* SAS datetime to timestamp */
data _null_
dcl timestamp ts;
dcl double d;
method init();
d = 1614773470.3;
ts = to_timestamp(d);
put d=DATETIME28.9 ts=;
end;
enddata;
run;

SAS writes the following output to the log:

Example 2: Converting a SAS Datetime Value That Is Missing
The following example shows how SAS handles the conversion of a missing SAS datetime value.
/* Missing SAS datetime to timestamp */
data _null_
  dcl timestamp ts;
  dcl double d;
  method init();
    d = .;
    ts = to_timestamp(d);
    put d=DATETIME28.9 ts=;
  end;
enddata;
run;

SAS writes the following output to the log:

d=                           . ts=

• “TO_DATE Function” on page 636
• “TO_DOUBLE Function” on page 637
• “TO_TIME Function” on page 640

TODAY Function

Returns the current date as a numeric SAS date value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

TODAY()

Details

The TODAY function does not take any arguments. It produces the current date in the form of a SAS date value, which is the number of days since January 1, 1960. To display a meaningful date, you must apply a date format to the output value.

For more information about how DS2 handles dates, see “Dates and Times in DS2” in SAS Viya: DS2 Programmer’s Guide.

Example

The following statement illustrates the TODAY function:
TRANSLATE Function

Replaces specific characters in a character expression.

**Category:** Character

**Returned data type:** NCHAR

**Syntax**

TRANSLATE(expression, to-characters, from-characters)

**Arguments**

*expression*

specifies any valid expression that evaluates to a character string. *expression* contains the original character value.

Data type: CHAR

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*to-characters*

specifies the characters that you want TRANSLATE to use as substitutes.

Data type: NCHAR

*from-characters*

specifies the characters that you want TRANSLATE to replace.

Data type: NCHAR

**Details**

Values of *to-characters* and *from-characters* correspond on a character-by-character basis; TRANSLATE changes the first character in *from-characters* to the first character in *to-characters*, and so on. If *to-characters* has fewer characters than *from-characters*, TRANSLATE changes the extra *from-characters* characters to blanks. If *to-characters* has more characters than *from-characters*, TRANSLATE ignores the extra *to-characters*.

**Comparisons**

The TRANWRD function differs from the TRANSTRN function because TRANSTRN allows the replacement string to have a length of zero. TRANWRD uses a single blank instead when the replacement string has a length of zero.
The `TRANSLATE` function converts every occurrence of a user-supplied character to another character. `TRANSLATE` can scan for more than one character in a single call. In doing this scan, however, `TRANSLATE` searches for every occurrence of any of the individual characters within a string. That is, if any letter (or character) in the target string is found in the source string, it is replaced with the corresponding letter (or character) in the replacement string.

The `TRANWRD` function differs from `TRANSLATE` in that it scans for words (or patterns of characters) and replaces those words with a second word (or pattern of characters).

**Example**

The following statement illustrates the `TRANSLATE` function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>`a=translate('XYZW','AB','VW');`</td>
<td>XYZB</td>
</tr>
<tr>
<td>`string1='AABBAABABB'; a=translate(string1,'12','AB');`</td>
<td>1122112122</td>
</tr>
</tbody>
</table>

**See Also**

Functions:
- “`TRANSTRN` Function” on page 644
- “`TRANWRD` Function” on page 647

---

**TRANSTRN Function**

Replaces or removes all occurrences of a substring in a character string.

- **Category:** Character
- **Returned data type:** VARCHAR, NVARCHAR

**Syntax**

\[ \text{TRANSTRN}(source-expression, target-expression, replacement-expression) \]

**Arguments**

- **source-expression**
  - specifies any valid expression that evaluates to a character string, whose characters you want to translate.
  - **Data type:** NCHAR

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*
**target-expression**

specifies any valid expression that evaluates to a character string, whose characters are searched for in source-expression.

Requirements:
- The length for target-expression must be greater than zero.

Data type: NCHAR

**replacement-expression**

specifies any valid expression that evaluates to a character string and that replaces target-expression.

Data type: NCHAR

**Details**

The TRANSTRN function replaces or removes all occurrences of a given substring within a character string. The TRANSTRN function does not remove trailing blanks in the target-expression string and the replacement-expression string. To remove all occurrences of target, specify replacement-expression as TRIMN(' ')

**Comparisons**

The TRANWRD function differs from the TRANSTRN function because TRANSTRN allows the replacement string to have a length of zero. TRANWRD uses a single blank instead when the replacement string has a length of zero.

The TRANSLATE function converts every occurrence of a user-supplied character to another character. TRANSLATE can scan for more than one character in a single call. In doing this scan, however, TRANSLATE searches for every occurrence of any of the individual characters within a string. That is, if any letter (or character) in the target string is found in the source string, it is replaced with the corresponding letter (or character) in the replacement string.

The TRANSTRN function differs from TRANSLATE in that TRANSTRN scans for substrings and replaces those substrings with a second substring.

**Examples**

**Example 1: Replacing All Occurrences of a Word**

In this example, the TRANSTRN function is used to replace Mrs. and Miss with Ms.

```sas
data _null_;
  dcl char(20) name;
  method run();
    name='Mrs. Joan Smith';
    name=transtrn(name, 'Mrs.', 'Ms.');
    put name;
    name='Miss Alice Cooper';
    name=transtrn(name, 'Miss', 'Ms.');
    put name;
  end;
enddata;
```
run;

The following lines are written to the SAS log:
Ms. Joan Smith
Ms. Alice Cooper

**Example 2: Removing Blanks from the Search String**
In this example, the TRIM function is used with `target` to exclude blanks. If you did not include the TRIM function, the TRANSTRN function would not replace the source string because the target string contains blanks.

```sas
data test (overwrite=yes);
  dcl char(10) target;
  dcl char(3) replacement;
  dcl char(8) salelist salelist2;
method run();
  salelist='CATFISH';
  target='FISH';
  replacement='NIP';
  salelist2=transtrn(salelist, trim(target), replacement);
  put salelist2;
end;
enddata;
run;
```

The following is written to the SAS log:
CATNIP

**Example 3: Zero Length in the Third Argument of the TRANSTRN Function**
The following example shows the results of the TRANSTRN function when the third argument, `replacement`, has a length of zero. In DS2, a character constant that consists of two quotation marks with a blank in between them represents a single blank, and not a zero-length string. In the following example, the results for `string1` are different from the results for `string2`.

```sas
data _null_; 
  dcl char string1 string2;
method run();
  string1='*' || transtrn('abcxabc', 'abc', trimn(' ')) || '*';
  put string1=;
  string2='*' || transtrn('abcxabc', 'abc', ' ') || '*';
  put string2=;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
string1=*x*  
string2=* x *
```

**See Also**

**Functions:**
TRANWRD Function

Replaces or removes all occurrences of a substring in a character string.

**Category:** Character

**Returned data type:** NCHAR

**Syntax**

TRANWRD(source-expression, target-expression, replacement-expression)

**Arguments**

*source-expression*

specifies any valid expression that evaluates to a character string, whose characters you want to replace.

*Data type:* NCHAR

*See* “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*target-expression*

specifies any valid expression that evaluates to a character string and that is searched for in *source-expression*.

*Requirement* The length of the *target-expression* must be greater than zero.

*Data type:* NCHAR

*See* “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*replacement-expression*

specifies any valid expression that evaluates to a character string and that replaces *target-expression*.

*Data type:* NCHAR

*See* “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The TRANWRD function replaces or removes all occurrences of a given substring (or a pattern of characters) within a character string. The TRANWRD function does not remove trailing blanks in the *target-expression* string and the *replacement-expression* string.
Comparisons

The TRANWRD function differs from the TRANSTRN function in that TRANSTRN allows the replacement string to have a length of zero. TRANWRD uses a single blank instead when the replacement string has a length of zero.

The TRANSLATE function converts every occurrence of a user-supplied character to another character. TRANSLATE can scan for more than one character in a single call. In doing this, however, TRANSLATE searches for every occurrence of any of the individual characters within a string. That is, if any letter (or character) in the target string is found in the source string, it is replaced with the corresponding letter (or character) in the replacement string.

The TRANWRD function differs from TRANSLATE in that it scans for substrings (or patterns of characters) and replaces those substrings with a second substring (or pattern of characters).

Examples

Example 1: Replacing All Occurrences of a Substring

The following statements illustrate replacing all occurrences of a substring using the TRANWRD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>text='Whatever you so, so it with all your might. -P.T. Barnum'; fix=tranwrd(text,'so','do');</td>
<td>Whatever you do, do it with all your might. -P.T. Barnum</td>
</tr>
</tbody>
</table>

Example 2: Removing Blanks from the Search String

This example illustrates incorrect data type declarations. The TRANWRD function does not replace the source string because TARGET is declared as `char(10)` and the TRANWRD function searches for the character string 'pail ' and not 'pail'.

```sas
data _null_;
  dcl char(100) text finaltext;
  dcl char(10) target;
  dcl varchar(10) rplc;
  method run();
  text='Believe and act as if it were impossible to pail.
     -Charles F. Kettering';
  target='pail';
  rplc='fail';
  finaltext=tranwrd(text, target, rplc);
  put finaltext=;
end;
enddata;
r
```

This line is written to the SAS log.

```
finaltext=Believe and act as if it were impossible to pail. -Charles F. Kettering
```
By changing the data type declaration to `VARCHAR(10)`, trailing blanks are excluded from the search:

data _null_;  
dcl char(100) text finaltext;  
dcl varchar(10) target;  
dcl varchar(10) rplc;  
method run();  
  text='Believe and act as if it were impossible to pail.  
    -Charles F. Kettering';  
target='pail';  
rplc='fail';  
finaltext=tranwrd(text, target, rplc);  
  put finaltext=;  
end;  
enddata;  
run ;

This line is written to the SAS log.

```
finaltext=Believe and act as if it were impossible to fail. -Charles F. Kettering
```

---

**TRIGAMMA Function**

Returns the value of the trigamma function.

**Category:** Mathematical

**Returned data type:** DOUBLE

**Syntax**

\[ \text{TRIGAMMA}(\text{expression}) \]

**Arguments**

- **expression**
  
  specifies any valid expression that evaluates to a numeric value.

**Restriction**

Nonpositive integers are invalid.

**Data type**

DOUBLE

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*
Details
The TRIGAMMA function returns the derivative of the DIGAMMA function. For expression > 0, the TRIGAMMA function is the second derivative of the LGAMMA function.

Example
The following statement illustrates the TRIGAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=trigamma(3);</td>
<td>0.39493406684822</td>
</tr>
</tbody>
</table>

See Also
Functions:
- “DIGAMMA Function” on page 304
- “LGAMMA Function” on page 437

TRIM Function
Removes trailing blanks from a character expression, and returns one blank if the string is missing.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias:</td>
<td>TRIMN</td>
</tr>
<tr>
<td>Returned data type:</td>
<td>VARCHAR, NVARCHAR</td>
</tr>
</tbody>
</table>

Syntax

TRIM('expression')

Arguments

expression
specifies any valid expression that evaluates to a character string.

Data type
CHAR, NCHAR

See

Details
The TRIM function copies a character argument, removes trailing blanks, and returns the trimmed argument as a result. If the argument is blank, TRIM returns one blank. TRIM is useful for concatenating because concatenation does not remove trailing blanks.
Comparisons

The TRIMN and TRIM functions are similar. TRIMN returns a string with a length of zero for a blank string. TRIM returns one blank for a blank string.

Example

The following statements illustrate the TRIM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>string='Testscore   '; results=trim(string)</td>
<td></td>
</tr>
</tbody>
</table>

See Also

Functions:

- “LEFT Function” on page 431
- “STRIP Function” on page 617
- “TRIMN Function” on page 651

TRIMN Function

Removes trailing blanks from character expressions, and returns a string with a length of zero if the expression is missing.

Category: Character

Returned data type: VARCHAR, NVARCHAR

Syntax

TRIMN(expression)

Arguments

expression

specifies any valid expression that evaluates to a character string.

Data type: CHAR, NCHAR

See

Details

Length of Returned Variable
Assigning the results of TRIMN to a variable does not affect the length of the receiving variable. If the trimmed value is shorter than the length of the receiving variable, SAS pads the value with new blanks as it assigns it to the variable.

The Basics
TRIMN copies a character argument, removes all trailing blanks, and returns the trimmed argument as a result. If the argument is blank, TRIMN returns a string with a length of zero. TRIMN is useful for concatenating because concatenation does not remove trailing blanks.

Comparisons
The TRIMN and TRIM functions are similar. TRIMN returns a string with a length of zero for a blank string. TRIM returns one blank for a blank string.

Example
The following statements illustrate the TRIMN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=&quot;A&quot;</td>
<td></td>
</tr>
<tr>
<td>put x;</td>
<td></td>
</tr>
<tr>
<td>x=&quot;   &quot;;</td>
<td></td>
</tr>
<tr>
<td>z=&quot;&gt;&quot;</td>
<td></td>
</tr>
<tr>
<td>put z;</td>
<td></td>
</tr>
</tbody>
</table>

TRUNC Function
Truncates a numeric value to a specified length.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Truncation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax
TRUNC(expression, length-expression)

Arguments
expression
specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

length-expression
specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Range</th>
<th>3–8</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Details
The TRUNC function truncates a full-length numeric expression (stored as a DOUBLE) to a smaller number of bytes, as specified in length-expression and pads the truncated bytes with 0s. The truncation and subsequent expansion duplicate the effect of storing numbers in less than full length and then reading them.

Example
The following statements illustrate the TRUNC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=trunc(3.1,3);</td>
<td>3.099609375</td>
</tr>
<tr>
<td>x=trunc(3.1,4);</td>
<td>3.09999847412109</td>
</tr>
<tr>
<td>x=trunc(3.1,5);</td>
<td>3.0999999403953</td>
</tr>
<tr>
<td>x=trunc(3.1,6);</td>
<td>3.0999999997671</td>
</tr>
<tr>
<td>x=trunc(3.1,7);</td>
<td>3.0999999999999</td>
</tr>
<tr>
<td>x=trunc(3.1,8);</td>
<td>3.1</td>
</tr>
</tbody>
</table>

UNIFORM Function
Returns a random variate from a uniform distribution.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Random Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias:</td>
<td>RANUNI</td>
</tr>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>See:</td>
<td>“Uniform Distribution” on page 570</td>
</tr>
</tbody>
</table>
**UPCASE Function**

Conversions all letters in an argument to uppercase.

**Category:** Character  
**Alias:** UPPER  
**Returned data type:** VARCHAR, NVARCHAR

**Syntax**

`UPCASE(expression)`

**Arguments**

`expression` specifies any valid expression that evaluates to a character string.

**Data type**  CHAR, NCHAR

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

“<sql-expression>” in *SAS FedSQL Language Reference for SAS Cloud Analytic Services*

**Details**

The UPCASE function copies a character expression, converts all lowercase letters to uppercase letters, and returns the altered value as a result.

**Comparisons**

The LOWCASE function converts all letters in an argument to lowercase letters. The UPCASE function converts all letters in an argument to uppercase letters.

**Example**

The following statement illustrates the UPCASE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>name=upcase('John B. Smith');</code></td>
<td>JOHN B. SMITH</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**

- “LOWCASE Function” on page 443
USS Function

Returns the uncorrected sum of squares.

**Category:** Descriptive Statistics

**Returned data type:** DOUBLE

**Syntax**

USS(expression [, ...expression])

**Arguments**

expression

specifies any valid expression that evaluates to a numeric value.

**Requirement**

At least one non-null or nonmissing argument is required. Otherwise, the function returns a null or missing value.

**Data type**

DOUBLE

**See**

**Example**

The following statements illustrate the USS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>a=uss(4,2,3.5,6);</td>
<td>68.25</td>
</tr>
<tr>
<td>a=uss(4,2,3.5,6,.);</td>
<td>68.25</td>
</tr>
</tbody>
</table>

**See Also**

Functions:

- “CSS Function” on page 285

UUIDGEN Function

Returns the short form of a Universally unique identifier (UUID).

**Category:** Special

**Returned data type:** CHAR
Syntax

UUIDGEN()

Without Arguments
The UUIDGEN function has no arguments.

Details
The UUIDGEN function returns a UUID (a unique value) for each call. The default result is 36 characters long and it looks like this:

5ab6fa40–426b-4375–bb22–2d0291f43319

Example
The following example returns a UUID. Note that a variable declaration of 36 characters is required.

data _null_;  
dcl char(36) x;  
method run();  
x=uuidgen();  
put x;  
end;  
enddata;  
run;

The following value is written to the SAS log. Each UUID is unique.

25C752D5-AFA1-4932-BEE6-39E4006C2AAB

VAR Function
Returns the variance.

Category: Descriptive Statistics
Returned data type: DOUBLE

Syntax

VAR(expression-1, expression-2 [ ,…expression-n])

Arguments

expression
specifies any valid expression that evaluates to a numeric value. The argument list can consist of a variable list.

Requirement
At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.
VERIFY Function

Returns the position of the first character that is unique to an expression.

**Category:** Character

**Returned data type:** DOUBLE

**Syntax**

```verbatim
VERIFY(target-expression, search-expression)
```

**Arguments**

*target-expression*

specifies any valid expression that evaluates to a character string that is to be searched.

**Requirement**

Literal character strings must be enclosed in single quotation marks.

**Data type**

NCHAR

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*search-expression*

specifies any valid expression that evaluates to a character string.

**Requirement**

Literal character strings must be enclosed in single quotation marks.

**Data type**

NCHAR

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*
Details

The VERIFY function returns the position of the first character in \textit{target-expression} that is not present in \textit{search-expression}. If there are no characters in \textit{target-expression} that are unique from those in \textit{search-expression}, VERIFY returns a 0.

Comparisons

The INDEX function returns the position of the first occurrence of \textit{search-expression} that is present in \textit{target-expression} where the VERIFY function returns the position of the first character in \textit{target-expression} that does not contain \textit{search-expression}.

Example

The following statements illustrate the VERIFY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x='abc';</code></td>
<td></td>
</tr>
<tr>
<td><code>y='abcdef';</code></td>
<td></td>
</tr>
<tr>
<td><code>z=verify(y,x);</code></td>
<td>4</td>
</tr>
<tr>
<td><code>x='abcdef';</code></td>
<td></td>
</tr>
<tr>
<td><code>y='abcdef';</code></td>
<td></td>
</tr>
<tr>
<td><code>z=verify(y,x);</code></td>
<td>0</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “INDEX Function” on page 360

VFORMAT Function

Returns the format that is associated with the specified variable.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Variable Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>NCHAR</td>
</tr>
</tbody>
</table>

Syntax

\texttt{VFORMAT}(\textit{variable} | \textit{variable-list}[i] | \textit{variable-array}[i])

Arguments

\textit{variable}

specifies a variable that is expressed as a scalar or as an array reference.

Restriction

You cannot use an expression as an argument.
variable-list
specifies a collection of DS2 variables.

variable-array
specifies a collection of homogenous DS2 variables.

\( i \)
specifies the element number of the named variable list or variable array.

Details
VFORMAT returns the complete format name, which includes the width and the period (for example, $\text{CHAR20}$.)

Example
The following example returns the format of a character variable.

```sas
proc ds2;
data _null_;    
declare varchar(7) str having format $\text{char7}$.;    
method run();    
a = vformat(str);    
put a=;    
end;    
enddata;    
run;    
quit;
```

SAS writes the following output to the log:

```
a=$\text{char7}$.  
```

- “VTYPE Function” on page 666
VINARRAY Function

Returns a value that indicates whether the specified variable is a member of an array.

**Category:** Variable Information  
**Returned data type:** INTEGER

**Syntax**

VINARRAY(\textit{variable} | \textit{variable-list}[i] | \textit{variable-array}[i])

**Arguments**

\textit{variable}

specifies a variable that is expressed as a scalar or as an array reference.

**Restriction**  
You cannot use an expression as an argument.

**Data type**  
All data types

\textit{variable-list}

specifies a collection of DS2 variables.

\textit{variable-array}

specifies a collection of homogenous DS2 variables.

\textit{i}

specifies the element number of the named variable list or variable array.

**Details**

VINARRAY returns a value of 1 if the given variable is a member of a variable array. Otherwise, VINARRAY returns a value of 0.

**Example**

The following example returns a value (0 or 1) depending on whether the specified variable is a member of an array:

```sas
data _null_;  
declare int a b c d;  
vararray int x[3] a b c;  
method init();  
declare int c_in;  
declare int d_in;  
c_in=vinarray(c); /* c is in array x */  
d_in=vinarray(d); /* d is not in an array */  
put c_in=;  
put d_in=;
```
end;
enddata;
run;

SAS writes the following output to the log:

| c_in=1 |
| d_in=0 |

## VINFORMAT Function

Returns the informat that is associated with the specified variable.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Variable Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>NCHAR</td>
</tr>
</tbody>
</table>

### Syntax

```
VINFORMAT( variable | variable-list[i] | variable-array[i] )
```

### Arguments

**variable**

specifies a variable that is expressed as a scalar or as an array reference.

**Restriction**

You cannot use an expression as an argument.

**Data type**

All data types

**variable-list**

specifies a collection of DS2 variables.

See "Variable Lists” in *SAS Viya: DS2 Programmer’s Guide*

**variable-array**

specifies a collection of homogenous DS2 variables.

See "Variable Arrays” in *SAS Viya: DS2 Programmer’s Guide*
i
specifies the element number of the named variable list or variable array.

Details
VINFORMAT returns the complete informat name, which includes the width and the period (for example, $CHAR20.).

Example
The following example returns an informat that is associated with the specified variable.

```sas
data _null_; 
  declare varchar(10) str having informat $char5.;
  method run();
  a=vinformat(str);
  put a=;
  end;
enddata;
run;
```

SAS writes the following output to the log:

```
a=$char5.
```

See Also

- “VLABEL Function” on page 662
- “VLENGTH Function” on page 664
- “VNAME Function” on page 665
- “VTYPE Function” on page 666

VLABEL Function

Returns the label that is associated with the specified variable.

- **Category:** Variable Information
- **Returned data type:** NCHAR

**Syntax**

```
VLABEL variable | variable-list[i] | variable-array[i]
```

Arguments

variable
   specifies a variable that is expressed as a scalar or as an array reference.

Data type    All data types

variable-list
   specifies a collection of DS2 variables.

variable-array
   specifies a collection of homogenous DS2 variables.

i
   specifies the element number of the named variable list or variable array.

Details

VLABEL returns the label that is associated with the specified variable. If there is no
label, VLABEL returns the variable name.

Example

The following example returns a label for a specified variable.

   data _null_;
      declare varchar(10) fname having label 'First Name';
      method run();
      a=vlable(fname);
      put a=;
      end;
   enddata;
   run;

   SAS writes the following output to the log:

   a=First Name

See Also

Functions:
   • “VINARRAY Function” on page 660
   • “VFORMAT Function” on page 658
   • “VINFORMAT Function” on page 661
   • “VLENGTH Function” on page 664
   • “VNAME Function” on page 665
   • “VTYPE Function” on page 666
VLENGTH Function

Returns the size of the specified variable.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Variable Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>BIGINT</td>
</tr>
</tbody>
</table>

Syntax

\[
\text{VLENGTH}(\text{variable} | \text{variable-list}[i] | \text{variable-array}[i])
\]

Arguments

**variable**

specifies a value that is expressed as a scalar or as an array reference.

**Restriction**

You cannot use an expression as an argument.

**Data type**

All data types

**variable-list**

specifies a collection of DS2 variables.

**variable-array**

specifies a collection of homogenous DS2 variables.

See “Variable Arrays” in *SAS Viya: DS2 Programmer’s Guide*

**i**

specifies the element number of the named variable list or variable array.

Details

The length of numeric data types is defined as the maximum number of digits used by the data type of the column, or the precision of the data. For character types, this is the length in characters of the data; for binary data types, this is the length in bytes of the data. For the TIME, TIMESTAMP, and all interval data types, this is the number of characters in the character representation of this data.

Example

The following example returns the length of the specified variable.

```sas
data _null_
declare char (?) str;
method run()
str='World';
a=vlength {str};
put a=;
end;
run;
```
SAS writes the following output to the log:

```
a=7
```

- “VINFORMAT Function” on page 661
- “VLABEL Function” on page 662
- “VNAME Function” on page 665
- “VTYPE Function” on page 666

---

**VNAME Function**

Returns the name of the specified variable.

- **Category:** Variable Information
- **Returned data type:** NCHAR

**Syntax**

```
VNAME(variable | variable-list[i] | variable-array[i])
```

**Arguments**

- **variable**
  - specifies a variable that can be expressed as a scalar or as an array reference.
  - **Restriction:** You cannot use an expression as an argument.
  - **Data type:** All data types

- **variable-list**
  - specifies a collection of DS2 variables.

- **variable-array**
  - specifies a collection of homogenous DS2 variables.
  - See “Variable Arrays” in *SAS Viya: DS2 Programmer’s Guide*

- **i**
  - specifies the element number of the named variable list or variable array.
Example

The following example returns the name of the specified variable.

```sas
data _null_; vararray int x[3] a b c;
  method run();
    y=vname(x[1]);
    put y=;
  end;
enddata;
run;
```

SAS writes the following output to the log:

```
y=a
```

VTYPE Function

Returns the full name of the data type that is associated with a variable.

<table>
<thead>
<tr>
<th>Category</th>
<th>Variable Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type</td>
<td>NCHAR</td>
</tr>
</tbody>
</table>

Syntax

`VTYPE(variable | variable-list[i] | variable-array[i])`

Arguments

`variable`

specifies a variable that is expressed as a scalar or as an array reference.

Restriction  You cannot use an expression as an argument.

Data type  All data types

`variable-list`

specifies a collection of DS2 variables.

**variable-array**

specifies a collection of homogenous DS2 variables.

See “Variable Arrays” in *SAS Viya: DS2 Programmer’s Guide*

**i**

specifies the element number of the named variable list or variable array.

**Details**

**VTYPE** returns the data type name for the data type of the variable.

**Example**

The following example returns the name of the data type that is associated with the specified variable.

```sas
data _null_; 
declare double d; 
declare timestamp t; 
declare nvarchar(10) n; 
method run(); 
    declare char(20) a b c; 
    a=vtype(d); 
    put a=; 
    b=vtype(t); 
    put b=; 
    c=vtype(n); 
    put c=; 
end; 
enddata; 
run; 
```

SAS writes the following output to the log:

```
a=double 
b=timestamp 
c=nvarchar 
```

**See Also**

- “VNAME Function” on page 665
WEEK Function

Returns the week-number value.

**Category:** Date and Time  
**Returned data type:** DOUBLE

**Syntax**

`WEEK([sas-date], ['descriptor'])`

**Without Arguments**

If no arguments are specified, the WEEK function returns the week-number value of the current date.

**Arguments**

`sas-date`

specifies the SAS date value. If the `sas-date` argument is not specified, the WEEK function returns the week-number value of the current date.

**Data type** DOUBLE

`descriptor`

specifies the value of the descriptor. The following descriptors can be specified in uppercase or lowercase characters.

**U**

specifies the number-of-the-week within the year. Sunday is considered the first day of the week. The number-of-the-week value is represented as a decimal number in the range 0–53. Week 53 has no special meaning.

**Tip** The U and W descriptors are similar, except that the U descriptor considers Sunday as the first day of the week, and the W descriptor considers Monday as the first day of the week.

**See** “The U Descriptor” on page 669

**V**

specifies the number-of-the-week whose value is represented as a decimal number in the range 1–53. Monday is considered the first day of the week and week 1 of the year is the week that includes both January 4 and the first Thursday of the year. If the first Monday of January is the second, third, or fourth, the preceding days are part of the last week of the preceding year.

**See** “The V Descriptor” on page 669

**W**

specifies the number-of-the-week within the year. Monday is considered the first day of the week. The number-of-the-week value is represented as a decimal number in the range 0–53. Week 53 has no special meaning.
The U and W descriptors are similar except that the U descriptor considers Sunday as the first day of the week, and the W descriptor considers Monday as the first day of the week.

See “The W Descriptor” on page 669

Default U
Data type CHAR

Details

The Basics
The WEEK function reads a SAS date value and returns the week number. The WEEK function is not dependent on locale, and uses only the Gregorian calendar in its computations.

The U Descriptor
The WEEK function with the U descriptor reads a SAS date value and returns the number of the week within the year. The number-of-the-week value is represented as a decimal number in the range 0-53, with a leading zero and maximum value of 53. Week 0 means that the first day of the week occurs in the preceding year. The fifth week of the year is represented as 05.

Sunday is considered the first day of the week. For example, the value of week(date'2016–01–01', 'u') is 0.

The V Descriptor
The WEEK function with the V descriptor reads a SAS date value and returns the week number. The number-of-the-week is represented as a decimal number in the range 01–53. The decimal number has a leading zero and a maximum value of 53. Weeks begin on a Monday, and week 1 of the year is the week that includes both January 4 and the first Thursday of the year. If the first Monday of January is the second, third, or fourth, the preceding days are part of the last week of the preceding year. In the following example, 01jan2016 and 31dec2015 occur in the same week. The first day (Monday) of that week is 28dec2015. Therefore, week(date'2016–01–01', 'v') and week(date'2015–12–31', 'v') both return a value of 53. This means that both dates occur in week 53 of the year 2015.

The W Descriptor
The WEEK function with the W descriptor reads a SAS date value and returns the number of the week within the year. The number-of-the-week value is represented as a decimal number in the range 0-53, with a leading zero and maximum value of 53. Week 0 means that the first day of the week occurs in the preceding year. The fifth week of the year would be represented as 05.

Monday is considered the first day of the week. Therefore, the value of week(date'2016–01–04', 'w') is 1.

Comparisons of Descriptors
U is the default descriptor. Its range is 0-53, and the first day of the week is Sunday. The V descriptor has a range of 1-53 and the first day of the week is Monday. The W descriptor has a range of 0-53 and the first day of the week is Monday.
The following list describes the descriptors and an associated week:

- **Week 0:**
  - U indicates the days in the current Gregorian year before week 1.
  - V does not apply.
  - W indicates the days in the current Gregorian year before week 1.

- **Week 1:**
  - U begins on the first Sunday in a Gregorian year.
  - V begins on the Monday between December 29 of the previous Gregorian year and January 4 of the current Gregorian year. The first ISO week can span the previous and current Gregorian years.
  - W begins on the first Monday in a Gregorian year.

- **End of Year Weeks:**
  - U specifies that the last week (52 or 53) in the year can contain less than 7 days. A Sunday to Saturday period that spans 2 consecutive Gregorian years is designated as 52 and 0 or 53 and 0.
  - V specifies that the last week (52 or 53) of the ISO year contains 7 days. However, the last week of the ISO year can span the current Gregorian and next Gregorian year.
  - W specifies that the last week (52 or 53) in the year can contain less than 7 days. A Monday to Sunday period that spans two consecutive Gregorian years is designated as 52 and 0 or 53 and 0.

### Example

The following example shows the values of the U, V, and W descriptors for the date August 16, 2013.

```sas
data _null_;
dcl double sasdate x y z;
method run();
sasdate=to_double(date'2013-08-16');
x=week(sasdate, 'u');
y=week(sasdate, 'v');
z=week(sasdate, 'w');
put x;
put y;
put z;
end;
enddata;
run;
```

The following lines are written to the SAS log.

32
33
32
WEEKDAY Function

From a SAS date value, returns an integer that corresponds to the day of the week.

Syntax

WEEKDAY(expression)

Arguments

expression

specifies any valid expression that represents a SAS date value.

Data type: DOUBLE

See

Details

The WEEKDAY function produces an integer that represents the day of the week, where 1 = Sunday, 2 = Monday, ..., 7 = Saturday.

For information about how DS2 handles date and time values, see “Dates and Times in DS2” in SAS Viya: DS2 Programmer’s Guide.

Example

The following statement illustrates the WEEKDAY function when the current day is Sunday:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=weekday(today());</td>
<td>1</td>
</tr>
</tbody>
</table>
**WHICHC Function**

Returns the first position of a character string from a list of character strings.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

**Syntax**

```sas
WHICHC(search-expression, expression-list-item-1, expression-list-item-2 [, ...expression-list-item-n])
```

**Arguments**

`search-expression`

specifies any valid expression that evaluates to a character string that is compared with a list of character string expressions.

- **Requirement**: Literal character strings must be enclosed in single quotation marks.
- **Data type**: NCHAR
- **See**: “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

`expression-list-item`

specifies any valid expression that evaluates to a character string and that is a member of a list of character string expressions.

- **Requirements**: Literal character strings must be enclosed in single quotation marks.
- **At least two expressions are required in the list.**
- **Data type**: NCHAR
- **See**: “DS2 Expressions” in SAS Viya: DS2 Programmer’s Guide

**Details**

The WHICHC function searches the character expression list, from left to right, for the first expression that matches the search expression. If a match is found, WHICHC returns its position in the expression list. If none of the expressions match the search expression, WHICHC returns a value of 0.

**Example**

In the following example, ‘Spain’ appears twice in the list. The WHICHC function returns the first position of ‘Spain’ in the list:
Statements

x=whichc('Spain', 'Denmark', 'Germany', 'Austria', 'Spain', 'China', 'Egypt', 'Spain', 'France');

Results

4

Functions:

• “WHICHN Function” on page 673

WHICHN Function

Returns the first position of a number from a list of numbers.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Mathematical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

WHICHN(search-expression, expression-list-item-1, expression-list-item-2
[,...expression-list-item-n])

Arguments

**search-expression**

specifies any valid expression that evaluates to a number and that is compared with a list of numeric expressions.

Data type: DOUBLE

**expression-list-item**

specifies any valid expression that evaluates to a number and is part of a list.

Requirement: At least two expressions are required in the list.

Data type: DOUBLE

Details

The WHICHN function searches the numeric expression list, from left to right, for the first expression that matches the search expression. If a match is found, WHICHN returns its position in the expression list. If none of the expressions match the search expression, WHICHN returns a value of 0. Arguments for the WHICHN function can be any numeric data type.
Example

In the following example, 4.5 appears two times in the list. The WHICHN function return the first position of 4.5 in the list:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=whichn(4.5, 7.3, 8.6, 4.5, 4.5, 2.1, 6.4);</td>
<td>3</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “WHICHC Function” on page 672

YEAR Function

Returns the year from a SAS date value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

YEAR(date)

Arguments

date

Specifies any valid expression that represents a SAS date value.

Data type DOUBLE

Details

The YEAR function produces a four-digit numeric value that represents the year.

Example

The following statement illustrates the YEAR function when the year is 2007.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>date=today();</td>
<td></td>
</tr>
<tr>
<td>y=year(date);</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2007</td>
</tr>
</tbody>
</table>
YIELDP Function

Returns the yield-to-maturity for a periodic cash flow stream, such as a bond.

Category: Financial
Returned data type: DOUBLE

Syntax

\[
\text{YIELDP}(A, c, n, K, k_{0}, p)
\]

Arguments

\(A\)

specifies the face value.

Range \(A > 0\)

Data type DOUBLE

\(c\)

specifies the nominal annual coupon rate, expressed as a fraction.

Range \(0 \leq c < 1\)

Data type DOUBLE

\(n\)

specifies the number of coupons per year.

Range \(n > 0\)

Data type INTEGER

\(K\)

specifies the number of remaining coupons from settlement date to maturity.

Range \(K > 0\)

Data type INTEGER

\(k_{0}\)

specifies the time from settlement date to the next coupon as a fraction of the annual basis.
Range \[ 0 < k_0 \leq \frac{1}{n} \]

Data type DOUBLE

\( P \)
specifies the price with accrued interest.

Range \( p > 0 \)

Data type DOUBLE

Details

The YIELDP function is based on the following relationship:

\[ P = \sum_{k=1}^{K} c(k) \cdot \frac{1}{(1 + \frac{y}{n})^{t_k}} \]

The following relationships apply to the preceding equation:

- \( t_k = nk_0 + k - 1 \)
- \( c(k) = \frac{c}{n}A \) for \( k = 1, \ldots, K - 1 \)
- \( c(K) = (1 + \frac{c}{n})A \)

The YIELDP function solves for \( y \).

Example

In the following example, the YIELDP function returns the yield-to-maturity of a bond that has a face value of 1000, an annual coupon rate of 0.01, 4 coupons per year, and 14 remaining coupons. The time from settlement date to next coupon date is 0.165, and the price with accrued interest is 800. The value returned is 0.0775031248.

```sas
data _null_; method run();
y=yieldp(1000,.01,4,14,.165,800);
puy y;
end;
enddata;
run;
```

SAS writes the following output to the log:

```
0.0775031247735
```

YRDIF Function

Returns the difference in years between two dates according to specified day count conventions; returns a person’s age.

Category: Date and Time
Returned data type: INTEGER

Syntax

\[ \text{YRDIF}(\text{start-date}, \text{end-date}[\text{, basis}]) \]

Arguments

\textit{start-date}

specifies a SAS date value that identifies the starting date.

Data type DOUBLE

\textit{end-date}

specifies a SAS date value that identifies the ending date.

Data type DOUBLE

\textit{basis}

identifies a character constant or variable that describes how SAS calculates a date difference or a person’s age. The following character strings are valid:

- '30/360'
  specifies a 30-day month and a 360-day year in calculating the number of years. Each month is considered to have 30 days, and each year 360 days, regardless of the actual number of days in each month or year.
  
  \begin{itemize}
  \item Alias '360'
  \end{itemize}
  
  \begin{itemize}
  \item Tip If either date falls at the end of a month, it is treated as if it were the last day of a 30-day month.
  \end{itemize}

- 'ACT/ACT'
  uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days that fall in 365-day years divided by 365 plus the number of days that fall in 366-day years divided by 366.
  
  Alias 'Actual'

- 'ACT/360'
  uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days divided by 360, regardless of the actual number of days in each year.

- 'ACT/365'
  uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days divided by 365, regardless of the actual number of days in each year.

- 'AGE'
  specifies that a person’s age will be computed.
  
  If you do not specify a third argument, AGE becomes the default value for \textit{basis}.

Data type CHAR
Details

Using YRDIF in Financial Applications

The Basics
The YRDIF function can be used in calculating interest for fixed income securities when the third argument, basis, is present. YRDIF returns the difference between two dates according to specified day count conventions.

Calculations That Use ACT/ACT Basis
In YRDIF calculations that use the ACT/ACT basis, both a 365-day year and 366-day year are taken into account. For example, if n365 equals the number of days between the start and end dates in a 365-day year, and n366 equals the number of days between the start and end dates in a 366-day year, the YRDIF calculation is computed as YRDIF=n365/365.0 + n366/366.0. This calculation corresponds to the commonly understood ACT/ACT day count basis that is documented in the financial literature. The values for basis also includes 30/360, ACT/360, and ACT/365. Each has well-defined meanings that must be conformed to in calculating interest payments for specific financial instruments.

Computing a Person’s Age
The YRDIF function can compute a person’s age. The first two arguments, start-date and end-date, are required. If the value of basis is AGE, then YRDIF computes the age. The age computation takes into account leap years. No other values for basis are valid when computing a person’s age.

Examples

Example 1: Calculating a Difference in Years Based on Basis
In the following example, YRDIF returns the difference in years between two dates based on each of the options for basis.

```sas
   data _null_; 
   method run();
      sdate= to_double(date’1998-10-16’);
      edate= to_double(date’2010-02-06’);
      y30360=yrdif(sdate, edate, ’30/360’);
      yactact=yrdif(sdate, edate, ’ACT/ACT’);
      yact360=yrdif(sdate, edate, ’ACT/360’);
      yact365=yrdif(sdate, edate, ’ACT/365’);
      put y30360=;
      put yactact=;
      put yact360=;
      put yact365=;
   end;
   enddata;
   run;
```

SAS writes the following results to the log:

```
y30360=11.3055555555555
yactact=11.3095890410958
yact360=11.475
yact365=11.317808219178
```
Example 2: Calculating a Person’s Age
You can calculate a person’s age by using three arguments in the YRDIF function. The third argument, basis, must have a value of AGE:

```sas
data _null_;  
  method run();
    sdate= to_double(date'1998-10-16');
    edate= to_double(date'2010-02-16');
    age=yrdif(sdate, edate, 'AGE');
    put age= 'years';
  end;
enddata;
run;
```

SAS writes the following results to the log:

```
age=11.3369863013698 years
```

---

YYQ Function

Returns a SAS date value from year and quarter year values.

**Category:** Date and Time  
**Returned data type:** DOUBLE

**Syntax**

`YYQ(year, quarter)`

**Arguments**

`year`

specifies any valid expression that evaluates to a two-digit or four-digit integer that represents the year.
The YEARCUTOFF= system option defines the year value for two-digit dates.

**Data type**  
DOUBLE

**See**  

**quarter**  
specifies the quarter of the year (1, 2, 3, or 4).

**Data type**  
DOUBLE

**See**  

### Details

The YYQ function returns a SAS date value that corresponds to the first day of the specified quarter. If either `year` or `quarter` is null or missing, or if the quarter value is not valid, the result is a null or missing value.

### Example

The following statements illustrate the YYQ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>DateValue=yyq(2006,3);</td>
<td>16983</td>
</tr>
<tr>
<td>Date7Value = put(DateValue, date7.);</td>
<td>01JUL06</td>
</tr>
<tr>
<td>Date9Value = put(DateValue, date9.);</td>
<td>01JUL2006</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>StartOfQuarter=yyq(2006,4);</td>
<td>17075</td>
</tr>
<tr>
<td>StartOfQuarter9=put(StartOfQuarter,date9.);</td>
<td>01OCT2006</td>
</tr>
</tbody>
</table>

Chapter 8
DS2 Informats

Overview of Informats

An informat is an instruction that determines how values are read into a column. For example, the following value contains a dollar sign and commas:

$1,000,000

To remove the dollar sign ($) and commas (,) before storing the numeric value 1000000 in a column, read this value with the COMMA11. informat.

General Informat Syntax

DS2 informats have the following form:

[ $ ] informat [w .] [d ]

Here is an explanation of the syntax:

$ indicates a character informat; its absence indicates a numeric informat.

informat names the informat. The informat is a SAS informat or a user-defined informat that was previously defined with the INVALUE statement in PROC FORMAT. For more information about user-defined informats, see PROC FORMAT in the SAS Viya Data Management and Utility Procedures Guide.
\( w \)

specifies the informat width, which for most informats is the number of columns in
the input data.

\( d \)

specifies an optional decimal scaling factor in the numeric informats. SAS divides
the input data by 10 to the power of \( d \).

**Note:** Even though SAS can read up to 32 decimal places when you specify some
numeric informats, floating-point numbers with more than 15 decimal places might
lose precision due to the limitations of the eight-byte floating-point representation
used by most computers.

Informats always contain a period (.) as a part of the name. If you omit the \( w \) and the \( d \)
values from the informat, SAS uses default values. If the data contains decimal points,
SAS ignores the \( d \) value and reads the number of decimal places that are actually in the
input data.

For more information about how informats work and a complete list of informats, see the
*SAS Viya Formats and Informats: Reference.*

---

**How Informats Are Used in DS2**

DS2 supports SAS informats as follows.

- Both informats supplied by SAS and user-defined informats can be associated with a
column. For information about how to create your own informat in SAS, see PROC

  **Note:** To create and access user-defined informats, a Base SAS session must be
available in order to access the SAS catalog file that stores the SAS informat
definitions.

- Only the SAS data set and SPD data sets support storing and retrieving an informat
with a column.

- Informats can be associated with all data types, but all data types will be converted to
either CHAR or DOUBLE.

- You can associate SAS informats with a column by using the HAVING clause of the
DS2 DECLARE statement. For more information, see “How to Specify Informats in
DS2” on page 682.

For more information and a complete list of informats supplied by SAS, see the section
on informats in the *SAS Viya Formats and Informats: Reference.*

---

**How to Specify Informats in DS2**

In DS2, specify informats as an attribute in the HAVING clause of the DECLARE
statement. For example, in the following statement, the column \( y \) is declared with the
IEEE8.2 format and the BITS5.2 informat.

\[ \text{dcl double } y \text{ having format ieee8.2 informat bits5.2;} \]

**Note:** In DS2, an informat for a column cannot be changed or removed.
Validation of DS2 Informsats

Informats are not validated by a data source or applied to a column until execution time. When metadata for a column is requested, the informat name will be returned without validation.

DS2 Informat Examples

dcl char(10) y having label 'varchar' format $5. informat $charzb4.3;
dcl double ssn having format best 10.4 informat comma10.4;
dcl double(6) salary having informat uscurrency.;
dcl char(12) site having informat $city.;
Dictionary

.NEW_. Operator

Constructs an instance of a package.

**Note:** The escape character ( \\ ) before the bracket indicates that the bracket is required in the syntax.

**See:** The _NEW_ operator for predefined DS2 packages is documented in the reference section for each package.

**Syntax**

```
package-variable = _NEW_ [ [THIS\] | [package-instance\] ]
package-name ( [constructor-arguments] );
```

**Arguments**

- **package-variable**
  - specifies a name that can reference an instance of the package.

- **[THIS]**
  - specifies that the package instance has global scope.

  **See** “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*

- **[package-instance]**
  - specifies that the new package instance has the same scope as `package-instance`. `package-instance` must be an existing package instance, and the type of `package-instance` can differ from the type of the new package instance.

  **See** “Package-Specific Scope” in *SAS Viya: DS2 Programmer’s Guide*
**package-name**
specifies the name of the package.

*Requirement:* *package-name* must be a DS2 predefined package type or created with a PACKAGE statement before the _NEW_ operator is executed.

**constructor-arguments**
specifies any constructor arguments that are passed to the constructor of the package instance.

**Details**
A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

After you have stored methods and variables in a package by using the PACKAGE statement, you can access them by declaring and instantiating the package. If you use the _NEW_ operator to instantiate the package, you must first use the DECLARE PACKAGE statement to declare the package variable.

```
declare package package-name variable-name;
variable-name = _new_ package-name();
```

For example, in the following lines of code, the DECLARE PACKAGE statement tells SAS that C is a variable of type COMPLEX package. The _NEW_ operator constructs an instance of the COMPLEX package and assigns it to the package variable C.

```
declare package complex c;
c = _new_ complex();
```

If you want to initialize package data, you can use a constructor. A constructor is a method that is used to instantiate a package and to initialize the package data. For example, you can provide initialization data by using parameters in the constructor syntax for the hash and hash iterator package.

```
declare package hash h();
h = _new_ hash(0, 'mytable', 'yes', 'replace', 'sumnum', 'y');
```

*Note:* You can use the DECLARE PACKAGE statement with constructor arguments to declare and instantiate a package in one step. The example shown above would look like this.

```
declare package hash h(0, 'mytable', 'yes', 'replace', 'sumnum', 'y');
```

For more information, see “DS2 Packages” in *SAS Viya: DS2 Programmer’s Guide* and “DECLARE PACKAGE Statement” on page 712.

**Comparisons**
You can use the DECLARE PACKAGE statement and the _NEW_ operator, or the DECLARE PACKAGE statement alone to declare and instantiate an instance of a package.

Overview of Statements

A DS2 statement is a series of items that can include keywords, identifiers, special characters, and operators. A DS2 statement can perform the following actions:

- perform variable assignments
- influence program control
- perform input and output of data
- create methods
- call methods and functions

All DS2 statements end with a semicolon.

There are three categories of statements:

- **Block**
  - use to create a programming blocks. For more information, see “Programming Blocks” in *SAS Viya: DS2 Programmer’s Guide*.

- **Global**
  - use anywhere in the global section of a programming block created by a DATA, PACKAGE, or THREAD statement

- **Local**
  - use only inside a DS2 method

Note that some statements belong to multiple categories. For example, the DECLARE statement can be both a global and a local statement.

## Block Statements

### Overview of Block Statements

There are five DS2 statements that differ from other statements in that they are used to group other statements in programming blocks. The block statements are as follows:

- **DO...END**
- **METHOD...END**
- **PACKAGE...ENDPACKAGE**
- **DATA...ENDDATA**
Block statements can be divided further into two categories: statements that create program blocks and statements that create program subblocks. Program block statements include PACKAGE...ENDPACKAGE, DATA...ENDDATA, and THREAD...ENDTHREAD. Program subblock statements include METHOD...END and DO...END.

In this documentation, these terms are used for programming blocks.

- A data programming block or data program refers to code bounded by DATA…ENDDATA statements.
- A package programming block or package refers to the stored library of variables and methods bounded by PACKAGE…ENDPACKAGE statements. The variables and methods of a package can be used by DS2 programs, threads, or other packages.
- A thread programming block, or thread program, refers to a stored program bounded by a THREAD…ENDTHREAD statements. The thread program can be called by the SET FROM statement in a DS2 program or package.
- A DO programming block, or DO loop, refers to a subblock of programming statements bounded by DO...END statements.
- A method programming block or method block refers to a subblock of programming statements bounded by a METHOD...END statements.

Each data program must have one and only one program block statement. A data program can and often will have multiple subblock statements. For more information about programming blocks, see “Programming Blocks” in SAS Viya: DS2 Programmer’s Guide.

**Program Block Statements**

Program blocks are created with the DATA, PACKAGE, and THREAD statements. These statements, and their concluding END statements, are used outside of any other statement, and the program blocks that they define can contain other statements. All other statements must be used inside one of these blocks.

A data program, a package, or a thread program contains two sections: a section of global declarations followed by a section of METHOD statements. This is an example of a data program.

```sas
data t;
  ...global declarations
  ...METHOD statement;
enddata;
```

All global declarations must precede the first METHOD statement in the program. A syntax error results if a global declaration is found after a METHOD statement in a program.

The DATA statement creates a data program. A data program consists of the global declaration list and the METHOD statement list contained within a program created by the DATA…ENDDATA statements. For information about compiling and executing a data program, see “DS2” in SAS Viya Data Management and Utility Procedures Guide. For more information about the DATA statement, see the “DATA Statement” on page 702.

A thread program is created by the THREAD...ENDTHREAD statements. A thread program consists of the global declaration list and the METHOD statement list contained within the THREAD...ENDTHREAD statements. The structure of a thread program is
essentially the same as that of a data program, but is used to execute several threads in parallel. When you use a DECLARE statement in another data program or package to reference the thread, the thread program is loaded into memory. You can then use the SET FROM statement in a subsequent data program to run the program in one or more operating system threads. For more information, see the “THREAD Statement” on page 780.

The package is defined by the PACKAGE…ENDPACKAGE statements. A package is a collection of variables and methods that can be called by a data program, a thread program, or another package. A package consists of the global declaration list and the METHOD statement list contained within a programming block created by the PACKAGE…ENDPACKAGE statements. A package is compiled and stored for later use. When you declare the package in a DS2 program, a thread program or another package, the stored package is loaded into memory. You can then access the methods and variables in the package. For more information, see the “PACKAGE Statement” on page 753.

Program Subblock Statements

Program subblock statements are created with the METHOD or DO statements. A DS2 program normally contains several subblocks of programming statements.

Each subblock contains two sections: a section of global declaration statements followed by a section of other local statements. This is an example of a METHOD subblock:

```
method m;
  ...global declarations
  ...local statements;
end;
```

All global declaration statements must precede all other local statements in the subblock. A syntax error will result if a global declaration statement is placed after any other type of statement in a programming subblock.

Global Declaration Statements

Global declaration statements are statements that must be in the declaration section of a program created by a DATA, PACKAGE, or THREAD statement. Global declaration statements generally provide information for your DS2 program or request information or data. Generally, global declaration statements are not executable; they take effect as soon as DS2 compiles program statements.

The following table lists DS2 statements that are allowed in the declaration section of a DS2 program.

<table>
<thead>
<tr>
<th>Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECLARE</td>
</tr>
<tr>
<td>DROP</td>
</tr>
<tr>
<td>DROP PACKAGE</td>
</tr>
<tr>
<td>DROP THREAD</td>
</tr>
<tr>
<td>FORWARD</td>
</tr>
<tr>
<td>KEEP</td>
</tr>
</tbody>
</table>

Note: The DECLARE and GLOBAL statements can be used both globally and within a method.
Local Statements

Local statements are statements that you can use inside a programming block created with a METHOD statement.

The following table lists DS2 method statements.

Note: All global declaration statements must proceed all other local statements in a method programming block.

Note: A METHOD statement is not a local statement. Therefore, a METHOD statement cannot be nested inside another METHOD statement.

- Assignment
- BY
- CONTINUE
- DECLARE
- DECLARE PACKAGE
- DECLARE THREAD
- DO
- GOTO
- IF, Subsetting
- IF-THEN/ELSE
- Labels
- LEAVE
- Null
- OUTPUT
- PUT
- RETURN
- SELECT
- SET
- SET FROM
- STOP
- Sum
Dictionary

ARRAY Assignment Statement
Assigns either a temporary array or a constant list to a temporary array.

Syntax

array-name := array-name;
array-name := (constant-list);

Arguments

array-name
specifies the name of the array.
constant-list
specifies a list that define the array elements.

Details

You can assign either a temporary array or a constant list to a temporary array.

When you assign one array to another array, the data types of the two arrays must be compatible (either the same or convertible). The number of dimensions do not have to be the same for the two arrays, and the total number of elements in each array do not have to be the same.

Example

The following statements are examples of array assignments.

ar1 := ('sales', 'inv', 'profit');
ar2 := (3*3.14159, 2*'5', 2*(1,2), 99);
ar7 := ar2;

See Also

Assignment Statement
Evaluates an expression and stores the result in a variable.

Category: Local
Syntax

\[
\text{variable} = \text{expression};
\]

Arguments

**variable**

names a new or existing variable.

**Range**  
\text{variable} can be a variable name, array reference, or SUBSTR function.

**Tip**  
Variables that are created by the Assignment statement are not automatically retained.

**expression**

is any valid DS2 expression.

**Tip**  
\text{expression} can contain the variable that is used on the left side of the equal sign. When a variable appears on both sides of a statement, the original value on the right side is used to evaluate the expression, and the result is stored in the variable on the left side of the equal sign.

See  
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

Details

Assignment statements evaluate the expression on the right side of the equal sign and store the result in the variable that is specified on the left side of the equal sign.

The following type conversions take place with the Assignment statement:

- If the variable has a data type and the expression’s data type does not match and can be converted, the expression is converted to the variable’s data type. If the expression cannot be converted, an error occurs.

- If the variable does not have a data type, then one of the following actions occurs:
  - If the expression’s value is not null and has a data type of CHAR, BINARY, DATE, or TIME, then the variable is given the data type of the expression.
  - If the expression’s value is not null and of numeric type, then the variable is given a data type of DOUBLE. If the expression’s value is null, then the variable is given a data type of DOUBLE.
  - If the expression’s type is CHAR or BINARY, then the variable is given the length of the expression's value. If the expression's value cannot be determined at compile time (for example, for VARCHAR strings), the variable is given the default length of 200.
  - If the expression’s type is TIME or TIMESTAMP, then the variable is given the expression's precision.

- If an assignment statement is `a = b = 5`, then `b = 5` is an expression. If `b` is a value other than 5, then `b = 5` is evaluated to 0. Therefore, `a` is assigned a value of 0. The first equal sign (`=`) is an assignment operator and the second equal sign is a logical equality operator. For more information, see “Example 2: Using an Expression with Multiple Equals Signs” on page 696.

Note: DS2 supports using `eq` as well as the equal sign. For example, `x = y < z < w;` is equivalent to `x = y < z & z < w;`. Another example is that `a = b = c =d;` equates to `a = ((b = c) & (c = d));`.
Examples

**Example 1: Different Types of Expressions**
These assignment statements use different types of expressions.

- `name='Nagasaki';`
- `FullName='Mr. '||name;`
- `price=price+markup;`
- `declare int i;`
  
  `declare double d;`
  
  `declare character(200) c;`
  
  `i = 5;`
  
  `d = 1.2345;`
  
  `d = d + i;`
  
  `c = 'abc';`
  
  `c = d;`
  
  `c = '123' || '456';`
  
  `i = c;`

**Example 2: Using an Expression with Multiple Equals Signs**
The result of these assignment statements is `a=0`. The values of `b`, `c`, and `d` are not changed.

```sas
proc ds2;
data;
dcl double a b c d;
method init();
a = b = c = d = 5;
put _all_;
end;
enddata;
run;
quit;
```

“DS2 Type Conversions for Expression Operands” in *SAS Viya: DS2 Programmer’s Guide*

**BY Statement**
Controls the operation of a MERGE or SET statement in a DS2 program and sets up special grouping variables.

**Category:** Local

**Restriction:** The BY statement must immediately follow a MERGE or SET statement. The BY statement is optional when using a SET statement.

**Tip:** Trailing blanks are always ignored when combining tables with a SET or MERGE statement.
Syntax

**BY [DESCENDING] column… [DESCENDING] column;**

**Arguments**

**DESCENDING**

specifies that the tables are sorted in descending order by the variable that is specified. DESCENDING means largest to smallest numerically, or reverse alphabetical for character variables.

**Restriction**

You cannot use the DESCENDING option with tables that are indexed because indexes are always stored in ascending order.

**column(s)**

names each column by which the table is sorted. These columns are referred to as BY variables.

**Requirement**

If you designate a name literal as the BY variable in BY-group processing and you want to refer to the corresponding FIRST. or LAST. temporary variables, you must include the FIRST. or LAST. portion of the two-level variable name within single quotation marks.

For example:

```sas
data sedanTypes;
  method run();
  set cars;
  by 'Sedan Types'n;
  if first.'Sedan Types'n then type=1;
  end;
enddata;
run;
```

**Tip**

The table can be sorted by more than one column.

**Details**

**How DS2 Indicates the Beginning and End of a BY Group**

DS2 indicates the beginning and end of a BY group by creating two temporary variables for each BY variable: FIRST.\texttt{variable} and LAST.\texttt{variable}. The value of these variables is either 0 or 1. DS2 sets the value of FIRST.\texttt{variable} to 1 when it reads the first row in a BY group, and sets the value of LAST.\texttt{variable} to 1 when it reads the last row in a BY group. These temporary variables are available for DS2 programming but are not added to the result set.

For a complete explanation of how SAS processes grouped data and of how to prepare your data, see “Combining Tables” in *SAS Viya: DS2 Programmer’s Guide*.

**In a Data Program**

The BY statement applies only to the SET or MERGE statement that precedes it in a data program, and only one BY statement can accompany each of these statements in a data program. An error occurs if the BY statement appears anywhere else in the data program.

**Note:** The BY statement honors the linguistic collation of data that is sorted by using the SORT procedure with the SORTSEQ=LINGUISTIC option.
For more information, see “Combining Tables” in *SAS Viya: DS2 Programmer’s Guide*.

**Processing BY Groups**
SAS assigns the following values to FIRST.*variable* and LAST.*variable*:

- **FIRST.*variable*** has a value of 1 under the following conditions:
  - when the current row is the first row that is read from the table.
  - when the value of the current row BY variable differs from the value of that BY variable in the previous row.
  - **FIRST.*variable*** has a value of 1 for any preceding variable in the BY statement.
    
    In all other cases, **FIRST.*variable*** has a value of 0.

- **LAST.*variable*** has a value of 1 under the following conditions:
  - when the current row is the last row that is read from the table.
  - when the value of the current row BY variable differs from the value of that BY variable in the next row.
  - **LAST.*variable*** has a value of 1 for any preceding variable in the BY statement.
    
    In all other cases, **LAST.*variable*** has a value of 0.

**Examples**

**Example 1: Specifying One or More BY Variables**
- Observations are in ascending order of the variable DEPT:
  ```sas
  by dept;
  ```
  - Observations are in alphabetical (ascending) order by CITY and, within each value of CITY, in ascending order by ZIPCODE:
    ```sas
    by city zipcode;
    ```

**Example 2: Specifying Sort Order**
- Observations are in ascending order of SALESREP and, within each SALESREP value, in descending order of the values of JANSALES:
  ```sas
  by salesrep descending jansales;
  ```
  - Observations are in descending order of BEDROOMS, and, within each value of BEDROOMS, in descending order of PRICE:
    ```sas
    by descending bedrooms descending price;
    ```

**Example 3: Using a BY Statement When Combining Tables with a SET Statement**
The following example creates two tables and uses a SET statement to combine the tables using the common column.

```sas
data mrg01a(overwrite=yes);
  dcl varchar(10) common animal;
  method init();
    common='a'; animal='Ant'; output;
    common='b'; animal='Bird'; output;
    common='c'; animal='Cat'; output;
```
The following table is generated.
Example 4: Using a BY Statement When Combining Tables with a MERGE Statement

The following example creates two tables and uses a MERGE statement to combine the tables using the common column.

data mrg01a(overwrite=yes);
  dcl char(10) common animal;
  method init();
    common='a'; animal='Ant'; output;
    common='b'; animal='Bird'; output;
    common='c'; animal='Cat'; output;
    common='d'; animal='Dog'; output;
    common='e'; animal='Eagle'; output;
    common='f'; animal='Frog'; output;
  end;
enddata;
run;

data mrg01b(overwrite=yes);
  dcl char(10) common plant;
  method init();
    common='a'; plant='Apple'; output;
    common='b'; plant='Banana'; output;
    common='c'; plant='Coconut'; output;
    common='d'; plant='Dewberry'; output;
    common='e'; plant='Eggplant'; output;
    common='f'; plant='Fig'; output;
    common='g'; plant='Grapefruit'; output;
  end;
enddata;
run;
/*  match merge */
data;
   method run();
      merge mrg01a mrg01b; by common;
   end;
   enddata;
run;

The following table is generated.

<table>
<thead>
<tr>
<th>common</th>
<th>animal</th>
<th>plant</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Ant</td>
<td>Apple</td>
</tr>
<tr>
<td>b</td>
<td>Bird</td>
<td>Banana</td>
</tr>
<tr>
<td>c</td>
<td>Cat</td>
<td>Coconut</td>
</tr>
<tr>
<td>d</td>
<td>Dog</td>
<td>Dewberry</td>
</tr>
<tr>
<td>e</td>
<td>Eagle</td>
<td>Eggplant</td>
</tr>
<tr>
<td>f</td>
<td>Frog</td>
<td>Fig</td>
</tr>
<tr>
<td>g</td>
<td></td>
<td>Grapefruit</td>
</tr>
</tbody>
</table>

See Also

Statements:
- “MERGE Statement” on page 736
- “SET Statement” on page 770

CONTINUE Statement
Stop processing the current DO loop iteration and resumes with the next iteration.

Category: Local

Syntax
CONTINUE;

Without Arguments
The CONTINUE statement has no arguments. It resumes processing statements with the next iteration of the DO loop.
Details
The CONTINUE statement can appear only in the statement list of an iterative DO loop (for example, DO i=, DO WHILE, or DO UNTIL).

Comparisons
• The CONTINUE statement stops the processing of the current iteration of a DO statement and resumes program execution with the next iteration of the current DO statement.
• The LEAVE statement stops the processing of the current DO statement and resumes program execution outside of the current DO statement.

Example
This example illustrates the use of the CONTINUE statement. The DO loop iterates and prints the incremented value of ctr. When ctr is equal to 3, the CONTINUE statement causes execution to jump to the next iteration of the DO loop, and prevents ctr from printing.

```sas
data _null_;  
dcl int ctr;  
method init();  
do ctr = 1 to 5;  
   if ctr = 3 then continue;  
   put ctr;  
end;  
end;  
enddata;
```

The following lines are written to the SAS log.

```
1
2
4
5
```

Statements:
• “DO Statement” on page 716
• “LEAVE Statement” on page 734

DATA Statement

Begins a DS2 program and provides names for any output tables.

Category: Block
Alias: TABLE
Syntax

DATA [ <table-expression> ] [... <table-expression> ] ; 
... program-body ... 
[ ENDDATA ; ]

<table-expression>::=
  table (table-options)
  | _ROWSET_ (table-options)
  | _NULL_

Without Arguments

If you do not specify any table names with the DATA statement, then the DS2 program returns table rows to the client application and no tables are created.

Arguments

table

  specifies the name of the table. table can be one of these forms.
  • catalog.schema.table-name
  • schema.table-name
  • catalog.table-name
  • table-name

catalog

  is an implementation of the ANSI SQL standard for an SQL catalog, 
  which is a data container object that groups logically related 
  schemas. The catalog is the first-level (top) grouping mechanism in 
  a data organization hierarchy that is used along with a schema to 
  provide a means of qualifying names. A catalog is a metadata object 
  in a SAS Metadata Repository.

schema

  is an implementation of the ANSI SQL standard for an SQL 
  schema, which is a data container object that groups files such as 
  tables and views and other objects supported by a data source such 
  as stored procedures. The schema provides a grouping object that is 
  used along with a catalog to provide a means of qualifying names.

table-name

  is the name of the table.

Notes

  If the table name has a dot in it and you are accessing a CAS table, you 
  must enclose the table name in double quotation marks. Here is an 
  example.

  data mycaslib."tdlibref.foo";

  If you do not use quotation marks around the table and schema names, 
  DS2 stores them as uppercase and includes double quotation marks. 
  Table and schema names that are enclosed in quotation marks are used as 
  is. That is, they remain quoted and with the original casing in the 
  quotation marks. For example, in data mytable;, the table name is 
  stored as "MYTABLE" and in data "MyTable";, the table name is 
  stored as "MyTable". This is important if table and schema names in 
  your data source are case-sensitive.
Using the PRESCRIBE_TAB_NAMES=no option on your LIBNAME statement can cause unexpected results.

_ROWSET_
  specifies that the DATA statement should not create a table, but it should instead return table rows to the client application.

