What’s New in SAS 9.4 FedSQL
Language Reference

SAS Viya 3.5

The following functionality was added to the FedSQL language:

- The ability to read and write to MongoDB and Salesforce nonrelational databases with FedSQL when appropriate SAS/ACCESS software is installed. The functionality is available when accessing the databases through a SAS library. It is also available when accessing the databases through the CAS server. For MongoDB and Salesforce statement and data type support in a SAS library, see “FedSQL Statements by Category” on page 830 and Appendix 2, “Data Type Reference,” on page 1017. For statement support on the CAS server, see SAS Viya: FedSQL Programming for SAS Cloud Analytic Services.

- There are improvements to data type support for various third-party relational databases when appropriate SAS/ACCESS software is installed. The features are available when the databases are accessed through a SAS library.
  - FedSQL now creates VARCHAR columns containing greater than 65,535 characters as type STRING in Hive. For more information, see “Data Types for Hive” on page 1035.
  - FedSQL now reads and writes Teradata NUMBER columns. For more information, see “Data Types for Teradata” on page 1070.
  - FedSQL now reads JSON columns in MySQL. For more information, see “Data Types for MySQL” on page 1047.
  - You no longer have to set the TIMEZONE system option to display date and time data as it was recorded in Salesforce.

- The COMPRESS function supports a Modifier argument. See “COMPRESS Function” on page 351.

- The documentation was enhanced:
  - The documentation describing the return values of FedSQL functions that are like-named in Base SAS has been updated. See “Overview of FedSQL Functions” on page 202.
  - A new example shows when to use the FORCE option in the DROP TABLE statement. See “DROP TABLE Statement” on page 865.
  - The documented syntax for the SELECT statement UNION, EXCEPT, and INTERSECT operators has been modified. See the “SELECT Statement” on
The documentation has been modified to remove mention of the FCMP procedure. The FCMP procedure is not supported for FedSQL.

A new appendix has been added. See Appendix 1, “Troubleshooting: Resolving FedSQL Errors,” on page 1013.

Appendix 6, “How to Perform Common PROC SQL Tasks with FedSQL” has been updated to include three new topics: “Overwrite an Existing Table with FedSQL” on page 1110, “Using Explicit Pass-Through” on page 1122, “Comparing Implicit SQL Pass-Through” on page 1123.

August 2019

The FedSQL language adds support as data sources for Google BigQuery and Snowflake. Access is Read and Write, and through a SAS library or a caslib. The data sources are supported both on SAS 9.4M6 and SAS Viya 3.4. Appropriate SAS/ACCESS software must be installed. The FedSQL language supports different functionality on the CAS server than it does in a SAS library. SAS FedSQL Language Reference describes the statements, table options, and data types support that is available for the data sources when they are accessed through a SAS library. For information about the FedSQL statements, table options, and data types that are available on the CAS server, see SAS Viya: FedSQL Programming for SAS Cloud Analytic Services.

May 2019

This documentation is enhanced with a new appendix: Appendix 6, “How to Perform Common PROC SQL Tasks with FedSQL,” on page 1109.

April 2019

The following functionality was added to the FedSQL language on SAS 9.4M6: support for MongoDB and Salesforce as data sources. The new data sources are accessed by assigning a SAS library. FedSQL support for both data sources is Read-only. In addition, explicit pass-through is supported. You must have appropriate SAS/ACCESS software. For more information, see statements for data retrieval and SQL pass-through in “FedSQL Statements by Category” on page 830. For information about data type support, see Appendix 2, “Data Type Reference,” on page 1017. No table options are supported for these data sources.
SAS 9.4M6

The following functionality was added to the FedSQL language:

- The FedSQL language adds support as a data source for databases that are compliant with JDBC on SAS 9.4. Access is Read and Write. Appropriate SAS/ACCESS software must be installed. For statement support, see “FedSQL Statements by Category” on page 830. For information about data type support, see Appendix 2, “Data Type Reference,” on page 1017.

- The FedSQL language creates VARCHAR columns containing greater than 65,535 characters as type STRING in Hive. Previously, the columns were created as VARCHAR, regardless of length. See “Data Types for Hive” on page 1035.

The documentation was modified as follows:

- The documentation for the CREATE TABLE statement was modified to include naming restrictions for HDMD and Hive data sources. For more information, see “CREATE TABLE Statement” on page 840.

- The documentation for the DESCRIBE VIEW statement was modified to clarify support for SAS data views. See “DESCRIBE VIEW Statement” on page 863.

- The documentation clarifies support for SAS system options. See Chapter 9, “FedSQL and System Options,” on page 1009.

SAS Viya 3.4

The following functionality was added to the FedSQL language.

- The FedSQL language adds support as data sources for these databases: databases that are compliant with JDBC and Spark databases. The new data sources are available only on SAS Viya 3.4. The new data sources can be accessed by assigning a SAS library or a CAS library. The FedSQL language supports different functionality on the CAS server than it does in a SAS library. SAS FedSQL Language Reference describes the statements, table options, and data type support that is available when accessing the data sources through a SAS library. For information about the FedSQL statements, table options, and data types that are available on the CAS server, see SAS Viya: FedSQL Programming for SAS Cloud Analytic Services.

- The FedSQL language supports explicit SQL pass-through on the CAS server. For more information, see SAS Viya: FedSQL Programming for SAS Cloud Analytic Services. For an example of how an explicit pass-through request is submitted in the fedSql.execDirect action, see SAS Viya: System Programming Guide.

- The SYSGET function returns the value of the specified operating environment variable.
The URLDECODE and URLENCODE functions are documented for FedSQL.

SAS Viya 3.3

The FedSQL language supports SAS library access to all SAS 9.4 third-party data sources in SAS Viya when appropriate SAS/ACCESS software is installed. It supports CAS library access to all data sources for which SAS Data Connector software is installed. The FedSQL language supports different functionality on the CAS server than it does in a SAS library. SAS FedSQL Language Reference describes the statements, table options, and data type support that is available when accessing the data sources through a SAS library. For information about the FedSQL statements, table options, and data types that are available on the CAS server, see SAS Viya: FedSQL Programming for SAS Cloud Analytic Services.

SAS 9.4M5

The following functionality was added to the FedSQL language:

- If you have SAS Viya configured in addition to SAS 9.4, you can submit FedSQL statements to SAS Cloud Analytic Services from your SAS 9.4 session. For more information, see “Running FedSQL Programs” on page 4 and “FedSQL and SAS Cloud Analytic Services” on page 6.

- Support for Amazon Redshift, Microsoft SQL Server, and Vertica data sources on SAS 9.4M5. Appropriate SAS/ACCESS software must be installed. Access is through a SAS library. See “FedSQL Statements” on page 829 for information about available statements. See “FedSQL Statement Table Options by Data Source” on page 911 for information about available table options. See Appendix 2, “Data Type Reference,” on page 1017 for information about data type support for each data source.

- You can now get information about views from DICTIONARY.COLUMNS queries for a SAS library. See “DICTIONARY Tables” on page 67.

- Support for FINANCE functions. For more information, see “FINANCE Function” on page 412.

- The ENCRYPT= table option supports stronger AES encryption for SAS data sets. For more information, see “ENCRYPT= Table Option” on page 955.

- SAS Scalable Performance Data (SPD) Server tables can now be encrypted with ENCRYPT= and ENCRYPTKEY= table options.

- PRE_TABLE_OPTS= and POST_TABLE_OPTS= table options for Hive. See “PRE_TABLE_OPTS= Table Option” on page 977 and “POST_TABLE_OPTS= Table Option” on page 976.

- Support for the following functions:
  ANYALNUM  CSC  INTTEST  NWKDOM
  ANYALPHA  CUMIPMT  INTZ  PDF
The following functionality was added to the FedSQL language:

- Support for HAWQ and Impala distributions of Hadoop. Appropriate SAS/ACCESS software must be installed. Access is through a SAS library. See “FedSQL Statements” on page 829 for information about available statements. See “FedSQL Statement Table Options by Data Source” on page 911 for information about available table options. See Appendix 2, “Data Type Reference,” on page 1017 for information about data type support for each data source.

- DICTIONARY.TABLES queries have been enhanced to return SECURITY and SERVICE columns. For a complete list of the columns returned by DICTIONARY.TABLES queries, see “DICTIONARY.TABLES” on page 1107.

- “DBCREATE_TABLE_OPTS= Table Option” on page 950 for Hive.

- “ENCODING= Table Option” on page 954 for SAS data sets.

- Expanded data type support for the SAS HDMD data source, including support for FLOAT and for reading and writing the DECIMAL/NUMERIC(p,s) data types.
See "Data Types for HDMD" on page 1033 for a complete list of supported data types.

- Expanded data type support for Hive:
  - support for reading the Hive ARRAY, MAP, STRUCT, and UNION complex types.
  - support for reading and writing the DECIMAL/NUMERIC(p,s) and BINARY data types. Full support of the DECIMAL/NUMERIC and BINARY types is provided in Hive 0.13 and later. In earlier Hive versions, DECIMAL/NUMERIC columns are not supported, and BINARY columns can be created but not retrieved.
  - support for writing the VARBINARY type. Columns of type VARBINARY type are created as type BINARY in Hive.
  - support for reading and writing TIME values.

For a complete list of the data types that are support for Hive, see "Data Types for Hive" in Appendix 2, "Data Type Reference," on page 1017.

- Hive has been enhanced to search tables that have more than one column of type TIME with the HOUR, MINUTE, and SECOND functions. See “HOUR Function” on page 508, “MINUTE Function” on page 600, and “SECOND Function” on page 741.

- MDS now supports UNIQUE and UNIQUE([COLUMN],[COLUMN]) syntax in the CREATE TABLE statement. See “CREATE TABLE Statement” on page 840.

- Documentation enhancements:
  - clarification of DICTIONARY support for third-party DBMS. See “DICTIONARY Tables” on page 67.
  - clarification of Hive and SAS data set support of the CHAR(n) [CHARACTER SET "character-set-identifier"] syntax in the CREATE TABLE statement. See “CREATE TABLE Statement” on page 840.
  - clarification of SAS data set and SPD Engine data set support of the CREATE INDEX ASCENDING and DESCENDING arguments. See “CREATE INDEX Statement” on page 838.
  - clarification of support for the TIME data type in ODBC-style interfaces. See “Data Types for Greenplum” on page 1030, “Data Types for HAWQ” on page 1032, and “Data Types for Netezza” on page 1049.
  - clarification of multi-byte support in the CHAR(n) and VARCHAR(n) data types for ODBC data sources. See “Data Types for ODBC” on page 1050.
  - Documented the minimum and maximum year values supported for the DATE type in Hive. See “Data Types for Hive” on page 1035.
  - Corrected information about support for FORMAT=, INFORMAT=, and LABEL= modifiers in Appendix 7, “FedSQL and the ANSI Standard,” on page 1133. These modifiers are not supported in the SELECT statement.
SAS 9.4M2

The following functionality was added to the FedSQL language:

- Support for Hive, SAS HDMD, and PostgreSQL data sources. Appropriate SAS/ACCESS software must be installed. Access is through a SAS library. See “FedSQL Statements” on page 829 for information about available statements. See “FedSQL Statement Table Options by Data Source” on page 911 for information about available table options. See Appendix 2, “Data Type Reference,” on page 1017 for information about data type support for each data source.

- “CAST Function” on page 293
- “DBCREATE_INDEX_OPTS= Table Option” on page 950 for ODBC

SAS 9.4M1

The following functionality was added to the FedSQL language:

- Support for Memory Data Store (MDS) and SAP HANA data sources. Access is through a SAS library. See “FedSQL Statements” on page 829 for information about available statements. See “FedSQL Statement Table Options by Data Source” on page 911 for information about available table options. See Appendix 2, “Data Type Reference,” on page 1017 for information about data type support for each data source.

- Rename table and rename column functionality in the ALTER TABLE statement. See “ALTER TABLE Statement” on page 831.

The documentation was enhanced to include the following:

- examples of join operations. See “Join Operations” on page 31.
- examples of EXCEPT, INTERSECT, and UNION operations. See “Default Query Expression Behavior” on page 49.
- examples of subqueries. See “Overview of Subqueries” on page 52, “Examples of Correlated Subqueries” on page 53, “Examples of Scalar Subqueries” on page 54, and “Examples of Non-Correlated Queries” on page 56.
- an explanation of how the PUT function can be used. See “Using Formats in FedSQL” on page 80 and “Using a User-Defined Format” on page 82.
Chapter 1

Introduction to the FedSQL Language
Introduction to the FedSQL Language

SAS FedSQL is a SAS proprietary implementation of ANSI SQL:1999 core standard. It provides support for new data types and other ANSI 1999 core compliance features and proprietary extensions. FedSQL provides a scalable, threaded, high-performance way to access, manage, and share relational data in multiple data sources. When possible, FedSQL queries are optimized with multi-threaded algorithms in order to resolve large-scale operations. Beginning in April 2019, FedSQL also supports reading of some non-relational data sources.

For applications, FedSQL provides a common SQL syntax across all data sources. That is, FedSQL is a vendor-neutral SQL dialect that accesses data from various data sources without having to submit queries in the SQL dialect that is specific to the data source. In addition, a single FedSQL query can target data in several data sources and return a single result set.

Benefits of FedSQL

FedSQL provides many benefits if you are working in an environment in which you need more features than are provided in the SQL procedure.

- FedSQL conforms to the ANSI SQL:1999 core standard. This conformance allows it to process queries in its own language and the native languages of other data sources that conform to the standard.
- FedSQL supports many more data types than previous SAS SQL implementations. Traditional data source access through SAS/ACCESS translates target data source data types to and from two legacy SAS data types, which are SAS numeric and SAS character. When FedSQL connects to a data source, the language matches or translates the target data source’s definition to these data types, as appropriate, which allows greater precision. Supported data types are described in “Data Types” on page 14.
- FedSQL handles federated queries. With the traditional DATA step or the SQL procedure, a SAS/ACCESS LIBNAME engine can access only the data of its intended data source.
- The FedSQL language can create data in any of the supported data sources, even if the target data source is not represented in a query. This enables you to store data in the data source that most closely meets the needs of your application.

Federated Queries

A federated query is one that accesses data from multiple data sources and returns a single result set. The data remains stored in the data source. For example, in this query, data is requested from an Oracle table and from two Teradata tables:

```sql
select Ora1.city, Ora1.State, Ora1.zip
from Oracle.Tbl1 Ora1, Teradata.Tbl2 Tera2, Teradata.Tbl3 Tera3
where Ora1.zip = Tera2.zip and Tera2.zip = Tera3.zip;
```

Running FedSQL Programs

You can submit FedSQL programs in one of the following ways:

- Through the SAS windowing environment or SAS Studio by using the FEDSQL procedure. The FedSQL procedure can be used to submit FedSQL statements in SAS 9.4, SAS Viya, and on the SAS Cloud Analytic Services (CAS) server. See Base SAS Procedures Guide.
Through the FedSQL.execDirect action to the CAS server. The FedSQL execDirect action can be called from a SAS Studio session or from a Python, Lua, or R program. In SAS Studio, the FedSQL.execDirect action is used with the CAS procedure. For more information about the FedSQL.execDirect action, see SAS Viya: System Programming Guide.

From a JDBC, ODBC, or OLE DB client by using SAS Federation Server. See SAS Federation Server: Administrator’s Guide.

From a DS2 program. See Appendix 3, "Using FedSQL and DS2," on page 1075.

Data Source Support

FedSQL can access the following data sources:
- Amazon Redshift
- Aster
- DB2 for UNIX and Windows operating environments
- CAS libraries
- Google BigQuery on Linux for x64
- Greenplum
- HAWQ
- Hadoop (Hive and HDMD)
- Impala
- databases that are compliant with JDBC
- Memory Data Store (MDS)
- Microsoft SQL Server
- MongoDB on Linux for x64
- MySQL
- Netezza
- databases that are compliant with ODBC
- Oracle
- PostgreSQL
- Salesforce
- SAP (Read-only)
- SAP HANA
- SAP IQ
- SAS data sets
Data Source Connection

In order to submit FedSQL statements to a data source, you must establish a connection to a data source.

The FEDSQL procedure generates a connection string by using the attributes of currently assigned librefs by default. You first submit a LIBNAME statement for the data source that you want to access (for example, a Base SAS LIBNAME statement or a Hadoop LIBNAME statement) and then run PROC FEDSQL. For more information, see “FEDSQL Procedure” in Base SAS Procedures Guide.

The SAS Federation Server LIBNAME engine obtains a data source connection by connecting to a SAS Federation Server and specifying a DSN that is defined on SAS Federation Server. You specify server connection properties and the DSN in a LIBNAME statement. You must have been given the name of a DSN by a SAS Federation Server administrator, and be familiar with the names of the catalogs and schemas accessed through the DSNs in order to access data. For more information, see SAS LIBNAME Engine for SAS Federation Server: User’s Guide.

SAS Federation Server encapsulates the information that is needed to connect to a data source in a Data Source Name (DSN) definition. A DSN is metadata that contains connection details. DSN definitions are created by a SAS Federation Server administrator. In order to use a DSN, you must first connect to SAS Federation Server. For more information about connecting to SAS Federation Server and submitting DSNs, see SAS Federation Server: Administrator’s Guide.

FedSQL and SAS Cloud Analytic Services

SAS Cloud Analytic Services is an in-memory processing environment. FedSQL functionality in CAS is limited. For information about the FedSQL statements, expressions, predicates, and table options that are supported in CAS, see SAS...
Purpose of This Documentation

The SAS FedSQL Language Reference provides the following information for the Federated Query Language (FedSQL).

- Conceptual information about the FedSQL language
- Detailed reference information for the major language elements:
  - formats
  - functions
  - expressions, operators, and predicates
  - statements
  - table options

Intended Audience

This document is intended for the following users:

- Application developers who write client applications and need an understanding of the FedSQL language. They write applications that create tables, bulk load tables, manipulate tables, and query data.
- Database administrators who design and implement the client/server environment. They administer the data by designing the databases and setting up the data source metadata. That is, database administrators build the data model.
- SAS programmers who write and submit Base SAS code such as SAS procedures and the SAS DATA step language and now want to take advantage of the FedSQL language.
- Programmers who want to create and query persisted SAS and DBMS data from a SAS library.

Typographical Conventions

Type styles have special meanings in the documentation of the FedSQL syntax. The following list explains the style conventions for the syntax:
**UPPERCASE BOLD**

identifies SAS keywords such as the names of statements and functions (for example, CREATE TABLE).

**UPPERCASE ROMAN**

identifies arguments and values that are literals (for example, FROM).

*italic*

identifies arguments or values that you supply. Items in italics can represent user-supplied values that are either one of the following.

- nonliteral values that are assigned to an argument (for example, END=variable).
- nonliteral arguments (for example, AS alias).

If more than one of an item in italics can be used, the items are expressed as item [, ...item].

**monospace**

identifies examples of SAS code.

---

**Syntax Conventions**

The *SAS FedSQL Language Reference* uses the Backus-Naur Form (BNF). Specifically, it uses the same syntax notation that is used by Jim Melton in *SQL:1999 Understanding Relational Language Components*.

The main difference between traditional SAS syntax and the syntax that is used in the SAS FedSQL language reference documentation is in how optional syntax arguments are displayed. In the traditional SAS syntax, angle brackets (< >) are used to denote optional syntax. In the FedSQL syntax, square brackets ([ ]) are used to denote optional syntax and angle brackets are used to denote non-terminal components.

The following symbols are used in the FedSQL syntax.

::=  
This symbol can be interpreted as “consists of” or “is defined as”.

< >  
Angle brackets identify a non-terminal component; that is, a syntax component that can be further resolved into lower level syntax grammar.

[ ]  
Square brackets identify optional arguments. Any argument that is not enclosed in square brackets is a required argument. Do not enter the square brackets unless they are preceded by a backward slash (/), which denotes that they are literal.

{}  
Braces provide a method to distinguish required multi-word arguments. Do not enter the braces unless they are preceded by a backward slash (/), which denotes that they are literal.

|  
A vertical bar indicates that you can choose one value from a group. Values separated by bars are mutually exclusive.
An ellipsis indicates that the argument or group of arguments that follow the ellipsis can be repeated any number of times. If the ellipsis and the following arguments are enclosed in square brackets, they are optional.

A backward slash indicates that next character is a literal.

The following examples illustrate the syntax conventions that are described in this section. These examples contain selected syntax elements, not the complete syntax.

```
CREATE TABLE {table | _NULL_}
[
[OPTIONS SAS-table-option=value […SAS-table-option=value]]

(<column-definition> […<column-definition> | <table-constraint>])

| AS query-expression

;

<column-definition>::=

  column data-type [<column-constraint> <DEFAULT value> [HAVING [FORMAT format] [INFORMAT informat] [LABEL='label']]]
```

- **CREATE TABLE** is in uppercase bold because it is the name of the statement.
- **table** is italics because it is an argument that you can supply.
- **_NULL_** is uppercase roman because it is a literal argument.
- The braces that are preceded by a backward slash (before and after the literal argument OPTIONS) indicate that the braces are literal. That is, the OPTIONS statement must be specified within braces.
- **<column-definition>** is in angle brackets because it is a non-terminal argument that is further resolved into lower level syntax grammar.
- The square brackets and ellipsis around the second instance of **<column-definition>** indicates that it is optional and you can repeat this argument any number of times, separated by commas.
- You can specify a **<column-definition>** or an AS **query-expression**, but not both.
- **AS** is in uppercase roman because it is a literal argument.
- **<column-definition>::=** illustrates a non-literal expansion.

Data Types

A data type is an attribute of every column in a table that specifies the type of data the column stores. For example, the data type is the characteristic of a piece of data that says it is a character string, an integer, a floating-point number, or a date or time. The data type also determines how much memory to allocate for the column’s value.

The following table lists the data types that are supported by FedSQL. Note that not all data types are available for table storage on each data source.

