What’s New in SAS 9.4 Scalable Performance Data Engine

Overview

The following are new or enhanced for SAS 9.4:

- ALIGN= data set option
- COMPRESS= LIBNAME statement option
- ENCRYPT=AES (Advanced Encryption Standard) data set option
- ENCRYPTKEY= data set option
- IOBLOCKSIZE= LIBNAME statement option
- In SAS 9.4M1, SPD Engine does not support DLDMGACTION=NOINDEX, but does support ABORT, FAIL, PROMPT, and REPAIR.
- In SAS 9.4M3, a new section named “Accessing SPD Engine Files on Another Host” on page 3 was added.
- In SAS 9.4M5, SPD Engine supports cross-environment data access (CEDA).

SPD Engine Data Set Options

New and enhanced SPD Engine data set options enable you to do the following:

- The new ALIGN= data set option specifies variable alignment. For more information, see “ALIGN= Data Set Option” on page 58.
- The ENCRYPT= data set option has been enhanced to include the AES algorithm for stronger security. For more information, see “Encrypting SPD Engine Data Sets” on page 24.
- The new ENCRYPTKEY= data set option specifies the key value for AES encryption. For more information, see “ENCRYPTKEY= Data Set Option” on page 75.
SPD Engine LIBNAME Statement Options

The new LIBNAME statement options enable you to do the following:

- In SAS Viya 3.5, the SPD Engine INENCODING LIBNAME option is available. This version of the INENCODING option does not work the same as the Base SAS INENCODING option.

- In SAS 9.4M2, the new IOBLOCKSIZE= LIBNAME statement option enables you to specify the size in bytes of a block of observations to be used in an I/O operation. For more information, see “IOBLOCKSIZE= LIBNAME Statement Option” on page 45.

- In SAS 9.4M2, the COMPRESS= LIBNAME statement option enables you to compress an SPD Engine data set on disk as it is being created.

Cross-Environment Data Access (CEDA)

In SAS 9.4M5, SPD Engine supports cross-environment data access (CEDA) with additional restrictions. In SAS 9.4M6 and SAS Viya 3.3, CEDA is supported in the FEDSQL procedure, FedSQL language, DS2 procedure, and DS2 language. See “Accessing SPD Engine Files on Another Host” on page 3.
Introduction to the SPD Engine

The SPD Engine is designed for high-performance data delivery. It enables an application rapid access to SAS data for processing. The SPD Engine delivers data to applications rapidly because it organizes the data into a streamlined file format that takes advantage of multiple CPUs to perform parallel input functions.
The SPD Engine uses threads to read blocks of data very rapidly and in parallel. Tasks are performed in conjunction with an operating system that enables threads to execute on any of the computer’s available CPUs. Although threaded Read tasks are an important part of the SPD Engine functionality, the real power of the SPD Engine comes from how it structures SAS data. The SPD Engine organizes data into a file format that includes partitioning the data. This data structure permits threads, running in parallel, to perform Read tasks efficiently.

The SPD Engine is a high-speed alternative to the default Base SAS engine for processing very large data sets. It reads data sets that contain billions of observations. For example, this includes data sets that expand beyond the size limit imposed by some operating systems and data sets that SAS analytic software and procedures must process faster.

The SPD Engine boosts performance in the following ways:

- support for hundreds of gigabytes of data
- scalability on symmetric multiprocessor (SMP) computers and massively parallel processor (MPP) computers
- parallel WHERE selections
- parallel loads
- parallel index creation
- parallel data delivery to applications
- automatic sorting on BY statements

The SPD Engine runs on UNIX, Windows, and z/OS (zFS file system only). The SPD Engine is not supported on the CAS server.

Note: Be sure to visit the Scalability and Performance Community focus area at http://support.sas.com/rnd/scalability for more information about scalability. For system requirements, visit the Install Center at http://support.sas.com/documentation/installcenter.

---

**SPD Engine Compatibility**

**Upgrading SAS 9**

If you upgrade from a previous release of SAS 9, you do not need to migrate your data sets if you stay in the same operating environment. If you upgrade across hosts, such as from a 32-bit to a 64-bit Windows operating environment, you might experience reduced performance or other restrictions due to cross-environment data access (CEDA). SPD Engine supports CEDA in SAS 9.4M5 and later.

To migrate your data sets, use a tool such as the COPY procedure or the CPORT and CIMPORT procedures. (SPD Engine does not support the MIGRATE procedure.) For more information, see the Base SAS Procedures Guide.
Accessing SPD Engine Files on Another Host

The SPD Engine has full Read and Write access to SPD Engine files on another host if they are in the same operating environment family. In SAS 9.4M5 and later, the SPD Engine has Read-Only access to data sets in a different operating environment family, under cross-environment data access (CEDA).

You are advised to access the data set at the location where it was created. For example, you can access files directly via a Network File System (NFS). Do not use operating system commands to move an SPD Engine data set. An SPD Engine data set that is moved by using operating system commands is not usable if the data set was created using alternate paths for data partition or index partition storage. See “DATAPATH= LIBNAME Statement Option” on page 38 and “INDEXPATH= LIBNAME Statement Option” on page 43.

Here are the operating environment families for the SPD Engine. In the following table, each row contains a group of operating environments that are compatible with each other. CEDA is used only when you create a file with a data representation in one row and process the file under a data representation of another row. For example, a data set created under Linux for x64 can be used under Solaris for x64 without invoking CEDA. However, a data set created under 32-bit SAS for Windows does invoke CEDA when the data set is processed under 64-bit SAS for Windows.

Table 1.1 Compatibility across Environments for the SPD Engine

Cross-Environment Data Access (CEDA) in SPD Engine

When CEDA processing is used, SAS writes a note to the log to inform you. CEDA processing is automatic and transparent, but you must be aware of the restrictions. For example, indexes are not supported, and the extra processing can reduce performance. For more information, see “Cross-Environment Data Access” in SAS Programmer’s Guide: Essentials.

If you want to avoid CEDA processing, then re-create the data set in your target environment by using a tool such as the COPY procedure or the CPORT and CIMPORT procedures. (SPD Engine does not support the MIGRATE procedure.)

For output processing that re-creates a data file, the SPD Engine behaves differently than the default Base SAS engine regarding file attributes. The encoding and data representation attributes of the current SAS session are used, and the CLONE option of PROC COPY is not supported. For more information, see the Base SAS Procedures Guide.

Additional Restrictions for CEDA in SPD Engine

WHERE expressions are processed by the SAS supervisor. The data is read sequentially (single threaded). The data cannot be read in parallel (multithreaded).

The automatic sort (BYSORT=YES) is not supported for CEDA processing. If a BY statement is issued and the data set is not indexed or in sort order, an error is written to the log.

Indexes are not supported by CEDA under any engine. Under SPD Engine, in addition, you might not be able to delete a data set if its indexes are in an INDEXPATH= location. This restriction is due to the fact that the path specification for UNIX and z/OS operating environments is different from the specification for Windows operating environments. See “INDEXPATH= LIBNAME Statement Option” on page 43.

The following restrictions can make a data set unreadable under CEDA. In addition, these restrictions can prevent you from using a tool such as the COPY procedure or the CPORT and CIMPORT procedures to re-create a data set in the current environment.

- Data files that are in a DATAPATH= location might not be accessible. This restriction is due to the fact that the path specification for UNIX and z/OS operating environments is different from the specification for Windows operating environments. See “DATAPATH= LIBNAME Statement Option” on page 38.

- AES-encrypted data sets have limited support under CEDA. An AES-encrypted SPD Engine data set is accessible if it is created and accessed within one of these operating environment families:
  - among 32-bit Windows and 64-bit Windows
  - among UNIX environments

  For example, an AES-encrypted data set that was created under UNIX cannot be accessed under Windows. If the data cannot be decrypted, then an error is written to the log and the data set is not opened.
In z/OS environments, the SPD Engine does not support CEDA processing of encrypted data sets. In other environments, encrypted data sets created under z/OS are not supported.

For data sets that are processed or created by the SPD Engine under z/OS environments, all CEDA processing is preproduction.

An SPD Engine data set that is moved by using operating system commands might not be usable. You are advised to access the data set at the location where it was created.

Using the SMP Computer

The SPD Engine exploits a hardware and software architecture known as symmetric multiprocessing. An SMP computer has multiple central processing units (CPUs) and an operating system that supports threads. An SMP computer is usually configured with multiple controllers and multiple disk drives per controller. When the SPD Engine reads a data file, it launches one or more threads for each CPU; these threads then read data in parallel from multiple disk drives, driven by one or more controllers per CPU. The SPD Engine running on an SMP computer provides the capability to read and deliver much more data to an application in a given elapsed time.

Reading a data set with an SMP computer that has 5 CPUs and 10 disk drives could be as much as 5 times faster than I/O on a single-CPU computer. In addition to threaded I/O, an SMP computer enables threading of application processes (for example, threaded sorting in the SORT procedure in SAS 9.1 or later).

The exact number of CPUs on an SMP computer varies by manufacturer and model. The operating system of the computer is also specialized; it must be capable of scheduling code segments so that they execute in parallel. If the operating system kernel is threaded, performance is further enhanced because it prevents contention between the executing threads.

As threads run on the SMP computer, managed by a threaded operating system, the available CPUs work together. The synergy between the CPUs and threads enables the software to scale processing performance. The scalability, in turn, significantly increases overall processing speed for tasks such as creating data sets, appending data, and querying the data by using WHERE statements.

Organizing SAS Data Using the SPD Engine

Because the SPD Engine organizes data for high-performance processing, an SPD Engine data set is physically different from a default Base SAS engine data set. The default Base SAS engine stores data in one file that contains both data and descriptor (metadata). The SPD Engine creates multiple files for each data set. Each of these files is called a component file. The files can span volumes, but are referenced as one data set. Each filename consists of the data set name, the filetype, and an alphanumeric identifier. See also “SPD Engine Component File Naming Conventions” on page 26.
Every SPD Engine data set has a metadata file with the .mdf filetype embedded in the filename. Usually, an SPD Engine data set has only one .mdf file. The .mdf file stores the pathnames of the data set's other component files.

If you index a data set, the SPD Engine creates a hybrid index. Each index is stored in two files, with .hbx and .idx filetype embedded in the filename.

The data component of an SPD Engine data set can be several files (partitions) per path or device, with .dpf filetype. Each of these partitions is a fixed length, specified when you create the data set.

Comparing the Default Base SAS Engine and the SPD Engine

Overview of Comparisons

Default Base SAS engine data sets and SPD Engine data sets have many similarities. They both store data in a SAS library, which is a logical collection of files. Because the SPD Engine data libraries can span devices and file systems, the SPD Engine is ideal for use with very large data sets. Also, the SPD Engine enables you to specify separate directories, or devices, for each component in the LIBNAME statement. “Overview of Comparisons” on page 6 provides details about designing and setting up the SPD Engine data libraries.

The SPD Engine Libraries and File Systems

An SPD Engine library can contain data files, metadata files, and index files. The SPD Engine does not support catalogs, SAS views, MDDBs, or other utility (byte) files.

The SPD Engine uses the zFS file system for z/OS.

Utility File Workspace

Utility files are generated during the SPD Engine operations that need extra space (for example, when creating parallel indexes or when sorting very large files). Default locations exist for all platforms but, if you have large amounts of data to process, the default location might not be large enough. The SPD Engine system option SPDEUTILLOC= lets you specify a set of file locations in which to store utility scratch files. For more information, see “SPDEUTILLOC System Option” on page 112.
Storing Temporary Data Sets

To create a library to store interim data sets, specify the SPD Engine option TEMP= in the LIBNAME statement. If you want current applications to refer to these interim files using one-level names, specify the library on the USER= system option.

The following example code creates a user libref for interim data sets. It is deleted at the end of the session.

```sas
libname user spde 'SAS-library' temp=yes;
```

data a; x=1;
run;
proc print data=a;

The USER= option can be set in the configuration file so that applications that reference interim data sets with one-level names can run in the SPD Engine.

Differences between the Default Base SAS Engine Data Sets and the SPD Engine Data Sets

The following chart compares the SPD Engine capabilities to default Base SAS engine capabilities.

</table>
Interoperability of the Default Base SAS Engine and the SPD Engine Data Sets

Default Base SAS engine data sets must be converted to the SPD Engine format so that the SPD Engine can access them. You can convert the default Base SAS engine data sets easily using the COPY procedure, the APPEND procedure, or a DATA step. (PROC MIGRATE cannot be used.) In addition, most of your existing SAS programs can run on the SPD Engine files with little modification other than to the LIBNAME statement. Chapter 2, “Creating and Loading SPD Engine Files,” on page 13 provides details about converting default Base SAS engine data sets to the SPD Engine format.

Sharing the SPD Engine Files

The SPD Engine supports member-level locking, which means that multiple users can have the same SPD Engine data set open for INPUT (read-only). However, if an SPD Engine data set has been opened for update or for index creation, then only that user can access it.

Features That Enhance I/O Performance

Overview of I/O Performance Enhancements

The SPD Engine has several features that enhance I/O performance. These features can dramatically increase the performance of I/O bound applications, in which large amounts of data must be delivered to the application for processing.
Multiple Directory Paths

You can specify multiple directory paths and devices for each component type because the SPD Engine can reference multiple physical files across volumes as a single logical file. For very large data sets, this feature circumvents any file size limits that the operating system might impose.

Physical Separation of the Data File and the Associated Indexes

Because each component file type can be stored in a different location, file dependencies are not a concern when deciding where to store the component files. Only cost, performance, and availability of disk space need to be considered.

WHERE Optimization

The SPD Engine automatically determines the best method to use to evaluate observations for qualifying criteria specified in a WHERE statement. WHERE statement efficiency depends on such factors as whether the variables in the expression are indexed. A WHERE evaluation planner is included in the SPD Engine. It can choose the best method to use to optimize evaluation of WHERE expressions that use indexes.

Most WHERE-expression syntax supports multithreaded processing. To know when WHERE processing is single threaded, set the SAS system option MSGLEVEL=I and check the log. Here is an example of a log message:

WARNING: A function, format, or informat has prevented SPD Engine from processing the where clause. The SAS supervisor will process it instead, and no parallel where-clause processing will occur.

Features That Boost Processing Performance

Automatic Sort Capabilities

The SPD Engine's automatic sort capabilities save time and resources for SAS applications that process large data sets. With the SPD Engine, you do not need to invoke the SORT procedure before you submit a SAS statement with a BY clause.
When the SPD Engine encounters a BY clause and the data is not already sorted or indexed on the BY variable, the SPD Engine automatically sorts the data. The automatic sort does not affect the permanent data set or produce a new output data set.

Queries Using Indexes

Large data sets can be indexed to maximize performance. Indexes permit rapid WHERE expression evaluations for indexed variables. The SPD Engine takes advantage of multiple CPUs to search the index component file efficiently.

Note: You cannot create an index or composite index on a variable if the variable name contains any of the following special characters (even with the VALIDMEMNAME=EXTEND option):

*  *  |  \  :  /  <  >  ?  -  .

Parallel Index Creation

In addition, the SPD Engine supports parallel index creation so that indexing large data sets is not time-consuming. The SPD Engine decomposes data set Append or Insert operations into a set of steps that can be performed in parallel. The level of parallelism depends on the number of indexes present in the data set. The more indexes you have, the greater the exploitation of parallelism during index creation. However, index creation requires utility file space and memory resources.

Note: You cannot create an index or composite index on a variable if the variable name contains any of the following special characters (even with the VALIDMEMNAME=EXTEND option):

*  *  |  \  :  /  <  >  ?  -  .

The SPD Engine Options

The SPD Engine works with many default Base SAS engine options. In addition, there are options that are used only with the SPD Engine that enable you to further manage the SPD Engine libraries and processing. See:

- SPD Engine Data Set Options on page 55
- SPD Engine LIBNAME Statement Options on page 31
- SPD Engine System Options on page 103

Introduction for Creating and Loading SPD Engine Files

This section provides details about allocating SPD Engine libraries and creating and loading SPD Engine data and indexes. Performance considerations related to these tasks are also discussed.

Allocating the Library Space

How to Allocate the Library Space

To realize performance gains through SPD Engine’s partitioned data read and threading capabilities, the SPD Engine libraries must be properly configured and managed. Optimally, a SAS system administrator performs these tasks.

An SPD Engine data set requires a file system with enough space to store the various component files. Often that file system includes multiple directories for these components. Usually, a single directory path (part of a file system) is constrained by a volume limit for the file system as a whole. This limit is the maximum amount of disk space configured for the file system to use.

Within this maximum disk space, you must allocate enough space for all of the SPD Engine component files. Understanding how each component file is handled is critical to estimating the amount of storage that you need in each library.

Configuring Space for All Components in a Single Path

In the simplest SPD Engine library configuration, all of the SPD Engine component files (data files, metadata files, and index files) can reside in a single path called the primary path. The primary path is the default path specification in the LIBNAME statement. The following LIBNAME statement sets up the primary file system for the MyLib library:

```
libname mylib spde '/disk1/spdedata';
```

Because there are no other path options specified, all component files are created in this primary path. Storing all component file types in the primary path is simple and works for very small data sets. It does not take advantage of the performance boost that storing components separately can achieve, nor does it take advantage of multiple CPUs.
Note: The SPD Engine requires complete pathnames to be specified.

Configuring Separate Library Space for Each Component File Type

Most sites use the SPD Engine to manage very large amounts of data, which can have thousands of variables and some of them indexed. At these sites, separate storage paths are usually defined for the various component types. In addition, using disk striping and RAID (Redundant Array of Independent Disks) can be very efficient. For more information, see “SPD Engine Disk I/O Setup” in Scalability and Performance at http://support.sas.com/md/scalability/spde/setup.html.

The metadata component files for all data sets in a library must reside in the primary path.

In addition, specifying separate paths for the data component files and index component files provides performance gains. You specify separate paths because the Read load is distributed across disk drives. Separating the data and index component files helps prevent disk contention and increases the level of parallelism that can be achieved, especially in complex WHERE evaluations. The following example code specifies a primary path for the metadata component files. The code uses the DATAPATH= option on page 38 and the INDEXPATH= option on page 43 to specify additional, separate paths for the data and index component files:

libname all_users spde '/disk1/metadata'
   datapath= ('/disk2/userdata' '/disk3/userdata')
   indexpath= ('/disk4/userindexes' '/disk5/userindexes');

The metadata component files are stored on disk1, which is the primary path. The data component files are on disk2 and disk3, and the index component files are on disk4 and disk5. For all path specifications, you must specify the complete pathname.

CAUTION
The primary path must be unique for each library. If two librefs are created with the same primary path but with differences in the other paths, data can be lost. You cannot use NFS in any path other than the primary path.

Note: If you are planning to store data in locally mounted drives and to access the data from a remote computer, use the remote pathname when you specify the LIBNAME. If /data01 and /data02 are locally mounted drives on the localA computer, use the pathnames /nfs/localA/data01 and /nfs/localA/data02 in the LIBNAME statement.