_NULL_
  specifies that the DATA statement should not create a table or return rows to the client application.

table-options
  specifies optional arguments that the DS2 program applies when it writes rows to the output table. For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

Tip  _NULL_ can be useful in debugging programs when using PUT statements.

Details

A DS2 program begins with the DATA statement and ends with the ENDDATA statement.

A DS2 program processes input data and produces output data. A DS2 program can run in two different ways: as a program and as a thread. When a DS2 program runs as a program, here are the results:

  - Input data can include both rows from database tables and rows from DS2 program threads.
  - Output data can be either database tables or rows that are returned to the client application.

When a DS2 program runs as a thread, here are the results:

  - Input data can include only rows from database tables, not other threads.
  - Output data includes the rows that are returned to the DS2 program that started the thread.

If you specify no table names in the DATA statement, or you specify the keyword _ROWSET_ , then the DS2 program returns table rows to the client application and no tables are created. If you specify no table names in the DATA statement, at least one global variable is required.

No rows are ever written to the _NULL_ table name. Therefore, if _NULL_ is the only table name present in the DATA statement, the DS2 program does not return any rows.

If any other table names are present, then the program creates a table for each table, and table rows will be written to those tables. For more information, see the “OUTPUT Statement” on page 747.

A warning is issued for tables with delimited column names that are submitted to data sources that are not case sensitive. Data sources that are not case-sensitive will remove the quotation marks and treat the column name as not delimited.

Comparisons

For a comparison between packages, DS2 programs, and threads, see “Block Statements” on page 690.
Examples

Example 1: Creating an Output Table
Use the DATA statement to create one or more output tables. You can use table options to customize the output table. The following DS2 program creates two output tables, EXAMPLE1 and EXAMPLE2. It uses the table option DROP to prevent the column IDNumber from being written to the EXAMPLE2 table.

```plaintext
data example1 example2 (drop=(IDnumber));
set sample;
...more statements...
enddata;
```

Example 2: When Not Creating a Table
Usually, the DATA statement specifies at least one table name to create an output table. Using the keyword _NULL_ as the table name causes the DS2 program to execute without writing rows to a table. This example writes to the log the value of NAME and ID for each row. An output table is not created.

```plaintext
data _null_;
set sample;
put Name ID;
enddata;
```

See Also

Statements:
- “OUTPUT Statement” on page 747
- “SET Statement” on page 770

DECLARE Statement
Declares one or more DS2 variables or temporary arrays.

Categories:
- Global
- Local

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. Array bounds must be contained by square brackets ([ ]).

Syntax

```
DECLARE [PRIVATE] { <data-type> <variable-list> [ <having-clause> ] } ;
```

< data-type > ::= 

- <exact-numeric-type> | <approximate-numeric-type> | <binary-string-type> | <string-type>
- | <date-type>

<exact-numeric-type> ::= 

- \{ INT | BIGINT | SMALLINT | TINYINT
- | DECIMAL [(precision [scale])] | NUMERIC [(precision [scale])] \}
<approximate-numeric-type> ::= { DOUBLE | DOUBLE PRECISION | FLOAT | REAL }

<string-type> ::= 
    NCHAR [ ( character-length ) ]
    | NVARCHAR [ ( character-length ) ]
    | CHAR [ ( character-length ) ] [ CHARACTER SET character-set-identifier ]
    | VARCHAR [ ( character-length ) ] [ CHARACTER SET character-set-identifier ]

<date-type> ::= 
    { TIME | TIMESTAMP } [ ( precision ) ] | DATE

<variable-list> ::= 
    { variable [ … variable ] }
    | { variable <array-declaration> [ variable … <array-declaration> ] } 

<array-declaration> ::= 
    \[ <array-bound> [ , … <array-bound> ] \]

<array-bound> ::= 
    { [dim-lower:] dim-upper} | { [dim-lower:] {DIM (a[, n]) | *}

<having-clause> ::= 
    HAVING <having-option> [ … <having-option> ]

<having-option> ::= 
    LABEL 'string' | n'string'
    | FORMAT format
    | INFORMAT format

Arguments

PRIVATE
specifies variables that can be accessed only from within the package.

INT | BIGINT | SMALLINT | TINYINT
specifies an integer variable or array.

Alias INTEGER for INT

See “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide

| DECIMAL[precision [, scale]] | NUMERIC[precision [, scale]]
specifies an exact numeric variable or array.

precision
specifies the maximum total number of decimal digits that can be stored, both to the left and to the right of the decimal point

Note Not all data sources can support a precision of 52 digits.
**scale**
specifies the maximum number of decimal digits that can be stored to the right of the decimal point

Range 0–precision

Note scale is less than or equal to precision.

See “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide

<table>
<thead>
<tr>
<th>DOUBLE</th>
<th>DOUBLE PRECISION</th>
<th>FLOAT</th>
<th>REAL</th>
</tr>
</thead>
</table>
specifies a floating-point variable or array.

See “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide

| BINARY (length) |
specifies a binary variable or array.

Requirement If you specify BINARY, you must also specify the length of the variable or array in bytes.

See “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide

| VARBINARY (length) |
specifies a varying-length binary variable or array.

 Alias BINARY VARYING

Requirement If you specify VARBINARY, you must also specify the length of the binary variable or array in bytes.

See “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide

| NCHAR | NVARCHAR | CHAR | VARCHAR |
specifies a character variable or array.

 Aliases NATIONAL CHARACTER, NATIONAL CHAR for NCHAR

NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING for NVARCHAR

CHARACTER for CHAR

CHARACTER VARYING for VARCHAR

See “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide

**character-length**
specifies the maximum number of characters that the string can hold for NCHAR, NVARCHAR, CHAR, and VARCHAR data types.

Default 8

Note
The number of bytes that character variables declared using CHAR use for storage depends on the session encoding. Those declared using any of the NCHAR variants have wider storage and can be used to represent character sets for which single-byte character storage is insufficient (for example, Unicode). If a session encoding requires multiple bytes per character (for
example, UTF-8), then CHAR and NCHAR are identical types and both use NCHAR.

**CHARACTER SET** character-set-identifier

specifies character set encoding information for CHAR and VARCHAR data types.

**Default**

Default encoding depends on your operating system and locale.

**Tip**

You can use a character string literal or a simple string for character set names. For example, you can specify "ibm-866" or 'ibm-866'.

**See**

For a complete list of character set encoding values, see “Character Sets for Encoding in NLS” in the *SAS Viya National Language Support: Reference Guide*.

**TIME**

specifies a time variable or array.

**TIMESTAMP**

specifies both a date and time variable or array.

**precision**

specifies the precision for a TIME or TIMESTAMP data type.

**Defaults**

0 for time

6 for timestamp

**Note**

If you are working with TIME and TIMESTAMP values in a data source other than SAS and you do not specify a precision, the default precision will always be the DS2 default precision of 0 for TIME and 6 for TIMESTAMP.

**DATE**

specifies a date variable or array.

**variable**

specifies the scalar variable or array name. You can specify one or more variables or arrays. However, variable can only be of the type specified in data-type. You can mix scalar and array variables of the same type.

**dim-lower and dim-upper**

specifies a positive or negative integer used to define the number and size of the array boundary.

**Tip**

If the lower bound of a dimension is not specified, then the lower bound defaults to 1.

**See**

“Temporary Array Variable Declaration” on page 710

**DIM(a[, n])**

specifies that the size of the upper bounds of the array is determined by the number of elements in a dimension of a previously declared array by using a DIM function call.

**a**

specifies the name of a previously declared array.
specifies the dimension, in a multidimensional array, for which you want to know the number of elements.

**Tip** If no \( n \) value is specified, the DIM function returns the number of elements in the first dimension of the array.

**Restriction** The DIM function is the only function that you can use to specify an upper array bounds. The DIM function cannot be used to specify the lower bound of a dimension.

**See** “DIM Function” on page 305

**LABEL 'string' | n'string'**

assigns a descriptive label to the variable or array. The label can be a CHAR literal (string) or NCHAR literal (nstring).

**See** “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide

**FORMAT format**

Associates any valid DS2 format with the variable or array.

**See** Chapter 6, “DS2 Formats,” on page 51

**INFORMAT informat**

Associates any valid SAS informat with the variable or array.

**See** Chapter 8, “DS2 Informats,” on page 681

**Details**

**Overview of the DECLARE Statement**

The DECLARE statement can be used to specify scalar variables and temporary arrays. More than one variable and array can be specified in a DECLARE statement. For example, the following DECLARE statement specifies two scalar variables named \( x \) and \( y \) and two temporary arrays named \( a \) and \( b \).

```plaintext
declare double a[10] x y b[20];
```

A DECLARE statement associates a data type with each variable in a variable list or an array. In the previous example, \( x, y, a, \) and \( b \) have a data type of DOUBLE.

In DS2, the DECLARE statement is also used for package and thread declarations. For more information about package and thread declaration, see the “DECLARE PACKAGE Statement” on page 712 and the “DECLARE THREAD Statement” on page 714.

By default, you receive a warning for any variable that is not declared. If you use a variable without declaring it, DS2 assigns the variable a data type (implicit declaration). The data type for an undeclared variable on the left side of an assignment statement is determined by the data type of the value on the right side of the assignment statement. However, you can use the DS2SCOND system option or the SCOND option on the DS2 procedure to control how DS2 handles an undeclared variable. You can use these options to require the declaration of all table columns and variables. If you specify DS2SCOND=ERROR or SCOND=ERROR, you must use a DECLARE statement for each column or variable. Declaration by assignment does not occur. For more information, see the “DS2SCOND= System Option” on page 800, “DS2” in SAS Viya
Scalar Variable Declarations

Scalar declarations can be used for numeric, character, date, or time data types. You can specify the maximum number of characters a string can contain. Here is an example.

```sql
declare char(200) s;
```

DS2 imposes no limit on this number, but, in practice, there might be some restriction due to machine limitation. The default length or precision for a particular data type depends on the data source.

For fixed-length character variables, the maximum length is used as the initial (and only) allocation for the string memory. For varying character strings, memory is allocated on an as-needed basis up to the maximum length. There might be an execution-time advantage to using varying character variables because they do not require blank-padding after an operation as fixed-length character variables do.

The number of bytes that character variables declared using CHAR use for storage depends on the session encoding. Those declared using any of the NCHAR variants have wider storage and can be used to represent character sets for which single-byte character storage is insufficient (for example, Unicode). If a session encoding requires multiple bytes per character (for example, UTF-8), then CHAR and NCHAR are identical types and both use NCHAR.

An error occurs if a variable is declared more than once in the same scope, and the declarations are not identical.

If you use a variable without declaring it, it receives the type of the value assigned to it. If no value is assigned, DS2 assigns the variable as type DOUBLE and assigns the value as a missing or null value.

Temporary Array Variable Declaration

You use the DECLARE statement to create a temporary array. The elements of a temporary array are temporary in that they are not located in the PDV and therefore do not appear in the result table.

Array declarations are similar to scalar declarations. In addition to the data type and name you also specify the number and size of the array bounds.

Array bounds are given as a signed integer pair, $[l,h]$, where $l$ represents the lowest index for the given bound and $h$ represents the highest index for the given bound. An error is returned if $h<l$. If you specify an array bound with only one integer, then that integer is interpreted as the highest index. The default lowest index is 1.

This example declares an array $a$ of type DOUBLE. Five elements are indexed from 1 to 5.

```sql
declare double a[5];
```

Multiple bounds (or dimensions) are specified using comma separators. This example declares a two-dimensional character array $b$ with 5 elements in the first dimension and 10 elements in the second dimension for a total of 50 elements in the array.

```sql
declare char b[5,10];
```

This example declares an array $c$ with two elements. The array is indexed with a lower bound of 0 and an upper bound of 1.

```sql
declare int c[0:1];
```
Temporary arrays exist only for the duration of the DS2 program. For more information, see “DS2 Arrays” in SAS Viya: DS2 Programmer’s Guide and “Temporary Arrays” in SAS Viya: DS2 Programmer’s Guide.

**HAVING Clause**

You can associate label, format, and informat attributes with one or more scalar variables or an array. The HAVING clause functions the same as the FORMAT, INFORMAT, and LABEL statements in Base SAS. However, in DS2, the attributes must be specified in the declaration statement of the variable or array.

For more information about how DS2 handles formats and informats, see “Using Formats in DS2” on page 54 and “How Informats Are Used in DS2” on page 682.

For more information about arrays and the HAVING clause, see “Declaring Arrays with a HAVING Clause” in SAS Viya: DS2 Programmer’s Guide.

**Note:** If variables are declared with a HAVING clause in a thread program and the variables are redeclared in a data program with a HAVING clause, the HAVING clause in the data program is used instead of the HAVING clause in the thread program. If there is no HAVING clause in the DECLARE statement in the data program, the HAVING clause in the thread program is not used.

**Examples**

**Example 1: Declaring Variables**

The following examples illustrate the DECLARE statement.

- declare bigint b2 b3;
- declare double d;
- declare char(200) c1 c2;
- declare varchar vc;
- declare nchar(100) wc;
- declare time(4) tm;
- declare date dt;
- declare varbinary(10) b;
- dcl double x having label 'Amount' format ieee8.2;
- dcl char(10) y having label 'varchar' format $quote.;

**Example 2: Declaring Temporary Arrays**

The following examples illustrate the DECLARE statement for temporary arrays.

- declare double darr[-5:4];
- declare char carr[1:2, 0:3];
- declare int iarr[10] having format octal7.;

**Example 3: Temporary Array Dimensions**

The following table contains examples of statements that specify temporary arrays and the dimensions of those arrays.
<table>
<thead>
<tr>
<th>Statement</th>
<th>Number of Dimensions</th>
<th>Range of Each Dimension</th>
<th>Number of Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>declare double a[100];</td>
<td>1</td>
<td>1:100</td>
<td>100</td>
</tr>
<tr>
<td>declare double a[10, 20, 30];</td>
<td>3</td>
<td>1:10 1:20 1:30</td>
<td>10x20x30 = 6000</td>
</tr>
<tr>
<td>declare double a[5:10];</td>
<td>1</td>
<td>5:10</td>
<td>6</td>
</tr>
<tr>
<td>declare double a[-3:3, 5, 7:9, 10];</td>
<td>4</td>
<td>-3:3 1:5 7:9 1:10</td>
<td>7x5x3x10 = 1050</td>
</tr>
<tr>
<td>declare double a[DIM(u)];</td>
<td>1</td>
<td>1:DIM(u)</td>
<td>DIM(u)</td>
</tr>
<tr>
<td>declare double a[DIM(u,1), 0:DIM(u,2)];</td>
<td>2</td>
<td>1:DIM(u,1) 0:DIM(u,2)</td>
<td>DIM(u,1)x(DIM(u,2)+1)</td>
</tr>
</tbody>
</table>

- “VARARRAY Statement” on page 784

System Options:

- “DS2SCOND= System Option” on page 800

---

**DECLARE PACKAGE Statement**

Creates a package variable and gives you the option to create an instance of the package.

**Category:** Local

**See:** The DECLARE PACKAGE statement for the predefined DS2 packages is documented in the reference section for each package.

**Syntax**

```plaintext
DECLARE PACKAGE package [(table-options)] variable [(constructor-arguments)] [...variable [(constructor-arguments)]];  
```

**Arguments**

- `package`
  
specifies the package name. `package` can be one of these forms.
• **catalog.schema.package**
  • **schema.package**
  • **catalog.package**
  • **package**

**catalog**

is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names. A catalog is a metadata object in a SAS Metadata Repository.

**schema**

is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

**package**

is the name of the package.

**Requirements**

The package name must match the name of a package created in a PACKAGE statement or be a predefined DS2 package, or an error will occur.

Package naming conventions are based on the data source. For more information, see the documentation for your data source.

**See**

“PACKAGE Statement” on page 753

**table-options**

specifies optional arguments that the DS2 program applies when it creates a package. For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

**variable**

specifies a name that can reference an instance of the package.

**constructor-arguments**

specifies any constructor arguments that are passed to the constructor of the package instance.

**Details**

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

An instance of a package can be constructed either with the _NEW_ operator or with the DECLARE PACKAGE statement. The DECLARE PACKAGE statement with constructor arguments creates a package variable and constructs a package instance:
declare package complex c();

The above statement is equivalent to the following two statements:

```
declare package complex c;
c = _new_ complex();
```

1. Creates a package COMPLEX variable `c` that is a null package reference.
2. Constructs a package COMPLEX instance and sets package variable `c` to reference the constructed package instance.

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

### DECLARE THREAD Statement

Creates an instance of a thread.

**Category:** Local

**Syntax**

```
DECLARE THREAD thread [(table-options)] instance( argument ) [… instance (argument)];
```

**Arguments**

- `thread`
  - specifies the thread name. `thread` can be one of these forms.
    - `catalog.schema.thread`
    - `schema.thread`
• catalog.thread
• thread

catalog
is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names. A catalog is a metadata object in a SAS Metadata Repository.

schema
is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

thread
is the name of the thread.

Requirements
The thread name must match the name of a thread created in a THREAD statement, or an error will occur.

Thread naming conventions are based on the data source. For more information, see the documentation for your data source.

See

table-options
specifies optional arguments that the DS2 program applies when it creates a thread. For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

instance
specifies a name that identifies an instance of the thread.

argument
specifies arguments used with instance.

Details
When a thread is declared, the variable representing the thread can be considered an instance of the thread. This means that two different thread variables represent two completely separate copies of a thread.

Thread variables can appear only in global scope, otherwise an error will be returned. If the thread named in the DECLARE statement does not exist, an error will be returned.

In this example, the thread work.t is instantiated and named thread_name:

declare thread work.t thread_name;

Once an instance of a thread has been created, you can use it in a SET FROM statement. For more information, see the “THREAD Statement” on page 780. For more information about threads, see “Overview of Threaded Processing” in SAS Viya: DS2 Programmer’s Guide.

Note: The SAS In-Database Code Accelerator enables you to publish a thread program to the database and execute that thread program in parallel inside the database. For
more information about using the SAS In-Database Code Accelerator, see *SAS In-

See Also

Statements:

- “SET FROM Statement” on page 774
- “THREAD Statement” on page 780

---

**DO Statement**

Specifies a group of statements to be executed as a unit.

**Category:** Local

### Syntax

```

statement-list...

END [end-label] ;

<index-variable-clause>::=

  start [TO stop [BY increment]]

<conditional-clause>::=

  WHILE ( expression ) | UNTIL ( expression )
```

### Without Arguments

The DO statement without the index variable argument and clauses is the simplest form of DO group processing. The statements between the DO and END statements are called a **DO group**. In a simple DO loop, statements in the DO group are executed one time only. You can nest DO statements within DO groups. A simple DO statement is often used within IF-THEN/ELSE statements to designate a group of statements to be executed depending on whether the IF condition is true or false.

### Arguments

- **index-variable**
  
  names a variable that is used as an index counter for the loop.

  **CAUTION:**
  
  Avoid changing the index variable within the DO group. If you modify the index variable within the iterative DO group, you might cause infinite looping.

- **Requirement**
  
  The variable must resolve to a numeric value.

- **Tips**
  
  If the variable is not declared as a local variable, it will end up in the table that is being created unless it is explicitly dropped. For more
information about local variables, see “Scope of DS2 Identifiers” in SAS Viya: DS2 Programmer’s Guide.

The index variable can be a THIS expression. For more information, see “THIS Expression” in SAS Viya: DS2 Programmer’s Guide.

**statement-list**

specifies any valid DS2 statements.

**end-label**

The END statement closes the DO loop. The optional *end-label* argument specifies an identifier. This label, created by using the Labels statement, must match the label immediately preceding the DO statement, or an error will occur. For more information, see the “Labels Statement” on page 733.

### Clauses

**< index-variable-clause >**

specifies a numeric scalar expression or series of expressions that determines the number of times that the DO group will be executed.

**start**

specifies the initial value of the index variable. *start* can be any expression that resolves to a numeric value.

When it is used without TO *stop*, the value of *start* can be a series of items expressed in this form:

```
item-1 <, ...item-n>
```

The items can be a number or an expression that yields a number. The DO group is executed once for each value in the list. If a WHILE condition is added, it applies only to the item that it immediately follows.

**Requirement**

When it is used with TO *stop*, *start* must be a number or an expression that yields a number.

**Notes**

The DO group is executed first with *index-variable* equal to *start*. The value of *start* is evaluated before the first execution of the loop.

If *index-variable* is an integral type and *start* is floating-point type, the value of *start* is converted to INTEGER type with possible loss of precision.

**TO *stop***

specifies the ending value of the index variable. *stop* can be any expression that resolves to a numeric value.

**Notes**

Execution continues based on the value of *increment* until one of the following conditions is met: the value of *index-variable* passes the value of *stop*, until a WHILE or UNTIL clause that is specified in the DO statement is satisfied, or until a statement in the DO group directs execution out of the loop. The value of *stop* is evaluated before the first execution of the loop.

If *index-variable* is an integral type and *stop* is floating-point type, the value of *stop* is converted to INTEGER type with possible loss of precision.
precision. Any change to stop made within the DO group does not affect the number of iterations.

**BY increment**
specifies a positive or negative value that controls the incrementing or decrementing of index-variable. increment can be any expression that resolves to a numeric value.

**Notes**
The value of increment is evaluated before the execution of the loop. When increment is positive, start must be the lower bound and stop must be the upper bound of the loop. If increment is negative, start must be the upper bound and stop must be the lower bound of the loop. If no increment is specified, the index variable is incremented by 1.

If index-variable is an integral type and increment is floating-point type, the value of increment is converted to INTEGER type with possible loss of precision. Any change to the increment made within the DO group does not affect the number of iterations.

**<conditional-clause>**
specifies a clause that returns true or false.

**WHILE ( expression )**
causes DO group statements to execute repetitively while a condition is true.

**Note**
A WHILE clause is evaluated before each execution of the loop, so that the statements inside the group are executed repetitively while the expression is true. If the expression is false the first time it is evaluated, the DO loop does not iterate even once.

**See**
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**UNTIL ( expression )**
causes DO group statements to execute repetitively until a condition is true.

**Note**
An UNTIL clause is evaluated after each execution of the loop, so that the statements inside the group are executed repetitively until the expression is true. The DO loop always iterates at least once.

**See**
“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

**Details**
The DO statement allows a group of statements to be executed as a unit. If iterative or conditional clauses are specified, this group of statements can be executed multiple times.

DO loop iteration with an integral index variable is performed using INTEGER arithmetic. Otherwise, DO loop iteration is performed using DOUBLE arithmetic. Because the representation of the DOUBLE type is a binary number, the accumulation of an imprecise number can introduce enough error to prevent execution of the DO loop the expected number of times. For example, this loop might not execute the expected number of times.

```do i = 0.001 to 10 by 0.001;
```

A DO statement defines a scoping block so that any variables declared in the DO statement have scope local to the scope of the DO statement.
There are three forms of the DO statement:

- The DO statement without clauses is the simplest form of DO-group processing. In this form, a group of statements is executed as a unit, usually as a part of IF-THEN/ELSE statements.
- The iterative DO statement can execute statements between DO and END statements repetitively, based on the values of an index variable.
- The DO statement can execute statements in a DO loop repetitively while a conditional clause is true, checking the condition before each iteration of the DO loop. The DO UNTIL form evaluates the condition at the bottom of the loop; the DO WHILE form evaluates the condition at the top of the loop.

The final value of the loop is, at most, the specified TO value. For example, `do i = 1 to 10` executes the loop 10 times. This is different from other languages (for example, C, where the last iteration is less than the TO value).

The CONTINUE statement can be used within the DO group to cause execution to immediately continue with the next iteration of the DO statement.

The LEAVE statement can be used within the DO statement to transfer execution to either the statement immediately following a specified target DO statement or the current DO statement.

**Examples**

**Example 1: DO Statement with No Clauses**

```plaintext
do;
  dcl int i j;
  i = 2;
  j = i + 5
end;
```

**Example 2: DO with an Index Variable Clause**

- `do j = 1 to 10 by 2;
  i + j;
end;`
- `do k = 11 to 0 by -3;
  i + k;
end;`
- `x = -2;
y = -1;
do k = 11 to 0 by x + y;
dcl int i;
if k < 5 then i = k;
else
  i = k - 1;
end;
- `dcl double i;
do i = 0 to 5 by 0.5;
  put i=;
  /* the values output are */
  /* 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5 */
end;`
Example 3: DO with an Index Variable Clause Containing a Series

dcl int i;
do i = 0 to 10 by 3, 6, 7, 8;
  put i=;
  /* the values output are*/
  /* 0, 3, 6, 9, 6, 7, 8 */
end;

Example 4: DO Statement with a WHILE Clause

k = 1;
do while(k <= 5);
  k = k + 1;
end;

Example 5: DO Statement with Both an Index Variable and a WHILE Clause

j = -2;
do k = 1 to 10 by 2 while (j <= 0);
  j = j + 1;
end;

Example 6: DO Statement with an UNTIL Clause

k = 1;
do until(k > 6);
  k = k + 1;
end;

Statements:
- “CONTINUE Statement” on page 701
- “Labels Statement” on page 733
- “LEAVE Statement” on page 734

DROP Statement

Excludes columns from output tables.

Category: Global

Note: This statement cannot be used within a method.

Syntax

DROP column-list | vararray;

Arguments

column-list
  specifies the name of one or more columns to omit from the output tables.
Restriction
Numbered range lists in the format \textit{col1–coln} are not supported.

\texttt{vararray}

specifies the name of a variable array.

See “VARARRAY Statement” on page 784

Details

The DROP statement applies to all the tables that are created within the same DS2 program and can appear only in the global statements section of a data, thread, or package program. The columns in the DROP statement are available for processing in the DS2 program. If no DROP or KEEP statement appears, all tables that are created in the DS2 program contain all columns. Do not use both DROP and KEEP statements within the same DS2 program.

Comparisons

• The DROP statement applies to all output tables that are named in the DATA statement. To exclude columns from some tables but not from others, use the \texttt{DROP=} table option in the DATA statement.

• The KEEP statement is a parallel statement that specifies a list of columns to write to output tables. Use the KEEP statement instead of the DROP statement if the number of columns to include is significantly smaller than the number to omit.

• The KEEP and DROP statements select columns to include in or exclude from output tables. The subsetting IF statement selects rows.

Example

• These examples show the correct syntax for listing columns with the DROP statement:
   - drop time shift batchnum;
   - drop grade1 grade2 grade3 grade4;

• In this example, the columns PURCHASE and REPAIR are used in processing but are not written to the output table INVENTORY:

   \begin{verbatim}
   data inventry;
      drop purchase repair;
      method run();
      set table-specification;
      totcost=sum(purchase,repair);
   end;
   enddata;
   \end{verbatim}

• In this example, the first three variables in variable array \texttt{x} are dropped from the output.

   \begin{verbatim}
   /* drop x1, x2, x3 */
   proc ds2;
   data mytest;
      vararray double x[10];
      drop x1-x3;
      method init();
      do i = 1 to 10;
   \end{verbatim}
\[ x[i] = i; \]
end;
output;
end;
enddata;
run;
quit;

Table Options:
- “DROP= Table Option” on page 813

DROP PACKAGE Statement

Deletes a DS2 package.

**Category:** Global

**Restriction:** This statement must be used outside of any other programming block. Programming blocks are delimited by the DATA...ENDDATA, THREAD...ENDTHREAD, or PACKAGE...ENDPACKAGE statements.

**Syntax**

DROP PACKAGE `package` [(`table-options`)];
RUN;

**Arguments**

`package`

specifies the name of the package to be deleted.

`table-options`

specifies optional arguments that the DS2 program applies when it deletes a package. For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

**Details**

The DROP PACKAGE statement drops, or deletes, the table that contains the code for the specified DS2 package. The table must have been previously created with a PACKAGE statement.

**Note:** The RUN statement is required after the DROP PACKAGE statement.

**Example**

These examples show the syntax for dropping a DS2 package:
drop package mypkg;
run;
drop package mypkg (pw='n1234');
run;

See Also

Statements:
• “PACKAGE Statement” on page 753

DROP THREAD Statement

Deletes a DS2 program thread.

Category: Global

Restriction: This statement must be used outside of any other programming block. Programming blocks are delimited by the DATA...ENDDATA, THREAD...ENDTHREAD, or PACKAGE...ENDPACKAGE statements.

Syntax

DROP THREAD thread [(table-options)];

Arguments

thread
 specifies the name of the thread to be deleted.

table-options
 specifies optional arguments that the DS2 program applies when it deletes a thread. For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

Details

The DROP THREAD statement drops, or deletes, the table that contains the code for the specified DS2 thread. The table must have been previously created with a THREAD statement.

Example

These examples show the syntax for dropping a DS2 program thread:
drop thread mythread;
drop thread mythread (pw='n1234');

See Also

Statements:
• “THREAD Statement” on page 780
DS2_OPTIONS Statement

Specifies or changes the default behavior of a DS2 program.

Requirement: The DS2_OPTIONS statement must appear at the top level of the DS2 program and applies only to the next DATA, PACKAGE, or THREAD statement.

Syntax

```
DS2_OPTIONS option(s);
```

Arguments

`option(s)` specifies one or more DS2 options. `option(s)` can be one of the following values:

- **DIVBYZERO=ERROR | IGNORE**
  specifies how DS2 processes a division by zero operation.
  - **ERROR**
    halts row processing and writes an error to the SAS log.
  - **IGNORE**
    writes a missing or null value to the result set. No message is written to the SAS log.

  Default: **ERROR**

- **MISSING_NOTE**
  writes a note to the SAS log when an invalid function argument generates a missing value.

  Default: An error message is written to the SAS log when an invalid function argument generates a missing value.

- **SAS**
  specifies that nonexistent values are processed as SAS missing values. This option overrides the ANSIMODE system or DS2 procedure option.

  Default: By default, DS2 processes nonexistent values as SAS missing values.

  Notes: You can also specify ANSIMODE in the PROC DS2 statement. For more information, see “PROC DS2 Statement” in SAS Viya Data Management and Utility Procedures Guide.

- **SCOND**
  specifies the level of messages that is displayed in the SAS log for the DS2 variable declaration strict mode, which requires that every variable must be declared in the DS2 program. For more information about the DS2 variable declaration strict mode, see “Variable Declaration” in SAS Viya: DS2 Programmer’s Guide.
WARNING
writes warning messages to the SAS log.

NONE
no messages are written to the SAS log.

NOTE
writes notes to the SAS log.

ERROR
writes error messages to the SAS log.

Default The default is determined by the DS2SCOND= system option. The default for DS2SCOND= is WARNING. For more information, see “DS2SCOND= System Option” on page 800.

Note You can also specify SCOND in the PROC DS2 statement. For more information, see “PROC DS2 Statement” in SAS Viya Data Management and Utility Procedures Guide.

TRACE
provides a trace of what statements are executed.

Restriction This option is valid only when using SAS In-Database Code Accelerator.

Requirement You must have Write permission to the current directory.

Note Because this option creates a trace of every statement that is executed, there could be a significant performance impact.

TYPEWARN
prints a warning to the SAS log when an implicit type conversion occurs.

Example
Here are some examples:

ds2_options typewarn trace;
ds2_options scond=error;
ds2_options divbyzero=ignore;

ENDDATA Statement
Marks the end of a DATA statement.

Category: Block
Alias: ENDTABLE

Syntax
ENDDATA;
Details

A DS2 program can have multiple package subprograms followed by an optional data program. The following restrictions apply:

• There can be only one data program and the data program must be the last subprogram.

• The ENDPACKAGE, ENDTREAD, or ENDDATA statements are optional for the last subprogram of the DS2 program. These statements are required for all other subprograms.

See Also

Statements:

• “DATA Statement” on page 702

ENDPACKAGE Statement

Marks the end of a PACKAGE statement.

Category: Block

Syntax

ENDPACKAGE;

Details

A DS2 program can have multiple subprograms followed by an optional data program. The following restrictions apply:

• There can be only one data program and the data program must be the last subprogram.

• The ENDPACKAGE, ENDTREAD, or ENDDATA statements are optional for the last subprogram of the DS2 program. These statements are required for all other subprograms.

See Also

Statements:

• “PACKAGE Statement” on page 753

ENDTHREAD Statement

Marks the end of a THREAD statement.

Category: Block
Syntax
ENDTHREAD;

Details
A DS2 program can have multiple thread subprograms followed by an optional data program. The following restrictions apply:

• There can be only one data program and the data program must be the last subprogram.

• The ENDPACKAGE, ENDTTHREAD, or ENDDATA statements are optional for the last subprogram of the DS2 program. These statements are required for all other subprograms.

See Also

Statements:
• “THREAD Statement” on page 780

FORWARD Statement

Indicates that the method definition follows the method expression.

Category: Global

Syntax
FORWARD method [ ...method ];

Arguments
method
specifies the name of the method to be defined.

Details
When a method definition appears after any method expression that refers to it, a FORWARD statement for the method must be declared before the method expression. Otherwise, the DS2 compiler cannot determine whether the method expression refers to a method.

Example

• In this example, the D method is called inside the RUN method. Because the D method is defined after it is called, a FORWARD statement must be specified before the D method is called.

  forward d;
  method run();
      d = d();
      d = d(100);
  end;
method d() returns double;
    return 99;
end;
method d(int y) returns int;
    return 100 + y;
end;

• This example creates a user-defined method, SIN, that masks the system function SIN. The user method calls the system function SIN.

forward sin;
method run()
    d = sin(3.14159/2);
    put 'd=' d;
end;
method sin(double x) returns double;
    return system.sin(x);
end;

GOTO Statement

Transfers execution immediately to a labeled statement.

Category: Local

Syntax

GOTO label;

Arguments

label
specifies a statement label that identifies the GOTO destination.

Details

The destination label for the GOTO statement must be within the same DS2 method. You must specify the label argument or an error will occur. Statement labels are defined by using the Labels statement.

Comparisons

GOTO statements can often be replaced by DO-END and IF-THEN/ELSE programming logic.

Example

In this example, when x = 2, program execution transfers to the DONE label.

method run()
    x = 1;
    do;
        if x=2 then goto done;
        put x;
        x+1;
end;
done:
   put x;
end;

Statements:

• “DO Statement” on page 716
• “Labels Statement” on page 733
• “LEAVE Statement” on page 734

IF Statement, Subsetting

Continues processing only those rows that meet the condition.

Category: Local

Syntax

IF expression;

Arguments

expression

is any valid expression that evaluates to true or false.

Details

The expression in a subsetting IF statement is evaluated to produce a result that is either a nonzero value or zero. A nonzero value causes the expression to be true; a result of zero causes the expression to be false.

The subsetting IF statement is equivalent to this IF-THEN statement:

if not (expression)
   then return;

If expression is true, DS2 will continue to execute statements in the program.

Note: In logical operations, including the subsetting IF statement, a SAS missing value and a null value evaluate to zero (or false).

Comparisons

Use the IF-THEN/ELSE statement to process statements when both true and false conditions are present or when more processing is required before values are generated.

See Also

Statements:
IF-THEN/ELSE Statement

Executes a statement for rows that meet specific conditions.

**Category:** Local

**Syntax**

\[
\text{IF expression THEN statement;} \\
\text{[ ELSE statement ;]}
\]

**Arguments**

*expression* is any valid expression that evaluates to true or false and is a required argument.

See “DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

*statement* can be any executable statement or DO group.

**Details**

The expression in an IF-THEN statement is evaluated to produce a result that is either a nonzero value or zero. A nonzero value causes the expression to be true; a result of zero causes the expression to be false.

**Note:** In logical operations, including the IF-THEN/ELSE statement, a SAS missing value and a null value evaluate to zero (or false). To check for a null value in an IF-THEN-ELSE statement, you must use the NULL function as shown in this example.

```sas
method init () ;
x=null;
if (null(x)) then
  put 'null';
else
  put 'not null';
end;
```

If the conditions that are specified in the IF clause are met, the IF-THEN statement executes a statement. An optional ELSE statement gives an alternative action if the THEN clause is not executed. The ELSE statement, if used, must immediately follow the IF-THEN statement.

Using IF-THEN statements *without* the ELSE statement causes all IF-THEN statements to be evaluated. If the IF clause is true, the statement after THEN is executed, otherwise the statement after ELSE is executed.

**Note:** For greater efficiency, construct your IF-THEN/ELSE statement with conditions of decreasing probability.

**Note:** You can use an IF expression to select between two values based on whether a conditional evaluates to true or false. In addition, IF expressions can be nested to
select between many values for a multi-way decision. For more information, see “IF Expression” in SAS Viya: DS2 Programmer’s Guide.

Comparisons

- Use a SELECT expression rather than a series of IF-THEN statements when you have a long series of mutually exclusive conditions. The SELECT expression is evaluated only once, which could result in improved performance.

- Use subsetting IF statements, without a THEN clause, to continue processing only those expressions that evaluate to nonzero values when the condition indicates that no more processing is required and no output is to be produced.

Example

These examples illustrate the IF-THEN/ELSE statement.

- if a = b then
d = e;
else
d = f;

- if status='OK' and type=3 then count+1;

- if x=0 then
  if y ne 0 then put 'X ZERO, Y NONZERO';
  else put 'X ZERO, Y ZERO';
  else put 'X NONZERO';

- if answer=9 then
  do;
    answer=.;
    put 'INVALID ANSWER FOR ' id=;
  end;
else
  do;
    answer=answer10;
    valid+1;
  end;

See Also

Statements:

- “IF Statement, Subsetting” on page 729

KEEP Statement

Includes columns in output tables.

Category: Global

Note: This statement cannot be used within a method.
Syntax

```
KEEP column-list | vararray;
```

Arguments

column-list

specifies the names of one or more columns to write to the output table.

Restriction

Numbered range lists in the format `col1–coln` are not supported.

vararray

specifies the name of a variable array.

See “VARARRAY Statement” on page 784

Details

The KEEP statement specifies that all columns in the column list should be included in the creation of output rows. When the KEEP statement is specified, all columns that are not included in the KEEP statement are dropped from the output rows. If no DROP or KEEP statement appears, all tables that are created in the DS2 program contain all columns. Do not use both DROP and KEEP statements within the same DS2 program.

Comparisons

• The KEEP statement applies to all output tables that are named in the DATA statement. To write different columns to different tables, you must use the KEEP= table option.

• The DROP statement is a parallel statement that specifies columns to omit from the output table.

• The KEEP and DROP statements select columns to include in or exclude from output tables. The subsetting IF statement selects rows.

• Do not confuse the KEEP statement with the RETAIN statement. The RETAIN statement holds a row value in a column from one iteration of the DS2 RUN method to the next iteration. The KEEP statement does not affect the row values, but specifies only which columns to include in any output tables.

Examples

Example 1

This example uses the KEEP statement to include only the columns NAME and AVG in the output table.

```
data;
  keep name avg;
  method run();
    set table-specification;
  end;
enddata;
```

Example 2

In this example, the first three variables in variable array x are kept in the output.
/* keep x1, x2, x3 */
proc ds2;
data mytest;
  vararray double x[10];
  keep x1-x3;
  method init();
    do i = 1 to 10;
      x[i] = i;
    end;
    output;
  end;
enddata;
run;
quit;

See Also

Statements:
- “DROP Statement” on page 720

Table Options:
- “KEEP= Table Option” on page 821

Labels Statement
Identifies a statement that is referred to by another statement.

Syntax

\[ label: \text{statement}; \ldots \text{statement} \];

Arguments

- **label** specifies any identifier, which is followed by a colon (:). You must specify the label argument.
- **statement** specifies any executable statement, including a null statement (;). You must specify the statement argument.

Details

A label associates an identifier with a given statement so that the statement can be referred to by other statements, such as GOTO and LEAVE. You can have multiple labels for a statement.
Comparisons

The LABEL attribute of the DECLARE statement's HAVING clause assigns a descriptive label to a column. A statement label identifies a statement or group of statements that are referred to in the same DS2 program by another statement, such as GOTO or LEAVE.

Example

- restock:
  - if x > 1 then
    - y = 3;
  - else
    - y = 5;
- label1:
  - label2:
    - do i = 1 to 3;
    - j = j * i;
    - end;

See Also

Statements:
- “GOTO Statement” on page 728
- “LEAVE Statement” on page 734

LEAVE Statement

Stops processing the current DO loop and transfers execution to either the statement following the current DO statement, or a labeled DO statement that encloses the current DO statement.

Category: Local

Syntax

LEAVE [ identifier ];

Without Arguments

The LEAVE statement stops the processing of the current DO statement and resumes processing with the next statement following the current DO statement.

Arguments

identifier
- label associated with the target DO statement.

Details

You can use the LEAVE statement to exit a DO loop prematurely. You can use the LEAVE statement either on its own or use it based on a condition (for example, in conjunction with an IF statement). If the LEAVE statement is not followed by an
identifier, then the target is the DO statement immediately enclosing the LEAVE statement. If the LEAVE statement is followed by an identifier, then the target is the DO statement with the label specified by the identifier. The target DO statement must enclose the current DO statement. An error occurs if the identifier specifies a statement other than a DO statement, or a DO statement that does not enclose the current DO statement. An error also occurs if the specified label does not exist.

Comparisons

- The LEAVE statement stops the processing of the current DO statement and resumes program execution outside of the current DO statement.
- The CONTINUE statement stops the processing of the current iteration of a DO statement and resumes program execution with the next iteration of the current DO statement.

Examples

Example 1: LEAVE Statement without an Identifier
This example illustrates the LEAVE statement without an identifier.

data _null_; 
  dcl int i; 
  method init(); 
    do i = 1 to 10; 
      if i > 4 then leave; 
      put i; 
    end; 
  end; 
enddata;

The following lines are written to the SAS log.

Example 2: LEAVE Statement with an Identifier
This example illustrates the LEAVE statement with an identifier.

data _null_; 
  dcl int sum i j k ; 
  method init(); 
    lab1: do i = 1 to 5; 
      sum + 1; 
    lab2: do j = 1 to 3; 
      sum + 1; 
      do k = 1 to 3; 
        put sum i j k; 
        sum + 1; 
        if j = 2 then 
          leave lab2; 
        if i = 2 then 
          leave lab1; 
        if k = 2 then
leave;
end;
end;
end;
end;
edndata;
The following lines are written to the SAS log.

```
2 1 1 1
3 1 1 2
5 1 2 1
8 2 1 1
```

See Also

Statements:
- “CONTINUE Statement” on page 701
- “DO Statement” on page 716

MERGE Statement
Joins rows from two or more tables into a single row.

**Category:** Local

**Restriction:** Tables that are in SPD Engine or HDMD format do not support the MERGE statement.

**Requirement:** The MERGE statement must be followed by a BY statement.

**Interactions:** The MERGE statement is allowed when you are using the SAS In-Database Code Accelerator. However, if you are using the SAS In-Database Code Accelerator for Hadoop, Hive .13 or later is required.

Setting the PROC DS2 BYPARTITION=NO option does not affect a MERGE statement when you are using in-database processing.

**Note:** The variables that are read using the MERGE statement are set to either a missing or null value.

**Tip:** The width of the resulting column is determined by the largest width across all the tables in a single SET statement. Trailing blanks are irrelevant to the MERGE statement.

**Syntax**

```
MERGE <table-reference> <table-reference> […] <table-reference>];
<table-reference>::=
    { table [ (table-option(s)) ] }
```

**Arguments**

- **table**
  
  specifies the name of the table. *table* can be one of these forms.
catalog is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names. A catalog is a metadata object in a SAS Metadata Repository.

schema is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

table-name is the name of the table.

Notes
If the table name has a dot in it and you are accessing a CAS table, you must enclose the table name in double quotation marks. Here is an example.

```mergesql
merge mycaslib."tdlibref.foo" mycaslib."orlibref.foo";
```

If you do not use quotation marks around the table and schema names, DS2 stores them as uppercase and includes double quotation marks. Table and schema names that are enclosed in quotation marks are used as is. That is, they remain quoted and with the original casing in the quotation marks. For example, in `data mytable;`, the table name is stored as "MYTABLE" and in `data "MyTable";`, the table name is stored as "MyTable". This is important if table and schema names in your data source are case-sensitive.

**CAUTION**
Using the `PRESERVE_TAB_NAMES=no` option in your LIBNAME statement can cause unexpected results.

(table-option(s)) specifies optional arguments that the DS2 program applies when it writes rows to the output table.

Note For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

Details

The MERGE statement is flexible and has a variety of uses in DS2 programming. This section describes basic uses of MERGE. Other applications include using more than one BY variable, merging more than two tables, and merging a few rows with all rows in another table.

Match-merging combines rows from two or more tables into a single row in a new table according to the values of a common variable. The number of rows in the new table is the sum of the largest number of rows in each BY group in all tables. To perform a match-merge, use a BY statement immediately after the MERGE statement. The
variables in the BY statement must be common to all tables. Only one BY statement can accompany each MERGE statement in a data program.

For more information, see “Match-Merging” in SAS Viya: DS2 Programmer’s Guide.

**CAUTION:**

BY variables in a DS2 merge that have a DECIMAL or NUMERIC data type are converted to a DOUBLE data type. If matching DECIMAL columns are not BY variables, the DECIMAL columns remain as a DECIMAL data type.

**CAUTION:**

If there is a type, scale, or precision mismatch between columns with a DECIMAL or NUMERIC data type between tables, the column is converted to a DOUBLE data type.

*Note:* The MERGE statement does not produce a Cartesian product on a many-to-many match-merge. Instead, it performs a sparse one-to-one merge while there are rows in the BY group in at least one table.

*Note:* The order of the data sets in the MERGE statement can affect the matching.

Note this difference in merging behavior. In comparison to DATA step merging, the result of the DS2 MERGE statement is a subset of the Cartesian product. By contrast, the result of the DATA step merge is not a subset because it uses a lazy retain strategy to fill in the PDV.

Here is the code.

```plaintext
merge T1 (in=inT1) T2 (in=inT2); by K;
```

The following example shows the DATA step retain strategy during the merging of the tables T1 and T2 by a common variable K. When match-merging of the second row of table T1 occurs, the value of column C is retained from the previous match of the BY variable. The variable inT2 is set to 1 indicating that table T2 contributed to the final table results.

**Figure 10.1 DATA Step Merge**

<table>
<thead>
<tr>
<th>K</th>
<th>A</th>
<th>B</th>
<th>K</th>
<th>A</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Cat</td>
<td>Apple</td>
<td>101</td>
<td>Cow</td>
<td>Red</td>
</tr>
<tr>
<td>101</td>
<td>Pig</td>
<td>Banana</td>
<td>102</td>
<td></td>
<td>Yellow</td>
</tr>
<tr>
<td>102</td>
<td>Duck</td>
<td>Fig</td>
<td>103</td>
<td></td>
<td>Blue</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>K</th>
<th>inT1</th>
<th>inT2</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>1</td>
<td>1</td>
<td>Cow</td>
<td>Apple</td>
<td>Red</td>
</tr>
<tr>
<td>101</td>
<td>1</td>
<td>1</td>
<td>Pig</td>
<td>Banana</td>
<td>Red</td>
</tr>
<tr>
<td>102</td>
<td>1</td>
<td>1</td>
<td></td>
<td>Fig</td>
<td>Yellow</td>
</tr>
<tr>
<td>103</td>
<td>0</td>
<td>1</td>
<td></td>
<td></td>
<td>Blue</td>
</tr>
</tbody>
</table>

In contrast to the DATA step merge, the DS2 merge clears the PDV between BY-group processing. Because the second row in table T1 does not have a corresponding match in table T2, column C remains empty and the variable inT2 is set to 0 indicating that table T2 did not contribute to the final table results.
Match-merging tables that do not contain a one-to-one row mapping between the table rows can produce unexpected results. Within a given BY group, observations in a BY group are not necessarily selected in the order in which they appear in the data set during match-merging.

**Comparisons**

If you specify a SET statement, SAS stops processing before all rows are read from all tables if the number of rows are not equal. In contrast, SAS continues processing all rows in all tables that are named in the MERGE statement.

**Example**

The following example creates two tables and uses a MERGE statement to combine the tables using the `common` column.

```sas
data mrg01a(overwrite=yes);
  dcl varchar(10) common animal;
  method init();
    common='a'; animal='Ant'; output;
    common='b'; animal='Bird'; output;
    common='c'; animal='Cat'; output;
    common='d'; animal='Dog'; output;
    common='e'; animal='Eagle'; output;
    common='f'; animal='Frog'; output;
  end;
enddata;
run;

data mrg01b(overwrite=yes);
  dcl varchar(10) common plant;
  method init();
    common='a'; plant='Apple'; output;
    common='b'; plant='Banana'; output;
    common='c'; plant='Coconut'; output;
    common='d'; plant='Dewberry'; output;
    common='e'; plant='Eggplant'; output;
    common='f'; plant='Fig'; output;
end;
enddata;
run;
```

```sas
MERGE Statement
```

```
```
common='g'; plant='Grapefruit'; output;
end;
enddata;
run;

/* match merge */
data;
method run();
merge mrg01a mrg01b; by common;
end;
enddata;
run;

The following table is generated.

<table>
<thead>
<tr>
<th>common</th>
<th>animal</th>
<th>plant</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Ant</td>
<td>Apple</td>
</tr>
<tr>
<td>b</td>
<td>Bird</td>
<td>Banana</td>
</tr>
<tr>
<td>c</td>
<td>Cat</td>
<td>Coconut</td>
</tr>
<tr>
<td>d</td>
<td>Dog</td>
<td>Dowberry</td>
</tr>
<tr>
<td>e</td>
<td>Eagle</td>
<td>Eggplant</td>
</tr>
<tr>
<td>f</td>
<td>Frog</td>
<td>Fig</td>
</tr>
<tr>
<td>g</td>
<td></td>
<td>Grapefruit</td>
</tr>
</tbody>
</table>

---

**METHOD Statement**

Defines a block of code that can be called and executed multiple times.

**Category:** Block

**Syntax**

```plaintext
[PRIVATE] METHOD method [[[IN_OUT] <parameter> [,... [IN_OUT]]<parameter>]]

[RETURNS data-type];
...method-body ...
END;
```
<parameter>::=  
  <data-type> variable  
< data-type >:::=  
  <exact-numeric-type> | <approximate-numeric-type> | <binary-string-type> |  
  <string-type>  
  | <date-type>  
<exact-numeric-type> ::=  
  {  
    INT | BIGINT | SMALLINT | TINYINT |  
    DECIMAL [(precision [,scale])] | NUMERIC [(precision [,scale])]  
  }  
<approximate-numeric-type> ::=  
  {  
    DOUBLE | DOUBLE PRECISION | FLOAT | REAL  
  }  
<binary-string-type>:::=  
  BINARY(length) | VARBINARY(length)  
<string-type>:::=  
  NCHAR [(character-length)]  
  | NVARCHAR [(character-length)]  
  | CHAR [(character-length)] [CHARACTER SET character-set-identifier]  
  | VARCHAR [(character-length)] [CHARACTER SET character-set-identifier]  
<date-type>:::=  
  {  
    TIME | TIMESTAMP } [(precision)] | DATE  

**Arguments**

**<PRIVATE>**  
specifies a method that can be accessed only from within the package.

See “Attributes and Methods” in *SAS Viya: DS2 Programmer’s Guide*

**method**  
specifies a name for the method. Method names have global scope.

**IN_OUT**  
specifies that the argument is to be manipulated by reference, not by value. The IN_OUT parameter manipulates the argument rather than a copy of the argument.

**Restriction**  
If the method contains any IN_OUT parameters, the method must not return a value.

**Requirements**  
The argument that is passed to the IN_OUT parameter must be a modifiable value, such as an identifier, not an expression.

The data type of the argument must be the same data type as the IN_OUT parameter.

**Tip**  
If the method declaration specifies a length for an IN_OUT parameter, a warning is issued and the length is ignored. The length of the supplied argument is always used.

**<parameter>**  
specifies a parameter that is passed to the method. The type can be any valid character, numeric, date type, or package. Parameters have scope that is local to the method and, by default, parameters are passed by value. A parameter is initialized to
be a copy of the value of the argument that is specified for the parameter, unless it is specified with the IN_OUT parameter or is a package. Package type variables are always passed by reference, even if the IN_OUT keyword is not specified.

Interaction If the IN_OUT parameter or a package parameter is specified, the value of the argument that is passed into the parameter might have changed when the method returns.

**INT | BIGINT | SMALLINT | TINYINT**

specifies an integer variable or array.

**Alias** INTEGER for INT

**See** “DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**DECIMAL[(precision [, scale])] | NUMERIC[(precision [, scale])]**

specifies an exact numeric variable or array.

**precision**

specifies the maximum total number of decimal digits that can be stored, both to the left and to the right of the decimal point

**Note** Not all data sources can support a precision of 52 digits.

**scale**

specifies the maximum number of decimal digits that can be stored to the right of the decimal point

**Range** 0–precision

**Note** scale is less than or equal to precision.

**See** “DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**DOUBLE | DOUBLE PRECISION | FLOAT | REAL**

specifies a floating-point variable or array.

**See** “DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**BINARY (length)**

specifies a binary variable or array.

**Requirement** If you specify BINARY, you must also specify the length of the variable or array in bytes.

**See** “DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**VARBINARY (length)**

specifies a varying-length binary variable or array.

**Alias** BINARY VARYING

**Requirement** If you specify VARBINARY, you must also specify the length of the binary variable or array in bytes.

**See** “DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*
NCHAR | NVARCHAR | CHAR | VARCHAR
specifies a character variable or array.

**Aliases**
- NATIONAL CHARACTER, NATIONAL CHAR for NCHAR
- NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING for NVARCHAR
- CHARACTER for CHAR
- CHARACTER VARYING for VARCHAR

**See**
“DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**character-length**
specifies the maximum number of characters that the string can hold for NCHAR, NVARCHAR, CHAR, and VARCHAR data types.

**Default** 8

**Tip** The number of bytes that character variables that are declared using CHAR use for storage depends on the session encoding. Those declared using any of the NCHAR variants have wider storage and can be used to represent character sets for which single-byte character storage is insufficient (for example, Unicode). If a session encoding requires multiple bytes per character (for example, UTF-8), then CHAR and NCHAR are identical types and both use NCHAR.

**CHARACTER SET character-set-identifier**
specifies character set encoding information for CHAR and VARCHAR data types.

**Default** Default encoding depends on your operating system and locale.

**Tip** You can use a character string literal or a simple string for character set names. For example, you can specify "ibm-866" or 'ibm-866'

**See** For a complete list of character set encoding values, see “Character Sets for Encoding in NLS” in the *SAS Viya National Language Support: Reference Guide*.

**TIME**
specifies a time variable or array.

**TIMESTAMP**
specifies both a date and time variable or array.

**precision**
specifies the precision for a TIME or TIMESTAMP data type.

**Defaults**
- 0 for time
- 6 for timestamp

**Note** If you are working with TIME and TIMESTAMP values in a data source other than SAS and you do not specify a precision, the default precision will always be the DS2 default precision of 0 for TIME and 6 for TIMESTAMP.
DATE
specifies a date variable or array.

variable
specifies the scalar variable or array name. You can specify one or more variables or arrays. However, variable must be of the type specified in data-type. You can mix scalar and array variables of the same type.

RETURNS data-type
specifies the data type of the value that the method returns. The type can be any valid character, numeric, or date type.

method-body
comprises the variable declarations and executable DS2 code that runs when the method is called. All variables that are declared in the method body are local to the method.

END
marks the end of the method.

Details
There are two types of methods in DS2: system methods, and user-defined methods. The METHOD statement enables you to create your own user-defined methods. For information about system methods, see Chapter 11, “DS2 System Methods,” on page 791.

If a method returns a value, each RETURN statement appearing in the method must have an associated return expression. For more information, see the “RETURN Statement” on page 765.

When a method definition appears after any method expression that refers to it, a FORWARD statement for the method must appear for the method before the method expression. User-defined methods that are not defined before the DS2 INIT, RUN, or TERM methods must be declared in a FORWARD statement. For more information, see the “FORWARD Statement” on page 727.

Note: TINYINT and SMALLINT method parameters are automatically promoted to INTEGER, and REAL method parameters are automatically promoted to DOUBLE. A warning message is given. For more information, see “DS2 Type Conversions” in SAS Viya: DS2 Programmer’s Guide.

Examples

Example 1: User-defined Methods
In these three examples, M, CONCAT, and ADD are user-defined methods.

- method m(int x, int y) returns int;
  return x + y;
end;

- method concat(char(100) x, char(100) y) returns char(200);
  return trim(x) || y;
end;

- method add(double x, double y);
  this.x = this.x + x;
  this.y = this.y + y;
end;
Example 2: Overloaded Methods
In the following examples, the D method and the CONCAT methods are overloaded. If any two method definitions have the same name, but different type signatures (that is, if the methods have different parameter lists), the method is overloaded.

```plaintext
method d(double x, double y) returns double;
   dcl double temp;
   temp = x * 99;
   return x + y + temp;
end;
method d(double x, int y) returns double;
   return x + y
end;
method d(int x);
   put x;
end;
method concat(char(100) x, char(100) y) returns char(200);
   return "pre" || trim(x) || y;
end;
method concat(char(100) x, char(100) y, char(100) z) returns char(200);
   return trim(x) || trim(y) || z;
end;
```

Example 3: Using the IN_OUT Argument
In the following example, the method `swapper` exchanges argument values. The IN_OUT argument enables the values to be changed where the method is called.

```plaintext
package xyzzy;
   method swapper(in_out double a, in_out double b);
      declare double x;
      x=a; a=b; b=x;
   end;
endpackage;
run;
data _null_;
   method init();
      dcl package xyzzy x();
      a=10; b=42;
      put 'before: ' a= b=;
      x.swapper(a,b);
      put 'after: ' a= b=;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
before: a=10 b=42
after: a=42 b=10
```

Example 4: Passing in a Package as a Method Argument
In the following example, the `person_list` package contains two methods `addP1` and `addP2`. The `addP1` and `addP2` methods each take the `person` package as an input parameter.

```
proc ds2;
```
package work.person / overwrite=yes;
declare varchar(32) lastname;
declare varchar(32) firstname;
method setNames(varchar(32) lastname_p, varchar(32) firstname_p);
    lastname = lastname_p;
    firstname = firstname_p;
end;
method getFullname() returns varchar(66);
    return (catx(', ', lastname, firstname));
end;
endpackage;
package work.person_list / overwrite=yes;
declare package work.person pl1;
declare package work.person pl2;
method addP1( package work.person pers_p);
    pl1 = pers_p;
end;
method addP2( package work.person pers_p);
    pl2 = pers_p;
end;
method getPersonList() returns varchar(256);
    return ( catx(':', pl1.getFullname(), pl2.getFullname()) );
end;
endpackage;
run;
data new (overwrite=yes);
declare char(66) myname;
declare char(256) allNames;
method init();
declare package work.person pers1 ();
declare package work.person pers2 ();
declare package work.person_list pl ();
pers1.setNames('Miller', 'Brad');
pers2.setNames('Smith', 'Colin');
myname = pers1.getFullname();
pl.addP1(pers1);
pl.addP2(pers2);
allNames = pl.getPersonList();
put myname=;
put allNames=;
end;
enddata;
run;
quit;
The following lines are written to the SAS log.

myname=Miller, Brad
allNames=Miller, Brad:Smith, Colin

• “Methods” in SAS Viya: DS2 Programmer’s Guide
null statement

Creates an empty statement.

**Syntax**

```
;
```

**Details**

The Null statement consists solely of a semicolon. It creates an empty statement.

**Example**

This example shows how the Null statement can be used to not execute any statements.

```
method init();
x = 1;
y = 0;
z = 1;
if x & y | not z then
    ;
else
    put 'else';
end;
```

**output statement**

Writes the current row to a table.

**Syntax**

```
OUTPUT [ { table [ ... table ] } | _ROWSET_ | _NULL_ ];
```
Without Arguments
Using OUTPUT without arguments causes the current row to be written to all tables that are named in the DATA statement or thread program. If no tables are specified in the DATA statement or thread program, then the row is written to the client application.

Arguments

table
specifies the name of the table to which to write rows. table can be one of these forms.

- catalog.schema.table-name
- schema.table-name
- catalog.table-name
- table-name

catalog is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names. A catalog is a metadata object in a SAS Metadata Repository.

schema is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

table-name is the name of the table.

Restriction
All names that are specified in the OUTPUT statement must also appear in the DATA statement.

Notes
If the table name has a dot in it and you are accessing a CAS table, you must enclose the table name in double quotation marks. Here is an example.

output mycaslib."tdlibref.foo";

If you do not use quotation marks around the table and schema names, DS2 stores them as uppercase and includes double quotation marks. Table and schema names that are enclosed in quotation marks are used as is. That is, they remain quoted and with the original casing in the quotation marks. For example, in data mytable;, the table name is stored as "MYTABLE" and in data "MyTable";, the table name is stored as "MyTable". This is important if table and schema names in your data source are case-sensitive.

Tip
You can specify up to as many tables in the OUTPUT statement as you specified in the DATA statement for that DS2 program.

CAUTION
Using the PRESERVE_TAB_NAMES=no option on your LIBNAME statement can cause unexpected results.
_ROWSET_
  specifies that the OUTPUT statement should not write rows to a table, but it should
  instead return table rows to the client application.

_NULL_
  specifies that the OUTPUT statement should not write rows to either a table or the
  client application.

Details

When and Where the OUTPUT Statement Writes Rows
The OUTPUT statement creates an output row, using values for the row that are
contained in the global variables when OUTPUT statement executes. The OUTPUT
statement writes the current row to a table immediately, not at the end of the DS2
program. If no table name is specified in the OUTPUT statement, the row is written to
the table or tables that are listed in the DATA statement.

DS2 keeps track of the values in the order in which the compiler encounters them within
a DS2 program, whether they are read from existing tables or created in the program.

Implicit versus Explicit Output
If you do not supply an OUTPUT statement, DS2 adds one implicitly at the end of the
RUN method that writes rows to the table or tables that are being created.

Placing an explicit OUTPUT statement in a DS2 program overrides the automatic
output, and adds a row to a table only when an explicit OUTPUT statement is executed.
Once you use an OUTPUT statement to write a row to any one table, however, there is
no implicit OUTPUT statement at the end of the RUN method. In this situation, a DS2
program writes a row to a table only when an explicit OUTPUT statement executes. You
can use the OUTPUT statement alone or as part of an IF-THEN/ELSE or SELECT
statement or in DO loop processing.

Using the OUTPUT Statement in DS2 Program Threads
OUTPUT statements in thread programs cannot contain any table names. Each output
row is returned to the thread program that started the thread.

Comparisons

• The OUTPUT statement writes rows to a table or to the client application; the PUT
  statement writes variable values or text strings to the SAS log.

• To control whenever a row is written to a table, use the OUTPUT statement. To
  control which columns are written to a table, use the KEEP= or DROP= table option
  in the DATA statement or use the KEEP or DROP statement.

Examples

Example 1: Sample Uses of OUTPUT
• This line of code writes the current row to a table.

  output;

• This line of code writes the current row to a table when a specified condition is true.

  if deptcode gt 2000 then output;
This line of code writes a row to the MARKUP table when the PHONE value is missing.

```plaintext
if phone=. then output markup;
```

**Example 2: Creating Multiple Rows from Each Row of Input**

You can create two or more rows from each row of input data. This DS2 program creates three rows in the RESPONSE table for each row in the SULFA table:

```plaintext
data response(drop= (time1 time2 time3));
method run();
set sulfa;
time=time1;
output;
time=time2;
output;
time=time3;
output;
end;
enddata;
```

**Example 3: Creating Multiple Tables from a Single Input Table**

You can create more than one table from one input table. In this example, OUTPUT writes rows to two tables, EASTERN and WESTERN:

```plaintext
data eastern western;
method run();
set cities;
if location = 'east' then output eastern;
else output western;
end;
enddata;
```

**Example 4: Creating One Row from Several Rows of Input**

You can combine several input rows into one row. In this example, OUTPUT creates one row that totals the values of DEFECTS in the first ten rows of the input table:

```plaintext
data discards;
donot drop defects;
method run();
set gadgets;
reps+1;
if reps=1 then total=0;
total+defects;
if reps=10 then do;
output;
stop;
end;
end;
enddata;
```

**Example 5: Output Using Threads**

The following example generates a result set of 20 random numbers. The data program starts 4 threads. Each thread generates and writes 5 random numbers with variable \( x \).
The data program reads the output of each thread with the SET statement and then writes the input random numbers to the data set `random_data`. 
/* Thread generates and outputs 5 random numbers */
thread thread_pgm;
    declare double x;
    method init();
        declare int i;
        streaminit(_threadid_);
        do i = 1 to 5;
            x = ranuni(1);
            output; /* output variable x */
        end;
    end;
endthread;

data random_data;
    dcl thread thread_pgm t;
    method run();
        /* Start 4 threads and read the output of each thread. */
        set from t threads=4;
    end;
enddata;
run;

The following output is generated.
<table>
<thead>
<tr>
<th>Obs</th>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.58602</td>
</tr>
<tr>
<td>2</td>
<td>0.78108</td>

**Statements:**
- “PUT Statement” on page 757
- “DATA Statement” on page 702
PACKAGE Statement

Creates a DS2 package.

**Category:** Block

## Syntax

**Form 1:**

```
PACKAGE package [/ENCRYPT=SAS | AES] [table-options];
... package-body ...
ENDPACKAGE;
```

**Form 2:**

```
PACKAGE fcmp-package-name [/ENCRYPT=SAS | AES] [table-options]
    LANGUAGE=['']FCMP[''] TABLE='library-name';
... package-body ...
ENDPACKAGE;
```

## Arguments

**package**

specifies the package name. `package` can be one of these forms.