Table 2.1 FedSQL Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>stores a large signed, exact whole number, with a precision of 19 digits. The range of integers is -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807. Integer data types do not store decimal values; fractional portions are discarded.</td>
</tr>
<tr>
<td>BINARY(n)</td>
<td>stores fixed-length binary data, where n is the maximum number of bytes to store. The maximum number of bytes is required to store each value regardless of the actual size of the value.</td>
</tr>
<tr>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>CHAR($n$)</td>
<td>stores a fixed-length character string, where $n$ is the maximum number of characters to store. Each character uses 1 byte of storage. The maximum number of characters is required to store each value regardless of the actual size of the value. If char(10) is specified and the character string is only five characters long, the value is right-padded with spaces.</td>
</tr>
<tr>
<td>DATE</td>
<td>stores a calendar date. A date literal is specified in the format yyyy-mm-dd: a four-digit year (0001 to 9999), a two-digit month (01 to 12), and a two-digit day (01 to 31). For example, the date September 24, 1975 is specified as 1975-09-24. FedSQL complies with ANSI SQL:1999 standards regarding dates. However, not all data sources support the full range of dates. For example, dates between 0001-01-01 and 1582-12-31 are not valid dates for a SAS data set, an SPD Engine data set, and an SPD Server table.</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>stores a signed, approximate, double-precision, floating-point number. Allows numbers of large magnitude and permits computations that require many digits of precision to the right of the decimal point.</td>
</tr>
<tr>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NUMERIC(p,s)</td>
</tr>
<tr>
<td>FLOAT(p)</td>
<td>stores a signed, approximate, single-precision, or double-precision, floating-point number. The user-specified precision determines whether the data type stores a single-precision or double-precision number. If the specified precision is equal to or greater than 25, the value is stored as a double-precision number, which is a DOUBLE. If the specified precision is less than 25, the value is stored as a single-precision number, which is a REAL. For example, <code>float(10)</code> specifies to store up to 10 digits, which results in a REAL data type.</td>
</tr>
<tr>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INTEGER</td>
<td>stores a regular size signed, exact whole number, with a precision of 10 digits. The range of integers is -2,147,483,648 to 2,147,483,647. Integer data types do not store decimal values; fractional portions are discarded. Now: Integer division by zero does not produce the same result on all operating systems. It is recommended that you avoid integer division by zero.</td>
</tr>
<tr>
<td>NCHAR((n))</td>
<td>stores a fixed-length character string such as CHAR but uses a Unicode national character set, where (n) is the maximum number of multibyte characters to store. Depending on the platform, Unicode characters use either two or four bytes per character and support all international characters.</td>
</tr>
<tr>
<td>NVARCHAR((n))</td>
<td>stores a varying-length character string such as VARCHAR but uses a Unicode national character set, where (n) is the maximum number of multibyte characters to store. Depending on the platform, Unicode characters use either two or four bytes per character and can support all international characters.</td>
</tr>
<tr>
<td>REAL</td>
<td>stores a signed, approximate, single-precision, floating-point number.</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>stores a small signed, exact whole number, with a precision of five digits. The range of integers is -32,768 to 32,767. Integer data types do not store decimal values; fractional portions are discarded.</td>
</tr>
<tr>
<td>TIME((p))</td>
<td>stores a time value. A time literal is specified in the format (hh:mm:ss[.nnnnnnnnn]); a two-digit hour 00 to 23, a two-digit minute 00 to 59, and a two-digit second 00 to 61 (supports leap seconds), with an optional fraction value. For example, the time 6:30 a.m. is specified as 06:30:00. When supported by a data source, the (p) parameter specifies the seconds precision. The seconds precision is an optional fraction value that is up to nine digits long.</td>
</tr>
<tr>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TIMESTAMP($p$)</td>
<td>stores both date and time values. A timestamp literal is specified in the format <code>yyyy-mm-dd:hh:mm:ss[.nnnnnnnnn]</code>: a four-digit year 0001 to 9999, a two-digit month 01 to 12, a two-digit day 01 to 31, a two-digit hour 00 to 23, a two-digit minute 00 to 59, and a two-digit second 00 to 61 (supports leap seconds), with an optional fraction value. For example, the date and time September 24, 1975 6:30 a.m. is specified as 1975-09-24:06:30:00. When supported by a data source, the $p$ parameter specifies the seconds precision. The seconds precision is an optional fraction value that is up to nine digits long.</td>
</tr>
<tr>
<td>TINYINT</td>
<td>stores a very small signed, exact whole number, with a precision of three digits. The range of integers is -128 to 127. Integer data types do not store decimal values; fractional portions are discarded.</td>
</tr>
<tr>
<td>VARBINARY($n$)</td>
<td>stores varying-length binary data, where $n$ is the maximum number of bytes to store. The maximum number of bytes is not required to store each value. If <code>varbinary(10)</code> is specified and the binary string uses only five bytes, only five bytes are stored in the column.</td>
</tr>
<tr>
<td>VARCHAR($n$)¹</td>
<td>stores a varying-length character string, where $n$ is the maximum number of characters to store. Each character uses 1 byte of storage. The maximum number of characters is not required to store each value. If <code>varchar(10)</code> is specified and the character string is only five characters long, only five characters are stored in the column.</td>
</tr>
</tbody>
</table>

¹ The CHAR, NCHAR, NVARCHAR, and VARCHAR data types have a length restriction of 10485760 characters for any column that is used as input or included in the output.

When defining a data type, use the data type keywords for either the data types that are supported by FedSQL or the data types that are supported by the target database SQL language. That is,

- If you submit FedSQL statements, use FedSQL data type keywords.
- If you request explicit SQL pass-through and submit SQL statements using the SQL language that is implemented by the specific data source, use the data type names for the target database. For information about how to define data types
using the SQL language for a specific data source, see the documentation for that data source.

Keep in mind that in order for data to be stored, the data type must be available for data storage in that data source. Although FedSQL supports several data types, the data types that can be defined for a particular table depend on the data source, because each data source does not necessarily support all FedSQL data types. In addition, data sources support variations of the standard SQL data types. That is, a specific data type that you specify might map to a different data type and might also have different attributes in the underlying data source. This occurs when a data source does not natively support a specific data type, but data values of a similar data type can be converted without data loss. For example, to support the INTEGER data type, a SAS data set maps the data type definition to SAS numeric, which is a DOUBLE.

For details about data source implementation for each data type, see Appendix 2, "Data Type Reference," on page 1017.

In addition, the CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source or the specified precision or scale is not within the data source range. For information about the CT_PRESERVE= connection argument, see SAS Federation Server: Administrator’s Guide.

Identifiers

Overview of Identifiers

An identifier is one or more tokens, or symbols, that name programming language entities, such as variables, method names, package names, and arrays, as well as data source objects, such as table names and column names.

FedSQL supports ANSI SQL:1999 core standards for both regular and delimited identifiers.

Regular identifiers are the type of identifiers that you see in most programming languages. They are not case-sensitive; the identifier Name is treated the same way as NAME, name, and NaMe: it becomes NAME. All lowercase letters in regular identifiers are changed to uppercase. Only certain characters are allowed in regular identifiers.

Delimited identifiers are case-sensitive and allow any character. Delimited identifiers are enclosed in double quotation marks.

By supporting ANSI SQL:1999 identifiers, FedSQL is compatible with data sources that also support the ANSI SQL:1999 identifiers.

Note: Identifiers for SAS data sets, SPD Engine data sets, and SPD Server tables are limited to 32 characters.
Note: When more than one data source is involved, the maximum length of an identifier is determined by the smallest maximum length that is supported by all of the data sources and FedSQL. For example, if your data sources are a SAS data set, which has a maximum of 32 characters, and MySQL, which has a maximum of 64 characters, the maximum length of an identifier would be 32 characters.

Regular Identifiers

When you name regular identifiers, use these rules:

- The length of a regular identifier can be 1 to 256 characters.
- The first character of a regular identifier must be a letter. Subsequent characters can be letters, digits, or underscores.
- Regular identifiers are case-insensitive.

The following regular identifiers are valid:

```plaintext
firstName
lastName
phone_num1
phone_num2
```

Letters in regular identifiers are stored internally as uppercase letters, which allows letters to be written in any case.

Note: Each data source has its own naming conventions, all of which are accepted by FedSQL. If your program contains identifiers that are specific for a particular data source, you must follow the naming conventions for that data source. See your database documentation for information about its naming conventions.

Delimited Identifiers

When you name delimited identifiers, follow these rules:

- The length of a delimited identifier can be 1 to 256 characters.
- Begin and end delimited identifiers with double quotation marks.
- Delimited identifiers consist of any sequence of characters, including spaces and special characters, between the beginning and ending double quotation marks.
- Delimited identifiers are case-sensitive.

A string of characters enclosed in double quotation marks is interpreted as an identifier and not as a character constant. Character constants can be enclosed only in single quotation marks.

Here is a list of valid delimited identifiers:

```plaintext
"x y z"
"Ö1*
"phone_num"
```
"a & B"

Letters in delimited identifiers are case-sensitive and their case is preserved when they are stored in FedSQL. When they are stored, the double quotation marks are removed.

You can use delimited identifiers for terms that might otherwise be a reserved word. For example, to use the term "char" other than for a character declaration, you would use it as the delimited identifier "char". For more information, see "FedSQL Reserved Words" on page 71.

Note: Each data source has its own naming conventions, all of which are accepted by FedSQL. When your program contains identifiers that are specific for a particular data source, you must follow the naming conventions for that data source. See your database documentation for information about table naming conventions for data source objects.

---

Referencing a Macro Variable in a Delimited Identifier

To reference a SAS macro variable in a delimited identifier, use the SAS macro function %TSLIT, which overrides the need for double quotation marks around the literal string and puts single quotation marks around the input value.

The %TSLIT macro function is stored in the default autocall macro library. The syntax is as follows:

%TSLIT(&macro-name)

Note: SAS macro variables are available only to FedSQL programs that are executed in a Base SAS session using PROC FEDSQL. They are not available to FedSQL programs that are executed outside the SAS System, such as on SAS Federation Server. SAS macro variables can be used to pre-process the source before it is prepared and executed. Functions like SYMPUT() and SYMGET() will not work in FedSQL.

---

Support for Non-Latin Characters

FedSQL supports non-Latin characters only in quoted identifiers. Only Latin characters can be used in non-delimited identifiers.
How FedSQL Processes Nulls and SAS Missing Values

FedSQL Modes for Nonexistent Data

Nonexistent data is represented by a SAS missing value in SAS data sets, SPD Engine data sets, and SPD Server tables. For all other data sources, nonexistent data is represented by an ANSI SQL null value. The SAS missing value indicators, ., ._, .A - .Z, and ‘.’ are known values that indicate nonexistent data. Table data with an ANSI null has no real data value; it is metadata that indicates an unknown value.

Because there are significant differences in processing null values and SAS missing values, FedSQL has two modes for processing nonexistent data: the ANSI SQL null mode (ANSI mode) and the SAS missing value mode (SAS mode).

The behavior of nonexistent data depends on how you connect to the data source:

- By default, a client application that connects to the data source via a client-side driver, such as JDBC or ODBC, processes data using ANSI mode.
- By default, a Base SAS session that submits PROC FEDSQL processes data using SAS mode. PROC FEDSQL provides the ANSIMODE option in order to process data in ANSI mode.

In most instances, no mode change is necessary to process nonexistent data. You might want to change the mode in the following circumstances:

- when a client application processes SAS data sets, SPD Engine data sets, or SPD Server tables and the mode for nonexistent data is in ANSI mode
- when the processing of SAS data sets, SPD Engine data sets, or SPD Server tables is complete and the client application is ready to return to ANSI mode

**CAUTION**
If the mode is not set for the desired results, data is lost. In ANSI mode, when FedSQL reads a numeric SAS missing data value from the data source, it converts it to a data type of DOUBLE. If the SAS missing data value is a special missing value, such as .A, the .A is lost when it is converted to a null. When a null value is written to a SAS data set, SPD Engine data set, or SPD Server table, FedSQL converts it to a SAS missing value, which is a period ( . ). In SAS mode, when a null of type CHAR is read from the data source, FedSQL converts it to a blank character. When the blank character is stored in a SAS data set, SPD Engine data set, or SPD Server table, that value can no longer be interpreted as an unknown value in ANSI mode.

For information about how to set FedSQL in ANSI mode and SAS mode, see the SAS documentation for your client environment.
Data Types for SAS Missing Mode

Currently, FedSQL applies SAS missing mode to columns of the DOUBLE and CHAR data types and to comparisons that involve those data types. SAS missing mode is not applied to columns that are defined with the FedSQL DATE, TIME, and TIMESTAMP data types. Those data types are converted to DOUBLE and assigned a SAS format for some data sources. For information about how FedSQL handles date and time values, see “Dates and Times in FedSQL” on page 60. FedSQL treats columns containing date and time values for these sources like DATE, TIME, and TIMESTAMP data types in all other ways.

Differences between Processing Null Values and SAS Missing Values

Processing SAS missing values is different from processing null values and has significant implications in these situations:

- when filtering data (for example, in a WHERE clause, a HAVING clause, or an outer join ON clause). SAS mode interprets null values as SAS missing values, which are known values, whereas ANSI mode interprets null values as unknown values.

- when submitting outer joins in ANSI mode, internal processing might generate nulls for intermediate result sets. FedSQL might generate SAS missing values in SAS mode for intermediate result sets. Therefore, for intermediate result sets, nulls are interpreted as unknown values in ANSI mode and in SAS mode, missing values are interpreted as known values.

- when comparing a blank character. SAS mode interprets the blank character as a missing value. In ANSI mode, a blank character is a blank character; it has no special meaning.

The following table lists attribute and behavior differences between null values and SAS missing values:

### Table 2.2 Attribute and Behavior Differences between Null Values and SAS Missing Values

<table>
<thead>
<tr>
<th>Attribute or Behavior</th>
<th>Null Values</th>
<th>SAS Missing Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>internal representation</td>
<td>metadata</td>
<td>floating point or character</td>
</tr>
<tr>
<td>evaluation by logical operators</td>
<td>is an unknown value that is compared by using three-valued logic, whose resolved values are True, False, and Unknown. For example, WHERE col1 = null returns UNKNOWN.</td>
<td>is a known value that, when compared, resolves to a Boolean result</td>
</tr>
<tr>
<td>Attribute or Behavior</td>
<td>Null Values</td>
<td>SAS Missing Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>collating sequence order</td>
<td>appears as the smallest value</td>
<td>appears as the smallest value</td>
</tr>
</tbody>
</table>

For information about the results of logical operations on null values, see “<search-condition>” on page 902.

Reading and Writing Nonexistent Data in ANSI Mode

Many relational databases such as Oracle and DB2 implement ANSI SQL null values. Therefore, the concept of null values using FedSQL is the same as using the SQL language for databases that support ANSI SQL. It is important to understand how FedSQL processes SAS missing values because data can be lost.

SAS missing value data types can be only DOUBLE or CHAR. Therefore, only the conversion for these data types is shown. The following table shows the value that is returned to the client application when FedSQL reads a null value or a SAS missing value from a data source in ANSI mode:

Table 2.3  Reading Nonexistent Data Values in ANSI Mode

<table>
<thead>
<tr>
<th>Column Data Type</th>
<th>Nonexistent Data Value</th>
<th>Value Returned to the Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE</td>
<td>., _, or .A - .Z</td>
<td>null</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>null</td>
<td>null</td>
</tr>
<tr>
<td>CHAR</td>
<td>' '</td>
<td>' '</td>
</tr>
<tr>
<td>CHAR</td>
<td>null</td>
<td>null</td>
</tr>
</tbody>
</table>

Note: The value ' ' is a blank space between single quotation marks, which, in ANSI mode, is a blank space, not nonexistent data.

This next table shows the value that is stored when nonexistent data values are written to data sources in ANSI mode:

Table 2.4  Writing Nonexistent Data Values in ANSI Mode

<table>
<thead>
<tr>
<th>Column Data Type</th>
<th>Nonexistent Data Value</th>
<th>Value Stored in a SAS Data Set, SPD Engine Data Set, or SPD Server Table</th>
<th>Value Stored in the ANSI SQL Null Supported Data Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE</td>
<td>., _, or .A - .Z</td>
<td>.</td>
<td>null</td>
</tr>
</tbody>
</table>
### Reading and Writing Nonexistent Data in SAS Mode

When the client application uses the SAS mode, nonexistent data values are treated like SAS missing values in the Base SAS environment.

The following table shows how nonexistent data values of data type DOUBLE and CHAR are read in SAS mode:

**Table 2.5  Reading Nonexistent Data Values in SAS Mode**

<table>
<thead>
<tr>
<th>Column Data Type</th>
<th>Nonexistent Data Value</th>
<th>Value Returned to the Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE</td>
<td>., _, or .A -.Z</td>
<td>., _, or .A -.Z</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>null</td>
<td>.</td>
</tr>
<tr>
<td>CHAR</td>
<td>' '</td>
<td>' '</td>
</tr>
<tr>
<td>CHAR</td>
<td>null</td>
<td>' '</td>
</tr>
</tbody>
</table>

**Note:** The value ‘ ‘ is a blank space between single quotation marks, which, in ANSI mode, is a blank space, not nonexistent data.

The next table shows how nonexistent data values are written to a data source in SAS mode:
### Table 2.6 Writing Nonexistent Data Values in SAS Mode

<table>
<thead>
<tr>
<th>Column Data Type</th>
<th>Nonexistent Data Value</th>
<th>Value Stored in a SAS Data Set, SPD Engine Data Set, or SPD Server Table</th>
<th>Value Stored in the ANSI SQL Null Supported Data Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE</td>
<td>null</td>
<td>.</td>
<td>null</td>
</tr>
<tr>
<td>CHAR</td>
<td>' '</td>
<td>' '</td>
<td>' '</td>
</tr>
<tr>
<td>CHAR</td>
<td>null</td>
<td>' '</td>
<td>' '</td>
</tr>
</tbody>
</table>

Note: The value '.' is a blank space between single quotation marks, which, in SAS mode, is nonexistent data.

### Testing and Modifying Nulls and SAS Missing Values

FedSQL provides the IFNULL function to test for a null value and the NULLIF expression to change a null value.

The IFNULL function takes two expressions as arguments. If the first expression is a null value, it returns the second expression. Otherwise, the function returns the first value:

\[
\text{IFNULL}(\text{expression}, \text{return\_value\_if\_null\_expression})
\]

If the value of \text{expression} is null, the function returns the value of \text{return\_value\_if\_null\_expression}.

In this example, all book names are returned for the books that have an unknown value of numCopies:

\[
\text{select bookName when ifnull(numCopies, 'T') = 'T';}
\]

The NULLIF expression also takes two expressions as arguments. If the two expressions are equal, the value that is returned is a null value. Otherwise, the value that is returned is the first SQL expression:

\[
\text{NULLIF}(\text{expression}, \text{test\_value\_expression})
\]

Here, if the value of numCopies is a negative value, –1, it is replaced with a null to indicate an unknown value:

\[
\text{update books set numCopies = nullif(numCopies, -1);}
\]

For more information, see "IFNULL Function" on page 511 and "NULLIF Expression" on page 818.
Type Conversions

Type Conversion Definitions

- **binary data type**
  - refers to the VARBINARY and BINARY data type.

- **character data type**
  - refers to the CHAR, VARCHAR, NCHAR, and NVARCHAR data types.

- **coercible data type**
  - a data type that can be converted to multiple data types, not just a character data type.

- **date/time data type**
  - refers to the DATE, TIME, and TIMESTAMP data types.

- **non-coercible data type**
  - a data type that can be converted only to a character data type.

- **numeric data type**
  - refers to the DECIMAL, NUMERIC, DOUBLE (or FLOAT), REAL, BIGINT, INT, SMALLINT, and TINYINT data types.

- **standard character conversion**
  - if an expression is not one of the character data types, it is converted to a CHAR data type.

- **standard numeric conversion**
  - if an expression has a coercible, non-numeric data type, it is converted to a DOUBLE data type.

Overview of Type Conversions

Operands in an expression must be of the same general data type — numeric, character, binary, or date/time — in order for FedSQL to resolve the expression. When it is necessary, FedSQL converts an operand's data type to another data type, depending on the operands and operators in the expression. This process is called type conversion. A type conversion occurs only if the underlying data source supports it. For example, the concatenation operator ( || ) operates on character data types. For a database that supports data types INTEGER and CHAR, in a concatenation of the character string “First” and the numeric integer 1, the INTEGER data type for the operand 1 is converted to a CHAR data type before the concatenation takes place.

When an operand data type is converted within the same general data type, the operand data type is promoted. Operands with a data type of SMALLINT and TINYINT are promoted to INTEGER, and operands of type REAL are promoted to
DOUBLE. Type promotion is performed for all operations on SMALLINT, TINYINT, and REAL, including arguments for method and function expressions.

Numeric and character data types are coercible. The BINARY, VARBINARY, and the date/time data types DATE, TIME, and TIMESTAMP are non-coercible and can be converted to only one of the character data types by using the PUT function.

When FedSQL evaluates an expression, if the data types of the operands match exactly, no type conversion or promotion is necessary and the expression is resolved. Otherwise, each operand must go through a standard numeric conversion or a standard character conversion, depending on the operator.

The results of a numeric or character expression are based on a data type precedence. If both operands have different types within the same general data type, the data type of the expression is that of the operand with the higher precedence, where 1 is the highest precedence. For example, for numeric data types, a data type of DOUBLE has the highest precedence. If an expression has an operand of type INTEGER and an operand of type DOUBLE, the data type of the expression is DOUBLE. A list of precedences can be found in the topics that follow, if applicable, for the different types of expressions.

### Type Conversion for Unary Expressions

In unary expressions, such as `++1` or `-444`, the standard numeric conversion is applied to the operand. The following table shows the data type for unary expressions:

<table>
<thead>
<tr>
<th>Expression Type</th>
<th>Expression Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unary plus</td>
<td>same as the operand or DOUBLE for converted operands</td>
</tr>
<tr>
<td>Unary minus</td>
<td>same as the operand or DOUBLE for converted operands</td>
</tr>
<tr>
<td>Unary not</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

### Type Conversion for Logical Expressions

In logical expressions, such as `(a <> start) OR (f = finish)`, the standard numeric conversion is applied to each operand. The following table shows the precedence that is used to determine the data type of the expression, where 1 is the highest precedence and 3 is the lowest. The data type of the expression is the data type of the operand that has the higher precedence.
### Table 2.8 Data Type Conversion for Logical Expressions

<table>
<thead>
<tr>
<th>Precedence</th>
<th>Data Type of Either Operand</th>
<th>Expression Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>DOUBLE</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>2</td>
<td>BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>3</td>
<td>all other numeric data types</td>
<td>INTEGER</td>
</tr>

</table>

### Type Conversion for Arithmetic Expressions

In arithmetic expressions, such as `a<>b` or `a + (b * c)`, the standard numeric conversion is applied to each operand.

The following table shows the precedence that is used to determine the data type of arithmetic expressions for the addition, subtraction, multiplication, and division operators, where 1 is the highest precedence and 3 is the lowest. The data type of the expression is the data type of the operand that has the higher precedence.

#### Table 2.9 Type Conversion for Addition, Subtraction, Multiplication, and Division Expressions

</table>
Type Conversion for Relational Expressions

In relational expressions, such as \( x \leq y \) or \( i > 4 \), the standard conversion that is applied depends on the operand data types. The data type of the expression is always BOOLEAN, as shown in the following tables.

**Table 2.11  Data Type Conversion for Relational Expressions except IN Expressions**

Type Conversion for Concatenation Expressions

In concatenation expressions, such as \( a \ | | b \) or \( x \ !! y \), the standard character conversion is applied to each operand. The following table shows the precedence used to determine the data type of the expression, where 1 is the highest precedence and 2 is the lowest. The data type of the expression is the data type of the operand that has the higher precedence.

### NLS Transcoding Failures

Transcoding is the process of converting character data from one encoding to another encoding. An NLS transcoding failure can occur during row input or output operations, or during string assignment. By default, this run-time error causes row processing to halt. You can change the default behavior by using one of the following options:

- **SAS Federation Server**: specify the `DEFAULT_ATTR=` connection option with the `XCODE_WARN=n` statement handle option.
- **PROC FEDSQL and PROC DS2**: set the `XCODE=` option.

Using the options, you can choose to ignore the errors and continue processing of the row.

For more information, see the SAS Federation Server and SAS procedure documentation.

### Join Operations

#### Overview of Join Operations

A join operation is a query that combines data from two or more tables or views based usually on relationships among the data in those tables. When multiple table specifications are listed in the FROM clause of a SELECT statement, they are processed to form one result set. The result set contains data from each contributing table and can be saved as a table or used as is. Most join operations contain at least one join condition, which is either in the FROM clause or in a WHERE clause.