Anticipating the Space for Each Component File

To properly configure the SPD Engine library space, you need to understand the relative sizes of the SPD Engine component files. The following information provides
a general overview. For more information, see “SPD Engine Disk I/O Setup” in Scalability and Performance at http://support.sas.com/rnd/scalability/spde/setup.html.

Metadata component files are relatively small files, but the primary path that you specify must be large enough to contain all of the metadata component files for the library. Metadata component files cannot grow beyond the space available in the path.

Index component files (both .idx and .hbx) can be medium to large, depending on the number of distinct values in each index and whether the index is a single or composite index. When an index component file grows beyond the space available in the current file path, a new index component file is created in the next path.

Data component files can be numerous, depending on the amount of data and the partition size specified for the data set. Each data partition is stored as a separate data component file. The size of the data partition is specified in the PARTSIZE= LIBNAME statement option on page 47 or in the PARTSIZE= data set option on page 89. Data component files are the only component files for which you can specify a partition size.

---

Storage of the Metadata Component Files

Metadata Component Files

The metadata component file for an SPD Engine data set stores the descriptive information about the data set and the pathnames to its constituent data component files and index component files. This concept is very important to understand because it directly affects whether you can add data sets (with their associated metadata component files) to the library.

The metadata component files for all of the data sets in a library must reside in the same location specified in the primary path. In effect, the files in the primary path act like a directory to the entire library. When an SPD Engine data set is accessed, the SPD Engine first opens the data set’s metadata component file to determine its attributes and to determine whether it can access all of its other component files. If a new data set for a library is created, and the space in the primary path is full, the SPD Engine cannot begin creating the metadata component file in that path, and the Create operation fails with an appropriate error message. To successfully create a new data set in this case, you must either free space in the primary path or assign a new library and copy some or all of the data sets to the new library. Data component files and index component files do not have that limitation. You can specify additional space at a later time for data component files and index component files.

Certain actions cause metadata component files to grow to exceed the file size or space limitations. In that case, the SPD Engine creates another partition of the metadata component file to accommodate the overflow. New metadata partitions can reside in the primary path or in the paths specified in the “METAPATH= LIBNAME Statement Option” on page 47. You cannot use the METAPATH= option to create space for a new data set’s first metadata partition. The METAPATH= option specifies space for only metadata component files beyond the first one.
Storage of the Index Component Files

An index component file is stored based on overflow space. When an index component file grows to exceed the file size or space limitations, the SPD Engine creates another partition of the index component file to accommodate the overflow. When several file paths are specified with the INDEXPATH= option, index component files are created in the first available space, and then they overflow to the next path when the previous path is filled. Unlike metadata component files, index component files do not have to be in the primary path.

Storage of the Data Component Files

The data component files are the only files for which you can specify the partition size. Partitioned data can be processed in threads easily, taking full advantage of multiple CPUs on your computer. The partition size for the data component file is fixed. It is set when the data set is created. The default is 128 megabytes, but you can specify a different partition size using the PARTSIZE= option. Performance depends on appropriate partition sizes. You are responsible for knowing the sizes and uses of the data. SPD Engine data sets can be created with a partition size that results in a balanced number of observations. (For more information, see “PARTSIZE= Data Set Option” on page 89 and “PARTSIZE= LIBNAME Statement Option” on page 47. Many data partitions can be created in each data path for a given data set. The SPD Engine uses the file paths that you specify with the DATAPATH= option to distribute partitions in a cyclic fashion. The SPD Engine creates the first data partition in one of the specified paths, the second partition in the next path, and so on. The SPD Engine continues to cycle through the file paths as many times as needed until all data partitions for the data set are stored. The file path for the first partition is selected at random. Assume that you specify the following in your LIBNAME statement:

```
datapath=('/data1' '/data2')
```

The SPD Engine stores the first partition in /DATA1, the second partition in /DATA2, the third partition in /DATA1, and so on. Cyclical distribution of the data partitions creates disk striping, which can be highly efficient. Disk striping is discussed in detail in “SPD Engine Disk I/O Setup” in Scalability and Performance at http://support.sas.com/rnd/scalability/spde/setup.html.

Initial Set of Paths

In the following example, the LIBNAME statement specifies the MyLib directory for the primary path. This path is used to store the metadata partitions. Other devices and directories are specified to store the data and index partitions.

```
libname myref spde 'Mylib'
   datapath=('/mydisk30' '/mydisk31')
   indexpath=('/mydisk36');
```

Assuming that all of the data sets created in the MyLib library were large enough to have several data partitions, they will all have their metadata in MyLib, their data in /mydisk30 and /mydisk31, and any indexes in /mydisk36. This specifically means that the metadata component files for those data sets include those pathnames.
Adding Subsequent Paths

Later, if more space is needed (for example, for appending more data), additional devices can be added for the data and index partitions, as in the following example:

```plaintext
libname myref spde 'Mylib'
  datapath=('/mydisk30' '/mydisk31' '/mydisk32')
  indexpath=('/mydisk36' '/mydisk37');
```

All of the data sets created with the MyLib library will have their metadata in MyLib, their data in one or more of the three paths, and any indexes in /mydisk36 or /mydisk37. If data was appended to an existing data set, the new data goes in one or more of the three paths and the metadata component file is updated accordingly.

If one or more of the data or index partitions do not have much free space, you can exclude them in the LIBNAME statement the next time you specify it:

```plaintext
libname myref spde 'Mylib'
  datapath=('/mydisk31' '/mydisk32' '/mydisk33')
  indexpath=('/mydisk37' '/mydisk38');
```

The SPD Engine is still able to access data sets that use the excluded paths because the data sets' metadata includes all of the used paths.

Omitting Paths

If you need to read only the data sets in a library, then because all of the necessary path information is already in the metadata component files, you can specify the LIBNAME statement without the extra DATAPATH= and INDEXPATH= options:

```plaintext
libname myref spde 'Mylib';
```

### Renaming, Copying, or Moving Component Files

**CAUTION**

Do not rename, copy, or move an SPD Engine data set or its component files using operating system commands.

You should always use the COPY procedure to copy SPD Engine data sets from one location to another or the DATASETS procedure to rename or delete SPD Engine data sets.

### Efficiency Using Disk Striping and Large Disk Arrays

Your system might have a file creation utility that enables you to override the file system limitations and create file systems (volumes) greater than the space on a single disk. You can use this utility to allocate SPD Engine libraries that span
Multiple disk devices, such as RAID. RAID configurations use a technique called disk striping that can significantly enhance I/O. For more information about disk striping and RAID, see “SPD Engine Disk I/O Setup” in Scalability and Performance at http://support.sas.com/rnd/scalability/spde/setup.html.

Note: If you are using Hadoop Distributed File System (HDFS) for storage, see SAS SPD Engine: Storing Data in the Hadoop Distributed File System.

Converting Default Base SAS Engine Data Sets to SPD Engine Data Sets

Using the COPY and APPEND Procedures

You can convert existing default Base SAS engine data sets to SPD Engine data sets using the following methods:
- PROC COPY
- PROC APPEND

Some attributes are dropped when the data set is created in the SPD Engine format. The following chart of file characteristics indicates whether the characteristic can be retained or dropped or if conversion results in an error.

Table 2.1 Conversion Results for Base SAS Engine Data Set Characteristics

<table>
<thead>
<tr>
<th>Base SAS Engine Data Set Characteristic</th>
<th>Conversion Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indexes</td>
<td>Rebuilt in SPD Engine (in parallel if ASYNCINDEX=YES)</td>
</tr>
<tr>
<td>COMPRESS=YES</td>
<td>CHAR</td>
</tr>
<tr>
<td>ENCRYPT=YES</td>
<td>AES</td>
</tr>
<tr>
<td>Integrity constraints</td>
<td>Dropped without error</td>
</tr>
<tr>
<td>Audit file</td>
<td>Dropped with warning</td>
</tr>
</tbody>
</table>
Converting Default Base SAS Engine Data Sets Using PROC COPY

To create an SPD Engine data set from an existing default Base SAS engine data set, you can simply use the COPY procedure. The PROC COPY statement copies the default Base SAS engine-formatted data set Local.Racquets to a new SPD Engine-formatted data set Sport.Racquets:

```sas
libname sport spde 'conversion_area';
proc copy in=local out=sport;
   select racquets;
run;
```

Even though the indexes on the default Base SAS engine data set are automatically regenerated as SPD Engine indexes (both .hdx and .idx files), they are not created in parallel because the data set option ASYNCINDEX=NO is the default.

If an SPD Engine data set is encrypted, only the data component files are encrypted. The metadata component files and both index component files are not encrypted.

Converting Default Base SAS Engine Data Sets Using PROC APPEND

Use the APPEND procedure when you need to specify data set options for a new SPD Engine data set.

The following example creates an SPD Engine data set from a default Base SAS engine data set using PROC APPEND. The ASYNCINDEX=YES data set option specifies to build the indexes in parallel. The PARTSIZE= option specifies to create partitions of 100 megabytes.

```sas
libname spdelib spde 'new_data';
libname somelib 'old_data';
proc append base=spdelib.cars (asyncindex=yes partsize=100)
   data=somelib.cars;
run;
```
Creating and Loading New SPD Engine Data Sets

To create a new SPD Engine data set, you can use the DATA step, any PROC statement\(^1\) with the OUT= option, or PROC SQL with the CREATE TABLE= option.

The following example uses the DATA step to create a new SPD Engine data set, CARDATA.OLD_AUTOS in the report_area directory.

```sas
libname cardata spde '/report_area';

data cardata.olds_autos(compress=no encrypt=yes pw=secret);
  input year $4. @6 manufacturer $12. @18 model $12. @31 body_style $5. @37
    engine_liters @42 transmission_type $1. @45 exterior_color
    $10. @55 mileage @62 condition;

datalines;
1966 Ford        Mustang      conv  3.5  M  white     143000 2
1967 Chevrolet   Corvair      sedan 2.2  M  burgundy   70000 3
1975 Volkswagen  Beetle       2door 1.8  M  yellow     80000 4
1987 BMW         325is        2door 2.5  A  black     110000 3
1962 Nash        Metropolitan conv 1.3  M  red       125000 3
;
run;
```

**Note:** Encryption and compression are mutually exclusive in SPD Engine. You can use the ENCRYPT= option only when you are creating an SPD Engine data file that is not compressed. You cannot create an SPD Engine data set with both encryption and compression.

Updates to a Compressed SPD Engine Data Set

When COMPRESS=YES | BINARY | CHAR, the SPD Engine compresses, by blocks, the data component file as it is created. If you copy a default Base SAS engine data set that is both compressed and encrypted, the encryption is retained, but the compression is dropped.

Once a compressed data set is created, you cannot change its block size. The compressed blocks are stored linearly, with no spaces between the blocks. The following figure illustrates how the blocks are initially stored on the disk:

---

1. except PROC MIGRATE
If updates to the data set after compression require more space than what is available in a block, SPD Engine creates a new block fragment to hold the overflow. If further updates again cause overflows, new block fragments are created, forming a chain. The following figure illustrates how the updates create a chain of blocks on the disk:

Performance is affected if the chains get too long. To remove the chains and resize the block, you must copy the data set to a new data set. Specify **IOBLOCKSIZE=** on page 83 to the block size appropriate for the output data set.

When the data set is expected to be updated frequently, it is recommended that you use **PADCOMPRESS=** on page 88. SPD Engine creates a padded space for each block, instead of creating new block fragments. The following figure illustrates how each block has padded space for updates:
If updates to the data set after compression require more space than what is available in a block, SPD Engine uses the padded space for each block. New block fragments are not created. The following figure illustrates how the updates decrease the padded space:

*Figure 2.4  Compressed Padded Blocks with Updates*

The CONTENTS procedure prints information about the compression. The following example explains the compressed info fields in the CONTENTS procedure output:

*Output 2.1  CONTENTS Procedure Compressed Info Output*

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of compressed blocks</td>
<td>202</td>
</tr>
<tr>
<td>Raw data blocksize</td>
<td>32736</td>
</tr>
<tr>
<td>Number of blocks with overflow</td>
<td>5</td>
</tr>
<tr>
<td>Max overflow chain length</td>
<td>3</td>
</tr>
<tr>
<td>Block number for max chain</td>
<td>80</td>
</tr>
<tr>
<td>Min overflow area</td>
<td>87</td>
</tr>
<tr>
<td>Max overflow area</td>
<td>181</td>
</tr>
</tbody>
</table>

Number of compressed blocks
- number of compressed blocks that are required to store data.

Raw data blocksize
- compressed block size in bytes calculated from the size specified in the IOBLOCKSIZE= data set option.

Number of blocks with overflow
- number of compressed blocks that needed more space. When data is updated and the compressed new block is larger than the compressed old block, an overflow block fragment is created.

Max overflow chain length
- largest number of overflows for a single block. For example, the maximum overflow chain length would be 2 if a compressed block was updated and became larger, and then updated again to a larger size.
Encrypting SPD Engine Data Sets

SPD Engine Encryption Overview

*Encryption* is the transformation of intelligible data (plain text) into an unintelligible form (cipher text) by a mathematical process. The cipher text is translated back into plain text when you apply the appropriate password or ENCRYPTKEY that is necessary for decrypting (unlocking) the cipher text.

Encryption helps protect information on-disk and in-transit:

- **Over-the-wire** encryption protects SAS data while in transit.
- **On-disk** encryption protects data at rest.

There are two types of algorithms that SAS uses to encrypt SPD Engine data sets at rest:

- **SAS Proprietary**
  - provided within Base SAS software. This algorithm provides a medium level of security. You use the ENCRYPT=YES data set option to invoke this encryption.
- **AES (Advanced Encryption Standard)**
  - is a *block cipher* that encrypts data in blocks of 128 bits by using a 256-bit key. You use SAS/SECURE software, which is included with default Base SAS software. You use the ENCRYPT=AES data set option to invoke this encryption.

</tbody>
</table>

---

### SAS Proprietary Algorithm

SAS Proprietary uses a 32-bit fixed encoding and is appropriate only for preventing accidental exposure of information. SAS Proprietary is licensed with Base SAS software and is available in all deployments.

---

### AES Algorithm

The AES algorithm is a block cipher that encrypts data in blocks of 128 bits by using a 256-bit key. AES encryption uses SAS/SECURE software, which is included with Base SAS software. For more information about SAS/SECURE, see *Encryption in SAS*.

#### Note:
AES encryption is not supported in OpenVMS on 64-bit Itanium.

AES encryption, which provides enhanced encryption for SPD Engine data sets, is available in SAS 9.4 and later. If you want an encrypted SPD Engine data set, you must use the ENCRYPTKEY= data set option with ENCRYPT=AES when you create the SPD Engine data set. The SPD Engine does not support ENCRYPT=AES2.

#### Note:
You cannot change the ENCRYPTKEY= value on an AES-encrypted SPD Engine data set without re-creating the data set.

The following rules apply to AES encryption of SPD Engine data sets:

- You must use the ENCRYPTKEY= data set option when creating a data set with AES encryption.
- To copy an AES-encrypted SPD Engine data set, the output engine must support AES encryption. Otherwise, the data set is not copied.
- If a default Base SAS data set with AES2 encryption is copied to create a new SPD Engine data set, the encryption converts to AES. A warning is written to the log.
- Releases before SAS 9.4 cannot use an AES-encrypted SPD Engine data set.
- If the SPD Engine data sets are AES-encrypted, all associated index files are also AES-encrypted. Metadata files are not AES-encrypted.
For more information, see “ENCRYPT= Data Set Option” on page 72 and “ENCRYPTKEY= Data Set Option” on page 75.

SPD Engine Component File Naming Conventions

When you create an SPD Engine data set, many component files can also be created. SPD Engine component files are stored with the following naming conventions:

\[
\begin{align*}
&\text{filename.mdf.0.p#.v#.spds9} \\
&\text{filename.dpf.fuid.p#.v#.spds9} \\
&\text{filename.idxsuffix.fuid.p#.v#.spds9} \\
&\text{filename.hbxsuffix.fuid.p#.v#.spds9}
\end{align*}
\]

- **filename**: valid SAS filename.
- **mdf**: identifies the metadata component file.
- **dpf**: identifies the partitioned data component files.
- **p#**: is the partition number.
- **v#**: is the version number.\(^1\)
- **fuid**: is the unique file ID, which is a hexadecimal equivalent of the primary (metadata) path.
- **hbxsuffix**: is one of two files for each index (if the table is indexed), where \textit{suffix} is the name of the index.
- **idxsuffix**: is the second of the two files for each index (if the table is indexed), where \textit{suffix} is the name of the index.
- **spds9**: denotes a SAS 9 SPD Engine component file.

Table 2.2 shows the data set component files that are created when you use this LIBNAME statement and DATA step:

```sas
libname sample spde '/DATA01/SAS-library' datapath=(''/DATA01/mydir' '/DATA02/mydir') indexpath=(''/IDX1/mydir');
data sample.mine(index=(ssn));
do i=1 to 100000;
```

---

\(^1\) The version number increases only when the data set is updated, that is, when the data set is opened in UPDATE mode. Operations such as PROC SORT that replace the data set reset the version number to one, instead of incrementing it.
Table 2.3  Data Set Component Files

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mine.mdf.0.0.0.spds9</td>

<td>index file for variable SSN</td>
</tr>
</tbody>
</table>

Efficient Indexing in the SPD Engine

Parallel Indexing

Indexes can improve the performance of WHERE expression processing and BY expression processing. The SPD Engine enables the rapid creation and update of indexes because it can process them in parallel.

The hybrid indexes of SPD Engine are appropriate for tables of varying sizes and data distributions. Indexes can improve performance in use cases such as table joins and WHERE clause evaluations.

Parallel Index Creation

You can create indexes on your SPD Engine data in parallel, asynchronously. To enable asynchronous parallel index creation, use the "ASYNCINDEX= Data Set Option" on page 62.

Use this option with the DATA step INDEX= option and with the PROC DATASETS MODIFY statement when creating a data set that has several indexes. Either method enables all of the declared indexes to be populated from a single scan of the data set.
The following example shows indexes created in parallel using the DATA step. A simple index is created on variable X and a composite index is created on variables A and B.

```plaintext
data foo.mine(index=(x y=(a b)) asyncindex=yes);
ex=1;
a="Doe";
b=20;
run;
```

To create multiple indexes in parallel, you must allocate enough utility disk space to create all of the key sorts at the same time. You must also allocate enough memory space. Use the `SPDEUTILLOC=` system option on page 112 to allocate disk space and `SPDEINDEXSORTSIZE` system option on page 109 in the configuration file or at invocation to allocate additional memory.

The DATASETS procedure has the flexibility to enable batched parallel index creation by using multiple MODIFY groups. Instead of creating all of the indexes at once, which would require a significant amount of space, you can create the indexes in groups as shown in the following example:

```plaintext
proc datasets lib=main;
    modify patients(asyncindex=yes);
        index create number;
        index create class;
    run;
    modify patients(asyncindex=yes)
        index create lastname firstname;
    run;
    modify patients(asyncindex=yes);
        index create fullname=(lastname firstname);
        index create class_sex=(class sex);
    run;
quit;
```

Indexes Number and Class are created in parallel, indexes LastName and FirstName are created in parallel, and indexes FullName and Class_Sex are created in parallel.