- `catalog.schema.package`
- `schema.package`
- `catalog.package`
- `package`

**catalog**

is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names. A catalog is a metadata object in a SAS Metadata Repository.

**schema**

is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

**package**

is the name of the package.

---

**Requirement**

Package naming conventions are based on the data source. For more information, see the documentation for your data source.

---

**/ENCRYPT=SAS|AES**

specifies the encryption algorithm. SAS specifies the SAS Proprietary algorithm. AES specifies the Advanced Encryption Standard (AES) algorithm.

**Default**

SAS
Interaction

The ENCRYPT option for the PACKAGE statement is different from and has different values than the ENCRYPT= table option. The ENCRYPT= table option affects only SAS output data sets. For more information, see “ENCRYPT= Table Option” on page 815.

/table-options

specifies optional arguments that the DS2 program applies when it creates a package. For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

Note

Options that are not recognized by DS2 are passed without error to the underlying data source.

package-body

contains the declarations and methods in the package.

fcmp-package-name

specifies the name of the FCMP package.

Restriction

This parameter is not supported in the CAS server.

See

library-name

specifies the name of the library where the FCMP function resides.

Restriction

This parameter is not supported in the CAS server.

Requirement

This location must be the library.dataset portion of the location that was specified in the OUTLIB option in the PROC FCMP statement.

See

The FCMP procedure in SAS Viya Data Management and Utility Procedures Guide

Details

Package Basics

A package is similar to a DS2 program. The package body consists of a set of global declarations and a list of methods. The main syntactical differences are the PACKAGE and ENDPACKAGE statements. These statements define a block with global scope. For more information about scope, see “Scope of DS2 Identifiers” in SAS Viya: DS2 Programmer’s Guide.

The package's library of methods can be called from any other DS2 program including another package. Consequently, the INIT, RUN, and TERM methods have no special meaning in a package.

After successful compilation of a package, a copy of the package's source code is stored in the catalog entry that is identified by the package name.

The PACKAGE statement is required for all user-defined packages and for the FCMP package that is supplied by SAS. The hash, hash iterator, logger, matrix, and SQLSTMT packages, which are supplied by SAS, do not require a PACKAGE statement. For more information, see “Introduction to DS2 Packages” in SAS Viya: DS2 Programmer’s Guide.
Packages are declared for use in a DS2 program or another package by using the DECLARE PACKAGE statement. When you declare a package, the variable representing the package is considered an instance of the package.

By default, DS2 packages are encrypted with SAS encryption. You can override this default and specify AES encryption by using the ENCRYPT=AES table option in the PACKAGE statement. SAS Proprietary is a fixed encoding algorithm that is included with Base SAS software. It requires no additional SAS product licenses. For more information, see Encryption in SAS Viya.

Table options can be specified in the PACKAGE statement. They are specified after the package name and preceded by a slash.

**FCMP Packages**

SAS provides an FCMP package that supports calls to FCMP functions and subroutines from within the DS2 language. For more information, see “Using the FCMP Package” in SAS Viya: DS2 Programmer’s Guide.

**Comparisons**

For a comparison of packages, DS2 programs, and threads, see “Block Statements” on page 690.

**Examples**

**Example 1: Creating a Complex Number Package**

This example creates a very simple complex number package. Two global variables, \( x \) and \( y \), represent the ordered pair of real numbers that constitute a complex number. This set of methods performs various operations on complex numbers, such as add and multiply.

```sas
package complex;
   dcl double x y;
   method init(double x, double y);
      this.x = x;
      this.y = y;
   end;
   method add(double x, double y);
      this.x = this.x + x;
      this.y = this.y + y;
   end;
   method mult(double x, double y);
      this.x = this.x * x - this.y * y;
      this.y = this.x * y + x * this.y;
   end;
   method norm() returns double;
      return sqrt(x ** 2 + y ** 2);
   end;
   method print();
      put 'x = ' x ' y= ' y;
   end;
endpackage;
run;
```

The following DS2 program instantiates and calls the methods defined in the previous PACKAGE statement.
data _null_;  
  method init();  
   dcl package complex c();  
   dcl package complex c2();  
   c.x=3;  
   c.y=4;  
   d = c.norm();  
   put 'd= ' d;  
   c.add(5, 6);  
   c.print();  
   c2.x=7;  
   c2.y=24;  
   d = c2.norm();  
   put 'd= ' d;  
   c2.print();  
end;  
enddata;  
run;

These lines are written to the SAS log:

d=  5  
x =  8  y=  10  
d=  25  
x =  7  y=  24

Example 2: Creating an FCMP Package

This example creates a square routine in FCMP and uses that routine in a DS2 program. The current directory is used as the "library" of FCMP packages.

libname base '.';

* fcmp defines a function, square;  
proc fcmp outlib = base.fcmpsubs.package1;  
   function square(a);  
      return (a*a);  
   endsub;  
run;

* define the ds2 package thru which the fcmp functions will be called;  
proc ds2;  
   package pkg /  
      overwrite=yes  
      language='fcmp'  
      table='base.fcmpsubs';  
run;

* call fcmp thru the ds2 wrapper package;  
data;  
   dcl package pkg p();  
   dcl double a b;  
   method init();  
   do a = 10 to 20;  
      b=p.square(a);  
      put a= b=;  
      end;  
   end;
enddata;
run;
quit;

The following lines are written to the SAS log.

```
a=10 b=100 
a=11 b=121 
a=12 b=144 
a=13 b=169 
a=14 b=196 
a=15 b=225 
a=16 b=256 
a=17 b=289 
a=18 b=324 
a=19 b=361 
a=20 b=400 
```

- “DECLARE PACKAGE Statement, FCMP Package” on page 831

---

**PUT Statement**

Prints the values of program variables, arrays, and constants to the SAS log.

**Category:** Local

---

**Syntax**

```
PUT < put-list > [ … <put-list> ] ;
<put-list>::=
   _ALL_
   | 'character-string'
   | ['character-string']<eq-expression> [=] [:] format [-L | -C | -R]]
<eq-expression>::=
   identifier
   | array-reference
   | this-expression
```

**Without Arguments**

PUT without arguments prints a blank line to the SAS log.
Arguments

_ALLL_
  prints the values of all variables, which includes predefined variables, to the SAS log.

'character-string'
  specifies a string of text that is written to the SAS log.

_identifier_
  names a variable whose value is written to the SAS log.

_array-reference_
  specifies an array element. The subscript can be any SAS expression that resolves to
  an integer value when the PUT statement executes. Use the array subscript asterisk
  (*) to write all elements of the array.

this-expression
  specifies a THIS expression.

=  
  If an equal sign is added after a variable or array element, then the output is preceded
  by the variable or array element name and an equal sign.

:  
  enables you to specify a format that the PUT statement uses to write the variable
  value. All leading and trailing blanks are deleted, and each value is followed by a
  single blank.

  Restriction  If you use “:”, you must specify a format.

_format_
  specifies a format to use when the data value is written to the SAS log. If you use a
  colon modifier (:) with the format name, all leading and trailing blanks are deleted
  and each value is followed by a single blank. To override the default alignment, you
  can add an alignment specification to a format:

  −L  left aligns the value.
  −C  centers the value.
  −R  right aligns the value.

  Tip  Ensure that the format width provides enough space to write the value and any
       commas, dollar signs, decimal points, or other special characters that the format
       includes.

Details

How to Use the PUT Statement

The PUT statement consists of the keyword PUT followed by a list of variables and
constants. You list the names of the variables whose values you want written, or you
specify a character string in quotation marks. If you do not specify a format, the PUT
statement writes a variable value with the default format, inserts a single blank, and then
writes the next value. If you specify a format, the output is written using the format
width. Character values are left-aligned in the field; leading and trailing blanks are
removed. Numeric values are right-aligned in the field.
How nonexistent data (SAS missing values or null values) are output depends on whether you are in ANSI mode or SAS mode. A period is generated for DOUBLE missing dot and null values when the default format, BEST32., is associated with the DOUBLE. For special missing values (.a-.z and ._), the character after the period is generated when using BEST32.. For example, if a variable held the value .a, A would be generated. INTEGER and other non-DDOUBLE numeric types cannot be missing. However, they can be null in which case nothing is generated by the PUT statement when the value is null. For more information, see “How DS2 Processes Nulls and SAS Missing Values” in SAS Viya: DS2 Programmer’s Guide.

How List Output Is Spaced
List output uses different spacing methods when it writes variable values and character strings. When a variable is written with list output, SAS automatically inserts a blank space. The output pointer stops at the second column that follows the variable value.

dcl int a b;
dcl varchar c d;
area = 9924;
city = 1001;
ctry1='Peru';
ctry2='Bolivia';
   put area city ctry1 ctry2;

These lines are written to the SAS log.

---------1------+----2
9924 1001 Peru Bolivia

However, when a character string is written, SAS does not automatically insert a blank space. The output pointer stops at the column that immediately follows the last character in the string.

To avoid spacing problems when both character strings and variable values are written, you might want to use a blank space as the last character in a character string.

If you use a colon modifier (:) with the format name, SAS writes the value with the specified format, inserts a blank space, and moves the pointer to the next column.

dcl int a b;
dcl varchar c d;
area = 9924;
POP = 1000;
ctry1='Peru';
ctry2='Bolivia';
   put area : octal10. pop : comma8.2 ctry1 ctry2;

These lines are written to the SAS log.

---------1------+----2------3------+
0000023304 1,000.00 Peru Bolivia

Formatted Output
You can use a format to control how SAS prints the variable values. The PUT statement uses the format that follows the variable name to write each value. With formatted output, SAS does not automatically add blanks between values. Formatted output moves the pointer the length of the format, even if the value does not fill that length. The pointer moves to the next column; an intervening blank is not inserted. If the value uses fewer columns than specified, character values are left-aligned and numeric values are right-aligned in the field that is specified by the format width.
dcl int a b;
dcl varchar c d;
pop = 1000
area = 9924;
ctry1='Peru';
ctry2='Bolivia';
put area octal10, pop comma8.2 ctry1 ctry2;

These lines are written to the SAS log.

If no format is specified, the variable's default format is used. You can associate a format with a column by using a HAVING clause in the DECLARE statement. For more information, see “DECLARE Statement” on page 705.

Comparisons

The PUT statement and the PUT function have similar behavior. However, the PUT statement directs its results to the SAS log whereas the PUT function returns an NCHAR value containing the result of formatting its argument.

Examples

Example 1: PUT Statements
This example contains several PUT statements.

Note: If an equal sign is added after a variable or array element, then the output is preceded by the variable or array element name and an equal sign. For example, these two code lines are equivalent.

Example 2: Using PUT to Write Arrays
This example write the contents of both temporary and variable arrays.
Example 3: Using the _ALL_ Argument

This example uses the _ALL_ argument in the PUT statement to print the values of all variables, including the predefined _N_ variable, to the SAS log.

```sas
proc ds2;
   data;
      dcl double a b c;
      method init();
         a = 116;
         b = 220;
         c = 37;
         put _all_;
      end;
   enddata;
   run;
   quit;
```

See Also

- “How to Write Array Content” in SAS Viya: DS2 Programmer’s Guide

Functions:

- “PUT Function” on page 553
Syntax

```plaintext
RENAME old-name {= | AS} new-name [ ... old-name {= | AS} new-name ];
```

Arguments

- **old-name**
  - specifies the name of a column as it appears in the input table, or in the current DS2 program for newly created columns.

- **new-name**
  - specifies the name to use in the output table.

Details

The RENAME statement enables you to change the names of one or more columns. The new column names are written to the output table only. Use the old column names in programming statements for the current DS2 program. RENAME applies to all output tables. In addition to changing the name of a column, the RENAME statement also changes the label for the column.

Comparisons

- The RENAME= table option enables you to specify the columns that you want to rename for each input or output table. Use it in input tables to rename columns before processing.
- If you use the RENAME= table option in an output table, you must continue to use the old column names in programming statements for the current DS2 program. The RENAME= table option affects only that output table. The RENAME statement affects all output tables.
- If you use both the RENAME statement and RENAME= output table option, the RENAME statement has precedence. If X is renamed to Y with a RENAME statement and X is renamed to Z with a RENAME= table option, the RENAME statement takes precedence and X will be renamed to Y.
- The RENAME= table option in the SET statement renames columns in the input table. You must use the new names in programming statements for the current DS2 program.

Example

The following examples illustrate the RENAME statement.

```plaintext
• rename prod=ProductName;
• rename street as Address cit as City st as State;
• rename oldsalary=newsalary;
```

See Also

- “RENAME= Table Option” on page 827
RETAI N Statement

Specifies that all columns or all columns in the column list will have their values retained between executions of the RUN method.

Category: Global

Syntax

Form 1: RETAIN;
Form 2: RETAIN column-list;
Form 3: RETAIN column-list < constant-value >;
Form 4: RETAIN column-list ( < constant-value > … < constant-value > );

< constant-value > ::= bit_constant
| hex_constant
| floating_constant
| decimal_constant
| sas_missing_value
| integer_constant
| string_constant
| null
| DATE character_constant
| TIME character_constant
| TIMESTAMP character_constant
Form 5: RETAIN vararray;

Without Arguments

(Form 1) If you do not specify any arguments, the RETAIN statement causes the values of all columns to be retained from one execution of the RUN method to the next.

Arguments

column-list
specifies column names whose values you want retained.

vararray
specifies the name of a variable array.

See “VARARRAY Statement” on page 784

Details

Column Behavior (Form 2)
The RETAIN statement specifies that all columns in the column list should have their values retained during each execution of the RUN method. Normally, columns in the PDV are set to either a missing or null value before the RUN method executes.
Assigning Initial Values (Forms 3 and 4)

Use a RETAIN statement to specify initial values for individual columns, a list of columns, or members of an array. If a value appears in a RETAIN statement, columns that appear before it in the list are set to that value initially.

(Form 3) You can assign one value to all columns. For example, the following statement assigns a value of 100 to columns A, B, and C.

```
retain a b c 100;
```

(Form 4) You can assign different values to each column. For example, the following statement assigns the values ‘Vancouver’, ‘BC’, and ‘Canada’ to columns CITY, PROVINCE, and COUNTRY.

```
retain city province country ('Vancouver', 'BC', 'Canada');
```

Note that you can also use an iterator to assign one value to all columns. For example, the following statement assigns a value of 100 to columns A, B, and C.

```
retain a b c (3* 100);
```

(Form 5) You can assign initial values to the array variables. The RETAIN initializer works across array boundaries. In addition, if the initial list is short, the remaining values are set to missing values. In this example, the value of ns[3] is a missing value.

```
proc ds2;
data y /overwrite=yes;
  vararray double c[5];
  vararray double sums[dim(c)];
  vararray double ns[dim(c)];

  retain sums ns (1 2 3 4 5 6 7);
  method init();
  end;

  method run();
    put sums[1]=;
    put sums[2]=;
    put sums[3]=;
    put sums[4]=;
    put sums[5]=;
    put ns[1]=;
    put ns[2]=;
    put ns[3]=;
  end;
enddata;
run;
quit;
```

Redundancy

It is redundant to name any of these items in a RETAIN statement, because their values are automatically retained from one iteration of the DS2 program to the next:

- columns that are read with a SET statement

  **Note:** It might not be redundant if the SET statement has multiple tables associated with it. Assume that table A defines variable x but table B does not. Without a RETAIN statement, variable x is set to missing when records are read from table
With a RETAIN statement, variable \( X \) has whatever value was last assigned to it by table \( A \) or by DS2 program logic.

- a column whose value is assigned in a sum statement
- data elements that are specified in an array

**Comparisons**

The RETAIN statement specifies columns whose values are preserved. The KEEP statement specifies columns that are to be included in any table that is being created.

**See Also**

**Statements:**
- “KEEP Statement” on page 731

---

**RETURN Statement**

Returns execution from a method to the method caller.

**Category:** Local

**Syntax**

```
RETURN [ expression ];
```

**Without Arguments**

When a RETURN statement does not have an \( expression \), control is transferred back to the caller of the method in which the RETURN statement is located. No value is returned to the caller of the method.

**Arguments**

\( expression \)

- specifies any valid expression that returns a single value. The expression's type is evaluated, and if necessary, converted to the type specified in the METHOD statement's RETURNS clause. The value of \( expression \) is then passed back to the caller of the method.

**Details**

When the RETURN statement is executed in the implicit loop, the next iteration of the implicit loop executes. The RETURN statement transfers control and, if \( expression \) is present, returns a value back to the caller of the method. Any method that returns a value (in other words, that has a RETURNS clause in the METHOD statement) must have RETURN \( expression \) statement as the last statement in the METHOD body. Otherwise, an error occurs. A warning occurs if a method has a RETURN \( expression \) statement, but does not have a RETURNS clause.

You can use the STOP statement to terminate the RUN method.
Example

In this example, the CONCAT method returns a concatenated string. The RETURN statement's type is converted to the type of the RETURNS clause. In this example, the return type is CHAR.

```sql
method concat(char(100) x, char(100) y) returns char(200);
  return trim(x) || y;
end;
```

See Also

Statements:

• “METHOD Statement” on page 740

---

**SELECT Statement**

Executes one of several statements or groups of statements.

**Category:** Local

**Syntax**

```
SELECT [ ( select-expression ) ];
  [ < when-list > [ ...< when-list> ] ];
  [ OTHERWISE statement-list ] ;
END [ end-label ];
<when-list>::=
  WHEN ( when-expression ) [ statement-list ]
```

**Arguments**

- **select-expression**
  - specifies an expression that evaluates to a single value of any type other than VARBINARY.

- **end-label**
  - The END statement closes the SELECT statement. The optional end-label argument specifies an identifier. This label, created by using the Labels statement, must match the label immediately preceding the SELECT statement, or an error will occur.

- **when-expression**
  - specifies any expression.

  Requirement You must specify at least one when-expression.

- **statement-list**
  - can be any executable statement or statements.
Details

Using WHEN Statements in a SELECT Group

The SELECT statement begins a SELECT group. SELECT groups contain WHEN statements that identify DS2 statements that are executed when a particular condition is true. Use at least one WHEN statement in a SELECT group. An optional OTHERWISE statement specifies a statement to be executed if no WHEN condition is met. An END statement ends a SELECT group.

Null statements that are used in WHEN statements cause no further action to be taken when the condition is true.

Note: SELECT statements can be nested.

Note: You can use a SELECT expression to select between multiple expressions based on the values of other expressions. For more information, see “SELECT Expression” in SAS Viya: DS2 Programmer’s Guide.

Evaluating the when-expression When a select-expression Is Included

If the select-expression is present, both the select-expression and when-expression are evaluated. The two are compared for equality and a value of true or false is returned. If the comparison is true, the statement-list is executed and processing exits the SELECT statement. No other conditions are tested.

If the comparison is false, execution proceeds to the next WHEN statement. If no WHEN statements remain, execution proceeds to the OTHERWISE statement, if one is present. If the result of all SELECT-WHEN comparisons is false and no OTHERWISE statement is present, no error is given and the DS2 program continues to execute.

Evaluating the when-expression When a select-expression Is Not Included

If no select-expression is present, the when-expression is evaluated to produce a result of true or false. If the result is true, the statement-list is executed and processing exits the SELECT statement. No other conditions are tested.

If the result is false, execution proceeds to the next WHEN statement, or to the OTHERWISE statement if one is present. (That is, the action that is indicated in the first true WHEN statement is performed.) If the result of all when-expressions is false and no OTHERWISE statement is present, an error message is issued. If more than one WHEN statement has a true when-expression, only the first WHEN statement is used. Once a when-expression is true, no other when-expressions are evaluated.

Evaluating the when-expression When a statement-list Is Not Included

If a when-expression appears without a statement-list, it uses the statement-list of the next when-expression. The following example produces an output of 10.

```
a = 10;
select(a);
when(10)
    when(20) put a=;
```

However, a when-expression without a statement-list breaks this behavior. This example produces no output.

```
a = 10;
```
select (a);
when (10) ;
when (20) put a=;

Note: This is not true for a when-expression that precedes OTHERWISE. In this case, a when-expression without a statement is treated as if it has an empty statement (;).

Comparisons
Use IF-THEN/ELSE statements for programs with few statements. Use subsetting IF statements without a THEN clause to continue processing only those rows that meet the condition that is specified in the IF clause.

Examples

Example 1: SELECT with a select-expression
This example illustrates how to use the SELECT statement with a select-expression.

```sql
select (a);
when (1) x=x*10;
when (2);
when (3) x=x*100;
when (4) x=x*100;
when (5) x=x*100;
otherwise;
end;
```

Example 2: SELECT without a select-expression
This is an example of a SELECT statement without a select-expression.

```sql
select;
when (mon in ('JUN', 'JUL', 'AUG')
and temp>70) put 'SUMMER ' mon=;
when (mon in ('MAR', 'APR', 'MAY'))
put 'SPRING ' mon=;
otherwise put 'FALL OR WINTER ' mon=;
end;
```

Example 3: SELECT without an IF Expression
This example uses a SELECT statement. You could also use IF expressions. IF expressions allow a more compact representation of calculations.

```sql
temp3=.;
select (age);
when(12) temp3=0;
when(13) temp3=-14.2769145744513;
when(14) temp3=-27.3577925153955;
when(15) temp3=-21.9485551871151;
when(16) temp3=-13.1764092846992;
when(17) temp3=-0.63898626243485;
end;
temp4=.;
select (sex);
when('F') temp4=-1.47186167693037;
when('M') temp4=1.47186167693037;
end;
```
temp5=.;
select (age);
  when (12) DO;
    select (sex);
      when ('F') temp5=0;
      when ('M') temp5=0;
    end;
  end;
  when (13) DO;
    select (sex);
      when ('F') temp5=7.47012474340756;
      when ('M') temp5=-7.47012474340756;
    end;
  end;
  when (14) DO;
    select (sex);
      when ('F') temp5=4.35656087162482;
      when ('M') temp5=-4.35656087162482;
    end;
  end;
  when (15) DO;
    select (sex);
      when ('F') temp5=2.40720037896732;
      when ('M') temp5=-2.40720037896732;
    end;
  end;
  when (16) DO;
    select (sex);
      when ('F') temp5=7.56020843202274;
      when ('M') temp5=-7.56020843202274;
    end;
  end;
  when (17) DO;
    select (sex);
      when ('F') temp5=-0.0520606347702515;
      when ('M') temp5=0.0520606347702515;
    end;
  end;
end;
predictedWeight = -182.556181904311 + temp3 + temp4 +
  4.85030791094268*height + temp5;

See Also

- “SELECT Expression” in *SAS Viya: DS2 Programmer’s Guide*

Statements:

- “IF Statement, Subsetting” on page 729
- “IF-THEN/ELSE Statement” on page 730
SET Statement

Reads rows from one or more tables.

**Category:** Local

**Interactions:** Only one SET statement is allowed when using the SAS In-Database Code Accelerator. If more than one SET statement is used in the thread program, the thread program is not run inside the database. Instead, the thread program runs on the client.

Multi-table SET statements and a SET statement with embedded SQL code are allowed when using the SAS In-Database Code Accelerator. However, if you are using the SAS In-Database Code Accelerator for Hadoop, Hive .13 or later is required.

**Note:** Braces in the syntax convention indicate a syntax grouping. The escape character ( \\ ) before a brace indicates that the brace is required in the syntax. sql-text must be enclosed in braces ( { } ).

**Tip:** The width of the resulting column is determined by the largest width across all the tables on a single SET statement. Trailing blanks are irrelevant to the SET statement.

**Syntax**

```plaintext
SET < table-reference > [ ... < table-reference > ] [INDSNAME=variable] ;
[ BY [ DESCENDING ] column [ ... [ DESCENDING ] column ] ] ;

< table-reference>::=
    { table [ (table-options) ] }
| {sql-text}
```

**Arguments**

**INDSNAME=variable**

creates and names a variable that stores the name of the table from which the current row is read. The stored name can be a table name or a physical name. The physical name is the name by which the operating environment recognizes the file.

<table>
<thead>
<tr>
<th>Data type</th>
<th>NCHAR</th>
</tr>
</thead>
</table>

**Tips**

Although the INDSNAME variable is automatically declared as NCHAR, you can explicitly declare it as CHAR.

Unless previously defined, the length of the variable is set to 41 characters. If the variable is declared as CHAR with a specific length, that length is not changed. If the value placed into the INDSNAME variable is longer than that length, then the value is truncated.

**column**

names each column by which the table is sorted.

**Tip**

The table can be sorted by more than one column.
**table**

specifies the name of the input table. *table* can be one of these forms.

- `catalog.schema.table-name`
- `schema.table-name`
- `catalog.table-name`
- `table-name`

`catalog` is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names. A catalog is a metadata object in a SAS Metadata Repository.

`schema` is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

`table-name` is the name of the table.

**Notes**

If the table name has a dot in it and you are accessing a CAS table, you must enclose the table name in double quotation marks. Here is an example.

```sql
set mycaslib."tdlibref.foo";
```

If you do not use quotation marks around the table and schema names, DS2 stores them as uppercase and includes double quotation marks. Table and schema names that are enclosed in quotation marks are used as is. That is, they remain quoted and with the original casing in the quotation marks. For example, in `data mytable;`, the table name is stored as "MYTABLE" and in `data "MyTable";`, the table name is stored as "MyTable". This is important if table and schema names in your data source are case-sensitive.

**CAUTION**

Using the `PRESERVE_TAB_NAMES=no` option in your LIBNAME statement can cause unexpected results.

**table-options**

specifies optional arguments that the DS2 program applies when it writes rows to the output table. For more information about table options, see Chapter 13, “DS2 Table Options,” on page 803.

**{sql-text}**

is any valid FedSQL code that resolves to a set of table rows.

**Restrictions**

This argument is not supported in the CAS server.

The SQL in a SET statement can reference columns only if they are included in the data source table.

**Requirement**

The FedSQL query must be enclosed in braces (`{ }`).
Tips
You can use sql-text to combine or interleave rows from one or more tables.

The SQL in a SET statement is evaluated statically at compile time.

See
“SELECT Statement” in SAS FedSQL Language Reference for SAS Cloud Analytic Services

DESCENDING
specifies that the tables are sorted in descending order by the column that is specified. DESCENDING means largest to smallest for numeric columns, or reverse alphabetical for character columns.

Details

What SET Does
The SET statement is flexible and has a variety of uses in DS2 programming. These uses are determined by the options and statements that you use with the SET statement:

• reading rows and columns from existing tables for further processing in a DS2 program
• concatenating and interleaving tables, and performing one-to-one reading of tables

Each time the SET statement executes, one row is read into the program data vector. SET reads all columns one row at a time from the input tables unless you specify otherwise. A SET statement can contain multiple tables; a DS2 program can contain multiple SET statements.

Note: A SET statement in a thread program shares a single reader for that SET statement. Each row in the input table is sent to exactly one thread.

Note: The SET statement is best used in the RUN method to take advantage of the RUN method’s implicit looping capability.

Examples

Example 1: Reading a Table
In this example, each row in the table NC.MEMBERS is read into the program data vector. Only those rows whose value of CITY is Raleigh are written to the new table RALEIGH.MEMBERS:

data raleigh.members;
  method run();
  set nc.members;
  if city='Raleigh';
  end;
enddata;
run;

Example 2: Concatenating Tables
If more than one table name appears in the SET statement, the resulting output table is a concatenation of all the tables that are listed. SAS reads all rows from the first table, and then all from the second table, and so on, until all rows from all the tables have been read. This example concatenates the three tables into one output table named FITNESS:

data fitness;
Example 3: Interleaving Tables
To interleave two or more tables, use a BY statement after the SET statement:

```sas
data april;
  method run();
  set payable recvable;
  by account;
  end;
enddata;
run;
```

Example 4: Combining a Single Row with All Rows in a Table
A row to be combined into an existing table can be one that is created by another DS2 program. In this example, the table AVGSALES has only one row:

```sas
data national;
  method init ();
  set avgsales;
  end;
  method run();
  set totsales;
  end;
enddata;
run;
```

Example 5: Reading from the Same Table More Than Once
In this example, SAS treats each SET statement independently. That is, it reads from one table as if it were reading from two separate tables. The LOCKTABLE=share option is used so that the same data set (in this case trial5) can be opened at the same time:

```sas
data drugxyz;
  method run();
  set trial5(locktable=share keep=(sample));
  if sample>2;
    set trial5;
  end;
enddata;
run;
```

For each iteration of the DS2 program, the first SET statement reads one row. The next time the first SET statement is executed, it reads the next row. Each SET statement can read different rows with the same iteration of the DS2 program.

See Also
- “BY-Group Processing When Running Thread Programs inside the Database” in SAS In-Database Products: User's Guide
- “Reading Data Using the SET Statement” in SAS Viya: DS2 Programmer’s Guide
SET FROM Statement

Runs a DS2 program as one or more threads.

Category: Local
Restriction: Multiple SET FROM statements are not allowed in a data program. Otherwise, an error occurs.

Syntax

SET FROM thread [ THREADS = threads ];

Arguments

`thread`

specifies the thread name that is executed by the SET statement. `thread` can be one of these forms.

- `catalog.schema.thread`
- `schema.thread`
- `thread`

`catalog`
is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names. A catalog is a metadata object in a SAS Metadata Repository.

`schemas`
is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

`thread`
is the name of the thread.
Requirements

The thread name must match the name of a thread created in a THREAD statement and the thread must be created before the SET FROM statement is executed, or an error will occur.

Thread naming conventions are based on the data source. For more information, see the documentation for your data source.

THREADS= threads

specifies the number of threads that are run for thread.

Restriction

This argument has no effect if the SAS In-Database Code Accelerator is used to access a database table. The SAS In-Database Code Accelerator always uses either the number of reducers specified in the config file with any maximum limitations that are set by the administrator or one reducer when processing the data program that is forced down to one reducer.

Requirement

threads must be an integer value.

Tip

If threads is not present, the thread runs as a single thread.

See “THREADS= Argument and the SAS In-Database Code Accelerator” on page 775

Details

The Basics

The SET FROM statement enables a DS2 program to run as a single thread or as multiple threads. The thread name specified in a SET FROM statement references a DS2 program thread that has been created by a THREAD statement.

Note: The SET FROM statement is best used in the RUN method to take advantage of the RUN method's implicit looping capability.

THREADS= Argument and the SAS In-Database Code Accelerator

If the thread program is run inside the database, the number of threads is set by the SAS In-Database Code Accelerator. The THREADS= argument has no effect if the SAS In-Database Code Accelerator for Greenplum, Hadoop, or Teradata is used to access a database table.

For more information about using the SAS In-Database Code Accelerator, see SAS In-Database Products: User’s Guide.

Comparisons

After the thread specified in SET FROM begins execution, the SET FROM statement executes similarly to the SET statement.

Similarities to note are:

• The PDV information for the thread is read by the DS2 program in which the SET FROM statement appears, so that all the output variables from the thread are declared automatically with correct types in the DS2 program.
• SET FROM and SET both loop through input until there are no more rows to read.

Here are differences to notice:

• Instead of reading from tables, the SET FROM statement reads the output from each of the threads.

• In general, the SET FROM statement’s input consists of the stream of output produced by all the running threads, via the thread’s OUTPUT statement. Because the execution order of threads is unpredictable, the input is not read sequentially like the SET statement reads tables. If the thread contains a SET statement that reads rows from tables, the rows are asynchronously divided among the threads. If a thread is not using a SET statement to read data, then the SET FROM statement’s input is similar to reading one or more copies of a table, but with no given order on the incoming rows.

Examples

**Example 1: Running a Single Thread**

In this example, threads X and Y are automatically declared in the DS2 program with the appropriate types. When the SET FROM statement executes, T is started as a single thread, its rows are read, and a simple calculation is done for each.

```
thread work.t;
  dcl int x;
  dcl double y;
  method init();
    dcl int i;
    do i = 1 to 5;
      x = i;
      y = i * 2.5;
      output;
    end;
  end;
endthread;
data;
  dcl thread work.t t;
  method run();
    set from t;
    sum = x + y;
    put ' x= ' x ' y= ' y ' sum= ' sum;
  end;
enddata;
```

The following lines are written to the SAS log.

<table>
<thead>
<tr>
<th>x= 1</th>
<th>y= 2.5</th>
<th>sum= 3.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>x= 2</td>
<td>y= 5</td>
<td>sum= 7</td>
</tr>
<tr>
<td>x= 3</td>
<td>y= 7.5</td>
<td>sum= 10.5</td>
</tr>
<tr>
<td>x= 4</td>
<td>y= 10</td>
<td>sum= 14</td>
</tr>
<tr>
<td>x= 5</td>
<td>y= 12.5</td>
<td>sum= 17.5</td>
</tr>
</tbody>
</table>

**Example 2: Running Multiple Threads**

This example modifies a thread, T, to run multiple threads by adding the THREADS option to the SET FROM statement.

```
thread work.t;
```
dcl int x;
dcl double y;
method init();
  dcl int i;
  do i = 1 to 5;
    x = i;
    y = i * 2.5;
    output;
  end;
end;
endthread;
data;
dcl thread work.t t;
method run();
  set from t threads=2;
  sum = x + y;
  put ' x= ' x ' y= ' y ' sum= ' sum;
end;
enddata;

This runs two threads for T. These lines are written to the SAS log.

<table>
<thead>
<tr>
<th>x= 1 y= 2.5 sum= 3.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>x= 2 y= 5 sum= 7</td>
</tr>
<tr>
<td>x= 3 y= 7.5 sum= 10.5</td>
</tr>
<tr>
<td>x= 4 y= 10 sum= 14</td>
</tr>
<tr>
<td>x= 5 y= 12.5 sum= 17.5</td>
</tr>
<tr>
<td>x= 1 y= 2.5 sum= 3.5</td>
</tr>
<tr>
<td>x= 2 y= 5 sum= 7</td>
</tr>
<tr>
<td>x= 3 y= 7.5 sum= 10.5</td>
</tr>
<tr>
<td>x= 4 y= 10 sum= 14</td>
</tr>
<tr>
<td>x= 5 y= 12.5 sum= 17.5</td>
</tr>
</tbody>
</table>

In this case, the output is sequential, although there is no guarantee that will happen consistently.

**Example 3: Accumulating Thread Values**

In this example, the thread T generates a value of 1. In the DS2 program, four threads are started, and all output values are summed and printed in the TERM method.

thread t;
  dcl int x;
  method init();
    x = 1;
    output;
  end;
endthread;
data;
dcl thread t t;
dcl int sum;
method init();
  sum = 0;
end;
method run();
  set from t threads=4;
  sum + x;
end;
method term();
STOP Statement

Stops execution of the current DS2 program.

Category: Local

Syntax

STOP;

Without Arguments

The STOP statement causes processing of the current DS2 program to stop immediately and resume processing statements after the end of the current DS2 program.

Details

If DS2 generates a table, the row being processed when STOP executes is not added. The STOP statement can be used alone or in an IF-THEN/ELSE statement or SELECT group.

The TERM method will always execute regardless of the method in which the STOP statement is executed. If you use the STOP statement in the TERM method, the TERM method will stop at the point where the STOP statement is executed.

If the STOP statement is executed in the INIT method or any method that is called from the INIT method, the RUN method will not execute.

Sum Statement

Adds or subtracts the result of an expression to an accumulator variable.

Category: Local

Note: The Sum statement can be used only with global variables. If you use the Sum statement with local variables, the values are not retained.
Syntax

```
variable + expression;
variable – expression;
```

Arguments

**variable**

specifies the name of the accumulator variable, which contains a numeric value.

**Restrictions**

If you use an undeclared array in the Sum statement, an error occurs and a message is written to the SAS log.

The variable name cannot be “x”.

**Tips**

The variable is automatically set to 0 before DS2 reads the first row. The variable's value is retained from one iteration to the next, as if it had appeared in a RETAIN statement.

To initialize a sum variable to a value other than 0, include it in a RETAIN statement with an initial value.

**expression**

is any valid DS2 expression.

**Tip**

DS2 treats an expression that produces a missing or null value as zero.

**See**

“DS2 Expressions” in *SAS Viya: DS2 Programmer’s Guide*

Details

**expression** is evaluated and the result added to the accumulator variable. When the plus sign (+) is used, the result is added to the accumulator variable. When a minus sign (–) is used, the negative result is added to, in essence subtracted from, the accumulator variable.

Comparisons

The Sum statement is equivalent to using the SUM function and the RETAIN statement, as shown in this example.

```
retain variable 0;
variable=sum(variable,expression);
```

Examples

**Example 1:**

Here are examples of the Sum statement.

```
i + 2;
balance - debit;
umvalid + (not missing(x));
```
Example 2: Using the Sum Statement with Global and Local Variables

The following example uses both global and local variables in a Sum statement. Note that the value of the local variable, \( x \), does not change.

```sas
data _null_;  
dcl int y;  
method m();  
dcl int x;  
x = 1;  
x + 2;  
y + 4;  
put x= y=;  
end;  

method init();  
   do i = 1 to 3;  
      m();  
   end;  
end;  
enddata;  
run;  
```

The following lines are written to the SAS log:

```
x=3 y=4  
x=3 y=8  
x=3 y=12
```

THREAD Statement

Creates a DS2 program thread.

**Category:** Block

**Syntax**

```
THREAD thread [ ( data-type variable [ , … data-type variable ] ) ]  
[/ENCRYPT=SAS | AES]/[table-options];  
   … thread-body …  
ENDTHREAD;
```

**Arguments**

- **thread**
  - specifies the thread name. `thread` can be one of these forms.
    - `catalog.schema.thread`
    - `schema.thread`
    - `catalog.thread`
    - `thread`
catalog
is an implementation of the ANSI SQL standard for an SQL catalog, which is a
data container object that groups logically related schemas. The catalog is the
first-level (top) grouping mechanism in a data organization hierarchy that is used
along with a schema to provide a means of qualifying names. A catalog is a
metadata object in a SAS Metadata Repository.

schema
is an implementation of the ANSI SQL standard for an SQL schema, which is a
data container object that groups files such as tables and views and other objects
supported by a data source such as stored procedures. The schema provides a
grouping object that is used along with a catalog to provide a means of qualifying
names.

thread
is the name of the thread.

Requirement Thread naming conventions are based on the data source. For more
information, see the documentation for your data source.

data-type
is an optional data type declaration. For more information, see “DS2 Data Types” in

variable
names an optional variable that identifies the parameter.

/ENCRYPT=SAS|AES
specifies the encryption algorithm. SAS specifies the SAS Proprietary algorithm.
AES specifies the Advanced Encryption Standard (AES) algorithm.

Default SAS

Interaction The ENCRYPT option for the THREAD statement is different from
and has different values than the ENCRYPT= table option. The
ENCRYPT= table option affects only SAS output data sets. For more
information, see “ENCRYPT= Table Option ” on page 815.

/table-options
specifies optional arguments that the DS2 program applies when it creates a thread.
For more information about table options, see Chapter 13, “DS2 Table Options,” on
page 803.

thread-body
contains the declarations and methods in the thread.

Details
A DS2 thread begins with the THREAD statement and ends with the ENDTHREAD
statement. These statements define a block with global scope. For more information
about global scope, see “Scope of DS2 Identifiers ” in SAS Viya: DS2 Programmer’s
Guide.

The thread body consists of a set of global declarations and a list of methods. You can
specify the number of threads used by a thread program by using the SET FROM
statement.

A DS2 program processes input data and produces output data. A DS2 program can run
in two different ways: as a program and as a thread. When a DS2 program runs as a
program, here are the results:
• Input data can include both rows from database tables and rows from DS2 program
  threads.
• Output data can be either database tables or rows that are returned to the client
  application.

When a DS2 program runs as a thread, here are the results:
• Input data can include only rows from database tables, not other threads.
• Output data includes the rows that are returned to the DS2 program that started the
  thread.

For more information about threads, see “Overview of Threaded Processing” in SAS Viya: DS2 Programmer’s Guide.

A DS2 thread must be given a name. This name identifies a catalog entry in which the
thread’s source code is stored after it successfully compiles. Other DS2 programs and
threads can then read and execute the thread by using the SET FROM statement.

When a thread is declared, a table is created with the name of the thread. A note is
written to the SAS log that indicates that a table was created and where it was created,
typically to the Work library. In most situations, a single-level named table does not
persist after a SAS session ends. However, some single-level named tables do persist.
Tables with multi-level names always persist after a SAS session. If a thread persists, it
can be executed multiple times without having to redeclare the thread. You can add a
DROP THREAD statement to your program to clean up unwanted tables.

Threads are declared for use in a DS2 program by using the DECLARE THREAD
statement. When you declare a thread, the variable representing the thread is considered
an instance of the thread. Thread variables can appear only in global scope. Otherwise,
an error occurs. For more information about instantiating a thread, see the DECLARE
THREAD statement.

Note: If variables are declared with a HAVING clause in a thread program and the
variables are redeclared in a data program with a HAVING clause, the HAVING
clause in the data program is used instead of the HAVING clause in the thread
program. If there is no HAVING clause in the DECLARE statement in the data
program, the HAVING clause in the thread program is not used.

Threads can have parameters, as in this example:

thread work.t (double d, char (100) sp);

When you are using parameterized threads, the parameter names and their types are
specified in the THREAD statement. The DS2 program that calls the thread must
initialize the thread’s parameters by calling the SETPARMS method. In this example, the
parameter D is initialized with a value of 99 and the parameter SP is initialized with a
value of ‘ijk’.

 t.setparms(99, ‘ijk’);

By default, DS2 threads are encrypted with SAS encryption. You can override this
default and specify AES encryption by using the ENCRYPT=AES table option in the
THREAD statement. SAS Proprietary is a fixed encoding algorithm that is included with
Base SAS software. It requires no additional SAS product licenses. For more
information, see Encryption in SAS Viya.

Table options can be specified in the THREAD statement. They are specified after the
package name and preceded by a slash.

Note: The SAS In-Database Code Accelerator enables you to publish a thread program
to the database and execute that thread program in parallel inside the database. For
more information about using the SAS In-Database Code Accelerator, see *SAS In-Database Products: User’s Guide*.

**Comparisons**

For a comparison between packages, DS2 programs, and threads, see “Block Statements” on page 690.

**Examples**

**Example 1: Simple Thread**
In this example, a single thread is created by using the THREAD statement.

```sas
thread t;
  dcl int x;
  method init();
    x = 99;
    output;
  end;
endthread;
```

**Example 2: Running Multiple Threads**
This example modifies a thread, T, to run multiple threads by adding the THREADS option to the SET FROM statement.

```sas
thread work.t;
  dcl int x;
  dcl double y;
  method init();
    dcl int i;
    do i = 1 to 5;
      x = i;
      y = i * 2.5;
      output;
    end;
  end;
endthread;
data;
  dcl thread work.t t;
  method run();
    set from t threads=2;
    sum = x + y;
    put ' x= ' x ' y= ' y ' sum= ' sum;
  end;
enddata;
```

This runs two threads for T. These lines are written to the SAS log.
In this case, the output is sequential, although there is no guarantee that will happen consistently.

VARARRAY Statement

Declares one or more DS2 variable arrays.

Syntax

VARARRAY <data-type> array-name <array-declaration> [<variable-list>] [<having-clause>];

<data-type>::=

<exact-numeric-type> | <approximate-numeric-type> | <binary-string-type> | <string-type> | <date-type>

<exact-numeric-type>::=

{INT | BIGINT | SMALLINT | TINYINT | DECIMAL [(precision [scale]) | NUMERIC [(precision [scale])] }

<approximate-numeric-type>::=

{DOUBLE | DOUBLE PRECISION | FLOAT | REAL}

<binary-string-type>::=

BINARY(length) | VARBINARY(length)

<string-type>::=

NCHAR [ (character-length)] | NVARCHAR [ (character-length)] | CHAR [ (character-length)] [CHARACTER SET character-set-identifier]
VARCHAR

$<$date-type>$::=\{\{TIME\}|\{TIMESTAMP\}\}[\{precision\}]|DATE$

$array-declaration::=\{array-bound\},…<array-bound>\}$

$array-bound::=\{\{dim-lower\}|dim-upper\} \{|\{dim-lower\} \{DIM(a[,n])\} | *}\}$

$<variable-list>::=\$

$\ |

$\text{name-varlist} | \\ \text{numbered-range-varlist} | \text{name-range-list} | \text{name-prefix-list} | \text{type-varlist} | \text{special-name-list}$

$<having-clause>::=\$

$\text{HAVING} <\text{having-option}> […] <\text{having-option}> \}$

$<\text{having-option}>::=\$

$\text{LABEL} \text{'}string\text{' }|n\text{'}string\text{'$|$|FORMAT format$|$|INFORMAT format$

Arguments

$\text{INT} | \text{BIGINT} | \text{SMALLINT} | \text{TINYINT}$

specifies an integer array.

$\text{Alias}\quad\text{INTEGER for INT}$

$\text{See}\quad\text{"DS2 Data Types" in SAS Viya: DS2 Programmer’s Guide}$

$\text{DECIMAL}[(\text{precision} [, \text{scale}])] | \text{NUMERIC}[(\text{precision} [, \text{scale}])]$

specifies an exact numeric variable or array.

$\text{precision}$

specifies the maximum total number of decimal digits that can be stored, both to the left and to the right of the decimal point

$\text{Note}\quad\text{Not all data sources can support a precision of 52 digits.}$

$\text{scale}$

specifies the maximum number of decimal digits that can be stored to the right of the decimal point

$\text{Range}\quad0–\text{precision}$

$\text{Note}\quad\text{scale is less than or equal to precision.}$

$\text{See}\quad\text{"DS2 Data Types" in SAS Viya: DS2 Programmer’s Guide}$

$\text{DOUBLE} | \text{DOUBLE PRECISION} | \text{FLOAT} | \text{REAL}$

specifies a floating-point array.

$\text{See}\quad\text{"DS2 Data Types" in SAS Viya: DS2 Programmer’s Guide}$
**BINARY** *(length)*
specifies a binary variable or array.

**Requirement**
If you specify BINARY, you must also specify the *length* of the variable or array in bytes.

**See**
“DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**VARBINARY** *(length) | BINARY** *(length)*
specifies a fixed-length or varying-length binary array.

**Alias** BINARY VARYING

**See**
“DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**NCHAR | NVARCHAR | CHAR | VARCHAR**
specifies a character array.

**Aliases**
NATIONAL CHARACTER, NATIONAL CHAR for NCHAR
NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING for NVARCHAR
CHARACTER for CHAR
CHARACTER VARYING for VARCHAR

**See**
“DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**character-length**
specifies the maximum number of characters that the string can hold for NCHAR, NVARCHAR, CHAR, and VARCHAR data types.

**Default** 8

**CHARACTER SET** *character-set-identifier*
specifies character set encoding information for CHAR and VARCHAR data types.

**Default** Default encoding depends on your operating system and locale.

**Tip**
You can use a character string literal or a simple string for character set names. For example, you can specify "ibm-866" or 'ibm-866'

**See**
For a complete list of character set encoding values, see “Character Sets for Encoding in NLS” in the *SAS Viya National Language Support: Reference Guide*.

**TIME**
specifies a time array.

**TIMESTAMP**
specifies both a date and time array.

**precision**
specifies the precision for a TIME or TIMESTAMP data type.

**Defaults**
0 for time
6 for timestamp
Note If you are working with TIME and TIMESTAMP values in a data source other than SAS and you do not specify a precision, the default precision will always be the DS2 default precision of 0 for TIME and 6 for TIMESTAMP.

DATE
specifies a date array.

dim-lower and dim-upper
specifies a positive or negative integer used to define the number and size of the array boundary.

Tip If the lower bound of a dimension is not specified, then the lower bound defaults to 1.

DIM(a[, n])
specifies that the size of the upper bounds of the array is determined by the number of elements in a dimension of a previously declared array by using a DIM function call.

a
specifies the name of a previously declared array.

n
specifies the dimension, in a multidimensional array, for which you want to know the number of elements.

Tip If no n value is specified, the DIM function returns the number of elements in the first dimension of the array.

Restriction The DIM function is the only function that you can use to specify an upper array bounds. The DIM function cannot be used to specify the lower bound of a dimension.

See “DIM Function” on page 305

*
specifies a one-dimensional array in which the lower bound is 1 and the upper bound is the number of variables in the variable list.

Requirement You must specify at least one variable in the variable list.

<variable-list>
specifies the name of the variable(s) that is to be referenced by the elements of the array.

Requirement variable must be the same type specified in data-type.

Tip You can specify one or more variables.

LABEL 'string' | n'string'
signals a descriptive label to the variable array. The label can be a CHAR literal (string) or NCHAR literal (nstring).
See “DS2 Data Types” in *SAS Viya: DS2 Programmer’s Guide*

**FORMAT format**
Associates any valid DS2 format with the variable or array.

See Chapter 6, “DS2 Formats,” on page 51

**INFORMAT informat**
Associates any valid SAS informat with the variable or array.

See Chapter 8, “DS2 Informats,” on page 681

**Details**
You use the `VARARRAY` statement to create a variable array. A variable array is a temporary grouping of global variables. Only one array can be specified in a `VARARRAY` statement.

Variable arrays exist only for the duration of the DS2 program.

The different forms of variable lists can be mixed within a single variable list specification. For example, `vararray double a[*] u x1-x3 u:;` is a valid statement.

The above variable list would expand to `u x1 x2 x3 u u1 u2`. Therefore, a seven-element variable array would be constructed. Note that a single variable can be referenced by multiple elements of a variable array.

For information about how to create a temporary array, see “DECLARE Statement” on page 705.

**Example**
The following table contains examples of statements that specify variable arrays and the dimensions of those arrays.

<table>
<thead>
<tr>
<th>Statement</th>
<th>Number of Dimensions</th>
<th>Range of Each Dimension</th>
<th>Number of Elements</th>
<th>Referenced Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>vararray double a[100];</code></td>
<td>1</td>
<td>1:100</td>
<td>100</td>
<td>a1...a100</td>
</tr>
<tr>
<td><code>vararray double a[2, 2];</code></td>
<td>2</td>
<td>1:2 1:2</td>
<td>4</td>
<td>a1 a2 a3 a4</td>
</tr>
<tr>
<td><code>vararray double a[-3:3, 5, 7:9, 10];</code></td>
<td>4</td>
<td>-3:3 1:5 7:9 1:10</td>
<td>7x5x3x10 = 1050</td>
<td>a1 ... a1050</td>
</tr>
<tr>
<td><code>vararray double a[3] x y z;</code></td>
<td>1</td>
<td>1:3</td>
<td>3</td>
<td>x y z</td>
</tr>
<tr>
<td><code>vararray double a[3] c1-c3;</code></td>
<td>1</td>
<td>1:3</td>
<td>3</td>
<td>c1 c2 c3</td>
</tr>
<tr>
<td><code>vararray double a[2, 2] t u v w;</code></td>
<td>2</td>
<td>1:2 1:2</td>
<td>4</td>
<td>t u v w</td>
</tr>
<tr>
<td><code>vararray double a[2, 2, 2] u v2-v4 w1-w3 x;</code></td>
<td>3</td>
<td>1:2 1:2 1:2</td>
<td>8</td>
<td>u v2 v3 v4 w1 w2 w3 x</td>
</tr>
<tr>
<td><code>vararray double a[*] x y z;</code></td>
<td>1</td>
<td>1:3</td>
<td>13</td>
<td>x y z</td>
</tr>
</tbody>
</table>
VARLIST Statement

Creates a named variable list.

Syntax

VARLIST list-name \[variable-list\];

Arguments

list-name
specifies the name of the variable list.

[variable-list]
specifies the variables that are to be referenced by the list.

Requirement
The variable-list must be enclosed in brackets ([]).

Details

Note that the VARLIST statement is limited to the global scope of the DS2 package or program. The VARLIST statement cannot be used to create a local variable list.

Example

In this example, the VARLIST statement creates a variable list named allvars, which contains all the PDV variables in the DS2 program.

varlist allvars [_all_];

Overview of System Methods

Methods are basic program execution units. A method defines a scoping block, so any parameters and any variable declarations in the method body are local to the method. In DS2, all program code must reside in some method.

System methods have a preset meaning in DS2. There are three system methods: INIT, RUN, and TERM. These methods cannot be overloaded. There is one optional system method that is used only with threads: SETPARMS.

The following table lists and summarizes the purpose of each DS2 system method.

<table>
<thead>
<tr>
<th>System Method</th>
<th>Execution Details</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| INIT( )       | Automatically executes one time, as the first method of a program. | As the name implies, INIT( ) is a good place to initialize global program variables. Most global variables are not initialized by the system. However, the system does initialize predefined variables, such as _N_ and _N_ , and variables that are used in Sum and RETAIN statements. If your program does not require the capabilities of the other system methods, you can code your entire program in the INIT( ) method. Just add DS2 statements, including but not limited to the following:
• DECLARE statements to create method-scope local variables
• Calls to one or more user-defined methods
• DS2 statements that perform variable assignments, call DS2 functions, execute loops or other logic, and so on
For more information, see “INIT Method” on page 792. |

</tr>
</thead>
<tbody>
<tr>
<td>INIT Method</td>
<td></td>
<td>792</td>
</tr>
<tr>
<td>RUN Method</td>
<td></td>
<td>793</td>
</tr>
<tr>
<td>SETPARMS Method</td>
<td></td>
<td>795</td>
</tr>
<tr>
<td>TERM Method</td>
<td></td>
<td>797</td>
</tr>
</tbody>
</table>
### System Method | Execution Details | Purpose
--- | --- | ---
**RUN( )** | Automatically executes after INIT( ) completes. | The RUN( ) method is the functional equivalent of the DATA step. That is, if your RUN( ) method contains a SET statement, the method runs as an implicit loop. You can also use RUN( ) to read rows from a thread program using the SET FROM statement.  
*Note:* You are not required to include code that leverages the implicit loop capabilities.  
If appropriate, you can code your entire program in the RUN( ) method, as described for INIT( ).  
For more information, see “RUN Method” on page 793.

**TERM( )** | Automatically executes one time, as the last method of a program. | As the name implies, TERM( ) is where final processing takes place, before the program exits.  
TERM( ) automatically resets global variables to uninitialized values, with the following exceptions:  
• predefined variables, such as _N and _N_  
• accumulator variables that were used in Sum statements  
• variables that were used in a RETAIN statement  
• package variables  
If appropriate, you can code your entire program in the TERM( ) method, as described for INIT( ).  
For more information, see “TERM Method” on page 797.

**SETPARMS( )** | Executes one time, when called from a data program, to initialize the values of a parameterized thread. | SETPARMS( ) initializes the values of a parameterized thread. Because only parameterized thread programs require this, SETPARMS( ) is the only system method that must be called.  
*Note:* Do not write a SETPARMS( ) method in your thread program.  
The system supplies the method for you.  
*Note:* Do not call SETPARMS( ) more than once. The initialization works only the first time.  
For more information, see “SETPARMS Method” on page 795.

For complete information about how methods work in DS2, see “Methods” in *SAS Viya: DS2 Programmer’s Guide.*

---

**Dictionary**

**INIT Method**

Calls a DS2 system method where program initializations can take place.

**Syntax**

```plaintext
METHOD INIT();
END;
```
**Without Arguments**
The METHOD INIT statement has no arguments. If you try to pass arguments, an error will occur.

**Details**
Typically, the INIT method will contain any initialization code such as variable initialization or opening of tables. Code in the INIT method will run once at the beginning of the DS2 program.

Every DS2 program will contain, either implicitly or explicitly, the INIT, RUN, and TERM methods. If you do not specify a METHOD INIT statement, DS2 will automatically provide one.

For more information about the INIT method and how DS2 programs work, see “Methods” in *SAS Viya: DS2 Programmer’s Guide*.

**Example**
```plaintext
method init();
  dcl int i;
  dcl double d;
  d = 99;
  do i = 1 to 3;
    d = d + i;
    output d;
  end;
end;
```

**See Also**
- “Methods” in *SAS Viya: DS2 Programmer’s Guide*

**Methods:**
- “RUN Method” on page 793
- “TERM Method” on page 797

---

**RUN Method**
Calls a DS2 system method where DS2 program code can run in an implicit loop.

**Syntax**
```plaintext
METHOD RUN();
END;
```

**Without Arguments**
The METHOD RUN statement has no arguments. If you try to pass arguments, an error will occur.
Details

Typically, the RUN method will contain the main DS2 program code. The RUN method has the same feature of automatic, implicit looping as the Base SAS DATA step. After the RUN method has been executed one time, the RUN method either runs again or control is passed to the TERM method.

Every DS2 program will contain, either implicitly or explicitly, the INIT, RUN, and TERM methods. If you do not specify a METHOD INIT or METHOD TERM statement, DS2 will automatically provide one.

After the INIT method runs and before the RUN method is executed, variables in the program data vector, which have not been retained (by using the RETAIN statement), will be set to either SAS missing values or null values depending on whether you are in SAS mode or ANSI mode.

Local variables in the RUN method completely cease to exist between invocations of RUN in the implicit loop. For each invocation of the RUN method, all local variables are constructed at the start of execution of the method and destroyed at end of execution of the method. All global variables, except column variables read by the SET statement, are set to missing or null between each iteration (RUN method invocation) of the implicit loop. To retain state data through the implicit loop, you must create a global variable AND also specify that the variable's value be retained across executions of the RUN method with the RETAIN statement. The RUN method will be executed \(x+1\) times for a table with \(x\) rows. If a SET statement is executed and finds no more rows, then the implicit looping of the RUN method ceases.

For more information about the RUN method and how DS2 programs work, see “Methods” in SAS Viya: DS2 Programmer’s Guide.

Comparisons

In Base SAS, the entire DATA step represents the implicit loop. In the DS2 language, the implicit loop is represented by the RUN method.

Example

DS2's flow of execution is to call the INIT method once, then the RUN method until the input tables are completely read, then the TERM method. The RUN method is where the implicit loop exists. The following program demonstrates this flow of control by finding the minimum of values in a table. The INIT method initializes the columns used to find the current minimum, the RUN method compares input values with the current minimum, and the TERM method writes the minimums to an table.

data xy_data;
  dcl double x y;
  method init();
    do x = 1 to 5;
      y = 2*x;
      output;
    end;
  end;
enddata;
run;
/* Find the minimum value for x and y */
data xy_mins;
dcl double min_x min_y;
retain min_x min_y;
keep min_x min_y;
method init();
    min_x = 999999;
    min_y = 999999;
end;
method run();
    set xy_data;
    if x < min_x then min_x = x;
    if y < min_y then min_y = y;
end;
method term();
    output;
end;
enddata;
run;
/* Send result table of minimums to output */
data;
method run();
    set xy_mins;
end;
enddata;
run;

SETPARMS Method

Initializes parameters for an instance of a DS2 thread.

Restriction: The SETPARMS method cannot be used with the SAS In-Database Code Accelerator.

Syntax

thread.Setpars(parameter-value[, ...parameter-value]);

Arguments

thread
    specifies an instance of the thread.

caller
    specifies the initial value of the thread parameter.
Details

When using parameterized threads, the parameter names and their types are specified in the THREAD statement. The DS2 program that invokes the thread must initialize the thread's parameters by calling the SETPARMS method. In this example, assume you have an instance of the thread, T, that takes two parameters, INV and PROD.

\[
\text{thread work.t (double inv, char (30) prod);}
\]

Using the SETPARMS method, the parameter INV is initialized with a value of 38824 and the parameter PROD is initialized with a value of 'rice'.

\[
t.setparms(38824, 'rice');
\]

Each argument is passed by value to the corresponding thread parameter. All arguments will be converted, if necessary, to the data type of the corresponding parameter. If the SETPARMS method is called for a thread, which has no parameters, an error will occur.

The SETPARMS method must be called to initialize parameters for a thread before the thread's SET FROM statement executes, or the parameters will initialize with SAS missing values or null values, depending on whether you are in SAS mode or ANSI mode. For more information, see “How DS2 Processes Nulls and SAS Missing Values” in SAS Viya: DS2 Programmer’s Guide.

Example

This example illustrates how to use threads with parameters.

\[
\text{thread work.t (double d, char (100) sp);}
\]

\[
\text{dcl int x;}
\]

\[
\text{dcl double y;}
\]

\[
\text{dcl nchar(20) s;}
\]

\[
\text{dcl char(30) c;}
\]

\[
\text{method init();}
\]

\[
\text{dcl int i;}
\]

\[
\text{s = 'abc' || sp;}
\]

\[
\text{c = 'uvwxyz' || sp;}
\]

\[
\text{do i = 1 to 100;}
\]

\[
\text{x = i;}
\]

\[
\text{y = i * 2.5 + d;}
\]

\[
\text{output;}
\]

\[
\text{end;}
\]

\[
\text{end;}
\]

\[
\text{endthread;}
\]

\[
\text{run;}
\]

\[
\text{data;}
\]

\[
\text{dcl thread work.t t;}
\]

\[
\text{method init();}
\]

\[
\text{t.setparms(99, 'ijk');}
\]

\[
\text{end;}
\]

\[
\text{method run();}
\]

\[
\text{set from t;}
\]

\[
\text{answer = x + y;}
\]

\[
\text{put 's= ' s ' x= ' x ' y= ' y ' c= ' c ' answer= ' answer;}
\]

\[
\text{end;}
\]

\[
\text{enddata;}
\]

\[
\text{run;}
\]

This is a partial listing of lines that are written to the SAS log:
**TERM Method**

Calls a DS2 system method where program finalizations can take place.

**Syntax**

```
METHOD TERM ();
END;
```

**Without Arguments**

The METHOD TERM statement has no arguments. If you try to pass arguments, an error will occur.

**Details**

Typically, the TERM method will contain any finalization code such as writing data to the SAS log. Code in the TERM method will run once at the end of the DS2 program.

Every DS2 program will contain, either implicitly or explicitly, the INIT, RUN, and TERM methods. If you do not specify a METHOD TERM statement, DS2 will automatically provide one.

For more information about the TERM method and how DS2 programs work, see “Methods” in *SAS Viya: DS2 Programmer’s Guide*.

Overview of System Options

System options are instructions that affect the processing of an entire SAS program or interactive SAS session from the time the option is specified until it is changed.

Here is the syntax for specifying system options in an OPTIONS statement:

```sas
OPTIONS options(s);
```

Here is an explanation of the syntax:

- **option**
  - specifies one or more SAS system options that you want to change.

The following example show how to use the system option DS2SCOND in an OPTIONS statement.

```sas
options ds2scond=none;
```

Dictionary

**DS2ACCEL= System Option**

Specifies whether DS2 code is enabled for parallel processing in supported environments using the SAS In-Database Code Accelerator.

- **Valid in:** Configuration file, SAS command, OPTIONS statement, SAS System Options window
  - Greenplum, Hadoop, and Teradata

```
PROC OPTIONS
GROUP= LANGUAGECONTROL
```
**Syntax**

`DS2ACCEL= ANY | NONE`

**Arguments**

- **ANY**
  - enables DS2 code to execute in supported parallel environments.

- **NONE**
  - disables DS2 code from executing in supported parallel environments.

**Details**

The SAS In-Database Code Accelerator enables you to publish a DS2 thread program to the database and execute the thread program in parallel inside the database. If you are using the SAS In-Database Code Accelerator for Teradata or Hadoop, the DS2 data program is also published and executed inside the database.

The `DS2ACCEL=` system option controls whether DS2 code is executed inside the database.

You can override the `DS2ACCEL=` system option by specifying the `DS2ACCEL=` option in the PROC DS2 statement.

**See Also**

- “Using the DS2ACCEL Option to Control In-Database Processing” in *SAS In-Database Products: User’s Guide*

**Procedures:**

- “DS2” in *SAS Viya Data Management and Utility Procedures Guide*

---

**DS2SCOND= System Option**

Specifies the level of messages that PROC DS2 displays in the SAS log for the DS2 variable declaration strict mode, which requires that every variable must be declared in the DS2 program.

**Valid in:** Configuration file, SAS invocation, OPTIONS statement, SAS System Options window

**PROC OPTIONS GROUP=** ErrorHandling

**Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in *SAS Viya System Options: Reference.*

**Syntax**

`DS2SCOND=ERROR | NONE | NOTE | WARNING`
**Arguments**

**ERROR**
writes Error messages to the SAS log.

Alias ERR

**NONE**
no messages are written to the SAS log.

**NOTE**
writes Notes to the SAS log.

**WARNING**
writes Warning messages to the SAS log. This is the default.

Alias WARN

**Details**

You can override the DS2SCOND system option by specifying the SCOND= option in the PROC DS2 statement.

**Procedures:**

- “DS2” in *SAS Viya Data Management and Utility Procedures Guide*
Overview of Table Options

Table options are analogous to data set options in Base SAS.

Table options specify actions that apply only to the tables with which they appear. These are some of the operations that table options enable you to perform:

- rename variables
- specify passwords
- specify options for bulk loading data
• drop variables from processing or from the result table

*Note:* Some table options are data source specific. Table options that are not recognized by DS2 are passed without error to the underlying table driver.

---

**Using Table Options in DS2**

Table options can be used on these DS2 statements:

- DECLARE PACKAGE
- DECLARE THREAD
- DROP PACKAGE
- DROP THREAD
- PACKAGE
- SET
- DATA
- THREAD

Some table options can apply to packages and threads.

Most table options can apply to either input or output tables. If a table option is associated with an input table, the action applies to the table that is being read. If the option appears in the DATA statement, SAS applies the action to the output table. In DS2, table options for output tables must appear in the DATA statement, not in any OUTPUT statements that might be present.

Some table options, such as COMPRESS=, are meaningful only when you create a SAS data set because they set attributes that exist for the duration of the data set. To change or cancel most table options, you must re-create the table.