For example, you can join the data of two tables based on the values of a column that exists in both tables. The following query joins the two tables Products and Sales. FedSQL creates the result set by retrieving the data for columns Product and Totals where the values match for the column Prodid.

```sql
select products.product, sales.totals
from products, sales
where products.prodid=sales.prodid;
```
Join Result Sets of Tables Products and Sales

Most joins are of two tables. However, you can join more than two tables. To perform a join operation of three or more tables, FedSQL first joins two tables based on the join condition. Then FedSQL joins the results to another table based on the join condition. This process continues until all tables are joined into the result set. The following query first joins tables Products and Sales, which produces a result set, and then joins the result set and the table Customers, which produces the final result set.

```
select products.product, sales.totals, customers.city
from products, sales, customers
where products.prodid=sales.prodid and sales.custid=customers.custid;
```

Join Result Set of Tables Products, Sales, and Customers

FedSQL supports several join operations such as simple joins, equijoins, cross joins, qualified joins, and natural joins. Appropriate syntax determines the type of join operation. In addition, the qualified and natural join operations can be affected by specifying the join type, which can be an inner join or an outer join.

Note: The join operation examples in this section use the tables Customers, Products, and Sales. To view the tables, see Appendix 4, “Tables Used in Examples,” on page 1077.
Understanding the Join Operations

Simple Join

A simple join is the most basic type of join where multiple tables, separated by commas, are listed in the FROM clause of a SELECT statement. There is no join condition. Joining tables in this way produces a result set where each row from the first table is combined with each row of the second table, and so on.

This simple join example selects all columns and all rows from the tables Products and Sales.

```sql
select * from products, sales;
```
This example is also a simple join, but the SELECT statement specifies one column from each of three tables. Each row from the first table is combined with each row from the second table, which are then combined with each row from the third table. The result is a large, basically meaningless result set. The following output shows only a portion of the result set.

```
select products.product, sales.totals, customers.country
from products, sales, customers;
```
Equijoin

An equijoin is a simple join that is subset with a WHERE clause. The join condition must be an equality comparison. An equijoin produces a more meaningful result than just a simple join, because only rows meeting the equality test are returned. Multiple match criteria can be specified by using the AND operator. When multiple match criteria are specified, only rows that meet all of the equality tests are returned.

This equijoin example selects all columns from the tables Products and Sales where the values match for the column Prodid, which exists in both tables. Because all columns are selected with the * notation, the Prodid column is duplicated in the result set.

```sql
select * from products, sales
  where products.prodid=sales.prodid;
```
Output 2.5  Equijoin of All Columns

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>PRODID</th>
<th>CUSTID</th>
<th>TOTALS</th>
<th>COUNTRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>1424</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
</tbody>
</table>

When you specify the columns ProdId, Product, and Totals in the SELECT statement, the column ProdId is not duplicated, even though it exists in both the Products and Sales tables. The result set includes the data where the values match for the column ProdId.

```sql
select products.prodid, products.product, sales.totals
from products, sales
where products.prodid=sales.prodid;
```

Output 2.6  Equijoin with Specified Columns

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>TOTALS</th>
</tr>
</thead>
<tbody>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>$189,400</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>$555,789</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>$781,183</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>$2,789,654</td>
</tr>
</tbody>
</table>

This equijoin example selects the columns Product, Totals, and City from the tables Products, Sales, and Customers. First, the result set includes the data where the values match for the column ProdId, which exists in tables Products and Sales. Then the result set is combined with the data where the values match for the column CustId, which exists in tables Sales and Customers.

```sql
select products.product, sales.totals, customers.city
from products, sales, customers
where products.prodid=sales.prodid and sales.custid=customers.custid;
```
Cross Join

A cross join is a relational join that results in a Cartesian product of two tables. A cross join is requested with the syntax CROSS JOIN. A cross join can be subset with a WHERE clause, but you cannot use an ON clause.

This cross join example selects all columns and all rows from the tables Products and Sales, which produces the same results as a simple join of two tables.

select * from products cross join sales;

<table>
<thead>
<tr>
<th>PRODUCT</th>
<th>TOTALS</th>
<th>CITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheat</td>
<td>$189,400</td>
<td>Boulder</td>
</tr>
<tr>
<td>Rice</td>
<td>$555,789</td>
<td>Nagasaki</td>
</tr>
<tr>
<td>Corn</td>
<td>$781,183</td>
<td>Tokyo</td>
</tr>
<tr>
<td>Corn</td>
<td>$2,789,654</td>
<td>Little Rock</td>
</tr>
</tbody>
</table>
Cross Join of Two Tables

This cross join example selects the columns Prodid, Product, and Totals from tables Products and Sales. The result set includes the data where the values match for the column Prodid. The results are the same as an equijoin of two tables.

```sql
select products.prodid, products.product, sales.totals
from products cross join sales
where products.prodid=sales.prodid;
```

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>PRODID</th>
<th>CUSTID</th>
<th>TOTALS</th>
<th>COUNTRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>1424</td>
<td>Rice</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>1424</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>1424</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>1424</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>1424</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>3975</td>
<td>5</td>
<td>$899,453</td>
<td>Argentina</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3975</td>
<td>5</td>
<td>$899,453</td>
<td>Argentina</td>
</tr>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3975</td>
<td>5</td>
<td>$899,453</td>
<td>Argentina</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>3975</td>
<td>5</td>
<td>$899,453</td>
<td>Argentina</td>
</tr>
</tbody>
</table>
Qualified Join

A qualified join provides an easy way to control which rows appear in the result set. You can use any columns to match rows from one table against those from another table. A qualified join is requested with the syntax `JOIN` and then the syntax `ON` or `USING` to specify the join condition. You can use a `WHERE` clause to further subset the query results.

- The `ON` clause specifies a join condition to filter the data. The `ON` clause accepts search conditions such as conditional expressions like the `WHERE` clause. The `ON` clause joins tables where the column names do not match in both tables. For columns that exist in both tables, the `ON` clause preserves the columns from each joined table separately in the result set.

- The `USING` clause specifies columns to test for equality. The columns listed in the `USING` clause must be present in both tables. The `USING` clause is like a shorthand way of defining join conditions without having to specify a qualifier. The `USING` clause is equivalent to a join condition where each column from the left table is compared to a column with the same name in the right table. For columns that exist in both tables, the `USING` clause merges the columns from the joined tables into a single column.

A qualified join can be an inner join or an outer join, which is requested with the syntax `INNER` or `OUTER`. If the join type specification is omitted, then an inner join is implied. See “Inner and Outer Join Types” on page 42.

This qualified join example selects all columns from the tables `Products` and `Sales`. The returned rows are filtered based on the column `Country` in the `Sales` table, where the value in Country equals United States. The column `Prodid` exists in both tables and is duplicated in the result set.

```sql
SELECT * FROM products JOIN sales
  ON (sales.country='United States');
```
Qualified Join with an ON Clause

This qualified join example selects all columns from the tables Products and Sales. The returned rows are filtered by selecting the values that match for the column Prodid, which exists in both tables. The USING clause is like a shorthand way of defining join conditions without having to specify a qualifier. The USING clause is equivalent to a join condition where each column from the left table is compared to a column with the same name in the right table. Unlike an equijoin and a cross join, the column Prodid is not duplicated in the result set.

```sql
select * from products
  join sales
  using (prodid);
```

Qualified Join with a USING Clause

This qualified join example selects columns Prodid, Product, and Totals from the tables Products and Sales. The returned rows are filtered based on the column Country where the value equals United States. The returned rows are further subset where the value for Product equals Rice.

```sql
select products.prodid, products.product, sales.totals
from products
  join sales
  on (sales.country='United States')
where products.product='Rice';
```
Output 2.12  Qualified Join with an ON Clause and a WHERE Clause

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>TOTALS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1424</td>
<td>Rice</td>
<td>$189,400</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>$2,789,654</td>
</tr>
</tbody>
</table>

Natural Join

A natural join selects rows from two tables that have equal values in columns that share the same name and the same type. A natural join is requested with the syntax `NATURAL JOIN`. If like columns are not found, then a cross join is performed. Do not use an ON clause with a natural join. When using a natural join, an ON clause is implied, matching all like columns. You can use a WHERE clause to subset the query results. A natural join functions the same as a qualified join with the USING clause. A natural join is a shorthand of USING. Like USING, like columns appear only once in the result set.

A natural join can be an inner join or an outer join, which is requested with the syntax `INNER` or `OUTER`. If the join type specification is omitted, then an inner join is implied. See “Inner and Outer Join Types” on page 42.

This natural join example selects all columns from the tables Products and Sales. The result set includes the data where the values match for the column Prodid, which exists in both tables. Unlike a cross join and a simple join of two tables, the natural join result set does not include duplicate Prodid columns.

```sql
select * from products natural join sales;
```

Output 2.13  Natural Join of All Columns

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>CUSTID</th>
<th>TOTALS</th>
<th>COUNTRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
</tbody>
</table>

This natural join example selects columns City and Totals from the tables Sales and Customers. The result set includes the data where the values match for the columns Custid and Country, which exist in both tables. The returned rows are subset where the value for Country equals United States.

```sql
select customers.city, sales.totals
from sales natural join customers
where customers.country='United States';
```
Output 2.14  Natural Join with a WHERE Clause

<table>
<thead>
<tr>
<th>City</th>
<th>Totals</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boulder</td>
<td>$189,400</td>
</tr>
<tr>
<td>Little Rock</td>
<td>$2,789,854</td>
</tr>
</tbody>
</table>

Inner and Outer Join Types

Overview of Inner and Outer Join Types

The result set from a qualified join and a natural join can be affected by specifying the join type, which can be an inner join or an outer join. By default, qualified joins and natural joins function as inner joins.

Inner Joins

An inner join returns a result set that includes all rows from the first table that matches rows from the second table. Inner joins return only those rows that satisfy the join condition. Unmatched rows from both tables are discarded. By default, qualified joins and natural joins function as inner joins. Including the syntax INNER has no additional effects on the result set.

```
select * from products inner join sales
on (sales.country='United States');
```

```
select customers.city, sales.totals
from sales natural inner join customers
where country='United States';
```

Outer Joins

An outer join returns a result set that includes all rows that satisfy the join condition as well as unmatched rows from one or both tables. An outer join can be a left, right, or full outer join. An inner join discards any rows where the join condition is not met, but an outer joins maintains some or all of the unmatched rows.

For an outer join, a specified WHERE clause is applied after the join is performed and eliminates all rows that do not satisfy the WHERE clause. Applying a WHERE clause to an outer join can sometimes defeat the purpose, because the WHERE clause deletes the very rows that the outer join retains.

- A left outer join preserves unmatched rows from the left table, which is the first table listed in the SELECT statement. A left outer join returns a result set that includes all rows that satisfy the join condition and rows from the left table that do not match the join condition. Therefore, a left outer join returns all rows from the left table, and only the matching rows from the right table. A left outer join is requested with the syntax LEFT [OUTER].
This qualified join example returns a result set that includes all rows from both tables that satisfy the join condition. The join condition filters rows based on the column `Country` where the value equals United States. The result set also includes rows from the Customers table that do not match the join condition. As a left outer join, all rows from the Customers table are returned.

```sql
select customers.city, sales.totals
from customers
left outer join
sales
on (customers.country='United States');
```

<table>
<thead>
<tr>
<th>CITY</th>
<th>TOTALS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boulder</td>
<td>$189,400</td>
</tr>
<tr>
<td>Little Rock</td>
<td>$189,400</td>
</tr>
<tr>
<td>Boulder</td>
<td>$555,789</td>
</tr>
<tr>
<td>Little Rock</td>
<td>$555,789</td>
</tr>
<tr>
<td>Boulder</td>
<td>$781,183</td>
</tr>
<tr>
<td>Little Rock</td>
<td>$781,183</td>
</tr>
<tr>
<td>Boulder</td>
<td>$2,789,654</td>
</tr>
<tr>
<td>Little Rock</td>
<td>$2,789,654</td>
</tr>
<tr>
<td>Nagasaki</td>
<td>.</td>
</tr>
<tr>
<td>Tokyo</td>
<td>.</td>
</tr>
<tr>
<td>Buenos Aires</td>
<td>.</td>
</tr>
</tbody>
</table>

This natural join example returns a result set that includes all rows from both tables that satisfy the join condition, which includes the data where the values match for the column `Prodid` The result set also includes a row from the Sales table that does not match the join condition. As a left outer join, all rows from the Sales table are returned.

```sql
select * from sales
natural left outer join
products;
```

<table>
<thead>
<tr>
<th>PRODID</th>
<th>CUSTID</th>
<th>TOTALS</th>
<th>COUNTRY</th>
<th>PRODUCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
<td>Wheat</td>
</tr>
<tr>
<td>1424</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
<td>Rice</td>
</tr>
<tr>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
<td>Corn</td>
</tr>
<tr>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
<td>Corn</td>
</tr>
<tr>
<td>3975</td>
<td>5</td>
<td>$899,453</td>
<td>Argentina</td>
<td></td>
</tr>
</tbody>
</table>
A right outer join preserves unmatched rows from the right table, which is the second table listed in the SELECT statement. A right outer join returns a result set that includes all rows that satisfy the join condition and rows from the right table that do not match the join condition. Therefore, a right outer join returns all rows from the right table, and only the matching rows from the left table. A right outer join is requested with the syntax RIGHT [OUTER].

This qualified join example returns a result set that includes all rows from both tables that satisfy the join condition. The join condition filters rows based on the column Country where the value equals United States. The result set also includes rows from the Sales table that do not match the join condition. As a right outer join, all rows from the Sales table are returned.

```
select * from products right outer join sales
   on (sales.country='United States');
```

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>PRODID</th>
<th>CUSTID</th>
<th>TOTALS</th>
<th>COUNTRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>1424</td>
<td>Rice</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>

<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
<td>3975</td>
<td>5</td>
<td>$899,453</td>
<td>Argentina</td>
</tr>
</tbody>
</table>

This natural join example returns a result set that includes all rows from both tables that satisfy the join condition, which includes the data where the values match for the column Prodid. The result set also includes a row from the Sales table that does not match the join condition. As a right outer join, all rows from the Sales table are returned.

```
select * from products natural right outer join sales;
```
A full outer join preserves unmatched rows from both tables. That is, a full outer join returns all matching and unmatching rows from the left and right table. A full outer join is requested with the syntax FULL [OUTER].

This qualified join example returns a result set that includes all rows from both tables that satisfy the join condition. The join condition filters rows based on the column Product containing the value Rice. The result set also includes all rows from both tables that do not match the join condition. As a full outer join, all rows from both tables are returned.

```
select * from products full outer join sales
  on (products.product='Rice');
```

This natural join example returns a result set that includes all rows from both tables that satisfy the join condition, which includes the data where the values match for the column Prodid. The result set also includes a row from the Sales table and a row from the Products table that does not match the join condition. As a full outer join, all rows from both tables are returned.

```
select * from products natural full outer join sales;
```
Joining Heterogeneous Data

Because typical organizations store data in multiple databases, FedSQL supports joining heterogeneous data. A heterogeneous join occurs when the tables in a join operation exist on different data sources. A heterogeneous join is one type of a federated query.

All FedSQL join operations can be performed as heterogeneous joins. For example, the following natural join is a heterogeneous join between an Oracle table and a Teradata table.

```
selct * from oracle.product natural left outer join tera.sales;
```

This heterogeneous join example queries both a SAS data set and an Oracle table. PROC FEDSQL uses the attributes of the librefs to connect to the two data sources. The SAS data set MyBase.Products contains the columns Prodid and Product. The Oracle table Oracle.Sales contains the columns Prodid, Totals, and Country. The SELECT statement joins the columns and rows from both tables based on the column Prodid, which exists in both tables.

```
libname mybase base 'C:\Base';
libname myoracle oracle user=scott password=tiger path=oraclev11;

proc fedsql;
   select mybase.products.prodid, mybase.products.product, myoracle.sales.totals
       from mybase.products, myoracle.sales
       where products.prodid=sales.prodid;
quit;
```
Output 2.15  FedSQL Heterogeneous Join of a SAS Data Set and an Oracle Table

This heterogeneous join example queries three tables: two Oracle tables and one SAS data set. In the query, the join of MyOracle.Products and MyOracle.Customers is performed by Oracle. The join of the Oracle result set with the SAS data set MyBase.Sales is performed by FedSQL.

```
libname mybase base 'C:\Base';
libname myoracle oracle user=scott password=tiger path=oraclev11;

proc fedsql;
  select myoracle.products.product, mybase.sales.totals, myoracle.customers.city
  from myoracle.products, mybase.sales, myoracle.customers
  where products.prodid=sales.prodid and sales.custid=customers.custid;
quit;
```

Output 2.16  FedSQL Heterogeneous Join of Two Oracle Tables and a SAS Data Set

<table>
<thead>
<tr>
<th>PRODUCT</th>
<th>TOTALS</th>
<th>CITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheat</td>
<td>$189,400</td>
<td>Boulder</td>
</tr>
<tr>
<td>Rice</td>
<td>$555,789</td>
<td>Nagasaki</td>
</tr>
<tr>
<td>Corn</td>
<td>$781,183</td>
<td>Tokyo</td>
</tr>
<tr>
<td>Corn</td>
<td>$2,789,654</td>
<td>Little Rock</td>
</tr>
</tbody>
</table>
FedSQL Expressions

Query Expressions and Subqueries

Overview of Query Expressions

A query expression or query consists of one or more SELECT statements that produce a result set. One way that multiple SELECT statements can be combined is by using subqueries. Another is by using set operators. This section discusses set operators. For information about subqueries, see “Overview of Subqueries” on page 52.

FedSQL supports UNION, EXCEPT, and INTERSECT set operators.

- The UNION set operator combines the result of two queries into a single result set that contains the unique rows from both queries.
- The EXCEPT operator combines the result of two queries into a single result set that contains unique rows from the first query.
- The INTERSECT operator combines the result of two queries into a single result set that contains unique instances of rows that are common to both queries.

By default, columns are combined by position in the input tables, regardless of the column names. Columns in the same relative position in the two queries must have compatible data types and lengths and each query must have the same number of columns for the set operation to succeed. The result set contains only the unique rows that result from a query expression. That is, the set operators automatically eliminate duplicate rows from the result sets.

The set operators support the optional keywords to change the default behavior.

Table 2.14  Optional Keywords for the UNION, EXCEPT, and INTERSECT Set Operators

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Returns all rows from both queries, including duplicates, instead of only unique rows.</td>
</tr>
<tr>
<td>CORRESPONDING</td>
<td>Combines columns from the queries by column name instead of by position. Columns with non-matching column names are ignored. The CORRESPONDING keyword returns rows for all columns that have matching names.</td>
</tr>
<tr>
<td>CORRESPONDING and BY</td>
<td>Combines columns by column name and returns only columns from a column list.</td>
</tr>
</tbody>
</table>

A query expression with set operators is evaluated as follows:
Each SELECT statement is evaluated to produce a virtual, intermediate result set.

Each intermediate result set then becomes an operand that is linked with a set operator to form an expression (for example, A UNION B). (When the CORRESPONDING and BY keywords are specified together, columns that are not in the column list are dropped.)

If the query expression involves more than two SELECT statements, then the result from the first two queries becomes an operand for the next set operator and operand, such as (A UNION B) EXCEPT C, ((A UNION B) EXCEPT C) INTERSECT D, and so on.

Evaluating a query expression produces a single output result set.

Default Query Expression Behavior

To understand how query expressions work, consider the following examples. The examples operate on two tables, named Numbers1 and Numbers2. The following figures show the content of the tables. For information about creating the tables, see Appendix 4, "Tables Used in Examples," on page 1077.

**Figure 2.1** Content of Numbers1 Table

<table>
<thead>
<tr>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>three</td>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>four</td>
<td>4</td>
<td>40</td>
</tr>
<tr>
<td>four</td>
<td>4</td>
<td>40</td>
</tr>
<tr>
<td>five</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>five</td>
<td>5</td>
<td>50</td>
</tr>
</tbody>
</table>

**Figure 2.2** Content of Numbers2 Table

<table>
<thead>
<tr>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>four</td>
<td>4</td>
<td>40</td>
</tr>
<tr>
<td>five</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>five</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>one</td>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>two</td>
<td>2</td>
<td>20</td>
</tr>
</tbody>
</table>

Note that the columns in these tables are of the same type and in the same position: X is a character column; Y and Z are numeric columns.

The following example code specifies the UNION operator:

```sql
select * from numbers1 union select * from numbers2;
```
The UNION operator returns the unique rows from both tables to display as a single, virtual table.

Output 2.17 Output from the UNION Operation

<table>
<thead>
<tr>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>five</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>four</td>
<td>4</td>
<td>40</td>
</tr>
<tr>
<td>one</td>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>three</td>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>two</td>
<td>2</td>
<td>20</td>
</tr>
</tbody>
</table>

The following example code specifies the EXCEPT operator:

```sql
select * from numbers1 except select * from numbers2;
```

The EXCEPT operator returns unique rows that exist in the first table, but not the second table.

Output 2.18 Output from the EXCEPT Operation

<table>
<thead>
<tr>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>three</td>
<td>3</td>
<td>30</td>
</tr>
</tbody>
</table>

The following example code specifies the INTERSECT operator:

```sql
select * from numbers1 intersect select * from numbers2;
```

The INTERSECT operator returns unique instances of rows that the specified tables have in common.

Output 2.19 Output from the INTERSECT Operation

<table>
<thead>
<tr>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>five</td>
<td>5</td>
<td>50</td>
</tr>
<tr>
<td>four</td>
<td>4</td>
<td>40</td>
</tr>
<tr>
<td>one</td>
<td>1</td>
<td>10</td>
</tr>
</tbody>
</table>

Now consider a third table, Numbers3.
Table Numbers3 has columns of the same name and type as tables Numbers1 and Numbers2, but the columns are in a different order. A request to combine table Numbers1 or Numbers2 with table Numbers3 will fail with `ERROR: types CHAR and DOUBLE cannot be matched`.

### Combining Queries with the CORRESPONDING Keyword

The CORRESPONDING keyword combines columns from input tables by column name, so the columns do not have to be in the same position. The matching columns must also be of compatible data types. For example, rows from a column of type VARCHAR can be combined with rows from a column of type CHAR. The input tables are not required to have the same number of columns.

Here is an example of a UNION set operation that uses the CORRESPONDING keyword. The request combines rows from tables Numbers1 and Numbers3, which were introduced in “Default Query Expression Behavior” on page 49.

```sql
select * from Numbers1 UNION CORRESPONDING select * from Numbers3;
```

### Output 2.20  Output from UNION with the CORRESPONDING Keyword

The UNION CORRESPONDING operation returns unique rows from both columns. The columns in the result set use the column ordering of the first query in the expression.

Here is an example of an EXCEPT set operation on the same tables that uses the CORRESPONDING keyword.

```sql
select * from Numbers1 EXCEPT CORRESPONDING select * from Numbers3;
```
The EXCEPT CORRESPONDING operation returns rows that are unique to the first query, again using the column ordering from the first query.

Here is an example of an INTERSECT set operation on tables Numbers1 and Number3 that specifies the CORRESPONDING keyword.

```sql
select * from Numbers1 INTERSECT CORRESPONDING
select * from Numbers3;
```

The result set includes an instance of the unique row that the two input tables have in common.