---

**Parallel Index Updates**

The SPD Engine also supports parallel index updating during data set Append operations. Multiple threads enable updates of the data store and index files. The SPD Engine decomposes a data set Append or Insert operation into a set of steps that can be performed in parallel. The level of parallelism attained depends on the number of indexes in the data set. As with parallel index creation, this operation uses memory and disk space for the key sorts that are part of the index append processing. Use system options `SPDEINDEXSORTSIZE=` to allocate memory and `SPDEUTILLOC=` to allocate disk space.

---

**Note:** The `ASYNCINDEX` option is not valid for parallel index updates.
Backing Up SPD Engine Files

When you back up an SPD Engine data set, remember the following requirements:

- Ensure that all of the files that make up the data set are backed up together, at the same time, even if they reside on different disks or file systems.
- Do not back up the data set while any files are being updated.
- After each backup, run a test to verify that the backup was a success.

Storing SPD Engine Data in HDFS

The SPD Engine can read, write, and update data in HDFS. Storing SPD Engine data in HDFS provides a low-cost alternative to storing big data. You can use the SPD Engine with standard SAS applications to retrieve data for analysis, perform administrative functions, and update data.
## Introduction to the SPD Engine LIBNAME Statement

Specifying LIBNAME options for the SPD Engine is the same as specifying LIBNAME options for the default Base SAS engine or SAS/ACCESS engines. This section provides details about LIBNAME options that are used only with the SPD Engine. The default Base SAS engine LIBNAME options that affect the SPD Engine are also listed.

When using the options, remember that the value of the data set option overrides the value of its corresponding LIBNAME option.
LIBNAME Statement: SPD Engine

Associates or disassociates a SAS library with a libref (a shortcut name) for the SPD Engine.

Valid in: Base SAS
Category: Data Access
See: To clear one or all librefs and list the characteristics of a SAS library, see the LIBNAME statement in *SAS Global Statements: Reference*.

Syntax

```
LIBNAME libref SPDE 'full-primary-path' <options> ;
```

Other Argument Group

**Note:** Operating Environment Information: A valid library specification and its syntax are specific to your operating environment. For details, see the SAS documentation for your operating environment.

**libref**

a name that is up to eight characters long and that conforms to the rules for SAS names.

**'full-primary-path'**

the complete pathname of the primary path for the SPD Engine library. The name must be recognized by the operating environment. Enclose the name in single or double quotation marks. Unless the DATAPATH= and INDEXPATH= options are specified, the index and data components are stored in the same location. The primary path must be unique for each library. Librefs that are different but reference the same primary path are interpreted to be the same library and can result in lost data.

**options**

one or more SPD Engine LIBNAME statement options.

Here is a list that contains reference information for all LIBNAME options that are valid for the SPD Engine LIBNAME statement.

Some of these LIBNAME options are also data set options. As in the default Base SAS engine, data set options take precedence over corresponding LIBNAME options if both options are set.
ACCESS= LIBNAME Statement Option

Determines the access level of the data source.

Default: none
Engine: SPD Engine only

Syntax

ACCESS=READONLY

Required Argument

READONLY
specifies that data sets can be read, but not updated or created.

Details

Using this option prevents writing to the data source. If this option is omitted, data sets can be read, updated, and created if you have the necessary data source privileges.

BYSORT= LIBNAME Statement Option

Specifies the SPD Engine to perform an automatic sort when it encounters a BY statement.

Default: YES
Interaction: “BYNOEQUALS= Data Set Option” on page 63
Engine: SPD Engine only

Syntax

BYSORT=YES | NO

Required Arguments

YES
specifies to automatically sort the data based on the BY variables when a BY statement is encountered instead of sorting the data ahead of time.

NO
specifies not to sort the data based on the BY variables. Specifying NO means that the data must already be sorted before the BY statement. Indexes are not used.

Note: Indexes are not used when BYSORT=NO is set.
Details

DATA or PROC step processing using the default Base SAS engine requires that if there is no index or if the observations are not in order, the data set must be sorted before a BY statement is issued. In contrast, by default, the SPD Engine sorts the data returned to the application if the observations are not in order. Unlike PROC SORT, which creates a new sorted data set, the SPD Engine's automatic sort does not change the permanent data set and does not create a new data set. However, utility file space is used. For more information, see “SPDEUTILLOC System Option” on page 112.

The default is BYSORT=YES. A BYSORT=YES argument enables the automatic sort, which generates the output for the observations in BY group order. If the data set option BYNOEQUALS=YES, then the observations within a group might be written in a different order from the order in the data set. Set BYNOEQUALS=NO to retain data set order.

The BYSORT=NO argument instructs the engine to do nothing to sort the data. The BYSORT=NO argument means that the data must already be sorted before the BY statement. Sorting can be from a previous PROC SORT or from the data set having been created in BY variable order. An error occurs if the data set is not sorted.

When BYSORT=NO, grouped data is delivered to the application in data set order. Indexes are not used to retrieve the observations in BY variable order. The data set option BYNOEQUALS= has no effect when BYSORT=NO.

If you specify the BYSORT= option in the LIBNAME statement, it can be overridden by specifying BYSORT= in the PROC or DATA steps. Set BYSORT=YES in the DATA or PROC step, for input opens, to override BYSORT=NO in the LIBNAME statement. Add BYSORT=YES as a data set option on the step for which you need to use a BY statement that has an index associated with it.

When you use the BYSORT=YES and the IDXWHERE= data set options, the following messages are written to the SAS log if you set the MSGLEVEL=1 SAS system option:

- If IDXWHERE=YES and there is an index on the BY variable, the index is used to order the rows of the table. The following message is written to the SAS log:

  Note: BY ordering was produced by using an index for table tablename.

- If IDXWHERE=NO or IDXWHERE=YES and there is no index on the BY variable, SPD Engine performs an automatic sort to order the rows of the table. The following message is written to the SAS log:

  Note: BY ordering was produced by performing an automatic sort on table tablename.

Comparisons

The BYSORT= data set option overrides the BYSORT= LIBNAME statement option.

Examples:

Example 1: Group Formatting with BYSORT=YES by Default

```sql
libname growth spde 'SAS-library';
data growth.teens;
  input Name $ Sex $ Age Height Weight;
```
Example 2: Using BYSORT=NO in the LIBNAME Statement

In the following example, SAS returns an error because BYSORT=YES was not specified on the DATA or PROC steps to override the BYSORT=NO specification in the LIBNAME statement. Whenever automatic sorting is suppressed (BYSORT=NO), the data must be sorted on the BY variable before the BY statement (for example, by using PROC SORT).

libname growth spde 'SAS-library' bysort=no;
proc print data=growth.teens;
by sex;
run;

Even though the data was not sorted using PROC SORT, no error occurred because BYSORT=YES is the default. The output is shown:

Output 3.1  Group Formatting with BYSORT=YES by Default

ERROR: Data set GROWTH.TEENS is not sorted in ascending sequence.
The current by-group has Sex = M and the next by-group has Sex = F.
NOTE: The SAS System stopped processing this step because of errors.

COMPRESS= LIBNAME Statement Option
Specifies to compress an SPD Engine data set on disk as it is being created.

Restriction: Cannot be used with ENCRYPT=YES or ENCRYPT=AES

Interactions:
"IOBLOCKSIZE= LIBNAME Statement Option" on page 45
"PADCOMPRESS= Data Set Option" on page 88

Engine: SPD Engine only

Syntax
COMPRESS= NO | CHAR | BINARY

Required Arguments
NO
performs no data set compression.

CHAR
specifies that data in an SPD Engine data set be compressed in blocks by using RLE (run-length encoding). RLE compresses data by reducing repeated runs of the same character (including a blank space) to two-byte or three-byte representations.

Alias YES

BINARY
specifies that data in an SPD Engine data set be compressed in blocks by using RDC (Ross Data Compression). RDC combines RLE and sliding window compression to compress the file by representing repeated byte patterns more efficiently.

Note: This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (character and numeric variables).

Details
When you specify COMPRESS=YES | BINARY | CHAR, the SPD Engine compresses, by blocks, the data component file as it is created. To specify the size of the compressed blocks, use the "IOBLOCKSIZE= Data Set Option" on page 83 when you create the data set. To add padding to the newly compressed blocks, specify "PADCOMPRESS= Data Set Option" on page 88 when creating or updating the data set. For more information, see “Updates to a Compressed SPD Engine Data Set” on page 21.
If you are migrating a default Base SAS engine data set that is both compressed and encrypted, the encryption is retained, but the compression is dropped.

The CONTENTS procedure identifies the compress setting. If the data set is compressed, PROC CONTENTS prints information about the compression. The following example explains the Compressed Info fields in the CONTENTS procedure output:

In general, COMPRESS=CHAR provides good compression when single bytes repeat; COMPRESS=BINARY provides good compression when strings of bytes repeat. At the same time, it is more costly to look for strings of bytes that repeat, than to look for single bytes that repeat. For examples, see “Example 1: COMPRESS=CHAR” on page 72 and “Example 2: COMPRESS=BINARY” on page 72.

Output 3.2 PROC CONTENTS Compressed Section

<table>
<thead>
<tr>
<th>- Compressed Info</th>
<th>-</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of compressed blocks</td>
<td>202</td>
</tr>
<tr>
<td>Raw data blocksize</td>

<td>80</td>
</tr>
<tr>
<td>Min overflow area</td>
<td>87</td>
</tr>
<tr>
<td>Max overflow area</td>
<td>181</td>
</tr>
</tbody>
</table>

Number of compressed blocks
number of compressed blocks that are required to store data.

Raw data blocksize
compressed block size in bytes calculated from the size specified in the IOBLOCKSIZE= data set option. It is the largest multiple of the observation length that fits in the block size.

Number of blocks with overflow
number of compressed blocks that needed more space. When data is updated and the compressed new block is larger than the compressed old block, an overflow block fragment is created.

Max overflow chain length
largest number of overflows for a single block. For example, the maximum overflow chain length would be 2 if a compressed block was updated and became larger, and then updated again to a larger size.

Block number for max chain
number of the block containing the largest number of overflow blocks.

Min overflow area
minimum amount of disk space that an overflow requires.

Max overflow area
maximum amount of disk space that an overflow requires.
Accessing compressed files usually requires more processing time. The files have to be decompressed before reading them and, if updating, they have to be compressed again when written to disk.

Comparisons

The COMPRESS= LIBNAME statement option overrides the COMPRESS= system option.

The COMPRESS= data set option overrides the COMPRESS= LIBNAME statement option.

If the COMPRESS= data set option or LIBNAME statement option is not set, then the value of the COMPRESS= system option is used. The COMPRESS= system option default value is NO.

DATAPATH= LIBNAME Statement Option

Specifies a list of paths in which to store data partitions (.dpf) for an SPD Engine data set.

Default: The primary path specified in the LIBNAME statement

Interactions: If cross-environment data access (CEDA) is used, data files that are in a DATAPATH= location might not be accessible. See "Accessing SPD Engine Files on Another Host" on page 3.

"PARTSIZE= LIBNAME Statement Option" on page 47

"PARTSIZE= Data Set Option" on page 89

Engine: SPD Engine Only

Syntax

DATAPATH=('path1' '<path2'>...)

Required Argument

'path'

is a complete pathname in single or double quotation marks within parentheses. Separate multiple arguments with spaces.

Note: The pathnames specified in the DATAPATH= option must be unique for each library. Librefs that are different but reference the same pathnames can result in lost data.

Note: If your data is in the zFS file system, only one path specification is required. The zFS system automatically spreads the partitions across multiple logical volumes.
Details

The SPD Engine creates as many partitions as needed to store all the data. The size of the partitions is set using the PARTSIZE= option, and partitions are created in the paths specified using the DATAPATH= option in a cyclic fashion.

Note: If you are planning to store data in locally mounted drives and access the data from a remote computer, use the remote pathname when you specify the LIBNAME. For example, if /data01 and /data02 are locally mounted drives on the localA computer, use the pathnames /nfs/localA/data01 and /nfs/localA/data02 in the LIBNAME statement.

Example: DATAPATH= for First Partition

The path for the first partition is randomly selected and then continues in a cyclical fashion:

libname mylib spde '/metadisk/metadata'
  datapath=('/disk1/dataflow1' '/disk2/dataflow2' '/disk3/dataflow3');

For example, if /disk2/dataflow2 is randomly selected as the first path, the first partition is located there. The second partition is located in /disk3/dataflow3, the third partition is located in /disk1/dataflow1, and so on.

ENDOBS= LIBNAME Statement Option

Specifies the end observation number in a user-defined range of observations to be processed.

Default: The last observation in the data set

Restrictions: Use ENDOBS= with input data sets only

Cannot be used with the OBS= system or data set option or the FIRSTOBS= system or data set option

Interactions: “ENDOBS= Data Set Option” on page 77

“STARTOBS= LIBNAME Statement Option” on page 50

“STARTOBS= Data Set Option” on page 91

Engine: SPD Engine only

Syntax

**ENDOBS=n**

Required Argument

*n* is the number of the end observation.
Details

By default, the SPD Engine processes all of the observations in the entire data set unless you specify a range of observations with the STARTOBS= and ENDOBS= options. If the STARTOBS= option is used without the ENDOBS= option, the implied value of ENDOBS= is the end of the data set. When both options are used together, the value of ENDOBS= must be greater than the value of STARTOBS=.

In contrast to the default Base SAS engine option FIRSTOBS=, the STARTOBS= and ENDOBS= SPD Engine system options can be used in the LIBNAME statement.

Note: The OBS= system option and the OBS= data set option cannot be used with STARTOBS= or ENDOBS= data set or LIBNAME options.

(See SPD Engine Data Set Options on page 55 for information about using the ENDOBS= data set option in WHERE processing.)

Comparisons

The ENDOBS= data set option overrides the ENDOBS= LIBNAME statement option.

Example: Using the ENDOBS= LIBNAME Statement Option

The following example shows that the STARTOBS= and ENDOBS= options subset the data before the WHERE clause executes. The example prints the four observations that were qualified by the WHERE expression (age >13 in PROC PRINT). The four observations are out of the five observations that were processed from the input data set:

```plaintext
libname growth spde 'SAS-library' endobs=5;
data growth.teens;
  input Name $ Sex $ Age Height Weight;
datalines;
Alfred M 14 69.0 112.5
Carol F 14 62.8 102.5
James M 13 57.3 83.0
Janet F 15 62.5 112.5
Judy F 14 64.3 90.0
Philip M 16 72.0 150.0
William M 15 66.5 112.0
;
proc print data=growth.teens;
  where age >13;
run;
```
IDXBY= LIBNAME Statement Option

Specifies whether to use an index when processing a BY statement in the SPD Engine.

Default: YES

Interactions:
“BYSORT= LIBNAME Statement Option” on page 33
“BYSORT= Data Set Option” on page 67

Engine: SPD Engine only

Syntax
IDXBY=YES | NO

Required Arguments
YES
uses an index when processing indexed variables in a BY statement.

Note: If the BY statement specifies more than one variable or the DESCENDING option, then the index is not used, even if IDXBY=YES.

NO
does not use an index when processing indexed variables in a BY statement.

Note IDXBY=NO performs an automatic sort when processing a BY statement.

Details
When you use the IDXBY= LIBNAME option, make sure that you use BYSORT=YES option and that the BY variable is indexed.

In some cases, you might get better performance from the SPD Engine if you automatically sort the data. To use the automatic sort, BYSORT=YES must be set and you should specify IDXBY=NO.
Set the SAS system option MSGLEVEL=I so that the BY processing information is written to the SAS log. When you use the IDXBY= LIBNAME option and the BYSORT=YES option, the following messages are written to the SAS log:

- If IDXBY=YES and there is an index on the BY variable, the index is used to order the rows of the table. The following message is written to the SAS log:

  NOTE: BY ordering was produced by using an index for table tablename.

- If you use IDXBY=NO, the following message is written to the SAS log:

  NOTE: BY ordering was produced by performing an automatic sort on table tablename.

Comparisons

The IDXBY= data set option overrides theIDXBY= LIBNAME statement option.

Examples:

Example 1: Using the IDXBY=NO LIBNAME Option

```sas
libname permdata spde 'SAS-library' idxby=no;
options msglevel=i;
proc means data=permdata.customer;
  var sales;
  by state;
run;
```

The following message is written to the SAS log:

```
NOTE: BY ordering was produced by performing an automatic sort on table PERMDATA.customer.
NOTE: There were 100 observations read from the data set PERMDATA.CUSTOMER.
```

Example 2: Using the IDXBY=YES LIBNAME Option

The following example uses IDXBY=YES:

```sas
libname permdata spde 'SAS-library' idxby=yes;
options msglevel=i;
proc means data=permdata.customer;
  var sales;
  by state;
run;
```

The following message is written to the SAS log:

```
NOTE: BY ordering was produced by using an index for table PERMDATA.customer.
NOTE: There were 2981 observations read from the data set PERMDATA.CUSTOMER.
```
INDEXPATH= LIBNAME Statement Option

Specifies a path or list of paths in which to store the two types of index component files (.hbx and .idx) associated with an SPD Engine data set.

Default: The primary path specified in the LIBNAME statement

Interaction: If cross-environment data access (CEDA) is used, and indexes are in an INDEXPATH= location, you might not be able to delete the data set. See "Accessing SPD Engine Files on Another Host" on page 3.

Engine: SPD Engine only

Syntax

INDEXPATH=('path1' <'path2'...>)

Required Argument

'path'

is a complete pathname, in single or double quotation marks within parentheses. Separate multiple arguments with spaces.

Note: The pathnames specified in the INDEXPATH= option must be unique for each library. Librefs that are different but reference the same pathnames can result in lost data.

Details

Unlike metadata component files, index component files do not have to be in the primary path. For more information, see "Storage of the Index Component Files" on page 17.

The INDEXPATH= option enables index I/O to be moved to another physical path or device. This enhances performance. For more information, see "Features That Enhance I/O Performance" on page 9.

The SPD Engine creates two index component files in the locations specified. If there are multiple paths specified with the INDEXPATH= option, the first path is randomly selected. If multiple paths are specified, index component files are created in the first path, and then they overflow to the next path when the first path is filled.

Note: If you are planning to store data in locally mounted drives and access the data from a remote computer, use the remote pathname when you specify the LIBNAME. For example, if /data01 and /data02 are locally mounted drives on the localA computer, use the pathnames /nfs/localA/data01 and /nfs/localA/data02 in the LIBNAME statement.
Example: Creating Index Component Files

The following example creates index component files that span the paths /disk1/idxflow1, /disk2/idxflow2, and /disk3/idxflow3.

```sas
libname mylib spde '/metadisk/metadata'
    datapath= ('/disk1/dataflow1' '/disk2/dataflow2' '/disk3/dataflow3')
    indexpath=('/disk1/idxflow1' '/disk2/idxflow2' '/disk3/idxflow3');
```

The path for the first index component files is randomly selected. SAS puts the index component files in the first location until that location is full, and then continues in a cyclical fashion. For example, if /disk2/idxflow2 is randomly selected, the first index component files are located there. When that location is full, the index component files overflow to /disk3/idxflow3, and then to /disk1/idxflow1.