When table options appear in both input and output tables in the same DS2 program, first SAS applies table options to input tables. Then SAS evaluates programming statements or applies table options to output tables. Likewise, table options that are specified for the table being created are applied after programming statements are processed. For example, when using the RENAME= table option, the new names are not associated with the columns until the DS2 program is compiled.

In some instances, table options conflict when they are used in the same statement. For example, you cannot specify both the DROP= and KEEP= table options for the same variable in the same statement. Timing can also be an issue in some cases. For example, if you are using KEEP= and RENAME= in a table that is specified in the SET statement, KEEP= must use the original column names. SAS processes KEEP= before the table is read. The new names that are specified in RENAME= apply to the programming statements that follow the SET statement.

Table options are applicable whenever you are reading or writing a table that contains data. Therefore, table options work with DS2 packages and threads because packages and threads are stored in tables.
How to Specify Table Options in DS2

Table options are either enclosed in parentheses or preceded by a forward slash (/), depending on which statement they are used in. Table options should be placed at the end of the statement when they are preceded by the forward slash.

Table options are enclosed in parentheses when used in these statements:

• DECLARE PACKAGE
• DECLARE THREAD
• DROP PACKAGE
• DROP THREAD
• SET
• DATA

If the table option is enclosed in parentheses and the option value can be several items separated by spaces, the option values are also enclosed in parentheses. For examples, see “DS2 Table Option Examples” on page 805.

Table options are preceded by a forward slash (/) when used in these statements:

• PACKAGE
• THREAD

DS2 Table Option Examples

The following are examples of table options that are enclosed in parentheses:

data a (bufno=10);
data prod (drop=(price sales));
declare package (pw=lk34890f) sales;
drop thread (write=24klj) complex;

Here are some examples of table options that are preceded by a forward slash (/):

package invent /overwrite=yes;
thread work.t (double d, char (100) sp) /read=44kl7;
Dictionary

**ALTER= Table Option**

Assigns an ALTER password to a data set that prevents users from replacing or deleting the file, and enables access to a Read- and Write-protected file.

Restriction: This table option is not supported in the CAS server.

Data source: SAS data set

**Syntax**

```plaintext
ALTER=alter-password
```

**Arguments**

`alter-password` must be a valid SAS name.

**Details**

The ALTER= option applies only to a SAS data set. You can use this option to assign a password or to access a read-protected, write-protected, or alter-protected file. When you replace a data set that is protected with an ALTER password, the new data set inherits the ALTER password.

The password is blotted out when the code is written in the SAS log. Here is an example:

```plaintext
set a(alter=XXXXXXX);
```

**Note:** A SAS password does not control access to a SAS file beyond the SAS System. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.

**BUFNO= Table Option**

Specifies the number of buffers to be allocated for processing a SAS data set.

Restriction: This table option is not supported in the CAS server.

Data source: SAS data set

**Syntax**

```plaintext
BUFNO= n | nK | hexX | MIN | MAX
```
Arguments

$n | nK$
specifies the number of buffers in multiples of 1 (bytes); 1,024 (kilobytes). For example, a value of 8 specifies 8 buffers, and a value of 1k specifies 1024 buffers.

$\text{hex}$
specifies the number of buffers as a hexadecimal value. You must specify the value beginning with a number (0-9), followed by an X. For example, the value 2dx sets the number of buffers to 45 buffers.

$\text{MIN}$
sets the minimum number of buffers to 0, which causes SAS to use the minimum optimal value for the operating environment. This is the default.

$\text{MAX}$
sets the number of buffers to the maximum possible number in your operating environment, up to the largest four-byte, signed integer, which is $2^{31}-1$, or approximately 2 billion.

Details

The buffer number is not a permanent attribute of the data set; it is valid only for the current SAS session or job.

BUFNO= applies to SAS data sets that are opened for input, output, or update.

A larger number of buffers can speed up execution time by limiting the number of input and output (I/O) operations that are required for a particular SAS data set. However, the improvement in execution time comes at the expense of increased memory consumption.

To reduce I/O operations on a small data set as well as speed execution time, allocate one buffer for each page of data to be processed. This technique is most effective if you read the same observations several times during processing.

Comparisons

• If the BUFNO= table option is not specified, then the value of the BUFNO= system option is used. If both are specified in the same SAS session, the value specified for the BUFNO= table option overrides the value specified for the BUFNO= system option.

• To request that SAS allocate the number of buffers based on the number of data set pages and index file pages, use the SASFILE global statement.

**BUFSIZE= Table Option**

Specifies the size of a permanent buffer page for an output SAS data set.

Restriction: Use with output data sets only.

Data source: SAS data set

Syntax

$\text{BUFSIZE}= n | nK | nM | nG | \text{hexX} | \text{MAX}$
Arguments

\( n | nK | nM | nG \)

specifies the page size in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). For example, a value of \( 8 \) specifies a page size of 8 bytes, and a value of \( 4k \) specifies a page size of 4096 bytes.

\( \text{hex}X \)

specifies the page size as a hexadecimal value. You must specify the value beginning with a number (0-9), followed by an \( X \). For example, the value \( 2dx \) sets the page size to 45 bytes.

\( \text{MAX} \)

sets the page size to the maximum possible number in your operating environment, up to the largest four-byte, signed integer, which is \( 2^{31}-1 \), or approximately 2 billion bytes.

Details

The page size is the amount of data that can be transferred for a single I/O operation to one buffer. The page size is a permanent attribute of the data set and is used when the data set is processed.

A larger page size can speed up execution time by reducing the number of times SAS has to read from or write to the storage medium. However, the improvement in execution time comes at the cost of increased memory consumption.

To change the page size, use the COPY procedure to copy the data set and either specify a new page or use the SAS default. To reset the page size to the default value in your operating environment, use BUFSIZE=0.

Note: If you use the COPY procedure to copy a data set to another library that is allocated with a different engine, the specified page size of the data set is not retained.

Operating Environment Information

The default value for BUFSIZE= is determined by your operating environment and is set to optimize sequential access. To improve performance for direct (random) access, you should change the value for BUFSIZE=. For the default setting and possible settings for direct access, see the BUFSIZE= option in the SAS documentation for your operating environment.

Comparisons

If the BUFSIZE= table option is not specified, then the value of the BUFSIZE= system option is used. If both are specified in the same SAS session, the BUFSIZE= table option overrides the value specified for the BUFSIZE= system option.

BULKLOAD= Table Option

Loads rows of data as one unit.

Default: NO

Data source: Aster, DB2 UNIX and PC, Greenplum, Hadoop, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, Sybase IQ, Teradata
Syntax
BULKLOAD=YES | NO

Arguments
YES
calls a DBMS-specific bulk-load facility in order to insert or append rows to a DBMS table.

NO
uses the dynamic SAS/ACCESS engine to insert or append data to a DBMS table.

Details
Using BULKLOAD=YES is the fastest way to insert rows into a DBMS table.
When BULKLOAD=YES, the first error encountered causes the remaining rows (including the erroneous row) in the buffer to be rejected. No other errors within the same buffer will be detected. In addition, all rows before the error are committed, even if DBCOMMIT= is set larger than the number of the erroneous row.

COMPRESS= Table Option
Specifies how observations are compressed in a new output SAS data set.

Restriction: Use with output data sets only.
Data source: SAS data set

Syntax
COMPRESS=NO | YES | CHAR | BINARY

Arguments
NO
specifies that the observations in a newly created SAS data set are uncompressed (fixed-length records).

YES | CHAR
specifies that the observations in a newly created SAS data set are compressed (variable-length records) by SAS using RLE (Run Length Encoding). RLE compresses observations by reducing repeated consecutive characters (including blanks) to two-byte or three-byte representations.

Alias    ON

Note    COMPRESS=CHAR is accepted by SAS 7 and later.
Tip    Use this compression algorithm for character data.

BINARY
specifies that the observations in a newly created SAS data set are compressed (variable-length records) by SAS using RDC (Ross Data Compression). RDC combines run-length encoding and sliding-window compression to compress the file.
Tip
This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (numeric variables). Because the compression function operates on a single record at a time, the record length needs to be several hundred bytes or larger for effective compression.

Details
Compressing a file is a process that reduces the number of bytes required to represent each observation. Advantages of compressing a file include reduced storage requirements for the file and fewer I/O operations necessary to read or write to the data during processing. However, more CPU resources are required to read a compressed file (because of the overhead of uncompressing each observation), and there are situations where the resulting file size might increase rather than decrease.

After a file is compressed, the setting is a permanent attribute of the file, which means that to change the setting, you must re-create the file. That is, to uncompress a file, copy the file and specify COMPRESS=NO.

Comparisons
The COMPRESS= table option overrides the COMPRESS= option in the LIBNAME statement.

When you create a compressed file, you can also specify REUSE=YES table option in order to track and reuse space. With REUSE=YES, new observations are inserted in space freed when other observations are updated or deleted. When the default REUSE=NO is in effect, new observations are appended to the existing file.

DBCREATE_TABLE_OPTS= Table Option
Specifies DBMS-specific options to be added to the DATA statement.

Data source: Aster, DB2 UNIX, Greenplum, Hadoop, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, Sybase IQ, Teradata

Syntax
DBCREATE_TABLE_OPTS= 'DBMS-option(s)'

Arguments
DBMS-option(s)
specifies one or more valid DBMS-specific options. If more than one option is specified, the options should be separated in the same way as options are separated in the DBMS.

Details
Basics
This option enables you to add DBMS-specific options to the DATA statement. The interface passes the DATA statement and its clauses to the DBMS, which executes the statement and creates the DBMS table. An example of this would be to use the COLUMN-DELIMITER= option to specify a column delimiter for Hadoop files.
\textit{Note}: If the SAS ACCESS DBCREATE_TABLE_OPTS LIBNAME option and the DBCREATE_TABLE_OPTS table option are used, the table option setting takes precedence.

\textbf{Quoting DBMS Options}

The DBMS-options must be enclosed with single-quotation marks. Elements within DBMS-options that are quoted should use double the quotation marks around the element. For example, if single quotation marks are used, you use two single quotation marks. If double quotation marks are used, you use two sets of double quotation marks. Here are some examples:

\begin{verbatim}
/* Using double quotes around DBMS-option element causes an error */
DBCREATE_TABLE_OPTS="FIELDS TERMINATED BY '\012' 

/* Using single quotes around DBMS-option element works */
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY '\012' 

/* You can double the quote character to insert one into a quoted value*/
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY ''\012'' 

/* doubled single quote passes single quote to database */
/* trailing space after last set of single quotes added for emphasis */
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY ''\012'' ' 

/* doubled double quotes passes double quotes to database */
/* trailing space after last set of double quotes added for emphasis */
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY ""\012"" ' 
\end{verbatim}

\textbf{Examples}

\textbf{Example 1}

In the following example, the Teradata table Teralib is created with the value of the \texttt{primary index} () option appended to the DATA statement.

\begin{verbatim}
libname teralib teradata server=terasvr database=model user=myid password=xxxx;

proc delete data=teralib.outtable;
proc ds2;
data teralib.outtable(overwrite=yes dbcreate_table_opts='primary index(i)');
   retain x 0;
   method run();
   do i=1 to 10 by 1 ;
      x=i;
      output;
   end;
   end;
enddata;
run;
quit;
\end{verbatim}

\textbf{Example 2}

In the following example, the Hive table \texttt{Hivelib.Dzoutput} is created and has the \texttt{partition by} option appended to the DATA statement. In this example, \texttt{Col1} exists in the table in the SET statement, \texttt{Hivelib.Dzpt}, although this is not required.

\begin{verbatim}
options set=SAS_HADOOP_JAR_PATH="jar-path";
\end{verbatim}
**DBKEY= Table Option**

Specifies a key column to optimize DBMS retrieval. Can improve performance when you are processing a join that involves a large DBMS table and a small SAS data set or DBMS table.

**Default:** none

**Data source:** Aster, DB2 UNIX and PC, Greenplum, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, Sybase IQ, Teradata

**Syntax**

```
DBKEY=([ ' ] column [ ' ] [... [ ' ] column [ ' ] ])
```

**Arguments**

*column*

Used by SAS to build an internal WHERE clause to search for matches in the DBMS table based on the key column. Here is an example:

```
select * from sas.a, dbms.b(dbkey=x) where a.x=b.x;
```

In this example, DBKEY= specifies column `x`, which matches the key column designated in the WHERE clause. However, if the DBKEY= column does NOT match the key column in the WHERE clause, then DBKEY= is not used.

**Details**

When processing a join that involves a large DBMS table and a relatively small SAS data set, you might be able to use DBKEY= to improve performance.

When you specify DBKEY=, it is *strongly* recommended that you ensure that an index exists for the key column in the underlying DBMS table. Performance can be severely degraded without an index.

**CAUTION:**

Improper use of this option can decrease performance.
**DBNULL= Table Option**

Indicates whether NULL is a valid value for the specified columns when a table is created.

**Default:** DBMS-specific

**Data source:** Aster, DB2 UNIX and PC, Greenplum, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, Sybase IQ, Teradata

---

**Syntax**

```
DBNULL= { _ALL_ = YES | NO } | ([column=YES | NO [ ... column=YES | NO ] ]
```

**Arguments**

- **_ALL_**
  - specifies that the YES or NO applies to all columns in the table. (This is valid in the interfaces to Informix, Oracle, Sybase, and Teradata only.)

- **YES**
  - specifies that the NULL value is valid for the specified columns in the DBMS table.

- **NO**
  - specifies that the NULL value is not valid for the specified columns in the DBMS table.

- **column**
  - specifies the name of a column.

**Details**

This option is valid only for creating DBMS tables. If you specify more than one column name, the names must be separated with spaces.

The DBNULL= option processes values from left to right, so if you specify a column name twice, or if you use the _ALL_ value, the last value overrides the first value that is specified for the column.

---

**DROP= Table Option**

For an input table, excludes the specified columns from processing; for an output table, excludes the specified columns from being written to the table.

**Data source:** All

---

**Syntax**

```
DROP= (column-list)
```

**Arguments**

- **column-list**
  - specifies the names of the columns to omit from the output table.
Restriction

Numbered range lists in the format col1–col5 and name prefix lists in the format col: are not supported.

Details

The DROP= table option specifies that all columns in the column-list should not be included in the creation of output rows. Normally, all columns in the program data vector are included in the output rows. If the drop attribute is specified, all columns not included in the drop statement will be used to create columns in the output rows.

If the DROP= table option is associated with an input table, the columns are not available for processing during program execution.

Comparisons

The DROP= table option differs from the DROP statement in these ways:

• In DS2 programs, the DROP= table option can apply to both input and output tables. The DROP statement applies only to output tables.

• In DS2 programs, when you create multiple output tables, use the DROP= table option to write different columns to different tables. The DROP statement applies to all output tables.

• The KEEP= table option specifies a list of columns to be included in processing or to be written to the output table.

Examples

Example 1: Excluding Columns from Output Tables

In this example, the variables SALARY and GENDER are not included in processing and they are not written to either output tables.

data plan1 plan2;
   method run ();
      set payroll(drop=(salary gender));
      if hired>'01jan07'd then output plan1;
      else output plan2;
   end;
enddata;

You cannot use SALARY or GENDER in any logic in the DS2 program because DROP= prevents the SET statement from reading them from PAYROLL.

Example 2: Processing Columns without Writing Them to the Output Table

In this example, SALARY and GENDER are not written to PLAN2, but they are written to PLAN1.

data plan1 plan2(drop=(salary gender));
   method run ();
      set payroll;
      if hired>'01jan07'd then output plan1;
      else output plan2;
   end;
enddata;

Table Options:
- “KEEP= Table Option” on page 821

**ENCRYPT= Table Option**

Specifies whether to encrypt an output SAS data set.

**Restrictions**: This table option is not supported in the CAS server.
Use with output data sets only.

**Data source**: SAS data set

**Syntax**

\[ \text{ENCRYPT= AES | NO | YES} \]

**Arguments**

**AES**

encrypts the file using the AES (Advanced Encryption Standard) algorithm.

**Requirement**

You must specify the ENCRYPTKEY= table option when using ENCRYPT=AES.

**Interaction**

AES provides enhanced encryption by using SAS/SECURE software. SAS/SECURE is a product within the SAS System. SAS/SECURE is included with Base SAS software. In prior releases, SAS/SECURE was an add-on product that was licensed separately. This change makes strong encryption available in all deployments (except where prohibited by import restrictions). SAS/SECURE must be installed on each computer that runs a client and a server that uses the encryption algorithms.

**See**

“ENCRYPTKEY= Table Option” on page 817

**CAUTION**

Record all ENCRYPTKEY= values when using ENCRYPT=AES.

If you forget the ENCRYPTKEY= value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= value. The following note will be written to the log:

Note: If you lose or forget the ENCRYPTKEY= value, there will be no way to open the file or recover the data.

**NO**

does not encrypt the data set.
YES
encrypts the data set using the SAS Proprietary algorithm.

CAUTION:
If you forget the passwords, you cannot reset them.

Interaction
This encryption method uses passwords that are stored in the data set.
At a minimum, you must specify the READ= table option or the PW=
table option at the same time that you specify ENCRYPT=YES.
Because the encryption method uses passwords, you cannot change any
password on an encrypted file without re-creating the table.

CAUTION Record all passwords when using ENCRYPT=YES. If you forget the
passwords, you cannot reset them.

Details
When you use ENCRYPT=SAS, the following rules apply:

• You can use the ENCRYPT= option only when you are creating a SAS data file.
• In order to copy an encrypted data file, the output engine must support encryption.
  Otherwise, the data file is not copied.
• Encrypted files work only in SAS 6.11 or later.
• If the data file is encrypted, all associated indexes are also encrypted.
• Encryption requires approximately the same amount of CPU resources as
  compression.
• You cannot use PROC CPORT in SAS Proprietary encrypted SAS data files.

When you use ENCRYPT=AES, the following rules apply:

• You must use the ENCRYPTKEY= table option when creating a table.
• When you copy an encrypted AES data file, the output engine must support AES
  encryption. Otherwise, the data file is not copied.
• You must have SAS/SECURE software to use AES encryption.
• You cannot change the ENCRYPTKEY= value in an AES encrypted data file
  without re-creating the data file.

Note: You can create an encrypted DS2 package or thread program by using the
ENCRYPT argument in the PACKAGE and THREAD statements.

Example
This example creates an encrypted SAS data set:

table salary(encrypt=SAS);

See Also

Statements:
• “PACKAGE Statement” on page 753
• “THREAD Statement” on page 780
Table Options:

- “ENCRYPTKEY= Table Option” on page 817

---

**ENCRYPTKEY= Table Option**

Specifies a key value for AES encryption.

**Restrictions:**
- This table option is not supported in the CAS server.
- Use only with AES encrypted data files.

**Requirement:**
- SAS/SECURE must be in use

**Interaction:**
- You cannot change the key value on an AES encrypted data set without re-creating the data set.

**Data source:**
- SAS data set

---

**Syntax**

```
ENCRYPTKEY= [" | '"]key-value[" | '"]
```

**Arguments**

`key-value`

assigns an encrypt key value. The key value can be up to 64-bytes long. You are able to create an ENCRYPTKEY= key value with or without quotation marks using the following rules:

**no quotation marks**
- alphanumeric characters and underscores only
- up to 64 bytes
- uppercase and lowercase letters
- must start with a letter
- no blank spaces
- is not case-sensitive

**Example**

```
encryptkey=key-value
encryptkey=key-value1
```

**single quotation marks**
- alphanumeric, special, and DBCS characters
- up to 64 bytes
- uppercase and lowercase letters
- blank spaces, but not all blanks
- is case-sensitive

**Example**

```
encryptkey='key-value'
encryptkey='1234*#mykey'
```

**double quotation marks**
- alphanumeric, special, and DBCS characters
• up to 64 bytes
• uppercase and lowercase letters
• enables macro resolution
• blank spaces, but not all blanks
• is case-sensitive

Example
encryptkey=*key-value*
enryptkey=*1234*#mykey*

%let mykey=abcdefghi12;
enryptkey=&key-value

Requirement
If you use ENCRYPT=AES, you must specify the ENCRYPTKEY= table option.

Note
When the ENCRYPTKEY= key value uses DBCS characters, the 64-byte limit applies to the character string after it has been transcoded to UTF-8 encoding. You can use the following DATA step to calculate the length in bytes of a key value in DBCS:

data _null_
  key=length(unicode('key-value','UTF8'));
  put 'key length=' key;
run;

Details

CAUTION:

Record the key value. If you forget the ENCRYPTKEY= key value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value because the key value is not stored with the table. The following warning will be written to the log:

WARNING: If you lose or forget the ENCRYPTKEY= value, there will be not be any way to open the file or recover the data.

You must use the ENCRYPTKEY= option when you are creating or accessing a SAS data set with AES encryption.

The ENCRYPTKEY= table option will not protect the table from deletion or replacement. Encrypted tables can be deleted by using any of the following scenarios without having to specify an ENCRYPTKEY= key value:

• the KILL option in PROC DATASETS
• the DROP statement in PROC SQL
• the DELETE procedure

The ENCRYPTKEY= option prevents access only to the contents of the table. To protect the table from deletion or replacement, the file must also contain an ALTER= password.

The following DATASETS procedure statements require you to specify the ENCRYPTKEY= key value when working with protected files: AGE, AUDIT, APPEND, CHANGE, CONTENTS, MODIFY, REBUILD, and REPAIR statements.

append base=name data=name(encryptkey=key-value);
run;
The option can be specified either in parentheses after the name of the SAS data file or after a forward slash.

It is possible to use a macro variable as the ENCRYPTKEY= key value. When you specify a macro variable for the ENCRYPTKEY= key value, you must enclose the macro variable in double quotation marks. If you do not use the double quotation marks, unpredictable results can occur. The following example defines a macro variable and uses the macro variable as the ENCRYPTKEY= key value:

```sas
%let secret=myvalue;
data my dsname(encrypt=aes encryptkey="&secret");
```

The following example uses the COPY statement from the DATASETS procedure and the SELECT statement:

```sas
copy in=OldLib out=NewLib;
  select salary(encryptkey=key-value);
run;
```

The option can be specified either in parentheses after the name of the table or after a forward slash.

**CAUTION:**

When using referential integrity constraints, all primary key and foreign key tables that reference each other must use the same encryption key.

**Note:** When DS2 runs outside of SAS, such as in the SAS Federation Server and in grid computing environments, the SAS macro facility is not available and DS2 programs with macros fail to compile.

**Example**

This example uses the ENCRYPT=AES option.

```sas
data salary (encrypt=aes encryptkey=green overwrite=yes);
dcl char(8) name;
dcl double yrsal;
dcl double bonuspct;
method init();
  name='Muriel'; yrsal=34567; bonuspct=3.2;
  name='Bjorn'; yrsal=74644; bonuspct=2.5;
  name='Freda'; yrsal=38755; bonuspct=4.1;
  name='Benny'; yrsal=29855; bonuspct=3.5;
  name='Agnetha'; yrsal=70998; bonuspct=4.1;
end;
run;
```

When you run the CONTENTS procedure, you will be prompted to specify the ENCRYPTKEY= key value.

```sas
proc contents data=salary;
run;
```

**See Also**

**Table Options:**
- “ENCRYPT= Table Option” on page 815
**IN= Table Option**

Creates an integer variable that indicates whether the table contributed data to the current row.

**Restriction:** Use with the SET and MERGE statements only.

**Data source:** All

---

**Syntax**

`IN=variable`

**Arguments**

`variable`

names the new variable whose value indicates whether that input table contributed data to the current row. Within a DS2 program, the value of the variable is 1 if the table contributed to the current row, and 0 otherwise.

**Interaction**

If the variable is not explicitly declared, it is automatically declared in the local scope of the SET or MERGE statement as INTEGER.

**Data type**

BIGINT, INTEGER, SMALLINT, TINYINT

---

**Details**

Specify the IN= table option in parentheses after a table name in the SET or MERGE statements. Values of IN= variables are available to program statements during the time the DS2 program is running, but the variables are not included in the table that is being created. To capture the value of the IN= variable in the table being created, assign it another variable.

When you use IN= with BY-group processing, the IN= variable is set to 1 if that table contributed to the current row. The IN= variable is set to 0 if the table did not contribute to the current row. The IN= variable is always set to 1 or 0 by the SET or MERGE statement, but it can be changed by subsequent programming logic.

**Note:** If the IN= variable is set before the SET or MERGE statement, that value is lost during execution of the SET or MERGE statement.

---

**Example**

The following example illustrates the IN= table option.

```plaintext
data _null_
  dcl int gro;
  method run();
    dcl smallint gpo;
    dcl tinyint gpf;
    set gas_price_option (in=gpo) gas_rbidx_option (in=gro)
                 gas_price_forward (in=gpf);
    put gpo= gro= gpf=;
  end;
enddata;
```

- “SET Statement” on page 770

KEEP= Table Option

For an input table, specifies the columns to process; for an output table, specifies the columns to write to the table.

Data source: All

Syntax

\texttt{KEEP=(column-list)}

Arguments

\texttt{column-list}

specifies the names of the columns to keep in the output table.

Restriction

Numbered range lists in the format \texttt{col1–col5} and name prefix lists in the format \texttt{col:} are not supported.

Details

The KEEP= table option specifies that all columns in the \texttt{column-list} should be included in the creation of output rows. Normally, all columns in the program data vector are included in the output rows. If the KEEP= table option is specified, all columns that are not included in the KEEP= table option are dropped from the output rows.

If the KEEP= table option is associated with an input table, only the columns that are specified by the KEEP= table option are available for processing during program execution.

Only global variables, by default, are included in the output. Local variables used for program loops and indexes do not need to be explicitly dropped from the output.

Comparisons

The KEEP= table option differs from the KEEP statement in these ways:

- In DS2 programs, the KEEP= table option can apply to both input and output tables. The KEEP statement applies only to output tables.
- In DS2 programs, when you create multiple output tables, use the KEEP= table option to write different columns to different tables. The KEEP statement applies to all output tables.
- The DROP= table option specifies columns to omit during processing or to omit from the output table.
Example

In this example, only IDNUM and SALARY are read from PAYROLL, and they are the only variables in PAYROLL that are available for processing.

```sas
data bonus;
  method run();
    set payroll(keep=(idnum salary));
    bonus=salary*1.1;
  end;
enddata;
```

See Also

Table Options:
- “DROP= Table Option” on page 813

---

**LABEL= Table Option**

Specifies a label for a table.

**Data source:** SAS data set

**Syntax**

```sas
LABEL='label'
```

**Arguments**

'`label`'

specifies a text string of up to 256 characters. If the label text contains single quotation marks, use double quotation marks around the label, or use two single quotation marks in the label text and enclose the string in single quotation marks. To remove a label from a table, assign a label that is equal to a blank that is enclosed in quotation marks.

**Details**

You can use the LABEL= option on both input and output tables. When you use LABEL= on input tables, it assigns a label for the table for the duration of the DS2 program. When it is specified for an output table, the label becomes a permanent part of that table.

A label assigned to a table remains associated with that table when you update a table in place. However, a label is lost if you use a table with a previously assigned label to create a new table in the DS2 program. For example, a label previously assigned to table ONE is lost when you create the new output table ONE:

```sas
data one;
  set one;
enddata;
```
Comparisons

The LABEL= option in the HAVING clause of the DECLARE statement also enables you to assign labels to variables.

Example

These examples assign labels to tables:

data w2 (label = '2009 W2 Info, Hourly');
data new (label = 'Sales'' list');
data acct (label = "Hillside''s Daily Account");
data sales (label = 'May (South)');

LOCKTABLE= Table Option

Places shared or exclusive locks on tables.

Data source: SAS data set

Syntax

LOCKTABLE=SHARE | EXCLUSIVE

Arguments

SHARE
  locks a table in shared mode, allowing other users or processes to read data from the tables, but preventing users from updating data.

EXCLUSIVE
  locks a table exclusively, preventing other users from accessing any table that you open.

Details

You can lock tables only if you are the owner or have been granted the necessary privilege.

If you use PROC DS2, the default value for the LOCKTABLE option is EXCLUSIVE.

OVERWRITE= Table Option

For a table, drops the output table before the replacement output table is populated with rows; for packages and threads, drops the existing package or thread if a package or thread by the same name exists.

Data source: All

Syntax

OVERWRITE=YES | NO
Arguments

YES | NO

specifies whether the output table is deleted before a replacement output table is created or whether a package or thread is dropped.

CAUTION:

For tables, use the OVERWRITE= YES statement only with data that is backed up or with data that you can reconstruct. Because the output table is deleted first, data will be lost if a failure occurs while the output table is being written.

Default NO

Details

Details for Tables

By default, in DS2, a table is not overwritten unless the OVERWRITE= table option is set to YES. If the output table exists and the OVERWRITE= table option is set to NO, an error will occur because the existing table will not be overwritten.

Details for Packages

If you set OVERWRITE= YES in a PACKAGE statement and a DS2 thread or a regular table exists with the same name as the package being created, the table will not be dropped. Only the package is dropped.

Details for Threads

If you set OVERWRITE= YES in a THREAD statement and a DS2 package or a regular table exists with the same name as the thread being created, the table will not be dropped. Only the thread is dropped.

Examples

Example 1: Using DROP, KEEP, and OVERWRITE

The following example uses the DROP=, KEEP=, and OVERWRITE= table options for tables a and b.

data
  a(keep=x overwrite=yes)
  _rowset_(drop=(x z))
  b(keep=z overwrite=yes);
  dcl double x y z;
  method init();
    do x = 1 to 10;
      y = 2*x;
      z = 3*x;
      output;
    end;
  end;
enddata;
run;
data;
  method run();
set a;
end;
enddata;
run;
data;

Example 2: Overwriting a Table

The following example creates a table, and then attempts to overwrite it without
OVERWRITE=YES.

data a;
method init();
do x = 1 to 10;
y = 2*x;
z = 3*x;
output;
end;
end;
enddata;
run;

/* This program fails because it is impossible to overwrite table A */
data a;
method run();
x = y + z;
output;
end;
enddata;
run;

/* This program deletes (drops) table A before attempting to create it, */
/* so the program executes without error. If there is an error during */
/* execution, the old version of A is lost. */
data a(overwrite=yes); method run();
x = y + z;
output;
end;
enddata;
run;

**PW= Table Option**

Assigns a READ, WRITE, and ALTER password to a SAS file, and enables access to a password-
protected SAS file.

**Restriction:** This table option is not supported in the CAS server.

**Data source:** SAS data set
Syntax
PW=password

Arguments
password
    must be a valid SAS name.

Details
The PW= option applies to all types of SAS files. You can use this option to assign a password to a SAS file or to access a password-protected SAS file.

When you replace a SAS data set that is protected by an ALTER password, the new data set inherits the ALTER password. When the code is written to the SAS log, the password is blotted out. Here is an example:

drop thread job2 (pw=xxxxxxxx);

Note: A SAS password does not control access to a SAS file beyond the SAS System. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.

See Also
Table Options:
• “ENCRYPT= Table Option ” on page 815
• “ALTER= Table Option ” on page 806
• “WRITE= Table Option” on page 829

READ= Table Option
Assigns a READ password to a SAS file that prevents users from reading the file, unless they enter the password.

Restriction: This table option is not supported in the CAS server.
Data source: SAS data set

Syntax
READ=read-password

Arguments
read-password
    must be a valid SAS name.

Details
The READ= option applies to all types of SAS files except catalogs. You can use this option to assign a password to a SAS file or to access a Read-protected SAS file. When the code is written to the SAS log, the password is blotted out. Here is an example:
DECLARE PACKAGE SALES (READ=XXXXXXX);

Note: A SAS password does not control access to a SAS file beyond the SAS System. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.

See Also

Table Options:

- “ENCRYPT= Table Option” on page 815
- “PW= Table Option” on page 825
- “WRITE= Table Option” on page 829

RENAME= Table Option

Changes the name of a column.

Data source: All

Syntax

RENAME=(old-name | AS new-name [...old-name | AS new-name])

Arguments

old-name

the column that you want to rename.

new-name

the new name of the column. It must be a valid name for the data source.

Details

The RENAME= table option enables you to change the names of one or more columns. If you use RENAME= when you create a table, the new column name is included in the output table. If you use RENAME= on an input table, the new name is used in DS2 programming statements.

If you use RENAME= in the same DS2 program with either the DROP= or the KEEP= table option, the DROP= and the KEEP= table options are applied before RENAME=. You must use the old name in the DROP= and KEEP= table options. You cannot drop and rename the same column in the same statement.

In addition to changing the name of a column, RENAME= also changes the label for the column.

Comparisons

- The RENAME= table option differs from the RENAME statement in the following ways.
  - The RENAME statement applies to all output tables. If you want to rename different columns in different tables, you must use the RENAME= table option.
The RENAME= table option enables you to specify the columns that you want to rename for each input or output table. Use it in input tables to rename columns before processing.

If you use both the RENAME statement and RENAME= output table option, the RENAME statement has precedence. If X is renamed to Y with a RENAME statement and X is renamed to Z with a RENAME= table option, the RENAME statement takes precedence and X will be renamed to Y.

Use the RENAME statement or the RENAME= table option when program logic requires that you rename columns such as two input tables that have columns with the same name.

Examples

Example 1: Renaming a Column at Time of Output
This example uses RENAME= in the DATA statement to show that the column is renamed when it is written to the output table. The column keeps its original name, X, during DS2 processing.

data two(rename=(x=keys))
method run();
set one;
  z=x+y;
run;
enddata;

Example 2: Renaming a Column at Time of Input
This example renames column X to a column named KEYS in the SET statement, which is a rename before DS2 processing. KEYS, not X, is the name to use for the column for DS2 processing.

data three;
  method run();
  set one(rename=(x AS keys));
  z=keys+y;
run;
enddata;

See Also

Statements:

- “RENAME Statement” on page 761

TYPE= Table Option

Specifies the data set type for a specially structured SAS data set.

Restriction: This table option is not supported in the CAS server.

Data source: SAS data set
Syntax

\texttt{TYPE=}data-set-type

Arguments

data-set-type

specifies the special type of the data set.

Details

Use the \texttt{TYPE=} table option in a DS2 program to create a special SAS data set in the proper format, or to identify the special type of the SAS data set in a procedure statement.

You can use the CONTENTS procedure to determine the type of a data set.

Most SAS data sets do not have a specified type. However, there are several specially structured SAS data sets that are used by some SAS/STAT procedures. These SAS data sets contain special variables and observations, and they are usually created by SAS statistical procedures.

Other values are available in other SAS software products and are described in the appropriate documentation.

Note: If you use a DS2 program with a \texttt{SET} statement to modify a special SAS data set, you must specify the \texttt{TYPE=} option in the \texttt{DATA} statement. The \texttt{data-set-type} is not automatically copied to the data set that is created.

See Also

Statements:

- “SET Statement” on page 770

\textbf{WRITE= Table Option}

Assigns a WRITE password to a SAS file that prevents users from writing to a file, unless they enter the password.

\begin{tabular}{ll}
\textbf{Restriction:} & This table option is not supported in the CAS server. \\
\textbf{Data source:} & SAS data set
\end{tabular}

Syntax

\texttt{WRITE=}write-password

Arguments

write-password

must be a valid SAS name.
The WRITE= option applies to all types of SAS files except catalogs. You can use this option to assign a password to a SAS file or to access a Write-protected SAS file. When the code is written to the SAS log, the password is blotted out. Here is an example:

drop thread job2a (write=XXXXXXX);

Note: A SAS password does not control access to a SAS file beyond the SAS System. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.

Dictionary

DECLARE PACKAGE Statement, FCMP Package

Creates a package variable and gives you the option to create an instance of the FCMP package.

**Category:** Local

**Restriction:** This operator is not supported in the CAS server.

**Requirement:** The PACKAGE statement is required before you use the DECLARE PACKAGE statement.

**Syntax**

DECLARE PACKAGE `fcmp-package-name` `variable` ( )

**Arguments**

`fcmp-package-name`

specifies the name of the FCMP package.

**Requirement**

The package name must match the name of a package created in a PACKAGE statement, or an error will occur.

**See**

“PACKAGE Statement” on page 753

`variable`

specifies a name that can reference an instance of the package.
Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use an FCMP package to support calls to functions and subroutines that are available or are created with the FCMP procedure. The FCMP package is predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

You create an FCMP package by using the PACKAGE statement then declare the FCMP package by using the DECLARE PACKAGE statement. This associates an FCMP package with an FCMP name. After you declare the new FCMP package, you can call the functions and subroutines that are created with the FCMP procedure.

There are two ways to construct an instance of an FCMP package.

- Use the DECLARE PACKAGE statement along with the _NEW_ operator:
  
  declare package fcmp pharma;
  pharma = _new_ fcmp();

- Use the DECLARE PACKAGE statement along with its constructor syntax:

  declare package fcmp pharma();

**Note:** Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

For more information about FCMP packages, see “Using the FCMP Package” in SAS Viya: DS2 Programmer’s Guide.

Examples

**Example 1: Using FCMP OUTARGS Parameters**

The following example creates FCMP subroutine named `package1` that uses OUTARGS parameters. The FCMP procedure’s OUTARGS parameter is treated as an IN_OUT parameter in the METHOD statement.

```plaintext
libname base '.';
proc fcmp outlib = base.fcmpsubs.package1;
  subroutine swapper(a,b);
    outargs a,b;
    t1 = b; b = a; a = t1;
  endsub;
run;
quit;

proc ds2;
  package pkg / overwrite=yes language='fcmp' table='base.fcmpsubs';
run;

data _null_;
  dcl package pkg p();
```

method init();
    dcl double x y;
    x=10;
    y=42;
    put 'before:' x= y=;
    p.swap(x,y);
    put 'after:' x= y=;
end;
enddata;
run;
quit;

The following lines are written to the SAS log.

| before: x=10 y=42 |
| after: x=42 y=10 |

**Example 2: FCMP Package Using DOUBLE Arguments**
This example walks through creation of a square routine in FCMP and using that routine from a DS2 program. The current directory is used as the "library" of FCMP packages.

libname base '.';

* fcmp defines a function, square;  
proc fcmp outlib = base.fcmpsubs.package1;  
    function square(a);  
        return (a*a);  
    endsub;  
run;  
quit;

* define the ds2 package thru which the fcmp functions will be called;  
proc ds2;  
    package pkg /overwrite=yes language='fcmp' table='base.fcmpsubs';  
run;

* demonstration of calling fcmp thru the ds2 wrapper package;  
data _null_;  
    dcl package pkg p();  
    dcl double a b;  
    method init();  
        do a = 10 to 20;  
            b=p.square(a);  
            put a= b=;  
        end;  
    end;  
enddata;
run;
quit;

The following lines are written to the SAS log.
Example 3: FCMP Package with Character Arguments

libname base '.';

proc fcmp outlib = base.fcmpsubs.package1;
  function f(a $) $ 10;
    return (trim(a) || trim(a));
  endsub;
run;

proc ds2;
  package pkg /overwrite=yes language='fcmp' table='base.fcmpsubs';
run;

data _null_;  
  dcl package pkg p();
  method runone(double arg, double expected);
    dcl double actual;
    actual=p.f(arg);
    if (actual ~= expected) then put 'ERROR:' arg= expected= actual=;
  end;
  method init();
    runone(5, 55);
    runone(345, 345345);
    runone(10, 1010);
    runone(4.2, .);     * cannot convert back to double w/ two '.' chars;
    runone(., .);
  end;
enddata;
run;
quit;

  • “Using the FCMP Package” in SAS Viya: DS2 Programmer’s Guide
  • “Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

Operators:
  • “_NEW_ Operator, FCMP Package” on page 835

Statements:
  • “PACKAGE Statement” on page 753
DELETE Method, FCMP Package

Deletes an FCMP package.

**Restriction:** This method is not supported in the CAS server.

**Note:** The DELETE method is not required. When an FCMP package goes out of scope, the package is deleted.

**Syntax**

`package.DELETE( );`

**Arguments**

`package`

specifies the name of the FCMP package variable.

**Details**

When you no longer need the FCMP package, delete it by using the DELETE method. If you attempt to use an FCMP package after you delete it, an error will be written to the log.

**See Also**

“Package Constructors and Destructors” in *SAS Viya: DS2 Programmer’s Guide*

.NEW_ Operator, FCMP Package

Constructs an instance of an FCMP package.

**Restriction:** This operator is not supported in the CAS server.

**Note:** The escape character (\) before the bracket indicates that the bracket is required in the syntax.

**Syntax**

`package-variable = _NEW_ ([THIS] | [package-instance]) fcmp-package-name( );`

**Arguments**

`package-variable`

specifies a name that can reference an instance of the package.

`[THIS]`

specifies that the package instance has global scope.

**See** “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*
[package-instance]
specifies that the new package instance has the same scope as package-instance. package-instance must be an existing package instance, and the type of package-instance can differ from the type of the new package instance.

See “Package-Specific Scope” in SAS Viya: DS2 Programmer’s Guide

fcmp-package-name
specifies the name of the package.

Requirement fcmp-package-name must be a predefined FCMP package created with a PACKAGE statement.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You create an FCMP package by using the PACKAGE statement then declare and instantiate the FCMP package by using the DECLARE PACKAGE statement. This associates an FCMP package with an FCMP package variable name. After you declare the new FCMP package, you can call the functions and subroutines that are created with the FCMP procedure.

There are two ways to construct an instance of an FCMP package.

• Use the DECLARE PACKAGE statement along with the _NEW_ operator:

  declare package pharma pkg;
  pkg = _new_ pharma();

• Use the DECLARE PACKAGE statement along with its constructor syntax:

  declare package pharma pkg();

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

ADD Method, Hash Package

Adds key values, data values, or both to the hash package.

**Applies to:** Hash package

### Syntax

**Form 1:**

```
package.ADD();
```

**Form 2:**

```
package.ADD([keys], [data]);
```

**Form 3:**

```
package.ADD([keys]);
```

### Arguments

- **package**
  - specifies an instance of the hash package variable.

- **[keys]**
  - specifies the key values by using a variable list.

  **Restriction**
  - If you specify keys only, the ADD method works only for key-only hash packages.

  **See**

- **[data]**
  - specifies the variables into which to add the hash data.

  **See**

### Details

You can store key and data values in the hash package using the ADD method.

There are two ways to pass keys and data values to the ADD method:

- **implicit variable method (Form 1)**
  - The key and data variables are implied in the ADD method invocation and do not have to be specified.

- **variable list method (Forms 2 and 3)**
  - The specified key and data variables are passed explicitly to the ADD method. If the hash package contains only keys, use Form 3.

**Note:**

- If you add a key that is already in the hash package, then the ADD method returns a nonzero value to indicate that the key is already in the hash package. Use the REPLACE method to replace the data that is associated with the specified key with new data. However, if you set the DUPLICATE constructor
parameter or method to **ADD** when you create the hash package, the ADD method returns a zero.

- If you do not specify the data variables with the DEFINEDATA method, the data variables are automatically assumed to be same as the keys.
- The ADD method does not set the value of the data variable to the value of the data item. It only sets the value in the hash package.

**Examples**

**Example 1: Using the Implicit Variable Method**

The following example uses the implicit variable method to define the key and data item.

```plaintext
data _null_;  
declare char(20) d;  
declare char(20) k;  
declare double rc;  
declare package hash h(4);  
method init();  
   /* Define constant value for key and data */  
   rc = h.defineKey ('k');  
   rc = h.defineData ('d');  
   rc = h.defineDone ();  
   /* Define constant value for key and data */  
   k='Homer';  
   d='Odyssey';  
   /* Use the ADD method to add the key and data to the hash package */  
   rc = h.add();  
   /* Define constant value for key and data */  
   k='Joyce';  
   d='Ulysses';  
   /* Use the ADD method to add the key and data to the hash package */  
   rc = h.add();  
end;  
enddata;  
run;
```

**Example 2: Adding Key and Data Values Using the Variable List Method**

The following example uses the implicit variable method to define the key and data item.

```plaintext
data _null_;  
declare char(20) d;  
declare char(20) k;  
declare double rc;  
method init();  
   declare package hash h([k], [d]);  
   /* Define constant value for key and data */  
   k='Homer';  
   d='Odyssey';  
   /* Use the ADD method to add the key and data to the hash package */  
   rc = h.add([k], [d]);  
   /* Define constant value for key and data */  
   k='Joyce';  
   d='Ulysses';
```
Example 3: Using the ADD and FIND Methods

The following example uses the ADD method to store the data in the hash package and associate the data with the key. The FIND method is then used to retrieve the data that is associated with the key value 'Homer'.

```sas
data _null_;  declare char(20) d;  declare char(20) k;  declare double rc;  method init();  declare package hash h([k], [d], 4);  /* Define constant value for key and data */  k='Homer';  put k=;  d='Odyssey';  put d=;  /* Use the ADD method to add the key and data to the hash package */  rc = h.add([k], [d]);  /* Define constant value for key and data */  k='Joyce';  d='Ulysses';  /* Use the ADD method to add the key and data to the hash package */  rc = h.add([k], [d]);  k='Homer';  /* Use the FIND method to retrieve the data associated with 'Homer' key */  if (h.find([k],[d]) = 0) then  put d=;  else  put 'Key Homer not found.';  end;  enddata;  run;
```

The FIND method assigns the data value 'Odyssey', which is associated with the key value 'Homer', to the variable D.

The following lines are written to the SAS log:

```
K=Homer
D=Odyssey
D=Odyssey
```

See Also

Methods:

- “DEFINEDATA Method” on page 855
CHECK Method

Checks whether the specified key is stored in the hash package.

**Applies to:** Hash package

### Syntax

Form 1:  
```
package.CHECK( );
```

Form 2:  
```
package.CHECK([keys]);
```

### Arguments

- **package**
  - specifies an instance of the hash package variable.

- **[keys]**
  - specifies the key values by using a variable list.

**See**  

### Details

You use the CHECK method to determine whether a key exists in the hash table but the data variable is not updated. The CHECK method returns a zero value if the key is found in the hash table and a nonzero value if the key is not found.

There are two ways to pass keys and data variables to the CHECK method:

- **implicit variable method (Form 1)**
  - The key variables are implied in the CHECK method invocation and do not have to be specified.

- **variable list method (Form 2)**
  - The specified key variables are passed explicitly to the CHECK method.

### Comparisons

The CHECK method returns only a value that indicates whether the key is in the hash package. The data variable that is associated with the key is not updated. The FIND method also returns a value that indicates whether the key is in the hash package. However, if the key is in the hash package, then the FIND method also sets the data variable to the value of the data item so that it is available for use after the method call.

### Example

In the following example, the CHECK method is used to determine whether the data is associated with the key value 'Homer'.

```sas
data _null_;
   declare char(20) d;
```
declare char(20) k;
declare double rc;
method init();
    declare package hash h([k], [d]);
    /* Define constant value for key and data */
    k='Homer';
    put k=;
    d='Odyssey';
    put d=;
    /* Use the ADD method to add the key and data to the hash package */
    rc = h.add([k], [d]);
    /* Define constant value for key and data */
    k='Joyce';
    d='Ulysses';
    /* Use the ADD method to add the key and data to the hash package */
    rc = h.add([k], [d]);
    k='Homer';
    /* Use the CHECK method to verify the data associated with 'Homer' key */
    if (h.check([k]) = 0) then
        put 'Key Homer is found.';
    else
        put 'Key Homer not found.';
    end;
enddata;
run;

The following lines are written to the SAS log.

```
k=Homer
d=Odyssey
Key Homer is found
```

---

CLEAR Method

Removes all items from a hash package without deleting the hash package instance.

**Applies to:** Hash package

**Syntax**

```
package.CLEAR();
```
Arguments

package
    specifies an instance of the hash package variable.

Details

The CLEAR method removes the items from within the hash package but leaves the hash package instance so that it can be reused. To remove a hash package completely, use the DELETE method.

To clear all items from the hash package MYHASH, use the following code:

```
rc = myhash.clear();
```

See Also

Methods:

- “DELETE Method, Hash, and Hash Iterator Package” on page 859

DATA Method

Specifies the data variables to be stored in the hash package by using a variable list.

Applies to: Hash package

Syntax

```
package.DATA([data]);
```

Arguments

package
    specifies an instance of the hash package variable.

[data]
    specifies the name of the data variables by using a variable list.

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You use a variable list to specify the data variables for a hash package using the DATA method. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

Note: Alternatively, you could use the DEFINEDATA method or constructors in the DECLARE PACKAGE statement to specify the data variables.

Keys and data consist of any number of character or numeric variables.
### Example

This example creates a hash package that contains two data variables and one key variable. The output is sorted in descending order.

```sas
data _null_
  dcl double x;
  dcl double rc;
  dcl date d;
  /* The output will be in descending order. */
  dcl package hash h(8, '', 'descending', '', '');
  dcl package hiter hi('h');

method init();
  rc = h.keys([d]);
  rc = h.data([d]);
  rc = h.data([x]);
  rc = h.definedone();
  d = date '1929-08-24'; x = 1; h.add();
  d = date '1930-09-25'; x = 2; h.add();
  d = date '1930-10-26'; x = 3; h.add();
  d = date '1930-10-27'; x = 4; h.add();
  d = date '1933-12-28'; x = 5; h.add();
  d = date '1999-12-01'; x = 999;
  do while (hi.next() = 0);
    put d= x=;
    d = date '1999-12-01'; x = 999;
  end;
enddata;
run;
```

The following lines are written to the SAS log.

<table>
<thead>
<tr>
<th>Date</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1929-12-28</td>
<td>5</td>
</tr>
<tr>
<td>1930-10-27</td>
<td>4</td>
</tr>
<tr>
<td>1930-10-26</td>
<td>3</td>
</tr>
<tr>
<td>1930-09-25</td>
<td>2</td>
</tr>
<tr>
<td>1929-08-24</td>
<td>1</td>
</tr>
</tbody>
</table>

- “DEFINEDONE Method” on page 857
- “KEYS Method” on page 875

### Statements:

- “DECLARE PACKAGE Statement, Hash Package” on page 846
DATASET Method

Specifies the name of a table to load into the hash package.

 Applies to: Hash package

Syntax

\[
\text{package.DATASET}([\text{data-source}] \mid \{\text{sql-text}\});
\]

Arguments

\text{package} specifies an instance of the hash package variable.

\text{data-source} specifies the name of a table.

Tip The name of the table can be a string literal or a character variable. If a literal is used, the table name must be enclosed in single quotation marks.

\{\text{sql-text}\}

is any valid FedSQL code that resolves to a set of table rows.

Restriction This argument is not supported in the CAS server.

Requirement The FedSQL query must be enclosed in braces ( \{ \} ).

Note The FedSQL query is specified in the following form: \{SELECT <select-list> FROM <table-specification>;\}. For more information, see “SELECT Statement” in SAS FedSQL Language Reference for SAS Cloud Analytic Services.

Details

You can specify the table to load into the hash package by using the DATASET method.

Note: Alternatively, you can use the \text{datasource} parameter in the DECLARE PACKAGE statement or the _NEW_ operator to specify the table.

See Also

Operators:

- “_NEW_ Operator, Hash Package” on page 878

Statements:

- “DECLARE PACKAGE Statement, Hash Package” on page 846
DECLARE PACKAGE Statement, Hash Package

Creates a package variable and gives you the option of creating an instance of the hash package.

Category: Local
Tip: The PACKAGE statement is not required for a hash package.

Syntax

Form 1: `DECLARE PACKAGE HASH variable ( );`
Form 2: `DECLARE PACKAGE HASH variable (hashexp, \{datasource | sql-text\}, 'ordered', 'duplicate', 'suminc', 'multidata');`
Form 3: `DECLARE PACKAGE HASH variable ([keys], [data], [hashexp, \{datasource | sql-text\}, 'ordered', 'duplicate', 'suminc', 'multidata']);`
Form 4: `DECLARE PACKAGE HASH variable ([keys], [hashexp, \{datasource | sql-text\}, 'ordered', 'duplicate', 'suminc', 'multidata']);`

Arguments

variable
specifies a variable that can reference an instance of the hash package.

[keys]
specifies the key values by using a variable list.

[data]
specifies the data variables by using a variable list and associates them with the specified keys.

hashexp
is the hash package's internal table size, where the size of the hash table is $2^n$.

The value of hashexp is used as a power-of-two exponent to create the hash table size. For example, a value of 4 for hashexp equates to a hash table size of $2^4$, or 16. The maximum value for hashexp is 16, which equates to a hash table size of $2^{16}$.

The hash table size is not equal to the number of items that can be stored. Think of the hash table as an array of containers. A hash table size of 16 would have 16 containers. Each container can hold an infinite number of items. The efficiency of the hash tables lies in the ability of the hash function to map items to and retrieve items from the containers.

In order to maximize the efficiency of the hash package lookup routines, you should set the hash table size according to the amount of data in the hash package. Try different hashexp values until you get the best result. For example, if the hash package contains one million items, a hash table size of 16 (hashexp = 4) would not be very efficient. A hash table size of 512 or 1024 (hashexp = 9 or 10) would result in better performance.
Range 0–20

Requirement A value for hashexp must be entered. If a value less than 0 is entered, then a default value of 8, which equates to a hash table size of $2^8$ or 256, is used. If a value greater than 20 is entered, then a default value of 20 is used.

Data type INTEGER

'datasource'
is the name of a table to load into the hash package.
The name of the table can be a literal or a character variable. The table name must be enclosed in single quotation marks.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for datasource must be entered. If the place holder is entered, then the hash is not loaded from a data source.

{sql-text} is any valid FedSQL SELECT statement that resolves to a set of table rows.

Restriction This argument is not supported in the CAS server.

Requirement The FedSQL query must be enclosed in braces ( {} ).

Note The FedSQL query is specified in the following form: {SELECT <select-list> FROM <table-specification>;}. For more information, see “SELECT Statement” in SAS FedSQL Language Reference for SAS Cloud Analytic Services.

'ordered'
specifies whether or how the data is returned in key-value order if you use the hash package with a hash iterator package or if you use the hash package OUTPUT method.

ordered can be one of the following values:

'ASCENDING' | 'A'
Data is returned in ascending key-value order. Specifying 'ASCENDING' is the same as specifying 'YES'.

'DESCENDING' | 'D'
Data is returned in descending key-value order.

'YES'
Data is returned in ascending key-value order. Specifying 'YES' is the same as specifying 'ASCENDING'.

'NO'
Data is returned in an undefined order.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for ordered must be entered. If the place holder is entered, then a default ordering of 'NO' is used.

duplicate determines whether to ignore duplicate keys when loading a table into the hash package. The default is to store the first key and ignore all subsequent duplicates.
**duplicate** can be one of the following values:

- **'REPLACE'**
  stores the last duplicate key record.

- **'ERROR'**
  reports an error to the log if a duplicate key is found.

- **'ADD'**
  stores the first key record found and not any of the duplicates.

**Requirement**
Either a placeholder of an empty string in quotation marks (") or a value for **duplicate** must be entered. If the placeholder is entered, then a default of 'ADD' is used.

**See**
“Example 3: Using the Duplicate Parameter with a Hash Package” on page 851

**'suminc'**

specifies a variable that maintains a summary count of hash package keys.

**Requirement**
Either a placeholder of an empty string in quotation marks (") or a value for **suminc** must be entered.

**Data type**
INTEGER

**Note**
This variable holds the sum increment—that is, how much to add to the key summary for each reference to the key. The **suminc** value treats a missing or null value as zero, like the SUM function. For example, a key summary changes using the current value of the variable.

**'multidata'**

specifies whether multiple data items are allowed for each key.

**multidata** can be one of the following values:

- **'YES' | 'Y' | 'MULTIDATA'**
  allows multiple data items for each key

- **'NO' | 'N' | 'SINGLEDATA'**
  allows only one data items for each key

**Requirement**
Either a placeholder of an empty string in quotation marks (") or a value for **multidata** must be entered. If the placeholder is entered, then a default of 'NO' is used.

**Details**

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

A particular hash package instance is defined by a set of key variables, a set of data variables, and optional initialization data. A hash package instance can be defined either fully at construction or at construction and through a subsequent series of method calls. If key variables and data variables are specified when the hash package instance is constructed (Forms 3 and 4), then the hash instance is constructed as fully defined. If key variables and data variables are not provided when the hash package instance is constructed (Form 2), then additional definition of the hash instance can be specified with a subsequent series of method calls followed by a single DEFINEDONE method.
call. The DEFINEDONE method indicates that specification of key variables, data variables, and other initialization data is complete. A hash package instance is not constructed if no variables or initialization data is provided (Form 1). In this instance, the hash instance is constructed with the _NEW_ operator or additional method calls followed by a single DEFINEDONE method call.

In the following example, hash h1 and hash h2 have equivalent definition. Hash h1 is fully defined when the hash is constructed because key and data variables are provided as constructor arguments. Hash h2 is only partially defined when the hash is constructed, and the hash definition is completed through a series of method calls followed by a single DEFINEDONE method call.

```sas
declare package hash h1([key1], [data1 data2 data3], 0, 'testdata', '', '', '', 'multidata');
declare package hash h2();

h2.keys([key1]);
h2.data([data1 data2 data3]);
h2.dataset('testdata');
h2.multidata();
h2.defineDone();
```

A DECLARE PACKAGE statement can create a hash package variable that is a null package reference. The hash package variable can then be set to reference a hash package instance constructed by a subsequent call of the _NEW_ operator.

```sas
declare package hash hashgnp;
hashgnp = _new_ hash(10, 'testpkg', 'yes');
```

(Optional) A DECLARE PACKAGE statement can both create the hash package variable and construct the hash package instance.

```sas
declare package hash hashgnp(10, 'testpkg', 'yes');
```

**Note:** Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*.

For more information about the hash package, see “Using the Hash Package” in *SAS Viya: DS2 Programmer’s Guide*.

### Examples

#### Example 1: Storing and Retrieving Data with a Hash Package
The following example declares a hash package named H that stores several key/value pairs and uses an iterator to write the keys in sorted order.

```sas
data _null_;
dcl double x;
dcl date d;
/* The output will be in descending order. */
dcl package hash h(8, '', 'descending', '', '');
dcl package hiter hi('h');
method init();
rc = h.defineKey('d');
rc = h.defineData('d');
rc = h.defineData('x');
rc = h.defineDone();

d = date '1929-08-24'; x = 1; h.add();
```
The following lines are written to the SAS log:

```
d=1933-12-28 x=5
d=1930-10-27 x=4
d=1930-10-26 x=3
d=1930-09-25 x=2
d=1929-08-24 x=1
```
declare package hash h(8,'small');

/* define SMALL table variable K as key and S as value */

method init();
   rc = h.defineKey('k');
   rc = h.defineData('s');
   rc = h.defineDone();
end;

/* use the SET statement to iterate over the LARGE table using */
/* keys in the LARGE table to match keys in the hash package */

method run();
   set large;
   if h.find() = 0 then output;
end;
enddata;
run;

Example 3: Using the Duplicate Parameter with a Hash Package
The following is an example of using the ADD, REPLACE, and ERROR options with the DUPLICATE parameter.

data dups(overwrite=yes);
   dcl double x y;
   method init();
      do x = 1 to 5;
         y = 2*x;
         output;
      end;
      x = 3; y = 99; output;
      x = 4; y = 100; output;
   end;
enddata;
run;

data _null_;  
   dcl double x y;
   dcl int rc1 rc2 rc3 rc4;
   dcl package hash h(8, 'dups', 'yes');
   dcl package hiter hi;
   method init();
      rc = h.defineKey('x');
      rc = h.defineData('x');
      rc = h.defineData('y');
      rc = h.defineDone();
      hi = _new_ hiter('h');
      do while (hi.next() = 0);
         put x= y=;
      end;
      put;
   end;
enddata;
data _null_;  
dcl double x y;  
dcl int rc1 rc2 rc3 rc4;  
dcl package hash h(8, 'dups', 'yes', 'add');  
dcl package hiter hi;  
method init();  
   rc = h.defineKey('x');  
   rc = h.defineData('x');  
   rc = h.defineData('y');  
   rc = h.defineDone();  
   hi = _new_ hiter('h');  
   do while (hi.next() = 0);  
      put x= y=;  
   end;  
   put;  
end;  
enddata;  
run;

data _null_;  
dcl double x y;  
dcl int rc1 rc2 rc3 rc4;  
dcl package hash h(8, 'dups', 'yes', 'replace');  
dcl package hiter hi;  
method init();  
   rc = h.defineKey('x');  
   rc = h.defineData('x');  
   rc = h.defineData('y');  
   rc = h.defineDone();  
   hi = _new_ hiter('h');  
   do while (hi.next() = 0);  
      put x = y =;  
   end;  
   put;  
end;  
enddata;  
run;

data _null_;  
dcl double x y;  
dcl int rc1 rc2 rc3 rc4;  
dcl package hash h(8, 'dups', 'yes', 'error');  
dcl package hiter hi;  
method init();  
   rc = h.defineKey('x');  
   rc = h.defineData('x');  
   rc = h.defineData('y');  
   rc = h.defineDone();  
   hi = _new_ hiter('h');  
   do while (hi.next() = 0);  
      put x = y =;  
   end;
The following lines are written to the SAS log when using the ADD option:

```
x=1 y=2
x=2 y=4
x=3 y=6
x=4 y=8
x=5 y=10
NOTE: Execution succeeded. No rows affected.
```

The following lines are written to the SAS log when using the REPLACE option:

```
x=1 y=2
x=2 y=4
x=3 y=99
x=4 y=100
x=5 y=10
NOTE: Execution succeeded. No rows affected.
```

When using the ERROR option, an error message is written to the SAS log:

```
x=1 y=2
x=2 y=4
x=3 y=6
x=4 y=8
x=5 y=10
NOTE: Execution succeeded. No rows affected.
ERROR: Duplicate key found when loading hash package from data source "dups".
ERROR: Hash data source load failed.
```

**Example 4: Using the ORDERED Parameter with a Hash Package**

The following example sets an ascending order for the hash package H and a descending order for the hash package H2.

```sas
    data _null_;   
      dcl double x y;   
      dcl package hash h(8, '', 'ascending');   
      dcl package hash h2(8, '', 'descending');   
      dcl package hiter hi('h');   
      dcl package hiter hi2('h2');   
      method init();   
          rc = h.defineKey('x');   
          rc = h.defineKey('y');   
          rc = h.defineDone();   
          rc = h2.defineKey('y');   
          rc = h2.defineKey('x');   
          rc = h2.defineDone();   
      do x = 1 to 10;   
```

y = 2 * x;
rc = h.add();
rc = h2.add();
end;

hi.first(); put y=
do while (hi.next() = 0);
   put y=
end;
put;

hi2.first(); put x=
do while (hi2.next() = 0);
   put x=
end;
end;
enddata;
run;

---

**DECLARE PACKAGE Statement, Hash Iterator Package**

Creates a hash iterator package variable and gives you the option of creating an instance of the hash iterator package.

**Category:** Local

**Tip:** The PACKAGE statement is not required for a hash iterator package.

**Syntax**

```
DECLARE PACKAGE HITER variable [( 'hash-name' | hash-package-instance)];
```

**Arguments**

- **variable**
  - specifies a name that can reference an instance of the hash iterator package variable.

- **'hash-name'**
  - specifies the name of the hash package with which the hash iterator is associated.
hash-package-instance

specifies the instance of the hash package with which the hash iterator is associated.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use the hash and hash iterator packages to quickly and efficiently store, search, and retrieve data based on unique lookup keys. The hash and hash iterator packages are predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

You declare a hash iterator package by using the DECLARE PACKAGE statement. This associates a hash iterator package with a hash and hash iterator name.

Note: You must declare and instantiate a hash package before you create a hash iterator package.

There are two ways to construct an instance of a hash iterator package.

• Use the DECLARE PACKAGE statement along with the _NEW_ operator:

  declare package hiter myhiter;
  myhiter = _new_ hiter('h');

• Use the DECLARE PACKAGE statement along with its constructor syntax:

  declare package hiter myiter('h');

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

Statements:

• “DECLARE PACKAGE Statement, Hash Package” on page 846

DEFINEDATA Method

Defines data variables for the hash package using implicit variables.

Applies to: Hash package
Syntax

```plaintext
package.DEFINEDATA('data');
```

Arguments

**package**

specifies an instance of the hash package variable.

**'data'**

specifies the name of the data variable.

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You call the DEFINEDATA method for each data variable that you create. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

**Note:** Alternatively, you could use the DATA variable list method or constructors in the DECLARE PACKAGE statement to specify the data variables.

Keys and data consist of any number of character or numeric variables.

Example

This example creates a hash package that contains two data variables and one key variable. The output is sorted in descending order.

```plaintext
data _null_
  dcl double x;
  dcl double rc;
  dcl date d;
  /* The output will be in descending order. */
  dcl package hash h(8, '', 'descending', '', '');
  dcl package hiter hi('h');
  method init();
    rc = h.definekey('d');
    rc = h.declaredata('d');
    rc = h.declaredata('x');
    rc = h.defineDone();
    d = date '1929-08-24'; x = 1; h.add();
    d = date '1930-09-25'; x = 2; h.add();
    d = date '1930-10-26'; x = 3; h.add();
    d = date '1930-10-27'; x = 4; h.add();
    d = date '1933-12-28'; x = 5; h.add();
    d = date '1999-12-01'; x = 999;
    do while (hi.next() = 0);
      put d= x=;
      d = date '1999-12-01'; x = 999;
    end;
  end;
enddata;
run;
```
The following lines are written to the SAS log.

d=1933-12-28 x=5
d=1930-10-27 x=4
d=1930-10-26 x=3
d=1930-09-25 x=2
d=1929-08-24 x=1

• “Defining Key and Data Variables” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “DATA Method” on page 843
• “DEFINEDONE Method” on page 857

Statements:

• “DECLARE PACKAGE Statement, Hash Package” on page 846

DEFINEDONE Method

Indicates that all key and data definitions are complete.