Here is an example of an INTERSECT CORRESPONDING BY set operation that also specifies the BY keyword. The code requests values for column Y.

```sql
select * from Numbers1 INTERSECT CORRESPONDING BY (Y)
select * from Numbers3;
```

Combining Set Operators

Here is an example that illustrates how the set operators can be used together.

```sql
select * from numbers1
           intersect
           select * from numbers2
           union corresponding
           select * from numbers3;
```

The first query expression selects the unique instances of rows that are common to tables Numbers1 and Numbers2. The second query expression merges unique rows from table Numbers3 with the intermediate result set. The CORRESPONDING keyword enables table Numbers3 to be evaluated against the intermediate the result set.

Overview of Subqueries

A *subquery* is a query expression that is nested as part of another query expression. It is specified within parenthesis and has the purpose of returning a value. A
A subquery can return atomic values (one column with one row in it – also known as a scalar query), row values (one row for one or many columns), or table values (one or many rows for one or many columns).

A subquery can be used in the SELECT, INSERT, UPDATE, and DELETE statements. The purpose of a subquery is to enable the contents of one table to influence a query or an action on another table.

Subqueries can appear in various places within a query:
- SELECT Statement
- WHERE Clause
- HAVING Clause
- FROM Clause

Scalar subqueries can be specified in all four locations, anywhere a scalar value can be used. Subqueries that return row values are typically specified in the WHERE clause. Subqueries that return table values are specified in the FROM clause.

A subquery can be dependent or independent of the outer query. When the information pursued in a subquery is dependent in some way on data known to the outer query, we say that the data is correlated with the outer query. A correlated subquery typically references the data in the outer query with a correlation name or uses the EXISTS or IN predicate, and uses data from the outer query. The information retrieved by the correlated subquery will change if the data processed by the outer query changes. A correlated subquery is evaluated for each row identified by the outer query, making the subquery resource-intensive. Many correlated queries can be restated in terms of a join operation.

A subquery that is not dependent on the outer query is referred to as a non-correlated query. A non-correlated subquery does not interact much with the data being accumulated in the rest of the query. The non-correlated subquery is evaluated just once and the result used repeatedly in the evaluation of an outer query. Most importantly, the result of the subquery does not change if the data processed by the outer query changes.

Subqueries can be nested. If more than one subquery is used in a query expression, then the innermost query is evaluated first, then the next innermost query, and so on, moving outward.

Examples of Correlated Subqueries
Here is an example of a correlated subquery that specifies the EXISTS predicate. It uses data from the example Employees and Depts tables. For information to create these tables, see “Employees” on page 1083 and “Depts” on page 1082.

```sql
select *
from employees e
where exists(select * from depts d
  where d.deptno = e.dept
  and e.pos <> 'Manager');
```

The EXISTS predicate stipulates to return information from the table in the outer query only for values that also exist in the inner query. Notice the second WHERE clause uses the column reference e.dept. If you look at the FROM clause in the outer query, you will see that e is a correlation name associated with the Employees table that is being used in the outer query.
Here is a more efficient way to write this query:

```sql
select *
from employees
where dept in (select deptno from depts
               where pos <> 'Manager');
```

This query does not require a correlation name. The contents of the Dept and Deptno columns are compared with the IN predicate. The query returns the same result as the previous query. Meanwhile, the inner query can be executed once and its results compared to each row in the Employees table.

### Examples of Scalar Subqueries

A scalar subquery returns one value for one column. As such, it is useful for aggregate queries.

Here is an example of a scalar subquery in the HAVING clause. The example uses the Employees and Depts tables that were used in "Examples of Correlated Subqueries" on page 53.

```sql
select dept, count(emp_name)
from mybase.employees e
group by dept
having dept in (select deptno from mybase.depts);
```

It is a simple request: count the number of employees in the Employees table, group the count by department, and return information only about departments having a matching value in the Deptno column of the Depts table.

### Output 2.25  Number of Employees by Department
Here is an example of a scalar subquery that is specified in the SELECT statement.

```sql
select d.deptno, 
    d.deptname, 
    d.manager, 
    (select count(*) from employees e 
       where e.dept = d.deptno and 
       e.pos <> 'Manager') as Employees 
from depts d;
```

The subquery counts the number of records in the Employees table, removes employee records that belong to managers, and then returns an aggregate value for each department code that has a match in both tables. That is, one value is returned for each department. It is also a correlated subquery.

**Output 2.26  Number of Employees by Manager**

![Table showing number of employees by manager](image)

*DEPTNO* | *DEPTNAME* | *MANAGER* | *EMPLOYEES*
--- | --- | --- | ---
10 | Sales | Jim Barnes | 2
20 | Research | Clifford James | 2
30 | Accounting | Barbara Sandman | 1
40 | Operations | William Baylor | 1

Here is an example of a scalar subquery in the WHERE clause:

```sql
select * 
from depts d 
where (select COUNT(*) FROM employees e 
       WHERE d.deptno = e.dept 
       and e.pos <> 'Manager') > 1;
```

As in the previous example, the subquery counts all of the rows in Employees table minus those that describe a manager and correlates them to the DeptNo column of the Depts table. However, the WHERE clause further qualifies the query to retrieve information only about departments that have more than one employee.

**Output 2.27  Departments with More Than One Employee**

![Table showing departments with more than one employee](image)

*DEPTNO* | *DEPTNAME* | *MANAGER*
--- | --- | ---
10 | Sales | Jim Barnes
20 | Research | Clifford James

Here is an example of a scalar subquery in the INSERT statement. This example uses data from the Densities example table, which has a column named Population. A new table, Summary, is created and populated with aggregated values from Densities table’s Population column. For more information about the Densities table, see “Densities” on page 1081.

```sql
create table summary ( 
    sum_pop double having format comma12.,
```
max_pop double having format comma12.,
min_pop double having format comma12.,
avg_pop double having format comma12.);

insert into summary {
    sum_pop,
    max_pop,
    min_pop,
    avg_pop
} values {
    (select sum(population) from densities),
    (select max(population) from densities),
    (select min(population) from densities),
    (select avg(population) from densities)
};
select * from summary;

Each subquery in the INSERT statement is a scalar subquery. Each subquery returns one value (the sum, maximum, minimum, and average values) from the data in one column, Population, to populate the new table.

Output 2.28  Content of the Summary Table

<table>
<thead>
<tr>
<th>SUM_POP</th>
<th>MAX_POP</th>
<th>MIN_POP</th>
<th>AVG_POP</th>
</tr>
</thead>
<tbody>
<tr>
<td>245,550,684</td>
<td>34,248,705</td>
<td>64,634</td>
<td>12,277,544</td>
</tr>
</tbody>
</table>

Examples of Non-Correlated Queries

A non-correlated subquery is executed before the outer query and the subquery is executed only once. The data from the outer query and the subquery are independent and one execution of the subquery will work for all the rows from the outer query.

The examples in this section use data from the following three tables.

Output 2.29  Table All1

<table>
<thead>
<tr>
<th>x</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
</tr>
<tr>
<td>4</td>
<td>four</td>
</tr>
<tr>
<td>5</td>
<td>five</td>
</tr>
<tr>
<td>6</td>
<td>six</td>
</tr>
</tbody>
</table>
This example code specifies a subquery in the SELECT statement. The subquery specifies to display only values from table All1 that exist in table One. Table All1 is not modified. The query affects outputted rows only:

```
select * from all1 where x in (select x from one);
```

**Output 2.32  Output of the SELECT Subquery**

The following example code specifies a subquery in the INSERT statement:

```
insert into two select * from all1 where exists (select * from one);
select * from two;
```

In this example, the content of table Two is expanded to include the contents of table All1 that also exist in table One.

**Output 2.33  Results of the INSERT Subquery**

This example code specifies a subquery in the DELETE statement:

```
delete from all1 where x in (select x from one);
```
select * from all1;

The code specifies to delete values from table All1 that match values in column X of table One.

**Output 2.34  Results of the DELETE Subquery**

The following example code specifies a subquery in an UPDATE statement:

update all1 set x = (select x from two);
select * from all1;

Column X in table All1 is updated with the value of column X in table Two.

**Output 2.35  Results of the UPDATE Subquery**

A non-correlated subquery allows you select, insert, delete, and modify unrelated blocks of data between two or more tables.

FedSQL Value Expressions

**Numeric Value Expressions**

Numeric value expressions enable you to compute numeric values by using addition (+), subtraction (–), multiplication (*), and division (/) operators. Numeric values can be numeric literals. These values can also be column names, variables, or subqueries as long as the column names, variables, or subqueries evaluate to a numeric value.

The data type of the result of a numeric value expression is based on the data type of the operands.
Here are examples of numeric value expressions.

-6  
salary * 1.07  
cost + (exp – discount)

Row Value Expressions

A row value expression, or row value constructor, is one or more value expressions enclosed in parentheses. Multiple value expressions are separated by commas.

A row value constructor can contain the following values.

- value-expression
- NULL
- DEFAULT
- row-subquery
- (row-value-constructor, row-value-constructor, …)
- ROW (row-value-constructor, row-value-constructor, …)

NULL makes the value for the corresponding column in the table null. DEFAULT makes the value for the corresponding column the default value. ARRAY[ ] is valid only if the destination is an array and creates an empty array. The row constructor values other than NULL, DEFAULT, and ARRAY[ ] can be simple values or value expressions.

A row value constructor operates on a list of values or columns rather than a single value or column. You can operate on an entire row at a time or a subset of a row.

Here is an example where you can use row value constructors in the INSERT statement to add multiple values to a table.

```sql
INSERT INTO inventory
    (prodname, qty, price)
VALUES ('rice', 3849, .37);
```

This example uses row value constructors in the WHERE clause to compare column values.

```sql
SELECT * FROM inventory
WHERE (inventory.prodname, inventory.price) =
    (competitor.prodname, inventory.price);
```
Dates and Times in FedSQL

Overview of Dates and Times in FedSQL

FedSQL supports the industry standard conventions for dates, times, and datetimes using the DATE, TIME, and TIMESTAMP data types. All third-party data sources that are supported by FedSQL support these data types. You can create SAS data sets, SPD Engine data sets, and SPD Server tables using these data types, but FedSQL converts these data types to a DOUBLE having a SAS date, time, or datetime format.

FedSQL can read and process SAS dates, time, and datetime values only as values with a data type of DOUBLE. FedSQL cannot convert a SAS date, time, or datetime value with a data type of DOUBLE to a value with a data type of DATE, TIME, or TIMESTAMP.

FedSQL date, time, and datetime functions can provide local current time as well as GMT current time.

FedSQL formats enable dates, times, and datetimes to be formatted in various ways.

FedSQL Date, Time, and Datetime Constants

You write FedSQL date, time, or datetime constants using the following syntax:

```
DATE 'yyyy-mm-dd'
TIME 'hh:nn:ss[.fraction]'
TIMESTAMP 'yyyy-mm-dd hh:mm:ss[.fraction]'
```

where

- `yyyy` is a four-digit year
- `mm` is a two-digit month, 01–12
- `dd` is a two-digit day, 01–31
- `hh` is a two-digit military hour, 00–23
- `nn` is a two-digit minute, 00–59
- `ss` is a two-digit second, 00–61
- `fraction` can be one to ten digits, 0–9, is optional, and represents a fraction of a second

The string portion of the value after the DATE, TIME, or TIMESTAMP keyword must be enclosed in single quotation marks.

In the date constant, the hyphens are required and the length of the date string must be at least 8. You are not required to precede single-digit dates with a zero (0).
In the time constant, the colons are required. If the fraction of a second is not present, the time string must be eight characters long and it can include or exclude the period. If the fraction of second is present, the fraction can be up to nine digits long. The time constant can be between 8 and 18 characters long.

In the timestamp constant, the hyphens in the date are required as well as the colons in the time. If the fraction of a second is not present, it can include or exclude the period. If fraction of a second is present, the fraction can be up to nine digits long. The timestamp constant can be between 19 and 29 characters long.

Here are examples of FedSQL date, time, and timestamp constants:

date'2008-01-31'
date'2008-1-1'
time'20:44:59'
timestamp'2007-02-02 07:00:00.7569'

Here is an example of creating a table that includes datetime values:

create table bikerace (name char(30), entry_number int, registration_date timestamp);
insert into bikerace values ('Andersen, Mark', 342, timestamp'2007-03-15 12:27:33');
insert into bikerace values ('Steinbek, Mark', 244, timestamp'2006-11-27 13:26:19');

Using Dates and Times in SAS Data Sets, SPD Engine Data Sets, and SPD Server Tables

When you create a table using the BASE driver or the SPD drivers, you specify columns for date, time, and datetime values by using the DATE, TIME, and TIMESTAMP data types. FedSQL converts values with these data types to a data type of DOUBLE having these SAS formats:

<table>
<thead>
<tr>
<th>FedSQL Date/Time Data Type</th>
<th>SAS Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE9.</td>
</tr>
<tr>
<td>TIME</td>
<td>TIME8.</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>DATETIME19.2</td>
</tr>
</tbody>
</table>

These SAS formats cannot be altered by using the FedSQL language ALTER TABLE statement. They can be altered only by using protocols in Base SAS to alter formats that are assigned to a column in a SAS data set, SPD Engine data set, or SPD Server table.

The following example creates a SAS data set that contains a date, time, and datetime value using the DATE, TIME, and TIMESTAMP data types, and illustrates how they are displayed using SAS formats:
create table basedt (d date, t time, ts timestamp);
insert into basedt values ('2013-03-14', '10:31:22',
    '2013-03-14 13:30:33.222');
select * from basedt;

Here is the output:

Output 2.36  Results for Date, Time, and Timestamp

![The SAS System](image)

Any format that you might specify for these date, time, and datetime values overrides the format that is stored with these values. The following SELECT statement uses the PUT function to format the datetime value using the DATETIME21.2 format in order to display the four-character year 2008:

select put(ts,datetime21.2) from basedt;

Here is the output:

Output 2.37  Results of Using the PUT Statement

![The SAS System](image)

Date, Time, and Datetime Functions

Here is a list and description of FedSQL date, time, and datetime functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_DATE</td>
<td>returns the current date for your time zone.</td>
</tr>
<tr>
<td>CURRENT_TIME</td>
<td>returns the current time for your timezone.</td>
</tr>
<tr>
<td>CURRENT_TIME_GMT()</td>
<td>returns the current GMT time.</td>
</tr>
</tbody>
</table>
### Function Description

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_TIMESTAMP</td>
<td>returns the current date and time for your timezone.</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP_GMT()</td>
<td>returns the current GMT date and time.</td>
</tr>
<tr>
<td>DAY</td>
<td>returns the numeric day of the month from a date or datetime value.</td>
</tr>
<tr>
<td>HOUR</td>
<td>returns the hour from a time or datetime value.</td>
</tr>
<tr>
<td>MINUTE</td>
<td>returns the minute from a time or datetime value.</td>
</tr>
<tr>
<td>MONTH</td>
<td>returns the numeric month from a date or datetime value.</td>
</tr>
<tr>
<td>SECOND</td>
<td>returns the second from a time or datetime value.</td>
</tr>
<tr>
<td>YEAR</td>
<td>returns the year from a date or datetime value.</td>
</tr>
</tbody>
</table>

---

### Date, Time, and Datetime Formats for SAS Data Sets, SPD Engine Data Sets, and SPD Server Tables

The following date, time, and datetime formats can be used to format SAS data sets, SPD Engine data sets, and SPD Server tables:

**Table 2.17  Date, Time, and Datetime Functions Arranged by Type**

<table>
<thead>
<tr>
<th>Type</th>
<th>Language Element</th>
<th>Input</th>
<th>Formatted Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date formats</td>
<td>DATE.</td>
<td>date'2013-03-17'</td>
<td>17MAR13</td>
</tr>
<tr>
<td></td>
<td>DATE9.</td>
<td>date'2013-03-17'</td>
<td>17MAR2013</td>
</tr>
<tr>
<td></td>
<td>DAY.</td>
<td>date'2013-03-17'</td>
<td>17</td>
</tr>
<tr>
<td>Type</td>

</table>
FedSQL DICTIONARY tables are similar to but different from Base SAS DICTIONARY tables. A FedSQL DICTIONARY table is a Read-only table that contains information about columns, tables, and catalogs, and statistics about tables and their associated indexes.

The following table describes the DICTIONARY tables that are available. For a complete description of all the columns in the DICTIONARY tables, see Appendix 5, “DICTIONARY Table Descriptions,” on page 1095.

### Table 2.18 DICTIONARY Tables

<table>
<thead>
<tr>
<th>DICTIONARY table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CATALOGS</td>
<td>contains information about catalogs in the current connection.</td>
</tr>
<tr>
<td>COLUMNS</td>
<td>contains information about columns in all known tables.</td>
</tr>
<tr>
<td>COLUMN_STATISTICS</td>
<td>contains table and index statistics that are based on the columns in the tables.</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>contains table and index statistics that are associated with the tables.</td>
</tr>
<tr>
<td>TABLES</td>
<td>contains information about table types and a list of table, catalog, or schema names of tables in the data source.</td>
</tr>
</tbody>
</table>

You can query DICTIONARY tables the same way you query any other table. For all DICTIONARY tables except CATALOG, you can include subsetting with a WHERE clause and ordering the results. Identifiers should be quoted. The following queries are examples.

**TIP** FedSQL sends table and column names to the underlying databases as uppercase when the table is created, unless you quote the names in the CREATE TABLE statement or the data source supports only lowercase storage. DICTIONARY queries are case-sensitive. Specify table and column names as uppercase unless you know them to be otherwise.

```sql
select * from dictionary.catalogs where catalog='SALECAT';
```
select * from dictionary.tables;
select * from dictionary.columns where table_name='YEAREND';
select * from dictionary.columns where table_name='view-name';
select distinct table_cat, table_schem from dictionary.tables;

Note: The DICTIONARY tables rely on data source support for their information. If the data source does not support the underlying function call, no rows are returned. For example, some data sources do not return information for the STATISTICS and COLUMN_STATISTICS dictionary tables.

DICTIONARY queries that do not specify a WHERE clause can take a long time to process, especially if there are a large number of tables in the data source.

Google BigQuery users: Column and table queries that are not qualified with a catalog and a schema issue a separate query for each schema available through the connection. For the best results, qualify your dictionary queries with the catalog and schema as follows:

select * from dictionary.columns where table_cat='catalog-name'
and table_name='table-name';

FedSQL Implicit Pass-Through Facility

Overview

Implicit pass-through (IP) is the process of translating SQL query code into equivalent data source-specific SQL code so that it can be passed directly to the data source for processing. IP improves query response time and enhances security.

The performance benefits that are provided by IP can be divided into two primary categories: data transfer volume reduction and leveraging of data source-specific capabilities. The volume of data being transferred is reduced by performing the query on the data source. The number of rows that are transferred from the data source to FedSQL can be significantly reduced, thereby decreasing the overall query processing time. The leveraging of data source-specific capabilities, such as massively parallel processing, are specific to a data source. Other examples of special capabilities are advanced join techniques, data partitioning, table statistics, and column statistics. These capabilities often allow the data source to perform the SQL query more quickly than FedSQL.

The security benefit of IP is that every part of an IP query that can be processed is processed on the data source side. This eliminates the need to have its associated tables, which might contain sensitive information, transmitted over to the FedSQL side for query processing.
How to Use FedSQL Implicit Pass-Through

FedSQL IP is performed automatically. You are not required to specify any options to use IP.

Single Source FedSQL Implicit Pass-Through

When a query is accessing a single data source, either the full query is implicitly passed down to the data source or the predicates (for example, the WHERE clauses) are passed down to subset the rows that must be transported into FedSQL for local processing. FedSQL can pass queries implicitly only when the SQL syntax is ANSI-compliant. The following limitations might prevent IP:

- functions that are FedSQL-specific, such as PUT.
- certain aggregate statistics such as SKEWNESS, STUDENTS_T, NMISS, KURTOSIS, CSS, USS, and PROBT.
- mathematical functions such as SIN, COS, ATAN, and TAN.
- ANSI-compliant FedSQL syntax might prevent IP if the data source is not ANSI compliant in that area.

Database tables must be in the same catalog in order to be merged and joined using implicit pass-through. Merges and joins of database tables that exist in different catalogs are processed on the client. A query that contains references to multiple schemas (but only one catalog) can be passed to the data source.

Multiple Source FedSQL Implicit Pass-Through

FedSQL can perform IP on queries that include multiple data sources. This is accomplished by breaking the query into multiple queries and passing these individual queries to their respective drivers. In addition to the restrictions listed in "Single Source FedSQL Implicit Pass-Through" on page 69, multiple source IP has the following additional limitations:

- A maximum of ten tables can be in one comma join.
- Each side of a set operation (for example, UNION, INTERSECT, and EXCEPT) must have tables from multiple sources for multiple source IP to perform correctly.
- If the query contains a correlated subquery, no multiple source IP is attempted.
FedSQL Explicit Pass-Through Facility

Overview

The FedSQL explicit pass-through facility enables you to connect to a data source and send SQL statements directly to that data source for execution. This facility also enables you to use the syntax of your data source, and it supports any non-ANSI standard SQL that is supported by your data source.

You can create a connection to the language processor. This connection supports standard SQL syntax. This connection can also accept native SQL syntax through the use of the CONNECTION TO component of the SELECT statement’s FROM clause, and the EXECUTE statement. Note that on SAS Federation Server, use of these statements is allowed only when the DSN is configured to use personal logins because of security restrictions.

CONNECTION TO Component of the FROM Clause

You should use the CONNECTION TO component of the SELECT statement’s FROM clause to submit native SQL requests that produce a result set.

The CONNECTION TO component has the following syntax:

```
FROM CONNECTION TO catalog (native-syntax) [[AS] alias]
```

Arguments

- `catalog` specifies the name of a catalog in the existing FedSQL connection.
- `native-syntax` specifies a select-type query (not DDL) to be run on the catalog’s driver.
- `alias` provides a name for the result set produced by the native query.

Example:

```
select oo.i, oo.rank, ff.onoff
from connection to catalog_a
  ( select i, rank() over (order by j) rank from table_a ) oo,
connection to catalog_b
  ( select distinct i, iif(k > 0.5, 1, 0) as onoff from table_a ) ff
where oo.i = ff.i
order by 1;
```

For more information, see the “SELECT Statement” on page 874.
EXECUTE Statement

You should use the EXECUTE statement if the native SQL does not produce a result set, such as DML and DDL statements. In addition, the EXECUTE statement accepts native SQL that produces a result set. For more information, see “EXECUTE Statement” on page 868.

Transactions in FedSQL

Some applications have a requirement to treat groups of updates to a particular data source as a single unit. That is, either the entire group of updates is applied to the data or none of them is applied. Applications can test for errors and execute specific commit and rollback operations to provide that functionality.

FedSQL supports both COMMIT and ROLLBACK statements, which provide data protection by ensuring that updates are either fully applied or rolled back to the pre-transaction state when an operation is interrupted.

A transaction is an atomic unit of work. That is, a transaction either completely succeeds or has no effect. After a logical, consistent set of changes has occurred, a transaction is ended either by committing the changes, which makes them permanent, or by canceling the changes, which returns the values that are changed by a transaction to their original state.

When a connection to a database is established, autocommit functionality is the default. That is, each individual FedSQL statement is treated as a transaction. As soon as the statement is executed, if no return code is detected, the transaction is automatically committed. If update problems are detected, FedSQL initiates a rollback of the transaction.

To allow a transaction to be made up of multiple FedSQL statements, the application must turn off autocommit functionality. When autocommit functionality is on, COMMIT and ROLLBACK statements have no effect.