---

**INENCODING= LIBNAME Statement Option**

Overrides and changes the encoding when reading or writing SAS data sets in the SAS library.

**Valid in:** SPD Engine LIBNAME statement

**Requirement:** To use this option in SAS Viya 3.5 or in SAS 9.4M6, you must apply a hot fix.

**Engine:** SPD Engine only

**Note:** The SPD Engine INENCODING option does not function the same way as the Base SAS INENCODING option.

**Syntax**

```
INENCODING= ANY | ASCIIANY | EBCDICANY | encoding-value
```

**Summary of Optional Arguments**

- **ANY**
- **ASCIIANY**
- **EBCDICANY**
- **encoding-value**

**Optional Arguments**

**ANY**

specifies no transcoding between ASCII and EBCDIC encodings.

**Alias** BINARY

**Note** ANY is a synonym for binary. Because the data is binary, the actual encoding is irrelevant.

**ASCIIANY**

specifies that no transcoding occurs, assuming that the mixed encodings are ASCII encodings.
EBCDICANY
specifies that no transcoding occurs, assuming that the mixed encodings are EBCDIC encodings.

encoding-value
specifies an encoding value. For a list of encoding values, see “Encoding Values in SAS Language Elements” in SAS National Language Support (NLS): Reference Guide.

Details

Note: To use the INENCODING option in SAS Viya 3.5, you must apply a hot fix.

The INENCODING= option is used to read SAS data sets in the SAS library.
The INENCODING= value is written to the SAS log when you use the LIST argument.
INENCODING= option is most appropriate when using an existing library that contains mixed encodings. To read a library that contains mixed encodings, you can set INENCODING= to ASCIIANY or EBCDICANY.

IOBLOCKSIZE= LIBNAME Statement Option

Specifies the size in bytes of a block of observations to be used in an I/O operation.

Default: 1,048,576 bytes (1 megabyte)

Range: The minimum block size is 32,768 bytes. The maximum block size is half the size of the SPD Engine data partition file.

Engine: SPD Engine only

Tip: When reading a data set, the block size can significantly affect performance. When retrieving a large percentage of the data, a larger block size improves performance. However, when retrieving a subset of the data such as with WHERE processing, a smaller block size performs better.

Syntax

\texttt{IOBLOCKSIZE=\textit{n}}

Required Argument
\textit{n}
is the size in bytes of a block of observations.

Details

The I/O block size determines the amount of data that is physically transferred together in an I/O operation. The SPD Engine uses blocks in memory to collect the rows to be written to or read from a data component file. The IOBLOCKSIZE= option specifies the size of the block, but the actual size is computed to accommodate the largest number of rows that fit in the specified size of \textit{n} bytes.
Therefore, the actual size is a multiple of the row length. If you set IOBLOCKSIZE= too small to fit two rows, an error is written to the log and the data set is not created.

In a very general sense, the larger the block size, the less I/O. The performance for reading data depends on the I/O operation in the following ways:

- Large blocks are more efficient for sequential I/O. An example of sequential I/O is a PRINT procedure that reads a full data set.
- Small blocks are more efficient for random I/O. An example of random I/O is a BY clause with an index on a data set that is not already sorted on the BY variable. Small blocks can also be more efficient for I/O that is not completely sequential. An example is the SUMMARY procedure, which does not perform a full sequential read.

If you are not certain whether a large or small block size is best, you are encouraged to run performance tests.

If you process a data set in multiple ways, you can specify a different block size based on the operation that you are performing. This feature is available for data sets that are not compressed or encrypted. The details are as follows.

Compressed or encrypted data set

IOBLOCKSIZE= determines how many rows are compressed or encrypted together, which determines the amount of data that is physically transferred for both reading and writing. The block size is a permanent attribute of the data set. To specify a different block size, you must copy the data set to a new data set, and specify a new block size for the new data set. It is possible to specify a different IOBLOCKSIZE= for the Read operation, but that block size affects only the output operation (the results of processing that are returned to the user) and does not affect the size of blocks that are read from disk. Therefore, specifying the same block size for creation and reading usually provides the best performance. When you first create a data set, follow the general guidelines for the majority of its intended use (sequential or random I/O). For random I/O on a compressed data set, use the minimum value during both data set creation and reading.

Not compressed or encrypted

For a data set that is not compressed or encrypted, IOBLOCKSIZE= is not a permanent attribute of the data set. For an uncompressed data set, the block size determines the size of the blocks that are used to read the data from disk to memory. The block size has no effect when writing data to disk. Therefore, you can specify a different block size based on the Read operation that you perform.

For details about the interaction between IOBLOCKSIZE= and PADCOMPRESS=, see “Updates to a Compressed SPD Engine Data Set” on page 21.

Comparisons

The IOBLOCKSIZE= data set option overrides the IOBLOCKSIZE= LIBNAME statement option.

Example: Using IOBLOCKSIZE=

```/*IOBLOCKSIZE set to 64K */
libname employees spde 'SAS-library' ioblocksize=65536;

/*IOBLOCKSIZE set to 512M */
libname sales spde 'SAS-library' ioblocksize= 524288;```
METAPATH= LIBNAME Statement Option

Specifies a list of paths in which to store overflow metadata (.mdf) component files for an SPD Engine data set.

Engine: SPD Engine only

Syntax

\texttt{METAPATH= (}'path1' <'path2'…\texttt{)}

Required Argument

\texttt{path}

is a complete pathname in single or double quotation marks within parentheses. Separate multiple arguments with spaces.

Details

The metadata component files for all of the data sets in a library must reside in the same location specified in the primary path. If a new data set for a library is created, and the space in the primary path is full, the SPD Engine cannot begin creating the metadata component file in the primary path. The Create operation fails with an appropriate error message. For more information, see "Storage of the Metadata Component Files" on page 16.

The METAPATH= option specifies space that is exclusively overflow space for metadata component files. The metadata component file for each data set must reside in the primary path. Overflow populates the METAPATH= location when the primary path is full.

\textbf{Note:} If you are planning to store data in locally mounted drives and access the data from a remote computer, use the remote pathname when you specify the LIBNAME. If \texttt{/data01} and \texttt{/data02} are locally mounted drives on the localA computer, use the pathnames \texttt{nfs/localA/data01} and \texttt{nfs/localA/data02} in the LIBNAME statement.

PARTSIZE= LIBNAME Statement Option

Specifies the maximum size (in megabytes, gigabytes, or terabytes) that the data component partitions can be. The value is specified when an SPD Engine data set is created. This size is a fixed size. This specification applies only to the data component files.

Default: 128 megabytes

Range: 16 megabytes to 8,796,093,022,207 megabytes. You can change the lower limit by setting the MINPARTSIZE= system option.

Interactions: "DATAPATH= LIBNAME Statement Option" on page 38
If you set MINPARTSIZE= larger than the PARTSIZE= default, then you must specify PARTSIZE= equal to or larger than MINPARTSIZE=.

Engine:
SPD Engine only

Syntax

\texttt{PARTSIZE=}\textit{n} | \textit{nm} | \textit{ng} | \textit{nT}

Required Argument

\textit{n} | \textit{nm} | \textit{ng} | \textit{nT}

is the size of the partition in megabytes, gigabytes, or terabytes. If \textit{n} is specified without M, G, or T, the default is megabytes. PARTSIZE=128 is the same as PARTSIZE=128M. The maximum value is 8,796,093,022,207 megabytes.

Restriction

This restriction applies only to 32-bit hosts with the following operating systems: z/OS, Linux SLES 9 x86, and the Windows family. If you create a data set with a partition size greater than or equal to 2 gigabytes, you cannot open the data set with any version of SPD Engine prior to SAS 9.2. The following error message is written to the SAS log: \texttt{ERROR: Unable to open data file because its data representation differs from the SAS session data representation.}

Details

SPD Engine data must be stored in multiple partitions for it to be subsequently processed in parallel. Specifying PARTSIZE= forces the software to partition SPD Engine data files at the specified size. The actual size of the partition is computed to accommodate the maximum number of observations that fit in the specified size of \textit{n} megabytes, gigabytes, or terabytes.

By splitting (partitioning) the data portion of an SPD Engine data set into fixed-sized files, the software can introduce a high degree of scalability for some operations. The SPD Engine can spawn threads in parallel (for example, up to one thread per partition for WHERE evaluations). Separate data partitions also enable the SPD Engine to process the data without the overhead of file access contention between the threads. Because each partition is one file, the trade-off for a small partition size is that an increased number of files (for example, UNIX i-nodes) are required to store the observations.

Scalability limitations using PARTSIZE= depend on how you configure and spread the file systems specified in the DATAPATH= option across striped volumes. (You should spread each individual volume’s striping configuration across multiple disk controllers or SCSI channels in the disk storage array.) The goal for the configuration is to maximize parallelism during data retrieval. For information about disk striping, see "I/O Setup and Validation" under “SPD Engine” in Scalability and Performance at http://support.sas.com/rnd/scalability.

The PARTSIZE= specification is limited by the SPD Engine system option MINPARTSIZE=, which is usually set and maintained by the system administrator. MINPARTSIZE= ensures that an inexperienced user does not arbitrarily create small partitions, thereby generating a large number of files.
The partition size determines a unit of work for many of the parallel operations that require full data set scans. But, more partitions does not always mean faster processing. The trade-offs involve balancing the increased number of physical files (partitions) required to store the data set against the amount of work that can be done in parallel by having more partitions. More partitions means more open files to process the data set, but a smaller number of observations in each partition. A general rule is to have 10 or fewer partitions per data path and 3 to 4 partitions per CPU.

To determine an adequate partition size for a new SPD Engine data set, you should be aware of the following:

- the types of applications that run against the data
- how much data you have
- how many CPUs are available to the applications
- which disks are available for storing the partitions
- the relationships of these disks to the CPUs

For example, if each CPU controls only one disk, then an appropriate partition size would be one in which each disk contains approximately the same amount of data. If each CPU controls two disks, then an appropriate partition size would be one in which the load is balanced. Each CPU does approximately the same amount of work.

Note: The PARTSIZE= value for a data set cannot be changed after a data set is created. To change PARTSIZE=, you must re-create the data set and specify a different PARTSIZE= value in the LIBNAME statement or on the new (output) data set.

Comparisons

The PARTSIZE= data set option overrides the PARTSIZE= LIBNAME statement option.

Example: Specifying the Partition Size

When you specify the partition size in the LIBNAME statement, you have to select a size that is appropriate for most of the data sets stored in that library. For example, suppose you have an 8-disk configuration. The smallest data set has 20 gigabytes of data, the largest has 50 gigabytes of data, and the remaining data sets have 36 gigabytes of data each. A partition size of 1250M is optimal for a 36-gigabyte data set (four partitions per disk). The 20-gigabyte data set uses two partitions per disk, and the 50-gigabyte data set uses five partitions per disk.

```
libname sales spde '/primdisk' partsize=1250M
datapath=('/disk01' '/disk02' '/disk03' '/disk04'
' '/disk05' '/disk06' '/disk07' '/disk08');
```

REPEMPLOY= LIBNAME Statement Option

Controls replacement of a data set when the new data set is empty.
Default: YES
Interaction: If REPLACE=NO, the REPEMPTY= option is ignored.

Syntax

REPEMPTY= YES | NO

Required Arguments

YES
specifies that a new, empty data set can replace an existing data set with the same name.

TIP To avoid overwriting existing data sets with new, empty data sets that are created by mistake, set REPEMPTY=NO.

NO
specifies that a new, empty data set cannot replace an existing data set with the same name.

Details

The following example code shows a common syntax error that creates an empty data set. If mylib.test exists already and the defaults, REPLACE=YES and REPEMPTY=YES, are in effect, then the existing data set is replaced by a new, empty data set.

data mylib.test;
run;

To prevent this error, set REPEMPTY=NO.

WARNING: Data set MYLIB.TEST was not replaced because REPEMPTY=NO and the replacement file is empty.

Comparisons

The data set option takes precedence over the LIBNAME statement option.

See Also

“REPEMPTY= Data Set Option” in SAS Data Set Options: Reference

STARTOBS= LIBNAME Statement Option

Specifies the starting observation number in a user-defined range of observations to be processed.

Default: The first observation in the data set
Restrictions: Use STARTOBS= with input data sets only
Cannot be used with the OBS= system or data set option or with the FIRSTOBS=
system or data set option

Interactions:  
“STARTOBS= Data Set Option” on page 91
“ENDOBS= LIBNAME Statement Option” on page 39
“ENDOBS= Data Set Option” on page 77

Engine:  
SPD Engine only

Syntax

**STARTOBS=**

Required Argument

* n  

is the number of the starting observation.

Details

By default, the SPD Engine processes all of the observations in the entire data set
unless you specify a range of observations with the STARTOBS= and ENDOBS=
options. If the ENDOBS= option is used without the STARTOBS= option, the implied
value of STARTOBS= is 1. When both options are used together, the value of
STARTOBS= must be less than the value of ENDOBS=.

In contrast to the default Base SAS engine option FIRSTOBS=, the STARTOBS=
and ENDOBS= SPD Engine options can be used in the LIBNAME statement.

**Note:** FIRSTOBS= default Base SAS engine option is not supported by the SPD
Engine. The OBS= system option and the OBS= data set option cannot be used
with STARTOBS= or ENDOBS= data set or LIBNAME options.

(See SPD Engine Data Set Options on page 55 for information about using the
STARTOBS= data set option in WHERE processing.)

Comparisons

The STARTOBS= data set option overrides the STARTOBS= LIBNAME statement
option.

Example: Using the WHERE Expression

The following example prints the five observations that were qualified by the
WHERE expression (age >13 in PROC PRINT). The five observations are out of the
six observations that were processed, starting with the second observation in the
data set:

```plaintext
libname growth spde 'SAS-library' startobs=2;
data growth.teens;
  input Name $ Sex $ Age Height Weight;
datalines;
  Alfred M 14 69.0 112.5
  Carol F 14 62.8 102.5
```

James M 13 57.3 83.0
Janet F 15 62.5 112.5
Judy F 14 64.3 90.0
Philip M 16 72.0 150.0
William M 15 66.5 112.0

; proc print data=growth.teens;
  where age >13;
run;

The output is shown:

Output 3.4  STARTOBS=

<table>

**TEMP= LIBNAME Statement Option**

Specifies to store the library in a temporary subdirectory of the primary path.

Default: NO

Engine: SPD Engine only

**Syntax**

TEMP= YES | NO

**Required Arguments**

YES
  specifies to create the temporary subdirectory.

NO
  specifies not to create a temporary subdirectory.

**Details**

The TEMP= option creates a temporary subdirectory of the primary directory that was named in the LIBNAME statement. The subdirectory and all component files are deleted at the end of the session.
You can use TEMP= with the SAS option USER= to store temporary data sets that can be referenced with a single-level name.

**Note:** When using the SIGNON statement in SAS/CONNECT software, the INHERITLIB= option cannot refer to an SPD Engine library that was defined with the TEMP= option.

### Example: Creating a Temporary Library

The following example illustrates two features:

- the use of the TEMP= LIBNAME option to create a temporary library
- the use of the USER= system option to enable the use of single-level table names for SPD Engine tables

For the temporary table q1temp, the metadata file is created in a temporary subdirectory of /data01. The data and index for q1temp are created in the locations specified in the DATAPATH= and INDEXPATH= options.