Applies to: Hash package

Syntax

package.DEFINEDONE( );

Arguments

package

specifies an instance of the hash package variable.

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You can define the key and data variables in one of three ways.

• Use the implicit variable methods DEFINEDATA and DEFINEKEY.
• Use the variable list methods DATA and KEYS.
• Use key and data variable lists as constructors in the DECLARE PACKAGE statement.

If the hash package is not completely defined using constructors in the DECLARE PACKAGE statement, you must call the DEFINEDONE method to complete initialization of the hash package.
Example

The following example creates a hash package, defines the key and data variables, and completes the initialization of the hash package:

```c
/* definedone with definedata method */
declare hash h(h);
rc = h.defineKey('k');
rc = h.defineData('d');
rc = h.defineDone();

/* same package using definedone with data method */
declare hash h;
rc=h.keys([k]);
rc=h.data([d]);
rc=definedone();
```

\textbf{DEFINEKEY Method}

Defines key variables for the hash package using implicit variables.

\textbf{Applies to:} Hash package

\textbf{Syntax}

\texttt{package.DEFINEKEY('key');}

\textbf{Arguments}

\texttt{package}

specifies an instance of the hash package variable.

\texttt{'key'}

specifies the name of the key variable.
Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You call the DEFINEKEY method for each key variable that you create. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

Note: Alternatively, you could use the KEYS variable list method or constructors in the DECLARE PACKAGE statement to specify the key variables.

Keys and data consist of any number of character or numeric variables.

Example

The following example creates a hash package and defines the key and data variables:

```
declare hash h();
rc = h.definekey('k');
rc = h.definedata('d');
rc = h.definedone();
end;
```

DELETE Method, Hash, and Hash Iterator Package

Deletes a hash or hash iterator package.

**Applies to:** Hash and hash iterator packages

**Note:** The DELETE method is not required. When a hash or hash iterator package goes out of scope, the package is deleted.

**Syntax**

```
package.DELETE();
```
Arguments

`package`

specifies an instance of the hash or hash iterator package variable.

Details

When you no longer need the hash or hash iterator package, delete it by using the DELETE method. If you attempt to use a hash or hash iterator package after you delete it, an error will be written to the log.

If you want to delete all the items from within a hash package and save the hash package to use again, use the CLEAR method.

See Also

“Package Constructors and Destruc tors” in SAS Viya: DS2 Programmer’s Guide

DUPLICATE Method

Determines whether to ignore duplicate keys when loading a table into the hash package. The default is to store the first key and ignore all subsequent duplicates.

 Applies to: Hash package

Syntax

```
package.DUPLICATE('option');
```

Arguments

`package`

specifies an instance of the hash package variable.

`'option'`

`option` can be one of the following values:

- 'REPLACE'
  
  stores the last duplicate key record.

- 'ERROR'
  
  reports an error to the log if a duplicate key is found.

- 'ADD'
  
  stores the first key record found and not any of the duplicates.

Default

ADD

Details

By default, all of the keys in a hash package are unique. This means one set of data variables exists for each key. In some situations, you might want to have duplicate keys in the hash package, that is, associate more than one set of data variables with a key.

If the table contains duplicate keys, by default, the first instance is stored in the hash package and subsequent instances are ignored. To store the last instance in the hash package, use the DUPLICATE method. The DUPLICATE method also writes an error to the SAS log if there is a duplicate key.
However, the hash package allows storage of multiple values for each key if you use the MULTIDATA parameter or method. The hash package keeps the multiple values in a list that is associated with the key. This list can be traversed and manipulated by using several methods such as HAS_NEXT or FIND_NEXT.

Note: Alternatively, you can use the duplicate parameter as a constructor in the DECLARE PACKAGE statement or the _NEW_ operator to specify duplicate keys.

---

FIND Method

Determine whether the specified key is stored in the hash package.

**Applies to:** Hash package

**Syntax**

Form 1:  
\[ package.FIND(); \]

Form 2:  
\[ package.FIND([keys], [data]); \]

Form 3:  
\[ package.FIND([keys]); \]

**Arguments**

package  
specifies an instance of the hash package variable.

[keys]  
specifies the key values by using a variable list.

Restriction  
If you specify only keys, the FIND method works only for key-only hash packages.

See  

[data]  
specifies the variables into which to copy the hash data.
Details

You use the key variable values to determine whether a key exists in the hash table. If the key exists, the data values are copied into the data variables. The FIND method returns a zero value if the key is found in the hash table and a nonzero value if the key is not found.

There are two ways to pass key and data variables to the FIND method:

• implicit variable method (Form 1)
  The key and data variables are implied in the FIND method invocation and do not have to be specified.

• variable list method (Forms 2 and 3)
  The specified key and data variables are passed explicitly to the FIND method. If the hash package contains only keys, use Form 3.

Comparisons

The FIND method returns a value that indicates whether the key is in the hash package. If the key is in the hash package, then the FIND method also sets the data variable to the value of the data item so that it is available for use after the method call. The CHECK method returns only a value that indicates whether the key is in the hash package. The data variable is not updated.

Example

See “Example 3: Using the ADD and FIND Methods” on page 840.

• “KEYS Method” on page 875

• “DEFINEKEY Method” on page 858

• “FIND_NEXT Method” on page 862

• “FIND_PREV Method” on page 865

FIND_NEXT Method

Sets the current list item to the next item in the current key’s multiple item list and sets the data for the corresponding data variables.
Applies to: Hash package

Syntax

Form 1:  package.FIND_NEXT();
Form 2:  package.FIND_NEXT([data]);

Arguments

package
specifies an instance of the hash package variable.

[data]
specifies the variables into which to copy the data associated with the current key.

Details

The FIND method determines whether the key exists in the hash package.

The HAS_NEXT method determines whether the key has multiple data items associated with it. When you have determined that the key has another data item, that data item can be retrieved by using the FIND_NEXT method, which sets the data variable to the value of the data item so that it is available for use after the method call. Once you are in the data item list, you can use the HAS_NEXT and FIND_NEXT methods to traverse the list.

There are two ways to pass data variables to the FIND_NEXT method:

- implicit variable method (Form 1)
  The data variables are implied in the FIND_NEXT method invocation and do not have to be specified.

- variable list method (Form 2)
  The specified data variables are passed explicitly to the FIND_NEXT method.

Example

This example uses the FIND_NEXT method to iterate through a table where several keys have multiple data items.

data testcases;
  dcl double k;
  dcl double expected;
  method init();
    k=0; expected=14; output; /* magic number */

    k=1; expected=1; output;
    k=2; expected=2; output;
    k=3; expected=1; output;
    k=4; expected=3; output;
    k=5; expected=2; output;
    k=6; expected=1; output;
    k=7; expected=1; output;
    k=8; expected=1; output;
  end;
  
  run;
end;
The following lines are written to the SAS log.
FIND_PREV Method

Sets the current list item to the previous item in the current key’s multiple item list and sets the data for the corresponding data variables.

Applies to: Hash package

Syntax

Form 1: `package.FIND_PREV();`
Form 2: `package.FIND_PREV([data]);`

Arguments

`package`

specifies an instance of the hash package variable.

`[data]`

specifies the variables into which to copy the data associated with the current key.

**Methods:**

- “FIND Method” on page 861
- “FIND_NEXT Method” on page 862
- “HAS_PREV Method” on page 873

---

**FIRST Method**

Returns the first value in the underlying hash package.

**Applies to:** Hash iterator package

**Syntax**

Form 1: `package.FIRST( );`

Form 2: `package.FIRST([data]);`
**Arguments**

`package`

specifies an instance of the hash iterator package variable.

`[data]`

specifies the variables into which to copy the data associated with the first hash item.

**Details**

The `FIRST` method returns the first data item in the hash package. If you specified `YES` or `ASCENDING` in the DECLARE PACKAGE statement, the `_NEW_` operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'least' key (smallest numeric value or first alphabetic character). This occurs because the data items are sorted in ascending key-value order in the hash package. Repeated calls to the NEXT method will iteratively traverse the hash package and return the data items in ascending key order.

Conversely, if you specified `DESCENDING` in the DECLARE PACKAGE statement, the `_NEW_` operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'highest' key (largest numeric value or last alphabetic character). This occurs because the data items are sorted in descending key-value order in the hash package. Repeated calls to the NEXT method will iteratively traverse the hash package and return the data items in descending key order.

Use the `LAST` method to return the last data item in the hash package.

*Note:* The `FIRST` method sets the data variable to the value of the data item so that it is available for use after the method call.

There are two ways to pass data variables to the `FIRST` method:

- implicit variable method (Form 1)
  
The data variables are implied in the `FIRST` method invocation and do not have to be specified.

- variable list method (Form 2)
  
The specified data variables are passed explicitly to the `FIRST` method.

**Example**

The following example uses the `FIRST`, `NEXT`, `PREV`, and `LAST` methods when starting a new iteration at a different location within the hash package:

```sas
data _null_;  
dcl double x y rc; 
dcl package hash h([x], [y]); 
dcl package hiter hi('h'); 
method init(); 
do x = 1 to 10; 
  y = 2*x; 
  rc = h.add([x], [y]); 
end; 
do while (hi.next([y]) = 0); 
  put y=; 
end; 
put;
```
The following lines are written to the SAS log.

```sas
hi.first([y]);
put y=
   do while [hi.next([y]) = 0];
      put y=";
   end;
put;
   do while [hi.prev([y]) = 0];
      put y=";
   end;
put;
hi.last([y]);
put y=
   do while [hi.prev([y]) = 0];
      put y=";
   end;
end;
enddata;
run;
```

HASHEXP Method

Defines the hash package’s internal table size. The size of the hash table is $2^n$.

**Applies to:** Hash package

**Syntax**

```
package.HASHEXP(exponent);
```

**Arguments**

- `package` specifies an instance of the hash package variable.
- `exponent` specifies the power-of-2 for the internal table size.

**Default** 8

**Data type** INTEGER

**Details**

The value specified for the HASHEXP method is used as a power-of-two exponent to create the hash table size. For example, a value of 4 equates to a hash table size of $2^4$, or 16. The maximum value for `exponent` is 16, which equates to a hash table size of $2^{16}$.

The hash table size is not equal to the number of items that can be stored. Think of the hash table as an array of containers. A hash table size of 16 would have 16 containers. Each container can hold an infinite number of items. The efficiency of the hash tables lies in the ability of the hash function to map items to and retrieve items from the containers.

In order to maximize the efficiency of the hash package lookup routines, you should set the hash table size according to the amount of data in the hash package. Try different `exponent` values until you get the best result. For example, if the hash package contains one million items, a hash table size of 16 (hashexp = 4) would not be very efficient. A hash table size of 512 or 1024 (hashexp = 9 or 10) would result in better performance.

*Note:* Alternatively, you can use the `hasheXP` parameter in the DECLARE PACKAGE statement or the `_NEW_` operator to specify the hash table size.

**See Also**

**Operators:**

- “_NEW_ Operator, Hash Package” on page 878

**Statements:**

- “DECLARE PACKAGE Statement, Hash Package” on page 846
HAS_NEXT Method

Determines whether there is a next item in the current key's multiple data item list.

**Applies to:** Hash package

**Syntax**

```plaintext
package.HAS_NEXT();
```

**Arguments**

`package`

specifies an instance of the hash package variable.

**Details**

If a key has multiple data items, you can use the HAS_NEXT method to determine whether there is a next item in the current key's multiple data item list. If there is another item, the method will return a nonzero value in the numeric variable `R`. Otherwise, it will return a zero.

The FIND method determines whether the key exists in the hash package. The HAS_NEXT method determines whether the key has multiple data items associated with it. When you have determined that the key has another data item, that data item can be retrieved by using the FIND_NEXT method, which sets the data variable to the value of the data item so that it is available for use after the method call. Once you are in the data item list, you can use the HAS_PREV and FIND_PREV methods in addition to the HAS_NEXT and FIND_NEXT methods to traverse the list.

**Example: Finding Data Items**

This example creates a hash package where several keys have multiple data items. It uses the HAS_NEXT to find all the data items.

```plaintext
data testcases;
  dcl double k;
  dcl double expected;
  method init();
    k=0; expected=14; output; /* magic number */
    k=1; expected=1; output;
    k=2; expected=2; output;
    k=3; expected=1; output;
    k=4; expected=3; output;
    k=5; expected=2; output;
    k=6; expected=1; output;
    k=7; expected=1; output;
    k=8; expected=1; output;
    k=9; expected=1; output;
  end;
enddata;
run;
```
data inp;
  dcl double k v;
  method init();
    do k = 1 to 10; v = k * k; output; end;
    k = 2; v = 3; output; /* newval < oldval */
    k = 4; v = 4242; output; /* newval > oldval */
    k = 4; v = 0; output; /* newval < oldval */
    k = 5; v = 25; output; /* newval = oldval */
  end;
  enddata;
run;

data _null_;  
  dcl double k v hn vn;
  dcl package hash h(8, 'inp', 'ascending', '', '', 'multidata');
  method init();
    h.defineKey('k');
    h.defineData('k');
    h.defineData('v');
    h.defineDone();
  end;
  method run();
    dcl double actual fn;
    **************************************************************************
    set testcases;
    fn = h.find();
    if (fn ^= 0) then
      actual = h.get_num_items();
    else do;
      actual=0;
      hn = 0;
      put k= fn=;
      do while (hn = 0 and fn = 0);
        actual+1;
        hn = h.has_next();
        fn = h.find_next();
        put k= fn= hn=;
      end;
    end;
    if (actual ^= expected) then
      put 'ERROR: ' k= expected= actual=;
    **************************************************************************
  end;
  enddata;
run;

**HAS_PREV Method**

Determines whether there is a previous item in the current key's multiple data item list.

**Applies to:** Hash package

**Syntax**

```
package.HAS_PREV();
```

**Arguments**

`package`

specifies an instance of the hash package variable.

**Details**

If a key has multiple data items, you can use the HAS_PREV method to determine whether there is a previous item in the current key's multiple data item list. If there is a previous item, the method will return a nonzero value in the numeric variable `R`. Otherwise, it will return a zero.

The FIND method determines whether the key exists in the hash package. The HAS_NEXT method determines whether the key has multiple data items associated with
it. When you have determined that the key has a previous data item, that data item can be retrieved by using the FIND_PREV method, which sets the data variable to the value of the data item so that it is available for use after the method call. Once you are in the data item list, you can use the HAS_PREV and FIND_PREV methods in addition to the HAS_NEXT and FIND_NEXT methods to traverse the list.

Example

See “Example: Retrieving a Summary Value” on page 905.

See Also

• “Non-Unique Key and Data Pairs” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “FIND Method” on page 861
• “FIND_PREV Method” on page 865
• “HAS_NEXT Method” on page 871

ITEM_SIZE Attribute

Returns the size (in bytes) for an item in a hash package.

Applies to: Hash package

Syntax

\[ \text{variable-name} = \text{package}.\text{ITEM_SIZE}; \]

Arguments

variable-name

specifies the name of the variable that contains the size of the item in the hash package after the method is complete.

package

specifies an instance of the hash package variable.

Details

The ITEM_SIZE attribute returns the size (in bytes) of an item, as well as the key and data variables and some internal information. You can set an estimate of how much memory the hash package is using with the ITEM_SIZE and NUM_ITEMS attributes. The ITEM_SIZE attribute does not reflect the initial overhead that the hash package requires, nor does it take into account any necessary internal alignments. Therefore, the use of ITEM_SIZE does not provide exact memory usage, but it does return a good approximation.

Example

For an example, see the “NUM_ITEMS Attribute” on page 884.
KEYS Method

Defines the key variables for the hash package using a variable list.

**Applies to:** Hash package

### Syntax

```
package.KEYS([keys]);
```

### Arguments

- **package**
  - specifies an instance of the hash package variable.
- **[keys]**
  - specifies the names of the key variables using a variable list.

**See** “Variable Lists” in *SAS Viya: DS2 Programmer’s Guide*

### Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You can use a variable list to specify the key variables for a hash package using the KEYS method. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

**Note:** Alternatively, you can use the DEFINEKEYS method or constructors in the DECLARE PACKAGE statement to specify key variables.

**Note:** You can have a hash package that contains only key variables and no data variables. This is a keys-only hash package.

Keys and data consist of any number of character or numeric variables.

### Example

The following example creates a hash package and defines the key and data variables:

```
declare hash h();
rc = h.keys([k]);
rc = h.data([d]);
rc = h.definedata();
end;
```
LAST Method

Returns the last value in the underlying hash package.

**Applies to:** Hash iterator package

**Syntax**

Form 1: 

```
package.LAST( );
```

Form 2: 

```
package.LAST([data]);
```

**Arguments**

- `package` specifies an instance of the hash iterator package variable.
- `data` specifies the variables into which to copy the data associated with the first hash item.

**Details**

The LAST method returns the last data item in the hash package. If you specified **YES** or **ASCENDING** in the DECLARE PACKAGE statement, the _NEW_ operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'highest' key (largest numeric value or last alphabetic character), because the data items are sorted in ascending key-value order in the hash package.

Conversely, if you specified **DESCENDING** in the DECLARE PACKAGE statement, the _NEW_ operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'least' key (smallest numeric value or first alphabetic character), because the data items are sorted in descending key-value order in the hash package.

Use the FIRST method to return the first data item in the hash package.

There are two ways to pass data variables to the LAST method:
• implicit variable method (Form 1)
The data variables are implied in the LAST method invocation and do not have to be specified.
• variable list method (Form 2)
The specified data variables are passed explicitly to the LAST method.

Example
For an example, see the “FIRST Method” on page 866.

Statements:
• “DECLARE PACKAGE Statement, Hash Package” on page 846

MULTIDATA Method
Specifies whether multiple data items are allowed for each key.

Applies to: Hash package

Syntax

\[ \text{package.MULTIDATA(['option'])}; \]

Arguments

\[ \text{package} \]
specifies an instance of the hash package variable.

\[ \text{'option'} \]
option can be one of the following values:

\[ \text{'Y' | 'YES' | 'MULTIDATA'} \]
allows multiple data items for each key.

\[ \text{'N' | 'NO' | 'SINGLEDATA'} \]
reports an error to the log if a duplicate key is found.

Default \ NO
Details

By default, all of the keys in a hash package are unique. This means one set of data variables exists for each key. In some situations, you might want to have duplicate keys in the hash package, that is, associate more than one set of data variables with a key.

If the table contains duplicate keys, by default, the first instance is stored in the hash package and subsequent instances are ignored. To store the last instance in the hash package, use the DUPLICATE method. The DUPLICATE method also writes an error to the SAS log if there is a duplicate key.

However, the hash package allows storage of multiple values for each key if you use the MULTIDATA parameter or method. The hash package keeps the multiple values in a list that is associated with the key. This list can be traversed and manipulated by using several methods such as HAS_NEXT or FIND_NEXT.

*Note:* Alternatively, you can use the multidata parameter in the DECLARE PACKAGE statement or the _NEW_ operator to specify whether multiple data items are allowed for each key.

See Also

- “Non-Unique Key and Data Pairs” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “DUPLICATE Method” on page 860

Operators:

- “_NEW_ Operator, Hash Package” on page 878

Statements:

- “DECLARE PACKAGE Statement, Hash Package” on page 846

_NEW_ Operator, Hash Package

Constructs an instance of a hash package.

*Note:* The escape character ( \ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1:  
\[
\text{package-variable} = \text{\_NEW\_}\ [\text{\_THIS\_}] | \text{\_package-instance\_]} \text{ HASH (hashexp, ’datasource’, ’ordered’, ’duplicate’, ’suminc’, ’multidata’);}
\]

Form 2:  
\[
\text{package-variable} = \text{\_NEW\_}\ [\text{\_THIS\_}] | \text{\_package-instance\_]} \text{ HASH (\_keys\_), \_data\_, [hashexp, ’datasource’, ’ordered’, ’duplicate’, ’suminc’, ’multidata’);}
\]

Form 3:  
\[
\text{package-variable} = \text{\_NEW\_}\ [\text{\_THIS\_}] | \text{\_package-instance\_]} \text{ HASH (\_keys\_), [hashexp, ‘datasource’ | \{sql-text\}, ’ordered’, ’duplicate’, ’suminc’, ’multidata’);}
\]
Arguments

package-variable
specifies a name that can reference an instance of the package.

[THIS]
specifies that the package instance has global scope.

See “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide

[package-instance]
specifies that the new package instance has the same scope as package-instance. package-instance must be an existing package instance, and the type of package-instance can differ from the type of the new package instance.

See “Package-Specific Scope” in SAS Viya: DS2 Programmer’s Guide

[keys]
specifies the key values by using a variable list.

data
specifies the data variables by using a variable list and associates them with the specified keys.

hashexp
is the hash package's internal table size, where the size of the hash table is \(2^n\).

The value of hashexp is used as a power-of-two exponent to create the hash table size. For example, a value of 4 for hashexp equates to a hash table size of \(2^4\), or 16. The maximum value for hashexp is 16, which equates to a hash table size of \(2^{16}\).

The hash table size is not equal to the number of items that can be stored. Think of the hash table as an array of containers. A hash table size of 16 would have 16 containers. Each container can hold an infinite number of items. The efficiency of the hash tables lies in the ability of the hash function to map items to and retrieve items from the containers.

In order to maximize the efficiency of the hash package lookup routines, you should set the hash table size according to the amount of data in the hash package. Try different hashexp values until you get the best result. For example, if the hash package contains one million items, a hash table size of 16 (hashexp = 4) would not be very efficient. A hash table size of 512 or 1024 (hashexp = 9 or 10) would result in better performance.

Requirement Either a placeholder of –1 or a value for hashexp must be entered. If the placeholder is entered, then a default value of 8, which equates to a hash table size of \(2^8\) or 256, is used.

Data type INTEGER

'datasource'
is the name of a table to load into the hash package.

The name of the table can be a literal or a character variable. The table name must be enclosed in single quotation marks.
Requirement Either a placeholder of an empty string in quotation marks (""") or a value for `datasource` must be entered. If the placeholder is entered, then the hash is not loaded from a data source.

```
{sql-text}
```

is any valid FedSQL SELECT statement that resolves to a set of table rows.

Restriction This argument is not supported in the CAS server.

Requirement The FedSQL query must be enclosed in braces ( { } ).

Note The FedSQL query is specified in the following form: `{SELECT <select-list> FROM <table-specification>;}`. For more information, see “SELECT Statement” in SAS FedSQL Language Reference for SAS Cloud Analytic Services.

`'ordered'` specifies whether or how the data is returned in key-value order if you use the hash package with a hash iterator package or if you use the hash package OUTPUT method. Here are the valid values:

- `'ASCENDING'` | `'A'`
  Data is returned in ascending key-value order. Specifying `'ASCENDING'` is the same as specifying `'YES'`.

- `'DESCENDING'` | `'D'`
  Data is returned in descending key-value order.

- `'YES'`
  Data is returned in ascending key-value order. Specifying `'YES'` is the same as specifying `'ASCENDING'`.

- `'NO'`
  Data is returned in an undefined order.

Requirement Either a placeholder of an empty string in quotation marks (""") or a value for `ordered` must be entered. If the placeholder is entered, then a default ordering of 'NO' is used.

`'duplicate'` determines whether to ignore duplicate keys when loading a table into the hash package. The default is to store the first key and ignore all subsequent duplicates. Here are the valid values:

- `'REPLACE'`
  stores the last duplicate key record.

- `'ERROR'`
  reports an error to the log if a duplicate key is found.

- `'ADD'`
  stores the first key record found and not any of the duplicates.

Requirement Either a placeholder of an empty string in quotation marks (""") or a value for `duplicate` must be entered. If the placeholder is entered, then a default of 'ADD' is used.

See “Example 3: Using the Duplicate Parameter with a Hash Package” on page 851
'suminc'
specifies a variable that maintains a summary count of hash package keys.

Requirement
Either a placeholder of an empty string in quotation marks (""") or a value for suminc must be entered.

Note
This variable holds the sum increment—that is, how much to add to the key summary for each reference to the key. The suminc value treats a missing or null value as zero, like the SUM function. For example, a key summary changes using the current value of the variable.

'multidata'
specifies whether multiple data items are allowed for each key. Here are the valid values:

'YES' | 'Y' | 'MULTIDATA'
allows multiple data items for each key

'NO' | 'N' | 'SINGLEDATA'
allows only one data item for each key

Requirement
Either a placeholder of an empty string in quotation marks (""") or a value for ordered must be entered. If the placeholder is entered, then a default ordering of 'NO' is used.

Details
A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When a hash package is declared, the variable representing the package can be considered an instance of the package. This means that two different package variables represent two completely separate copies of a package.

You declare a hash package using the DECLARE PACKAGE statement. After you declare the new hash package, you can use the _NEW_ operator to instantiate the package.

```
declare package hash myhash();
myhash = _new_ hash();
```

A particular hash package instance is defined by a set of key variables, a set of data variables, and optional initialization data. A hash package instance can be defined either fully at construction or at construction and through a subsequent series of method calls. If key variables and data variables are specified when the hash package instance is constructed (Forms 2 and 3), then the hash instance is constructed as fully defined. If key variables and data variables are not provided when the hash package instance is constructed (Form 1), then additional definition of the hash instance can be specified with a subsequent series of method calls followed by a single DEFINEDONE method call. The DEFINEDONE method indicates that specification of key variables, data variables, and other initialization data is complete.

For example, you can provide initialization data by using parameters in the constructor syntax for the hash package

```
declare package hash h();
h = _new_ hash(0, 'mytable', 'yes', 'replace', 'sumnum', 'y');
```

Note: You can use the DECLARE PACKAGE statement constructor to declare and instantiate a hash or hash iterator package in one step. For more information, see _NEW_ Operator, Hash Package 881

**Note:** Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*.

**See Also**
- “Using the Hash Iterator Package” in *SAS Viya: DS2 Programmer’s Guide*
- “Package Constructors and Destructors” in *SAS Viya: DS2 Programmer’s Guide*

**Operators:**
- “_NEW_ Operator, Hash Iterator Package” on page 882

**Statements:**
- “DECLARE PACKAGE Statement, Hash Package” on page 846

---

**_NEW_ Operator, Hash Iterator Package**

Creates an instance of a hash iterator package.

**Note:** The escape character ( \ ) before the bracket indicates that the bracket is required in the syntax.

**Syntax**

```
package-variable = _NEW_ [THIS] | [package-instance] ] HITER ('hash-name');
```

**Arguments**

- `package-variable`
  - specifies a name that can reference an instance of the package.

- `[THIS]`
  - specifies that the package instance has global scope.

- `[package-instance]`
  - specifies that the new package instance has the same scope as `package-instance`. `package-instance` must be an existing package instance, and the type of `package-instance` can differ from the type of the new package instance.

**Requirement**

You must declare and instantiate a hash package before you create a hash iterator package.
Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When a hash iterator package is declared, the variable representing the package can be considered an instance of the package. This means that two different package variables represent two completely separate copies of a package.

You declare a hash iterator package using the DECLARE PACKAGE statement. After you declare the new hash iterator package, use the _NEW_ operator to instantiate the package.

```
declare package hiter myiter;
myiter = _new_ hiter('myhash');
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a hash iterator package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package hiter myiter('myhash');
```

*Note:* Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide.*

See Also

- “Using the Hash Iterator Package” in *SAS Viya: DS2 Programmer’s Guide*
- “Package Constructors and Destructors” in *SAS Viya: DS2 Programmer’s Guide*

Operators:

- “_NEW_ Operator, Hash Package” on page 878

Statements:

- “DECLARE PACKAGE Statement, Hash Iterator Package” on page 854

---

**NEXT Method**

*Returns the next value in the underlying hash package.*

**Applies to:** Hash iterator package

**Syntax**

Form 1:  
```
package.NEXT();
```

Form 2:  
```
package.NEXT([data]);
```

**Arguments**

- **package**
  
  specifies an instance of the hash iterator package variable.
[data]
specifies the variables into which to copy the data associated with the next hash item.

**Details**

Use the NEXT method iteratively to traverse the hash package and return the data items in key order. The FIRST method returns the first data item in the hash package. You can use the PREV method to return the previous data item in the hash package.

There are two ways to pass data variables to the NEXT method:

- implicit variable method (Form 1)
  
  The data variables are implied in the NEXT method invocation and do not have to be specified.

- variable list method (Form 2)
  
  The specified data variables are passed explicitly to the NEXT method.

**Example**

For an example, see the “FIRST Method” on page 866.

**See Also**

Methods:

- “FIRST Method” on page 866
- “PREV Method” on page 889

**NUM_ITEMS Attribute**

Returns the number of items in the hash package.

**Applies to:** Hash package

**Syntax**

```
variable-name=package.NUM_ITEMS;
```

**Arguments**

- `variable-name`
  
  specifies the name of a variable that contains the number of items in the hash package after the method is complete.

- `package`
  
  specifies an instance of the hash package variable.

**Details**

The NUM_ITEMS attribute returns the number of key/data pairs stored in the hash table.
Example

The following example uses the NUM_ITEMS attribute to count the number of items within the hash package and the ITEM_SIZE attribute to report the size of an item in the hash package.

```plaintext
data _null_;  
dcl int item_size num_items;  
dcl double x;  
dcl timestamp t;  
dcl package hash h(8, '', 'yes');  
dcl package hiter hi('h');  
method init();  
   rc = h.defineKey('t');  
   rc = h.defineData('t');  
   rc = h.defineData('x');  
   rc = h.defineDone();  
   item_size = h.item_size;  
   num_items = h.num_items;  
   put item_size=;  
   put num_items=;  
   put;  
   t = timestamp '1927-08-24 12:51:36.00'; x = 1; h.add();  
   t = timestamp '1928-08-24 12:51:36.00'; x = 1; h.add();  
   t = timestamp '1929-08-24 12:51:36.00'; x = 1; h.add();  
   t = timestamp '1929-09-24 12:51:36.00'; x = 1; h.add();  
   t = timestamp '1929-09-25 12:51:36.00'; x = 1; h.add();  
   t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.add();  
   t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.add();  
   t = timestamp '1929-09-25 13:52:37.00'; x = 1; h.add();  
   t = timestamp '1929-09-25 13:52:37.01'; x = 1; h.add();  
   t = timestamp '1930-09-25 13:52:37.01'; x = 1; h.add();  
   num_items = h.num_items;  
   put num_items=;  
   do while (hi.next() = 0);  
      put t= x=;  
   end;  
   put;  
   t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.remove();  
   t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.remove();  
   num_items = h.num_items;  
   put num_items=;  
   do while (hi.next() = 0);  
      put t= x=;  
   end;  
end;  
enddata;  
run;
```
The following lines are written to the SAS log:

```
item_size=72
num_items=0

num_items=11
t=1927-08-24 12:51:36 x=1
t=1928-08-24 12:51:36 x=1
t=1929-08-24 12:51:36 x=1
t=1929-09-24 12:51:36 x=1
t=1929-09-25 12:51:36 x=1
t=1929-09-25 13:51:36 x=1
t=1929-09-25 13:52:36 x=1
```

```
t=1929-09-25 13:52:37 x=1
t=1929-09-25 13:52:37.010000000 x=1
t=1930-09-25 13:52:37.010000000 x=1
t=1930-10-25 13:52:37.010000000 x=1
```

```
num_items=9
t=1927-08-24 12:51:36 x=1
t=1928-08-24 12:51:36 x=1
t=1929-08-24 12:51:36 x=1
t=1929-09-24 12:51:36 x=1
t=1929-09-25 12:51:36 x=1
t=1929-09-25 13:52:37 x=1
t=1929-09-25 13:52:37.010000000 x=1
t=1930-09-25 13:52:37.010000000 x=1
```

```
t=1930-10-25 13:52:37.010000000 x=1
```

See Also

Attributes:

- “ITEM_SIZE Attribute” on page 874

ORDERED Method

Specifies whether or how the data is returned in key-value order if you use the hash package with a hash iterator package or if you use the hash package OUTPUT method.

**Applies to:** Hash package

**Syntax**

```
package.ORDERED('option');
```

**Arguments**

`package`

specifies an instance of the hash package variable.

`option`

`option` can be one of the following values:

- `'ASCENDING'` | `'A'`
  
  Data is returned in ascending key-value order. Specifying `'ASCENDING'` is the same as specifying `'YES'`.
'DESCENDING' | 'D'
    Data is returned in descending key-value order.

'YES'
    Data is returned in ascending key-value order. Specifying 'YES' is the same as specifying 'ASCENDING'.

'NO'
    Data is returned in an undefined order.

Default: NO

Details

If you specify YES or ASCENDING in the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'least' key (smallest numeric value or first alphabetic character). This occurs because the data items are sorted in ascending key-value order in the hash package. Repeated calls to the NEXT method will iteratively traverse the hash package and return the data items in ascending key order.

Conversely, if you specify DESCENDING parameter in the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'highest' key (largest numeric value or last alphabetic character). This occurs because the data items are sorted in descending key-value order in the hash package. Repeated calls to the NEXT method will iteratively traverse the hash package and return the data items in descending key order.

Use the FIRST method returns the first data item in the hash package. Use the LAST method to return the last data item in the hash package.

Note: Alternatively, you can use the ordered parameter in the DECLARE PACKAGE statement or the _NEW_ operator to specify whether the data is returned in key-value order.

See Also

Methods:

- “FIRST Method” on page 866
- “LAST Method” on page 876

Operators:

- “_NEW_ Operator, Hash Package” on page 878

Statements:

- “DECLARE PACKAGE Statement, Hash Package” on page 846
Applies to: Hash package

Syntax

```
package.OUTPUT (["output-table"]);
```

Arguments

`package`

specifies an instance of the hash iterator package variable.

`["output-table"]`

specifies the name of the output table.

The name of the hash table can be a literal or character variable.

Tip The name of the table can be a literal or a character variable. If a literal is used, the table name must be enclosed in single quotation marks.

Details

Hash package keys are not automatically stored as part of the output table. The keys must be defined as data items by using the DEFINEDATA method, the DATA method, or the DECLARE PACKAGE statement to be included in the output table.

Example

```
data a(overwrite=yes);
  dcl double x;
  method init();
    do x = 1 to 10;
      output;
    end;
  end;
enddata;
run;
data _null_; 
  method init();
    dcl package hash h(4, 'a');
    rc = h.defineData('x');
    rc = h.defineKey('x');
    rc = h.defineDone();
    x = 11; 
    h.add();
    x = 12; 
    h.add();
    x = 13; 
    h.add();
    x = 14; 
    h.add();
    rc = h.output('out');
  end;
enddata;
run;
```
PREV Method

Returns the previous value in the underlying hash package.

Applies to: Hash iterator package

Syntax

Form 1:  
Form 2:  

Arguments

specifies an instance of the hash iterator package variable.

specifies the variables into which to copy the data associated with the previous hash item.

Details

Use the PREV method iteratively to traverse the hash package and return the data items in reverse key order. The FIRST method returns the first data item in the hash package. The LAST method returns the last data item in the hash package. You can use the NEXT method to return the next data item in the hash package.

There are two ways to pass data variables to the PREV method:

• implicit variable method (Form 1)

  The data variables are implied in the PREV method invocation and do not have to be specified.

• variable list method (Form 2)

  The specified data variables are passed explicitly to the PREV method.

Example

For an example, see the “FIRST Method” on page 866.
REF Method
Consolidates a FIND and ADD methods into a single method call.

**Applies to:** Hash package

**Syntax**

Form 1:  
```plaintext
package.REF();
```

Form 2:  
```plaintext
package.REF([keys], [data]);
```

Form 3:  
```plaintext
package.REF([keys]);
```

**Arguments**

*package*

specifies an instance of the hash package variable.

*keys*

specifies the key variables by using a variable list.

**Restriction**

If you specify only keys, the FIND method works only for key-only hash packages.

**See**

*data*

specifies the variables into which to add the hash data.

**See**

**Details**

You can consolidate FIND and ADD methods into a single REF method.

There are two ways to pass key and data variables to the REF method:

- implicit variable method (Form 1)
  
  The key and data variables are implied in the REF method invocation and do not have to be specified.

- variable list method (Forms 2 and 3)
  
  The specified key and data variables are passed explicitly to the REF method. If the hash package contains only keys, use Form 3.
Example

data _null_;  
dcl double x y;  
dcl int rc;  
dcl package hash h([x], [x y]);  
dcl package hiter hi('h');  
method init();  
  x = 7; y = 13;  
  rc = h.add([x], [x y]);  
  put x= rc=;  
  do x = 5 to 10;  
    y = 2*x;  
    rc = h.ref([x], [x y]);  
    put x= rc=;  
  end;  
  do while (hi.next([x y]) = 0);  
    put x= y=;  
  end;  
end;  
enddata;  
run;

The following lines are written to the SAS log.

- “Storing and Retrieving Data” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “ADD Method, Hash Package” on page 838
- “CHECK Method” on page 841
- “FIND Method” on page 861

**REMOVE Method**

Removes the data that is associated with the specified key from the hash package.

**Applies to:** Hash package
Syntax
Form 1:  
```plaintext
package.REMOVE();
```
Form 2:  
```plaintext
package.REMOVE([keys]);
```

Arguments

- **package**
  - specifies an instance of the hash package variable.

- **[keys]**
  - specifies the key values by using a variable list.

Details

The REMOVE method uses the values in the key variables to find and remove an existing key in a hash table.

You specify the key and then use the REMOVE method to remove the key and data in a hash package.

There are two ways to pass key variables to the REMOVE method:

- **implicit variable method (Form 1)**
  - The key variables are implied in the REMOVE method invocation and do not have to be specified.

- **variable list method (Form 2)**
  - The specified key variables are passed explicitly to the REMOVE method.

Note: The REMOVE method does not modify the value of data variables. It removes only the value in the hash package.

Note: If you specify YES the DECLARE PACKAGE statement, the _NEW_ operator, or the MULTIDATA method when you instantiate the hash package, the REMOVE method will remove all data items for the specified key.

Example

```plaintext
data _null_;  
dcl double x rc;  
dcl timestamp t;  
dcl package hash h(0, '', 'yes');  
dcl package hiter hi('h');  
method init();  
  rc = h.Keys([t]);  
  rc = h.Data([t x]);  
  rc = h.defineDone();  
  t = timestamp '1927-08-24 12:51:36.00'; x = 1; h.add();  
  t = timestamp '1928-08-24 12:51:36.00'; x = 1; h.add();  
  t = timestamp '1929-08-24 12:51:36.00'; x = 1; h.add();  
  t = timestamp '1929-09-24 12:51:36.00'; x = 1; h.add();  
  t = timestamp '1929-09-25 12:51:36.00'; x = 1; h.add();
```
t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.add();
t = timestamp '1929-09-25 13:52:37.00'; x = 1; h.add();
t = timestamp '1930-09-25 13:52:37.01'; x = 1; h.add();
t = timestamp '1930-10-25 13:52:37.01'; x = 1; h.add();
t = timestamp '1999-12-01 12:00:00.00'; x = 999;
do while (hi.next([t x]) = 0);
  put t= x=;
  t = timestamp '1999-12-01 12:00:00.00'; x = 999;
end;
put '**************************************';
t = timestamp '1929-09-25 13:51:36.00'; x = 1;
  h.remove();
t = timestamp '1929-09-25 13:52:36.00'; x = 1;
  h.remove();
t = timestamp '1999-12-01 12:00:00.00'; x = 999;
do while (hi.next([t x]) = 0);
  put t= x=;
  t = timestamp '1999-12-01 12:00:00.00'; x = 999;
end;
enddata;
run;

REMOVEALL Method

Removes the data that is associated with all keys from the hash package.

**Applies to:** Hash package

---

**Syntax**

Form 1: `package.REMOVEALL();`

Form 2: `package.REMOVEALL([keys]);`

**Arguments**

`package`

specifies an instance of the hash package variable.

`[keys]`

specifies the key values by using a variable list.

---

**Details**

The REMOVEALL method deletes both the keys and the data from the hash package.

There are two ways to pass key variables to the REMOVEALL method:

- implicit variable method (Form 1)
  
  The key variables are implied in the REMOVEALL method invocation and do not have to be specified.

- variable list method (Form 2)
  
  The specified key variables are passed explicitly to the REMOVEALL method.

*Note:* The REMOVEALL method does not modify the value of data variables. It removes only the value in the hash package.

---

**REMOVEDUP Method**

Removes the data that is associated with the current key’s current data item from the hash package.

**Applies to:** Hash package

**Syntax**

\[ \text{package.REMOVEDUP()} ; \]

**Arguments**

- `package` specifies an instance of the hash package variable.

**Details**

The REMOVEDUP method deletes the current data item from the hash package for keys that have multiple data items.

*Note:* The REMOVEDUP method does not modify the value of data variables. It removes only the value in the hash package.

*Note:* If only one data item is in the key's data item list, the key and data will be removed from the hash package.

**Comparisons**

The REMOVEDUP method removes the data that is associated with the current key's current data item from the hash package. The REMOVE method removes the data that is associated with the specified key from the hash package.

**Example**

This example creates a hash package where several keys have multiple data items. Duplicate data items in the key are removed.

```plaintext
data testdup;
  length key data 8;
  input key data;
datalines;
  1 10
  2 11
  1 15
  3 20
  2 16
  2 9
  3 100
  5 5
  1 5
  4 6
```

proc ds2;
data _null_;  
dcl double key "data" k d;  
method init();  
dcl package hash h([key], [key "data"], 8, 'testdup', 'yes', ' ', 'yes');  
dcl package hiter i(h);  
dcl int rc;  
do k = 1 to 5;  
do while (h.find([k], [k d]) = 0 and h.has_next() = 0);  
   h.find_next([k d]);  
   h.removedup();  
end;  
end;  
rc = i.first([k d]);  
do while (rc = 0);  
   put k= d=;  
   rc = i.next([k d]);  
end;  
end;  
enddata;  
run;  
quit;

The following lines are written to the SAS log.

key=1 data=10  
key=2 data=11  
key=3 data=20  
key=4 data=6  
key=5 data=5

See Also

• “Replacing and Removing Data” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “REPLACE Method” on page 891  
• “REMOVEALL Method” on page 894

REPLACE Method

Replaces the data that is associated with the specified key with new data.

Applies to: Hash package
Syntax

Form 1:  `package.REPLACE();`
Form 2:  `package.REPLACE([keys], [data]);`
Form 3:  `package.REPLACE([keys]);`

Arguments

`package`

specifies an instance of the hash package variable.

`[keys]`

specifies the key values by using a variable list.

Restriction  If you specify only keys, the REPLACE method works only for key-only hash packages.

`[data]`

specifies the variables for which the data is replaced.

Details

The REPLACE method uses the values in the key variables to find a key/data pair in the hash table. If a pair is found, the data is replaced with the current value in the data variables (Forms 1 and 2).

For hash packages that have only keys (Form 3), the only effect that the REPLACE method has is that the summary statistics for the keys is updated.

Example

data _null_;  
dcl double x rc;  
dcl timestamp t;  
dcl package hash h(0, '', 'yes');  
dcl package hiter hi('h');  
method init();  
  rc = h.defineKey('t');  
  rc = h.defineData('t');  
  rc = h.defineData('x');  
  rc = h.defineDone();  
t = timestamp '1927-08-24 12:51:36.00'; x = 1; h.add();  
t = timestamp '1928-08-24 12:51:36.00'; x = 1; h.add();  
t = timestamp '1929-08-24 12:51:36.00'; x = 1; h.add();  
t = timestamp '1929-09-25 12:51:36.00'; x = 1; h.add();  
t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.add();  
t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.add();  
t = timestamp '1929-09-25 13:52:37.00'; x = 1; h.add();  
t = timestamp '1929-09-25 13:52:37.01'; x = 1; h.add();  
t = timestamp '1930-09-25 13:52:37.01'; x = 1; h.add();  
t = timestamp '1930-10-25 13:52:37.01'; x = 1; h.add();
t = timestamp '1999-12-01 12:00:00.00'; x = 999;
do while (hi.next() = 0);
    put t= x=;
    t = timestamp '1999-12-01 12:00:00.00'; x = 999;
end;
put '**************************************';
t = timestamp '1929-09-25 13:51:36.00'; x = 64; h.replace();
t = timestamp '1929-09-25 13:52:36.00'; x = 64; h.replace();
t = timestamp '1999-12-01 12:00:00.00'; x = 999;
do while (hi.next() = 0);
    put t= x=;
    t = timestamp '1999-12-01 12:00:00.00'; x = 999;
end;
end;
enddata;

The following lines are written to the SAS log.

```
t=1927-08-24 12:51:36 x=1
t=1928-08-24 12:51:36 x=1

Methods:

- “REPLACEDUP Method” on page 898

REPLACEDUP Method

Replaces the data that is associated with the current key's current data item with new data.

Applies to: Hash package
Syntax

```
package.REPLACEDUP();
```

**Arguments**

**package**

- specifies an instance of the hash package variable.

**Details**

The REPLACEDUP method replaces the current data item from the hash package for keys that have multiple data items.

**Note:** The REPLACEDUP method does not replace the value of the data variable with the value of the data item. It replaces only the value in the hash package.

**Note:** If you call the REPLACEDUP method and the key is not found, then the key and data are added to the hash package.

**Comparisons**

The REPLACEDUP method replaces the data that is associated with the current key's current data item with new data. The REPLACE method replaces the data that is associated with the specified key with new data.

**Example**

This example creates a hash package where several keys have multiple data items. When a duplicate data item is found, 300 is added to the value of the data item.

```
data testdup;
   length key data 8;
   input key data;
datalines;
   1 10
   2 11
   1 15
   3 20
   2 16
   2 9
   3 100
   5 5
   1 5
   4 6
   5 99
;
proc ds2;
data _null_;  
dcl double key "data" k d;  
method init();  
dcl package hash h([key], [key "data"], 8, 'testdup','yes', '', '', 'yes');  
dcl package hiter i(h);  
dcl int rc;

do k = 1 to 5;  
do while (h.find([k], [k d]) = 0);
```
put k= d=;
   do while (h.has_next() = 0);
      h.find_next([k d]);
      put 'dup ' k= d=;
      d = d + 300;
      h.replacedup();
   end;
   h.has_next();
end;
end;
end;

put 'iterating...';
rc = i.first([k d]);
do while (rc = 0);
   put k= d=;
   rc = i.next([k d]);
end;
end;
enddata;
run;
quit;

The following lines are written to the SAS log.

```plaintext
key=1 data=10
dup key=1 15
dup key=1 5
key=2 data=11
dup key=2 16
dup key=2 9

key=2 data=11
key=2 data=316
key=2 data=309
key=3 data=20
key=3 data=400
key=4 data=6
key=5 data=5
key=5 data=399
```

See Also

- “Replacing and Removing Data” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “REPLACE Method” on page 896
**SETCUR Method**

Specifies a starting key item for iteration.

**Applies to:** Hash iterator package

---

**Syntax**

Form 1: `package.SETCUR();`

Form 2: `package.SETCUR([keys], [data]);`

**Arguments**

- `package` specifies the name of the hash iterator package variable.

- `[keys]` specifies the key variables by using a variable list.

- `[data]` specifies the variables into which to store the data item.

---

**Details**

The hash iterator enables you to start iteration on any item in the hash package. The SETCUR method sets the starting key for iteration. You reference the starting item with the specified key variables. If the item exists, the data associated with the item is stored in the data variables.

You can use the FIRST or LAST methods to start iteration on the first or last item, respectively.

There are two ways to pass key and data variables to the SETCUR method:

- implicit variable method (Form 1)

  The key and data variables are implied in the SETCUR method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified key and data variables are passed explicitly to the SETCUR method.

---

**Example**

The following example uses the SETCUR method to start iteration at RA= 18 31.6 instead of the first or last items:

```plaintext
declare hiter iter('myhash');
myhash.defineKey('ra');
myhash.defineData('obj', 'ra');
myhash.defineDone();
```
SUM Method

Retrieves the summary value for a given key from the hash table and stores the value in a variable.

Applies to: Hash package

Syntax

Form 1:  `summary-variable=package.SUM();`
Form 2:  `summary-variable=package.SUM([keys]);`

Required Arguments

`summary-variable`

specifies a variable that holds the current summary value of the current key.

Note  A return code that specifies success or failure is not returned by the method.

`package`

specifies an instance of the hash package variable.

`[keys]`

specifies the key values by using a variable list.

Details

You use the SUM method to retrieve key summaries from the hash package. The SUM method retrieves the summary value for a given key when only one data item exists per key. For more information, see “Maintaining Key Summaries” in SAS Viya: DS2 Programmer’s Guide.

There are two ways to pass key variables to the SUM method:

• implicit variable method (Form 1)

  The key variables are implied in the SUM method invocation and do not have to be specified.
variable list method (Form 2)

The specified key variables are passed explicitly to the SUM method.

Comparisons

The SUMDUP method retrieves the summary value for the current data item of the current key when more than one data item exists for a key.

Example: Retrieving the Key Summary for a Given Key

The following example uses the SUM method to retrieve the key summary for a given key, 99.

```sas
data _null_;
  declare double k count total;
  declare package hash myhash(0, '', 'a', '', 'count');
  method init();
    myhash.defineKey('k');
    myhash.defineDone();

  k = 99;
  count = 1;
  myhash.add();

  /* COUNT is given the value 2.5 and the */
  /* FIND sets the summary to 3.5*/
  count = 2.5;
  myhash.find();

  /* The COUNT of 3 is added to the FIND and */
  /* sets the summary to 6.5. */
  count = 3;
  myhash.find();

  /* The COUNT of -1 sets the summary to 5.5. */
  count = -1;
  myhash.find();

  /* The SUM method gives the current value of */
  /* the key summary to the variable TOTAL. */
  total = myhash.sum();

  /* The PUT statement prints total=5.5 in the log. */
  put total=;
end;
enddata;
run;
```

See Also

**SUMDUP Method**

Retrieves the summary value for the current data item of the current key and stores the value in a variable.

**Applies to:** Hash package

### Syntax

**Form 1:**

```plaintext
summary-variable = package.SUMDUP();
```

**Form 2:**

```plaintext
summary-variable = package.SUMDUP([keys]);
```

### Arguments

- **summary-variable**
  - specifies a variable that holds the current summary value for the current data item of the current key.

  **Note**  
  - A return code that specifies success or failure is not returned by the method.

- **package**
  - specifies an instance of the hash package variable.

- **[keys]**
  - specifies the key values by using a variable list.

**See**  

### Details

You use the SUMDUP method to retrieve key summaries from the hash package when a key has multiple data items. For more information, see “Maintaining Key Summaries” in *SAS Viya: DS2 Programmer’s Guide*.

There are two ways to pass key variables to the SUMDUP method:

- **implicit variable method (Form 1)**
  - The key variables are implied in the SUMDUP method invocation and do not have to be specified.

- **variable list method (Form 2)**
  - The specified key variables are passed explicitly to the SUMDUP method.

### Comparisons

The SUMDUP method retrieves the summary value for the current data item of the current key when more than one data item exists for a key. The SUM method retrieves the summary value for a given key when only one data item exists per key.
Example: Retrieving a Summary Value

The following example uses the SUMDUP method to retrieve the summary value for the current data item.

```plaintext
data hashinp;
  dcl double k v;
  method init();
    k=1; v=2; output;
    k=1; v=4; output;
    k=1; v=8; output;
    k=2; v=2; output;
    k=3; v=4; output;
    k=2; v=8; output;
  end;
enddata;
rundata(keep=(k v sumres));
data results(keep=(k v sumres));
dcl double k v si sumres;
dcl package hash h(8, 'hashinp', 'ascending', '', 'si', 'multidata');

method testsuminc(double kval, double suminc);
dcl double rc;
si = suminc;

### SUMINC Method

Specifies a variable that maintains a summary count of hash package keys.

**Applies to:** Hash package

#### Syntax

```
package.SUMINC(suminc-variable);
```

#### Arguments

- **package**
  - specifies an instance of the hash package variable.
**suminc-variable**

specifies a variable that maintains a summary count of hash package keys.

**Details**

You can maintain a summary count for a hash package key by using the SUMINC parameter or method. SUMINC instructs the hash package to allocate internal storage in each record to store a summary value in the record each time that the record is used by a FIND, CHECK, or REF method. The SUMINC value is also used to maintain a summary count of hash parameter keys after a FIND, CHECK, or REF method. SUMINC is given a variable, which holds the sum increment, that is, how much to add to the key summary for each reference to the key. The SUMINC value can be greater than, less than, or equal to 0.

The SUMINC value is also used to initialize the summary on an ADD method. Each time the ADD method occurs, the key to the SUMINC value is initialized.

The SUMINC variable treats a missing or null value as zero, like the SUM function. For example, a key summary changes using the current value of the variable.

For more information, see “Maintaining Key Summaries” in *SAS Viya: DS2 Programmer’s Guide*.

**Note:** Alternatively, you can use the suminc parameter in the DECLARE PACKAGE statement or the _NEW_ operator to retrieve the summary value for the current data item of the current key.

**Example**

See the example in the “SUMDUP Method” on page 904.

Method Naming Convention

When discussing a similar set of methods, this document uses a short name and an asterisk (*) to designate the set of methods as a whole.

For example, when the discussion involves both the SETREQUESTBODYASBINARY and SETREQUESTBODYASSTRING methods, the documentation reads “the SETREQUESTBODY* methods”.

Dictionary

**ABORT Method**

Stops the execution of the HTTP method.

**Syntax**

```plaintext
package.ABORT();
```

**Arguments**

- `package` specifies an instance of the HTTP package variable.

**Details**

Call the ABORT method to stop the HTTP method that is currently running. The ABORT method is useful when you are streaming data and decide that you do not need to see the entire response body.

**See Also**

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

**Methods:**

- “EXECUTEMETHOD Method” on page 918
- “EXECUTEMETHODSTREAM Method” on page 919

---

**ADDREQUESTHEADER Method**

Adds a header to the HTTP method request.

**Syntax**

```plaintext
package.ADDREQUESTHEADER('name', 'value');
```

**Arguments**

- `package` specifies an instance of the HTTP package variable.
- `'name'` specifies the name of the header field.
- `'value'` specifies the value of the header field.
Details
The header is appended to the end of the list of headers.

Example

```javascript
h.addRequestHeader('Cookie', 'SSID=3lk3q84095jk79lgjf');
```

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “CREATEGETMETHOD Method” on page 911
- “CREATEHEADMETHOD Method” on page 915
- “CREATEPOSTMETHOD Method” on page 916

---

**CREATEGETMETHOD Method**

Creates an HTTP GET method to retrieve a resource from a web server.

**Syntax**

```
package.CREATGETMETHOD('url');
```

**Arguments**

```
package
```

specifies an instance of the HTTP package variable.

```
'url'
```

specifies the URL of the resource.

**Details**

Use the CREATEGETMETHOD method to create an HTTP GET method. After you create the GET method, call one of the EXECUTEMETHOD* methods to request the specified resource from the web server.

**Examples**

**Example 1: Create a GET Method and Retrieve an HTTP Resource**

The following example requests an HTTP resource and displays the headers and body of the response from the web server.

```javascript
data _null_;  
  method init();  
  declare package http h();  
  declare varchar(1024) character set utf8 body headers;
```
declare int rc status;

/* Build and send a GET method for the 'FR' resource */
h.createGetMethod('http://api.worldbank.org/countries/FR');
h.executeMethod();

/* If the resource was returned by the server, show the response */
status = h.getStatusCode(); /* get the HTTP status code */
put 'Country code: FR, executeMethod() status:' status;
if status eq 200 then do; /* 200 = OK */
    /* retrieve the headers from the response that came from the server */
    h.getResponseHeadersAsString(headers, rc);
    put 'Headers:';
    put headers;
    /* retrieve the body from the response that came from the server */
    h.getResponseBodyAsString(body, rc);
    put 'Body:';
    put body;
end;
end;
enddata; run;

The following lines are written to the log:

Country code: FR, executeMethod() status: 200
Headers:
HTTP/1.1 200 OK
Content-Length: 627
Content-Type: text/xml; charset=UTF-8
Server: WorldBank
Web Server2
Date: Sat, 22 Mar 2014 00:43:30 GMT
X-Cache: MISS from transproxy
Via: 1.1
transproxy (squid)
Connection: keep-alive

Body:
<?xml version="1.0" encoding="utf-8"?>
<wb:countries page="1" pages="1" per_page="50" total="1"
xmlns:wb="http://www.worldbank.org">  
<wb:country id="FRA">
  <wb:name>France</wb:name>
  <wb:region id="ECS">Europe &amp; Central Asia (all income levels)</wb:region>
  <wb:adminregion id="/" />
  <wb:incomeLevel id="OEC">High income: OECD</wb:incomeLevel>
  <wb:lendingType id="LNX">Not classified</wb:lendingType>
  <wb:capitalCity>Paris</wb:capitalCity>
  <wb:longitude>2.35097</wb:longitude>
  <wb:latitude>48.8566</wb:latitude>
</wb:country>
</wb:countries>
Example 2: Create GET Methods Using Expressions in the Resource URL

The following example generates a separate GET request for each country code in the input data set. Each code is concatenated into the expression that forms the URL of the resource. Note that the final code, ZZ, is not a valid country code.

``` SAS
proc ds2;
data country_codes /overwrite=yes;
dcl char(2) code;
method init();
  code='ES'; output;
  code='FR'; output;
  code='GB'; output;
  code='ZZ'; output; /* unknown country code */
end;
enddata; run; quit;

proc ds2;
data _null_;  
method run();
declare package http h();
declare varchar(1024) character set utf8 body;
declare int rc status;

/* Build and send a GET method for each country code */
set country_codes;
  h.executeMethod();

/* If the resource was returned by the server, show the response */
status = h.getStatusCode(); /* get the HTTP status code */
  put 'Country code:' code 'executeMethod() status code:' status;
  if status eq 200 then do; /* 200 = OK */
    /* retrieve the body from the response that came from the server */
    h.getResponseBodyAsString(body, rc);
    put 'Body:';
    put body;
  end;
end;
enddate; run; quit;
```
The following lines are written to the log:

```xml
Country code: ES executeMethod() status code: 200
Body:

Country code= FR executeMethod() status code = 200
Body:

Country code= GB executeMethod() status code = 200
Body:

Country code= ZZ executeMethod() status code = 200
Body:
<xml version="1.0" encoding="utf-8"?><wb:error xmlns:wb="http://www.worldbank.org"><wb:message id="120" key="Parameter 'country' has an invalid value">The provided parameter value is not valid</wb:message></wb:error>
```

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “EXECUTEMETHOD Method” on page 918
CREATEHEADMETHOD Method

Creates an HTTP HEAD method to test whether a web resource exists and to retrieve its headers.

Syntax

```plaintext
package.CREATEHEADMETHOD('url');
```

Arguments

- `package`
  - specifies an instance of the HTTP package variable.
- `'url'`
  - specifies the URL of the resource.

**Tip** The URL can include query strings (name/value pairs).

Details

Use the CREATEHEADMETHOD method to create an HTTP HEAD method. After you create the HEAD method, call the EXECUTEMETHOD method to send the request to the web server.

Example

The following example creates a HEAD method, sends the request to the web server, and displays the headers of the response.

```plaintext
data _null_;  
method init();  
declare package http h();  
declare varchar(1024) character set utf8 headers;  
declare int rc status;  
declare char(2) code;

/* Build and send a HEAD method for a resource */
code = 'GB';
h.createHeadMethod('http://api.worldbank.org/countries/' || code || '/indicators/NY.GNP.PCAP.CD/?date=1990:1990');
h.executeMethod();

/* If the resource headers were returned by the server, show them */
status = h.getStatusCode(); /* get the HTTP status code */
put 'Country code:' code 'executeMethod() status:' status;
if status eq 200 then do; /* 200 = OK */
  /* retrieve the headers from the response that came from the server */
  h.getResponseHeadersAsString(headers, rc);
  put 'Headers:';
  put headers;
end;
end;
```
The following lines are written to the log:

```plaintext
Country code: GB executeMethod() status: 200
Headers:
HTTP/1.1 200 OK
Content-Length: 0
Content-Type: text/xml; charset=UTF-8
Server: WorldBank Web
Server1
Date: Tue, 25 Mar 2014 21:05:48 GMT
X-Cache: MISS from transproxy
Via: 1.1 transproxy
(Squid)
Connection: keep-alive
```

See Also

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “EXECUTEMETHOD Method” on page 918

---

**CREATEPOSTMETHOD Method**

Creates an HTTP POST method to request the web server to accept data for a resource.

**Syntax**

```plaintext
package.CREATEPOSTMETHOD('url');
```

**Arguments**

- `package`
  - specifies an instance of the HTTP package variable.
- `'url'`
  - specifies the URL of the resource.

  **TIP** The URL can include query strings (name/value pairs).

**Details**

Use the CREATEPOSTMETHOD method to create an HTTP POST method. Because the POST method requires a body, complete the POST method by doing the following:

- Add the body content by calling one of the SETREQUESTBODY* methods, depending on the content type.
- Indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the `Content-Type` header.

Then, call the EXECUTEMETHOD method to send the request to the web server.
Note: The content length is computed by the DS2 HTTP client after transcoding the data.

DECLARE PACKAGE Statement, HTTP Package

Creates a package variable and enables you to create an instance of the HTTP package.

Category: Local

Tip: The PACKAGE statement is not required for an HTTP package.

Syntax

DECLARE PACKAGE HTTP variable( );

Arguments

variable

specifies a variable that can reference an instance of the HTTP package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use an HTTP package to construct an HTTP client to access HTTP web servers. The HTTP package is predefined for DS2 programs.

You declare an HTTP package by using the DECLARE PACKAGE statement. When a package is declared, a variable is created that can reference an instance of the package. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of an HTTP package:

• Use the DECLARE PACKAGE statement along with the _NEW_ operator:

  declare package http httpclt;
  httpclt = _new_ http();

• Use the DECLARE PACKAGE statement along with its constructor syntax:

  declare package http httpclt();
Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

See Also

- “Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

Operators:

- “_NEW_ Operator, HTTP Package” on page 926

DELETE Method, HTTP Package

Deletes an HTTP package instance and frees its resources.

Note: The DELETE method is not required. When an HTTP package goes out of scope, the package is deleted.

Syntax

```
package.DELETE();
```

Arguments

- `package` specifies the name of the HTTP package variable.

Details

When you no longer need the HTTP package, delete it by using the DELETE method. If you attempt to use an HTTP package instance after you delete it, an error is written to the log.

See Also

“Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

EXECUTEMETHOD Method

Executes the HTTP method and enables retrieval of the response body as a complete entity.

Syntax

```
package.EXECUTEMETHOD();
```

Arguments

- `package` specifies an instance of the HTTP package variable.
Details

You must create a GET, HEAD, or POST method before you call the EXECUTEMETHOD method to send the request to the web server. The EXECUTEMETHOD method sends the last method that was created.

If the response has a body, the response body must be retrieved as an entire entity by using one of the GETRESPONSEBODYAS* methods.

Note: The EXECUTEMETHOD method does not support streaming of the response body. If you use one of the STREAMRESPONSEBODYAS* methods to retrieve the response body after sending the request with the EXECUTEMETHOD method, a run-time error occurs. Use the EXECUTEMETHODSTREAM method instead.

See Also

• “Using the HTTP Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “EXECUTEMETHODSTREAM Method” on page 919
• “GETSTATUSCODE Method” on page 925
• “GETRESPONSECONTENTTYPE Method” on page 922
• “GETRESPONSEBODYASBINARY Method” on page 920
• “GETRESPONSEBODYASSTRING Method” on page 921
• “SETSOCKETTIMEOUT Method” on page 930

EXECUTEMETHODSTREAM Method

Executes the HTTP method and enables streaming of the response body from the HTTP server.

Syntax

package.EXECUTEMETHODSTREAM( );

Arguments

package

specifies an instance of the HTTP package variable.

Details

Use the EXECUTEMETHODSTREAM method when you want to stream the response body from the web server in chunks, using either the STREAMRESPONSEBODYASBINARY or STREAMRESPONSEBODYASSTRING method. This is useful when you want to process the response without waiting for all of the data to arrive from the server.

You must create a GET method before you call the EXECUTEMETHODSTREAM method to send the request to the web server. The EXECUTEMETHODSTREAM method sends the last method that was created.
Note: The EXECUTEMETHODSTREAM method does not support retrieval of the response body as an entire entity. If you use one of the GETRESPONSEBODYAS* methods to retrieve the response body after sending the request with the EXECUTEMETHODSTREAM method, a run-time error occurs. Use the EXECUTEMETHOD method instead.

• “GETRESPONSECONTENTTYPE Method” on page 922
• “SETSOCKETTIMEOUT Method” on page 930
• “STREAMRESPONSEBODYASBINARY Method” on page 930
• “STREAMRESPONSEBODYASSTRING Method” on page 931

GETRESPONSEBODYASBINARY Method

Returns the entire body from the HTTP response in binary format.

Syntax

\[ \text{package.GETRESPONSEBODYASBINARY}(\text{variable, rc}); \]

Arguments

\[ \text{package} \]

specifies an instance of the HTTP package variable.

\[ \text{variable} \]

specifies the binary variable to hold the entire response body.

\[ \text{rc} \]

specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the GETRESPONSEBODYASBINARY method to retrieve the response body in binary format. The response body is returned as one entity.