Not all data sources provide transaction management. For example, transaction management is not available for SAS data sets, SPD Engine data sets, and SPD Server tables. However, transaction support is available for data sources such as Oracle and Teradata. See the server administration documentation for information about how to turn off autocommit functionality. For example, see SAS Federation Server: Administrator’s Guide or the FEDSQL procedure documentation for information about connection options that turn autocommit functionality off.

FedSQL Reserved Words

The following words are reserved as FedSQL language keywords and cannot be used as variable names or in any other way.
Note: You can use delimited identifiers for terms that might otherwise be a reserved word. For example, to use the term “char” other than for a character declaration, you would use it as the delimited identifier “char”. For more information, see “Delimited Identifiers” on page 20.

Overview of Formats

A format is an instruction that FedSQL uses to write data values. You use formats to control the written appearance of data values, or, in some cases, to group data values together for analysis. For example, the ROMANw. format, which converts numeric values to roman numerals, writes the numeric value 2013 as MMXIII.

When you create a SAS data set, SPD Engine data set, or SPD Server table with FedSQL, formatting instructions can be stored with the data set, and automatically applied by the SAS Output Delivery System (ODS) when the data set is displayed in a Base SAS session. Formats must be explicitly specified in the PUT function for the other SAS/ACCESS engines, because the data source drivers do not store information about formats and informats.

General Format Syntax

FedSQL formats have the following syntax:

\[
[ \$ ] \text{format} [w] \cdot [d]
\]

Arguments

\$ 
indicates a character format; its absence indicates a numeric informat.

\text{format}

names the format. The format is a SAS format, a FedSQL format, or a user-defined format that was previously defined with the INVALUE statement in PROC FORMAT. For more information about user-defined formats, see PROC FORMAT in Base SAS Procedures Guide.

\(w\)

specifies the format width, which for most formats is the number of columns in the input data.

\(d\)

specifies a decimal scaling factor in the numeric formats. FedSQL divides the input data by 10 to the power of \(d\).

Tip  When the value of \(d\) is greater than 15, the precision of the decimal value after the 15th decimal place might not be accurate.

Formats always contain a period (.) as a part of the name. If you omit the \(w\) and the \(d\) values from the format, SAS uses default values. The \(d\) value that you specify with a format tells FedSQL to display that many decimal places, regardless of how many decimal places are in the data. Formats never change or truncate the internally stored data values.

For example, in DOLLAR10.2, the \(w\) value of 10 specifies a maximum of 10 columns for the value. The \(d\) value of 2 specifies that two of these columns are for the decimal part of the value, which leaves eight columns for all the remaining
characters in the value. This includes the decimal point, the remaining numeric value, a minus sign if the value is negative, the dollar sign, and commas, if any.

If the format width is too narrow to represent a value, FedSQL tries to squeeze the value into the space available. Character formats truncate values on the right. Numeric formats sometimes revert to the BESTw. format. The BESTw. format is the default format for writing numeric values. BESTw. rounds the value, and if SAS can display at least one significant digit in the decimal portion within the width specified, BESTw. produces the result in decimal. Otherwise, it produces the result in scientific notation. SAS always stores the complete value regardless of the format that you use to represent it. At least 3 columns must be available for the BESTw. format to be applied. FedSQL prints blanks if you do not specify an adequate width. To illustrate, the following request:

```sql
select put(12345, 3.);
```

returns the output 1E4. Meanwhile, this request:

```sql
select put(12345, 2.);
```

returns a blank value.

If you use an incompatible format, such as using a numeric format to write character values, FedSQL first attempts to use an analogous format of the other type. If this is not feasible, an error message that describes the problem appears in the SAS log.

### Using Formats in FedSQL

#### How to Store, Change, Delete, and Use Stored Formats

Storage of format metadata is supported in SAS data sets, SPD Engine data sets, and SPD Server tables only. As a result, when they are used in Base SAS, SAS data sets that were created with FedSQL behave the same as data sets that were created with SAS.

You specify formats in the CREATE TABLE statement as an attribute of the HAVING clause. For more information, see "CREATE TABLE Statement" on page 840. For example, in the following statement, the column `profit` is declared with the EURO13.2 format:

```sql
create table monthly (profit double having format euro13.2);
```

To change or remove a stored format, you must use Base SAS. When you want to display a different format for a column that has a stored format value when reading a table with FedSQL, use the PUT function.

FedSQL supports stored formats as follows:

- Both user-defined formats and formats that are supplied by SAS can be stored. For more information, see "Using a User-Defined Format" on page 82.

- All formats that are supplied by SAS can be stored. For a list of formats, see SAS Formats and Informats: Reference. FedSQL does not validate the formats. If the stored format is invalid, an error occurs, but only when the invalid format is used in the client application.
Formats can be stored only for columns of data types CHAR and DOUBLE.

To access the stored formats, you must have a Base SAS session available. The Base SAS session contains the SAS format definitions and SAS catalog file that stores the user-defined SAS format definitions.

You can store and retrieve format names. The format name is associated with a column by storing the format as a metadata attribute on the column. The metadata then can be retrieved for subsequent operations.

How to Format Output with the PUT Function

The PUT function enables you to associate a format with data in third-party data sources, as well as with SAS data. Formats are specified as arguments in the PUT function to generate formatted data. In the following example, the PUT function returns the formatted value of 4503945867 using the DOLLAR17.2 format. The example returns the value $4,503,945,867.00.

```
select put(4503945867, dollar17.2);
```

FedSQL supports formats that are specified with the PUT function as follows:

- If the PUT function is used without a format, an error occurs.
- The PUT function supports a subset of the formats that are available for Base SAS when the FedSQL language is executed outside a Base SAS session. For a list, see “Formats Supported with the PUT Function, by Category” on page 87.
- Formats can be associated with any of the data types that are supported by FedSQL. However, the data types are converted. Any value that is passed to the PUT function with a numeric format is converted to NVARCHAR, VARBINARY, or BINARY. The type conversions are carried out based on the format name. Any value that is passed with a character format to the PUT function is converted to NVARCHAR.
- The format that is specified in PUT is transient. The PUT function does not affect the stored data.
- The PUT function does not require a Base SAS session to be available; however, the functionality is limited when a session is not available.

See also the “PUT Function” on page 708.

Validation of FedSQL Formats

When a format is stored in a data set using FedSQL, no validation occurs. When metadata for a column is requested, the format name is returned without validation. The format is validated at execution time.

The PUT function validates the specified format upon use.
FedSQL Format Examples

```sql
create table mybase.sales
    ( prod char(10) having format $10.,
      totals double having format dollar6. );

select put (totals, dollar10.) as totals from mybase.sales;

select put(13500, comma6.);
```

Using a User-Defined Format

You can use the SAS FORMAT procedure to define custom formats that replace raw data values with formatted character values. For example, the following PROC FORMAT code creates a custom numeric format called DEPTNO. that maps department codes to their corresponding department name.

```sas
proc format;
    value deptno
        10 = 'Sales'
        20 = 'Research'
        30 = 'Accounting'
        40 = 'Operations';
run;
```

The resulting user-defined format can be stored in a SAS data set, SPD Engine data set, or SPD Server table, or it can be applied to a third-party data source by using the PUT function. The following code uses the PUT function and DEPTNO. format to change the numeric department codes in the DEPT column of the EMPLOYEES table to their corresponding character-based department name.

```sas
select emp_name, hire_date, put(dept, deptno.) as dept
    from employees limit 4;
quit;
```

The content of the source Employees table is shown in Figure 3.4 on page 82. The output of the PUT function is shown in Figure 3.5 on page 83.

*Figure 3.1  Content of the Source EMPLOYEES Table*
Format Categories

Formats can be categorized by the types of values that they operate on. Each FedSQL format belongs to one of the following categories:

**CAS**
- identifies formats that can be used on the CAS server.

**Character**
- writes character data values from character variables.

**Date and Time**
- writes character data values from character variables.

**Numeric**
- writes numeric data values from numeric variables.

NLS Formats Supported by FedSQL

National Language Support (NLS) is a set of features that enable a software product to function properly in every global market for which the product is targeted. The SAS System contains NLS features to ensure that SAS applications can be written so that they conform to local language conventions. Typically, software that is written in the English language works well for users who use both the English language and also data that is formatted using the conventions that are observed in the United States. However, without NLS, these products might not work well for users in other regions of the world. NLS in SAS enables regions such as Asia and Europe to process data successfully in their native languages and environments. The FedSQL language supports the following NLS formats. For more information, see *SAS National Language Support (NLS): Reference Guide*. 

For more information about how to create your own format in SAS, see PROC FORMAT in *Base SAS Procedures Guide*.

### Dictionary

#### $BASE64Xw. Format

Converts character data into ASCII text by using Base 64 encoding.

**Categories:**

- Character
- CAS

**Alignment:** Left

**Syntax**

$BASE64Xw.

**Arguments**

- **w** specifies the width of the output field. You can use the following formula to determine the width:

  \[
  \text{format-width} = \frac{(\text{variable-length} + 2)}{3} \times 4
  \]

  When the variable-length+2 is divided by 3, the results are truncated to an integer and multiplied by 4. For example, if a variable length is 28, as for the input value `www.mydomain.com/myhiddenURL` in the examples below, the width calculation is \((28+2)/3\times 4=40\). If the format width is too small, the value is not converted. No message is written to the SAS log.

**Default**

1

**Range**

1–32767

**Note**

The default width of 1 is insufficient to produce a formatted value. Do not specify $BASE64X without a width.
Details

Base 64 is an industry encoding method whose encoded characters are determined by using a positional scheme that uses only ASCII characters. Several Base 64 encoding schemes have been defined by the industry for specific uses, such as email or content masking. SAS maps positions 0–61 to the characters A–Z, a–z, and 0–9. Position 62 maps to the character +, and position 63 maps to the character /.

Here are some uses of Base 64 encoding:

- embed binary data in an XML file
- encode passwords
- encode URLs

The '=' character in the encoded results indicates that the results have been padded with zero bits. In order for the encoded characters to be decoded, the '=' must be included in the value to be decoded.

Example

The following examples illustrate the BASE64Xw. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put ('FCA01A7993BC', $base64x64.);</td>
<td>RkNBMDFBNzk5M0JD</td>
</tr>
<tr>
<td>select put ('MyPassword', $base64x64.);</td>
<td>TXlqYXNzd29yZA==</td>
</tr>
<tr>
<td>select put ('www.mydomain.com/myhiddenURL',</td>
<td>d3d3Lm15ZG9tYW1uLmNVbi9teWhpZGRlblVSTA==</td>
</tr>
<tr>
<td>$base64x64.);</td>
<td></td>
</tr>
</tbody>
</table>

$BINARYw. Format

Converts character data to binary representation.

Categories: Character

CAS

Alignment: Left

Syntax

$BINARYw.

Arguments

w

specifies the width of the output field.
The default width is calculated based on the length of the variable to be printed.

**Range**

1–32767

**Comparisons**

The $BINARYw.$ format converts character values to binary representation. The BINARYw. format converts numeric values to binary representation.

**Example**

The example table uses the input value AB to illustrate the effect of the $BINARYw.$ format.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put('AB', $binary16.);</code></td>
<td>ASCII</td>
</tr>
<tr>
<td></td>
<td>0100000101000010</td>
</tr>
</tbody>
</table>

**See Also**

**Formats:**
- “$BINARYw. Format” on page 109
- “$HEXw. Format” on page 99

**$CHARw. Format**

Writes standard character data.

**Categories:**
- Character
- CAS

**Alignment:**
- Left

**Alias:**
- $w$ and $Fw$

**Syntax**

$CHARw$

**Arguments**

$w$

specifies the width of the output field.
8 if the length of variable is undefined; otherwise, the length of the variable.

1–32767

Comparisons

The $CHARw., $w., and $Fw. formats are identical. They do not trim leading blanks.

Example

The example table uses the input value XYZ to illustrate the effect of the $CHARw. format.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put ('XYZ',$char1.);</td>
<td>X</td>
</tr>
<tr>
<td>select put ('XYZ',$char2.);</td>
<td>XY</td>
</tr>
<tr>
<td>select put ('XYZ',$char.);</td>
<td>XYZ</td>
</tr>
</tbody>
</table>

See Also

<table>
<thead>
<tr>
<th>Formats:</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;$w. Format&quot; on page 105</td>
</tr>
</tbody>
</table>

$HEXw. Format

Converts character data to hexadecimal representation.

Syntax

$HEXw.

Arguments

w

specifies the width of the output field.

Default

The default width is calculated based on the length of the variable to be printed.
Range 1–32767

Tips To ensure that SAS writes the full hexadecimal equivalent of your data, make $w$ twice the length of the variable or field that you want to represent.

If $w$ is greater than twice the length of the variable that you want to represent, $\text{HEX}w$ pads it with blanks.

Details
The $\text{HEX}w$. format converts each character into two hexadecimal characters. Each blank counts as one character, including trailing blanks.

Comparisons
The $\text{HEX}w$. format converts real binary numbers to their hexadecimal equivalent.

Example
The following example illustrates the $\text{HEX}w$. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put ('AB',\$hex5.);</code></td>
<td>4142</td>
</tr>
</tbody>
</table>

Formats:
- "$\text{BINARY}w$. Format" on page 97
- "$\text{HEX}w$. Format" on page 139

$\text{OCTAL}w$. Format
Converting character data to octal representation.

Categories: Character
CAS

Alignment: Left

Syntax
$\text{OCTAL}w$. 
Arguments

$w$

specifies the width of the output field.

**Default**
The default width is calculated based on the length of the variable to be printed.

**Range**
1–32767

**Tip**
Because each character value generates three octal characters, increase the value of $w$ by three times the length of the character value.

Comparisons

The $OCTAL_w.$ format converts character values to the octal representation of their character codes. The OCTAL_w. format converts numeric values to octal representation.

Example

The following examples illustrate the $OCTAL_w.$ format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put ('art', $octal15.);</td>
<td>141162164</td>
</tr>
<tr>
<td>select put ('rice', $octal15.);</td>
<td>162151143145</td>
</tr>
<tr>
<td>select put ('bank', $octal15.);</td>
<td>142141156153</td>
</tr>
</tbody>
</table>

See Also

**Formats:**

- "OCTAL_w. Format" on page 158

$QUOTE_w. Format$

Writes data values that are enclosed in single quotation marks.

**Categories:**
Character
CAS

**Alignment:**
Left

**Syntax**

$QUOTE_w.$
Arguments

\( w \)

specifies the width of the output field.

**Default** 2 if the length of the variable is undefined; otherwise, the length of the variable + 2.

**Range** 2–32767

**Tip** Make \( w \) wide enough to include the left and right quotation marks.

Details

When you use the \($QUOTEw.\) format, all literals must be in single quotation marks.

The following list describes the output that SAS produces when you use the \($QUOTEw.\) format.

- When your data value is not enclosed in quotation marks, SAS encloses the output in double quotation marks.

- When your data value is not enclosed in quotation marks, but the value contains a single quotation mark, SAS takes the following actions:
  - encloses the data value in double quotation marks
  - does not change the single quotation mark.

- When your data value begins and ends with single quotation marks, and the value contains double quotation marks, SAS takes the following actions:
  - encloses the data value in double quotation marks
  - duplicates the double quotation marks that are found in the data value
  - does not change the single quotation marks.

- When your data value begins and ends with single quotation marks, and the value contains two single contiguous quotation marks, SAS takes the following actions:
  - encloses the value in double quotation marks
  - does not change the single quotation marks.

- When your data value begins and ends with single quotation marks, and contains both double quotation marks and single, contiguous quotation marks, SAS takes the following actions:
  - encloses the value in double quotation marks
  - duplicates the double quotation marks that are found in the data value
  - does not change the single quotation marks.

- When the length of the target field is not large enough to contain the string and its quotation marks, SAS returns all blanks.

**Note:** An embedded quotation mark must be enclosed within additional quotation marks. If you specify a value of "A"B, then $QUOTE5. truncates the B in the value and writes "A"."
Example
The following examples illustrate the $QUOTEw. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put('SAS',$quote.);</code></td>
<td>&quot;SAS&quot;</td>
</tr>
<tr>
<td><code>select put('SAS''s',$quote.);</code></td>
<td>&quot;SAS's&quot;</td>
</tr>
<tr>
<td><code>select put('ad''verb',$quote16.);</code></td>
<td>&quot;ad'verb&quot;</td>
</tr>
<tr>
<td><code>select put(&quot;ad&quot;''&quot;verb&quot;&quot;,$quote20.);</code></td>
<td>&quot;&quot;ad'&quot;&quot;&quot;&quot;verb&quot;&quot;&quot;&quot;</td>
</tr>
</tbody>
</table>

$REVERJw. Format

Writes character data in reverse order and preserves blanks.

Categories: Character  
CAS

Alignment: Right

Syntax
$REVERJw.

Arguments

\( w \)

specifies the width of the output field.

Default 1 if \( w \) is not specified

Range 1–32767

Comparisons

The $REVERJw. format is similar to the $REVERS\( w \). format except that
$REVERS\( w \). left aligns the result by trimming all leading blanks.

Example
The following examples illustrate the $REVERJw. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put('ABCD###',$reverj7.);</code></td>
<td>###DCBA</td>
</tr>
</tbody>
</table>
Statements | Results
---|---
select put('###ABCD',$reverj7.); DCBA###

See Also

Formats:

- "$REVERSw. Format" on page 104

$REVERSw. Format

Writes character data in reverse order and left aligns.

Categories: Character

CAS

Alignment: Left

Syntax

$REVERSw.

Arguments

$w

specifies the width of the output field.

Default 1 if $w is not specified

Range 1–32767

Comparisons

The $REVERSw. format is similar to the $REVERJw. format except that $REVERJw. does not left align the result.

Example

The following examples illustrate the $REVERSw. format:

Statements | Results
---|---
select put('ABCD###',$revers7.); ###DCBA

select put('###ABCD',$revers7.); DCBA###
See Also

Formats:
- "$REVERJw. Format" on page 103

$UPCASEw. Format

Converts character data to uppercase.

Categories: Character
CAS

Alignment: Left

Syntax

$UPCASEw.

Arguments

w

specifies the width of the output field.

Default 8 if the length of the variable is undefined; otherwise, the length of the variable.

Range 1–32767

Details

Special characters, such as hyphens and other symbols, are not altered.

Example

The following example illustrates the $UPCASEw. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put('coxe-ryan',$upcase9.);</td>
<td>COXE-RYAN</td>
</tr>
</tbody>
</table>

$w. Format

Writes standard character data.

Categories: Character
CAS
Alignment: Left
Alias: $Fw.

Syntax
$w.

Arguments

$w

specifies the width of the output field.

Default 1 if the length of the identifier is undefined; otherwise, the length of the identifier

Range 1–32767

Comparisons
The $w. format and the $CHARw. format are identical, and they do not trim leading blanks.

Example
The following examples illustrate the $w. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put('#Cary',$5.);</td>
<td>#Cary</td>
</tr>
<tr>
<td>select put('#Cary',$f5.);</td>
<td>#Cary</td>
</tr>
<tr>
<td>select put('Carolina',$5.);</td>
<td>Carol</td>
</tr>
</tbody>
</table>

1 The character # represents a blank space.

See Also

Formats:

- "$CHARw. Format" on page 98
- "w.d Format" on page 171

BESTw. Format
SAS chooses the best notation.

Categories: Numeric
Syntax

**BESTw.**

Arguments

**w**

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>1–32</td>
</tr>
<tr>
<td>Tip</td>
<td>If you print numbers between 0 and .01 exclusively, use a field width of at least 7 to avoid excessive rounding. If you print numbers between 0 and –.01 exclusively, use a field width of at least 8.</td>
</tr>
</tbody>
</table>

Details

The **BESTw.** format is the default format for writing numeric values. When there is no format specification, SAS chooses the format that provides the most information about the value according to the available field width. **BESTw.** rounds the value, and if SAS can display at least one significant digit in the decimal portion, within the width specified, **BESTw.** produces the result in decimal. Otherwise, it produces the result in scientific notation. SAS always stores the complete value regardless of the format that you use to represent it.

Comparisons

- The **BESTw.** format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.
- The **Dw.p** format writes numbers with the desired precision and more alignment than the **BESTw.** format.

Example

The example table uses the value 1257000 to illustrate the effect of the **BESTw.** format.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(1257000,best6.);</code></td>
<td><code>1.26E6</code></td>
</tr>
<tr>
<td><code>select put(1257000,best3.);</code></td>
<td><code>1E6</code></td>
</tr>
</tbody>
</table>
BESTDw.p Format

Prints numeric values, lining up decimal places for values of similar magnitude, and prints integers without decimals.