```sas
libname perm spde '/permanent-pathname';
libname mywork spde /data01'
  datapath=('data02' '/data03')
  indexpath=('data04') temp=yes;
option user=mywork;
data q1temp (index=(lastname));
  set perm.q1;
  where region='W';
run;
```
# SPD Engine Data Set Options

## Introduction to SPD Engine Data Set Options

Specifying data set options for the SPD Engine is the same as specifying data set options for the default Base SAS engine or SAS/ACCESS engines. This section provides details about data set options that are used only with the SPD Engine. The default Base SAS engine data set options that affect the SPD Engine are also listed.

When using the options, remember that the value of the data set option overrides the value of its corresponding LIBNAME option.
Syntax

\[(\text{option-1=value-1} <(\text{option-2=value-2})...)\]

specifies a data set option in parentheses after a SAS data set name. To specify several data set options, separate them with spaces.

SPD Engine Data Set Options List

ALIGN=
   specifies variable alignment.

ASYNCINDEX=
   specifies to create indexes in parallel when creating multiple indexes on an SPD Engine data set.

BYNONEQUALS=
   specifies the index output order of data set observations that have identical values for the BY variable.

BYSORT=
   specifies the SPD Engine to perform an automatic sort when it encounters a BY statement. BYSORT= is also a LIBNAME statement option.

COMPRESS=
   specifies to compress SPD Engine data sets on disk as they are being created. COMPRESS= is also a LIBNAME statement option.

Note: Compression and encryption are mutually exclusive in the SPD Engine.

ENDOBS=
   specifies the end observation number in a user-defined range of observations to be processed. ENDOBS= is also a LIBNAME statement option.

 IDXBY=
 specifies whether to use an index when processing a BY statement in the SPD Engine. IDXBY= is also a LIBNAME statement option.

 IDXWHERE=
 specifies whether to use an index when processing a WHERE expression in the SPD Engine.

Note: Compression and encryption are mutually exclusive in the SPD Engine.
IOBLOCKSIZE=
  specifies the size in bytes of a block of observations to be compressed.
  IOBLOCKSIZE= is also a LIBNAME statement option.

LISTFILES=
  specifies whether the CONTENTS procedure lists the complete pathnames of all
  of the component files in an SPD Engine data set.

PADCOMPRESS=
  specifies the number of bytes to add to compressed blocks in a data set opened
  for OUTPUT or UPDATE.

PARTSIZE=
  specifies the maximum size that the data component partitions can be.
  PARTSIZE= is also a LIBNAME statement option.

REPEMPTY=
  controls replacement of a data set when the new data set is empty.

STARTOBS=
  specifies the starting observation number in a user-defined range of
  observations to be processed. STARTOBS= is also a LIBNAME statement
  option.

SYNCADD=
  specifies to process one observation at a time or a block of observations at a
time.

THREADNUM=
  specifies the maximum number of threads to use for SPD Engine processing.

UNIQUESAVE=
  specifies to save (in a separate file) any observations that were rejected because
  of nonunique key values during an append or insert to a data set with unique
  indexes when SYNCADD=NO.

WHERENOINDEX=
  specifies a list of indexes to exclude when making WHERE expression
  evaluations.

SAS Data Set Options That Behave Differently with the SPD Engine Than with the Default
Base SAS Engine

CNTLLEV=
  only the value MEM is accepted

COMPRESS=
  no user-supplied values are accepted

**CAUTION**

*Compression and encryption are mutually exclusive in the SPD Engine.* If
you are copying a default Base SAS engine data set to an SPD Engine data set and
the data set is compressed and encrypted, the compression is dropped. You cannot create an SPD Engine data set with both encryption and compression.

**DLD MGM A CTION=**

does not support DLD MGM A CTION=NOINDEX, but does support ABORT, FAIL, PROMPT, and REPAIR.

**ENC R YP T=**
encrypts data files

---

**CAUTION**

Compression and encryption are mutually exclusive in SPD Engine.

---

**SAS Data Set Options Not Supported by the SPD Engine**

- BUFNO=
- BUFSIZE=
- ENCODING=
- EXTENDOBSCOUNTER=
- FIRSTOBS=
- GENMAX=
- GENNUM=
- IDXNAME=
- OUTREP=
- POINTOBS=
- REUSE=
- TOBSNO=

---

**Dictionary**

**ALIGN= Data Set Option**

specifies variable alignment.

Valid in: DATA step and PROC step

Default: YES
Syntax

ALIGN= YES | NO

Required Arguments

YES

enables variable alignment.

NO

disables variable alignment to allow the SPD Engine data set to be compatible with the SPD Server.

Details

Variable Alignment

Base SAS imposes proper numeric data alignment on an observation on disk by the careful arrangement of the variables within the observation. Like the default Base SAS engine, the SPD Engine ensures that all of the numeric values are grouped together at the beginning of the observation. It also ensures that the total observation length is an even multiple of 8-bytes by adding extra-padding bytes at the end of the observation when necessary. The SAS memory system ensures that all allocated memory starts on an 8-byte boundary and that all of the numeric values are 8 bytes long. Grouping the numeric values together at the beginning of the observation ensures that they will all be properly aligned and can be used directly from the memory.

An observation in an SPD Engine data set is read from disk into memory. All of the bytes are read at once, and their relative alignment is maintained in memory. For maximum performance when accessing that observation data, all numeric data values need to be properly aligned. Therefore, the need to move the values to a new location is avoided. The normal behavior of the SPD engine is to ensure that all of the numeric values in an observation are aligned on an 8-byte boundary when written to disk. This allows the SPD engine to retrieve the observation data from disk and store it in memory. The SPD Engine application uses the observation data directly from that location without the need to move it.

Using the SPD Server

The SPD Server does not support the data alignment feature. Data sets created by the SPD Engine that are used by the SPD Server must be created with data alignment disabled. Using the ALIGN=NO option causes the data stored in the data set to not be aligned. As a result, the data must be moved from its original memory location that it was read into and into a different memory location that is aligned.

The purpose of the ALIGN=NO data set option is to specify that no data alignment is done by the SPD Engine. This is not useful in most situations, but it is necessary when using the SPD Server. The SPD Server does not support variable alignment capability. In some situations, the SPD Server will refuse to operate on a data set that has aligned variables.
CAUTION
Do not use the ALIGN=NO option unless the data set is destined for the SPD Server. Unaligned variable data will cause a significant decrease in performance when processed by Base SAS.

Examples:

Example 1: Data Set with Variable Alignment
The first data set shows the default behavior—it has aligned variables. Note that the observation length is not the sum of the variable lengths. The observation length has been rounded up to be an even multiple of 8. Also, the variables have been rearranged so that the numeric variables come first in the observation.
**Example Code 4.1  Data Set with Variable Alignment**

```plaintext
data testdata.size;
  length text $10  width 8  chars 8;
  text='Zero';      width=1;   chars=4;  output;
  text='Ten';       width=2;   chars=3;  output;
  text='Twenty';    width=2;   chars=6;  output;
run;

NOTE: The data set TESTDATA.SIZE has 3 observations and 3 variables.

proc sql;
  select obslen
  from dictionary.tables
  where memname="SIZE";

Observation
  Length
  ----------
    32

select varnum, name, npos, length
from dictionary.columns
where memname="SIZE"
order by npos;

Column
  Number                                      Column    Column
in Table  Column Name                       Position    Length
-------------------------------
  2  width                                    0         8
  3  chars                                    8         8
  1  text                                    16        10
quit;

/* ------------------------------------------------------------------- */

data testdata.size (align=no);
  length text $10  width 8  chars 8;
  text='Zero';      width=1;   chars=4;  output;
  text='Ten';       width=2;   chars=3;  output;
  text='Twenty';    width=2;   chars=6;  output;
run;

NOTE: The data set TESTDATA.SIZE has 3 observations and 3 variables.
```

**Example 2: Data Set without Variable Alignment**

The second data set is identical except that the variables are not aligned. Note that the observation length is just the sum of the variable lengths. The observation length is not rounded to an even multiple of 8-bytes. The variables appear in the order in which they were encountered in the DATA step in the LENGTH statement. The variables were not rearranged for alignment.
Example Code 4.2  Data Set without Variable Alignment

```sas
data testdata.size (align=no);
  length text $10   width 8    chars 8;
  text='Zero';      width=1;   chars=4;  output;
  text='Ten';       width=2;   chars=3;  output;
  text='Twenty';    width=2;   chars=6;  output;
run;
```

NOTE: The data set TESTDATA.SIZE has 3 observations and 3 variables.

```sas
proc sql;
  select obslen
  from dictionary.tables
  where memname="SIZE";
      Observation
      Length
      --------
       26

  select varnum, name, npos, length
  from dictionary.columns
  where memname="SIZE"
  order by npos;
```

<table>
<thead>
<tr>
<th>Column Number in Table</th>
<th>Column Name</th>
<th>Column Position</th>
<th>Column Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>text</td>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>width</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>chars</td>
<td>18</td>
<td>8</td>
</tr>
</tbody>
</table>

`quit;`

NOTE: The data set TESTDATA.SIZE has 3 observations and 3 variables.

ASYNCINDEX=  Data Set Option

Specifies to create indexes in parallel when creating multiple indexes on an SPD Engine data set.

<table>
<thead>
<tr>
<th>Valid in:</th>
<th>DATASETS procedure or with the INDEX data set option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default:</td>
<td>NO</td>
</tr>
<tr>
<td>Engine:</td>
<td>SPD Engine only</td>
</tr>
</tbody>
</table>

**Syntax**

```
ASYNCINDEX= YES | NO
```

**Required Arguments**

**YES**
- creates the indexes in parallel (asynchronously).

**NO**
- creates one index at a time (synchronously).
Details

The SPD Engine can create multiple indexes with a single scan of a data set. The SPD Engine spawns a single thread for each index created, and then processes the threads simultaneously. Although creating indexes in parallel is much faster than scanning the data set for each index, the default for this option is NO because parallel index creation requires extra utility space to store the sorting files and requires additional memory. If index creation fails due to insufficient resources, you can do one or both of the following:

- Increase the size of the utility file space using the SPDEUTILLOC= system option.
- Set the SAS system option to MEMSIZE=0 and increase the utility space that is used for index sorting using the SPDEINDEXSORTSIZE= system option.

Example: Creating Indexes in Groups

The DATASETS procedure has the flexibility to use batched parallel index creation using multiple MODIFY groups. Instead of creating all of the indexes at once, which would require a significant amount of space, you can create the indexes in groups as shown in the following example. Indexes PatientNo and PatientClass are created together as are the indexes LastName and FirstName. The other indexes are created serially.

```sas
proc datasets lib=main;
    modify patients(asyncindex=yes);
        index create PatientNo PatientClass;
    run;
    modify patients(asyncindex=yes);
        index create LastName FirstName;
    run;
    modify patients(asyncindex=no);
        index create FullName=(LastName FirstName)
            ClassSex=(PatientClass PatientSex);
    run;
quit;
```

BYNOEQUALS= Data Set Option

Specifies whether the output order of data set observations that have identical values for the BY variable is guaranteed to be in the data set order.

- Valid in: DATA step and PROC step
- Used by: BYSORT=YES data set option
- Default: NO
- Engine: SPD Engine only

---

1. For z/OS, increase the REGION size.
Syntax

BYNONEQUALS=\texttt{YES} | \texttt{NO}

Required Arguments

\texttt{YES}  
\hspace{1cm} does not guarantee that the output order of data set observations that have identical values for the \texttt{BY} variable is in data set order.

\texttt{NO}  
\hspace{1cm} guarantees that the output order of data set observations that have identical values for the \texttt{BY} variable is in data set order.

Details

When a group of observations that have identical values for the \texttt{BY} statement is output, the order of the observations in the output is the same as the data set order. This happens because the default is \texttt{BYNONEQUALS=NO}. By specifying \texttt{YES}, the processing time is decreased, but the observations are not guaranteed to be output in the data set order.

The data set or LIBNAME option \texttt{BYSORT=} must be \texttt{YES} (the default) because the \texttt{BYNONEQUALS=} option has no effect when \texttt{BYSORT=} \texttt{NO}.

The following table shows when the SPD Engine preserves physical order in the output:

\begin{table}[h]
\centering
\caption{SPD Engine Preserves Physical Order}
\begin{tabular}{|l|l|}
\hline
\textbf{Condition:} & \textbf{Data Set Order Preserved?} \\
\hline
If \texttt{BY} is present & \texttt{YES} (\texttt{BYNONEQUALS=NO} and \texttt{BYSORT=} \texttt{YES} by default) \\
\hline
If \texttt{BY} is present and \texttt{BYNONEQUALS=} \texttt{YES} & \texttt{NO} \\
\hline
If \texttt{BY} is present and \texttt{BYSORT=} \texttt{NO} & \texttt{YES} (because no automatic sort occurs) \\
\hline
If neither \texttt{BY} nor \texttt{WHERE} is present & \texttt{YES} \\
\hline
If \texttt{WHERE} is present & \texttt{NO} \\
\hline
\end{tabular}
\end{table}

Examples:

Example 1: \texttt{BYNONEQUALS=} \texttt{YES}

In the following example, the observations that have identical \texttt{BY} values on the key variable are output in unpredictable order because \texttt{BYNONEQUALS=} \texttt{YES}:

```r
\texttt{title 'With BYNONEQUALS=YES';}
\texttt{proc print data=labs.performance(bynoequals=yes) noobs;}
\texttt{by score;}
```
run;

The output is shown:

Output 4.1  BYNOEQUALS=YES

Example 2: BYNOEQUALS=NO

The following example shows the output with BYNOEQUALS=NO:

title 'With BYNOEQUALS=NO;
proc print data=labs.performance(bynoequals=no) noobs;
  by score;
run;

The output is shown:

Output 4.2  BYNOEQUALS=NO

With BYNOEQUALS=NO

Score=High

BYSORT= Data Set Option

Specifies the SPD Engine to perform an automatic sort when it encounters a BY statement.

Valid in: DATA step and PROC step
Default: YES
Interaction: “BYNOEQUALS= Data Set Option” on page 63
Engine: SPD Engine only

Syntax

BYSORT= YES | NO

Required Arguments

YES
specifies to automatically sort the data based on the BY variables when a BY statement is encountered instead of sorting the data ahead of time.

NO
specifies not to sort the data based on the BY variables. Specifying NO means that the data must already be sorted before the BY statement.

Note: Indexes are not used when BYSORT=NO is set.

Details

DATA or PROC step processing using the default Base SAS engine requires that if there is no index or if the observations are not in order, the data set must be sorted before a BY statement is issued. In contrast, by default, the SPD Engine sorts the data returned to the application if the observations are not in order. Unlike PROC SORT, which creates a new sorted data set, the SPD Engine’s automatic sort does not change the permanent data set and does not create a new data set. However, utility file space is used. For more information, see “SPDEUTILLOC System Option” on page 112.

The default is BYSORT=YES. A BYSORT=YES argument enables the automatic sort, which generates the output for the observations in BY group order. If the data set option BYNOEQUALS=YES, then the observations within a group might be written in a different order from the order in the data set. Set BYNOEQUALS=NO to retain data set order.

The BYSORT=NO argument instructs the engine to do nothing to sort the data. The BYSORT=NO argument means that the data must already be sorted before the BY statement. Sorting can be from a previous PROC SORT or from the data set having been created in BY variable order. An error occurs if the data set is not sorted.

When BYSORT=NO, grouped data is delivered to the application in data set order. Indexes are not used to retrieve the observations in BY variable order. The data set option BYNOEQUALS= has no effect when BYSORT=NO.
If you specify the BYSORT= option in the LIBNAME statement, it can be overridden by specifying BYSORT= in the PROC or DATA steps. Set BYSORT=YES in the DATA or PROC step, for input opens, to override BYSORT=NO in the LIBNAME statement.

When you use the BYSORT=YES and the IDXWHERE= data set options, the following messages are written to the SAS log if you set the MSGLEVEL=I SAS system option:

- If IDXWHERE=YES and there is an index on the BY variable, the index is used to order the rows of the table. The following message is written to the SAS log:
  
  Note: BY ordering was produced by using an index for table tablename.

- If IDXWHERE=NO or IDXWHERE=YES and there is no index on the BY variable, SPD Engine performs an automatic sort to order the rows of the table. The following message is written to the SAS log:
  
  Note: BY ordering was produced by performing an automatic sort on table tablename.

Comparisons

The BYSORT= data set option overrides the BYSORT= LIBNAME statement option.

Examples:

Example 1: Group Formatting with BYSORT=YES by Default

```sas
libname growth spde 'SAS-library';
data growth.teens;
  input Name $ Sex $ Age Height Weight;
datalines;
  Alfred M 14 69.0 112.5
  Carol F 14 62.8 102.5
  James M 13 57.3 83.0
  Janet F 15 62.5 112.5
  Judy F 14 64.3 90.0
  Philip M 16 72.0 150.0
  William M 15 66.5 112.0
;
proc print data=growth.teens; by sex;
run;
```

Even though the data was not sorted using PROC SORT, no error occurred because BYSORT=YES is the default.

The output is shown:
Output 4.3  Group Formatting with BYSORT=YES by Default

The SAS System

Sex=F

<table>
<thead>
<tr>
<th>Obs</th>
<th>Name</th>
<th>Age</th>
<th>Height</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Carol</td>
<td>14</td>
<td>62.8</td>
<td>102.5</td>
</tr>
<tr>
<td>4</td>
<td>Janet</td>
<td>15</td>
<td>62.5</td>
<td>112.5</td>
</tr>
<tr>
<td>5</td>
<td>Judy</td>
<td>14</td>
<td>64.3</td>
<td>90</td>
</tr>
</tbody>
</table>

Sex=M

<table>
<thead>
<tr>
<th>Obs</th>
<th>Name</th>
<th>Age</th>
<th>Height</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Alfred</td>
<td>14</td>
<td>69.0</td>
<td>112.5</td>
</tr>
<tr>
<td>3</td>
<td>James</td>
<td>13</td>
<td>57.3</td>
<td>83</td>
</tr>
<tr>
<td>6</td>
<td>Philip</td>
<td>16</td>
<td>72.0</td>
<td>150.0</td>
</tr>
<tr>
<td>7</td>
<td>William</td>
<td>15</td>
<td>66.5</td>
<td>112.0</td>
</tr>
</tbody>
</table>

Example 2: BYSORT=NO

With BYSORT=NO in the PROC PRINT statement, SAS returns an error whenever automatic sorting is suppressed (BYSORT=NO). The data must be sorted on the BY variable before the BY statement (for example, by using PROC SORT).

libname growth spde 'SAS-library';
proc print data=growth.teens (bysort=no);
   by sex;
run;
ERROR: Data set GROWTH.TEENS is not sorted in ascending sequence.
The current BY-group has Sex = M and the next BY-group has Sex = F.
NOTE: The SAS System stopped processing this step because of errors.

COMPRESS= Data Set Option

Specifies to compress SPD Engine data sets on disk as they are being created.

Valid in: DATA step and PROC step
Restriction: Cannot be used with ENCRYPT=YES or ENCRYPT=AES
Interactions: “IOBLOCKSIZE= Data Set Option” on page 83
                  “PADCOMPRESS= Data Set Option” on page 88
Engine: SPD Engine only
Syntax

**COMPRESS=** NO | CHAR | BINARY

Required Arguments

**NO**

performs no data set compression.

**CHAR**

specifies that data in an SPD Engine data set be compressed in blocks by using RLE (run-length encoding). RLE compresses data by reducing repeated runs of the same character (including a blank space) to two-byte or three-byte representations.

**Alias** YES

**BINARY**

specifies that data in an SPD Engine data set be compressed in blocks by using RDC (Ross Data Compression). RDC combines RLE and sliding window compression to compress the file by representing repeated byte patterns more efficiently.

**Note:** This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (character and numeric variables).

Details

When you specify COMPRESS=YES | BINARY | CHAR, the SPD Engine compresses, by blocks, the data component file as it is created. To specify the size of the compressed blocks, use the “IOBLOCKSIZE= Data Set Option” on page 83 when you create the data set. To add padding to the newly compressed blocks, specify “PADCOMPRESS= Data Set Option” on page 88 when creating or updating the data set. For more information, see “Updates to a Compressed SPD Engine Data Set” on page 21.

If you are migrating a default Base SAS engine data set that is both compressed and encrypted, the encryption is retained, but the compression is dropped.

The CONTENTS procedure identifies the compress setting. If the data set is compressed, PROC CONTENTS prints information about the compression. The following example explains the Compressed Info fields in the CONTENTS procedure output:

In general, COMPRESS=CHAR provides good compression when single bytes repeat; COMPRESS=BINARY provides good compression when strings of bytes repeat. At the same time, it is more costly to look for strings of bytes that repeat, than to look for single bytes that repeat. For examples, see “Example 1: COMPRESS=CHAR” on page 72 and “Example 2: COMPRESS=BINARY” on page 72.
**Output 4.4  PROC CONTENTS Compressed Section**

<table>
<thead>
<tr>
<th>- Compressed Info</th>
<th>-</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of compressed blocks</td>
<td>202</td>
</tr>
<tr>
<td>Raw data blocksize</td>
<td>32736</td>
</tr>
<tr>
<td>Number of blocks with overflow</td>
<td>5</td>
</tr>
<tr>
<td>Max overflow chain length</td>
<td>3</td>
</tr>
<tr>
<td>Block number for max chain</td>
<td>80</td>
</tr>
<tr>
<td>Min overflow area</td>
<td>87</td>
</tr>
<tr>
<td>Max overflow area</td>
<td>181</td>
</tr>
</tbody>
</table>

Number of compressed blocks  
number of compressed blocks that are required to store data.

Raw data blocksize  
compressed block size in bytes calculated from the size specified in the IOBLOCKSIZE= data set option. It is the largest multiple of the observation length that fits in the block size.

Number of blocks with overflow  
number of compressed blocks that needed more space. When data is updated and the compressed new block is larger than the compressed old block, an overflow block fragment is created.

Max overflow chain length  
largest number of overflows for a single block. For example, the maximum overflow chain length would be 2 if a compressed block was updated and became larger, and then updated again to a larger size.

Block number for max chain  
number of the block containing the largest number of overflow blocks.

Min overflow area  
minimum amount of disk space that an overflow requires.

Max overflow area  
maximum amount of disk space that an overflow requires.

Accessing compressed files usually requires more processing time. The files have to be decompressed before reading them and, if updating, they have to be compressed again when written to disk.

**Comparisons**

The COMPRESS= data set option overrides the COMPRESS= LIBNAME statement option and the COMPRESS= system option.

If the COMPRESS= data set option or LIBNAME statement option is not set, then the value of the COMPRESS= system option is used. The COMPRESS= system option default value is NO.
Examples:

Example 1: COMPRESS=CHAR