You can call the GETRESPONSEBODYASBINARY method after using the EXECUTEMETHOD method to retrieve the response body returned by the web server.

Note: The GETRESPONSEBODYASBINARY method does not return until the web client has received all the data from the web server.

Note: The response body is not transcoded.

Note: The EXECUTEMETHOD method does not support streaming of the response body.
GETRESPONSEBODYASSTRING Method

Returns the entire body from the HTTP response in character string format.

Syntax

```
package.GETRESPONSEBODYASSTRING(variable, rc);
```

Arguments

- `package`
  - specifies an instance of the HTTP package variable.
- `variable`
  - specifies the variable to hold the entire response body.
- `rc`
  - specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the GETRESPONSEBODYASSTRING method to retrieve the response body in character string format. The response body is returned as one entity.

You can call the GETRESPONSEBODYASSTRING method after using the EXECUTEMETHOD method to retrieve the response body returned by the web server.

Note: The GETRESPONSEBODYASSTRING method does not return until the web client has received all the data from the web server.

Note: The response body is transcoded to the encoding of the string if the encodings are different.

Note: The EXECUTEMETHOD method does not support streaming of the response body.

Example

```
data _null_;  
method init();  
  declare package http h();  
  declare varchar(1024) character set utf8 body;  
  declare int rc status;  
  declare char(2) code;
```
/* Build and send a GET method for a resource */
code = 'FR';
h.createGetMethod('http://api.worldbank.org/countries/'
   || code || '/indicators/NY.GNP.PCAP.CD/?date=1990:1991');
h.executeMethod();

/* If the resource was returned by the server, show the response */
status = h.getStatusCode();   /* get the HTTP status code */
put 'Requested resource for country code:' code 'executeMethod() status:' status;
if status eq 200 then do;     /* 200 = OK */
   /* retrieve the body from the response that came from the server */
   h.getResponseBodyAsString(body, rc);
   put 'Body:';
   put body;
end;
end;
enddata; run;

The following lines are written to the log.

```
Requested resource for country code: FR executeMethod() status: 200
Body:
<?xml version="1.0" encoding="utf-8"?>
<wb:data page="1" pages="1" per_page="50" total="2"
     xmlns:wb="http://www.worldbank.org">
  <wb:data>

GETRESPONSECONTENTTYPE Method

Returns the content type from the HTTP response.
Syntax

```
content-type-variable=package.GETRESPONSECONTENTTYPE( );
```

Arguments

```
content-type-variable
```
specifies the variable to hold the content type value of the HTTP response.

*Note:* Consult an HTTP reference for a list of possible content types.

```
package
```
specifies an instance of the HTTP package.

Details

Use the GETRESPONSECONTENTTYPE method to retrieve the content type from the latest response message.

Example

```
data _null_;  
method init();  
  declare package http h();  
  declare varchar(1024) character set utf8 body contentType headers;  
  declare int rc status;

  /* Build and send a HEAD method for the 'ES' resource */
  h.createHeadMethod('http://api.worldbank.org/countries/ES');
  h.executeMethod();

  /* If the resource was returned by the server, show the response */
  status = h.getStatusCode();  /* get the HTTP status code */
  put 'Country code: ES, executeMethod() status:' status;
  if status eq 200 then do;  /* 200 = OK */
    /* retrieve the content type from the response that came from the server */
    contentType = h.getResponseContentType();
    put 'Content type:' contentType;
  end;
  end;
enddata; run;
```

The following lines are written to the log.

```
Country code: ES, executeMethod() status: 200
Content type: text/xml; charset=UTF-8
```

See Also

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “EXECUTEMETHOD Method” on page 918
- “EXECUTEMETHODSTREAM Method” on page 919
GETRESPONSEHEADERSASSTRING Method

Returns the response headers from the HTTP method in character string format.

Syntax

```package.GETRESPONSEHEADERSASSTRING(variable, rc);```

Arguments

- `package` specifies an instance of the HTTP package variable.
- `variable` specifies the variable to hold the response headers.
- `rc` specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the GETRESPONSEHEADERSASSTRING method to retrieve all headers from the HTTP response. You can use the GETRESPONSEHEADERSASSTRING method after using either the EXECUTEMETHOD method or the EXECUTEMETHODSTREAM method to send any HTTP request to the server.

Example

The following example creates and sends a HEAD method and uses the GETRESPONSEHEADERSASSTRING method to display the headers of the response from the web server.

```data _null_; method init();
declare package http h();
declare varchar(1024) character set utf8 headers;
declare int rc status;
declare char(2) code;
/* Build and send a HEAD method for a resource */
code = 'GB';
h.createHeadMethod('http://api.worldbank.org/countries/' || code || '/indicators/NY.GNP.PCAP.CD/?date=1990:1990');
h.executeMethod();
/* If the resource headers were returned by the server, show them */
status = h.getStatusCode(); /* get the HTTP status code */
put 'Country code:' code 'executeMethod() status:' status;
if status eq 200 then do; /* 200 = OK */
/* retrieve the headers from the response that came from the server */
h.getResponseHeadersAsString(headers, rc);
put 'Headers:';```
The following lines are written to the log:

```
Country code: GB executeMethod() status: 200
Headers:
HTTP/1.1 200 OK
Content-Length: 0
Content-Type: text/xml; charset=UTF-8
Server: WorldBank Web
Server1
Date: Tue, 25 Mar 2014 21:05:48 GMT
X-Cache: MISS from transproxy
Via: 1.1 transproxy
 {squid}
Connection: keep-alive
```

- “EXECUTEMETHODSTREAM Method” on page 919

GETSTATUSCODE Method

Returns the HTTP status code from the most recently executed HTTP method.

Syntax

```
status-code-variable=package.GETSTATUSCODE();
```

Arguments

- `status-code-variable`
  - specifies the variable to hold the HTTP status code value.
  - **Note:** Consult an HTTP reference for possible status codes.

- `package`
  - specifies an instance of the HTTP package variable.

Details

Use the GETSTATUSCODE method to retrieve the HTTP status code from the most recently executed HTTP method.
Example

data _null_
  method init();
  declare package http h();
  declare int status;

  /* Build and send a HEAD method for a resource */
  h.createHeadMethod('http://support.sas.com/documentation/');
  h.executeMethod();

  /* If the resource was returned by the server, show the response */
  status = h.getStatusCode();   /* get the HTTP status code */
  put 'HEAD method created for resource:';
  put 'http://support.sas.com/documentation/';
  put 'executeMethod() status:' status;
end;
enddata; run;

The following lines are written to the log.

HEAD method created for resource:
http://support.sas.com/documentation/
executeMethod() status: 200

• “EXECUTEMETHODSTREAM Method” on page 919

.NEW_ Operator, HTTP Package

Constructs an instance of an HTTP package.

Note: The escape character (\) before the bracket indicates that the bracket is required in the syntax.

Syntax

\package-variable\=\_NEW_\[\{THIS\}\ | \{package-instance\}\] HTTP();

Arguments

\package-variable
  specifies a name that can reference an instance of the package.

\[THIS\]
  specifies that the package instance has global scope.

See “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide
[**package-instance**]

specifies that the new package instance has the same scope as **package-instance**. **package-instance** must be an existing package instance and is referenced by its package variable name. The package type of **package-instance** does not have to be the same as the instance that is being instantiated.

*Note:* Associating the scope of one package instance with another is useful when you want instances to be automatically deleted at the same time.

See “Package-Specific Scope” in *SAS Viya: DS2 Programmer’s Guide*

---

**Details**

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When an HTTP package is declared, the variable representing the package can be considered an instance of the package. This means that two different HTTP package variables represent two completely separate copies of the package.

You declare an HTTP package by using the DECLARE PACKAGE statement. After you declare the new HTTP package, use the **_NEW_** operator to instantiate the package.

```sas
declare package http h;
    h = _new_ http();
```

As an alternative to the two-step process of using the DECLARE PACKAGE statement and the **_NEW_** operator to declare and instantiate an HTTP package, you can declare and instantiate a package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```sas
declare package http h();
```

*Note:* Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*.

**See Also**

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*
- “Package Constructors and Destructors” in *SAS Viya: DS2 Programmer’s Guide*

**Statements:**

- “DECLARE PACKAGE Statement, HTTP Package” on page 917
- “PACKAGE Statement” on page 753

---

**SETREQUESTBODYASBINARY Method**

Adds the specified body to the HTTP method request in binary format.

**Syntax**

```sas
package.SETREQUESTBODYASBINARY(variable);
```
Arguments

package
   specifies an instance of the HTTP package variable.

variable
   specifies the binary variable that contains the request body data.

Details

Use the SETREQUESTBODYASBINARY method to add the request body, in binary format, to the HTTP method.

To complete the HTTP method, indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the Content-Type: header. Then, call the EXECUTEMETHOD method to send the request to the web server.

Note: The content length is computed by the DS2 HTTP client after transcoding the data.

See Also

• “Using the HTTP Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “ADDREQUESTHEADER Method” on page 910
• “CREATEPOSTMETHOD Method” on page 916
• “EXECUTEMETHOD Method” on page 918
• “SETREQUESTBODYASSTRING Method” on page 928
• “SETREQUESTCONTENTTYPE Method” on page 929

SETREQUESTBODYASSTRING Method

Adds the specified body to the HTTP method request in character string format.

Syntax

package.SETREQUESTBODYASSTRING(variable);

Arguments

package
   specifies an instance of the HTTP package variable.

variable
   specifies the string variable that contains the request body data.

Details

Use the SETREQUESTBODYASSTRING method to add the request body, in character string format, to the HTTP method.
To complete the HTTP method, indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the Content-Type: header. Then, call the EXECUTEMETHOD method to send the request to the web server.

Note: The content length is computed by the DS2 HTTP client after transcoding the data.

Note: If the encoding of the provided request data differs from the specified content type, the data is transcoded to the encoding that is specified by content type.

See Also

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “ADDDREQUESTHEADER Method” on page 910
- “CREATEPOSTMETHOD Method” on page 916
- “EXECUTEMETHOD Method” on page 918
- “SETREQUESTBODYASBINARY Method” on page 927
- “SETREQUESTCONTENTTYPE Method” on page 929

SETREQUESTCONTENTTYPE Method

Specifies the content type of the body of the HTTP method request.

Syntax

```
package.SETREQUESTCONTENTTYPE(content-type);
```

Arguments

- `content-type` specifies the variable that contains the content type value.

  Note: Consult an HTTP reference for possible content types.

- `package` specifies an instance of the HTTP package variable.

Details

Use the SETREQUESTCONTENTTYPE method to specify the content type of the body of the HTTP method.

See Also

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “CREATEPOSTMETHOD Method” on page 916
- “EXECUTEMETHOD Method” on page 918
SETSOCKETTIMEOUT Method

Specifies the socket time-out value to wait for a response from an HTTP web server.

Syntax

```
package.SETSOCKETTIMEOUT(time-out-value);
```

Arguments

- **package**: specifies an instance of the HTTP package variable.
- **time-out-value**: specifies the default socket time-out, in milliseconds, to wait for a response from the web server.

Details

Use the SETSOCKETTIMEOUT method to specify how long to wait for a response from the web server.

The SETSOCKETTIMEOUT method can be set for each new CREATE method when the default time-out is too long or too short.

Example

```
h. setSocketTimeout(1000);
```

See Also

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

STREAMRESPONSEBODYASBINARY Method

Streams the body, in chunks, from the HTTP response in binary format.

Syntax

```
package.STREAMRESPONSEBODYASBINARY(variable, rc);
```

Arguments

- **package**: specifies an instance of the HTTP package variable.
- **variable**: specifies the variable that will contain the response data chunk.
rc specifies the variable to hold the return code value.

*Note:* A return code value of 0 indicates success; a value of 1 indicates failure.

**Details**

Use the STREAMRESPONSEBODYASBINARY method to retrieve the response body in binary format. The response body is streamed, in chunks.

You can call the STREAMRESPONSEBODYASBINARY method after using the EXECUTEMETHODSTREAM method.

If you do not want to complete the streaming of the body data, call the ABORT method to stop the execution of the method.

*Note:* The EXECUTEMETHODSTREAM method does not support retrieval of the response body as one entity.

**See Also**

- “Using the HTTP Package” in *SAS Viya: DS2 Programmer’s Guide*

**Methods:**

- “ABORT Method” on page 910
- “EXECUTEMETHODSTREAM Method” on page 919

Dictionary

CREATEPARSER Method

Creates a JSON Parser instance.
Syntax

Form 1:  `package.CREATEPARSER ( );`
Form 2:  `package.CREATEPARSER (json-text, tipping-size);`
Form 3:  `package.CREATEPARSER (json-text);`
Form 4:  `package.CREATEPARSER (tipping-size);`

Arguments

`package`  
specifies an instance of the JSON package.

`json-text`  
specifies the input JSON text to be parsed.

`tipping-size`  
specifies the minimum number of characters of output JSON text to accumulate before calling the string call-back routine for strings longer than `tipping-size`.

Default  
0, which indicates that only complete strings are returned to the string callback, regardless of length.

Restriction  
The maximum number of characters that can be returned is `(tipping-size + 4)` when `tipping-size` is set.

Details

If you use Form 1 or Form 4 of the CREATEPARSER method syntax, you should subsequently call the SETPARSERINPUT method to provide the JSON text to be parsed.

Example

For an example, see “GETNEXTTOKEN Method” on page 937.

See Also

• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “DESTROYPARSER Method” on page 936
• “SETPARSERINPUT Method” on page 949

CREATEWRITER Method

Creates a JSON writer instance.
Syntax

```sas
package.CREATEWRITER (flags=‘PRETTY’ | ‘NOPRETTY’);
```

**Arguments**

- `package` specifies an instance of the JSON package.
- `flags=’PRETTY’ | ‘NOPRETTY’` specifies how to format the JSON output. `flags` can be one of the following values:
  - `'PRETTY'` creates a more human-readable format that uses indentation to illustrate the JSON container structure.
  - `'NOPRETTY'` writes the output in a single line

**Default** NOPRETTY

**Note** More flags might be available in future releases.

**Details**

The DS2 JSON package's writer currently does not support streaming. Instead, the Write instances are gathered in memory until retrieved by calling the WRITERGETTEXT method.

**Example**

For an example, see “WRITEARRAYOPEN Method” on page 949.

**See Also**

**Methods:**

- “DESTROYWRITER Method” on page 937
- “WRITERGETTEXT Method” on page 956

---

**DECLARE PACKAGE Statement, JSON Package**

Creates a package variable and enables you to create an instance of the JSON package.

**Category:** Local

**Syntax**

```sas
DECLARE PACKAGE JSON variable ();
```
Arguments

variable

specifies a name that can reference an instance of the JSON package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a JSON package to create and parse JSON text. The JSON package is predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a JSON package.

• Use the DECLARE PACKAGE statement along with the _NEW_ operator:

```
declare package json j;
j = _new_ json();
```

• Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package json j();
```

See Also

• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide
• “Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

Operators:

• “_NEW_ Operator, JSON Package” on page 948

DESTROYPARSER Method

Destroys a JSON Parser instance.

Syntax

```
package.DESTROYPARSER ( );
```

Arguments

package

specifies an instance of the JSON package.

Example

For an example, see “GETNEXTTOKEN Method” on page 937.
DESTROYWRITER Method

Destroys a JSON writer instance.

Syntax

```
package.DESTROYWRITER ();
```

Arguments

- `package` specifies an instance of the JSON package.

Example

For an example, see “WRITEARRAYOPEN Method” on page 949.

See Also

GETNEXTTOKEN Method

Returns the next validated JSON language item or element from the JSON text.

Syntax

```
Form 1:  package.GETNEXTTOKEN (rc, token-type, parse-flags,);
Form 2:  package.GETNEXTTOKEN (rc, token, token-type, parse-flags,);
Form 3:  package.GETNEXTTOKEN (rc, token, token-type, parse-flags, line-number, column-number);
```

Arguments

- `package` specifies an instance of the JSON package.
rc
specifies the variable to hold the return code value. Possible return code values are as follows:

0      Success
100    The output token argument's maximum length was not large enough and truncation occurred.
101    Done. This return code typically means that the parser finished parsing a complete JSON document on the previous call to getNextToken, and the current call is returning 101("done") because there is no more text to parse. The setParserInput method can be used to provide more JSON text if desired.
300    End of text. The parser encountered the end of text and the text did not complete a JSON document. The setParserInput method can be used to provide more JSON text if desired.
301    An error occurred while parsing the text.

token-type
token-type can be one of the following values:

4      Boolean true
8      Boolean false
16     Left bracket ( [ )
32     Right bracket ( ] )
64     Left brace ( { )
128    Right brace ( } )
256    String
512    Numeric
1024   Null

parse-flags
parse-flags output value can be an integer flag set consisting of one or more of the following flags:

0x00000001  token is a label in an object
0x00000002  token is not complete
0x00000003  token is an integral numeric
0x00000004  token is a floating point number

token
is the next token or string.

line-number
Updates the given integer variable argument with the line number within the text where the token is located.

Tip  You can use the line number to help determine the location of the token within the text.
column-number

Updates the given integer variable argument with the column number within the text where the token is located.

Tip You can use the column number to help determine the location of the token within the text.

Details

All of the arguments to the GETNEXTTOKEN method are passed by reference.

You can use the IS* methods to test the token type.

Example

The following example parses elements in JSON text and returns the token, token type, and parse flag.

```
proc ds2;
data _null_; method init();
dcl package json j();
dcl int rc tokenType parseFlags;
dcl nvarchar(128) token labl strval t1 ;
t1 = '{"lab1":1} /* comment 1 */,{"lab2":2} /* comment 2 */';
rc = j.createParser( t1 );
put 'createParse' rc=;
do while ( rc < 101 );
   j.getNextToken( rc, token, tokenType, parseFlags );
   put rc= token= tokenType= parseFlags=;
end;
rc = j.destroyParser();
put 'destroyParser' rc=;
end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
createParse rc=0
rc=0 token={ tokenType=16 parseFlags=0
rc=0 token={ tokenType=64 parseFlags=0
rc=0 token=lab1 tokenType=256 parseFlags=1
rc=0 token=1 tokenType=512 parseFlags=3
rc=0 token=} tokenType=128 parseFlags=0
rc=0 token={ tokenType=64 parseFlags=0
rc=0 token=lab2 tokenType=256 parseFlags=1
rc=0 token=2 tokenType=512 parseFlags=3
rc=0 token=} tokenType=128 parseFlags=0
rc=0 token=} tokenType=12 parseFlags=0
rc=101 token= tokenType=0 parseFlags=0
destroyParser rc=0
```

See Also

Methods:
ISBOOLEANFALSE Method

Returns true if the token is false.

Syntax

package.ISBOOLEANFALSE (token-type);

Arguments

package
    specifies an instance of the JSON package.

token-type
    specifies the token type that was obtained from the GETNEXTTOKEN method.

Details

You can use the ISBOOLEANFALSE method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

Methods:

- “GETNEXTTOKEN Method” on page 937
- “ISBOOLEANTRUE Method” on page 941
- “WRITEBOOLEANFALSE Method” on page 950
ISBOOLEANTRUE Method
Returns true if the token is true.

Syntax

```
package.ISBOOLEANTRUE (token-type);
```

Arguments

- `package` specifies an instance of the JSON package.
- `token-type` specifies the token type that was obtained from the GETNEXTTOKEN method.

Details
You can use the ISBOOLEANTRUE method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

Methods:
- “GETNEXTTOKEN Method” on page 937
- “ISBOOLEANFALSE Method” on page 940
- “WRITEBOOLEANTRUE Method” on page 951

ISFLOAT Method
Returns true if the token is a floating point number in text form.

Syntax

```
package.ISFLOAT (token-type, parse-flags);
```

Arguments

- `package` specifies an instance of the JSON package.
- `token-type` specifies the token type that was obtained from the GETNEXTTOKEN method.
- `parse-flags` specifies the parse flags that were obtained from the GETNEXTTOKEN method.
Details
You can use the ISFLOAT method to test the token type that was obtained from the
GETNEXTTOKEN method.

See Also
• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:
• “GETNEXTTOKEN Method” on page 937
• “ISINTEGER Method” on page 942
• “ISNUMERIC Method” on page 945

ISINTEGER Method
Returns true if the token is an integer in text form.

Syntax
package.ISINTEGER (token-type, parse-flags);

Arguments
package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

parse-flags
specifies the parse flags that were obtained from the GETNEXTTOKEN method.

Details
You can use the ISINTEGER method to test the token type that was obtained from the
GETNEXTTOKEN method.

See Also
• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:
• “GETNEXTTOKEN Method” on page 937
• “ISFLOAT Method” on page 941
• “ISNUMERIC Method” on page 945
ISLABEL Method
Returns true if the token is an object label.

Syntax

\[
\text{package.ISLABEL (token-type, parse-flags);}
\]

Arguments

\[
\text{package} \quad \text{specifies an instance of the JSON package.}
\]

\[
\text{token-type} \quad \text{specifies the token type that was obtained from the GETNEXTTOKEN method.}
\]

\[
\text{parse-flags} \quad \text{specifies the parse flags that were obtained from the GETNEXTTOKEN method.}
\]

Details

You can use the ISLABEL method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

Methods:

- “GETNEXTTOKEN Method” on page 937

ISLEFTBRACE Method
Returns true if the token is a left brace ( { ).

Syntax

\[
\text{package.ISLEFTBRACE (token-type);}
\]

Arguments

\[
\text{package} \quad \text{specifies an instance of the JSON package.}
\]

\[
\text{token-type} \quad \text{specifies the token type that was obtained from the GETNEXTTOKEN method.}
\]

Details

You can use the ISLEFTBRACE method to test the token type that was obtained from the GETNEXTTOKEN method.
ISLEFTBRACKET Method

Returns true if the token is a left bracket ( [ ).

Syntax

    package.ISLEFTBRACKET (token-type);

Arguments

    package
        specifies an instance of the JSON package.
    token-type
        specifies the token type that was obtained from the GETNEXTTOKEN method.

Details

You can use the ISLEFTBRACKET method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

    • “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

    • “GETNEXTTOKEN Method” on page 937
    • “ISRIGHTBRACKET Method” on page 946

ISNULL Method

Returns true if the token is null.

Syntax

    package.ISNULL (token-type);

Arguments

    package
        specifies an instance of the JSON package.
ISNUMERIC Method
Returns true if the token is numeric in text form.

Syntax

\[ \text{package.ISNUMERIC (token-type);} \]

Arguments

package
specifies an instance of the JSON package.

token-type
receives the token type that was obtained from the GETNEXTTOKEN method.

Details
You can use the ISNUMERIC method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “GETNEXTTOKEN Method” on page 937
• “WRITENULL Method” on page 955

ISPARTIAL Method
Returns true if the token is incomplete because of tipping.
Syntax

`package.ISPARTIAL (parse-flags);`

Arguments

- `package`: specifies an instance of the JSON package.
- `parse-flags`: receives the parse flags that were obtained from the `GETNEXTTOKEN` method.

Details

You can use the `ISPARTIAL` method to test the token type that was obtained from the `GETNEXTTOKEN` method.

See Also

- “Using the JSON Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “`GETNEXTTOKEN` Method” on page 937

---

**ISRIGHTBRACE Method**

Returns true if the token is a right brace ( ) .

Syntax

`package.ISRIGHTBRACE (token-type);`

Arguments

- `package`: specifies an instance of the JSON package.
- `token-type`: receives the token type that was obtained from the `GETNEXTTOKEN` method.

Details

You can use the `ISRIGHTBRACE` method to test the token type that was obtained from the `GETNEXTTOKEN` method.

See Also

- “Using the JSON Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “`GETNEXTTOKEN` Method” on page 937
ISRIGHTBRACKET Method

Returns true if the token is a right bracket ( ] ).

Syntax

\[ \text{package.ISRIGHTBRACKET (token-type);} \]

Arguments

- **package** specifies an instance of the JSON package.
- **token-type** receives the token type that was obtained from the GETNEXTTOKEN method.

Details

You can use the ISRIGHTBRACKET method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- “Parsing JSON Text” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “GETNEXTTOKEN Method” on page 937
- “ISLEFTBRACKET Method” on page 944

ISSTRING Method

Returns true if the token is a string.

Syntax

\[ \text{package.ISSTRING (token-type);} \]

Arguments

- **package** specifies an instance of the JSON package.
- **token-type** receives the token type that was obtained from the GETNEXTTOKEN method.
Details

You can use the ISSTRING method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “GETNEXTTOKEN Method” on page 937

_NAME_ Operator, JSON Package

Constructs an instance of a JSON package.

**Note:** The escape character (\) before the bracket indicates that the bracket is required in the syntax.

**Syntax**

```plaintext
package-variable = _NEW_ [[THIS] | package-instance] JSON();
```

**Arguments**

- `package-variable`
  - specifies a name that can reference an instance of the package.
- `[THIS]`
  - specifies that the package instance has global scope.
  - See “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide
- `[package-instance]`
  - specifies that the new package instance has the same scope as `package-instance`. `package-instance` must be an existing package instance, and the type of `package-instance` can differ from the type of the new package instance.
  - See “Package-Specific Scope” in SAS Viya: DS2 Programmer’s Guide

**Details**

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When a JSON package is declared, the variable representing the package can be considered an instance of the package. This means that two different package variables represent two completely separate copies of a package.

You declare a JSON package using the DECLARE PACKAGE statement. After you declare the new JSON package, use the _NEW_ operator to instantiate the package.

```plaintext
declare package json jsontxt;
jsontxt = _new_ json();
```
As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a JSON package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

declare package json jsontxt( );

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer's Guide.

See Also
• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide
• “Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

Statements:
• “DECLARE PACKAGE Statement, JSON Package” on page 935

SETPARSERINPUT Method
Provides JSON text to the parser when it needs more text.

Restriction: This method is valid only if the parser does not have any text; an error is returned if it does.

Syntax

package.SETPARSERINPUT([json-text,]);

Arguments

package
specifies an instance of the JSON package.

json-text
specifies the JSON text for the parser.

See Also
• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:
• “CREATEPARSER Method” on page 933

WRITEARRAYOPEN Method

Writes the open bracket ([ ] ) signifying the beginning of an array.
Syntax

\texttt{package.WRITEARRAYOPEN}();

Arguments

\texttt{package}

specifies an instance of the JSON package.

Details

The WRITEARRAYOPEN method explicitly opens an array container, which you must explicitly close with the WRITECLOSE method.

Example

The following example creates a writer instance and writes a numeric value to a JSON array container.

\begin{verbatim}
data _null_;  
   method init();  
      dcl package json j();  
      dcl double dblVal;  
      dcl int rc;  
      dcl nvarchar(15) jsontxt;  

      rc = j.createWriter();  
      rc = j.writeArrayOpen();  
      dblVal = 12345678.1234;  
      rc = j.writeDouble( dblVal, 13, 5 );  
      rc = j.writeClose();  
      j.writerGetText( rc, jsontxt );  
      put jsontxt=;  
      rc = j.destroywriter();  
   end;  
enddata;  
run;
\end{verbatim}

The following line is written to the SAS log:

\fontfamily{phv}\selectfont jsontxt=\begin{verbatim}1.2346e{+07} \end{verbatim}

• “Using the JSON Package” in \textit{SAS Viya: DS2 Programmer’s Guide}

Methods:

• “WRITECLOSE Method” on page 951

WRITEBOOLEANFALSE Method

Writes a Boolean false value to the text.
WRITEBOOLEANFALSE Method

Syntax

\texttt{package.WRITEBOOLEANFALSE ();}

Arguments

\texttt{package}

specifies an instance of the JSON package.

See Also

\begin{itemize}
  \item “Using the JSON Package” in \textit{SAS Viya: DS2 Programmer’s Guide}
\end{itemize}

Methods:

\begin{itemize}
  \item “ISBOOLEANFALSE Method” on page 940
  \item “WRITEBOOLEANTRUE Method” on page 951
\end{itemize}

WRITEBOOLEANTRUE Method

Writes a Boolean true value to the text.

Syntax

\texttt{package.WRITEBOOLEANTRUE ();}

Arguments

\texttt{package}

specifies an instance of the JSON package.

See Also

\begin{itemize}
  \item “Using the JSON Package” in \textit{SAS Viya: DS2 Programmer’s Guide}
\end{itemize}

Methods:

\begin{itemize}
  \item “ISBOOLEANTRUE Method” on page 941
  \item “WRITEBOOLEANFALSE Method” on page 950
\end{itemize}

WRITECLOSE Method

Closes the corresponding object ( } ) or array ( ] ).

Syntax

\texttt{package.WRITECLOSE ();}
Arguments

package
  specifies an instance of the JSON package.

Details

The WRITECLOSE method closes the most recently opened container of either type that was explicitly opened with the WRITARRAYOPEN or WRITEOBJOPEN method. You should call the WRITECLOSE method for containers only if you explicitly opened the container with a WRITE*OPEN method.

Example

For an example, see “WRITARRAYOPEN Method” on page 949.

See Also

• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “WRITEOBJOPEN Method” on page 955
• “WRITARRAYOPEN Method” on page 949

WRITEDOUBLE Method

Writes a DOUBLE value in text form.

Syntax

Form 1:  package.WRITEDOUBLE (double-value);
Form 2:  package.WRITEDOUBLE (double-value, width);
Form 3:  package.WRITEDOUBLE (double-value, width, precision);
Form 4:  package.WRITEDOUBLE (double-value, width, precision, options);

Arguments

package
  specifies an instance of the JSON package.

double-value
  specifies the value to be written.

width
  specifies the width of the formatted value.
  Default  0

precision
  indicates the number of digits that appear after the radix character.
options

specifies a flag for formatting. options can be one of the following values:

BESTFIT
formats the value using decimal notation in the form of \([-\]dd\)ddd.dd or scientific notation in the form of \([-\]d.dd\)dE±dd. The formatting style depends on the value.

Notes Valid width is 1–32 characters.

BESTFITBIG
formats the value using decimal notation in the form of \([-\]dd\)d.ddd.dd or scientific notation in the form of \([-\]d.dd\)dE±dd. The formatting style depends on the value.

Notes Valid width is 1–32 characters.

SASBEST
Conforms to the BEST\(w\). format rules. The value is formatted within the specified width. Decimal notation is produced if possible. Otherwise, scientific notation is produced in the style \([-\]d\)\)d.ddd\)E±d\(d\)

Note Trailing zeros after the radix character are suppressed.

SASEW
Conforms to the E\(w\). format rules. The value is formatted within the specified width. Scientific notation is always produced in the style \([-\]d\)\)d.ddd\)E±d\(d\).

Notes Valid width is 7–32 characters.

SASEWD
Conforms to the SAS XP Services \%\(\)d\(\)wdee rules. The value is formatted within the specified \(\)w\(\)d. Scientific notation is always produced in the style \([-\]d\)\)d.dd\)E±d\(d\).

Notes Valid width is 7–32 digits.

Valid precision is 0–31 digits.

SASWD
Conforms to the \(\)w\(\)d format rules.

Note The value is formatted within the specified \(\)w\(\)d. If \(\)w\(\)d is too small, it reverts to the behavior indicated by SASBEST.

DECIMAL
Formats the value using decimal notation in the style \([-\]d\)\)d.dd, using \(\)precision to determine the number of digits after the radix.

Note The radix character does not appear if there are no digits to display after it or if \(\)precision is set to zero.
FRACTION
 Formats the fractional part of the value in the style of \([-]0.dddd\).

Note The digit before the radix character is always zero.

INTEGER
 Formats the fractional part of the value in the style of \([-]dddd\).

Note The fractional part of the value is ignored and no radix character is added to the result.

SNOTE
 formats the value using scientific notation in the form of \([-]d.ddde\pm dd\), using the lowercase ‘e’ to precede the exponent.

SNOTEBIG
 formats the value using scientific notation in the form of \([-]d.dddE\pm dd\), using the uppercase ‘E’ to precede the exponent.

Default BESTFIT

Example
The following example writes DOUBLE values to an array.

data _null_;
  dcl package logger lgr( 'App.tk.D2PKG.JSON' );
  dcl package json j();
  dcl nvarchar(256) matrixA;
  dcl int rc;

  method init();
    rc = j.createWriter();
    rc = j.writeArrayOpen();
    rc = j.writeArrayOpen();
    rc = j.writeDouble(1.1);    rc = j.writeDouble(1.2);
    rc = j.writeClose();
    rc = j.writeArrayOpen();
    rc = j.writeDouble(2.1);    rc = j.writeDouble(2.2);
    rc = j.writeClose();
    rc = j.writeClose();
    j.writerGetText( rc, matrixA );
    lgr.log( 4, 'matrix A = $s', matrixA );
    rc = j.destroyWriter();
  end;
enddata;
run;

The following lines are written to the SAS log:

NOTE: matrix A = [[1.1,1.2],[2.1,2.2]]

See Also
WRITENULL Method

Writes a null value to the text.

Syntax

```
package.WRITENULL ( );
```

Arguments

`package`

specifies an instance of the JSON package.

See Also

Methods:

- “ISNULL Method” on page 944

WRITEOBJOPEN Method

 Writes the open brace ( { ) signifying the beginning of an object.

Syntax

```
package.WRITEOBJOPEN ( );
```

Arguments

`package`

specifies an instance of the JSON package.

Details

The WRITEOBJOPEN method explicitly opens an object container, which you must explicitly close with the WRITECLOSE method.

See Also

Methods:

- “WRITECLOSE Method” on page 951
WRITERGETTEXT Method

Obtains the JSON text that is produced by the writer.

Syntax

```plaintext
package.WRITERGETTEXT(rc, json-text);
```

Arguments

- `package`
  specifies an instance of the JSON package.

- `rc`
  specifies the variable to hold the return code value. Possible return code values are as follows:
  - 0 Success
  - 100 The output token argument's maximum length was not large enough and truncation occurred.
  - 300 End of text. The parser encountered the end of text and the text did not complete a JSON document.
  - 301 A status condition was returned.

- `json-text`
  specifies a variable that receives the JSON text.

Details

The DS2 JSON package's writer currently does not support streaming. Instead, the Write instances are gathered in memory until retrieved by calling the WRITERGETTEXT method.

Example

The following example creates an array containing two elements, that in turn, consist of two more arrays. Those two arrays contain three elements, each of which is a numeric value, `[[1, 2, 3], [4, 5, 6]]`. This data can be interpreted as a numeric table containing two rows and three columns. Knowing that, you can parse out each token and write the data as an array.

```plaintext
proc ds2;
data _null_;   
dcl package logger lgr( 'App.tk.D2PKG.JSON' );
dcl package json j();
dcl nvarchar(8192) txt;
dcl int rc;

method run();
  rc = j.createWriter( 'PRETTY' );
  rc = j.writeValueArrayOpen();
  rc = j.writeValueArrayOpen();
```
The following lines are written to the SAS log.

NOTE: text follows: [
    [1,
     2,
     3],
    [4,
     5,
     6]
]

See Also

• “Using the JSON Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “CREATEWRITER Method” on page 934

WRITESTRING Method

Writes a string to the JSON text.

Note: Braces in the syntax convention indicate a syntax grouping.

Syntax

package.WRITESTRING ({[' | "}]string{[' | "]}, flags);

Arguments

package
    specifies an instance of the JSON package.
{ <'> | '<' }string { <'> | '<' } }
specifies the string to write.

Tip The string can be a string literal in single quotation marks, a normal identifier
without quotation marks, or a delimited identifier in double quotation marks.

flags
specifies options for special handling of the string. The following values are
possible:

0 0 indicates no flags.

16 16 (JSN_SkipScan) indicates that the normal scanning and JSON encoding of the
input string should be skipped. This means that either the string is known to
contain no invalid or JSON escape characters, or the caller has already performed
JSON scanning or encoding on the string. In the latter case, only quotation marks
and separators would be inserted with the given string.
For normal scanning, omit the flag so that normal scanning and JSON encoding
can proceed.

32 32 (JSN_TrimBlanks) causes the writer to trim trailing blanks from the string.

48 48 causes both the writer to skip scanning and trim blanks.

Example
The following example illustrates different types of string values.

data _null_;  
dcl package logger lgr ( 'App.tk.D2PKG.JSON' );
dcl package json j();
dcl nvarchar(2000) txt;
dcl varchar(20) "a**b";
dcl varchar(20) myStr;
dcl int rc;

method init();
rc = j.createWriter();  
rcc = j.writeString( 'aaaAAA', 0 );
"a**b" = 'bbbBBB';
rcc = j.writeString( "a**b", 0 );
myStr = 'cccCCC';
rcc = j.writeString( myStr, 0 );
rcc = j.writeClose();
j.writerGetText( rc, txt );
lgr.log( 3, 'txt = $s', txt );
rcc = j.destroyWriter();
end;
enddata;
run;

Chapter 18
DS2 Logger Package Methods, Operators, and Statements

---

**Dictionary**

**DECLARE PACKAGE Statement, Logger Package**

Creates a package variable and gives you the option of creating an instance of the logger package.

**Category:** Local

**Tip:** The PACKAGE statement is not required for a logger package.

**Syntax**

```plaintext
DECLARE PACKAGE LOGGER variable ([logger-name]);
```

**Arguments**

- `variable`
  - specifies a name that can reference an instance of the logger package.

- `logger-name`
  - specifies the name of the logger that is defined in the SAS logging facility.

**Default** SAS root logger

**Details**

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a logger package to interface with the SAS logging facility. The logger package is predefined for DS2 programs.
You declare a logger package by using the DECLARE PACKAGE statement. This associates a logger package with a logger name. After you declare the new logger package, you can send messages to the logger at a specified logging level.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a logger package.

- Use the DECLARE PACKAGE statement along with the _NEW_ operator:
  ```
  declare package logger logpkg;
  logpkg = _new_ logger();
  ```

- Use the DECLARE PACKAGE statement along with its constructor syntax:
  ```
  declare package logger logpkg();
  ```

For more information about the logger package, see “Using the Logger Package” in SAS Viya: DS2 Programmer’s Guide.

**Example**

This example creates an instance of a logger package.

```sas
data _null_
   dcl package logger l();
   method init();
   l.log('i', 'Hello World!');
end;
enddata;
```

**See Also**

- “Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

**Operators:**

- “_NEW_ Operator, Logger Package” on page 966

### DELETE Method, Logger Package

Deletes a logger package.

**Note:** The DELETE method is not required. When a logger package goes out of scope, the package is deleted.

**Syntax**

```sas
package.Delete();
```
**Arguments**

*package*

specifies an instance of the logger package variable.

**Details**

When you no longer need the logger package, delete it by using the DELETE method. If you attempt to use a logger package after you delete it, an error will be written to the log.

**See Also**

“Package Constructors and Destructors” in *SAS Viya: DS2 Programmer’s Guide*

---

**ISLEVELACTIVE Method**

Returns a value that indicates whether the logger package that is associated with the logger name suppresses a message at the logger level.

**Syntax**

```
package.ISLEVELACTIVE(['level']);
```

**Arguments**

*package*

specifies an instance of the logger package variable.

['level']

a numeric value that specifies the level at which a logging request is applied for the specified logger package.

**Requirements**

*level* must be a string that contains either the severity value or a one-character abbreviation for the severity value. Valid values are listed as follows.

- 2 or 'T' for TRACE
- 3 or 'D' for DEBUG
- 4 or 'I' for INFO
- 5 or 'W' for WARN
- 6 or 'E' for ERROR
- 7 or 'F' for FATAL

If a character is used for *level*, the character must be enclosed in single quotation marks. Numeric values can be quoted but do not need to be.

**Example**

These are examples of the ISLEVELACTIVE method.

```
mylog.islevelactive(5);
```

```
testlog.islevelactive('F');
```
LOG Method, Logger Package

Send the specified message to the logger at the specified level.

Note:

Syntax

Form 1:  
\[ \text{package}.\text{LOG}([\text{"level"}], [\text{"raw-message"}]); \]

Form 2:  
\[ \text{package}.\text{LOG}([\text{"level"}], \text{[message-format]}\text{argument-1} [\ldots, \text{argument-9}]); \]

Arguments

package

specifies an instance of the logger package variable.

[\text{"level"}]

a numeric value that specifies the level at which a logging request is applied for the specified logger package.

Requirements  
level must be a string that contains either the severity value or a one-character abbreviation for the severity value. Valid values are listed as follows. Note that any part of the word that indicates the level is valid. For example, i, in, inf, or info is valid.

- 2 or 'T' for TRACE
- 3 or 'D' for DEBUG
- 4 or 'I' for INFO
- 5 or 'W' for WARN
- 6 or 'E' for ERROR
- 7 or 'F' for FATAL

If a character is used for level, the character must be enclosed in single quotation marks. Numeric values can be quoted but do not need to be.

[\text{"raw-message"}]

specifies the message to write at the level.

Range  
1–65535 characters

Requirement  
The message is a string and must be enclosed in single quotation marks.

Tip  
The message can be any character type expression. Here is an example, \text{x.log}(5, [\text{"Error while processing function"} \text{|| trimn(FNAME)}]);. However, using a character expression causes a conversion from a CHAR data type to an NCHAR data type. It is faster to use a character string.
**message-format**

specifies a message format that is used to produce the log message. The message format contains at least one $s format marker.

**Requirement**
The number of $s format markers must be less than or equal to the number of arguments. Otherwise, an error occurs.

**Interaction**
If the LOG method has more than two parameters and the level is valid, each $s format marker is replaced by the content of the corresponding argument.

**Tip**
To display a dollar sign ($) in your message, use $$ in the $s format marker.

**argument**

specifies a value that replaces the $s format marker in the message-format.

**Interaction**
If the LOG method has more than two parameters and the level is valid, each $s format marker in the message-format is replaced by the content of the corresponding argument.

**Tip**
Extra arguments are ignored when using formatted output.

### Details

**Unformatted Messages (Form 1)**

A LOG method call with exactly two parameters, an active logger, and a valid level, sends the specified message to the associated logger in its raw format.

**Formatted Messages (Form 2)**

A LOG method call with more than two parameters, an active logger, and a valid level, sends a formatted message to the associated logger. Each $s format marker in the message-format is replaced by the content of the corresponding argument.

### Examples

**Example 1: Unformatted Messages**

These are examples of unformatted messages.

```plaintext
mylog.log('T', 'The output was written to the log');
testlog.log(7, 'The output could not be written');
```

**Example 2: Formatted Messages**

The following example shows several combinations of $s format markers.

```plaintext
data _NULL_;  
dcl package logger root();  
method init();  
   /* $$ is not evaluated here - one parameter */  
   root.log(n'note', 'one-parm dollar pair: $$');  
   /* $s is not evaluated here - one parameter */  
   root.log(n'note', 'one-parm dollar-s: $s');  
   /* $$ is evaluated here */
root.log(n'note', 'two-parm dollar pair: $$', '');
/* $$ is evaluated here and "mine" is substituted for $$ */
root.log(n'note', 'dollar pair: $$; me:mine');
/* "mine" is substituted for $$ */
root.log(n'note', 'me:$s', 'mine');
/* "mine" is substituted for the first $$ */
root.log(n'note', 'me:$s thee:$s', 'mine', 'thine');
/* there are five arguments */
root.log(n'note', 'one:$s two:$s three:$s four:$s five:$s', 1N, 2, 3.0, n'4', '5');
end;
enddata;
run;
quit;

The following lines are written to the SAS log.

```
NOTE: hello world
NOTE: one-parm dollar pair: $$
NOTE: one-parm dollar-s: $s
NOTE: two-parm dollar pair: $
NOTE: dollar pair: $; me:mine
NOTE: me:mine
NOTE: me:mine thee:thine
NOTE: one:1 two:2 three:3 four:4 five:5
```

See Also

.NEW_ Operator, Logger Package

Constructs an instance of a logger package.

**Note:** The escape character (\) before the bracket indicates that the bracket is required in the syntax.

**Syntax**

```
package-variable = _NEW_ [THIS] | [package-instance] LOGGER([logger-name]);
```

**Arguments**

- **package-variable**
  - specifies a name that can reference an instance of the package.

- **[THIS]**
  - specifies that the package instance has global scope.

  - See “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide

- **[package-instance]**
  - specifies that the new package instance has the same scope as package-instance. package-instance must be an existing package instance, and the type of package-instance can differ from the type of the new package instance.
See “Package-Specific Scope” in *SAS Viya: DS2 Programmer’s Guide*

**logger-name**

specifies the name of the logger that is defined in the SAS logging facility.

Default  SAS root logger

**Details**

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When a logger package is declared, the variable representing the package can be considered an instance of the package. This means that two different package variables represent two completely separate copies of a package.

You declare a logger package using the DECLARE PACKAGE statement. After you declare the new logger package, use the _NEW_ operator to instantiate the package.

```
declare package logger mylog;
mylog = _new_ logger( );
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a logger package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package logger mylog( );
```

*Note:* Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide.*

Dictionary

ABS Method
Returns a matrix that contains the absolute value of each value in the input matrix.

Syntax
\[ r = \text{package}.\text{ABS()} \]

Arguments
- \( r \) specifies a matrix that contains the absolute value of each value in the input matrix.
- \text{package} specifies an instance of the matrix package variable.

See Also

ADD Method, Matrix Package
Adds one matrix to another.

Syntax
\[ r = \text{package-1}.\text{ADD}(\text{package-2}) \]

Arguments
- \( r \) specifies the matrix that is automatically created by the ADD method.
- \text{package-1} specifies an instance of the first matrix package variable that is used in the addition operation.
package-2
specifies an instance of the second matrix package variable that is used in the
addition operation.

Details
The matrix dimensions for the ADD method must be the same size in order for the
matrix addition to take place. Each \([i, j]\) element in the first matrix is added to its
corresponding \([i, j]\) element in the second matrix.
If you add matrices that have missing values, you do not receive an error.
It is also possible to perform scalar addition by using a 1x1 matrix.

Examples

**Example 1: Adding Two Matrices**
Here is an example of using the ADD method to add two 3x3 matrices. Each \([i, j]\)
element in the first matrix is added to its corresponding \([i, j]\) element in the second
matrix.

```sas
data _null_;
dcl double a[3,3];
dcl double b[3,3];
dcl double c[3,3];
method run();
dcl package matrix m;
dcl package matrix m2;
dcl package matrix r;
dcl double i j;

a := (1,2,3,4,5,6,7,8,9);
b := (1,5,9,2,6,10,3,7,1);

m = _new_ matrix(a, 3, 3);
m2 = _new_ matrix(b, 3, 3);
r = m.add(m2);
r.toarray(c);
do i = 1 to 3;
do j = 1 to 3;
   put c[i,j];
end;
end;
enddata;
run;
```
The following lines are written to the SAS log.
Example 2: Scalar Addition of Two Matrices

Here is an example of how to perform scalar addition by using a 1x1 matrix.

```sas
Example 2: Scalar Addition of Two Matrices

Here is an example of how to perform scalar addition by using a 1x1 matrix.

data _null_;
  dcl double c[3,3];
  dcl double d[1,1];
  dcl double f[3,3];
  method run();
    dcl package matrix m3;
    dcl package matrix m4;
    dcl package matrix r;
    dcl double i j;

    c := (-0, 0, -1, 1, -2.2, 2.2, -3.3, 4.4, 5.5);
    d := (1);

    m3 = _new_ matrix(c, 3, 3);
    m4 = _new_ matrix(d, 1, 1);

    r = m3.add(m4);
    r.toarray(f);

    do i = 1 to 3;
      do j = 1 to 3;
        put f[i,j];
      end;
    end;
  end;
run;

In this example, 1 was added to each entry in matrix m3. The scalar addition produces a 3x3 matrix that has the following values:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>-1.2</td>
<td>3.2</td>
</tr>
<tr>
<td>-2.3</td>
<td>5.4</td>
<td>6.5</td>
</tr>
</tbody>
</table>

See Also

Methods:

- “SUB Method” on page 1027
ALL_AND Method

Produces a scalar result in an ALL_AND comparison between all elements in one matrix and all elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ALL_AND}(\text{package-2}); \]

Arguments

- \( x \) specifies the scalar result.
- \( \text{package-1} \) specifies an instance of the first matrix package variable that is used in the ALL AND comparison.
- \( \text{package-2} \) specifies an instance of the second matrix package variable that is used in the ALL AND comparison.

Details

The ALL_AND logical operation produces a result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. If all of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can also use a scalar comparison.

Comparisons

The ANY_AND operation is similar to the ALL_AND operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = \text{m1.all_and(m2)}; \]

See Also

Methods:

- “ALL_OR Method” on page 980
- “AND Method” on page 981
- “ANY_AND Method” on page 981
ALL_EQ Method

Completes a scalar result in an ALL_EQ (ALL equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ALL_EQ}(\text{package-2}); \]

Arguments

- \( x \): specifies the scalar result.
- \( \text{package-1} \): specifies an instance of the first matrix package variable that is used in the ALL equal-to comparison.
- \( \text{package-2} \): specifies an instance of the second matrix package variable that is used in the ALL equal-to comparison.

Details

The ALL_EQ relational operation produces a scalar result that indicates whether an \([i, j]^{th}\) element of the first matrix satisfies the comparison with the \([i, j]^{th}\) element of the second matrix. The scalar result is 0 or 1. All of the \([i, j]\) element comparisons must be true for the result to be 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_EQ operation is similar to the ALL_EQ operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = m1.\text{all_eq}(m2); \]

See Also

Methods:

- “ANY_EQ Method” on page 982
ALL_GE Method

Produces a scalar result in an ALL_GE (ALL greater-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ALL GE}(\text{package-2}); \]

Arguments

\[ x \]

specifies the scalar result.

\[ \text{package-1} \]

specifies an instance of the first matrix package variable that is used in the ALL greater-than-or-equal-to comparison.

\[ \text{package-2} \]

specifies an instance of the second matrix package variable that is used in the ALL greater-than-or-equal-to comparison.

Details

The ALL_GE relational operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. All of the \([i, j]\) element comparisons must be true for the result to be 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_GE operation is similar to the ALL_GE operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = \text{m1.all_ge(m2)}; \]

See Also

Methods:

- “ALL_LE Method” on page 977
- “ALL_NE Method” on page 979
- “ANY_GE Method” on page 983
ALL_GT Method

Produces a scalar result in an ALL_GT (ALL greater-than) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1.ALL_GT(package-2)}; \]

Arguments

- \( x \):
  - specifies the scalar result.
- \( \text{package-1} \):
  - specifies an instance of the first matrix package variable that is used in the ALL greater-than comparison.
- \( \text{package-2} \):
  - specifies an instance of the second matrix package variable that is used in the ALL greater-than comparison.

Details

The ALL_GT relational operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. All of the \([i, j]\) element comparisons must be true for the result to be 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_GT operation is similar to the ALL_GT operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = m1.\text{all_gt}(m2); \]

See Also

Methods:

- “ALL_LT Method” on page 978
- “ANY_GT Method” on page 984
ALL_LE Method

Produces a scalar result in an ALL_LE (ALL less-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ALL_LE}\text{(package-2)}; \]

Arguments

\( x \)

specifies the scalar result.

\( \text{package-1} \)

specifies an instance of the first matrix package variable that is used in the ALL less-than comparison.

\( \text{package-2} \)

specifies an instance of the second matrix package variable that is used in the ALL less-than comparison.

Details

The ALL_LE relational operation produces a scalar result that indicates whether an \([i, j]^{th}\) element of the first matrix satisfies the comparison with the \([i, j]^{th}\) element of the second matrix. The scalar result is 0 or 1. All of the \([i, j]\) element comparisons must be true for the result to be 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_LE operation is similar to the ALL_LE operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = \text{m1.all_le(m2)}; \]

ALL_LT Method

Produces a scalar result in an ALL_LT (ALL less-than) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ALL_LT}(\text{package-2}); \]

Arguments

\( x \)

specifies the scalar result.

\( \text{package-1} \)

specifies an instance of the first matrix package variable that is used in the ALL less-than comparison.

\( \text{package-2} \)

specifies an instance of the second matrix package variable that is used in the ALL less-than comparison.

Details

The ALL_LT relational operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. All of the \([i, j]\) element comparisons must be true for the result to be 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_LT operation is similar to the ALL_LT operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = m1.\text{all_lt}(m2); \]

See Also

Methods:

- “ALL_GT Method” on page 976

- “ANY_LT Method” on page 986
ALL_NE Method

Produces a scalar result in an ALL_NE (ALL not-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ALL_NE}(\text{package-2}); \]

Arguments

- \( x \) specifies the scalar result.
- \( \text{package-1} \) specifies an instance of the first matrix package variable that is used in the ALL not-equal-to comparison.
- \( \text{package-2} \) specifies an instance of the second matrix package variable that is used in the ALL not-equal-to comparison.

Details

The ALL_NE relational operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. All of the \([i, j]\) element comparisons must be true for the result to be 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_NE operation is similar to the ALL_NE operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = \text{m1.all_ne(m2)}; \]

See Also

Methods:

- “ALL_EQ Method” on page 974
- “ANY_NE Method” on page 987
ALL_OR Method

Produces a scalar result in an ALL_OR comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ALL}_{\text{OR}}(\text{package-2}); \]

Arguments

- \( x \) specifies the scalar result.
- \( \text{package-1} \) specifies an instance of the first matrix package variable that is used in the ALL OR comparison.
- \( \text{package-2} \) specifies an instance of the second matrix package variable that is used in the ALL OR comparison.

Details

The ALL_OR logical operation produces a result that indicates whether an \([i, j]^{th}\) element of the first matrix satisfies the comparison with the \([i, j]^{th}\) element of the second matrix. The scalar result is 0 or 1. If all of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_OR operation is similar to the ALL_OR operation except that if any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

Example

\[ x = \text{m1.all_or(m2)}; \]

See Also

Methods:

**AND Method**

Compares two matrices based on the AND logical operation, and returns the resulting matrix.

**Syntax**

\[ r = \text{package-1} \text{.AND} (\text{package-2}); \]

**Arguments**

- \( r \)
  - Specifies a matrix that contains the results of an AND comparison between the values of two matrices.
- \( \text{package-1} \)
  - Specifies an instance of the first matrix package variable that is used in the AND comparison.
- \( \text{package-2} \)
  - Specifies an instance of the second matrix package variable that is used in the AND comparison.

**Details**

The AND logical operator behaves similarly to the binary relational operations (LT, LE, GE, GT, NE, and EQ). In each case, the AND logical operation will be applied to the \([i, j]^{th}\) elements of two matrices and placed in the result matrix \( r \).

The matrix sizes must match or you can use a scalar comparison.

**Example**

\[ r = \text{m1.} \text{.and(m2)}; \]

**See Also**

**Methods:**

- “ALL_AND Method” on page 973
- “ANY_AND Method” on page 981
- “OR Method” on page 1023

---

**ANY_AND Method**

Produces a scalar result in an ANY_AND comparison between elements in one matrix and elements in another matrix.
Syntax

\[ x = \text{package-1}.\text{ANY\_AND}(\text{package-2}); \]

Arguments

- \( x \) specifies the scalar result.
- \( \text{package-1} \) specifies an instance of the first matrix package variable that is used in the ANY AND comparison.
- \( \text{package-2} \) specifies an instance of the second matrix package variable that is used in the ANY AND comparison.

Details

The ANY_AND logical operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. If any of the logical \([i, j]\) operations is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_AND operation is similar to the ANY_AND operation except that all of the logical \([i, j]\) operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

\[ x = \text{m1}.\text{any\_and}(\text{m2}); \]

See Also

Methods:

- “ALL_OR Method” on page 980
- “AND Method” on page 981
- “ANY_OR Method” on page 988

ANY_EQ Method

Produces a scalar result in an ANY_EQ (ANY equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ANY\_EQ}(\text{package-2}); \]
Arguments

\[ x \]

specifies the scalar result.

\textit{package-1}

specifies an instance of the first matrix package variable that is used in the ANY equal-to comparison.

\textit{package-2}

specifies an instance of the second matrix package variable that is used in the ANY equal-to comparison.

Details

The ANY\_EQ relational operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. If any of the \([i, j]\) element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL\_EQ operation is similar to the ANY\_EQ operation except that all of the logical \([i, j]\) operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

\[ x=m1.\text{any\_eq}(m2); \]

See Also

\underline{ANY\_GE Method}

Produces a scalar result in an ANY\_GE (ANY greater-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x=\text{package-1}.\text{ANY\_GE}(\text{package-2}); \]

Arguments

\[ x \]

specifies the scalar result.
**package-1**

specifies an instance of the first matrix package variable that is used in the ANY greater-than-or-equal-to comparison.

**package-2**

specifies an instance of the second matrix package variable that is used in the ANY greater-than-or-equal-to comparison.

**Details**

The ANYGE relational operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. If any of the \([i, j]\) element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

**Comparisons**

The ALLGE operation is similar to the ANYGE operation except that all of the logical \([i, j]\) operations have to be true for the result to be 1. Otherwise, the result is 0.

**Example**

\[x = \text{m1.any_ge(m2)};\]

**See Also**

• “ANY_NE Method” on page 987

---

**ANY_GT Method**

Produces a scalar result in an ANY_GT (ANY greater-than) comparison between elements in one matrix and elements in another matrix.

**Syntax**

\[x = \text{package-1.ANY_GT(package-2)};\]

**Arguments**

\[x\]

specifies the scalar result.

\[package-1\]

specifies an instance of the first matrix package variable that is used in the ANY greater-than comparison.
package-2
specifies an instance of the second matrix package variable that is used in the ANY greater-than comparison.

Details
The ANY_GT relational operation produces a scalar result that indicates whether an 
[i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons
The ALL_GT operation is similar to the ANY_GT operation except that all of the logical [i, j] operations has to be true for the result to be 1. Otherwise, the result is 0.

Example
```
x=m1.any_gt(m2);
```

See Also

Methods:
• “ALL_GT Method” on page 976
• “ANY_GE Method” on page 983
• “ANY_LT Method” on page 986

ANY_LE Method
Produces a scalar result in an ANY_LE (any less-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax
```
x=package-1.ANY_LE(package-2);
```

Arguments
x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY less-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY less-than comparison.
Details
The ANY_LE relational operation produces a scalar result that indicates whether an \([i,j]\)th element of the first matrix satisfies the comparison with the \([i,j]\)th element of the second matrix. The scalar result is 0 or 1. If any of the \([i,j]\) element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons
The ALL_LE operation is similar to the ANY_LE operation except that all of the logical \([i,j]\) operations has to be true for the result to be 1. Otherwise, the result is 0.

Example
\[ x=m1.any_le(m2); \]

See Also

Methods:
• “ALL_LE Method” on page 977
• “ANY_GE Method” on page 983
• “ANY_LT Method” on page 986

ANY_LT Method
Produces a scalar result in an ANY_LT (ANY less-than) comparison between elements in one matrix and elements in another matrix.

Syntax
\[ x=package-1.any_LT(package-2); \]

Arguments
\[ x \]
  specifies the scalar result.

\[ package-1 \]
  specifies an instance of the first matrix package variable that is used in the ANY less-than comparison.

\[ package-2 \]
  specifies an instance of the second matrix package variable that is used in the ANY less-than comparison.

Details
The ANY_LT relational operation produces a scalar result that indicates whether an \([i,j]\)th element of the first matrix satisfies the comparison with the \([i,j]\)th element of the
second matrix. The scalar result is 0 or 1. If any of the \([i, j]\) element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

**Comparisons**

The ALL_LT operation is similar to the ANY_LT operation except that all of the logical \([i, j]\) operations has to be true for the result to be 1. Otherwise, the result is 0.

**Example**

The following example produces a result of 1 because the \([1, 2]\) element of matrix \(m\) (=2) is less than the \([1, 2]\) element of matrix \(m2\) (=5). All of the other elements do not satisfy the comparison. If the \([1, 2]\) element of matrix \(m\) was changed to 6, for example, the result would be 0.

```sas
data _null_;
dcl double a[3,3];
dcl double b[3,3];
dcl double r;
method run();
dcl package matrix m;
dcl package matrix m2;

a := (1,2,10,4,7,11,15,9,12);
b := (1,5,9,2,6,10,3,7,11);

m = _new_ matrix(a, 3, 3);
m2 = _new_ matrix(b, 3, 3);

r = m.any_lt(m2);
put r=;
end;
enddata;
run;
```

**See Also**

**Methods:**

- “ALL_LT Method” on page 978

- “ANY_LE Method” on page 985

**ANY_NE Method**

Produces a scalar result in an ANY_NE (ANY not-equal-to) comparison between elements in one matrix and elements in another matrix.
Syntax

\[ x = \text{package-1}.\text{ANY}_{\text{NE}}(\text{package-2}); \]

Arguments

- \( x \) specifies the scalar result.
- \( \text{package-1} \)
  - specifies an instance of the first matrix package variable that is used in the ANY not-equal-to comparison.
- \( \text{package-2} \)
  - specifies an instance of the second matrix package variable that is used in the ANY not-equal-to comparison.

Details

The ANY_NE relational operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. If any of the \([i, j]\) element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_NE operation is similar to the ANY_NE operation except that all of the logical \([i, j]\) operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

\[ x = \text{m1}.\text{any}_{\text{ne}}(\text{m2}); \]

See Also

Methods:

- “ALL_NE Method” on page 979

ANY_OR Method

Produces a scalar result in an ANY_OR comparison between elements in one matrix and elements in another matrix.

Syntax

\[ x = \text{package-1}.\text{ANY}_{\text{OR}}(\text{package-2}); \]
**Arguments**

\( x \)

specifies the scalar result.

\( \text{package-1} \)

specifies an instance of the first matrix package variable that is used in the ANY OR comparison.

\( \text{package-2} \)

specifies an instance of the second matrix package variable that is used in the ANY OR comparison.

**Details**

The ANY\_OR logical operation produces a scalar result that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The scalar result is 0 or 1. If any of the \([i, j]\) element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

**Comparisons**

The ALL\_OR operation is similar to the ANY\_OR operation except that all of the logical \([i, j]\) operations have to be true for the result to be 1. Otherwise, the result is 0.

**Example**

\[ x=\text{ml.any_or(m2)}; \]

**See Also**

**Methods:**

- “ALL\_OR Method” on page 980
- “ANY\_AND Method” on page 981
- “OR Method” on page 1023

---

**COLS Method**

Returns the number of columns in the specified matrix.

**Syntax**

\[ \text{variable-name=package.COLS();} \]

**Arguments**

\( \text{variable-name} \)

specifies the name of a variable that contains the number of columns after the method is complete.
package
  specifies an instance of the matrix package variable.

Example
See the example in the ROWS method on page 1026.

See Also
• “Using the MATRIX Package” in SAS Viya: DS2 Programmer’s Guide

Methods:
• “ROWS Method” on page 1026

COPY Method
Copies one matrix to another.

Syntax
\[ r = \text{package}.\text{COPY}(); \]

Arguments
\[ r \]
  specifies the matrix that is automatically created by the COPY method.

package
  specifies an instance of the matrix package variable.

Details
The COPY method copies a matrix into a new matrix.

Example
This example creates a new copy of a 3x4 matrix.

```
data _null_; 
  dcl double a[3,4]; 
  dcl double b[3,4]; 

  method run(); 
    dcl package matrix m; 
    dcl package matrix r; 
    dcl double i j; 
    a := (1,2,3,4,5,6,7,8,9,10,11,12); 
    m = _new_ matrix(a, 3, 4); 
    r = m.copy(); 
    r.toarray(b); 
```

do i = 1 to 3;
  do j = 1 to 4;
    put b[i,j];
  end;
end;
enddata;
run;

DECLARE PACKAGE Statement, Matrix Package

Creates an instance of a MATRIX package.

**Category:** Local

**Syntax**

DECLARE PACKAGE MATRIX variable ([row-dimension, column-dimension]);

**Arguments**

*variable* specifies a name that can reference an instance of the matrix package.

*row-dimension* specifies the number of rows in the matrix instance.

*column-dimension* specifies the number of columns in the matrix instance.

**Details**

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

The matrix package provides a DS2-level implementation of SAS/IML functionality. The matrix package is predefined for DS2 programs.
When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

A matrix package is created by declaring and instantiating the package using the DECLARE PACKAGE statement.

This example creates an empty 2x2 matrix, and stores the instance in the variable m.

```
declare package matrix m(2, 2);
```

A matrix must be initialized before it can be used, and initialization is done in the code stream, not in the declarations. You can use the following actions to load data into a matrix instance.

- `_NEW_` operator to load an array
- IN method to load an array
- SET statement to load external data

\textit{Note:} Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in \textit{SAS Viya: DS2 Programmer’s Guide}.

\textbf{See Also}

\textbf{Methods:}

- “IN Method” on page 1008

\textbf{Operators:}

- “\_NEW\_ Operator, Matrix Package” on page 1017

\textbf{Statements:}

- “SET Statement” on page 770

---

\textbf{DELETE Method, Matrix Package}

Deletes a matrix package.

\textit{Note:} The \texttt{DELETE} method is not required. When a matrix package goes out of scope, the package is deleted.

\textbf{Syntax}

```
package\_DELETE();
```
**Arguments**

*package*

specifies an instance of the matrix package variable.

**Details**

When you no longer need the matrix package, delete it by using the DELETE method. If you attempt to use a matrix package after you delete it, an error will be written to the log.

**See Also**

“Package Constructors and Destructors” in *SAS Viya: DS2 Programmer’s Guide*

---

**DET Method**

Computes the determinant of a square matrix.

**Syntax**

\[ d = \text{package}.\text{DET}(); \]

**Arguments**

*d*

specifies the matrix that is automatically created by the DET method.

*package*

specifies an instance of the matrix package variable.

**Details**

The input matrix for a determinant must be square. Otherwise, you receive a run-time error. The output from the DET method is a real or complex number that is called the determinant.

**Example**

The following example computes a determinant for a 3x3 matrix.