**Categories:**
- Numeric
- CAS

**Note:**
In SAS 9.4, the output of the BESTDw format is right-aligned; in CAS, the output is left-aligned.

**Syntax**

```
BESTDw.\[p]\n```

**Arguments**

- **w**
  - specifies the width of the output field.
  - Default: 12
  - Range: 1–32

- **p**
  - specifies the precision.
  - Default: 3
  - Range: 0 to \(w-1\)
  - Requirement: must be less than \(w\)
  - Tip: If \(p\) is omitted or is specified as 0, then \(p\) is set to 3.

**Details**

The BESTDw.p format writes numbers so that the decimal point aligns in groups of values with similar magnitude. Integers are printed without a decimal point. Larger values of \(p\) print the data values with more precision and potentially more shifts in the decimal point alignment. Smaller values of \(p\) print the data values with less precision and a greater chance of decimal point alignment.
The format chooses the number of decimal places to print for ranges of values, even when the underlying values can be represented with fewer decimal places.

Comparisons

- The BESTw. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.
- The Dw.p format writes numbers with the desired precision and more alignment than the BESTw format.
- The BESTDw.p format is a combination of the BESTw. format and the Dw.p format in that it formats all numeric data, and it does a better job of aligning decimals than the BESTw. format.
- The w.d format aligns decimal points, if possible, but it does not necessarily show the same precision for all numbers.

Example

The following examples illustrate the BESTDw.p format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (12345, bestd14.);</td>
<td>12345</td>
</tr>
<tr>
<td>select put (123.45, bestd14.);</td>
<td>123.4500000</td>
</tr>
<tr>
<td>select put (1.2345, bestd14.);</td>
<td>1.2345000</td>
</tr>
<tr>
<td>select put (.12345, bestd14.);</td>
<td>0.1234500</td>
</tr>
<tr>
<td>select put (1.23456789, bestd14.);</td>
<td>1.23456789</td>
</tr>
</tbody>
</table>

- “BESTw. Format” on page 106
- “Dw.p Format” on page 113
- “w.d Format” on page 171

BINARYw. Format

Converts numeric values to binary representation.

Categories: Numeric
CAS

Alignment: Left
Syntax

**BINARYw.**

Arguments

\( w \)

specifies the width of the output field.

Default: \( 8 \)

Range: \( 1–64 \)

Comparisons

**BINARYw.** converts numeric values to binary representation. The **$BINARYw.** format converts character values to binary representation.

Example

The following examples illustrate the **BINARYw.** format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (123.45, binary8.);</td>
<td>01111011</td>
</tr>
<tr>
<td>select put (123, binary8.);</td>
<td>01111011</td>
</tr>
<tr>
<td>select put (-123, binary8.);</td>
<td>10000101</td>
</tr>
</tbody>
</table>

See Also

Formats:

- "$BINARYw. Format" on page 97
- "HEXw. Format" on page 139

**COMMAw.d Format**

Writes numeric values with a comma that separates every three digits and a period that separates the decimal fraction.

Categories: Numeric, CAS

Alignment: Right
Syntax

**COMMA_{w,d}**

Arguments

- **w**
  - Specifies the width of the output field.
  - Default: 6
  - Range: 1–32
  - Tip: Make \( w \) wide enough to write the numeric values, the commas, and the optional decimal point.

- **d**
  - Specifies the number of digits to the right of the decimal point in the numeric value.
  - Range: 0–31
  - Requirement: must be less than \( w \)

Comparisons

- The COMMA_{w,d} format is similar to the COMMAX_{w,d} format, but the COMMAX_{w,d} format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The COMMA_{w,d} format is similar to the DOLLAR_{w,d} format except that the COMMA_{w,d} format does not print a leading dollar sign.

Example

The following examples illustrate the COMMA_{w,d} format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put (23451.23, comma10.2);</code></td>
<td>23,451.23</td>
</tr>
<tr>
<td><code>select put (123451.234, comma10.2);</code></td>
<td>123,451.23</td>
</tr>
</tbody>
</table>

See Also

Formats:

- "COMMAX_{w,d} Format" on page 112
- "DOLLAR_{w,d} Format" on page 124
COMMAXw.d Format

Writes numeric values with a period that separates every three digits and a comma that separates the decimal fraction.

Categories: Numeric
           CAS

Alignment: Right

Syntax

COMMAX[w].d

Arguments

w

specifies the width of the output field.

Default  6

Range    1–32

Tip      Make w wide enough to write the numeric values, the commas, and the optional decimal point.

d

specifies the number of digits to the right of the decimal point in the numeric value.

Range    0–31

Requirement must be less than w

Comparisons

The COMMAw.d format is similar to the COMMAXw.d format, but the COMMAXw.d format reverses the roles of the decimal point and the comma. This convention is common in European countries.

Example

The following examples illustrate the COMMAXw.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (23451.23, commax10.2);</td>
<td>23.451,23</td>
</tr>
<tr>
<td>select put (123451.234, commax10.2);</td>
<td>123.451,23</td>
</tr>
</tbody>
</table>
Dw.p Format

Prints variables, possibly with a great range of values, lining up decimal places for values of similar magnitude.

Categories: Numeric
CAS
Alignment: Right

Syntax

\[ \text{D}[\text{w}].[\text{p}] \]

Arguments

\textbf{w}

specifies the width of the output field.

\begin{tabular}{ll}
Default & 12 \\
Range & 1–32
\end{tabular}

\textbf{p}

specifies the significant digits.

\begin{tabular}{ll}
Default & 3 \\
Range & 0–16 \\
Requirement & must be less than \text{w}
\end{tabular}

Details

The \textit{Dw.p} format writes numbers so that the decimal point aligns in groups of values with similar magnitude. Larger values of \textit{p} print the data values with more precision and potentially more shifts in the decimal point alignment. Smaller values of \textit{p} print the data values with less precision and a greater chance of decimal point alignment.

Comparisons

\begin{itemize}
\item The \textit{BESTw} format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up.
\end{itemize}
Dw.p writes numbers with the desired precision and more alignment than BESTw.

The BESTDw.p format is a combination of the BESTw. format and the Dw.p format in that it formats all numeric data, and it does a better job of aligning decimals than the BESTw. format.

The w.d format aligns decimal points, if possible, but it does not necessarily show the same precision for all numbers.

Example

The following examples illustrate the Dw.p format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (12345,d10.4);</td>
<td>12345.0</td>
</tr>
<tr>
<td>select put (1234.5,d10.4);</td>
<td>1234.5</td>
</tr>
<tr>
<td>select put (123.45,d10.4);</td>
<td>123.45000</td>
</tr>
<tr>
<td>select put (12.345,d10.4);</td>
<td>12.34500</td>
</tr>
<tr>
<td>select put (1.2345,d10.4);</td>
<td>1.23450</td>
</tr>
<tr>
<td>select put (.12345,d10.4);</td>
<td>0.12345</td>
</tr>
</tbody>
</table>

- "w.d Format" on page 171

DATEw. Format

Writes SAS date values in the form ddmmyy, ddmmyyyy, or dd-mmm-yyyy.

Categories: Date and Time

Alignment: Right

Syntax

DATEw.
Arguments

\texttt{w}

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>5–9</td>
</tr>
<tr>
<td>Tip</td>
<td>Use a width of 9 to print a 4-digit year.</td>
</tr>
</tbody>
</table>

Details

The \texttt{DATEw.} format writes SAS date values in the form \texttt{ddmmyy}, \texttt{ddmmyyyy}, or \texttt{dd-mmm-yyyy} where

\begin{itemize}
  \item \textit{dd} is an integer that represents the day of the month.
  \item \textit{mmm} is the first three letters of the month name.
  \item \textit{yy} or \textit{yyyy} is a two-digit or four-digit integer that represents the year.
\end{itemize}

\textbf{Note:} SAS calculates date values based on the number of days since January 1, 1960.

Example

The example table uses the input value of 19431, which is the SAS date value that corresponds to March 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{select put (19431, date5.;);}</td>
<td>14MAR</td>
</tr>
<tr>
<td>\texttt{select put (19431, date6.;);}</td>
<td>14MAR</td>
</tr>
<tr>
<td>\texttt{select put (19431, date7.;);}</td>
<td>14MAR13</td>
</tr>
<tr>
<td>\texttt{select put (19431, date8.;);}</td>
<td>14MAR13</td>
</tr>
<tr>
<td>\texttt{select put (19431, date9.;);}</td>
<td>14MAR2013</td>
</tr>
</tbody>
</table>

See Also

\textbf{Formats:}

- “\texttt{DATETIMEw.d Format}” on page 118
- “\texttt{DAYw. Format}” on page 119
DATEAMPMw.d Format

Writes SAS datetime values in the form ddmmmyy:hh:mm:ss.ss with AM or PM.

Categories: Date and Time
Cas

Alignment: Right

Syntax

\texttt{DATEAMPMw.\{d\}}

Arguments

\textit{w}

specifies the width of the output field.

Default 19

Range 7–40

Tip SAS requires a minimum \textit{w} value of 13 to write AM or PM. For widths between 10 and 12, SAS writes a 24-hour clock time.

\textit{d}

specifies the number of digits to the right of the decimal point in the seconds value.

Range 0–39

Requirement must be less than \textit{w}
Note

If \( w - d < 17 \), SAS truncates the decimal values.

Details

The DATEAMPM\( w.d \) format writes SAS datetime values in the form \( ddmmyy:hh:mm:ss.ss \), where

- \( dd \) is an integer that represents the day of the month.
- \( mmm \) is the first three letters of the month name.
- \( yy \) is a two-digit integer that represents the year.
- \( hh \) is an integer that represents the hour.
- \( mm \) is an integer that represents the minutes.
- \( ss.ss \) is the number of seconds to two decimal places.

Comparisons

The DATETIME\( w.d \) format is similar to the DATEAMPM\( w.d \) format except that DATETIME\( w.d \) does not print AM or PM at the end of the time.

Example

The example table uses the input value of 1679344494, which is the SAS datetime value that corresponds to 08:34:54 PM on March 19, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (1679344494,dateampm);</td>
<td>19MAR13:08:34:54 PM</td>
</tr>
<tr>
<td>select put (1679344494,dateampm7.);</td>
<td>19MAR13</td>
</tr>
<tr>
<td>select put (1679344494,dateampm10.);</td>
<td>19MAR13:20</td>
</tr>
<tr>
<td>select put (1679344494,dateampm13.);</td>
<td>19MAR13:08 PM</td>
</tr>
<tr>
<td>select put (1679344494,dateampm22.2.);</td>
<td>19MAR13:08:34:54.00 PM</td>
</tr>
</tbody>
</table>

DATETIMEw.d Format

Writes SAS datetime values in the form *ddmmmyy:hh:mm:ss.ss*.

**Categories:**  
Date and Time  
CAS

**Alignment:**  
Right

**Syntax**

`DATETIMEw.[d]`

**Arguments**

**w**  
specifies the width of the output field.

Default 16

Range 7–40

**Tips**  
SAS requires a minimum *w* value of 16 to write a SAS datetime value with the date, hour, and seconds. Add an additional two places to *w* and a value to *d* to return values with optional decimal fractions of seconds.

If *w* – *d* < 17, SAS truncates the decimal values.

**d**  
specifies the number of digits to the right of the decimal point in the seconds value.

Range 0–39

**Requirement** must be less than *w*

**Details**

The DATETIMEw.d format writes SAS datetime values in the form *ddmmmyy:hh:mm:ss.ss*, where

*dd*  
is an integer that represents the day of the month.

*mmm*  
is the first three letters of the month name.

*yy*  
is a two-digit integer that represents the year.

*hh*  
is an integer that represents the hour in 24-hour clock time.

*mm*  
is an integer that represents the minutes.
is the number of seconds to two decimal places.

Comparisons
The DATEAMPMw.d format is similar to the DATETIMEw.d format except that DATEAMPMw.d prints AM or PM at the end of the time.

Example
The example table uses the input value of 1699674559, which is the SAS datetime value that corresponds to 3:49:19 AM on November 10, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (1699674559,datetime.);</td>
<td>10NOV13:03:49:19</td>
</tr>
<tr>
<td>select put (1699674559,datetime7.);</td>
<td>10NOV13</td>
</tr>
<tr>
<td>select put (1699674559,datetime12.);</td>
<td>10NOV13:03</td>
</tr>
<tr>
<td>select put (1699674559,datetime18.);</td>
<td>10NOV13:03:49:19</td>
</tr>
<tr>
<td>select put (1699674559,datetime18.1);</td>
<td>10NOV13:03:49:19.0</td>
</tr>
<tr>
<td>select put (1510285759,datetime19.);</td>
<td>10NOV2013:03:49:19</td>
</tr>
<tr>
<td>select put (1699674559,datetime20.1);</td>
<td>10NOV2013:03:49:19.0</td>
</tr>
<tr>
<td>select put (1699674559,datetime21.2);</td>
<td>10NOV2013:03:49:19.00</td>
</tr>
</tbody>
</table>

---

**DDMMYYw. Format**

Writes SAS date values in the form \texttt{ddmm[yy]|yy} or \texttt{dd/mm[yy]yy}, where a forward slash is the separator and the year appears as either 2 or 4 digits.

**Categories:** Date and Time

CAS

**Alignment:** Right

Syntax

**DDMMYY**\textsubscript{w}.

Arguments

\texttt{w}

specifies the width of the output field.
Default: 8
Range: 2–10
Interaction: When \( w \) has a value of from 2 to 5, the date appears with as much of the day and the month as possible. When \( w \) is 7, the date appears as a two-digit year without slashes.

Details
The DDMMYYw. format writes SAS date values in the form \( ddmmyy \) or \( ddmmlm/yyy \), where
- \( dd \)
  - is an integer that represents the day of the month.
- \( / \)
  - is the separator.
- \( mm \)
  - is an integer that represents the month.
- \( yyyy \)
  - is a two-digit or four-digit integer that represents the year.

Example
The following examples use the input value of 19704, which is the SAS date value that corresponds to December 12, 2013.

<table>
<thead>
<tr>
<th>Statements</th>

Formats:
- “DATEw. Format” on page 114
- “DDMMYYXw. Format” on page 122
- “MMDDYYw. Format” on page 145
- “YYMMDDw. Format” on page 181
**DDMMYYxw. Format**

Writes SAS date values in the form `ddmm[yy]yy` or `ddXmmX[yy]yy`, where X represents a specified separator and the year appears as either 2 or 4 digits.

**Categories:** Date and Time
CAS

**Alignment:** Right

**Syntax**

`DDMMYYxw`.

**Arguments**

- **x**
  - identifies a separator or specifies that no separator appear between the day, the month, and the year. Valid values for x are any of the following:
    - B: separates with a blank
    - C: separates with a colon
    - D: separates with a hyphen
    - N: indicates no separator
    - P: separates with a period
    - S: separates with a slash.

- **w**
  - specifies the width of the output field.
    - **Default**: 8
    - **Range**: 2–10

**Interactions**

- When `w` has a value of from 2 to 5, the date appears with as much of the day and the month as possible. When `w` is 7, the date appears as a two-digit year without separators.

- When `x` has a value of N, the width range changes to 2–8.
Details

The DDMMYYxw. format writes SAS date values in the form $ddmmyy$ or $ddXmmXyy$y, where

$dd$

is an integer that represents the day of the month.

$X$

is a specified separator.

$mm$

is an integer that represents the month.

$yy$

is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 19431, which is the SAS date value that corresponds to March 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19431,ddmmyyc5.);</td>
<td>14:03</td>
</tr>
<tr>
<td>select put(19431,ddmmyyd8.);</td>
<td>14-03-13</td>
</tr>
<tr>
<td>select put(19431,ddmmyyn8.);</td>
<td>14032013</td>
</tr>
<tr>
<td>select put(19431,ddmmyyp10.);</td>
<td>14.03.2013</td>
</tr>
</tbody>
</table>

DOLLARw.d Format

Writers numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

Categories:    Numeric
              CAS

Alignment:    Right

Syntax

DOLLARw.d

Arguments

w
specifies the width of the output field.

Default  6
Range    2–32

d
specifies the number of digits to the right of the decimal point in the numeric value.

Range    0–31
Requirement must be less than w

Details

The DOLLARw.d format writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

The hexadecimal representation of the code for the dollar sign character ($) is 5B on EBCDIC systems and 24 on ASCII systems. The monetary character that these codes represent might be different in other countries, but DOLLARw.d always produces one of these codes.

Comparisons

- The DOLLARw.d format is similar to the DOLLARXw.d format, but the DOLLARXw.d format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The DOLLARw.d format is the same as the COMMAw.d format except that the COMMAw.d format does not write a leading dollar sign.
Example
The following example illustrates the DOLLARw.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(1254.71,dollar10.2);</code></td>
<td>$1,254.71</td>
</tr>
</tbody>
</table>

DOLLARXw.d Format

Writes numeric values with a leading dollar sign, a period that separates every three digits, and a comma that separates the decimal fraction.

Categories: Numeric  
CAS

Alignment: Right

Syntax

\[ \text{DOLLARXw.[d]} \]

Arguments

\[ w \]

specifies the width of the output field.

Default  6  
Range  2–32

\[ d \]

specifies the number of digits to the right of the decimal point in the numeric value.

Default  0  
Range  2–31  
Requirement must be less than \( w \)
Details

The DOLLARXw.d format writes the numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

The hexadecimal representation of the code for the dollar sign character ($) is 5B on EBCDIC systems and 24 on ASCII systems. The monetary character that these codes represent might be different in other countries, but DOLLARXw.d always produces one of these codes.

Comparisons

- The DOLLARXw.d format is similar to the DOLLARw.d format, but the DOLLARXw.d format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The DOLLARXw.d format is the same as the COMMAXw.d format except that the COMMAw.d format does not write a leading dollar sign.

Example

The following example illustrates the DOLLARXw.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1254.71,dollarx10.2);</td>
<td>$1.254,71</td>
</tr>
</tbody>
</table>

Formats:
- "COMMAXw.d Format" on page 112
- "DOLLARw.d Format" on page 124

DOWNNAMEw. Format

Writes SAS date values as the name of the day of the week.

Categories: Date and Time
CAS
Alignment: Right

Syntax

DOWNNAMEw.
Arguments

$w$

specifies the width of the output field.

Default: 9

Range: 1–32

Tip: If you omit $w$, SAS prints the entire name of the day.

Example

The example table uses the input value of 19431, which is the SAS date value that corresponds to March 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19431,downame.);</td>
<td>Thursday</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DATEw. Format” on page 114
- “DTWKDATXw. Format” on page 130
- “WEEKDATEw. Format” on page 172
- “WEEKDATXw. Format” on page 174
- “WEEKDAYw. Format” on page 175

DTDATEw. Format

Expects a SAS datetime value as input and writes the SAS date values in the form $ddmmmyy$ or $ddmmmyyyy$.

Categories: Date and Time

CAS

Alignment: Right

Syntax

**DTDATEw.**

Arguments

$w$

specifies the width of the output field.
Details
The DTDATEnw. format writes SAS date values in the form \texttt{ddmmmyy} or \texttt{ddmmmyyyy}, where

- \texttt{dd} is an integer that represents the day of the month.
- \texttt{mmm} are the first three letters of the month name.
- \texttt{yy} or \texttt{yyyy} is a two-digit or four-digit integer that represents the year.

Comparisons
The DTDATEnw. format produces the same type of output that the DATEw. format produces. The difference is that the DTDATEnw. format requires a SAS datetime value.

Example
The example table uses the input value of 1823167525, which is the SAS datetime value that corresponds to 11:25:25 AM on October 9, 2017, and prints both a two-digit and a four-digit year for the DTDATEnw. format.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1823167525,dtdate.);</td>
<td>09OCT17</td>
</tr>
<tr>
<td>select put(1823167525,dtdate9.);</td>
<td>09OCT2017</td>
</tr>
</tbody>
</table>

DTMONNNYYw. Format
Writers the date part of a SAS datetime value as the month and year in the form \texttt{mmmyy} or \texttt{mmmyyyy}.

Categories:
- Date and Time
- CAS
Syntax

**DTMONYYw.**

Arguments

`w`
- specifies the width of the output field.

Default 5
- Range 5–7

Details

The **DTMONYYw.** format writes SAS datetime values in the form `mmmyy` or `mmmyyyy`, where

- `mmm` is the first three letters of the month name.
- `yy` or `yyyy` is a two-digit or four-digit integer that represents the year.

Comparisons

The **DTMONYYw.** format and the **MONYYw.** format are similar in that they both write date values. The difference is that **DTMONYYw.** expects a SAS datetime value as input, and **MONYYw.** expects a SAS date value.

Example

The example table uses as input the value 1823167525, which is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 a.m.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(1823167525,dtmonyy.);</code></td>
<td>2017:4</td>
</tr>
<tr>
<td><code>select put(1823167525,dtmonyy5.);</code></td>
<td>OCT17</td>
</tr>
<tr>
<td><code>select put(1823167525,dtmonyy6.);</code></td>
<td>OCT17</td>
</tr>
<tr>
<td><code>select put(1823167525,dtmonyy7.);</code></td>
<td>OCT2017</td>
</tr>
</tbody>
</table>

DTWKDATXw. Format

 Writes the date part of a SAS datetime value as the day of the week and the date in the form day-of-week, dd month-name yy (or yyyy).

 Categories: Date and Time
 CAS
 Alignment: Right

 Syntax

 \textbf{DTWKDATX}w.

 Arguments

 \textbf{w} specifies the width of the output field.

 Default \hspace{1cm} 29
 Range \hspace{1cm} 3–37

 Details

 The DTWKDATXw. format writes SAS date values in the form day-of-week, dd month-name, yy or yyyy, where

 \[ \text{day-of-week} \]
 is either the first three letters of the day name or the entire day name.

 \[ \text{dd} \]
 is an integer that represents the day of the month.

 \[ \text{month-name} \]
 is either the first three letters of the month name or the entire month name.

 \[ \text{yy or yyyy} \]
 is a two-digit or four-digit integer that represents the year.

 Comparisons

 The DTWKDATXw. format is similar to the WEEKDATXw. format in that they both write date values. The difference is that DTWKDATXw. expects a SAS datetime value as input, and WEEKDATXw. expects a SAS date value.

 Example

 The example table uses as input the value 1823167525, which is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 a.m.
DTYEARw. Format

W

Specifies the width of the output field.

Default: 4

Range: 2–4

Details
remove after conversion

See Also

Formats:
- "DATEw. Format" on page 114
- "WEEKDATEw. Format" on page 172
- "WEEKDATXw. Format" on page 174
Comparisons

The DTYEARw. format is similar to the YEARw. format in that they both write date values. The difference is that DTYEARw. expects a SAS datetime value as input, and YEARw. expects a SAS date value.

Example

The example table uses as input the value 1823167525, which is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 a.m.

<table>
<thead>
<tr>
<th>Statements</th>

DTYYQCw. Format

Writes the date part of a SAS datetime value as the year and the quarter, and separates them with a colon (:).

Categories: Date and Time
CAS
Alignment: Right

Syntax