```sas
data mylib.CharRepeats(compress=char);
  length ca $ 200;
  do i=1 to 100000;
    ca='aaaaaaaaaaaaaaaaaaaaa';
    cb='bbbbbbbbbbbbbbbbbbbbbb';
    cc='cccccccccccccccccccccc';
    output;
  end;
run;
```

The following message is written to the SAS log:

```
NOTE: Compressing data set MYLIB.CHARREPEATS decreased size by 88.55 percent.
Compressed is 45 pages; un-compressed would require 393 pages.
```

Example 2: COMPRESS=BINARY

```sas
data mylib.StringRepeats(compress=binary);
  length cabcd $ 200;
  do i=1 to 1000000;
    cabcd='abcdabcdabcdabcdabcdabcdabcdabcd';
    cefgh='efghefghefghefghefghefghefghefghefghefg';
    cijkl='ijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijklijkليك
```

The following message is written to the SAS log:

```
NOTE: Compressing data set MYLIB.STRINGREPEATS decreased size by 70.27 percent.
Compressed is 1239 pages; un-compressed would require 4167 pages.
```

**ENCRYPT= Data Set Option**

Specifies whether to encrypt an output SPD Engine data set.

- **Valid in:** DATA step and PROC step
- **Default:** NO
- **Restrictions:** Use only with output data sets
  - ENCRYPT=YES or ENCRYPT=AES cannot be used with COMPRESS=
**Syntax**

\[ ENCRYPT= \text{AES} | \text{NO} | \text{YES} \]

**Syntax Description**

**AES**

encrypts the data set using the AES (Advanced Encryption Standard) algorithm. AES provides stronger encryption using SAS/SECURE software, which is included with Base SAS software. You must use the ENCRYPTKEY= data set option when using ENCRYPT=AES. For more information, see "ENCRYPTKEY= Data Set Option" on page 75.

**CAUTION** Record all ENCRYPTKEY= key values if you specify ENCRYPT=AES. If you forget the ENCRYPTKEY= key value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value. The following note is written to the log:

Note: If you lose or forget the ENCRYPTKEY= key value, there will be no way to open the file or recover the data.

**NO**

does not encrypt the data set.

**YES**

encrypts the data set using the SAS Proprietary algorithm. This encryption method uses passwords that are stored in the data set. At a minimum, you must specify the READ= or the PW= data set option at the same time that you specify ENCRYPT=YES. Because the encryption method uses passwords, you cannot change any password on an encrypted data set without re-creating the data set.

**CAUTION** Record all passwords if you specify ENCRYPT=YES. If you forget a password, you cannot reset it without assistance from SAS. The process is time-consuming and resource-intensive.

**Details**

Encryption and compression are mutually exclusive in SPD Engine.

You cannot create an SPD Engine data set with both encryption and compression. If you use ENCRYPT=YES or ENCRYPT=AES and the COMPRESS= data set or LIBNAME option, the following error is generated:

**ERROR:** The data set was not created because compression and encryption cannot both be specified.

You cannot copy a Base SAS data set that is both compressed and encrypted to an SPD Engine library.

When using ENCRYPT=YES, the following rules apply:

- To copy an encrypted data set, the output engine must support encryption. Otherwise, the data set is not copied.
- If the data set is encrypted, all associated index files and metadata files are also encrypted.
- Encryption requires approximately the same amount of CPU resources as compression.
You cannot use PROC CPORT on SAS Proprietary-encrypted data sets. When using ENCRYPT=AES, the following rules apply:

- You must use the ENCRYPTKEY= data set option when creating a data set with AES encryption.
- To copy an AES-encrypted data set, the output engine must support AES encryption. Otherwise, the data set is not copied.
- If the data set is AES-encrypted, all associated index files are also AES-encrypted.
- Releases before SAS 9.4 cannot use an AES-encrypted data set.
- You use SAS/SECURE software, which is included with Base SAS software, to use AES encryption.

You cannot change the ENCRYPTKEY= key value on an AES-encrypted data set without re-creating the data set.

The SPD Engine does not support ENCRYPT=AES2. If a default Base SAS data set with AES2 encryption is copied to create a new SPD Engine data set, the encryption converts to AES. A warning is written to the log.

Examples:

Example 1: Using ENCRYPT=YES Option

The following example uses the SAS Proprietary algorithm:

```sas
libname depta sp 'SAS-library';
data salary(encrypt=yes read=green);
  input name $ yrsal bonuspct;
datalines;
Muriel  34567  3.2
Bjorn   74644  2.5
Freda   38755  4.1
Benny   29855  3.5
Agnetha 70998  4.1;
```

To use this data set, specify the Read password:

```sas
proc contents data=salary(read=green);
run;
```

Example 2: Using ENCRYPT=AES Option

The following example uses the AES algorithm:

```sas
data salary(encrypt=aes encryptkey=green);
  input name $ yrsal bonuspct;
datalines;
Muriel  34567  3.2
Bjorn   74644  2.5
Freda   38755  4.1
Benny   29855  3.5
Agnetha 70998  4.1;
```

To use this data set, specify the ENCRYPTKEY= key value:
Example 3: Copying AES-Encrypted Data Sets

Here are two examples of using ENCRYPTKEY= data set options and the COPY procedure:

PROC COPY IN=inlib OUT=outlib ENCRYPTKEY=secret;
    SELECT abc (ENCRYPTKEY=secreta) DEF(ENCRYPTKEY=secretb)...

PROC COPY IN=inlib OUT=outlib;
    SELECT abc (ENCRYPTKEY=secreta) DEF(ENCRYPTKEY=secretb)...

**ENCRYPTKEY= Data Set Option**

Specifies a key value for AES encryption.

<table>
<thead>
<tr>
<th>Valid in:</th>
<th>DATA step and PROC step</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range:</td>
<td>1 to 64 bytes</td>
</tr>
<tr>
<td>Restrictions:</td>
<td>Use with SAS 9.4 or later only</td>
</tr>
<tr>
<td></td>
<td>Use only with AES-encrypted data sets</td>
</tr>
<tr>
<td>Requirement:</td>
<td>The key-value is case sensitive, and it must be enclosed in single or double quotation marks.</td>
</tr>
</tbody>
</table>

**Syntax**

`ENCRYPTKEY="key-value"`

**Syntax Description**

*key-value*

Assigns an encrypt key value. You must use the ENCRYPTKEY= data set option with ENCRYPT=AES. The key value can be up to 64-bytes long. The key-value is case sensitive, and it must be enclosed in single or double quotation marks.

Single quotation marks support a key value that is:

- alphanumeric, special, and DBCS characters
- up to 64 bytes
- uppercase and lowercase letters
- case sensitive

```
encryptkey='key-value'
encryptkey='1234*#mykey'
```

Double quotation marks support a key value that is:
alphanumeric, special, and DBCS characters
up to 64 bytes
uppercase and lowercase letters
case sensitive
a macro variable

encryptkey="key-value"
encryptkey="1234*#mykey"

When the ENCRYPTKEY= key value uses DBCS characters, the 64-byte limit applies to the character string after it has been transcoded to UTF-8 encoding. You can use the following DATA step to calculate the length in bytes of a key value in DBCS:

```sas
data _null_;  
  mykey=length(unicode('key-value','UTF8'));  
  put 'key length=' mykey;  
run;
```

You cannot change the ENCRYPTKEY= key value on an AES-encrypted data set without re-creating the data set.

Details

**CAUTION**

You must remember the ENCRYPTKEY= key value. If you forget the ENCRYPTKEY= key value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value.

You must use the ENCRYPTKEY= data set option when creating or accessing an SPD Engine data set with AES encryption.

The ENCRYPTKEY= data set option does not protect the data set from deletion or replacement. Encrypted data sets can be deleted using any of the following scenarios without having to specify a key value:

- the KILL option in PROC DATASETS
- the DROP statement in PROC SQL
- the DELETE procedure

The ENCRYPTKEY= data set option prevents access only to the contents of the data set. To protect the data set from deletion or replacement, the data set must also contain an ALTER= password.

You must specify the ENCRYPTKEY= option when you copy AES-encrypted data sets. The key value follows the data set name in the SELECT statement. The following example uses the SELECT statement:

```sas
proc copy in=OldLib out=NewLib;  
  select salary(encryptkey="key-value");  
run;
```

When working with data sets protected by the ENCRYPTKEY= key value in the DATASETS procedure, you can specify the key value in the AGE, APPEND,
CONTENTS, and MODIFY statements. The ENCRYPTKEY= data set option can be specified either in parentheses after the name of the SAS data set or after a forward slash.

It is possible to use a macro variable as the ENCRYPTKEY= key value. To use a macro variable, you must use double quotation marks. The following code defines a macro variable:

```
%let secret=MyValue;
```

The following code uses the macro variable as the ENCRYPTKEY= key value:

```
data my.dsnname(encrypt=aes encryptkey="&secret");
```

When you specify a macro variable as the ENCRYPTKEY= key value, you must enclose the macro variable in double quotation marks. If you do not use the double quotation marks, unpredictable results can occur.

Example: Using ENCRYPTKEY= Data Set Option

This example uses the ENCRYPT=AES option:

```
data spdelib.salary(encrypt=aes encryptkey="green");
    input name $ yrsal bonuspct;
    datalines;
Muriel    34567  3.2
Bjorn     74644  2.5
Freda     38755  4.1
Benny     29855  3.5
Agnetha   70998  4.1
To use this data set, specify the ENCRYPTKEY= key value:
    proc contents data=spdelib.salary(encryptkey="green");
    run;
```

ENDOBS= Data Set Option

Specifies the end observation number in a user-defined range of observations to be processed.

Valid in: DATA step and PROC step

Default: The last observation in the data set

Restrictions: Use ENDOBS= with input data sets only

Cannot be used with the OBS= system or data set option or the FIRSTOBS= system and data set option

Interactions: “ENDOBS= LIBNAME Statement Option” on page 39
“STARTOBS= LIBNAME Statement Option” on page 50
“STARTOBS= Data Set Option” on page 91

Engine: SPD Engine only

Syntax

```
ENDOBS=n
```
Required Argument

$n$

is the number of the end observation.

Details

Specifying a Range of Observations

By default, the SPD Engine processes all of the observations in the entire data set unless you specify a range of observations with the STARTOBS= or ENDOBS= options. If the STARTOBS= option is used without the ENDOBS= option, the implied value of ENDOBS= is the end of the data set. When both options are used together, the value of ENDOBS= must be greater than the value of STARTOBS=.

The ENDOBS= data set option in the SPD Engine works the same way as the OBS= data set option in the default Base SAS engine. The only difference is when ENDOBS= is specified in a WHERE expression.

Using ENDOBS= with a WHERE Expression

When ENDOBS= is used in a WHERE expression, the ENDOBS= value represents the last observation to process, rather than the number of observations to return. The following examples show the difference.

Note: The OBS= system option and the OBS= data set option cannot be used with STARTOBS= or ENDOBS= data set or LIBNAME options.

Comparisons

The ENDOBS= data set option overrides the ENDOBS= LIBNAME statement option.

Examples:

Example 1: Using the ENDOBS= Data Set Option

A data set is created and processed by the SPD Engine with ENDOBS=5 option specified. The WHERE expression is applied to the data set ending with observation number 5. The PRINT procedure prints four observations, which are the observations qualified by the WHERE expression.

```
libname growth spde 'SAS-library';
data growth.teens;
   input Name $ Sex $ Age Height Weight;
   list;
datalines;
Alfred M 14 69.0 112.5
Carol F 14 62.8 102.5
James M 13 57.3 83.0
Janet F 15 62.5 112.5
Judy F 14 64.3 90.0
Philip M 16 72.0 150.0
```
Example 2: OBS= with SPD Engine

The same data set is processed with OBS=5 specified. PROC PRINT prints five observations, which are all of the observations qualified by the WHERE expression, ending with the fifth qualified observation.

```
libname growth `SAS-library';
data growth.teens;
   input Name $ Sex $ Age Height Weight;
   list;
datalines;
   Alfred M 14 69.0 112.5
   Carol F 14 62.8 102.5
   James M 13 57.3 83.0
   Janet F 15 62.5 112.5
   Judy F 14 64.3 90.0
   Philip M 16 72.0 150.0
   Zeke M 14 71.1 105.1
   Alice F 14 65.1 91.0
   William M 15 66.5 112.0;
proc print data=growth.teens (obs=5);
   where age >13;
   title 'WHERE age > 13 using V9';
run;
```

**Output 4.5 ENDOBS=**

**WHERE age > 13 using SPD Engine**

</tbody>
</table>
IDXBY= Data Set Option

Specifies whether to use an index when processing a BY statement in the SPD Engine.

Valid in: DATA step and PROC step
Default: YES
Engine: SPD Engine only

Syntax
IDXBY= YES | NO

Required Arguments
YES
uses an index when processing indexed variables in a BY statement.

Note: If the BY statement specifies more than one variable or the DESCENDING option, then the index is not used, even if IDXBY=YES.

NO
does not use an index when processing indexed variables in a BY statement.

Note: IDXBY=NO performs an automatic sort when processing a BY statement.

Details
When you use the IDXBY= data set option, make sure that you use the BYSORT=YES option and that the BY variable is indexed.

In some cases, you might get better performance from the SPD Engine if you automatically sort the data. To use the automatic sort, BYSORT=YES must be set and you should specify IDXBY=NO.
Set the SAS system option MSGLEVEL=I so that the BY processing information is written to the SAS log. When you use the IDXBY= data set option and the BYSORT=YES option, the following messages are written to the SAS log:

- If IDXBY=YES and there is an index on the BY variable, the index is used to order the rows of the table. The following message is written to the SAS log:
  
  ```
  NOTE: BY ordering was produced by using an index for table tablename.
  ```

- If IDXBY=NO, the following message is written to the SAS log:
  
  ```
  NOTE: BY ordering was produced by performing an automatic sort on table tablename.
  ```

Comparisons

The IDXBY= data set option overrides the IDXBY= LIBNAME statement option.

Examples:

Example 1: Using the IDXBY=NO Data Set Option

```sas
options msglevel=i;
proc means data=permdata.customer(IDXBY=no);
  var sales;
  by state;
run;
```

The following message is written to the SAS log:

```sas
NOTE: BY ordering was produced by performing an automatic sort on table PERMDATA.customer.
NOTE: There were 2981 observations read from the data set PERMDATA.CUSTOMER.
```

Example 2: Using the IDXBY=YES Data Set Option

```sas
proc means data=permdata.customer(IDXBY=yes);
  var sales;
  by state;
run;
```

The following message is written to the SAS log:

```sas
NOTE: BY ordering was produced by using an index for table PERMDATA.customer.
NOTE: There were 2981 observations read from the data set PERMDATA.CUSTOMER.
```

IDXWHERE= Data Set Option

Specifies whether to use an index when processing a WHERE expression in the SPD Engine.

Valid in: DATA step and PROC step
**IDXWHERE=** is used with the SPD Engine’s WHERE expression planning software called WHINIT. WHINIT tests the performance of index use with WHERE processing in various applications. Set the SAS system option MSGLEVEL=I so that the WHERE processing information is output to the SAS log.

When you use the IDXWHERE= data set option and the BYSORT=YES option, the following messages are written to the SAS log:

- If IDXWHERE=YES and there is an index on the BY variable, the index is used to order the rows of the table. The following message is written to the SAS log:

  Note: BY ordering was produced by using an index for table tablenamex.

- If IDXWHERE=NO or IDXWHERE=YES and there is no index on the BY variable, SPD Engine performs an automatic sort to order the rows of the table. The following message is written to the SAS log:

  Note: BY ordering was produced by performing an automatic sort on table tablenamex.

The SPD Engine uses WHINIT, a rules-based WHERE expression planner, to select the most appropriate evaluation strategy for a query. The SAS system option MSGLEVEL=I surfaces WHINIT messages to the SAS log that can help you determine whether one or more indexes are used in a query. For more details about WHINIT, see “SPDEWHEVAL System Option” on page 113.

**Note:** Do not arbitrarily suppress index use when using WHERE and BY statements together. You use a WHERE statement to filter the observations and a BY statement to order the observations. The filtered observations qualified by the WHERE statement are fed directly into a sort step as part of the parallel WHERE expression evaluation. The final, ordered observation set is produced as the result. Index use in WHERE processing greatly improves the filtering and feeding performance into the sort step.
Examples:

Example 1: Using WHINIT Log Output with IDXWHERE=NO

This example shows that evaluation strategy 2 is used in the WHERE expression because IDXWHERE=NO was specified.

Example Code 4.3  IDXWHERE=NO

```plaintext
34   options msglevel=i;
35   proc means data=permdata.customer(idxwhere=no);
36      var sales;
37      where state="CA";
38   run;
whinit: WHERE (sstate='CA')
whinit returns: ALL EVAL2
NOTE: There were 2981 observations read from the data set PERMDATA.CUSTOMER. WHERE state='CA';
```

Example 2: Using WHINIT Log Output with IDXWHERE=YES

This example shows that evaluation strategy 1 was used because IDXWHERE=YES was specified.

Example Code 4.4  IDXWHERE=YES