```sas
data _null_;  
dcl double a[3,3];

method run();
  dcl package matrix m;
  dcl double d;

  a := (1,3,2,5,4,6,9,8,9);  
m = _new_ matrix(a, 3, 3);  
d = m.det();  
put d=;
end;
enddata;
run;
```
The following line is written to the SAS log.

d=23

## EDIV Method

Performs an elementwise scalar division.

### Syntax

```
x=package-1.EDIV(package-2);
```

### Arguments

- **x**
  - specifies the matrix that is automatically created by the EDIV method.

- **package-1**
  - specifies an instance of the first matrix package variable that is used in the elementwise division operation.

- **package-2**
  - specifies an instance of the second matrix package variable that is used in the elementwise division operation.

### Details

The EDIV method enables you to apply the elementwise scalar division of one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EDIV method produces a result matrix from the element-by-element operations on the two argument matrices.

### Example

```
x=m1.ediv(m2);
```

See Also

Methods:

- “EMULT Method” on page 1000
EMAX Method

Performs an elementwise comparison of two matrices and returns the largest elements.

Syntax

$x = \text{package-1}.\text{EMAX}(\text{package-2});$

Arguments

$x$

specifies the matrix that is automatically created by the EMAX method.

$\text{package-1}$

specifies an instance of the first matrix package variable that is used in the elementwise maximum operation.

$\text{package-2}$

specifies an instance of the second matrix package variable that is used in the elementwise maximum operation.

Details

The EMAX method enables you to apply an elementwise maximum value comparison to one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EMAX method produces a result matrix from the element-by-element operations on the two argument matrices.

Examples

**Example 1: Comparing Maximum Values Using a 1x1 Matrix**

The following example creates a matrix that contains the maximum value from two 2x2 matrices.

```plaintext
data _null_;  
dcl double a[2,2];  
dcl double b[2,2];  
dcl double f[2,2];  
  
method run();  
  dcl package matrix m;  
  dcl package matrix m1;  
    dcl package matrix r;  
    dcl double i j;  
```
```
a := (2, 2, 3, 4);
b := (4, 5, 1, 0);

m = _new_ matrix(a, 2, 2);
ml = _new_ matrix(b, 2, 2);

r = m.emax(ml);
r.toarray(f);

do i = 1 to 2;
doi j = 1 to 2;
put f[i,j];
end;
end;
enddata;
run;

The resulting matrix has the following values.

4  5
3  4

Example 2: Vector Operation on a Matrix

In this example, the maximum operator is applied to all the rows of matrix m by using the matrix ml as a row.
```
data _null_
method init()
dcl package matrix m;
dcl package matrix ml;
dcl package matrix r;
dcl double i j;
dcl double a[4];
dcl double b[2];
dcl double f[2,2];

a := (2, 2, 3, 4);
b := (1, 5);
m = _new_ matrix(a, 2, 2);
ml = _new_ matrix(b, 2, 2);
r = m.emax(ml);
r.toarray(f);
do i = 1 to 2;
doi j = 1 to 2;
put f[i,j];
end;
end;
enddata;
run;

The resulting matrix has the following values.

2
5
3
5

- “EMIN Method” on page 997

---

**EMIN Method**

Performs an elementwise comparison of two matrices and returns the smallest elements.

**Syntax**

$$x = package-1.EMIN(package-2);$$

**Arguments**

- $x$ specifies the matrix that is automatically created by the EMIN method.
- $package-1$ specifies an instance of the first matrix package variable that is used in the elementwise minimum operation.
- $package-2$ specifies an instance of the second matrix package variable that is used in the elementwise minimum operation.

**Details**

The EMIN method enables you to apply an elementwise minimum value comparison of one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EMIN method produces a result matrix from the element-by-element operations on the two argument matrices.

**Example**

The following example creates a matrix that contains the maximum value from two 2x2 matrices.

```plaintext
data _null_;  
dcl double a[2,2];  
dcl double b[2,2];  
dcl double f[2,2];  
    method run();  
```
dcl package matrix m;
dcl package matrix m1;
dcl package matrix r;
dcl double i j;

a := (2, 2, 3, 4);
b := (4, 5, 1, 0);

m = _new_ matrix(a, 2, 2);
m1 = _new_ matrix(b, 2, 2);

r = m.emin(m1);
r.toarray(f);

do i = 1 to 2;
do j = 1 to 2;
   put f[i,j];
end;
end;
enddata;
run;

The resulting matrix has the following values.

2  2
1  0

---

**EMOD Method**

Returns the remainder of the division of elements of the first matrix by elements of the second matrix in an elementwise scalar operation.

**Syntax**

\[ x = \text{package-1.EMOD(package-2)}; \]

**Arguments**

- \( x \) specifies the matrix that is automatically created by the EMOD method.
- \( \text{package-1} \) specifies an instance of the first matrix package variable that is used in the elementwise MOD comparison.
package-2

specifies an instance of the second matrix package variable that is used in the elementwise MOD comparison.

Details

The EMOD elementwise operation enables you to find the remainder of a division operation on one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EMOD method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

The following example divides the elements in matrix, \( \mathbf{m} \), by the elements in matrix, \( \mathbf{m2} \). The EMOD method is used to return the matrix of remainders, \( \mathbf{f} \).

```plaintext
data _null_;  
dcl double a[2,2];
dcl double b[2,2];
dcl double f[2,2];

method run();  
dcl package matrix m;
dcl package matrix m1;
dcl package matrix r;
dcl double i j;

a := (125, 17, 39, 40);
b := (40, 5, 12, 8);

m = _new_matrix(a, 2, 2);
m1 = _new_matrix(b, 2, 2);

r = m.emod(m1);
r.toarray(f);

do i = 1 to 2;
do j = 1 to 2;
  put f[i,j];
end;
end;
enddata;
run;
```

The resulting matrix has the following values.

\[
\begin{array}{cc}
5 & 2 \\
3 & 0
\end{array}
\]
EMULT Method

Performs an elementwise scalar multiplication.

Syntax

\[ r = \text{package-1}.\text{EMULT}(\text{package-2}); \]

Arguments

\( r \)

specifies the matrix that is automatically created by the EMULT method.

\( \text{package-1} \)

specifies an instance of the first matrix package variable that is used in the elementwise multiplication operation.

\( \text{package-2} \)

specifies an instance of the second matrix package variable that is used in the elementwise multiplication operation.

Details

The EMULT method enables you to apply the elementwise scalar multiplication on one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each \([i,j]\) element

The EMULT method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

The following example shows how to perform an elementwise scalar multiplication. Each element of matrix \(c\) is multiplied by 2.

data _null_
   dcl double c[3,3];
   dcl double d[1,1];
   dcl double f[3,3];

   method run();
      dcl package matrix m3;
      dcl package matrix m4;
      dcl package matrix r;
      dcl double i j;
c := (-0, 0, -1, 1, -2.2, 2.2, -3.3, 4.4, 5.5);
d := (2);

m3 = _new_ matrix(c, 3, 3);
m4 = _new_ matrix(d, 1, 1);

r = m3.emult(m4);
r.toarray(f);

do i = 1 to 3;
    do j = 1 to 3;
        put f[i,j];
    end;
end;
enddata;
enddata;
run;

The resulting matrix has the following values.

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>-2</td>
</tr>
<tr>
<td>2</td>
<td>-4.4</td>
<td>4.4</td>
</tr>
<tr>
<td>-6.6</td>
<td>8.8</td>
<td>11</td>
</tr>
</tbody>
</table>

**EPOW Method**

Raises a number to a specified power in an elementwise operation.

**Syntax**

\[ x = \text{package-1}.\text{EPOW}(\text{package-2}); \]

**Arguments**

- **x**
  - specifies the matrix that is automatically created by the EPOW method.

- **package-1**
  - specifies an instance of the first matrix package variable that is used in the elementwise operation.

- **package-2**
  - specifies an instance of the second matrix package variable that is used in the elementwise operation.
Details

The EPOW elementwise operation enables you to raise a value exponentially in one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EPOW method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

The following example raises each element of matrix \( c \) to a power of 2.

```sas
data _null_;
dcl double c[3,3];
dcl double d[1,1];
dcl double f[3,3];
method run();
dcl package matrix m3;
dcl package matrix m4;
dcl package matrix r;
dcl double i j;

c := (0, 15, 1.7, 13, -2.2, 10, -3.3, 7, 2);
d := (2);

m3 = _new_ matrix(c, 3, 3);
m4 = _new_ matrix(d, 1, 1);

r = m3.epow(m4);
r.toarray(f);
do i = 1 to 3;
do j = 1 to 3;
   put f[i,j];
end;
end;
enddata;
run;
```

The resulting matrix has the following values.

```
0     225    2.89
169   4.84   100
10.89 49     4
```

**EQ Method**

Produces a scalar result in an equal-to comparison between elements in one matrix and elements in another matrix.

---

**Syntax**

\[ r = \text{package-1}.\text{EQ}(\text{package-2}); \]

**Arguments**

- \( r \) specifies a matrix that contains the results of an equal-to comparison between the values of two matrices.
- \( \text{package-1} \) specifies an instance of the first matrix package variable that is used in the equal-to comparison.
- \( \text{package-2} \) specifies an instance of the second matrix package variable that is used in the equal-to comparison.

**Details**

The EQ relational operation produces a matrix that indicates whether an \([i, j]^{\text{th}}\) element of the first matrix satisfies the comparison with the \([i, j]^{\text{th}}\) element of the second matrix. The result is 0 or 1. If the \([i, j]\) elements are equal, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

**Example**

The following example compares the elements in two matrices for equality. Note that missing values are compared.

```plaintext
data _null_;
dcl double a[2,2];
dcl double b[2,2];
dcl double f[2,2];
method run();
dcl package matrix m;
dcl package matrix m1;
dcl package matrix r;
dcl double i j;
a := (2, 2, 3, .);
b := (4, 5, 1, .);
m = _new_ matrix(a, 2, 2);
m1 = _new_ matrix(b, 2, 2);
```

---

1003
The resulting matrix has the following values.

```
0   0
0   1
```

### EXP Method

Returns a matrix that contains an exponential value for each value in the input matrix.

**Syntax**

```
r = package.EXP();
```

**Arguments**

- `r`
  - specifies the matrix that is automatically created by the EXP method.
- `package`
  - specifies an instance of matrix package variable.

**Details**

The EXP method creates a matrix that contains each element of the input matrix raised to the $e^b$ power.

**Example**

The following example raises each element of a matrix to the $e^b$ power.

```r
data _null_;
dcl double a[3, 3];
```
dcl double c[3, 3];

method run();
   dcl package matrix m;
   dcl package matrix r;
   dcl double i j;

   a := (1, 2, 3, 1, 2, 3, 1, 2, 3);

   m=_new_ matrix(a, 3, 3);
   r=m.exp();
   r.toarray(c);

   do i=1 to 3;
      do j=1 to 3;
         put c[i, j];
      end;
   end;
enddata;
run;

FLOOR Method

Returns a matrix that contains the integer part of each value in the input matrix.

Syntax

\[ r = \text{matrix-package.FLOOR()} \]

Arguments

- \( r \)
  - specifies a matrix that contains the integer part of each value in the input matrix.

- \text{matrix-package}
  - specifies an instance of matrix package variable.
Example

The following example creates a matrix that contains the integer part of input matrix, \( m \).

```sas
data _null_;  
dcl double a[2, 2];  
dcl double c[2, 2];

method run();  
dcl package matrix m;  
dcl package matrix r;  
dcl double i j;

a := (1323.43, -.72, 3.38, 45);
m=_new_ matrix(a, 2, 2);  
r=m.floor();  
r.toarray(c);

do i=1 to 2;  
do j=1 to 2;  
   put c[i, j];  
end;  
end;
enddata;
run;
```

The resulting matrix has the following values.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>

**GE Method**

Produces a scalar result in a greater-than-or-equal-to comparison between elements in one matrix and elements in another matrix.

**Syntax**

\[ r = \text{package-1.GE}(\text{package-2}); \]

**Arguments**

- \( r \)
  - specifies a matrix that contains the results of a greater-than-or-equal-to comparison between the values of two matrices.

- \text{package-1}
  - specifies an instance of the first matrix package variable that is used in the greater-than-or-equal-to comparison.
package-2
 specifies an instance of the second matrix package variable that is used in the
greater-than-or-equal-to comparison.

Details
The GE relational operation produces a matrix that indicates whether an \([i, j]\)th element
of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix.
The result is 0 or 1. If the \([i, j]\) element greater-than-or-equal-to comparison is true, the
result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Example
\[ r = m1.ge(m2); \]

See Also

Methods:
- “GT Method” on page 1007
- “LE Method” on page 1012

GT Method
Produces a scalar result in a greater-than comparison between elements in one matrix and elements in
another matrix.

Syntax
\[ r = package-1.GT(package-2); \]

Arguments
- \( r \)
  specifies a matrix that contains the results of a greater-than comparison between the
  values in two matrices.
- \( package-1 \)
  specifies an instance of the first matrix package variable that is used in the greater-
  than comparison.
- \( package-2 \)
  specifies an instance of the first matrix package variable that is used in the greater-
  than comparison.

Details
The GT relational operation produces a matrix that indicates whether an \([i, j]\)th element
of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix.
The result is 0 or 1. If the \([i, j]\) element greater-than comparison is true, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Example

\[ r = m1.greater-than(m2); \]

- “LT Method” on page 1015

### IN Method

Loads an array into a matrix.

**Alias:** LOAD

**Syntax**

\[ \text{package}.IN(array-name); \]

**Arguments**

- **package**
  - specifies an instance of the matrix package variable.

- **array-name**
  - specifies an array that is used in loading the matrix.

**Restriction**

The array dimensions must match the matrix dimensions. Otherwise, an error occurs.

**Tip**

You can use variable arrays.

**See**

**Details**

The IN method loads an array into a matrix. This process might be useful if an array `a` can change as the program executes and you want to repeatedly reset the values of matrix `m`. Here is an example:

```plaintext
dcl double a[3, 3];
dcl package matrix m;

m=new matrix(3, 3);
m.in(a);
```
You can use variable arrays to load data into a matrix. Here is an example:

```plaintext
vararray double va[3,3];
dcl package matrix m;

m.in(va);
```

You can also use variable arrays to input and output data using the SET and OUT statements.

## Examples

### Example 1: Loading and Writing Data

This example reads data from a data set in matrix form, finds the matrix inverse, and writes the result matrix to an output table. The example uses the IN and OUT methods. The IN method loads data from a variable array into a matrix. The OUT method writes the data in the matrix to a variable array. The SET and OUPUT statements are used in the program to read data from an array and write the results to an output array.

The IN and OUT methods are overloaded to accept an integer argument that tells which row of the matrix to load. For the IN method, the variable array row data is read into the matrix. For the OUT method, the matrix row data is written to the variable array.

/* DATA step to create an array of data */
data x;
array a[4];

/* Create a 4x4 matrix. */
a1 = 1; a2 = 5; a3 = 2; a4 = 3;
output;
a1 = 3; a2 = 3; a3 = 1; a4 = 7;
output;
a1 = 2; a2 = 3; a3 = 8; a4 = 9;
output;
a1 = 3; a2 = 6; a3 = 7; a4 = 4;
output;
run;

proc ds2;
data inv/overwrite=yes;
/* global declarations */
vararray double v[4];
vararray double a[4];
keep v1 v2 v3;
dcl package matrix m;
dcl package matrix r;
dcl package matrix inv;
dcl double c[4, 4];
dcl double i j;

/* Create an empty matrix to hold the input values. */
method init();
    m=_new_ [this] matrix(4, 4);
    i=1;
end;

/* Read and initialize each row of the matrix from VARARRAY a. */
method run();
    set x;
    m.in(a, i);
    i + 1;
end;

method term();
    /* Find the inverse of the matrix. */
    inv=m.inverse();

    /* Check whether it gives an identity matrix. */
    r=m.mult(inv);
    /* Write each row of inverse to the output table */
    /* using VARARRAY v. */
    do i=1 to 4;
        inv.out(v, i);
        output;
    end;

    /* Print the result to see if it's the identity. */
    r.toarray(c);
    do i=1 to 4;
        do j=1 to 4;
            put c[i, j];
        end;
    end;
end;
enddata;
run;
quit;

The following lines are written to the SAS log.

1
-2.7755575615628E-17

Statements:
• “OUTPUT Statement” on page 747
• “SET Statement” on page 770

INVERSE Method
Computes the inverse of a matrix.

Syntax

\texttt{im=matrix-package.INVERSE();}

Arguments

\texttt{im}

specifies the matrix that is automatically created by the INVERSE method.

\texttt{matrix-package}

specifies an instance of matrix package variable.

Details

It is possible to perform basic matrix operations on a single matrix. The INVERSE matrix operation computes the inverse of a matrix. If the matrix is not square or is singular (not invertible), you receive a run-time error.
Example

The following example computes the inverse of a 3x3 matrix, and checks, using matrix multiplication, whether the resulting inverse produces the identity matrix.

data _null_;  
dcl double a[3,3];  
dcl double b[3,3];  
method run();  
dcl package matrix m im r;  
dcl double i j;  
a := (1, 2, -1, 2, 1, 0, -1, 1, 2);  
m = _new_ matrix(a, 3, 3);  
im = m.inverse();  
r = m.mult(im);  
r.toarray(b);  
do i = 1 to 3;  
do j = 1 to 3;  
put b[i,j];  
end;  
end;  
enddata;  
run;  

Some values of the resulting matrix are not exactly zero. The values might be very small numbers, such as 1.110223046251E-16. These small numbers are the exact results that the SAS/IML subsystem provides.

LE Method

Produces a scalar result in a less-than-or-equal-to comparison between elements in one matrix and elements in another matrix.

Syntax

\[ r = \text{package-1.LE(package-2)}; \]

Arguments

\( r \)

specifies a matrix that contains the results of a less-than-or-equal-to comparison between the values of two matrices.
**Details**

The LE relational operation produces a matrix that indicates whether an \([i, j]^{th}\) element of the first matrix satisfies the comparison with the \([i, j]^{th}\) element of the second matrix. The result is 0 or 1. If the \([i, j]\) element less-than-or-equal-to comparison is true, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

**Examples**

**Example 1: Comparing Two Matrices Using the LE Method**

The following example uses the LE method. The \([i, j]\)th element of matrix \(m\) is compared with the \([i, j]\) element of matrix \(m2\), using 0 or 1 for the result entries.

```plaintext
data _null_;  
dcl double a[3,3];  
dcl double b[3,3];  
dcl double c[3,3];  
method run();  
dcl package matrix m;  
dcl package matrix m2;  
dcl package matrix r;  
dcl double i j;  

   a := (1,2,3,4,5,6,7,8,9);  
   b := (1,5,9,2,6,10,3,7,11);  

   m = _new_ matrix(a, 3, 3);  
   m2 = _new_ matrix(b, 3, 3);  

   r = m.le(m2);  
r.toarray(c);  

   do i = 1 to 3;  
      do j = 1 to 3;  
         put c[i,j];  
      end;  
   end;  
enddata;  
run;
```

The resulting matrix has the following values.

```
1  1  1  
0  1  1  
0  0  1  
```
Example 2: Using a Scalar Matrix
The following example uses a scalar matrix with the LE method.

```sas
data _null_;  
dcl double a[3,3];  
dcl double b[1,1];  
dcl double c[3,3];
 method run();  
dcl package matrix m;  
dcl package matrix m2;  
dcl package matrix r;  
dcl double i j;
    a := (1,3,3,4,5,6,7,8,9);  
b := (4);
    m = _new_ matrix(a, 3, 3);  
m2 = _new_ matrix(b, 1, 1);
    r = m.le(m2);  
r.toarray(c);
    do i = 1 to 3;  
        do j = 1 to 3;  
            put c[i,j];  
        end;  
    end;
    end;
enddata;
run;
```

The resulting matrix has the following values.

```
1   1   1
1   0   0
0   0   0
```

LOG Method, Matrix Package

Returns a matrix that contains the natural logarithm for each value in the input matrix.

**Syntax**

```
r=package.LOG();
```
**Arguments**

\( r \)

specifies a matrix that is automatically created by the LOG method.

\( \text{package} \)

specifies an instance of matrix package variable.

**See Also**

---

**LT Method**

Produces a scalar result in a less-than comparison between elements in one matrix and elements in another matrix.

**Syntax**

\[ r = \text{package-1}.\text{LT}(\text{package-2}); \]

**Arguments**

\( r \)

specifies a matrix that contains the results of a less-than comparison between the values in two matrices.

\( \text{package-1} \)

specifies an instance of the first matrix package variable that is used in the less-than comparison.

\( \text{package-2} \)

specifies an instance of the second matrix package variable that is used in the less-than comparison.

**Details**

The LT relational operation produces a matrix that indicates whether an \([i, j]^{th}\) element of the first matrix satisfies the comparison with the \([i, j]^{th}\) element of the second matrix. The result is 0 or 1. If the \([i, j]\) element less-than comparison is true, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

**Examples**

**Example 1: Comparing Two Matrices Using the LT Method**

The following example uses the LT method. The \([i, j]^{th}\) element of matrix \(\text{m}\) is compared with the \([i, j]\) element of matrix \(\text{m2}\), using 0 or 1 for the result entries.

```sas
data _null_
  dcl double a[3,3];
  dcl double b[3,3];
  dcl double c[3,3];
```
method run();
  dcl package matrix m;
  dcl package matrix m2;
  dcl package matrix r;
  dcl double i j;

  a := (1,2,3,4,5,6,7,8,9);
  b := (1,5,9,2,6,10,3,7,11);

  m = _new_ matrix(a, 3, 3);
  m2 = _new_ matrix(b, 3, 3);

  r = m.lt(m2);
  r.toarray(c);

  do i = 1 to 3;
    do j = 1 to 3;
      put c[i,j];
    end;
  end;
enddata;
run;

The resulting matrix has the following values.

0   1   1
0   1   1
0   0   1

Example 2: Using a Scalar Matrix
The following example uses a scalar matrix with the LT method.

data _null_
  dcl double a[3,3];
  dcl double b[1,1];
  dcl double c[3,3];
method run();
  dcl package matrix m;
  dcl package matrix m2;
  dcl package matrix r;
  dcl double i j;

  a := (1,3,3,4,5,6,7,8,9);
  b := (4);

  m = _new_ matrix(a, 3, 3);
  m2 = _new_ matrix(b, 1, 1);

  r = m.lt(m2);
  r.toarray(c);

  do i = 1 to 3;
    do j = 1 to 3;
      put c[i,j];
    end;
  end;
The resulting matrix has the following values.

\[
\begin{bmatrix}
1 & 1 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}
\]

---

**_NEW_ Operator, Matrix Package**

Constructs an instance of a matrix package.

**Note:** The escape character ( \ ) before the bracket indicates that the bracket is required in the syntax.

**Syntax**

```
package-variable = _NEW_ [[THIS] | [package-instance]]
   MATRIX([array-name], rows, columns)
```

**Arguments**

- `package-variable` specifies a name that can reference an instance of the matrix package.

- `[THIS]` specifies that the package instance has global scope.

  **See** “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*

- `[package-instance]` specifies that the new package instance has the same scope as `package-instance`. `package-instance` must be an existing package instance, and the type of `package-instance` can differ from the type of the new package instance.

  **See** “Package-Specific Scope” in *SAS Viya: DS2 Programmer’s Guide*

- `array-name` specifies the name of an array to load into the matrix package.

- `rows` specifies the number of rows in the matrix.
columns

specifies the number of columns in the matrix.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When a matrix package is declared, the variable representing the package can be considered an instance of the package. This means that two different matrix package variables represent two completely separate copies of a package.

A matrix must be initialized before it can be used, and initialization is done in the code stream, not in the declarations. To initialize a matrix, you must use the _NEW_ operator.

A matrix can be initialized with values from a DS2 array. Here is an example:

```ds2
method init();
    dcl double a[3, 3];
    dcl package matrix m;

    a := (1, 2, -1, 2, 1, 0, -1, 1, 2);
    m = _new_ matrix(a, 3, 3);
end;
```

In this example, a 3x3 array is initialized with values that you specify, and is used to set up the matrix \( m \). The values are read in row-major order, and the matrix that is produced has the following values:

\[
\begin{pmatrix}
1 & 2 & -1 \\
2 & 1 & 0 \\
-1 & 1 & 2
\end{pmatrix}
\]

You can also initialize a matrix by using a variable array, as the following example shows:

```ds2
vararray double a [3, 3];
dcl package matrix m;

method init();
    a := (1, 2, -1, 2, 1, 0, -1, 1, 2);
    m = _new_ matrix(a, 3, 3);
end;
```

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

See Also

- “Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

Statements:

- “DECLARE PACKAGE Statement, Matrix Package” on page 991
**MULT Method**

Multiplies one matrix by another matrix.

---

**Syntax**

\[
r = \text{matrix-package-1}.\text{MULT}(\text{matrix-package-2});
\]

**Arguments**

- \( r \) specifies the matrix that is automatically created by the MULT method.
- \( \text{matrix-package-1} \) specifies the name of the first matrix package that is used in the multiplication operation.
- \( \text{matrix-package-2} \) specifies the name of the second matrix package that is used in the multiplication operation.

**Details**

The MULT method automatically creates a matrix that contains the result of matrix multiplication. The result matrix has the same number of rows as the first matrix and the same number of columns as the second matrix.

The following considerations apply when performing matrix multiplication.

- Array dimensions for the matrices that are used in multiplication operations must be compatible. Multiplication requires that the number of columns in the first matrix be equal to the number of rows in the second matrix. Otherwise, a run-time error is generated.
- If you multiply matrices that have missing values, you will receive a run-time error.

**Examples**

**Example 1: Simple Matrix Multiplication**

The following example uses the MULT method to perform a simple matrix multiplication. A 3x4 matrix, \( m \), is multiplied by a 4x3 matrix, \( m_2 \), to obtain a 3x3 result, which is stored in matrix, \( r \). The values in matrix \( r \) can be placed into a 3x3 array, \( c \), and written to the SAS log.

```sas
data _null_;  
dcl double a[3,4];  
dcl double b[4,3];  
dcl double c[3,3];  
method run();  
dcl package matrix m;  
dcl package matrix m2;  
dcl package matrix r;  
dcl double i j;
```
a := (1,2,3,4,5,6,7,8,9,10,11,12);
b := (1,5,9,2,6,10,3,7,11,4,8,12);

m = _new_ matrix(a, 3, 4);
m2 = _new_ matrix(b, 4, 3);
r = m.mult(m2);
r.toarray(c);

do i = 1 to 3;
do j = 1 to 3;
put c[i,j];
end;
end;
enddata;
run;

The following lines are written to the SAS log.

```
30
70
110
70
174
278
110
278
446
```

**Example 2: Multiply Two Matrices That Are Read from External Data**

This example multiplies two matrices that are read from external data. The IN method, which is an alias for the LOAD method, reads the matrices and the OUT method writes the output. For more information, see the “IN Method” on page 1008 and the “OUT Method” on page 1024.

proc ds2;
  data x(keep = (a1 a2 a3)) y(keep = (b1 b2 b3 b4))/overwrite=yes;
  vararray double a[3];
  vararray double b[4];

  method init();
    dcl double i j;
    /* Create output for matrix a */
    do i = 1 to 4;
      do j = 1 to 3;
        a[j] = 2 * j + i;
      end;
      output x;
    end;

    /* Create output for matrix b */
    do i = 1 to 3;
      do j = 1 to 4;
        b[j] = 3 * j - 2 * i;
      end;
```
See Also

Methods:
NE Method

Produces a scalar result in a not-equal-to comparison between elements in one matrix and elements in another matrix.

Syntax

\[ r = \text{matrix-package-1}.\text{NE} (\text{matrix-package-2}); \]

Arguments

- \( r \) specifies a matrix that contains the results of a not-equal-to comparison between the values in two matrices.
- \( \text{matrix-package-1} \) specifies the name of the first matrix package that is used in the not-equal-to comparison.
- \( \text{matrix-package-2} \) specifies the name of the second matrix package that is used in the not-equal-to comparison.

Details

The NE relational operation produces a matrix that indicates whether an \([i, j]\)th element of the first matrix satisfies the comparison with the \([i, j]\)th element of the second matrix. The result is 0 or 1. If the \([i, j]\) elements are not equal, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Example

The following example compares the elements in two matrices for inequality. Note that missing values are compared.

```plaintext
data _null_
method run()
  dcl double a[2,2];
  dcl double b[2,2];
  dcl double f[2,2];

  a := (2, 2, 3, .);
  b := (4, 5, 1, .);
  m = _new_ matrix(a, 2, 2);
  m1 = _new_ matrix(b, 2, 2);
```

r = m.ne(m1);  
  r.toarray(f);  
  do i = 1 to 2;  
    do j = 1 to 2;  
      put f[i,j];  
    end;  
  end;  
enddata;  
run;  

The resulting matrix has the following values.  
1 1  
1 0

Methods:  
• “EQ Method” on page 1003  
• “GE Method” on page 1006  
• “LE Method” on page 1012  

---  

OR Method  
Compares two matrices based on the OR logical operation, and returns the resulting matrix.  

Syntax  

\[ r = \text{matrix-package-1}.\text{OR(matrix-package-2)}; \]

Arguments  
\[ r \]

specifies a matrix that contains the results of an OR comparison between the values of two matrices.  

\[ \text{matrix-package-1} \]

specifies the name of the first matrix package that is used in the OR comparison.  

\[ \text{matrix-package-2} \]

specifies the name of the second matrix package that is used in the OR comparison.  

Details  
The OR logical operator behaves similarly to the binary relational operations (LT, LE, GE, GT, NE, and EQ). In each case, the OR logical operation is applied to the \([i, j]^{th}\) elements of two matrices and placed in the result matrix \(r\).
Example

\[ r = m1 \lor m2; \]

---

**OUT Method**

Writes matrix row data to a variable array.

**Syntax**

```
matrix-package.OUT(array-name);
```

**Arguments**

- `matrix-package`
  - specifies a matrix package to be used with the OUT method.
- `array-name`
  - specifies a matrix that is used in writing output.

**Restriction**

The array dimensions must match the matrix dimensions. Otherwise, an error occurs.

**Tip**

You can use variable arrays.

**See**

- “DS2 Arrays” in *SAS Viya: DS2 Programmer’s Guide*

**Details**

The OUT method writes matrix row data to a variable array. Variable arrays can be used to input and output data using an existing DS2 table and output statements. For example, you can read data from a table in matrix form, find the matrix inverse, and write the result matrix to an output table. See the example below.

The OUT method can be overloaded to accept an integer argument that tells which row of a matrix to write to a variable array.

The synonym for the OUT method is the TOVARARRAY method. The following two statements are equivalent:

```
r.tovararray(va, i);
r.out(va, i);
```

The OUT method, which writes data, is often used with the IN method. The IN and OUT methods are overloaded to accept an integer argument that tells which row of a matrix to
load. For the IN method, the variable array row data is read into the matrix. For the OUT method, the matrix row data is written to the variable array. In this way, matrices can be loaded and unloaded a row at a time from and to external data storage using variable arrays.

Examples

Example 1
This example writes each row of an inverse to an output table using the variable array v.

```plaintext
do i=1 to 4;
   inv.out(v, i);
   output;
end;
```

Example 2
Similar to the standard IN method, a complete matrix can also be written to a variable array:

```plaintext
vararray double va(3, 3);
dcl package matrix r;

r=_new_ matrix(3, 3);
r.out(va);
```

In this example, a matrix does not need to be written row-by-row. The entire matrix can be written to the variable array. You can use this method in the case where the DS2 output statement (which is row-based) is not being used.

Example 3: Loading and Writing Data
For another example of using the IN and OUT methods, see “Example 2: Multiply Two Matrices That Are Read from External Data” on page 1020.

Example 4: Writing the Entire Matrix to the Array
Similar to the standard LOAD method, a complete matrix can also be written to a variable array:

```plaintext
vararray double va[3, 3];
dcl package matrix r;
   r=_new_ matrix(3, 3);
r.out(va);
```

This example shows that matrix data does not need to be written row-by-row. You can write the entire matrix to the array. You could use this technique in a case where the DS2 OUTPUT statement (which is row-based) is not used.

See Also

- “Matrix Data Output” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “IN Method” on page 1008
- “OUT Method” on page 1024
Statements:

- “OUTPUT Statement” on page 747
- “SET Statement” on page 770

ROWS Method

Returns the number of rows in the specified matrix.

Syntax

```
variable-name = matrix-package.ROWS();
```

Arguments

- `variable-name`: specifies the name of a variable that contains the number of rows after the method is complete.
- `matrix-package`: specifies a matrix package to use with the ROWS method.

Example

The following example returns the number of rows and columns in the matrix, `m`.

```
data _null_;  
dcl double a[2, 3];  
  
method run();  
  dcl package matrix m;  
  dcl double mr mc;  
  a := (1,2,3,4,5,6);  
  m = _new_ matrix(a, 2, 3);  
  mr = m.rows();  
  mc = m.cols();  
  put mr =;  
  put mc =;  
  
end;  
run;
```

The following lines are written to the SAS log.

```
  mr=2  
  mc=3
```

See Also

Methods:
SQRT Method

Returns a matrix that contains the square root of each value in the input matrix.

Syntax

```r = matrix-package.SQRT( );```

Arguments

- `r` specifies a matrix that contains the square root of each value in the input matrix.
- `matrix-package` specifies a matrix package to use with the SQRT method.

See Also

SUB Method

Subtracts one matrix from another.

Syntax

```r = matrix-package-1.SUB(matrix-package-2);```

Arguments

- `r` specifies the matrix that is automatically created by the SUB method.
- `matrix-package-1` specifies the name of the first matrix package that is used in the subtraction operation.
- `matrix-package-2` specifies the name of the second matrix package that is used in the subtraction operation.

Details

The matrix dimensions for the SUB method must be the same size in order for the matrix subtraction to take place. Each [i, j] element in the first matrix is subtracted from its corresponding [i, j] element in the second matrix.

If you subtract matrices that have missing values, you do not receive an error.

It is also possible to perform scalar subtraction by using a 1x1 matrix.
Example

Here is an example of using the SUB method to subtract two matrices.

data _null_;  
dcl double c[3,3];  
dcl double d[1,1];  
dcl double f[3,3];  
method run();  
dcl package matrix m3;  
dcl package matrix m4;  
dcl package matrix r;  
dcl double i j;  

c := (-0, 0, -1, 1, -2.2, 2.2, -3.3, 4.4, 5.5);  
d := (1);  

m3 = _new_ matrix(c, 3, 3);  
m4 = _new_ matrix(d, 1, 1);  

r = m3.sub(m4);  
r.toarray(f);  

do i = 1 to 3;  
    do j = 1 to 3;  
        put f[i,j];  
    end;  
end;  
enddata;  
run;  

The following lines are written to the SAS log.

-1
-1
-2
0
-3.2
1.2
-4.3
3.4
4.5

See Also

Methods:

- “ADD Method, Matrix Package” on page 970

TOARRAY Method

Moves the values from a matrix package into a DS2 array.
Syntax

array-name.TOARRAY(matrix-package);

Arguments

array-name
  specifies the name of an array to which matrix values are moved.

matrix-package
  specifies the matrix package from which values are moved into an array.

Details

You use the TOARRAY method to move values from a matrix to a DS2 array. The array can then be used directly in a DS2 program.

Note: You can also move values to a variable array by using the TOVARARRAY method.

Example

This example moves the values from a matrix into a DS2 array.

data _null_;  
dcl double a[3,3];  
dcl double c[3,3];  

method init();  
dcl double i j;  
dcl package matrix m;  

  a := (1,2,3,4,5,6,7,8,9);  
  m=_new_ matrix(a,3,3);  
  m.toarray(c);  
  do i=1 to 3;  
    do j=1 to 3;  
      put c[i,j];  
    end;  
  end;  
enddata;  
run;

The resulting array has the following values.

1  2  3  
4  5  6  
7  8  9  

See Also

• “Matrix Data Output” in SAS Viya: DS2 Programmer’s Guide
• “DS2 Arrays” in SAS Viya: DS2 Programmer’s Guide

Methods:
TOVARARRAY Method

Moves the values from a matrix package into a variable array.

Syntax

```
variable-array-name.TOVARARRAY(matrix-package);
```

Arguments

- `variable-array-name` specifies the name of a variable array to which matrix values are moved.
- `matrix-package` specifies the matrix package from which values are moved into a variable array.

Details

You use the TOVARARRAY method to move values from a matrix to a DS2 variable array. The variable array can then be used directly in a DS2 program.

*Note:* You can also move values to an array by using the TOARRAY method.

Example

This example shows how to move the values from a matrix into a variable array.

```plaintext
data _null_
  dcl double a[3, 3];
  vararray double c[3, 3];

  method run();
    dcl package matrix m;
    dcl double i j;

    a := (1,2,3,4,5,6,7,8,9);

    m=_new_ matrix(a, 3, 3);
    m.tovararray(c);

    do i=1 to 3;
      do j=1 to 3;
        put c[i, j];
      end;
    end;
  end;
run;
```

The resulting array has the following values.

```
1 2 3
4 5 6
7 8 9
```
TRANS Method

Returns a matrix that transposes the rows and columns of the input matrix.

Syntax

\[ r = \text{matrix-package}.\text{TRANS}(); \]

Arguments

\( r \)

specifies the matrix that contains the transposition of the input matrix.

\( \text{matrix-package} \)

specifies a matrix package to use with the TRANS method.

Details

The TRANS method exchanges the rows and columns of a given matrix producing the transpose of matrix. If \( v \) is the value in the \( i^{th} \) row and \( j^{th} \) column of matrix, then the transpose of matrix contains \( v \) in the \( j^{th} \) row and \( i^{th} \) column. If matrix contains \( n \) rows and \( p \) columns, the transpose has \( p \) rows and \( n \) columns.

Example

The following example transposes a 3x4 matrix to produce a 4x3 result matrix.

```clojure
data _null_;  
dcl double a[3, 4];  
dcl double b[4, 3];

method run();  
dcl package matrix m;  
dcl package matrix r;  
dcl double i j;

a := (1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12);  

m=_new_ matrix(a, 3, 4);  
r=m.trans();  
r.toarray(b);

do i=1 to 4;  
  do j=1 to 3;
```
The input matrix is shown here.

1  2  3  
4  5  6  
7  8  9  
10 11 12

The transposed, result matrix is shown here.

1  5  9  
2  6  10  
3  7  11  
4  8  12

BINDPARAMETERS Method

Binds a list of variables to the parameters in the FedSQL statement.

Restriction: This method is not supported in the CAS server.

Syntax

package.BINDPARAMETERS ([parameter-variable-list]);

Arguments

package

specifies an instance of the SQLSTMT package.

[parameter-variable-list]

specifies a variable list or named variable list that contains the variables to bind to the FedSQL statement’s parameters.

Requirement

Variables must be in the form of a variable list, which must be enclosed in brackets ([[]]) or a named variable list.

Tip

The number of variables in the variable list must match the number of parameters in the FedSQL statement.

See

Details

If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the SQLSTMT package’s SETtype methods.

The BINDPARAMETERS method binds the variables in the specified variable list to the parameters in the FedSQL statement.

Parameter values must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and a SETtype method is invoked.

If the type of a bound variable differs from the corresponding parameter’s type, the bound variable’s value is converted to the parameter’s type.
The BINDPARAMETERS method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

A run-time error also results if the BINDPARAMETERS method is called after the FedSQL statement is executed.

Methods:

- “BINDRESULTS Method” on page 1035
- SET “type” methods in this chapter

BINDRESULTS Method

Binds a list of variables to the columns of the result set of the FedSQL statement.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```sql
package.BINDRESULTS (parameter-variable-list);
```

**Arguments**

- `package`
  - specifies an instance of the SQLSTMT package.

- `parameter-variable-list`
  - specifies a variable list or named variable list that contains the variables to bind to the columns of the result set.

**Requirement**

Variables must be in the form of a variable list, which must be enclosed in brackets ([]) or a named variable list.

**Tip**

The number of variables in the variable list must match the number of columns in the result set.

**See**

**Details**

The FETCH method returns the next row of data from the result set. If variables are bound to the result set columns with the BINDRESULTS method, then the fetched data for each result set column is placed in the variable bound to that column. If the type of a variable differs from the corresponding column’s type, the column data value is converted to the variable’s type.

The result data must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.
A run-time error results if the BINDRESULTS method is called after the result data is fetched.

The BINDRESULTS method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

See Also

Methods:

- “BINDPARAMETERS Method” on page 1034
- SET “type” methods in this chapter

CLOSERESULTS Method

Releases the result set from the last execution of the statement.

Restriction: This method is not supported in the CAS server.

Syntax

```package.CLOSERESULTS();```

Arguments

```package```

specifies an instance of the SQLSTMT package.

Details

An SQLSTMT instance maintains only one result set. The result set is automatically released when the FedSQL statement is executed or deleted.

The CLOSERESULTS method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

See Also

DECLARE PACKAGE Statement, SQLSTMT Package

Creates a package variable and enables you to create an instance of the SQLSTMT package.

Category: Local

Restriction: This statement is not supported in the CAS server.

Note: Braces in the syntax convention indicate a syntax grouping. The escape character ( \ ) before a brace indicates that the brace is required in the syntax.
Syntax

Form 1:  
\texttt{DECLARE PACKAGE SQLSTMT variable ['sql-text[,][parameter-variable-list]]};

Form 2:  
\texttt{DECLARE PACKAGE SQLSTMT variable ['sql-text[, connection-string]]};

Form 3:  
\texttt{DECLARE PACKAGE SQLSTMT variable ( );}

Form 4:  
\texttt{DECLARE PACKAGE SQLSTMT variable ;}

Arguments

\textit{variable} 
specifies a name that can reference an instance of the SQLSTMT package.

\textit{sql-text} 
is a valid FedSQL statement or string variable that contains a FedSQL statement that inserts into, updates, selects from, or deletes rows from a table.

Requirement 
The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes 
The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL parses the string containing the SQL statement rather than DS2.

\textit{parameter-variable-list} 
specifies variables that are bound to the parameters contained in the FedSQL statement.

Requirements 
Variables must be in the form of a variable list that must be enclosed in brackets ([ ]) or a named variable list.

Parameter data must be specified exclusively with either bound variables or exclusively with the SQLSTMT SET type methods.

See 

\textit{connection-string} 
contains the fully specified connection string.

Default 
If a connection string is not provided, the SQLSTMT package instance uses the connection string that is generated by the HPDS2 procedure or the DS2 procedure by using the attributes of the currently assigned libref.

Note 
The connection string is a string literal.

Tip 
A connection string defines how to connect to the data. A connection string identifies the query language to be submitted as well as the information required to connect to the data source or sources.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.
The SQLSTMT package provides a way to pass FedSQL statements to a DBMS for execution. The FedSQL statements could create, modify, or delete tables. If the FedSQL statements selects rows from a table, the SQLSTMT package provides methods for interrogating the rows returned in a result set. The SQLSTMT package is predefined for DS2 programs.

You declare an SQLSTMT package by using the DECLARE PACKAGE statement. This associates an SQLSTMT package with an SQLSTMT name.

There are two ways to construct an instance of an SQLSTMT package.

• Use the DECLARE PACKAGE statement along with the _NEW_ operator:
  
  declare package sqlstmt sqlpkg;
  sqlpkg = _new_ sqlstmt('update db2.dataset2 set y=? where x=?', [y x]);

• Use the DECLARE PACKAGE statement along with its constructor syntax:
  
  declare package sqlstmt sqlpkg('update db2.dataset2 set y=? where x=?', [y x]);

If the DECLARE statement includes arguments for construction within its parentheses (and no arguments is valid for the SQLSTMT package), then the package instance is allocated. If no parentheses are included, then a variable is created but the package instance is not allocated.

When an SQLSTMT instance is created with SQL text (Forms 1 and 2), the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the SQLSTMT package’s SET type methods. The DECLARE PACKAGE statement binds the variables in the optional variable list to the parameters in the FedSQL statement.

When an SQLSTMT instance is created without FedSQL text (Form 3), the SQLSMT instance is allocated and left in an unprepared state. Use the PREPARE method to prepare the FedSQL statement at a later time.

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

For more information about SQLSTMT packages, see “Using the SQLSTMT Package” in SAS Viya: DS2 Programmer’s Guide.

Methods:

• “BINDPARAMETERS Method” on page 1034
• “PREPARE Method” on page 1067
• SET “type” methods in this chapter

Operators:

• “_NEW_ Operator, SQLSTMT Package” on page 1065
DELETE Method, SQLSTMT Package

Deletes an instance of the SQLSTMT package.

**Restriction:** This method is not supported in the CAS server.

**Note:** The DELETE method is not required. When an SQLSTMT package goes out of scope, the package is deleted.

**Syntax**

```sql
package.DELETE();
```

**Arguments**

`package`

specifies an instance of the SQLSTMT package variable.

**Details**

When you no longer need the SQLSTMT package, delete it by using the DELETE method. If you attempt to use an SQLSTMT package after you delete it, an error will be written to the log.

**See Also**

- “Using the SQLSTMT Package” in *SAS Viya: DS2 Programmer’s Guide*
- “Package Constructors and Destructors” in *SAS Viya: DS2 Programmer’s Guide*

EXECUTE Method

Executes the FedSQL statement.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```sql
package.EXECUTE();
```

**Arguments**

`package`

specifies an instance of the SQLSTMT package.

**Details**

The EXECUTE method executes the FedSQL statement and returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error; 2 is returned if there is no data (NODATA). The NODATA condition exists when a FedSQL UPDATE or DELETE statement does not affect any rows.
An SQLSTMT instance maintains only one result set. The result set from the previous execution, if any, is released before the FedSQL statement is executed.

The FedSQL statement executes dynamically at run time. Because the statement is prepared at run time, it can be built and customized dynamically during the execution of the DS2 program.

**See Also**

“Using the SQLSTMT Package” in *SAS Viya: DS2 Programmer’s Guide*

---

**FETCH Method**

Fetches the next row of data from the result set of the FedSQL statement.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```idl
package.FETCH ([result-variable-list]);
```

**Arguments**

- `package`
  - specifies an instance of the SQLSTMT package.
- `[result-variable-list]`
  - specifies a variable list that contains the variables to bind to the columns of the result set.

**Details**

The FETCH method returns the next row of data from the result set. A status indicator is returned. Zero is returned for successful execution; 1 is returned if there is an error; 2 is returned if there is no data (NODATA). The NODATA condition exists if the next row to be fetched is located after the end of the result set.

If variables are bound to the result set columns with the BINDRESULTS method or by the FETCH method, then the fetched data for each result set column is placed in the variable bound to that column. If the variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

A run-time error results if FETCH is called before the statement is executed.

An SQLSTMT instance maintains only one result set. The result set from the previous execution, if any, is released before the FedSQL statement is executed. You can also use the CLOSERESULTS method to release the result set at any time.

**See Also**

- “Using the SQLSTMT Package” in *SAS Viya: DS2 Programmer’s Guide*

**Methods:**

- “BINDRESULTS Method” on page 1035
- GET “type” methods in this chapter
GETBIGINT Method

Returns the value of the designated result set column as type BIGINT.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETBIGINT method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

Syntax

\[ \text{variable} = \text{package.GETBIGINT (index)}; \]
\[ \text{package.GETBIGINT (index, variable, rc)}; \]

Arguments

\textit{variable}

specifies the variable that will hold the value of the designated result set column.

Note: If the designated result set column’s type is not type BIGINT, the column value is converted to type BIGINT and then returned.

\textit{package}

specifies an instance of the SQLSTMT package.

\textit{index}

specifies the result set column index ordered sequentially, starting at 1.

\textit{rc}

specifies the variable in which to place the return code. The following values are possible:

\begin{itemize}
  \item 0 (SUCCESS) the result set column data is retrieved.
  \item 1 (ERROR) an error occurred during data retrieval.
  \item 2 (NODATA) there is no more data to be retrieved.
\end{itemize}

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET\textit{type} methods.

The GETBIGINT method returns the value of the designated result set column as type BIGINT. If the designated result set column’s type is not type BIGINT, the column value is converted to type BIGINT and then returned.

A run-time error results if the GETBIGINT method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET\textit{type} methods. A run-time error results if variables are bound to result set columns and a GET\textit{type} method is invoked.
For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

---

**GETBINARY Method**

Returns the designated result set column as type BINARY.

**Restriction:** This method is not supported in the CAS server.

**Note:** You can call the GETBINARY method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the rc status indicator.

**Syntax**

```
variable = package.GETBINARY (index);
pkgname.GETBINARY (index, variable, rc);
```

**Arguments**

`variable`

specifies the variable that will hold the value of the designated result set column.

**Note**

If the designated result set column’s type is not type BINARY, the column value is converted to type BINARY and then returned.

`package`

specifies an instance of the SQLSTMT package.

`index`

specifies the result set column index ordered sequentially, starting at 1.

`rc`

specifies the variable in which to place the return code. The following values are possible:

- 0
  (SUCCESS) the result set column data is retrieved.
Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET type methods.

The GETBINARY method returns the value of the designated result set column as type BINARY. If the designated result set column’s type is not type BINARY, the column value is converted to type BINARY and then returned.

A run-time error results if the GETBINARY method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET type methods. A run-time error results if variables are bound to result set columns and a GET type method is invoked.

GETCHAR Method

Returns the designated result set column as type CHAR.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the rc status indicator.

Syntax

```
variable=package.GETCHAR (index);
package.GETCHAR (index, variable, rc);
```

Arguments

```
variable
```

specifies the variable that will hold the value of the designated result set column.
If the designated result set column’s type is not type CHAR, the column value is converted to type CHAR and then returned.

**package**
specifies an instance of the SQLSTMT package.

**index**
specifies the result set column index ordered sequentially, starting at 1.

**rc**
specifies the variable in which to place the return code. The following values are possible:

0  
(SUCCESS) the result set column data is retrieved.

1  
(ERROR) an error occurred during data retrieval.

2  
(NODATA) there is no more data to be retrieved.

**Details**

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETCHAR method returns the value of the designated result set column as type CHAR. If the designated result set column’s type is not type BIGINT, the column value is converted to type CHAR and then returned.

A run-time error results if the GETCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in *SAS Viya: DS2 Programmer’s Guide*.

GETCOLUMNCOUNT Method

Returns the number of columns in the result set.

Restriction: This method is not supported in the CAS server.

Syntax

variable=package.GETCOLUMNCOUNT();

Arguments

variable specifies the variable that will hold the number of columns in the result set.

package specifies an instance of the SQLSTMT package.

See Also

Methods:

- “GETCOLUMNNAME Method” on page 1045
- “GETCOLUMNTYPENAME Method” on page 1046

GETCOLUMNNAME Method

Returns the column name of the result set column with the designated index.

Restriction: This method is not supported in the CAS server.

Data source: SAS data set

Syntax

variable=package.GETCOLUMNNAME(index);
package.getColumnName(index, variable, rc);

Arguments

variable specifies the variable that will hold the name of the designated result set column.

package specifies an instance of the SQLSTMT package.

index specifies the result set column index ordered sequentially, starting at 1.

rc specifies the variable in which to place the return code. The following values are possible:
(SUCCESS) the result set column data is retrieved.

1 (ERROR) an error occurred during data retrieval.

See Also

Methods:

• “GETCOLUMNCOUNT Method” on page 1045
• “GETCOLUMNTypENAME Method” on page 1046

GETCOLUMNTypENAME Method

Returns the data type of the result set column with the designated index.

Restriction: This method is not supported in the CAS server.

Data source: SAS data set

Syntax

```
variable=package.GETCOLUMNTypENAME(index);
package.getColumnTypeName(index, variable, rc);
```

Arguments

- **variable**
  - specifies the variable that will hold the data type of the result set column.

- **package**
  - specifies an instance of the SQLSTMT package.

- **index**
  - specifies the result set column index ordered sequentially, starting at 1.

- **rc**
  - specifies the variable in which to place the return code. The following values are possible:
    0 (SUCCESS) the result set column data is retrieved.
    1 (ERROR) an error occurred during data retrieval.

Details

GETCOLUMNTypENAME returns only the data types that are supported by DS2. For more information, see “DS2 Data Types” in SAS Viya: DS2 Programmer’s Guide.

See Also

Methods:
GETDATE Method

Returns the designated result set column as type DATE.

**Restriction:** This method is not supported in the CAS server.

**Data source:** SAS data set

**Note:** You can call the GETDATE method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

**Syntax**

variable = package.GETDATE (index);

package.GETDATE (index, variable, rc);

**Arguments**

**variable**

specifies the variable that will hold the value of the designated result set column.

**Note**

If the designated result set column’s type is not type DATE, the column value is converted to type DATE and then returned.

**package**

specifies an instance of the SQLSTMT package.

**index**

specifies the result set column index ordered sequentially, starting at 1.

**rc**

specifies the variable in which to place the return code. The following values are possible:

0  
(SUCCESS) the result set column data is retrieved.

1  
(ERROR) an error occurred during data retrieval.

2  
(NODATA) there is no more data to be retrieved.

**Details**

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETDATE method returns the value of the designated result set column as type DATE. If the designated result set column’s type is not type DATE, the column value is converted to type DATE and then returned.

A run-time error results if the GETDATE method is called before the result set is fetched.
The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

GETDECIMAL Method

Returns the designated result set column as type DECIMAL.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETDECIMAL method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

Syntax

\[ variable=package.GETDECIMAL \( index \); \]
\[ package.GETDECIMAL \( index, variable, rc \); \]

Arguments

\( variable \)

specifies the variable that will hold the value of the designated result set column.

Note: If the designated result set column’s type is not type DECIMAL, the column value is converted to type DECIMAL and then returned.

\( package \)

specifies an instance of the SQLSTMT package.

\( index \)

specifies the result set column index ordered sequentially, starting at 1.

\( rc \)

specifies the variable in which to place the return code. The following values are possible:

0

(SUCCESS) the result set column data is retrieved.
Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETDECIMAL method returns the value of the designated result set column as type DECIMAL. If the designated result set column’s type is not type DECIMAL, the column value is converted to type DECIMAL and then returned.

A run-time error results if the GETDECIMAL method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

GETDOUBLE Method

Returns the designated result set column as type DOUBLE.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETDOUBLE method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

Syntax

\[ \text{variable} = \text{package.GETDOUBLE (index)}; \]
\[ \text{package.GETDOUBLE (index, variable, rc)}; \]

Arguments

\text{variable}

specifies the variable that will hold the value of the designated result set column.

\text{Note}

If the designated result set column’s type is not type DOUBLE, the column value is converted to type DOUBLE and then returned.
package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0  (SUCCESS) the result set column data is retrieved.

1  (ERROR) an error occurred during data retrieval.

2  (NODATA) there is no more data to be retrieved.

Details
The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET type methods.

The GETDOUBLE method returns the value of the designated result set column as type DOUBLE. If the designated result set column’s type is not type DOUBLE, the column value is converted to type DOUBLE and then returned.

A run-time error results if the GETDOUBLE method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET type methods. A run-time error results if variables are bound to result set columns and a GET type method is invoked.

For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

GETINTEGER Method
Gets the designated result set column as type INTEGER.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETINTEGER method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

Syntax

variable=package.GETINTEGER (index);
package.GETINTEGER (index, variable, rc);

**Arguments**

**variable**

specifies the variable that will hold the value of the designated result set column.

**Note** If the designated result set column’s type is not type INTEGER, the column value is converted to type INTEGER and then returned.

**package**

specifies an instance of the SQLSTMT package.

**index**

specifies the result set column index ordered sequentially, starting at 1.

**rc**

specifies the variable in which to place the return code. The following values are possible:

0  (SUCCESS) the result set column data is retrieved.

1  (ERROR) an error occurred during data retrieval.

2  (NODATA) there is no more data to be retrieved.

**Details**

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETINTEGER method returns the value of the designated result set column as type INTEGER. If the designated result set column’s type is not type INTEGER, the column value is converted to type INTEGER and then returned.

A run-time error results if the GETINTEGER method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

**GETNCHAR Method**

Gets the designated result set column as type NCHAR.

**Restriction:** This method is not supported in the CAS server.

**Note:** You can call the GETCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the rc status indicator.

**Syntax**

```
variable = package.GETNCHAR(index);
package.GETNCHAR(index, variable, rc);
```

**Arguments**

- `variable` specifies the variable that will hold the value of the designated result set column.
  
  **Note** If the designated result set column’s type is not type NCHAR, the column value is converted to type NCHAR and then returned.

- `package` specifies an instance of the SQLSTMT package.

- `index` specifies the result set column index ordered sequentially, starting at 1.

- `rc` specifies the variable in which to place the return code. The following values are possible:
  
  0  
  
  (SUCCESS) the result set column data is retrieved.

  1  
  
  (ERROR) an error occurred during data retrieval.

  2  
  
  (NODATA) there is no more data to be retrieved.

**Details**

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETNCHAR method returns the value of the designated result set column as type NCHAR. If the designated result set column’s type is not type NCHAR, the column value is converted to type NCHAR and then returned.
A run-time error results if the GETNCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

- “SETVARCHAR Method” on page 1086

### GETNUMERIC Method

**Returns** the designated result set column as type NUMERIC.

**Restriction:** This method is not supported in the CAS server.

**Note:** You can call the GETNUMERIC method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

**Syntax**

```plaintext
variable=package.GETNUMERIC (index);
pkgname.GETNUMERIC (index, variable, rc);
```

**Arguments**

- `variable` specifies the variable that will hold the value of the designated result set column.
  
  **Note** If the designated result set column’s type is not type NUMERIC, the column value is converted to type NUMERIC and then returned.

- `package` specifies an instance of the SQLSTMT package.

- `index` specifies the result set column index ordered sequentially, starting at 1.
rc

specifies the variable in which to place the return code. The following values are possible:

0
  (SUCCESS) the result set column data is retrieved.

1
  (ERROR) an error occurred during data retrieval.

2
  (NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETNUMERIC method returns the value of the designated result set column as type NUMERIC. If the designated result set column’s type is not type NUMERIC, the column value is converted to type NUMERIC and then returned.

A run-time error results if the GETNUMERIC method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

Methods:

• “SETNUMERIC Method” on page 1077

GETNVARCHAR Method

Returns the designated result set column as type NVARCHAR.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETVARCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the rc status indicator.

Syntax

variable=package.GETNVARCHAR (index);
package.GETNVARCHAR (index, variable, rc);
Arguments

`variable` specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type NVARCHAR, the column value is converted to type NVARCHAR and then returned.

`package` specifies an instance of the SQLSTMT package.

`index` specifies the result set column index ordered sequentially, starting at 1.

`rc` specifies the variable in which to place the return code. The following values are possible:

0 (SUCCESS) the result set column data is retrieved.

1 (ERROR) an error occurred during data retrieval.

2 (NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETNVARCHAR method returns the value of the designated result set column as type NVARCHAR. If the designated result set column’s type is not type NVARCHAR, the column value is converted to type NVARCHAR and then returned.

A run-time error results if the GETNVARCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

GETREAL Method

Returns the designated result set column as type REAL.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETREAL method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

Syntax

\[ \text{variable} = \text{package.GETREAL(index)}; \]
\[ \text{package.GETREAL(index, variable, rc)}; \]

Arguments

variable

specifies the variable that will hold the value of the designated result set column.

Note: If the designated result set column’s type is not type REAL, the column value is converted to type REAL and then returned.

package

specifies an instance of the SQLSTMT package.

index

specifies the result set column index ordered sequentially, starting at 1.

cmp

specifies the variable in which to place the return code. The following values are possible:

0 (SUCCESS) the result set column data is retrieved.

1 (ERROR) an error occurred during data retrieval.

2 (NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET type methods.

The GETREAL method returns the value of the designated result set column as type REAL. If the designated result set column’s type is not type REAL, the column value is converted to type REAL and then returned.

A run-time error results if the GETREAL method is called before the result set is fetched.
The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in *SAS Viya: DS2 Programmer’s Guide*.

---

**GETSMALLINT Method**

Returns the designated result set column as type SMALLINT.

- **Restriction:** This method is not supported in the CAS server.
- **Note:** You can call the GETSMALLINT method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

**Syntax**

```plaintext
variable = package.GETSMALLINT (index);
package.GETSMALLINT (index, variable, rc);
```

**Arguments**

- **variable**
  
  specifies the variable that will hold the value of the designated result set column.

  **Note:** If the designated result set column’s type is not type SMALLINT, the column value is converted to type SMALLINT and then returned.

- **package**
  
  specifies an instance of the SQLSTMT package.

- **index**
  
  specifies the result set column index ordered sequentially, starting at 1.

- **rc**
  
  specifies the variable in which to place the return code. The following values are possible:

  0  
  
  (SUCCESS) the result set column data is retrieved.

  1  
  
  (ERROR) an error occurred during data retrieval.

  2  
  
  (NODATA) there is no more data to be retrieved.
Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET{type} methods.

The GETSMALLINT method returns the value of the designated result set column as type SMALLINT. If the designated result set column’s type is not type SMALLINT, the column value is converted to type SMALLINT and then returned.

A run-time error results if the GETSMALLINT method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET{type} methods. A run-time error results if variables are bound to result set columns and a GET{type} method is invoked.

For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

GETTIME Method

Returns the designated result set column as type TIME.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETTIME method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

Syntax

\[ \text{variable} = \text{package.GETTIME (index)}; \]
\[ \text{package.GETTIME (index, variable, rc)}; \]

Arguments

variable
 specifies the variable that will hold the value of the designated result set column.
Note If the designated result set column’s type is not type TIME, the column value is converted to type TIME and then returned.

**package**

specifies an instance of the SQLSTMT package.

**index**

specifies the result set column index ordered sequentially, starting at 1.

**rc**

specifies the variable in which to place the return code. The following values are possible:

- 0 (SUCCESS) the result set column data is retrieved.
- 1 (ERROR) an error occurred during data retrieval.
- 2 (NODATA) there is no more data to be retrieved.

**Details**

The GETTIME method returns the value of the designated result set column as type TIME. If the designated result set column’s type is not type TIME, the column value is converted to type TIME and then returned.

A run-time error results if the GETTIME method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

**GETTIMESTAMP Method**

Returns the designated result set column as type TIMESTAMP.

**Restriction:** This method is not supported in the CAS server.
You can call the GETTIMESTAMP method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

**Syntax**

\[ \text{variable} = \text{package.GETTIMESTAMP} (\text{index}); \]
\[ \text{package.GETTIMESTAMP} (\text{index}, \text{variable}, \text{rc}); \]

**Arguments**

*variable*  
specifies the variable that will hold the value of the designated result set column.

*Note*  
If the designated result set column’s type is not type TIMESTAMP, the column value is converted to type TIMESTAMP and then returned.

*package*  
specifies an instance of the SQLSTMT package.

*index*  
specifies the result set column index ordered sequentially, starting at 1.

*rc*  
specifies the variable in which to place the return code. The following values are possible:

0  
(SUCCESS) the result set column data is retrieved.

1  
(ERROR) an error occurred during data retrieval.

2  
(NODATA) there is no more data to be retrieved.

**Details**

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETTIMESTAMP method returns the value of the designated result set column as type TIMESTAMP. If the designated result set column’s type is not type TIMESTAMP, the column value is converted to type TIMESTAMP and then returned.

A run-time error results if the GETTIMESTAMP method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in *SAS Viya: DS2 Programmer’s Guide*.

GETTINYINT Method

Returns the designated result set column as type TINYINT.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETTINYINT method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the rc status indicator.

Syntax

\[
\text{variable} = \text{package.GETTINYINT (index)}; \\
\text{package.GETTINYINT (index, variable, rc)};
\]

Arguments

\text{variable} specifies the variable that will hold the value of the designated result set column.

Note: If the designated result set column’s type is not type TINYINT, the column value is converted to type TINYINT and then returned.

\text{package} specifies an instance of the SQLSTMT package.

\text{index} specifies the result set column index ordered sequentially, starting at 1.

\text{rc} specifies the variable in which to place the return code. The following values are possible:

0 (SUCCESS) the result set column data is retrieved.

1 (ERROR) an error occurred during data retrieval.

2 (NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET\text{type} methods.
The GETTINYINT method returns the value of the designated result set column as type TINYINT. If the designated result set column’s type is not type TINYINT, the column value is converted to type TINYINT and then returned.

A run-time error results if the GETTINYINT method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

For more information, see “Accessing Result Set Data” in SAS Viya: DS2 Programmer’s Guide.

GETVARBINARY Method

Returns the designated result set column as type VARBINARY.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETVARBINARY method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the rc status indicator.

Syntax

variable=package.GETVARBINARY (index);
package.GETVARBINARY (index, variable, rc);

Arguments

variable

specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column’s type is not type VARBINARY, the column value is converted to type VARBINARY and then returned.

package

specifies an instance of the SQLSTMT package.
index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:
0  (SUCCESS) the result set column data is retrieved.
1  (ERROR) an error occurred during data retrieval.
2  (NODATA) there is no more data to be retrieved.

Details
The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETtype methods.

The GETVARBINARY method returns the value of the designated result set column as type VARBINARY. If the designated result set column’s type is not type VARBINARY, the column value is converted to type VARBINARY and then returned.

A run-time error results if the GETVARBINARY method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETtype methods. A run-time error results if variables are bound to result set columns and a GETtype method is invoked.

GETVARCHAR Method
Returns the designated result set column as type VARCHAR.

Restriction: This method is not supported in the CAS server.

Note: You can call the GETVARCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the rc status indicator.
Syntax

```plaintext
variable=package.GETVARCHAR (index);
package.GETVARCHAR (index, variable, rc);
```

Arguments

`variable`

specifies the variable that will hold the value of the designated result set column.

Note  If the designated result set column’s type is not type VARCHAR, the column value is converted to type VARCHAR and then returned.

`package`

specifies an instance of the SQLSTMT package.

`index`

specifies the result set column index ordered sequentially, starting at 1.

`rc`

specifies the variable in which to place the return code. The following values are possible:

0  (SUCCESS) the result set column data is retrieved.
1  (ERROR) an error occurred during data retrieval.
2  (NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GETYPE methods.

The GETVARCHAR method returns the value of the designated result set column as type VARCHAR. If the designated result set column’s type is not type VARCHAR, the column value is converted to type VARCHAR and then returned.

A run-time error results if the GETVARCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GETYPE methods. A run-time error results if variables are bound to result set columns and a GETYPE method is invoked.

For more information, see “Accessing Result Set Data” in *SAS Viya: DS2 Programmer’s Guide*.

Methods:

• “GETCHAR Method” on page 1043
• “GETNCHAR Method” on page 1052
ISPREPARED Method

Returns a value that indicates whether the SQLSTMT package instance is prepared.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```plaintext
package.ISPREPARED();
```

**Arguments**

- **package**
  - specifies an instance of the SQLSTMT package.