```
DTYYQCw.
```

Arguments

- `w` specifies the width of the output field.
Details

The DTYYQCw. format writes SAS datetime values in the form yy or yyyy, followed by a colon (:) and the numeric value for the quarter of the year.

Example

The example table uses as input the value 1823167525, which is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 a.m.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1823167525,dtyyqc.);</td>
<td>17:4</td>
</tr>
<tr>
<td>select put(1823167525,dtyyqc4.);</td>
<td>17:4</td>
</tr>
<tr>
<td>select put(1823167525,dtyyqc5.);</td>
<td>17:4</td>
</tr>
<tr>
<td>select put(1823167525,dtyyqc6.);</td>
<td>2017:4</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DATEw. Format” on page 114
- “DATETIMEw.d Format” on page 118

Ew. Format

Wrote numeric values in scientific notation.

Categories: Numeric
CAS

Alignment: Right

Syntax

Ew.
Arguments

$w$

specifies the width of the output field.

Default: 12

Range: 7–32

Details

SAS reserves the first column of the result for a minus sign.

Example

The following examples illustrate the $ew$. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1257,e10.);</td>
<td>1.257E+03</td>
</tr>
<tr>
<td>select put(-1257,e10.);</td>
<td>-1.257E+03</td>
</tr>
</tbody>
</table>

EURO$w$.d Format

Writes numeric values with a leading euro symbol (€), a comma that separates every three digits, and a period that separates the decimal fraction.

Categories: Numeric, CAS

Alignment: Right

Syntax

`EUROw.d`

Arguments

$w$

specifies the width of the output field.

Default: 6

Range: 1–32

Tip: If you want the euro symbol to be part of the output, be sure to choose an adequate width.
**d**
specifies the number of digits to the right of the decimal point in the numeric value.

<table>
<thead>
<tr>
<th>Default</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0–31</td>
</tr>
<tr>
<td>Requirement</td>
<td>must be less than ( w )</td>
</tr>
</tbody>
</table>

**Comparisons**

- The EURO\(w.d\) format is similar to the EUROX\(w.d\) format, but EUROX\(w.d\) format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The EURO\(w.d\) format is similar to the DOLLAR\(w.d\) format, except that DOLLAR\(w.d\) format writes a leading dollar sign instead of the euro symbol.

**Note:** The EURO\(w.d\) format uses the euro character (U+20AC). If you use the DBCS version of SAS and an encoding that does not support the euro character, an error will occur. To prevent this error, change your session encoding to an encoding that supports the euro character.

**Example**

These examples use 1254.71 as the value of amount.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1254.71,euro10.2);</td>
<td>E1,254.71</td>
</tr>
<tr>
<td>select put(1254.71,euro5.);</td>
<td>1,255</td>
</tr>
<tr>
<td>select put(1254.71,euro9.2);</td>
<td>E1,254.71</td>
</tr>
<tr>
<td>select put(1254.71,euro15.3);</td>
<td>E1,254.710</td>
</tr>
</tbody>
</table>

EUROXw.d Format

Writes numeric values with a leading euro symbol (€), a period that separates every three digits, and a comma that separates the decimal fraction.

Categories: Numeric
CAS
Alignment: Right

Syntax

\texttt{EUROXw.d}

Arguments

\texttt{w}

specifies the width of the output field.

Default 6
Range 1–32
Tip If you want the euro symbol to be part of the output, be sure to choose an adequate width.

\texttt{d}

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0
Range 0–31
Requirement must be less than \texttt{w}

Comparisons

- The EUROXw.d format is similar to the EUROW.d format, but EUROW.d format reverses the roles of the comma and the decimal point. This convention is common in English-speaking countries.
- The EUROXw.d format is similar to the DOLLARXw.d format, except that DOLLARXw.d format writes a leading dollar sign instead of the euro symbol.

Note: The EUROXw.d format uses the euro character (U+20AC). If you use the DBCS version of SAS and an encoding that does not support the euro character, an error will occur. To prevent this error, change your session encoding to an encoding that supports the euro character.
Example

These examples use 1254.71 as the value of amount.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1254.71,eurox10.2);</td>
<td>E1.254,71</td>
</tr>
<tr>
<td>select put(1254.71,eurox5.);</td>
<td>1.255</td>
</tr>
<tr>
<td>select put(1254.71,eurox9.2);</td>
<td>E1.254,71</td>
</tr>
<tr>
<td>select put(1254.71,eurox15.3);</td>
<td>E1.254,710</td>
</tr>
</tbody>
</table>

See Also

Formats:
- "EUROw.d Format" on page 134

FLOATw.d Format

Generates a native single-precision, floating-point value by multiplying a number by 10 raised to the \(d\)th power.

**Syntax**

FLOAT\(w.[d]\)

**Arguments**

\(w\)

- specifies the width of the output field.

  **Requirement** \(width\) must be 4

\(d\)

- specifies the power of 10 by which to multiply the value.

  **Default** 0
  **Range** 0–31
Details

This format is useful in operating environments where a float value is not the same as a truncated double. Values that are written by FLOAT4. typically are those meant to be read by some other external program that runs in your operating environment and that expects these single-precision values. If the value that is to be formatted is a missing value, or if it is out-of-range for a native single-precision, floating-point value, a single-precision value of zero is generated.

Example

The following example illustrates the FLOAT4.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1, float4.);</td>
<td>0000803F</td>
</tr>
</tbody>
</table>

1 The result is a hexadecimal representation of a binary number that is stored in IEEE form.

See Also

Formats:

- “IEEEw.d Format” on page 143

FRACTw. Format

Converts numeric values to fractions.

Categories: Numeric
CAS

Alignment: Right

Syntax

FRACTw.

Arguments

w

specifies the width of the output field.

Default 10
Range 4–32
Details
Dividing the number 1 by 3 produces the value 0.33333333. To write this value as 1/3, use the FRACTw. format. FRACTw. writes fractions in reduced form, that is, 1/2 instead of 50/100.

Example
The following example illustrates the FRACTw. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(0.6666666667,fract8.);</td>
<td>2/3</td>
</tr>
<tr>
<td>select put(0.2784,fract8.);</td>
<td>174/625</td>
</tr>
</tbody>
</table>

HEXw. Format
Converts real binary (floating-point) values to hexadecimal representation.

Categories: Numeric
CAS
Alignment: Left

Syntax
HEXw.

Arguments
w
specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
<th>Tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>1–16</td>
<td>If $w&lt;16$, the HEXw. format converts real binary numbers to fixed-point integers before writing them as hexadecimal characters. It also writes negative numbers in two's complement notation, and right aligns digits. If $w$ is 16, HEXw. displays floating-point values in their hexadecimal form.</td>
</tr>
</tbody>
</table>

Details
In any operating environment, the least significant byte written by HEXw. is the rightmost byte. Some operating environments store integers with the least significant digit as the first byte. The HEXw. format produces consistent results in any operating environment regardless of the order of significance by byte.
Note: Different operating environments store floating-point values in different ways. However, the HEX16 format writes hexadecimal representations of floating-point values with consistent results in the same way that your operating environment stores them.

Comparisons

The HEXw numeric format and the $HEXw character format both generate the hexadecimal equivalent of values.

Example

The following examples illustrate the HEXw format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(35.4, hex8.);</td>
<td>00000023</td>
</tr>
<tr>
<td>select put(88, hex8.);</td>
<td>00000058</td>
</tr>
<tr>
<td>select put(2.33, hex8.);</td>
<td>00000002</td>
</tr>
<tr>
<td>select put(-150, hex8.);</td>
<td>FFFFFFF6A</td>
</tr>
</tbody>
</table>

See Also

Formats:

- "BINARYw. Format" on page 109
- "$HEXw. Format" on page 99

HHMMw.d Format

Writes SAS time values as hours and minutes in the form hh:mm.

Categories: Date and Time

CAS

Alignment: Right

Syntax

```
HHMMw.[d]
```
Arguments

\( w \)

specifies the width of the output field.

Default 5

Range 2–20

\( d \)

specifies the number of digits to the right of the decimal point in the minutes value. The digits to the right of the decimal point specify a fraction of a minute.

Default 0

Range 0–19

Requirement must be less than \( w \)

Details

The HHMM\( w \).d format writes SAS datetime values in the form \( hh:mm \), where

\( hh \)

is an integer.

\( mm \)

is the number of minutes that range from 00 through 59.

SAS rounds hours and minutes that are based on the value of seconds in a SAS time value.

Comparisons

The HHMM\( w \).d format is similar to the TIME\( w \).d format except that the HHMM\( w \).d format does not print seconds.

The HHMM\( w \).d format and the TIME\( w \).d format write a leading blank for the single-hour digit. The TOD\( w \).d format writes a leading zero for a single-hour digit.

Example

The example table uses the input value of 46796, which is the SAS time value that corresponds to 12:59:56 PM.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(46796,hhmm.);</td>
<td>13:00</td>
</tr>
<tr>
<td>select put(46796,hhmm8.2);</td>
<td>12:59.93</td>
</tr>
</tbody>
</table>

In the first example, SAS rounds up the time value four seconds based on the value of seconds in the SAS time value. In the second example, by adding a decimal specification of 2 to the format shows that fifty-six seconds is 93% of a minute.

HOURw.d Format

Writes SAS time values as hours and decimal fractions of hours.

Categories: Date and Time
CAS
Alignment: Right

Syntax

HOURw.[d]

Arguments

w
specifies the width of the output field.
Default: 2
Range: 2–20

d
specifies the number of digits to the right of the decimal point in the hour value. Therefore, SAS prints decimal fractions of the hour.
Range: 0–19
Requirement: must be less than w

Details

SAS rounds hours based on the value of minutes in the SAS time value.
Example

The example table uses the input value of 41400, which is the SAS time value that corresponds to 11:30 AM.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(41400, hour4.1);</td>
<td>11.5</td>
</tr>
</tbody>
</table>

**IEEEw.d Format**

Generates an IEEE floating-point value by multiplying a number by 10 raised to the \( d \)th power.

**Categories:**

- Numeric
- CAS

**Alignment:**

- Left

**CAUTION:**

Large floating-point values and floating-point values that require precision might not be identical to the original SAS value when they are written to an IBM mainframe by using the IEEE format and read back into SAS using the IEEE informat.

**Syntax**

```
IEEEw.[d]
```

**Arguments**

- \( w \)
  
  specifies the width of the output field.

  **Default:** 8
  
  **Range:** 3–8
  
  **Tip:** If \( w \) is 8, an IEEE double-precision, floating-point number is written. If \( w \) is 5, 6, or 7, an IEEE double-precision, floating-point number is written, which assumes truncation of the appropriate number of bytes. If \( w \) is 4, an IEEE single-precision floating-point number is written. If \( w \) is 3, an
IEEE single-precision, floating-point number is written, which assumes truncation of one byte.

\[ d \]

specifies to multiply the number by \(10^d\).

Default: 0

Range: 0–10

Details

This format is useful in operating environments where IEEEw.d is the floating-point representation that is used. In addition, you can use the IEEEw.d format to create files that are used by programs in operating environments that use the IEEE floating-point representation.

Typically, programs generate IEEE values in single-precision (4 bytes) or double-precision (8 bytes). Programs perform truncation solely to save space on output files. Machine instructions require that the floating-point number be one of the two lengths. The IEEEw.d format allows other lengths, which enables you to write data to files that contain space-saving truncated data.

Example

The following examples illustrate the IEEEw.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1,ieee4.);</td>
<td>3FF00000</td>
</tr>
<tr>
<td>select put(1,ieee5.);</td>
<td>3FF0000000</td>
</tr>
</tbody>
</table>

1 The result contains hexadecimal representations of binary numbers stored in IEEE form.

Formats:
- "FLOATw.d Format" on page 137

JULIANw. Format

Writes SAS date values as Julian dates in the form yyddd or yyyyddd.

Categories: Date and Time
CAS

Alignment: Left
Syntax

JULIANw.

Arguments

w

specifies the width of the output field.

Default 5
Range 5–7

Tip If w is 5, the JULIANw. format writes the date with a two-digit year. If w is 7, the JULIANw. format writes the date with a four-digit year.

Details

The JULIANw. format writes SAS date values in the form yyddd or yyyyddd, where

yy or yyyy

is a two-digit or four-digit integer that represents the year.

ddd

is the number of the day, 1–365 (or 1–366 for leap years), in that year.

Example

The example table uses the input value of 19431, which is the SAS date value that corresponds to March 14, 2013 (the 73rd day of the year).

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19431, julian5.);</td>
<td>13073</td>
</tr>
<tr>
<td>select put(19431, julian7.);</td>
<td>2013073</td>
</tr>
</tbody>
</table>

See Also

Formats:

"DATEw. Format" on page 114
Syntax

**MMDDYY**\(w\).

Arguments

\(w\)

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>2–10</td>
</tr>
</tbody>
</table>

Interaction

When \(w\) has a value of from 2 to 5, the date appears with as much of the month and the day as possible. When \(w\) is 7, the date appears as a two-digit year without slashes.

Details

The **MMDDYY**\(w\) format writes SAS date values in the form *mmdd[yy]yy* or *mm/dd/[yy]yy*, where

- *mm* is an integer that represents the month.
- /* is the separator.
- *dd* is an integer that represents the day of the month.
- *[yy]yy* is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 19431, which is the SAS date value that corresponds to March 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(19431,mmddyy2.);</code></td>
<td>03</td>
</tr>
<tr>
<td><code>select put(19431,mmddyy3.);</code></td>
<td>03</td>
</tr>
<tr>
<td><code>select put(19431,mmddyy4.);</code></td>
<td>0314</td>
</tr>
<tr>
<td><code>select put(19431,mmddyy5.);</code></td>
<td>03/14</td>
</tr>
<tr>
<td><code>select put(19431,mmddyy6.);</code></td>
<td>031413</td>
</tr>
<tr>
<td><code>select put(19431,mmddyy7.);</code></td>
<td>031413</td>
</tr>
</tbody>
</table>
MMDDYYXW. Format

Writes SAS date values in the form *mmdd[yy]yy* or *mmXddX[yy]yy*, where X represents a specified separator and the year appears as either 2 or 4 digits.

### Categories:
- Date and Time
- CAS

### Alignment:
- Right

### Syntax

\[ \text{MMDDYY} \text{XW.} \]

### Arguments

\[ x \]

Identifies a separator or specifies that no separator appear between the month, the day, and the year. Valid values for \( x \) are any of the following:

- B separates with a blank
- C separates with a colon
- D separates with a hyphen
- N indicates no separator
- P separates with a period
- S separates with a slash.
\( w \) specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>2–10</td>
</tr>
</tbody>
</table>

**Interactions**

When \( w \) has a value of from 2 to 5, the date appears with as much of the month and the day as possible. When \( w \) is 7, the date appears as a two-digit year without separators.

When \( x \) has a value of \( N \), the width range changes to 2–8.

**Details**

The MMDDYYxw. format writes SAS date values in the form \( mmdd\{yy\}yy \) or \( mmXddX\{yy\}yy \), where

- \( mm \) is an integer that represents the month.
- \( X \) is a specified separator.
- \( dd \) is an integer that represents the day of the month.
- \( \{yy\}yy \) is a two-digit or four-digit integer that represents the year.

**Example**

The following examples use the input value of 19431, which is the SAS date value that corresponds to March, 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19431,mmddyc5.);</td>
<td>03:14</td>
</tr>
<tr>
<td>select put(19431,mmddyd8.);</td>
<td>03-14-13</td>
</tr>
<tr>
<td>select put(19431,mmddyn9.);</td>
<td>03132013</td>
</tr>
<tr>
<td>select put(19431,mmddyp10.);</td>
<td>03.14.2013</td>
</tr>
</tbody>
</table>

**See Also**

**Formats:**

- “DATEw. Format” on page 114
- “DDMMYYxw. Format” on page 122
- “MMDDYYw. Format” on page 145
- “YYMMDDxw. Format” on page 183
**MMSSw.d Format**

Writes SAS time values as the number of minutes and seconds since midnight.

Categories:
- Date and Time
- CAS

Alignment: Right

**Syntax**

\[
\text{MMSS}w.[d]
\]

**Arguments**

\[
w
\]

specifies the width of the output field.

- **Default**: 5
- **Range**: 2–20
- **Tip**: Set \( w \) to a minimum of 5 to write a value that represents minutes and seconds.

\[
d
\]

specifies the number of digits to the right of the decimal point in the seconds value. Therefore, the SAS time value includes fractional seconds.

- **Range**: 0–19
- **Restriction**: must be less than \( w \)

**Example**

The example table uses the SAS input value of 4530.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(4530,mmss.);</code></td>
<td>75:30</td>
</tr>
</tbody>
</table>

**See Also**

**Formats:**

- “HHMMw.d Format” on page 140
- “TIMEw.d Format” on page 165
MMYYw. Format

Writes SAS date values in the form \textit{mmM\{yy\}yy}, where M is the separator and the year appears as either 2 or 4 digits.

Categories: Date and Time
CAS

Alignment: Right

Syntax

\texttt{MMYYw.}

Arguments

\texttt{w}

specifies the width of the output field.

Default: 7
Range: 5–32

Interaction

When \textit{w} has a value of 5 or 6, the date appears with only the last two digits of the year. When \textit{w} is 7 or more, the date appears with a four-digit year.

Details

The \texttt{MMYYw.} format writes SAS date values in the form \textit{mmM<yy>yy}, where

\textit{mm}  
is an integer that represents the month.

\textit{M}  
is the character separator.

\textit{\{yy\}yy}  
is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 19431, which is the SAS date value that corresponds to March 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19431,mmyy5.);</td>
<td>03M13</td>
</tr>
<tr>
<td>select put(19431,mmyy6.);</td>
<td>03M13</td>
</tr>
</tbody>
</table>
See Also

Formats:
- “DATEw. Format” on page 114

- “YYMMw. Format” on page 178

MMYYxw. Format

Writes SAS date values in the form \texttt{mm[yy]yy} or \texttt{mmX[yy]yy}. The \texttt{x} in the format name is a character that represents the special character. The special character separates the month and the year. That special character can be a hyphen (-), period (.), blank character, slash (/), colon (:), or no separator. The year can be either 2 or 4 digits.

Categories: Date and Time
CAS

Alignment: Right

Syntax

\texttt{MMYYxw.}

Arguments

\texttt{x}

identifies a separator or specifies that no separator appear between the month and the year. Valid values for \texttt{x} are any of the following:

\texttt{C}

- separates with a colon

\texttt{D}

- separates with a hyphen

\texttt{N}

- indicates no separator

\texttt{P}

- separates with a period

\texttt{S}

- separates with a forward slash.
**w**

specifies the width of the output field.

- **Default:** 7
- **Range:** 5–32

**Interactions**

When \( x \) is set to N, no separator is specified. The width range is then 4–32, and the default changes to 6.

When \( x \) has a value of C, D, P, or S and \( w \) has a value of 5 or 6, the date appears with only the last two digits of the year. When \( w \) is 7 or more, the date appears with a four-digit year.

When \( x \) has a value of N and \( w \) has a value of 4 or 5, the date appears with only the last two digits of the year. When \( x \) has a value of N and \( w \) is 6 or more, the date appears with a four-digit year.

---

**Details**

The MMYY\(xw\). format writes SAS date values in the form \( mm[yy]yy \) or \( mmX[yy]yy \), where

- \( mm \) is an integer that represents the month.
- \( X \) is a specified separator.
- \( [yy]yy \) is a two-digit or four-digit integer that represents the year.

**Example**

The following examples use the input value of 19560, which is the SAS date value that corresponds to July 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19560,mmyyc5.);</td>
<td>07:13</td>
</tr>
<tr>
<td>select put(19560,mmyyd7.);</td>
<td>07-2013</td>
</tr>
<tr>
<td>select put(19560,mmyyn4.);</td>
<td>0713</td>
</tr>
<tr>
<td>select put(19560,mmyyp8.);</td>
<td>07.2013</td>
</tr>
<tr>
<td>select put(19560,mmyys10.);</td>
<td>07/2013</td>
</tr>
</tbody>
</table>

**See Also**

**Formats:**

- **DATEw. Format** on page 114
MONNAMEw. Format

Writes SAS date values as the name of the month.

Categories: Date and Time
CAS
Alignment: Right

Syntax

MONNAMEw.

Arguments

w

specifies the width of the output field.

Default 9
Range 1–32
Tip Use MONNAME3. to print the first three letters of the month name.

Details

If necessary, SAS truncates the name of the month to fit the format width.

Example

The example table uses the input value of 19431, which is the SAS date value that corresponds to March 14, 2014.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19431,monname1.);</td>
<td>M</td>
</tr>
<tr>
<td>select put(19431,monname3.);</td>
<td>Mar</td>
</tr>
<tr>
<td>select put(19431,monname5.);</td>
<td>March</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “MONTHw. Format” on page 154
MONTHw. Format

Writers SAS date values as the month of the year.

Categories: Date and Time

CAS

Alignment: Right

Syntax

MONTHw.

Arguments

w specifies the width of the output field.

Default 2

Range 1–32

Details

The MONTHw. format writes the month (1 through 12) of the year from a SAS date value.

Example

The example table uses the input value of 19431, which is the SAS date value that corresponds to March 14, 2014.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19431,month.);</td>
<td>3</td>
</tr>
</tbody>
</table>

See Also

Formats:

- "MONNAMEw. Format" on page 153

MONYYw. Format

Writers SAS date values as the month and the year in the form mmyy or mmyyyy.
Syntax

**MONYYw.**

Arguments

- **w**
  - specifies the width of the output field.
  - Default: 5
  - Range: 5–7

Details

The **MONYYw.** format writes SAS date values in the form `mmm y` or `mmm yyyy`, where

- **mmm**
  - is the first three letters of the month name.

- **yy** or **yyyy**
  - is a two-digit or four-digit integer that represents the year.

Comparisons

The **MONYYw.** format and the **DTMONYYw.** format are similar in that they both write date values. The difference is that **MONYYw.** expects a SAS date value as input, and **DTMONYYw.** expects a datetime value.

Example

The example table uses the input value of 19704, which is the SAS date value that corresponds to December 12, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(19704,monyy5.);</code></td>
<td>DEC13</td>
</tr>
<tr>
<td><code>select put(19704,monyy7.);</code></td>
<td>DEC2013</td>
</tr>
</tbody>
</table>

**Formats:**

- “**DATEw. Format**” on page 114
- “**DTMONYYw. Format**” on page 128
NEGPARENw.d Format

Writes negative numeric values in parentheses.

Categories: Numeric
           CAS

Alignment: Right

Syntax

\text{NEGPAREN}w,d

Arguments

\text{w} \\
\text{d}

\text{w} specifies the width of the output field.

\begin{align*}
\text{Default} & \quad 6 \\
\text{Range} & \quad 1–32
\end{align*}

\text{d} specifies the number of digits to the right of the decimal point in the numeric value.

\begin{align*}
\text{Default} & \quad 0 \\
\text{Range} & \quad 0–31
\end{align*}

Details

The NEGPARENw.d format attempts to right align output values. If the input value is negative, \text{NEGPAREN}w,d displays the output by enclosing the value in parentheses, if the field that you specify is wide enough. Otherwise, it uses a minus sign to represent the negative value. If the input value is non-negative, \text{NEGPAREN}w,d displays the value with a leading and trailing blank to ensure proper column alignment. It reserves the last column for a close parenthesis even when the value is positive.
Comparisons

The NEGPARENw.d format is similar to the COMMAw.d format in that it separates every three digits of the value with a comma.

Example

The following examples illustrate the NEGPARENw.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(100, negparen6.);</td>
<td>100</td>
</tr>
<tr>
<td>select put(-200, negparen6.);</td>
<td>(200)</td>
</tr>
<tr>
<td>select put(-2000, negparen8.);</td>
<td>(2,000)</td>
</tr>
</tbody>
</table>

NENGOw. Format

Writes SAS date values as Japanese dates in the form e.yymmdd.

Categories:  Date and Time  
CAS  
Alignment:  Left  

Syntax

NENGOw.

Arguments

w  
 specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>2–10</td>
</tr>
</tbody>
</table>

Details

The NENGOw. format writes SAS date values in the form e.yymmdd, where

- e  
  is the first letter of the name of the imperial era (Meiji, Taisho, Showa, Heisei, or Reiwa).

- yy  
  is an integer that represents the year.
is an integer that represents the month.

$dd$

is an integer that represents the day of the month.

If the width is too small, SAS omits the period.

Example

The example table uses the input value of 19431, which is the SAS date value that corresponds to March 14, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(19431, nengo3.)</code>;</td>
<td>H25</td>
</tr>
<tr>
<td><code>select put(19431, nengo6.)</code>;</td>
<td>H25/03</td>
</tr>
<tr>
<td><code>select put(19431, nengo8.)</code>;</td>
<td>H.250314</td>
</tr>
<tr>
<td><code>select put(19431, nengo9.)</code>;</td>
<td>H25/03/14</td>
</tr>
<tr>
<td><code>select put(19431, nengo10.)</code>;</td>
<td>H.25/03/14</td>
</tr>
</tbody>
</table>

See Also

**Formats:**

- "DATEw. Format" on page 114

**OCTALw. Format**

Converts numeric values to octal representation.

<table>
<thead>
<tr>
<th>Categories:</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CAS</td>
</tr>
</tbody>
</table>

| Alignment:  | Left    |

**Syntax**

**OCTALw.**

**Arguments**

$w$

specifies the width of the output field.

Default 3
Details
If necessary, the OCTALw. format converts numeric values to integers before displaying them in octal representation.

Comparisons
OCTALw. converts numeric values to octal representation. The $OCTALw. format converts character values to octal representation.

Example
The following example illustrates the OCTALw. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (3592, octal16.);</td>
<td>000000000007010</td>
</tr>
</tbody>
</table>

See Also

Formats:
- "$OCTALw. Format" on page 100

PERCENTw.d Format

Writes numeric values as percentages.

Categories: Numeric
CAS

Alignment: Right

Syntax

PERCENTw.d

Arguments

w

specifies the width of the output field.

Default: 6

Range: 4–32
\( d \)

specifies the number of digits to the right of the decimal point in the numeric value.

<table>
<thead>
<tr>
<th>Range</th>
<th>0–31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirement</td>
<td>must be less than ( w )</td>
</tr>
</tbody>
</table>

Details

The PERCENT\( w.d \) format multiplies values by 100, formats them the same as the BEST\( w.d \) format, and adds a percent sign (%) to the end of the formatted value, while it encloses negative values in parentheses. The PERCENT\( w.d \) format allows room for a percent sign and parentheses, even if the value is not negative.

Example

The following examples illustrate the PERCENT\( w.d \) format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(0.1,percent10.);</td>
<td>10%</td>
</tr>
<tr>
<td>select put(1.2,percent10.);</td>
<td>120%</td>
</tr>
<tr>
<td>select put(-.05,percent10.);</td>
<td>(5%)</td>
</tr>
</tbody>
</table>

See Also

Formats:
- "PERCENT\( {\text{n}}.d \) Format" on page 160

PERCENT\( {\text{n}}.d \) Format

Produces percentages, using a minus sign for negative values.

Categories: Numeric
           CAS

Alignment: Right

Syntax