```plaintext
39   proc means data=permdata.customer(idxwhere=yes);
40      var sales;
41      where state="CA";
42      run;
whinit: WHERE (sstate='CA')
--
whinit: SBM-INDEX STATE uses 45% of segs (WITHIN maxsegratio 75%)
whinit returns: ALL EVAL1(w/SEGLIST)
NOTE: There were 2981 observations read from the data set PERMDATA.CUSTOMER. WHERE state='CA';
```

IOBLOCKSIZE= Data Set Option

Specifies the size in bytes of a block of observations to be used in an I/O operation.

Valid in: DATA step and PROC step

Default: 1,048,576 bytes (1 megabyte)

Range: The minimum block size is 32,768 bytes. The maximum block size is half the size of the SPD Engine data partition file.

Restriction: When reading a data set, the block size can significantly affect performance. When retrieving a large percentage of the data, a larger block size improves performance. However, when retrieving a subset of the data such as with WHERE processing, a smaller block size performs better.

Engine: SPD Engine only
Syntax

**IOBLOCKSIZE=\( n \)**

Required Argument

\( n \)

is the size in bytes of a block of observations.

Details

The I/O block size determines the amount of data that is physically transferred together in an I/O operation. The SPD Engine uses blocks in memory to collect the rows to be written to or read from a data component file. The IOBLOCKSIZE= option specifies the size of the block, but the actual size is computed to accommodate the largest number of rows that fit in the specified size of \( n \) bytes. Therefore, the actual size is a multiple of the row length. If you set IOBLOCKSIZE= too small to fit two rows, an error is written to the log and the data set is not created.

In a very general sense, the larger the block size, the less I/O. The performance for reading data depends on the I/O operation in the following ways:

- Large blocks are more efficient for sequential I/O. An example of sequential I/O is a PRINT procedure that reads a full data set.
- Small blocks are more efficient for random I/O. An example of random I/O is a BY clause with an index on a data set that is not already sorted on the BY variable. Small blocks can also be more efficient for I/O that is not completely sequential. An example is the SUMMARY procedure, which does not perform a full sequential read.

If you are not certain whether a large or small block size is best, you are encouraged to run performance tests.

If you process a data set in multiple ways, you can specify a different block size based on the operation that you are performing. This feature is available for data sets that are not compressed or encrypted. The details are as follows.

Compressed or encrypted data set

IOBLOCKSIZE= determines how many rows are compressed or encrypted together, which determines the amount of data that is physically transferred for both reading and writing. The block size is a permanent attribute of the data set. To specify a different block size, you must copy the data set to a new data set, and specify a new block size for the new data set. It is possible to specify a different IOBLOCKSIZE= for the Read operation, but that block size affects only the output operation (the results of processing that are returned to the user) and does not affect the size of blocks that are read from disk. Therefore, specifying the same block size for creation and reading usually provides the best performance. When you first create a data set, follow the general guidelines for the majority of its intended use (sequential or random I/O). For random I/O on a compressed data set, use the minimum value during both data set creation and reading.

Not compressed or encrypted

For a data set that is not compressed or encrypted, IOBLOCKSIZE= is not a permanent attribute of the data set. For an uncompressed data set, the block size determines the size of the blocks that are used to read the data from disk to memory. The block size has no effect when writing data to disk. Therefore, you can specify a different block size based on the Read operation that you perform.
For details about the interaction between IOBLOCKSIZE= and PADCOMPRESS=, see “Updates to a Compressed SPD Engine Data Set” on page 21.

Comparisons
The IOBLOCKSIZE= data set option overrides the IOBLOCKSIZE= LIBNAME statement option.

Example: Using IOBLOCKSIZE=

/*IOBLOCKSIZE set to 64K */
data sport.maillist(ioblocksize=65536);
/*IOBLOCKSIZE set to 32K */
data sport.maillist(ioblocksize=32768 compress=yes);

LISTFILES= Data Set Option
Specifies whether the CONTENTS procedure lists the complete pathnames of all of the component files of an SPD Engine data set.

Valid in: PROC CONTENTS only
Default: NO
Engine: SPD Engine only

Syntax
LISTFILES= YES | NO

Required Arguments
YES
lists the complete pathnames of all of the component files of an SPD Engine data set.

NO
does not list the pathnames.

Details
The LISTFILES= data set option is used only with the SPD Engine. The CONTENTS procedure is used to list the complete pathnames of all of the component files of an SPD Engine data set.

Example: LISTFILES Option

proc contents data=company.depts (listfiles=yes);

The following CONTENTS procedure output shows the complete pathnames of all of the component files:
### The SAS System

</table>
PADCOMPRESS= Data Set Option

Specifies the number of bytes to add to compressed blocks in a data set opened for OUTPUT or UPDATE.

Valid in: DATA step and PROC step

Default: 0

Interactions:

“COMPRESS= Data Set Option” on page 69
“IOBLOCKSIZE= Data Set Option” on page 83

Engine: SPD Engine only

Syntax

PADCOMPRESS=n

Required Argument

n
is the number of bytes to add.
Details

Compressed SPD Engine data sets occupy blocks of space on the disk. The size of a block is derived from the IOBLOCKSIZE= data set option specified when the data set is created. When the data set is updated, a new block fragment might need to be created to hold the update. More updates might then create new fragments, which, in turn, increases the number of I/O operations needed to read a data set.

By increasing the block padding in certain situations where many updates to the data set are expected, fragmentation can be kept to a minimum. However, adding padding can waste space if you do not update the data set.

You must weigh the cost of padding all compression blocks against the cost of possible fragmentation of some compression blocks.

Specifying the PADCOMPRESS= data set option when you create or update a data set adds space to all of the blocks as they are written back to the disk. The PADCOMPRESS= setting is not retained in the data set's metadata.

PARTSIZE= Data Set Option

Specifies the maximum size (in megabytes, gigabytes, or terabytes) that the data component partitions can be. The value is specified when an SPD Engine data set is created. This size is a fixed size. This specification applies only to the data component files.

Valid in: DATA step and PROC step
Used by: MINPARTSIZE= system option
Default: 128 megabytes
Range: 16 megabytes to 8,796,093,022,207 megabytes. You can change the lower limit by setting the MINPARTSIZE= system option.
Interactions: “DATAPATH= LIBNAME Statement Option” on page 38
“MINPARTSIZE System Option” on page 108
If you set MINPARTSIZE= larger than the PARTSIZE= default, then you must specify PARTSIZE= equal to or larger than MINPARTSIZE=.

Engine: SPD Engine only

Syntax

PARTSIZE=n | nM | nG | nT

Required Argument

n | nM | nG | nT

is the size of the partition in megabytes, gigabytes, or terabytes. If n is specified without M, G, or T, the default is megabytes. For example, PARTSIZE=128 is the same as PARTSIZE=128M. The maximum value is 8,796,093,022,207 megabytes.

Restriction This restriction applies only to 32-bit hosts with the following operating systems: z/OS, Linux SLES 9 x86, and the Windows family. In SAS 9.3, if you create a data set with a partition size greater than or equal to 2 gigabytes, you cannot open the data set
Details

Multiple partitions are necessary to read the data in parallel. The option PARTSIZE= forces the software to partition SPD Engine data files at the specified size. The actual size of the partition is computed to accommodate the maximum number of observations that fit in the specified size of \( n \) megabytes, gigabytes, or terabytes. If you have a table with an observation length greater than 65K, you might find that the PARTSIZE= that you specify and the actual partition size do not match. To get these numbers to match, specify a PARTSIZE= that is a multiple of 32 and the observation length.

By splitting (partitioning) the data portion of an SPD Engine data set into fixed-sized files, the software can introduce a high degree of scalability for some operations. The SPD Engine can spawn threads in parallel (for example, up to one thread per partition for WHERE evaluations). Separate data partitions also enable the SPD Engine to process the data without the overhead of file access contention between the threads. Because each partition is one file, the trade-off for a small partition size is that an increased number of files (for example, UNIX i-nodes) are required to store the observations.

Scalability limitations using PARTSIZE= depend on how you configure and spread the file systems specified in the DATAPATH= option across striped volumes. (You should spread each individual volume’s striping configuration across multiple disk controllers or SCSI channels in the disk storage array.) The goal for the configuration, at the hardware level, is to maximize parallelism during data retrieval. For information about disk striping, see “I/O Setup and Validation” under “SPD Engine” in Scalability and Performance at http://support.sas.com/rnd/scalability.

The PARTSIZE= specification is limited by the SPD Engine system option MINPARTSIZE=, which is usually maintained by the system administrator. MINPARTSIZE= ensures that an inexperienced user does not arbitrarily create small partitions, thereby generating a large number of data files.

The partition size determines a unit of work for many of the parallel operations that require full data set scans. But, more partitions does not always mean faster processing. The trade-offs involve balancing the increased number of physical files (partitions) required to store the data set against the amount of work that can be done in parallel by having more partitions. More partitions means more open files to process the data set, but a smaller number of observations in each partition. A general rule is to have 10 or fewer partitions per data path, and 3 to 4 partitions per CPU. (Some operating systems have a limit on the number of open files that you can use.)

To determine an adequate partition size for a new SPD Engine data set, you should be aware of the following:

- the types of applications that run against the data
- how much data you have
- how many CPUs are available to the applications
- which disks are available for storing the partitions
- the relationships of these disks to the CPUs
For example, if each CPU controls only one disk, then an appropriate partition size would be one in which each disk contains approximately the same amount of data. If each CPU controls two disks, then an appropriate partition size would be one in which the load is balanced. Each CPU does approximately the same amount of work.

Note: The PARTSIZE= value for a data set cannot be changed after a data set is created. To change PARTSIZE=, you must re-create the data set and specify a different PARTSIZE= value in the LIBNAME statement or on the new (output) data set.

Comparisons
The PARTSIZE= data set option overrides the PARTSIZE= LIBNAME statement option.

Example: Using a DATA Step
You have 100 gigabytes of data and 8 disks, so you can store 12.5 gigabytes per disk. Optimally, you want 3 to 4 partitions per disk. A partition size of 3.125 gigabytes is appropriate. So, you can specify PARTSIZE=3200M.

data salecent.sw (partsize=3200m);

Using the same amount of data, you anticipate the amount of data doubles within a year. You can either specify the same PARTSIZE= and have about 7 partitions per disk, or you can increase PARTSIZE= to 5000M and have 5 partitions per disk.

STARTOBS= Data Set Option
Specifies the starting observation number in a user-defined range of observations to be processed.

Valid in: DATA step and PROC step
Default: The first observation in the data set
Restrictions: Use STARTOBS= with input data sets only
Cannot be used with the OBS= system or data set option or with the FIRSTOBS= system and data set option
Interactions: “STARTOBS= LIBNAME Statement Option” on page 50
“ENDOBS= LIBNAME Statement Option” on page 39
“ENDOBS= Data Set Option” on page 77
Engine: SPD Engine only

Syntax
STARTOBS=n

Note: The PARTSIZE= value for a data set cannot be changed after a data set is created. To change PARTSIZE=, you must re-create the data set and specify a different PARTSIZE= value in the LIBNAME statement or on the new (output) data set.
Required Argument

\[ n \]

is the number of the starting observation.

Details

Specifying a Range of Observations

By default, the SPD Engine processes all of the observations in the entire data set unless you specify a range of observations with the STARTOBS= and ENDOBS= options. If the ENDOBS= option is used without the STARTOBS= option, the implied value of STARTOBS= is 1. When both options are used together, the value of STARTOBS= must be less than the value of ENDOBS=.

The STARTOBS= data set option in the SPD Engine works the same way as the FIRSTOBS= SAS data set option in the default Base SAS engine. The only difference is when STARTOBS= is specified in a WHERE expression.

Note: The FIRSTOBS= SAS data set option is not supported by the SPD Engine. The OBS= system option and the OBS= data set option cannot be used with the STARTOBS= or ENDOBS= data set or LIBNAME options.

Using STARTOBS= with a WHERE Expression

When STARTOBS= is used in a WHERE expression, the STARTOBS= value represents the first observation on which to apply the WHERE expression. Compare this value to the default Base SAS engine data set option FIRSTOBS=, which specifies the starting observation number within the subset of data qualified by the WHERE expression.

Comparisons

The STARTOBS= data set option overrides the STARTOBS= LIBNAME statement option.

Examples:

Example 1: STARTOBS= with SPD Engine

A data set is created and processed by the SPD Engine with STARTOBS=5 specified. The WHERE expression is applied to the data set, beginning with observation number 5. The PRINT procedure prints six observations, which are the observations qualified by the WHERE expression.

```sas
libname growth spde 'SAS-library';
data growth.teens;
  input Name $ Sex $ Age Height Weight;
  list;
datalines;
Alfred M 14 69.0 112.5
Carol F 14 62.8 102.5
James M 13 57.3 83.0
```

proc print data=growth.teens (firstobs=5);
  where age >13;
SYNCADD= Data Set Option

Specifies to process one observation at a time or multiple observations at a time when adding observations.

Valid in: PROC SQL
Default: NO
Interaction: UNIQUESAVE=
Engine: SPD Engine only

Syntax

SYNCADD= YES | NO

Required Arguments

YES

processes a single observation at a time (synchronously).

NO

processes multiple observations at a time (asynchronously).

Details

With SYNCADD=YES, observations are processed one at a time. With PROC SQL, if you are inserting observations into a data set with a unique index, and the SPD Engine encounters an observation with a nonunique value, the following occurs:

- the Insert operation stops
- all transactions just added are backed out
- the original data set on disk is unchanged
Adding observations with SYNCADD=NO is obviously much faster. However, when inserting a few observations into a data set with a unique index using PROC SQL, the SPD Engine can back out all the observations if one duplicate value is found. Specifically, the following occurs:

- the SPD Engine rejects the observation
- the SPD Engine continues processing
- a status code is issued only at the end of the Insert operation

To save the rejected observations in a separate data set, set the UNIQUESAVE= data set option to YES.

Example: Inserting Observations with Duplicate Values into a Data Set with a Unique Index

In the following example, two identical data sets, WITH_NO and WITH_YES, are created. Both have a unique index.

PROC SQL is used to insert three new observations, one of which has duplicate values. The SYNCADD=YES option is used. PROC SQL stops when the duplicate values are encountered and restores the data set.

PROC SQL is used again to insert these three new observations (as before). In this case, the SYNCADD=NO option is used. The observation with duplicate values is rejected. The SAS log is shown:
Example Code 4.5  Inserting Observations

libname addlib spde 'c:\temp';
NOTE: Libref ADDLIB was successfully assigned as follows:
   Engine:        SPDE

      values('six_no',   6, 60 )
      values('seven_no', 2, 70 )
      values('eight_no', 8, 80 )
   ;
NOTE: 3 rows were inserted into ADDLIB.WITH_NO.
WARNING: Duplicate values not allowed on index x for file WITH_NO, 1 observations rejected.
quit;

proc compare data=addlib.with_no compare=addlib.with_yes;
run;

NOTE: There were 7 observations read from the data set ADDLIB.WITH_NO.
NOTE: There were 5 observations read from the data set ADDLIB.WITH_YES.
THREADNUM= Data Set Option

Specifies the maximum number of I/O threads the SPD Engine can spawn for processing an SPD Engine data set.

Valid in: DATA step and PROC step
Default: The value of the SPDEMAXTHREADS= system option, if set; otherwise, the default is two times the number of CPUs on your computer
Interaction: “SPDEMAXTHREADS System Option” on page 110
Engine: SPD Engine only

Syntax

THREADNUM=n

Required Argument

n specifies the number of threads.

Details

THREADNUM= enables you to specify the maximum number of I/O threads that the SPD Engine spawns for processing an SPD Engine data set. The THREADNUM= value applies to any of the following SPD Engine I/O processing:

- WHERE expression processing
- parallel index creation

Adjusting THREADNUM= enables the system administrator to adjust the level of CPU resources the SPD Engine can use for any process. For example, setting THREADNUM=4 limits the process to, at most, four CPUs, thereby enabling greater throughput for other users or applications.

When THREADNUM= is greater than 1, parallel processing is likely to occur. Therefore, physical order might not be retained in the output.

You can also use this option to explore scalability for WHERE expression evaluations.

The SPDEMAXTHREADS= system option imposes an upper limit on the consumption of system resources and constrains the THREADNUM= value.

Note: The SAS system option NOTHREADS does not affect the SPD Engine.

Note: Setting THREADNUM=1 means that no parallel processing occurs, which is behavior consistent with the default Base SAS engine.
Example: Using %MACRO

The SPD Engine system option SPDEMAXTHREADS= is set to 128 for the session. A SAS macro shows the effects of parallelism in the following example:

```sas
%macro dotest(maxthr);
  %do nthr=1 %to &maxthr;
  data _null_;  
  set mylib.precs(threadnum= &nthr);  
    where occup= '022'  
    and state in('37','03','06','36');  
  run;
%mend dotest;
```

UNIQUESAVE= Data Set Option

Specifies to save observations with nonunique key values (the rejected observations) to a separate data set when adding observations to data sets with unique indexes.

**Valid in:** PROC APPEND and PROC SQL

**Used by:** SPDSUSDS automatic macro variable

**Default:** NO

**Interaction:** “SYNCADD= Data Set Option” on page 94

**Engine:** SPD Engine only

**Syntax**

```
UNIQUESAVE= YES | NO
```

**Required Arguments**

- **YES**
  - if SYNCADD=NO, writes rejected observations to a separate, system-created data set, which can be accessed by a reference to the macro variable SPDSUSDS.

- **NO**
  - does not write rejected observations to a separate data set.

**Details**

Use UNIQUESAVE=YES when you are adding observations to a data set with unique indexes and the data set option SYNCADD=NO is set.

SYNCADD=NO specifies that an Insert operation should process observations in blocks (pipelining), instead of one at a time. Duplicate index values are detected only after all the observations are applied to a data set. With UNIQUESAVE=YES, the rejected observations are saved to a separate data set whose name is stored in the SPD Engine macro variable SPDSUSDS. You can specify the macro variable in place of the data set name to identify the rejected observations.
Note: When SYNCADD=YES, the UNIQUESAVE= option is ignored. For more information see the SYNCADD= data set option.

Example: Using the UNIQUESAVE= Option with the APPEND Procedure

In the following example, a data set with two unique indexes is created and another data set with duplicate values is then appended to the first one. Because the UNIQUESAVE=YES option is specified, a data set containing the rejected observations is created. That data set includes a variable identifying the variable that had the duplicate value. The SAS log is shown.
Example Code 4.6  UNIQUESAVE= Option

```
1 libname employee spde 'c:\temp';
2   NOTE: Libref EMPLOYEE was successfully assigned as follows:
3       Engine:        SPDE
4       Physical Name: c:\temp\n
5 data employee.emp1 (index=(phone/unique room/unique));
6       input name $ phone room;
7       list;
8       datalines;
9          RULE:      ----+----1----+----2----+----3----+----4----+----5----+----6----+----7----+----8----+
10         Jill 4344 456
11         Jack 5589 789
12         Jim  8888 345
13         Sam  3334 657
14   NOTE: The data set EMPLOYEE.EMP1 has 4 observations and 3 variables.
15 run;
16 data employee.emp2;
17       input name $ phone room;
18       list;
19       datalines;

WHERENOINDEX= Data Set Option

Specifies a list of indexes to exclude when making WHERE expression evaluations.

Valid in: DATA step and PROC step
Default: Blank
Restriction: Cannot be used with IDXWHERE=NO data set option
Engine: SPD Engine only

Syntax

WHERENOINDEX=(name(s))

Required Argument

(name(s))
a list of index names to exclude from the WHERE planner.
Example: Excluding Indexes

The data set PRECS is defined with indexes:

```sas
proc datasets lib=mylib;
  modify precs;
    index create stser=(state serialno) occind=(occup industry) hour89;
  quit;
```

When evaluating the next query, the SPD Engine does not use the indexes for either the STATE or HOUR89 variables.