**Details**

The ISPREPARED method returns a value of 0 (false) if the SQLSTMT package instance is not prepared. A nonzero value (true) is returned if the SQLSTMT package instance is prepared.

**See Also**

**Methods:**

- “PREPARE Method” on page 1067

**Statements:**

- “DECLARE PACKAGE Statement, SQLSTMT Package” on page 1036

.NEW_ Operator, SQLSTMT Package

Constructs an instance of an SQLSTMT package.

**Restriction:** This operator is not supported in the CAS server.

**Note:** The escape character ( \ ) before the bracket indicates that the bracket is required in the syntax.

**Syntax**

**Form 1:**

```plaintext
package-variable=_NEW_[THIS] | [package-instance]] SQLSTMT ('sql-text' [[parameter-variable-list]]);
```
**Form 2:**

```
package-variable=_NEW_[THIS] | [package-instance]] SQLSTM'T
('sql-text', connection-string));
```

**Form 3:**

```
package-variable=_NEW_ [THIS] | [package-instance]] SQLSTM'T (d);
```

**Arguments**

`package-variable`

specifies a name that can reference an instance of the SQLSTM'T package.

`[THIS]`

specifies that the package instance has global scope.

See  “Packages and Scope” in *SAS Viya: DS2 Programmer’s Guide*

`[package-instance]`

specifies that the new package instance has the same scope as `package-instance`. `package-instance` must be an existing package instance, and the type of `package-instance` can differ from the type of the new package instance.

See  “Package-Specific Scope” in *SAS Viya: DS2 Programmer’s Guide*

`'sql-text'`

is a valid FedSQL statement that inserts into, updates, selects from, or deletes rows from a table.

**Requirement**

The FedSQL statement must be enclosed in single quotation marks (').

**Notes**

The statement can be a string literal, a string value generated from an expression, or a string value that is stored in a variable.

The rules for identifiers for the FedSQL language apply to variables used in the SQLSTM'T package, rather than the DS2 rules for identifiers. This occurs because FedSQL parses the string containing the SQL statement rather than DS2.

`[parameter-variable-list]`

specifies variables that are bound to the parameters contained in the FedSQL statement.

**Requirements**

Variables must be in the form of a variable list that must be enclosed in brackets ([]) or a named variable list.

Parameter values must be specified exclusively with either bound variables or exclusively with the SQLSTM'T SET type methods.

`connection-string`

contains the fully specified connection string.

**Default**

If a connection string is not provided, the SQLSTM'T package instance uses the connection string that is generated by the HPDS2 procedure or the DS2 procedure by using the attributes of the currently assigned libref.
Note: The connection string can be a string literal, a string value generated from an expression, or a string value that is stored in a variable.

Tip: A connection string defines how to connect to the data. A connection string identifies the query language to be submitted as well as the information required to connect to the data source or sources.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use an SQLSTMT package to create and delete tables, select rows from a table, and access the returned result set. The SQLSTMT package is predefined for DS2 programs.

You can declare an SQLSTMT package by using the DECLARE PACKAGE statement. This associates an SQLSTMT package with an SQLSTMT name.

There are two ways to construct an instance of an SQLSTMT package.

- Use the DECLARE PACKAGE statement along with the _NEW_ operator:
  ```
  declare package sqlstmt sqlpkg;
  sqlpkg = _new_ sqlstmt('update db2.dataset2 set y=? where x=?', [y x]);
  ```

- Use the DECLARE PACKAGE statement along with its constructor syntax:
  ```
  declare package sqlstmt sqlpkg('update db2.dataset2 set y=? where x=?', [y x]);
  ```

When an SQLSTMT instance is created with SQL text, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the SQLSTMT package’s SET_TYPE methods. The DECLARE PACKAGE statement binds the variables in the optional variable list to the parameters in the FedSQL statement.

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

See Also

- “Package Constructors and Destructors” in SAS Viya: DS2 Programmer’s Guide

Methods:

- “BINDPARAMETERS Method” on page 1034

Statements:

- “DECLARE PACKAGE Statement, SQLSTMT Package” on page 1036

PREPARE Method

Prepares a FedSQL statement.

Restriction: This method is not supported in the CAS server.
**Syntax**

Form 1:  
```
PREPARE ('sql-text');
```

Form 2:  
```
PREPARE ('sql-text', connection-string);
```

**Arguments**

'`sql-text`'

is a valid FedSQL statement or string variable that contains a FedSQL statement that inserts into, updates, selects from, or deletes rows from a table.

**Requirement**  
The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

**Notes**  
The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

connection-string

contains the fully specified connection string.

**Default**  
If a connection string is not provided, the SQLSTMT package instance uses the connection string that is generated by the HPDS2 procedure or the DS2 procedure by using the attributes of the currently assigned libref.

**Note**  
The connection string is a string literal.

**Tip**  
A connection string defines how to connect to the data. A connection string identifies the query language to be submitted as well as the information required to connect to the data source or sources.

**Details**

The PREPARE method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

A run-time error occurs if you call the PREPARE method and the FedSQL statement is already prepared.

**See Also**

**Methods:**

- “ISPREPARED Method” on page 1065

**Statements:**

- “DECLARE PACKAGE Statement, SQLSTMT Package” on page 1036
**SETBIGINT Method**

Sets the designated parameter to the specified value of type BIGINT.

**Restriction:**
This method is not supported in the CAS server.

**Syntax**

```language
package.SETBIGINT (index, value);
```

**Arguments**

- `package` specifies an instance of the SQLSTMT package.
- `index` specifies the parameter index ordered sequentially, starting at 1.
- `value` specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

**Tip** `value` can be a literal, variable, or expression.

**Details**

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type BIGINT, the BIGINT value is converted to the designated parameter's type. For example, if you use `setbigint(1, 3)` to set parameter 1 to BIGINT value 3, and parameter 1 is type CHAR, the BIGINT value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETBIGINT method is invoked.

The SETBIGINT method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in *SAS Viya: DS2 Programmer’s Guide*.

**See Also**

- “Using the SQLSTMT Package” in *SAS Viya: DS2 Programmer’s Guide*

**Methods:**

- “GETBIGINT Method” on page 1041
- “GETINTEGER Method” on page 1050
SETBINARY Method

Sets the designated parameter to the specified value of type BINARY.

Restriction: This method is not supported in the CAS server.

Syntax

```
package.SETBINARY (index, value);
```

Arguments

- **package**
  - specifies an instance of the SQLSTMT package.

- **index**
  - specifies the parameter index ordered sequentially, starting at 1.

- **value**
  - specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

  Tip: `value` can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s `SETtype` methods.

If the designated parameter’s type is not type BINARY, the BINARY value is converted to the designated parameter’s type. For example, if you use `setbinary(1, 0110)` to set parameter 1 to BINARY value 0110, and parameter 1 is type CHAR, the BINARY value 0110 is converted to the CHAR value 0110 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the `SETtype` methods. A run-time error results if variables are bound to parameters and the SETBINARY method is invoked.

The SETBINARY method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.
**SETCHAR Method**

Sets the designated parameter to the specified value of type CHAR.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```plaintext
package.SETCHAR(index, value);
```

**Arguments**

- **package** specifies an instance of the SQLSTMT package.
- **index** specifies the parameter index ordered sequentially, starting at 1.
- **value** specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

**Tip** value can be a literal, variable, or an expression.

**Details**

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type CHAR, the CHAR value is converted to the designated parameter's type. For example, if you use `setchar(1, 3)` to set parameter 1 to CHAR value 3, and parameter 1 is type INTEGER, the CHAR value 3 is converted to the INTEGER value 3 and the INTEGER value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETCHAR method is invoked.

The SETCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in *SAS Viya: DS2 Programmer’s Guide*.

- “SETVARCHAR Method” on page 1086

**SETDATE Method**

Sets the designated parameter to the specified value of type DATE.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```sas
package.SETDATE (index, value);
```

**Arguments**

- `package` specifies an instance of the SQLSTMT package.
- `index` specifies the parameter index ordered sequentially, starting at 1.
- `value` specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

**Tip** `value` can be a literal, variable, or expression.

**Details**

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s `SETtype` methods.

If the designated parameter's type is not type DATE, the DATE value is converted to the designated parameter's type.

Parameter data must be specified exclusively with bound variables or exclusively with the `SETtype` methods. A run-time error results if variables are bound to parameters and the SETDATE method is invoked.
The SETDATE method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.

---

**SETDECIMAL Method**

Sets the designated parameter to the specified value of type DECIMAL.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```plaintext
package.SETDECIMAL (index, value);
```

**Arguments**

- `package` specifies an instance of the SQLSTMT package.
- `index` specifies the parameter index ordered sequentially, starting at 1.
- `value` specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

**Tip** `value` can be a literal, variable, or expression.

**Details**

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type DECIMAL, the DECIMAL value is converted to the designated parameter's type. For example, if you use `setdecimal(1, 13.4)` to set parameter 1 to DECIMAL value 13.4, and parameter 1 is type CHAR, the
DECIMAL value 13.4 is converted to the CHAR value 13.4 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETDECIMAL method is invoked.

The SETDECIMAL method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.

• “Using the SQLSTMT Package” in SAS Viya: DS2 Programmer’s Guide

Methods:

• “GETDECIMAL Method” on page 1048

SETDOUBLE Method

Sets the designated parameter to the specified value of type DOUBLE.

Restriction: This method is not supported in the CAS server.

Syntax

```sql
package.SETDOUBLE (index, value);
```

Arguments

```sql
package
```

specifies an instance of the SQLSTMT package.

```sql
index
```

specifies the parameter index ordered sequentially, starting at 1.

```sql
value
```

specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

Tip `value` can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type DOUBLE, the DOUBLE value is converted to the designated parameter's type. For example, if you use `setdouble(1, 33443452)` to set parameter 1 to DOUBLE value 33443452, and parameter 1 is type
CHAR, the DOUBLE value 33443452 is converted to the CHAR value 33443452 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETDOUBLE method is invoked.

The SETDOUBLE method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in *SAS Viya: DS2 Programmer’s Guide*.

---

### SETINTEGER Method

Sets the designated parameter to the specified value of type INTEGER.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```plaintext
package.SETINTEGER(index, value);
```

**Arguments**

- `package`
  - specifies an instance of the SQLSTMT package.
- `index`
  - specifies the parameter index ordered sequentially, starting at 1.
- `value`
  - specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

**Tip**

`value` can be a literal, variable, or expression.

**Details**

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type INTEGER, the INTEGER value is converted to the designated parameter's type. For example, if you use `setinteger(1, 3)` to set parameter 1 to INTEGER value 3, and parameter 1 is type CHAR, the
INTEGER value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETINTEGER method is invoked.

The SETINTEGER method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.

• “SETTINYINT Method” on page 1084

SETNCHAR Method

Sets the designated parameter to the specified value of type NCHAR.

Restriction: This method is not supported in the CAS server.

Syntax

package.SETNCHAR (index, value);

Arguments

package
  specifies an instance of the SQLSTMT package.

index
  specifies the parameter index ordered sequentially, starting at 1.

value
  specifies the value to which to set the designated parameter. The designated parameter is specified by index.

Tip  value can be a literal, variable, or expression.
Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETType methods.

If the designated parameter's type is not type NCHAR, the NCHAR value is converted to the designated parameter's type. For example, if you use `setnchar(1, 3)` to set parameter 1 to NCHAR value 3, and parameter 1 is type INTEGER, the NCHAR value 3 is converted to the INTEGER value 3 and the INTEGER value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETType methods. A run-time error results if variables are bound to parameters and the SETNCHAR method is invoked.

The SETNCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.

---

**SETNUMERIC Method**

Sets the designated parameter to the specified value of type NUMERIC.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```plaintext
package.SETNUMERIC (index, value);
```

**Arguments**

- `package`
  - specifies an instance of the SQLSTMT package.
index
  specifies the parameter index ordered sequentially, starting at 1.

value
  specifies the value to which to set the designated parameter. The designated
  parameter is specified by index.

Tip   value can be a literal, variable, or expression.

Details
When an SQLSTMT instance is created, the FedSQL statement is allocated and
prepared. If the FedSQL statement contains parameters, values to substitute for the
parameters must be obtained to execute the FedSQL statement. The substitution values
can be specified with either the current values of bound variables or with the package’s
SETtype methods.

If the designated parameter’s type is not type NUMERIC, the NUMERIC value is
converted to the designated parameter's type. For example, if you use setnumeric(1,
3) to set parameter 1 to NUMERIC value 3, and parameter 1 is type CHAR, the
NUMERIC value 3 is converted to the CHAR value 3 and the CHAR value is used to set
the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with
the SETtype methods. A run-time error results if variables are bound to parameters and
the SETNUMERIC method is invoked.

The SETNUMERIC method returns a status indicator. Zero is returned for successful
execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS

• “GETNUMERIC Method” on page 1053

SETNVARCHAR Method
Sets the designated parameter to the specified value of type NVARCHAR.

Restriction:    This method is not supported in the CAS server.

Syntax
package.SETNVARCHAR (index, value);

Arguments
package
  specifies an instance of the SQLSTMT package.
**index**
specifies the parameter index ordered sequentially, starting at 1.

**value**
specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

Tip  value can be a literal, variable, or expression.

**Details**
When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type NVARCHAR, the NVARCHAR value is converted to the designated parameter's type. For example, if you use `setnvarchar(1, 3)` to set parameter 1 to NVARCHAR value 3, and parameter 1 is type INTEGER, the NVARCHAR value 3 is converted to the INTEGER value 3 and the INTEGER value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETNVARCHAR method is invoked.

The SETNVARCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

---

**SETREAL Method**
Sets the designated parameter to the specified value of type REAL.

**Restriction:** This method is not supported in the CAS server.
Syntax

`package.SETREAL(index, value);`

Arguments

`package`

specifies an instance of the SQLSTMT package.

`index`

specifies the parameter index ordered sequentially, starting at 1.

`value`

specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

Tip  `value` can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s `SETtype` methods.

If the designated parameter’s type is not type REAL, the REAL value is converted to the designated parameter's type. For example, if you use `setreal(1, 3)` to set parameter 1 to REAL value 3, and parameter 1 is type CHAR, the REAL value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the `SETtype` methods. A run-time error results if variables are bound to parameters and the `SETREAL` method is invoked.

The `SETREAL` method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in *SAS Viya: DS2 Programmer’s Guide*.

**SETCQLINT Method**

Sets the designated parameter to the specified value of type SMALLINT.

**Restriction:**  This method is not supported in the CAS server.
Syntax

`package.SETSMALLINT (index, value);`

Arguments

`package`

specifies an instance of the SQLSTMT package.

`index`

specifies the parameter index ordered sequentially, starting at 1.

`value`

specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

Tip  
`value` can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s `SETtype` methods.

If the designated parameter's type is not type SMALLINT, the SMALLINT value is converted to the designated parameter's type. For example, if you use `setsmallint(1, 3)` to set parameter 1 to SMALLINT value 3, and parameter 1 is type CHAR, the SMALLINT value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the `SETtype` methods. A run-time error results if variables are bound to parameters and the SETSMALLINT method is invoked.

The SETSMALLINT method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in `SAS Viya: DS2 Programmer’s Guide`.

SETTIME Method

Sets the designated parameter to the specified value of type TIME.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```plaintext
package.SETTIME (index, value);
```

**Arguments**

- `package`
  - specifies an instance of the SQLSTMT package.
- `index`
  - specifies the parameter index ordered sequentially, starting at 1.
- `value`
  - specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

**Tip** `value` can be a literal, variable, or expression.

**Details**

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s `SET` method.

If the designated parameter's type is not type TIME, the TIME value is converted to the designated parameter's type.

Parameter data must be specified exclusively with bound variables or exclusively with the `SET` method. A run-time error results if variables are bound to parameters and the SETTIME method is invoked.

The SETTIME method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in *SAS Viya: DS2 Programmer’s Guide*.

**See Also**

**Methods:**

- “GETDATE Method” on page 1047
- “GETTIME Method” on page 1058
- “GETTIMESTAMP Method” on page 1059
- “SETDATE Method” on page 1072
SETTIMESTAMP Method

Sets the designated parameter to the specified value of type TIMESTAMP.

Restriction: This method is not supported in the CAS server.

Syntax

```plaintext
package.SETTIMESTAMP (index, value);
```

Arguments

- `package` specifies an instance of the SQLSTMT package.
- `index` specifies the parameter index ordered sequentially, starting at 1.
- `value` specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

Tip: `value` can be a literal, variable, or expression.

Details

When an SQLSTM instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type TIMESTAMP, the TIMESTAMP value is converted to the designated parameter's type.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETTIMESTAMP method is invoked.

The SETTIMESTAMP method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.

See Also

Methods:

- “GETDATE Method” on page 1047
- “GETTIME Method” on page 1058
- “GETTIMESTAMP Method” on page 1059
SETTINYINT Method

Sets the designated parameter to the specified value of type TINYINT.

Restriction: This method is not supported in the CAS server.

Syntax

```
package.SETTINYINT (index, value);
```

Arguments

- **package**: specifies an instance of the SQLSTMT package.
- **index**: specifies the parameter index ordered sequentially, starting at 1.
- **value**: specifies the value to which to set the designated parameter. The designated parameter is specified by `index`.

Tip: `value` can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type TINYINT, the TINYINT value is converted to the designated parameter's type. For example, if you use `settinyint(1, 3)` to set parameter 1 to TINYINT value 3, and parameter 1 is type CHAR, the TINYINT value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETTINYINT method is invoked.

The SETTINYINT method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in *SAS Viya: DS2 Programmer’s Guide*.

See Also

- “Using the SQLSTMT Package” in *SAS Viya: DS2 Programmer’s Guide*
SETVARBINARY Method

Sets the designated parameter to the specified value of type VARBINARY.

Restriction: This method is not supported in the CAS server.

Syntax

\[ \text{package}.\text{SETVARBINARY}(\text{index}, \text{value}); \]

Arguments

- \text{package} specifies an instance of the SQLSTMT package.
- \text{index} specifies the parameter index ordered sequentially, starting at 1.
- \text{value} specifies the value to which to set the designated parameter. The designated parameter is specified by \text{index}.

Tip \text{value} can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type VARBINARY, the VARBINARY value is converted to the designated parameter's type. For example, if you use \text{setvarbinary}(1, 0110) to set parameter 1 to VARBINARY value 0110, and parameter 1 is type CHAR, the VARBINARY value 0110 is converted to the CHAR value 0110 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETVARBINARY method is invoked.

The SETVARBINARY method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.
For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.

### SETVARCHAR Method

Sets the designated parameter to the specified value of type VARCHAR.

**Restriction:** This method is not supported in the CAS server.

**Syntax**

```lang
package.SE TVARCHAR (index, value);
```

**Arguments**

- **package**
  - specifies an instance of the SQLSTMT package.
- **index**
  - specifies the parameter index ordered sequentially, starting at 1.
- **value**
  - specifies the value to which to set the designated parameter. The designated parameter is specified by index.

**Tip** value can be a literal, variable, or expression.

**Details**

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package’s SETtype methods.

If the designated parameter's type is not type VARCHAR, the VARCHAR value is converted to the designated parameter's type. For example, if you use `setvarchar(1, pass)` to set parameter 1 to VARCHAR value `pass`, and parameter 1 is type CHAR, the VARCHAR value `pass` is converted to the CHAR value `pass` and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SETtype methods. A run-time error results if variables are bound to parameters and the SETVARCHAR method is invoked.
The SETVARCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see “Specifying FedSQL Statement Parameter Values” in SAS Viya: DS2 Programmer’s Guide.

Chapter 21
DS2 TZ Package Methods, Operators, and Statements

Dictionary

DECLARE PACKAGE Statement, TZ Package
Creates a package variable and enables you to create an instance of the TZ package.

Category: Local

Syntax

DECLARE PACKAGE TZ variable ([time-zone-id]);

Arguments

variable
specifies a name that can reference an instance of the TZ package.

time-zone-id
specifies a time zone ID.

Default
The value specified in the TIMEZONE= system option.
Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a TZ package for time zone processing. The TZ package is predefined for DS2 programs. For more information about time zones in SAS, see "SAS Viya National Language Support: Reference Guide."

You declare a TZ package by using the DECLARE PACKAGE statement. This associates a TZ package with a time zone name. After you declare the new TZ package, you can format your date and time data accordingly.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a TZ package.

- Use the DECLARE PACKAGE statement along with the _NEW_ operator:
  ```
  declare package tz tzpkg;
  tzpkg = _new_ tz();
  ```

- Use the DECLARE PACKAGE statement along with its constructor syntax:
  ```
  declare package tz tzpkg();
  ```

See Also

- “Package Constructors and Destructors” in "SAS Viya: DS2 Programmer’s Guide"

Operators:

- “_NEW_ Operator, TZ Package” on page 1097

System Options:

- “TIMEZONE= System Option” in "SAS Viya System Options: Reference"

GETLOCALTIME Method

Returns current local time.

Syntax

```variable=package.GETLOCALTIME ([time-zone-ID]);
```

Arguments

- `variable` specifies the variable that will hold the value of the time zone ID of required local time.
package
specifies an instance of the TZ package.

time-zone-ID
specifies the time zone ID of the required local time.

Example
The following example uses multiple time zones.

data _null_;  
  method init();
  
declare package tz tokyo('Asia/Tokyo')
    london('Europe/London')
    new_york('America/New_York');
dcl double tokyo_time london_time new_york_time utc_time;
dcl integer tokyo_off london_off new_york_off;
  
tokyo_time = tokyo.getLocalTime();
tokyo_off = tokyo.getOffset();
london_time = london.getLocalTime();
london_off = london.getOffset();
new_york_time = new_york.getLocalTime();
new_york_off = new_york.getOffset();
  
utc_time = tokyo.getUTCTime(); /* can use any timezone */
  
put utc_time = datetime. ;
put tokyo_time = datetime. tokyo_off time5. ;
put london_time = datetime. london_off time5. ;
put new_york_time = datetime. new_york_off time5. ;
  
end;
enddata;
run;

The following lines are written to the SAS log.

utc_time=08APR15:12:48:41
tokyo_time=08APR15:21:48:41  9:00
london_time=08APR15:13:48:41  1:00
new_york_time=08APR15:08:48:41 -4:00

See Also
• “Using the TZ Package” in SAS Viya: DS2 Programmer’s Guide

Methods:
• “GETUTCTIME Method” on page 1097
GETOFFSET Method

Returns the time zone offset of the time zone from Universal Coordinated Time (UTC) at the specified local
time. If local time is not specified, current local time is used.

Syntax

Form 1:  
```
variable=package.GETOFFSET();
```

Form 2:  
```
variable=package.GETOFFSET(local-time);
```

Form 3:  
```
variable=package.GETOFFSET(time-zone-ID);
```

Form 4:  
```
variable=package.GETOFFSET(local-time, time-zone-ID);
```

Arguments

variable  
specifies the variable that will hold the value of the time zone offset.

package  
specifies an instance of the TZ package.

local-time  
specifies the local time used to get the time zone offset.

Default  
If local time is not specified, the current local time is used.

Tip  
localTime is a SAS date time value. It is used as the number of seconds
since January 1, 1960 00:00:00 local time.

time-zone-ID  
specifies the time zone ID of the required time zone offset.

See  
“Time Zone IDs and Time Zone Names” in SAS Viya National Language
Support: Reference Guide

Details

UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a
datetime value that uses the ISO 8601 basic form yyyymmddThhmmss+ |– hhmm or the
ISO 8601 extended form yyyy-mm-ddThh:mm:ss+ |– hh:mm.

The time zone offset specifies the number of hours and minutes that a time zone is off
from the UTC in the form + |– hh:mm or + |– hh:mm

Example

The following example returns the offset from the 'Asia/Tokyo' time zone to the
'America/New_York' time zone. The example also illustrates the different ways in which
the time zone ID can be expressed.

data _null_;  
  method init();

  declare package tz tzone('asia/tokyo');
dcl double new_york;
dcl char(40) cstr;

new_york = tzone.getOffset('America/New_York');
put new_york time.;

new_york = tzone.getOffset(n'America/New_York');
put new_york time.;

cstr = 'America/New_York';
new_york = tzone.getOffset(cstr);
put new_york time.;

end;
enddata;
run;

The following lines are written to the SAS log.

-4:00:00
-4:00:00
-4:00:00

Methods:
• “GETOFFSETUTC Method” on page 1093

GETOFFSETUTC Method
Returns the time zone offset of the time zone from UTC at the specified UTC time.

Syntax

\[
\text{variable=package.GETOFFSETUTC (UTC-time, time-zone-ID);}
\]

Without Arguments

If no arguments are specified, the GETOFFSETUTC method returns the time zone offset for the specified TIMEZONE= system option.

Arguments

\*variable\*

specifies the variable that will hold the value of the time zone offset.

\*package\*

specifies an instance of the TZ package.

\*UTC-time\*

specifies the UTC time used to get the time zone offset.
UTC-time is a SAS datetime value at UTC. It is stored as the number of seconds since January 1, 1960 00:00:00 at UTC.

time-zone-ID
specifies the time zone ID of the required time zone offset.

Details
UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a datetime value that uses the ISO 8601 basic form yyyymmddThhmmss+|-hhmm or the ISO 8601 extended form yyyy-mm-ddThh:mm:ss+|-hh:mm.

The time zone offset specifies the number of hours and minutes that a time zone is off from the UTC in the form +|-hhmm or +|-hh:mm

See Also
• “Using the TZ Package” in SAS Viya: DS2 Programmer’s Guide

Methods:
• “GETOFFSET Method” on page 1092

GETTIMEZONEID Method
Returns the current time zone ID.

Syntax

variable=package.GETTIMEZONEID ( );

Arguments

package
specifies an instance of the TZ package.

variable
specifies the variable that will hold the value of the time zone ID of the TZ package instance.

Details

The time zone ID specifies a region or area value that is defined by SAS. For more information about time zone IDs, see SAS Viya National Language Support: Reference Guide.

Example

The following example uses the TZ package to calculate time durations.

options timezone='asia/tokyo' ; /* TIMEZONE ID of origin */
proc ds2;
data _null_
method route(package tz origin,
       package tz dest,
       timestamp departure,
       time duration);

dcl nvarchar(50) tzid dest_tzid;
dcl nvarchar(8)  tzname dest_tzname home_tzn ;
dcl double dept dur arrival utc ;
dcl double home_dept home_arr ;

declare package tz home();

utc = origin.toUTCtime(departure);
dur = TO_DOUBLE(duration);
arrival = dest.toLocalTime(utc+dur);
tzid = origin.getTimezoneID();
tzname = origin.getTimezoneName();
dest_tzid = dest.getTimezoneID();
dest_tzname = dest.getTimezoneName();

home_dept = home.toLocalTime(utc);
home_arr = home.toLocalTime(utc+dur);
home_tzn = home.getTimezoneName();

put 'Time Zone: ' tzid 'to' dest_tzid ;
put 'Departure Time: ' departure datetime.  tzname  '/'
      home_dept datetime. home_tzn;
put '   Arrival Time: ' arrival datetime. dest_tzname  '/'
      home_arr datetime. home_tzn ;
put;

end ;
method init();

/* print itinerary */
declare package tz NRT('Asia/Tokyo') ;
declare package tz ORD('America/Chicago') ;
declare package tz RDU('America/New_York');

route(NRT,ORD,timestamp '2014-10-19 10:45:00',time '11:35:00') ;
route(ORD,RDU,timestamp '2014-10-19 11:03:00',time '01:56:00') ;
route(RDU,ORD,timestamp '2014-10-25 07:45:00',time '02:02:00') ;
route(ORD,NRT,timestamp '2014-10-25 10:50:00',time '12:55:00') ;

end;
enddata;
run;
quit;
The following lines are written to the SAS log.

<table>
<thead>
<tr>

Methods:

- “GETTIMEZONENAME Method” on page 1096

---

**GETTIMEZONENAME Method**

Returns the current time zone name.

**Syntax**

```
variable=package.GETTIMEZONENAME ( );
```

**Arguments**

- `package`
  - specifies an instance of the TZ package.

- `variable`
  - specifies the variable that will hold the value of the time zone name of the TZ package instance.

**Details**

The time zone name specifies a region or area value that is defined by SAS. For more information about time zone names, see SAS Viya National Language Support: Reference Guide.

**Example**

See the example in “GETTIMEZONEID Method” on page 1094.
See Also

- “Using the TZ Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “GETTIMEZONEID Method” on page 1094

---

**GETUTCTIME Method**

Returns the current UTC time.

**Syntax**

```
variable=package.GETUTCTIME();
```

**Arguments**

- **variable**
  - specifies the variable that will hold the value of the current UTC time.
- **package**
  - specifies an instance of the TZ package.

See Also

- “Using the TZ Package” in *SAS Viya: DS2 Programmer’s Guide*

Methods:

- “GETLOCALTIME Method” on page 1090

---

**_NEW_ Operator, TZ Package**

Constructs an instance of a TZ package.

**Note:** The escape character (\) before the bracket indicates that the bracket is required in the syntax.

**Syntax**

```
package-variable = _NEW_ [[THIS] | [package-instance]] TZ([time-zone-id]);
```

**Arguments**

- **package-variable**
  - specifies a name that can reference an instance of the package.
- **[THIS]**
  - specifies that the package instance has global scope.
See “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide

[package-instance]

specifies that the new package instance has the same scope as package-instance. package-instance must be an existing package instance, and the type of package-instance can differ from the type of the new package instance.

See “Package-Specific Scope” in SAS Viya: DS2 Programmer’s Guide

time-zone-id

specifies a time zone ID.

Default The value specified in the TIMEZONE= system option.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

When a TZ package is declared, the variable representing the package can be considered an instance of the package. This means that two different package variables represent two completely separate copies of a package.

You declare a TZ package using the DECLARE PACKAGE statement. After you declare the new TZ package, use the _NEW_ operator to instantiate the package.

```plaintext
declare package tz localtz;
localtz = _new_ tz( );
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a TZ package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```plaintext
declare package tz localtz( );
```

Note: Package variables are subject to all variable scoping rules. For more information, see “Packages and Scope” in SAS Viya: DS2 Programmer’s Guide.

Statements:

• “DECLARE PACKAGE Statement, TZ Package” on page 1089

TOISO8601 Method

Converts local time to an ISO8601 string with time zone offset.

Syntax

Form 1: `variable=package.TOISO8601 (local-time);`
Form 2: \texttt{variable=package.TOISO8601 (local-time, time-zone-ID)};

\textbf{Arguments}

\texttt{variable}

specifies the variable that will hold the value of an ISO8601 string such as '2014-10-10T00:01:02.00+09:00'.

\texttt{package}

specifies an instance of the TZ package.

\texttt{local-time}

specifies the local time to convert. \texttt{local-time} can be DOUBLE or TIMESTAMP format.

\texttt{time-zone-ID}

specifies the time zone ID of the required local time. Time zone ID 'UTC' can be used to specify UTC time.

\textbf{See Also}

\textbf{Methods:}

- “TOLOCALTIME Method” on page 1099
- “TOTIMESTAMPZ Method” on page 1100
- “TOUTCTIME Method” on page 1101

\textbf{TOLOCALTIME Method}

Converts UTC time to local time.

\textbf{Syntax}

Form 1: \texttt{variable=package.TOLOCALTIME (UTC-time)};

Form 2: \texttt{variable=package.TOLOCALTIME (UTC-time, time-zone-ID)};

\textbf{Arguments}

\texttt{variable}

specifies the variable that will hold the value of the local time that is converted from the specified UTC time.

\texttt{package}

specifies an instance of the TZ package.

\texttt{UTC-time}

specifies the current UTC time in DOUBLE or TIMESTAMP format.

\texttt{time-zone-ID}

specifies the time zone ID of the required local time.
Details
UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a datetime value that uses the ISO 8601 basic form yyyymmddThhmmss+|-hhmm or the ISO 8601 extended form yyyy-mm-ddThh:mm:ss+|-hh:mm.

Example
See the example in “GETTIMEZONEID Method” on page 1094.

See Also
• “Using the TZ Package” in SAS Viya: DS2 Programmer’s Guide

Methods:
• “TOISO8601 Method” on page 1098
• “TOTIMESTAMPZ Method” on page 1100
• “TOUTCTIME Method” on page 1101

TOTIMESTAMPZ Method
Converts local time to a TIMESTAMP string with time zone.

Syntax
variable=package.TOTIMESTAMPZ (local-time[, time-zone-ID]);

Arguments

variable
specifies the variable that will hold the value of a string such as '2014-10-14 00:01:20 Asia/Tokyo'.

package
specifies an instance of the TZ package.

local-time
specifies the local time to convert. local-time can be DOUBLE or TIMESTAMP format.

time-zone-ID
specifies the time zone ID of the required local time. Time zone ID 'UTC' can be specified to use UTC time.

See Also
• “Using the TZ Package” in SAS Viya: DS2 Programmer’s Guide
TOUTCTIME Method

Converts local time to UTC time.

Syntax

Form 1: \[ \text{variable} = \text{package}.\text{TOUTCTIME} (\text{local-time}); \]

Form 2: \[ \text{variable} = \text{package}.\text{TOUTCTIME} (\text{local-time}, \text{time-zone-ID}); \]

Arguments

\text{variable} \\
\quad \text{specifies the variable that will hold the value of the current UTC time in DOUBLE or TIMESTAMP format.}

\text{package} \\
\quad \text{specifies an instance of the TZ package.}

\text{local-time} \\
\quad \text{specifies the local time to convert. local-time can be DOUBLE or TIMESTAMP format.}

\text{time-zone-ID} \\
\quad \text{specifies the time zone ID of the required local time.}

Details

UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a datetime value that uses the ISO 8601 basic form \text{yyyy-mm-ddThh:mm:ss±hh:mm} or the ISO 8601 extended form \text{yyyy-mm-ddThh:mm:ss±hh:mm}.

Example

See the example in “GETTIMEZONEID Method” on page 1094.

Appendix 1
Data Type Reference

Data Types for SAS Data Sets

The following table lists the data type support for a SAS data set.

The BINARY and VARBINARY data types are not supported for data type definition.

For some data type definitions, the data type is mapped to CHAR, which is a SAS character data type, or DOUBLE, which is a SAS numeric data type. For data source-specific information about the SAS numeric and SAS character data types, see “DATA Step Basics” in SAS Cloud Analytic Services: Accessing and Manipulating Data.

Table A1.1  Data Types for SAS Data Sets

<table>

<td>Fixed-length character string. <strong>Note:</strong> Cannot contain ANSI SQL null values.</td>
<td>CHAR((n))</td>
</tr>
</tbody>
</table>

* The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

** Do not apply date and time SAS formats to a numeric data type. For date and time values, use the DATE, TIME, or TIMESTAMP data types.

*** Because the values are stored as a double precision, floating-point number, you can use the values in arithmetic expressions.

† UTF-8 is an MBCS encoding. Depending on the operating environment, UTF-8 characters are of varying width, from 1 to 4 bytes. The value for \(n\), which is the maximum number of multibyte characters to store, is multiplied by the maximum length for the operating environment. Note that when you are transcoding, such as from UTF-8 to WLatin2, the variable lengths (in bytes) might not be sufficient to hold the values, and the result is character data truncation.
Data Types for CAS

The following table lists the data type support for a CAS table.

The BINARY, DECIMAL/NUMERIC, REAL, and VARBINARY data types are not supported for data type definition in CAS.

**Table A1.2  Data Types for CAS Tables**

<table>
<thead>
<tr>
<th>Data Type Definition Keyword*</th>
<th>CAS Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
</table>
| BIGINT**                      | DOUBLE        | 64-bit double precision, floating-point number.  
Note: There is potential for loss of precision. | DOUBLE |
| CHAR(\(n\))                  | CHAR(\(n\))  | Fixed-length character string. If a string value is less than \(n\) in length, the value is blank-padded to \(n\). †  
Note: ANSI SQL null values in a string are converted to SAS missing values. | CHAR(\(n\)) †† |
| DATE ***                      | DOUBLE        | 64-bit double precision, floating-point number. By default, applies the DATE9 SAS format. | DOUBLE |
| DOUBLE**                      | DOUBLE        | 64-bit double precision, floating-point number. | DOUBLE |
| FLOAT**                       | DOUBLE        | 64-bit double precision, floating-point number. | DOUBLE |

| NCHAR(\(n\))                 | CHAR(\(n\))  | Fixed-length national character string. If a string value is less than \(n\) in length, the value is blank-padded to \(n\). †  
Note: ANSI SQL null values in a string are converted to SAS missing values. | CHAR(\(n\)) |
<table>
<thead>
<tr>
<th>Data Type Definition Keyword*</th>
<th>CAS Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
</table>
| NVARCHAR(n)                   | VARCHAR(n)   | Varying-length character string. \( n \) is the maximum length of the string that can be stored.†  
*Note: ANSI SQL null values in a string are converted to SAS missing values. |
| SMALLINT**                    | DOUBLE       | 64-bit double precision, floating-point number. | DOUBLE |
| TIME(p)***                    | DOUBLE       | 64-bit double precision, floating-point number. By default, applies the TIME8. SAS format. | DOUBLE |
| TIMESTAMP(p)***               | DOUBLE       | 64-bit double precision, floating-point number. By default, applies the DATETIME25.6 SAS format. | DOUBLE |
| TINYINT**                     | DOUBLE       | 64-bit double precision, floating-point number. | DOUBLE |
| VARCHAR(n)                    | VARCHAR(n)   | Varying-length character string. \( n \) is the maximum length of the string that can be stored.†  
††Note: ANSI SQL null values in a string are converted to SAS missing values. |

* The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

** Do not apply date and time SAS formats to a numeric data type. For date and time values, use the DATE, TIME, or TIMESTAMP data types.

*** Because the values are stored as a double precision, floating-point number, you can use the values in arithmetic expressions.

† For a DS2 character data type, the value for \( n \) is the number of characters to store. For a CAS character type, the value for \( n \) is the number of bytes to store. CAS tables use the UTF-8 character set. UTF-8 is a multi-byte character set encoding. UTF-8 characters are of varying width, from 1 to 4 bytes. When a DS2 character value is saved to a CAS character column, the string data will be truncated if the value requires more than \( n \) bytes in its UTF-8 encoded representation. When a DS2 character value is used to read a CAS character column, the string data will be truncated if the value requires more than \( n \) characters in the active session encoding.

†† DS2 character types use the session encoding by default. This data type enables you to specify an alternate character set encoding when defining columns. When the DS2 data type specifies an encoding other than UTF-8 in a DS2 CAS action, the data will be transcoded to and from UTF-8 when data is written to or read from CAS.

Example: Find Minimums

Example Overview: Find Minimums

This example demonstrates how to use the three system-defined methods, INIT, RUN, and TERM.

A DS2 program executes in the following sequence:

1. Any global variables are declared.
2. The INIT method is called. INIT is typically used for variable initialization.
3. The RUN method is called. The RUN method is where the implicit loop exists. RUN executes until all input tables are completely read.
4. The TERM method is called. Final processing is performed.

The following program demonstrates this flow of control by finding the minimum values in a table. In this program, the INIT method initializes the variables used to find the current minimum, the RUN method compares input values with the current minimum, and the TERM method writes the minimums to an output table.

Example Code: Find Minimums

```ds2
proc ds2;
/* Create table to work with in this example */
data xy_data;
   dcl double x y;
   method init();
      do x = 1 to 5;
         y = 2*x;
         output;
      end;
   end;
enddata;
run;
/* Find the minimum value for x and y */
data xy_mins;
   dcl double min_x min_y;
   retain min_x min_y;
   keep min_x min_y;
   method init();
      min_x = 999999;
      min_y = 999999;
   end;
   method run();
      set xy_data;
      if x < min_x then min_x = x;
      if y < min_y then min_y = y;
   end;
```
Example Output: Find Minimums

<table>
<thead>
<tr>
<th>MIN_X</th>
<th>MIN_Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

Example: SQL in a DS2 Program

Example Overview: SQL in a DS2 Program

This example illustrates how to use an SQL statement in a DS2 program. To access the output from an SQL query, put the query in a SET statement. When the SET statement runs, it sequentially reads the rows that are returned by the query.

Example Code: SQL in a DS2 Program

In this example, the first DS2 program calculates annual balances for an account into which contributions of $2000 are made every year from 2004 to 2014. The account carries a 7% interest rate, compounded annually. The second program generates the table. The third program writes the results of an SQL query. The query selects all rows from INVESTMENT where the value of INVESTMENT_YEAR is greater than 2010.

```plaintext
proc ds2;
data investment;
dcl integer investment_year;
dcl double capital;
method init();
capital = 0;
do investment_year = 2004 to 2014;
capital = capital + (2000 + .07 * (capital+2000));
output;
end;
end;
enddata;
run;
```
data;
    method run();
    set investment;
    end;
enddata;
run;
data;
    method run();
    set {select * from investment where investment_year > 2010};
    end;
enddata;
run;
quit;

Example Output: SQL in a DS2 Program

<table>
<thead>
<tr>
<th>INVESTMENT_YEAR</th>
<th>CAPITAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>2004</td>
<td>2140</td>
</tr>
<tr>
<td>2005</td>
<td>4429.8</td>
</tr>
<tr>
<td>2006</td>
<td>6879.886</td>
</tr>
<tr>
<td>2007</td>
<td>9501.478</td>
</tr>
<tr>
<td>2008</td>
<td>12306.58</td>
</tr>
<tr>
<td>2009</td>
<td>15308.04</td>
</tr>
<tr>
<td>2010</td>
<td>18519.61</td>
</tr>
<tr>
<td>2011</td>
<td>21955.98</td>
</tr>
<tr>
<td>2012</td>
<td>25632.9</td>
</tr>
<tr>
<td>2013</td>
<td>29567.2</td>
</tr>
<tr>
<td>2014</td>
<td>33776.9</td>
</tr>
</tbody>
</table>
Example: Make Two New Tables Based on a Condition

Example Overview: Make Two New Tables Based on a Condition

This example illustrates how to create tables based on a condition. Programs 1 and 2 create two tables, DEPT1_ITEMS and DEPT2_ITEMS, that hold costs for items used by two departments. The third program creates two tables, HIGHCOSTS and LOWCOSTS, based on the costs of the items in the two items tables. Programs 4 and 5 generate the contents of the costs tables.

Example Code: Make Two New Tables Based on a Condition

```plaintext
proc ds2;
/* Program 1 */
data dept1_items (overwrite=yes);
dcl varchar(20) item;
dcl double cost;
method init();
   item = 'staples'; cost =  1.59; output;
   item = 'pens';  cost =  3.26; output;
   item = 'envelopes'; cost = 11.42; output;
end;
enddata;
run;
/* Program 2 */
data dept2_items (overwrite=yes);
dcl varchar(20) item;
dcl double cost;
method init();
   item = 'erasers'; cost =  5.43; output;
   item = 'paper';  cost = 26.92; output;
   item = 'toner';  cost = 62.29; output;
end;
enddata;
run;
/* Program 3 */
data lowCosts (overwrite=yes) highCosts (overwrite=yes);
method run();
   set dept1_items dept2_items;
   if cost <= 10.00 then
      output lowCosts;
   else
      output highCosts;
end;
enddata;
run;
/* Program 4 */
data;
method run();
```
Example Output: Make Two New Tables Based on a Condition

<table>
<thead>
<tr>
<th>ITEM</th>
<th>COST</th>
</tr>
</thead>
<tbody>
<tr>
<td>staples</td>
<td>1.59</td>
</tr>
<tr>
<td>pens</td>
<td>3.26</td>
</tr>
<tr>
<td>erasers</td>
<td>5.43</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ITEM</th>
<th>COST</th>
</tr>
</thead>
<tbody>
<tr>
<td>envelopes</td>
<td>11.42</td>
</tr>
<tr>
<td>paper</td>
<td>26.92</td>
</tr>
<tr>
<td>toner</td>
<td>62.29</td>
</tr>
</tbody>
</table>

Example: Change Case of Text Output

Example Overview: Change Case of Text Output

The code in this example reads the two tables created in the previous example, DEPT1_COSTS and DEPT2_COSTS, and outputs rows with values in the COST column of less than or equal to $10 in lower case, and values greater than $10 in uppercase.

Example Code: Change Case of Text Output

```plaintext
proc ds2;
  data;
```
method run();
    set dept1_items dept2_items;
    if cost <= 10.00 then
        item = lowercase(item);
    else
        item = uppercase(item);
    end;
enddata;
run;
quit;

Example Output: Change Case of Text Output

<table>
<thead>
<tr>
<th>ITEM</th>
<th>COST</th>
</tr>
</thead>
<tbody>
<tr>
<td>staples</td>
<td>1.59</td>
</tr>
<tr>
<td>pens</td>
<td>3.26</td>
</tr>
<tr>
<td>ENVELOPES</td>
<td>11.42</td>
</tr>
<tr>
<td>erasers</td>
<td>5.43</td>
</tr>
<tr>
<td>PAPER</td>
<td>26.92</td>
</tr>
<tr>
<td>TONER</td>
<td>62.29</td>
</tr>
</tbody>
</table>

Example: Scope

Example Overview: Scope

This example shows the use of CHAR and VARCHAR types and their operators and functions. Also, in this example, the variables A, B, and C are locally scoped to the INIT method. That is, their value is not seen outside of the INIT method and is not written to the result table.

Example Code: Scope

proc ds2;
data;
    dcl char(24) abc abc2;
    method init();
        dcl char(8) a b c;

        a = repeat('a',5);
        b = repeat('b',6);
        c = repeat('c',7);

        abc = a || b || c;
Example: Functions

Example Output: Scope

```
abc2 = trim(a) || trim(b) || c;
end;
enddata;
run;
data;
dcl char(24) abc abc2;
method init();
dcl varchar(8) a b c;

a = repeat('a',5);
b = repeat('b',6);
c = repeat('c',7);

abc = a || b || c;
abc2 = trim(a) || trim(b) || c;
end;
enddata;
run;
quit;
```

Example Output: Scope

```
<table>
<thead>
<tr>
<th>abc</th>
<th>abc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaaaaa bbbbbbb ccccccc</td>
<td>aaaaaabbbbbcccccccc</td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>
<th>abc</th>
<th>abc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaaaaabbbbbbbcccccccc</td>
<td>aaaaaabbbbbcccccccc</td>
</tr>
</tbody>
</table>
```

Example: Functions

Example Overview: Functions

This example shows how to use a function in DS2. The code computes the number of bits required to store an integer.

Example Code: Functions

```
proc ds2;
data;
dcl integer i bits;
```
method init();
    do i = 1 to 1000 by 100;
        bits = ceil(log(i) / log(2));
        output;
    end;
end;
enddata;
run;
quit;

**Example Output: Functions**

<table>
<thead>
<tr>
<th>i</th>
<th>bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>101</td>
<td>7</td>
</tr>
<tr>
<td>201</td>
<td>8</td>
</tr>
<tr>
<td>301</td>
<td>9</td>
</tr>
<tr>
<td>401</td>
<td>9</td>
</tr>
<tr>
<td>501</td>
<td>9</td>
</tr>
<tr>
<td>601</td>
<td>10</td>
</tr>
<tr>
<td>701</td>
<td>10</td>
</tr>
<tr>
<td>801</td>
<td>10</td>
</tr>
<tr>
<td>901</td>
<td>10</td>
</tr>
</tbody>
</table>

**Example: Arrays**

**Example Overview: Arrays**

The first program illustrates basic array procedures. In the final section, elements of dblNegSubArray are specified by using numeric expressions inside the array brackets. Expressions that resolve to a number that falls out of the bounds of the declared size of the array give an error message.

The second program gives several examples of array assignments. When an array is assigned, data types that do not match the type of the target array are converted to the target array type.

Note that if you add an equal sign after a variable or array element in a PUT statement, then the output is preceded by the variable or array element name and an equal sign.

**Example Code: Arrays**
/* Basic Arrays */
data _null_
  dcl char(10)  strArray[4] str;
  dcl double    dblArray[3];
  dcl int       intArray[10];
  dcl double    dblNegSubArray[-4:-1];
  dcl int x;
method init();

Example: SELECT Statement

Example Overview: SELECT Statement

This example illustrates the SELECT statement. In this example, a DO loop encloses a SELECT statement. The SELECT statement reads the current value of the loop counter I and outputs a character when the WHEN statement is true. The REPEAT statement repeatedly prints the character based on the value of the loop counter.

Example Code: SELECT Statement

```plaintext
proc ds2;
data;
dcl char(10) s;
method run();
dcl char(1) x;
dcl int i;
do i=1 to 10;
   select(i);
      when(1) x='A';
      when(2) x='B';
      when(3) x='C';
      when(4) x='D';
      when(5) x='E';
      when(6) x='F';
      when(7) x='G';
      when(8) x='H';
      when(9) x='I';
      otherwise x='J';
end;
s=repeat(x,i);
output;
end;
enddata;
run;
quit;
```
Example Output: SELECT Statement

Example Code: GOTO and LEAVE Statements with Labels

```
proc ds2;
data;
dcl double i j;
method init();
i = 1;
head:
j = 2*i;
i = i+1;
if i < 10 then do;
   output;
goto head;
end;
end;
```
enddata;
run;
data _null_;  
dcl int x y; 
method init();  
    put 'loop test 1';  
    x = 1;  
    y = 2; 
    if (x ~= -5) then 
        do i = 1 to 10;  
            put i;  
            if i > 4 then leave;  
        end;  
    else  
        put 'else';  
    end;  
end;  
enddata;  
run;
data _null_;  
dcl int g;  
method init();  
    put 'label test 1';  
    x = 1;  
    y = 2; 
    if (x > -5) then lab:  
        do i = 1 to 10;  
            do j = 1 to 5;  
                put i j;  
                if i > 4 then leave lab;  
            end;  
        end;  
    else  
        do;  
            put 'else';  
        end;  
    end;  
enddata;  
run;  
quit;
Example Output: GOTO and LEAVE Statements with Labels

The following output is the result of using GOTO to branch to a label.

<table>
<thead>
<tr>
<th>i</th>
<th>j</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>

2 2
2 3
2 4
2 5
3 1
3 2
3 3
3 4
3 5
4 1
4 2
4 3
4 4
4 5
5 1
```
Example: Overloaded Methods

Example Overview: Overloaded Methods

This example illustrates how to set up overloaded methods. For more information about methods, see the “METHOD Statement” on page 740.

Example Code: Overloaded Methods

```plaintext
proc ds2;
data _null_;  
method concat(nvarchar(200) x, nvarchar(200) y) returns nvarchar(400);  
    return x || y;
end;

method concat(nvarchar(200) x, nvarchar(200) y, nvarchar(200) z)  
    returns nvarchar(600);  
    return x || y || z;
end;

method run();  
    y = concat(n'abc', n'def');  
    put 'y= ' y;  
    y = concat(n'abc', n'def', n'ghi');  
    put 'y= ' y;
end;
enddata;
run;
data _null_;  
method d() returns double;  
    return 99;
end;

method d(double x, double y, double z) returns double;  
    return x + y + z;
end;

method d(int x, int y, int z) returns int;  
    return x + y + z + 500;
end;

method run();  
    dcl double d;  
    d = d(1,2,3);  
    put 'd= ' d;  
    d = d(100.1, 100.2, 100.3);  
    put 'd= ' d;
end;
enddata;
run;
quit;
```
Example Output: Overloaded Methods

The following lines are written to the SAS log.

```
y= abcdef
y= abcdedghi
d= 506
```

Example: Analyze a Table Using Multiple Threads

Example Overview: Analyze a Table Using Multiple Threads

This example shows the creation of a table that is then analyzed using multiple threads.

Example Code: Analyze a Table Using Multiple Threads

```
libname spde spde 'c:\temp\spde';
proc delete data=spde.incomes; run;
proc delete data=spde.results1; run;
proc delete data=spde.results2; run;

proc ds2;
data spde.incomes;
dcl double income citycode;
dcl char(8) name;
method run();
do j = 1 to 1E6;
  name = 'John'; income = 23234; citycode=1; output;
  name = 'Jane'; income = 62348; citycode=1; output;
  name = 'Joe'; income = 32932; citycode=2; output;

The following table is generated.
Example: Data Cleaning

Example Overview: Data Cleaning

Sometimes, due to input error, data values might have leading and trailing blanks. Unless you specifically filter for this possibility, joins and similar database operations that depend on identically formatted data values will not perform correctly. Another problem that can occur is unintentional duplication of records (that is, multiple records (rows) with the same key). This example shows programs that remove blanks from data values, and list duplicate rows for potential deletion.

The first DS2 program creates a simple data table, EMPLOYEES1, that contains duplicate rows and string values, some of which contain blanks.

The second program uses the STRIP function to remove leading and trailing blanks from values in the EMP column. The table is written to EMPLOYEES2.

The third program uses an embedded SQL SELECT statement to display the duplicates. You can use this output to determine which records should be deleted. Note that this program would have not generated correct output if you did not first remove the blanks from the data values, because the SELECT statement would not have grouped the data accurately.

Example Code: Data Cleaning

```plaintext
proc ds2;
data employees1 (overwrite=yes);
dcl double id;
dcl char emp;
method init();
id = 60918 ; emp = 'user1'; output;
id = 60919 ; emp = 'user2'; output;
id = 60920 ; emp = 'user3'; output;
id = 60918 ; emp = 'user1'; output;
id = 60922 ; emp = 'user4'; output;
id = 60925 ; emp = 'user5 '; output;
id = 60926 ; emp = 'user6'; output;
id = 60919 ; emp = 'user2'; output;
id = 60928 ; emp = 'user7'; output;
id = 60918 ; emp = 'user1'; output;
end;
enddata;
run;
data employees2 (overwrite=yes);
method run();
set employees1;
emp = strip(emp);
end;
enddata;
run;
data ;
```
method run();
    set {select id as dupid,  count(id) as dups
        from  employees2
        group by id
        having count(id) > 1};
end;
enddata;
run;
quit;

**Example: SUBSTR Function**

**Example Overview: SUBSTR Function**

The example shows how to use the SUBSTR function. SUBSTR is used to convert the word CAT to DOG by changing one character at a time.

**Example Code: SUBSTR Function**

```plaintext
proc ds2;
data _null_;  
method init();  
a = 'cat';
put 'a=' a;

substr(a,2,1) = 'o';
put 'a=' a;
substr(a,1,1) = 'd';
put 'a=' a;
substr(a,3,1) = 'g';
put 'a=' a;
b = a;
end;
enddata;
run;
```
**Example Output: SUBSTR Function**

The following lines are written to the SAS log.

```
a= cat
a= cot
a= dot
b= dog
```

---

**Example: PUT with SAS Formats**

**Example Overview: PUT with SAS Formats**

This example illustrates how to use SAS formats with the PUT statement.

**Example Code: PUT with SAS Formats**

```sas
proc ds2;
  data _null_
  method init();
    dcl double d;
    dcl int i;
    dcl char(32) x;
    
    d = 99;
    x = put(d, best12.6);
    put 'x=' x;
    
    d = 100;
    x = put(d, best.);
    put 'x=' x;
    
    i = 10847;
    x = put(i, mmddyy8.);
    put 'x=' x;
    
    c = 'abc';
    x = put(c, $char8.);
    put 'x=' x;
  end;
enddata;
run;
quit;
```
Example Output: PUT with SAS Formats

The following lines are written to the SAS log.

| x= 99   |
| x= 100  |
| x= 09/12/89 |
| x= abc |

Example: Generate Statistics from Table Data

Example Overview: Generate Statistics from Table Data

This example analyzes the price movement of a simulated stock table. The first DS2 program creates the stock price table. There are two weeks of the open, high, low, and close prices for the stock.

The second program performs the analysis. A 2-day moving average of closing prices is created by assigning the previous two days' closing prices to elements of the CY array, averaging them by using the MEAN function, and then sending them to output as C_MA. The INIT method initializes the array CY and C_MA variables to the first price in the STOCK table. The RUN method assigns values to the array as it loops through the table.

The CTR variable is incremented each time through the RUN method. The moving average is not valid until two days of prices have been averaged, so the output begins with the third record (that is, when CTR > 2). After a row has been written, the CY array is updated.

The following statistics are also calculated:

- the daily change in closing price, \( \text{Chng} \), calculated by subtracting yesterday's close, \( \text{CY}[1] \), from today's close
- the change from open to the closing price, \( \text{O}_C \)
- the range of the day's prices, \( \text{H}_L \), calculated by subtracting the low price from the high price

Example Code: Generate Statistics from Table Data

```sas
proc ds2;
  data stock (overwrite=yes);
    dcl date d;
    dcl double o h l c;
    method init();
      d = date '2010-09-18' ; o = 20; h = 22.25; l = 18; c = 21.5; output;
      d = date '2010-09-19' ; o = 21; h = 23.5; l = 19.25; c = 22; output;
      d = date '2010-09-20' ; o = 22.25; h = 24.75; l = 20; c = 21; output;
      d = date '2010-09-21' ; o = 21; h = 21.5; l = 18.75; c = 19; output;
      d = date '2010-09-22' ; o = 18; h = 19; l = 17.25; c = 17; output;
```

Example: Matrices and Non-linear Equations

Example Overview: Matrices and Non-linear Equations

This example solves a system of non-linear equations using Newton’s iterative process. In this example, the root (to within a given epsilon) is found after five iterations of the loop, and is equal to (.5, 0, -.5236). Zero appears as an extremely small number.

One interesting feature to note in Newton’s example is how the result matrix can be reused. In a simple method calculation, \( r = m \cdot \text{mult}(m2) \); the result matrix instance is automatically created. However, if the result instance already exists, and its size is correct, the method will reuse the result matrix for efficiency purposes. Note how this is done in Newton’s computation loop. When the matrix is created the first time, the left side result is reused in computations such as \( ji = jm \cdot \text{inverse}() \);. Otherwise, you would have to free the old matrix and allocate a new one each time.

Example Code: Matrices and Non-linear Equations

```plaintext
proc ds2;
/*
 * Solve the system of equations
 *
 * 3*x1 + cos(x2*x3) - .5                = 0
 * x1^2 - 81(x2 + .1)^2 + sin(x3) + 1.06 = 0
 * e^(-x1*x2) + 20*x3 + (10pi-3)/3       = 0
 *
 * using Newton's method:
 * X_m = X_m0 - J^-1(X_m0) * F(X_m0)
 * /

Example: Use the SQLSTMT Package in Another Package

Example Overview: Use the SQLSTMT Package in Another Package

This example shows how to use an instance of a package SQLSTMT in another package. It also shows the use of the _NEW_ operator to delay construction of the SQLSTMT instance until after the creation of the table that is referenced by the FedSQL statement. If the SQLSTMT instance was constructed before the referenced table was created, then the prepare of the FedSQL statement fails in the constructor.

Example Code: Use the SQLSTMT Package in Another Package

```plaintext
defibonnaci;
def_int nMax: /* maximum index in this series */
defint n; /* index of fib in Fibonacci series */
defdouble fib; /* Fibonacci number */
defpackage sqlstmt stmt;
/* note that stmt is not created */
sqlexec('create table ' || tablename || ' (n int, fib double);'

/* Using _new_ allows delay of prepare of SQL statement until after */
/* output table is created */
stmt = _new_sqlstmt('insert into ' || tablename || '
values (?, ?)');

/* fibonnaci(0) = 0 */
stmt.setInteger(1, 0); /* column n */
stmt.setDouble(2, 0); /* column fib */
stmt.execute();

/* fibonnaci(1) = 1 */
stmt.setInteger(1, 1); /* column n */
stmt.setDouble(2, 1); /* column fib */
stmt.execute();

first = 0;
second = 1;
do n = 2 to nMax;
    fib = first + second;
```

Example: Update the Values of a Table By Using Two Databases

Example Overview: Update the Values of a Table By Using Two Databases

The following example illustrates how the SQLSTMT package can facilitate updating a table in one database based on the values in another table in a second database. In the example program, stmt1 queries for all the x and y columns from the ORACLE table db1.dataset1. Then for each rowset in the result set from db1.dataset1, stmt2 finds the rows in BASE table db2.dataset2 that have the same x column values as the x value read from db1.dataset1. Stmt2 then updates the BASE table db2.dataset2 y column values of the found rows to be the same as the y value read from db1.dataset1.

Example Code: Update the Values of a Table By Using Two Databases

```plaintext
libname db1 odbc user=XXXX pw=XXXX dsn=exadat;
libname db2 './base';

proc ds2;
data _null_;    
declare double x y;
    method run();
        dcl package sqlstmt stmt1('select x,y from db1.dataset1');
        dcl package sqlstmt stmt2('update db2.dataset2 set y=? where x=?',
        [y x]);

        stmt1.execute();
        stmt1.bindResults([x y]);
        do while (stmt1.fetch() = 0);
```
Example: Store FedSQL Statements in a Hash Package

Example Overview: Store FedSQL Statements in a Hash Instance

The following example shows how to use a hash package to manage a set of FedSQL statements. A set of FedSQL statements is dynamically allocated and stored in a hash package. The hash package is indexed by an integer key which is used to retrieve the appropriate FedSQL statement from the hash package.

Example Code: Store FedSQL Statements in a Hash Package

```plaintext
proc ds2;
/* Create 5 tables testdata1...testdata5. *
* Each table has 3 double columns (x,y,z) and no rows. */
data _null_;  
method init();
declare int i;
declare int rc;

d0 i = 1 to 5;
rc = sqlexec('create table testdata' || i ||
'(x double, y double, z double)');
if (rc ne 0) then put 'TEST FAILED';
end;
end;
enddata;
run;
quit;

proc ds2;
data _null_;  
/* Create an sqlstmt reference. * /
declare package sqlstmt s;
/* Create a hash instance. */
declare package hash h();

/* Hash key: sqlstmts are accessed by index 1..5. */
declare int i;
/* Variables to bind to sqlstmt parameters. */
declare double u v w;
```
method init();
declare int rc;

h.definekey('i');  /* Key is index 1..5. */
h.definedata('s');  /* Data is an sqlstmt reference. */
h.definedone();

/* Dynamically create 5 sqlstmt instances and add */
/* each sqlstmt to hash table. */
do i = 1 to 5;

/* Dynamically create an sqlstmt in global ([this]) scope. 
* Variables [u v w] are bound to the parameters of 
* the sqlstmt. */
s = _new_[this] sqlstmt('insert into testdata' 
|| i || ' values (?,?,?)', [u v w]);

/* Add the sqlstmt to hash h with key i. */
rc = h.add();
if (rc ne 0) then put 'TEST FAILED';
end;
end;

/* Retrieve the sqlstmts from the hash table and execute */
/* the sqlstmts to insert rows in the tables. */

method run();
declare int j;
declare int rc;

/* For each of 5 data tables testdata1...testdata5, */
/* insert 9 rows. */
do j = 1 to 9;
do i = 1 to 5;

/* Find the sqlstmt in hash by index i. */
rc = h.find();
if (rc ne 0) then put 'TEST FAILED';

/* Set values to insert into the table testdata i. */
u = i;  /* data for 1st column (x) */
v = -j;  /* data for 2nd column (y) */
w = i*10+j;  /* data for 3rd column (z) */

/* Execute the sqlstmt to insert the row. */
rc = s.execute();
if (rc ne 0) then put 'TEST FAILED';

/* Explicitly close the result set to free resources. 
* If not explicitly closed, result set would be 
* automatically closed at next execute of the sqlstmt. */
rc = s.closeResults();
if (rc ne 0) then put 'TEST FAILED';
end;
end;
end;

/* Explicitly delete each sqlstmt instance. Note if not
 * explicitly deleted, the sqlstmt instances would automatically
 * be deleted when their enclosing scope (global) was destroyed. */

method term();
   declare int rc;
   do i = 1 to 5;
      rc = h.find();
      if (rc ne 0) then put 'TEST FAILED';
      s.delete();
      end;
   end;
enddata;
run;
quit;

proc print data=testdata1; quit;
proc print data=testdata2; quit;
proc print data=testdata3; quit;
proc print data=testdata4; quit;
proc print data=testdata5; quit;

The following tables are generated.