In this case, the AND combination of the conditions for the OCCUP and INDUSTRY variables produce a very small yield. Few observations satisfy the conditions. To avoid the extra index I/O (computer time) that the query requires for a full-indexed evaluation, use the following SAS code:

```sas
proc sql;
  create table hr80spde
    as select state, age, sex, hour89, industry, occup from mylib.precs
       (wherenoindex=(stser hour89))
    where occup='022'
       and state in('37','03','06','36')
       and industry='012'
       and hour89 > 40;
  quit;
```

**Note:** Specify the index names in the WHEREINOINDEX list, not the variable names. In the previous example, both the composite index for the STATE variable, STSER, and the simple index, HOUR89, are excluded.
Introduction to SPD Engine System Options

SAS system options are instructions that affect your SAS session. They control how SAS performs operations, such as SAS system initialization, hardware and software interfacing, and the input, processing, and output of jobs and SAS files. The SPD Engine system options work the same way as SAS system options. This section discusses system options that are used only with the SPD Engine, and Base SAS system options that behave differently with the SPD Engine.

Syntax

Here is an example that specifies the system option MAXSEGRATIO in an options statement:

```sas
options maxsegratio=50;
```

When you specify an option on the command line or in a configuration file, the syntax is specific to your operating environment. For details, see the SAS documentation for your operating environment.
SAS System Options That Behave Differently with the SPD Engine Than with the Default Base SAS Engine

MSGLEVEL=I
produces WHERE optimization information in the SAS log.

COMPRESS=
cannot perform user-defined compression.

DLMGACTION=
does not support DLMGACTION=NOINDEX, but does support ABORT, FAIL, PROMPT, and REPAIR.

DLCREATEDIR
does not work with the SPD Engine.

ERRORS=MAX
sets the maximum number of observations to 2147483647 for which SAS can issue error messages.

FIRSTOBS=
cannot be used in the SPD Engine.

SORTPGM=
using the BEST option can cause performance issues.

VALIDMEMNAME=
has the following restrictions on member name when you use VALIDMEMNAME=EXTEND:
- a member name cannot have a period, such as class.group.
- a member name cannot start with $, such as$class.

VALIDVARNAME=
cannot create an index or composite index on a variable if the variable name contains any of the following special characters:
*  |  \  :  /  <  >  ?  -

Dictionary

COMPRESS System Option
Specifies to compress SPD Engine data sets on disk as they are being created.
Valid in: Configuration file, SAS invocation, OPTIONS statement, System Options window
COMPRESS System Option

Category: System administration: Performance

Restriction: Cannot be used with ENCRYPT=YES or ENCRYPT=AES

Interactions: “IOBLOCKSIZE= Data Set Option” on page 83
               “PADCOMPRESS= Data Set Option” on page 88

Engine: SPD Engine only

Syntax

Form 1:  -COMPRESS NO | CHAR | BINARY
Form 2:  COMPRESS= NO | CHAR | BINARY

Required Arguments

NO
performs no data set compression.

CHAR
specifies that data in an SPD Engine data set be compressed in blocks by using RLE (run-length encoding). RLE compresses data by reducing repeated runs of the same character (including a blank space) to two-byte or three-byte representations.

Alias YES

BINARY
specifies that data in an SPD Engine data set be compressed in blocks by using RDC (Ross Data Compression). RDC combines RLE and sliding window compression to compress the file by representing repeated byte patterns more efficiently.

Note: This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (character and numeric variables).

Details

When you specify COMPRESS=YES | BINARY | CHAR, the SPD Engine compresses, by blocks, the data component file as it is created. To specify the size of the compressed blocks, use the “IOBLOCKSIZE= Data Set Option” on page 83 when you create the data set. To add padding to the newly compressed blocks, specify “PADCOMPRESS= Data Set Option” on page 88 when creating or updating the data set. For more information, see “Updates to a Compressed SPD Engine Data Set” on page 21.

If you are migrating a default Base SAS engine data set that is both compressed and encrypted, the encryption is retained, but the compression is dropped.

The CONTENTS procedure identifies the compress setting. If the data set is compressed, PROC CONTENTS prints information about the compression. The following example explains the Compressed Info fields in the CONTENTS procedure output:

In general, COMPRESS=CHAR provides good compression when single bytes repeat; COMPRESS=BINARY provides good compression when strings of bytes
repeat. At the same time, it is more costly to look for strings of bytes that repeat, than to look for single bytes that repeat. For examples, see “Example 1: COMPRESS=CHAR” on page 72 and “Example 2: COMPRESS=BINARY” on page 72.

**Output 5.1** *PROC CONTENTS Compressed Section*

<table>
<thead>
<tr>
<th><strong>- Compressed Info</strong></th>
<th><strong>-</strong></th>

</table>

Number of compressed blocks
number of compressed blocks that are required to store data.

Raw data blocksize
compressed block size in bytes calculated from the size specified in the IOBLOCKSIZE= data set option. It is the largest multiple of the observation length that fits in the block size.

Number of blocks with overflow
number of compressed blocks that needed more space. When data is updated and the compressed new block is larger than the compressed old block, an overflow block fragment is created.

Max overflow chain length
largest number of overflows for a single block. For example, the maximum overflow chain length would be 2 if a compressed block was updated and became larger, and then updated again to a larger size.

Block number for max chain
number of the block containing the largest number of overflow blocks.

Min overflow area
minimum amount of disk space that an overflow requires.

Max overflow area
maximum amount of disk space that an overflow requires.

Accessing compressed files usually requires more processing time. The files have to be decompressed before reading them and, if updating, they have to be compressed again when written to disk.

**Comparisons**

The COMPRESS= system option is overridden by the COMPRESS= LIBNAME statement option and the COMPRESS= data set option.
If the COMPRESS= data set option or LIBNAME statement option is not set, then the value of the COMPRESS= system option is used. The COMPRESS= system option default value is NO.

MAXSEGRATIO System Option

Controls what percentage of index segments to identify as candidate segments before processing the WHERE expression. This occurs when evaluating a WHERE expression that contains indexed variables.

Valid in: Configuration file, SAS invocation, OPTIONS statement, System Options window
Category: System administration: Performance
Default: 75
Engine: SPD Engine only

Syntax
Form 1: -MAXSEGRATIO \( n \)
Form 2: MAXSEGRATIO=\( n \)

Required Argument
\( n \)
specifies an upper limit for the percentage of index segments that the SPD Engine identifies as containing the value referenced in the WHERE expression. The default is 75, which specifies for the SPD Engine to do the following:
- use the index to identify segments that contain the particular WHERE expression value
- stop identifying candidate segments when more than 75% of all segments are found to contain the value

The range of valid values is integers between 0 and 100. If \( n=0 \), the SPD Engine does not try to identify candidate segments, but instead applies the WHERE expression to all segments. If \( n=100 \), the SPD Engine checks 100% of the segments to identify candidate segments, and then applies the WHERE expression only to those candidate segments.

Details
For WHERE queries on indexed variables, the SPD Engine determines the number of index segments that contain one or more variable values that match one or more of the conditions in the WHERE expression. Often, a substantial performance gain can be realized if the WHERE expression is applied only to the segments that contain observations satisfying the WHERE expression.

The SPD Engine uses the value of MAXSEGRATIO= to determine at what point the cost of applying the WHERE expression to every segment would be less than the cost of continuing to identify candidate segments. When the calculated ratio exceeds the ratio specified in MAXSEGRATIO=, the SPD Engine stops identifying candidate segments and applies the WHERE expression to all segments.
Note: For a few tables, 75% might not be the optimal setting. To determine a better setting, run a performance benchmark, adjust the percentage, and rerun the performance benchmark. Comparing results shows you how the specific data population that you are querying responds to shifting the index-segment ratio.

Examples:

Example 1: Identifying Index Segments
The following example causes the SPD Engine to begin identifying index segments that might satisfy the WHERE expression until the percentage of identified segments, compared to the total number of segments, exceeds 65. If the percentage exceeds 65, the SPD Engine stops identifying candidate segments and applies the WHERE expression to all segments:

```plaintext
options maxsegratio=65;
```

Example 2: Applying the WHERE Expression to All Segments
The following example causes the SPD Engine to apply the WHERE expression to all segments without first identifying any candidate segments:

```plaintext
options maxsegratio=0;
```

Example 3: Not Stopping Until All Index Segments Are Evaluated
The following example causes the SPD Engine to begin identifying index segments and to not stop until it has evaluated all segments. Then, the WHERE expression is applied to all candidate segments that were identified:

```plaintext
options maxsegratio=100;
```

MINPARTSIZE System Option

Specifies the minimum partition size to use when creating SPD Engine data sets.

- **Valid in:** Configuration file, SAS invocation
- **Category:** System administration: Performance
- **Default:** 16 megabytes
- **Range:** 0 bytes to 2,147,483,647 bytes
- **Interactions:**
  - “PARTSIZE= Data Set Option” on page 89
  - “PARTSIZE= LIBNAME Statement Option” on page 47

If you set MINPARTSIZE larger than the PARTSIZE= default, then you must specify PARTSIZE= equal to or larger than MINPARTSIZE.

- **Engine:** SPD Engine only
Syntax

-MINPARTSIZE n | nK | nM | nG

Required Argument

\( n \)

is the size of the partition in bytes, kilobytes, megabytes, or gigabytes. The maximum value for the minimum partition size is 2GB–1 or 2047 megabytes.

Restriction

This restriction applies only to 32-bit hosts with the following operating systems: z/OS, Linux SLES 9 x86, and the Windows family. If you create a data set with a partition size greater than or equal to 2 gigabytes, you cannot open the data set with any version of SPD Engine prior to SAS 9.2. The following error message is written to the SAS log: ERROR: Unable to open data file because its data representation differs from the SAS session data representation.

Details

Specifying MINPARTSIZE sets a lower limit for the partition size that can be specified with the PARTSIZE= option. The MINPARTSIZE specification could affect whether the partitions are created with approximately the same number of observations. A small partition size means more open files during processing. Your operating system might have a limit on the number of open files used.

SPDEINDEXSORTSIZE System Option

Specifies the memory space size that the sorting utility can use when sorting values for creating an index.

Valid in: Configuration file, SAS invocation, OPTIONS statement, System Options window

Category: System administration: Performance

Default: 32M

Engine: SPD Engine only

Syntax

Form 1: -SPDEINDEXSORTSIZE n | nK | nM | nG

Form 2: SPDEINDEXSORTSIZE=n | nK | nM | nG

Required Argument

\( n \)

is the size of memory space in bytes, kilobytes, megabytes, or gigabytes.

Range: 1,048,576 to 10,736,369,664 bytes
Details

The SPD Engine can create multiple indexes with a single scan of a data set. The SPD Engine spawns a single thread for each index created, and then processes the threads simultaneously. Although creating indexes in parallel is much faster than scanning the data set for each index, the default for this option is NO because parallel index creation requires extra utility space to store the sorting files and requires additional memory. If index creation fails due to insufficient resources, you can do one or both of the following:

- Increase the size of the utility file space using the SPDEUTILLOC= system option.
- Set the SAS system option to MEMSIZE=0 and increase the utility space that is used for index sorting using the SPDEINDEXSORTSIZE= system option.

The maximum SPDEINDEXSORTSIZE= value is 10 GB, but this value cannot be honored on host systems that are limited to 2 GB. On host systems that have a 64-bit LONG data type, SPD Engine honors values greater that 2 GB. On hosts systems that have a 32-bit LONG data type, SPD Engine honors only the memory used up to 2 GB. The SPDEINDEXSORTSIZE option value can be set to a larger value, but the larger value is not honored.

Note: You receive a warning in the SAS log when the larger value is not honored and used.

SPDEMAXTHREADS System Option

Specifies the maximum number of threads that the SPD Engine can spawn for I/O processing.

Valid in: Configuration file, SAS invocation
Category: System administration: Performance
Default: 0
Engine: SPD Engine only

Syntax

-SPDEMAXTHREADS n

Required Argument

n is the maximum number of threads the SPD Engine can spawn. The range of valid values is 0 to 65,536. The default is zero, which means that the SPD Engine uses the value of THREADNUM= if set. Otherwise, the SPD Engine sets the number of threads to spawn to be equivalent to the number of CPUs.

1. For z/OS, increase the REGION size.
Details

Specifying SPDEMAXTHREADS sets an upper limit on the number of threads to spawn for the SPD Engine processing, which includes the following:

- WHERE expression processing
- parallel index creation

SPDEMAXTHREADS constrains the THREADNUM= data set option.

SPDESORTSIZE System Option

Specifies the memory space size that is needed for sorting operations used by the SPD Engine.

Valid in: Configuration file, SAS invocation, OPTIONS statement, System Options window
Category: System administration: Performance
Default: 32M
Engine: SPD Engine only

Syntax

Form 1: -SPDESORTSIZE \( n \) | \( nK \) | \( nM \) | \( nG \)
Form 2: SPDESORTSIZE=\( n \) | \( nK \) | \( nM \) | \( nG \)

Required Argument

\( n \)

is the size of memory space in bytes, kilobytes, megabytes, or gigabytes.

Range 1,048,576 to 10,736,369,664 bytes

Details

The SPD Engine can perform an automatic sort in parallel. The sort size that you specify for SPDESORTSIZE= should be multiplied by the number of processes that are in parallel. This total for sort size should be less than the physical memory available to your process. The proper specification of SPDESORTSIZE= can improve performance by restricting the swapping of memory that is controlled by the operating environment.

Perform one of the following if the sort process needs more memory than you specified:

- restart SAS with the SAS system option MEMSIZE=0 (For z/OS, increase the REGION size.)
- increase the size of the utility file space using the SPDEUTILLOC= system option

You increase the memory that is used when sorting values for creating an index using the SPDEINDEXSORTSIZE= option. If you specify to create indexes in parallel, specify a large-enough space using the SPDEUTILLOC= system option.
The SORTSIZE= option documented for the default Base SAS engine affects PROC SORT operations. The SPDESORTSIZE= specification affects sorting operations specific to the SPD Engine.

The maximum SPDESORTSIZE= value is 10 GB, but this value cannot be honored on host systems that are limited to 2 GB. On host systems that have a 64-bit LONG data type, SPD Engine honors values greater that 2 GB. On host systems that have a 32-bit LONG data type, SPD Engine honors only the memory used up to 2 GB. The SPDESORTSIZE option value can be set to a larger value, but the larger value is not honored.

Note: You receive a warning in the SAS log when the larger value is not honored and used.

---

SPDEUTILLOC System Option

Specifies one or more file system locations in which the SPD Engine can temporarily store utility files.

Valid in: Configuration file, SAS invocation
Category: System administration: Performance
Engine: SPD Engine only
See: The SAS Companion for your operating system details how to specify system options

Syntax

-SPDEUTILLOC directory | ("directory-1" "directory-2"…)

Required Arguments

directory
  is an existing directory where the utility files are created.

("directory-1" "directory-2" …)
  is a series of existing directories where the utility files are created. You can use single or double quotation marks.

Note: location can be enclosed in single or double quotation marks. Quotation marks are required if location contains embedded blanks.

Details

Operating Environment Information: The SAS Companion for your operating system details how to specify system options.

The SPD Engine creates temporary utility files during certain processing, such as automatic sorting and creating indexes. To successfully complete the process, you must have enough space to store the utility files. The SPDEUTILLOC system option enables you to specify an adequate amount of space for processing. However, for OpenVMS on HP Integrity Servers, the libraries must be ODS-5 files. When multiple
directories are specified in the SPDEUTILLOC system option, the directory for the first utility file is randomly selected when processing starts. The selection continues in a cyclical fashion to the other directories. Utility files are temporary and are removed after processing is completed.

**Note:** To avoid syntax errors, specify multiple directories in the configuration file.

SAS recommends that you always specify the SPDEUTILLOC option or the UTILLOC option to ensure that you have enough space for processes that create utility files.

Here are the default utility file locations, in order of precedence:

1. If the system option SPDEUTILLOC is set, it has first priority and is used. If this location is not valid, then the SAS Work library location is used.
2. If SPDEUTILLOC is not set, then the SAS system option UTILLOC is used. If this location is not valid, then the SAS Work library location is used.
3. If neither SPDEUTILLOC nor UTILLOC is set, then the SAS Work library location is used. (The SPD Engine must have Write permission to the SAS Work library location in order to use it.)
4. In extremely rare circumstances, if none of the above locations is available, then environment variables are used, in the following order of precedence: SASTEMP, TEMP, TMP, and TMPDIR. Note that on Windows, TEMP is usually set. On UNIX, the environment variable can be TEMP, TMP, or TMPDIR.
5. If none of the above locations is available, then on UNIX or z/OS, the /tmp directory is used. (Windows does not have an equivalent default.)

---

**SPDEWHEVAL System Option**

Specifies the process to determine which observations meet the condition or conditions of a WHERE expression.

**Valid in:** Configuration file, SAS invocation, OPTIONS statement, System Options window

**Category:** System administration: Performance

**Default:** COST

**Engine:** SPD Engine only

**Syntax**

**Form 1:**

```
-SPDEWHEVAL COST | EVAL1 | EVAL3EVAL4
```

```
SPDEWHEVAL=COST | EVAL1 | EVAL3EVAL4
```

**Required Arguments**

**COST**

specifies that the SPD Engine decides which evaluation strategy to use to optimize the WHERE expression. This process calculates the number of threads to be used, which minimizes the overhead of spawning underused threads. This is the default.
EVAL1
is a multi-threaded index evaluation strategy that can quickly determine the rows that satisfy the WHERE expression using multiple threads. The number of threads that are spawned to retrieve the observations is equal to the THREADNUM= value.

EVAL3EVAL4
is a single-threaded index evaluation strategy that is used for a simple or compound WHERE expression. All the key variables have a simple index and no condition tests for non-equality. Multi-threading might be used to retrieve the observations.

Details
The SPD Engine uses WHINIT, a rules-based WHERE expression planner, to select the most appropriate evaluation strategy for a query. The SAS system option MSGLEVEL=1 surfaces WHINIT messages to the SAS log that can help you determine whether one or more indexes are used in a query.

COST, the default setting for SPDEWHEVAL=, analyzes the WHERE expression and any available indexes. Based on the analysis, the SPD Engine chooses an evaluation strategy to optimize the WHERE expression. The evaluation strategy can be EVAL1, EVAL3EVAL4, or a strategy that sequentially reads the data if no indexes are available. The analysis also determines whether an index or indexes cannot improve processing time.

COST optimizes the number of threads to use for processing the WHERE expression. COST determines and spawns the number of threads that can be efficiently used. Based on the value of THREADNUM=, COST can save significant processing time by not spawning threads that are underused.

COST is the recommended value for SPDEWHEVAL=, unless the WHERE expression exactly meets one of the other evaluation strategy criterion. It is strongly recommended that benchmark tests be used to determine whether a value other than COST is more efficient.

EVAL1 might be more efficient if the WHERE expression is complex and there are multiple indexes for the variables. EVAL1 spawns multiple threads to determine which segments meet the conditions of the WHERE expression. Multiple threads can also be used to retrieve the observations.

Note: In a few situations, COST might not perform the best. To determine whether changing the value to EVAL1 or EVAL3EVAL4 can produce better performance, run a performance benchmark, change the value, and re-run the performance benchmark. Comparing results shows you how the specific data population that you are querying responds to rules-based WHERE planning.