```plaintext
PERCENT\( {\text{n}}.d \)
```
Arguments

\textit{w}

specifies the width of the output field.

- **Default**: 6
- **Range**: 4–32

\textit{d}

specifies the number of digits to the right of the decimal point in the numeric value.

- **Range**: 0–31
- **Requirement**: must be less than \textit{w}

Details

The \textit{PERCENTNw.d} format multiplies negative values by 100, formats them the same as the \textit{BESTw.d} format, adds a minus sign to the beginning of the value, and adds a percent sign (%) to the end of the formatted value. The \textit{PERCENTNw.d} format allows room for a percent sign and a minus sign, even if the value is not negative.

Comparisons

The \textit{PERCENTNw.d} format produces percents by using a minus sign instead of parentheses for negative values. The \textit{PERCENTw.d} format produces percents by using parentheses for negative values.

Example

The following examples illustrate the \textit{PERCENTNw.d} format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(-0.1,percentn10.);</td>
<td>-10%</td>
</tr>
<tr>
<td>select put(.2,percentn10.);</td>
<td>20%</td>
</tr>
<tr>
<td>select put(.8,percentn10.);</td>
<td>80%</td>
</tr>
<tr>
<td>select put(-0.05,percentn10.);</td>
<td>-5%</td>
</tr>
<tr>
<td>select put(-6.3,percentn10.);</td>
<td>-630%</td>
</tr>
</tbody>
</table>

QTRw. Format

Writes SAS date values as the quarter of the year.

Categories: Date and Time
                CAS
Alignment: Right

Syntax

QTR\textit{w}.

Arguments

\textit{w}

specifies the width of the output field.

Default: 1

Range: 1–32

Example

The example table uses the input value of 19624, which is the SAS date value that corresponds to September 23, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19624,qtr.);</td>
<td>3</td>
</tr>
</tbody>
</table>

See Also

**Formats:**

- “YYQw. Format” on page 186
- “YYQxw. Format” on page 187
- “YYQZw. Format” on page 192

QTRRw. Format

Writes SAS date values as the quarter of the year in Roman numerals.
**QTRRw. Format**

**Syntax**

```
QTRRw.
```

**Arguments**

- `w` specifies the width of the output field.

  - **Default**: 3
  - **Range**: 3–32

**Example**

The example table uses the input value of 19624, which is the SAS date value that corresponds to September 23, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(19624,qtrr.);</code></td>
<td>III</td>
</tr>
</tbody>
</table>

**See Also**

**Formats**:

- “QTRw. Format” on page 162
- “YYQRw. Format” on page 189
- “YYQRxw. Format” on page 190

---

**ROMANw. Format**

**Syntax**

```
ROMANw.
```
Arguments

w

specifies the width of the output field.

Default 6

Range 2–32

Details

The ROMANw. format truncates a floating-point value to its integer component before the value is written.

Example

The following example illustrates the ROMANw. format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(2006,roman.);</td>
<td>MMVI</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DATEw. Format” on page 114
- “JULIANw. Format” on page 144

SIZEKw.d Format

Writes a numeric value in the form nK for kilobytes.

Categories: Numeric

CAS

Alignment: Right

Syntax

SIZEKw.[d]

Arguments

w

specifies the width of the output field.

Default 9
Range 2–33

d specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 0–31

Details
To write a numeric value in the form nK by using the SIZEKw.d format, the value of n is calculated by dividing the numeric value by 1,024. The symbol K indicates that the value is a multiple of 1,024.

Example
The following examples illustrate the SIZEw.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (1024, sizek.);</td>
<td>1K</td>
</tr>
<tr>
<td>select put (200943, sizek.);</td>
<td>197K</td>
</tr>
</tbody>
</table>

TIMEw.d Format

Writes SAS time values as hours, minutes, and seconds in the form hh:mm:ss.ss using the military 24-hour clock.

Categories: Date and Time
CAS

Alignment: Right

Syntax

TIMEw.[d]

Arguments

w specifies the width of the output field.

Default 8

Range 2–20
Tip
Make w large enough to produce the desired results. To obtain a complete time value with three decimal places, you must allow at least 12 spaces: eight spaces to the left of the decimal point, one space for the decimal point itself, and three spaces for the decimal fraction of seconds.

\[ d \]

specifies the number of digits to the right of the decimal point in the seconds value.

<table>
<thead>
<tr>
<th>Default</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0–19</td>
</tr>
<tr>
<td>Requirement</td>
<td>must be less than (w)</td>
</tr>
</tbody>
</table>

Details
The\(\text{TIME}w.d\) format writes SAS time values in the form \(hh:mm:ss.ss\), where

- \(hh\)
  is an integer.

  Note: If \(hh\) is a single digit, \(\text{TIME}w.d\) places a leading blank before the digit. For example, the \(\text{TIME}w.d\) format writes 9:00 instead of 09:00.

- \(mm\)
  is the number of minutes, ranging from 00 through 59.

- \(ss.ss\)
  is the number of seconds, ranging from 00 through 59, with the fraction of a second following the decimal point.

Comparisons
The\(\text{TIME}w.d\) format is similar to the\(\text{HHMM}w.d\) format except that \(\text{TIME}w.d\) includes seconds.

The \(\text{TIME}w.d\) format and the \(\text{HHMM}w\) format write a leading blank for a single-hour digit. The \(\text{TOD}w.d\) format writes a leading zero for a single-hour digit.

Example
The example table uses the input value of 59083, which is the SAS time value that corresponds to 4:24:43 PM.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(59083,time.);</td>
<td>16:24:43</td>
</tr>
</tbody>
</table>

Functions:
- “HOUR Function” on page 508
- “MINUTE Function” on page 600
- “SECOND Function” on page 741

TIMEAMPMw.d Format

Writes SAS time values as hours, minutes, and seconds in the form \( hh:mm:ss.ss \) with AM or PM.

Categories: Date and Time
CAS
Alignment: Right

Syntax

TIMEAMPMw.[d]

Arguments

\( w \)

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>11</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>2–20</td>
</tr>
</tbody>
</table>

\( d \)

specifies the number of digits to the right of the decimal point in the seconds value.

<table>
<thead>
<tr>
<th>Default</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0–19</td>
</tr>
<tr>
<td>Requirement</td>
<td>must be less than ( w )</td>
</tr>
</tbody>
</table>
Details

The TIMEAMPMw.d format writes SAS time values in the form \( hh:mm:ss.ss \) with AM or PM, where

- \( hh \) is an integer that represents the hour.
- \( mm \) is an integer that represents the minutes.
- \( ss.ss \) is the number of seconds to two decimal places.

Times greater than 23:59:59 PM appear as the next day.

Make \( w \) large enough to produce the desired results. To obtain a complete time value with three decimal places and AM or PM, you must allow at least 11 spaces \((hh:mm:ss PM)\). If \( w \) is less than 5, SAS writes AM or PM only.

Comparisons

- The TIMEAMPMMw.d format is similar to the TIMEMw.d format except, that TIMEAMPMMw.d prints AM or PM at the end of the time.
- TIMEw.d writes hours greater than 11:59:59, and TIMEAMPMMw.d does not.

Example

The example table uses the input value of 59083, which is the SAS time value that corresponds to 4:24:43 PM.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(59083,timeampm3.);</td>
<td>PM</td>
</tr>
<tr>
<td>select put(59083,timeampm5.);</td>
<td>4 PM</td>
</tr>
<tr>
<td>select put(59083,timeampm7.);</td>
<td>4:24 PM</td>
</tr>
<tr>
<td>select put(59083,timeampm1.);</td>
<td>4:24:43 PM</td>
</tr>
</tbody>
</table>

**Formats:**
- "DATEAMPw.d Format" on page 116
- "TIMEw.d Format" on page 165

TODw.d Format

Writes SAS time values and the time portion of SAS datetime values in the form \( hh:mm:ss.ss \).
Syntax

**TODw.d**

Arguments

**w**

specifies the width of the output field.

- Default: 8
- Range: 2–20
- Tip: SAS writes a zero for a zero hour if the specified width is sufficient, for example, 02:30 or 00:30.

**d**

specifies the number of digits to the right of the decimal point in the seconds value.

- Default: 0
- Range: 0–19
- Requirement: must be less than \( w \)

Details

The TOD\(_w,d\) format writes SAS datetime values in the form \( hh:mm:ss.ss \), where

- \( hh \) is an integer that represents the hour.
- \( mm \) is an integer that represents the minutes.
- \( ss.ss \) is the number of seconds to two decimal places.

Comparisons

The TOW\(_w,d\) format writes a leading zero for a single-hour digit. The TIME\(_w,d\) format and the HHMM\(_w,d\) format write a leading blank for a single-hour digit.

Example

The following example illustrates the TOD\(_w,d\) format:
VAXRBw.d Format

Writers real binary (floating-point) data in VMS format.

Categories:
- Numeric
- CAS

Alignment: Right

Syntax

VAXRBw.[d]

Arguments

w
specifies the width of the output field.

Default: 8
Range: 2–8

d
specifies the power of 10 by which to divide the value.

Default: 0
Range: 0–31

Details

Use the VAXRBw.d format to write data in native VAX/VMS floating-point notation.

Example

The following example illustrates the VAXRBw.d format:

Statements | Results
--- | ---
select put(1472049623,tod9.); | 14:40:23

See Also

Formats:
- “TIMEw.d Format” on page 165
- “TIMEAMPMw.d Format” on page 167
w.d Format

Writes standard numeric data one digit per byte.

Categories: Numeric
CAS
Alignment: Right
Alias: Fw.d

Syntax

\[ w.d \]

Arguments

\( w \)
specifies the width of the output field.

Range \( 1–32 \)

Tip Allow enough space to write the value, the decimal point, and a minus sign, if necessary.

\( d \)
specifies the number of digits to the right of the decimal point in the numeric value. This argument is optional.

Range \( 0–31 \)

Requirement must be less than \( w \)

Tip If \( d \) is 0 or you omit \( d \), \( w.d \) writes the value without a decimal point.

Details

The \( w.d \) format rounds to the nearest number that fits in the output field. If \( w.d \) is too small, SAS might shift the decimal to the BESTw. format. The \( w.d \) format writes negative numbers with leading minus signs. In addition, \( w.d \) right aligns before writing and pads the output with leading blanks.

1 The result is the hexadecimal representation for the integer.
Comparisons

The Zw.d format is similar to the w.d format except that Zw.d pads right-aligned output with 0s instead of blanks.

Example

The following example illustrates the w.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put (23.45, 6.3);</td>
<td>23.450</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “Dw.p Format” on page 113
- “$w. Format” on page 105
- “Zw.d Format” on page 193

WEEKDATEw. Format

Writes SAS date values as the day of the week and the date in the form day-of-week, month-name dd, yy (or yyyy).

Categories: Date and Time
CAS
Alignment: Right

Syntax

WEEKDATEw.

Arguments

w

specifies the width of the output field.

Default 29
Range 3–37
Details

The WEEKDATEw. format writes SAS date values in the form *day-of-week, month-name dd, yy (or yyyy)*, where

*dd*

is an integer that represents the day of the month.

*yy or yyyy*

is a two-digit or four-digit integer that represents the year.

If *w* is too small to write the complete day of the week and month, SAS abbreviates as needed.

Comparisons

The WEEKDATEw. format is the same as the WEEKDATXw. format except that WEEKDATXw. prints *dd* before the month's name.

Example

The example table uses the input value of 19537 which is the SAS date value that corresponds to June 28, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19537,weekdate3.);</td>
<td>Fri</td>
</tr>
<tr>
<td>select put(19537,weekdate9.);</td>
<td>Friday</td>
</tr>
<tr>
<td>select put(19537,weekdate15.);</td>
<td>Fri, Jun 28, 13</td>
</tr>
<tr>
<td>select put(19537,weekdate17.);</td>
<td>Fri, Jun 28, 2013</td>
</tr>
</tbody>
</table>

- "TODw.d Format" on page 168
- "WEEKDATXw. Format" on page 174
- "YYMMDDDw. Format" on page 181
WEEKDATXw. Format

 Writes SAS date values as the day of the week and date in the form day-of-week, dd month-name yy (or yyyy).

 Categories: Date and Time
          CAS

 Alignment: Right

 Syntax

 WEEKDATXw.

 Arguments

 w
 specifies the width of the output field.

 Default 29
 Range 3–37

 Details

 The WEEKDATXw. format writes SAS date values in the form day-of-week, dd month-name, yy (or yyyy), where

 dd
 is an integer that represents the day of the month.

 yy or yyyy
 is a two-digit or a four-digit integer that represents the year.

 If w is too small to write the complete day of the week and month, then SAS abbreviates as needed.

 Comparisons

 The WEEKDATEw. format is the same as the WEEKDATXw. format, except that WEEKDATEw. prints dd after the month’s name.

 The WEEKDATXw. format is the same as the DTWKDATXw. format, except that DTWKDATXw. expects a datetime value as input.

 Example

 The example table uses the input value of 19405, which is the SAS date value that corresponds to February 16, 2013.
### Statements

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(19405, weekdatx.);</code></td>
<td><code>Saturday, 16 February 2013</code></td>
</tr>
</tbody>
</table>

---

- “TODw.d Format” on page 168
- “WEEKDATEw. Format” on page 172
- “YYMMDDw. Format” on page 181

---

### WEEKDAYw. Format

Writes SAS date values as the day of the week.

**Categories:** Date and Time  
CAS

**Alignment:** Right

---

### Syntax

**WEEKDAYw.**

**Arguments**

- `w`  
  specifies the width of the output field.

  **Default**: 1  
  **Range**: 1–32

---

### Details

The WEEKDAYw. format writes a SAS date value as the day of the week (where 1=Sunday, 2=Monday, and so on).
Example

The example table uses the input value of 19405, which is the SAS date value that corresponds to February 16, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19405,weekday.);</td>
<td>7</td>
</tr>
</tbody>
</table>

See Also

Formats:

- “DOWNAMEw. Format” on page 126

YEARw. Format

Writes SAS date values as the year.

Categories: Date and Time
            CAS

Alignment: Right

Syntax

YEARw.

Arguments

w

specifies the width of the output field.

Default 4

Range 2–32

Tip If w is less than 4, the last two digits of the year print. Otherwise, the year value prints as four digits.

Comparisons

The YEARw. format is similar to the DTYEARw. format in that they both write date values. The difference is that YEARw. expects a SAS date value as input, and DTYEARw. expects a SAS datetime value.
Example

The example table uses the input value of 19537, which is the SAS date value that corresponds to June 28, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19537,year2.);</td>
<td>13</td>
</tr>
<tr>
<td>select put(19537,year4.);</td>
<td>2013</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “DTYEARw. Format” on page 131

YENw.d Format

Writes numeric values with yen signs, commas, and decimal points.

Categories: Numeric
            CAS

Alignment: Right

Syntax

YEN\textit{w.d}

Arguments

\textit{w}

specifies the width of the output field.

Default 1

Range 1–32

\textit{d}

specifies the number of digits to the right of the decimal point in the numeric value.

Restriction must be either 0 or 2

Tip If \textit{d} is 2, then YENw.d writes a decimal point and two decimal digits.
     If \textit{d} is 0, then YENw.d does not write a decimal point or decimal digits.
Details

The YENw.d format writes numeric values with a leading yen sign and with a comma that separates every three digits of each value.

The hexadecimal representation of the code for the yen sign character is 5B on EBCDIC systems and 5C on ASCII systems. The monetary character these codes represent can be different in other countries.

Example

The following example illustrates the YENw.d format:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1254.71,yen10.2);</td>
<td>¥1,254.71</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “DOLLARw.d Format” on page 124
- “EUROw.d Format” on page 134

YYMMw. Format

Writes SAS date values in the form [yy]yyMmm, where M is the separator and the year appears as either 2 or 4 digits.

Categories: Date and Time
            CAS
Alignment: Right

Syntax

YYMMw.

Arguments

w

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
<th>Interaction</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>5–32</td>
<td>When w has a value of 5 or 6, the date appears with only the last two digits of the year. When w is 7 or more, the date appears with a four-digit year.</td>
</tr>
</tbody>
</table>
YYMMw. Format writes SAS date values in the form [yy]yyMmm, where
[yy]yy
is a two-digit or four-digit integer that represents the year.

M
is the character separator.

mm
is an integer that represents the month.

Example
The following examples use the input value of 19656, which is the SAS date value
that corresponds to October 25, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19656, yyym5.);</td>
<td>13M10</td>
</tr>
<tr>
<td>select put(19656, yyym6.);</td>
<td>13M10</td>
</tr>
<tr>
<td>select put(19656, yyym.);</td>
<td>2013M10</td>
</tr>
<tr>
<td>select put(19656, yyym7.);</td>
<td>2013M10</td>
</tr>
<tr>
<td>select put(19656, yyym10.);</td>
<td>2013M10</td>
</tr>
</tbody>
</table>

See Also

Formats:
- "DATEw. Format" on page 114
- "MMYYw. Format" on page 150
- "YYMMxw. Format" on page 179

YYMMxw. Format

Writes SAS date values in the form [yy]yymm or [yy]yy-mm. The x in the format name represents the special character that separates the year and the month. This special character can be a hyphen (-), period (.), slash(/), colon(:), or no separator. The year can be either 2 or 4 digits.

Categories: Date and Time
CAS

Alignment: Right
Syntax

\[\text{YYMM}_{xw}.\]

Arguments

\(x\)
identifies a separator or specifies that no separator appear between the year and the month. Valid values for \(x\) are any of the following:

- \(C\) separates with a colon
- \(D\) separates with a hyphen
- \(N\) indicates no separator
- \(P\) separates with a period
- \(S\) separates with a forward slash

\(w\)
specifies the width of the output field.

Default 7
Range 5–32

Interactions

When \(x\) is set to \(N\), no separator is specified. The width range is then 4–32, and the default changes to 6.

When \(x\) has a value of \(C\), \(D\), \(P\), or \(S\) and \(w\) has a value of 5 or 6, the date appears with only the last two digits of the year. When \(w\) is 7 or more, the date appears with a four-digit year.

When \(x\) has a value of \(N\) and \(w\) has a value of 4 or 5, the date appears with only the last two digits of the year. When \(x\) has a value of \(N\) and \(w\) is 6 or more, the date appears with a four-digit year.

Details

The YYMM\(xw.\) format writes SAS date values in one of the following forms:

- \(yy/mm/dd\)
- \([yy]\)yy-mm\(x\)dd
- <yy>yy
  - is a two-digit or four-digit integer that represents the year.
- \(x\)
  - is a specified separator.
- \(mm\)
  - is an integer that represents the month.
Example

The following examples use the input value of 19537, which is the SAS date value that corresponds to June 28, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19537, yymmc5.);</td>
<td>13:06</td>
</tr>
<tr>
<td>select put(19537, yymmd.);</td>
<td>2013-06</td>
</tr>
<tr>
<td>select put(19537, yymmn4.);</td>
<td>1306</td>
</tr>
<tr>
<td>select put(19537, yymmp8.);</td>
<td>2013.06</td>
</tr>
<tr>
<td>select put(19537, yymms10.);</td>
<td>2013/06</td>
</tr>
</tbody>
</table>

See Also

Formats:
- "DATEw. Format" on page 114
- "MMYYxw. Format" on page 151
- "YYMMw. Format" on page 178

YYMMDDw. Format

Writes SAS date values in the form yymmd or [yy]yy-mm-dd, where a hyphen (-) is the separator and the year appears as either 2 or 4 digits.

Categories: Date and Time
CAS

Alignment: Right

Syntax

YYMMDDw.

Arguments

w
specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>2–10</td>
</tr>
</tbody>
</table>
Interaction

When \( w \) has a value of from 2 to 5, the date appears with as much of the year and the month as possible. When \( w \) is 7, the date appears as a two-digit year without a hyphen.

Details

The YYMMDDw. format writes SAS date values in one of the following forms:

- \( yymmd \) is a two-digit or four-digit integer that represents the year.
- \( yy \) is the separator.
- \( mm \) is an integer that represents the month.
- \( dd \) is an integer that represents the day of the month.

To format a date that has a four-digit year and no separators, use the YYMMDDx. format.

Example

The following examples use the input value of 19450, which is the SAS date value that corresponds to April 2, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19450, yymmd2.);</td>
<td>13</td>
</tr>
<tr>
<td>select put(19450, yymmd3.);</td>
<td>13</td>
</tr>
<tr>
<td>select put(19450, yymmd4.);</td>
<td>1304</td>
</tr>
<tr>
<td>select put(19450, yymmd5.);</td>
<td>13-04</td>
</tr>
<tr>
<td>select put(19450, yymmd6.);</td>
<td>130402</td>
</tr>
<tr>
<td>select put(19450, yymmd7.);</td>
<td>130402</td>
</tr>
<tr>
<td>select put(19450, yymmd8.);</td>
<td>13-04-02</td>
</tr>
<tr>
<td>select put(19450, yymmd10.);</td>
<td>2013-04-02</td>
</tr>
</tbody>
</table>

Formats:

- "DATEw. Format" on page 114
YYMMDDxw. Format

Writes date values in the form [yy]yymmd or [yy]yy-mm-dd. The x in the format name is a character that represents the special character which separates the year, month, and day. This special character can be a hyphen (-), period (.), blank character, slash (/), colon (:), or no separator. The year can be either 2 or 4 digits.

Categories: Date and Time
CAS

Alignment: Right

Syntax

YYMMDDxw.

Arguments

x

identifies a separator or specifies that no separator appear between the year, the month, and the day. Valid values for x are any of the following:

B
separates with a blank

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a slash.

w
specifies the width of the output field.

Default 8
Details

The YYMMDDxw. format writes SAS date values in one of the following forms:

\[ yymmd\]
\[ [yy]yyxmmxddd\]

where

\[ [yy]yy\]
- is a two-digit or four-digit integer that represents the year.

\[ x\]
- is a specified separator.

\[ mm\]
- is an integer that represents the month.

\[ dd\]
- is an integer that represents the day of the month.

Example

The following examples use the input value of 19704, which is the SAS date value that corresponds to December 12, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(19704, yymmdc5.);</code></td>
<td>13:12</td>
</tr>
<tr>
<td><code>select put(19704, yymmdd8.);</code></td>
<td>13-12-12</td>
</tr>
<tr>
<td><code>select put(19704, yymmp10.);</code></td>
<td>2013.12.12</td>
</tr>
</tbody>
</table>

YYMONw. Format

Writes SAS date values in the form yymmm or yyyyymm.

Categories:  
- Date and Time
- CAS

Alignment:  
- Right

Syntax

YYMONw.

Arguments

w  
specifies the width of the output field. If the format width is too small to print a four-digit year, only the last two digits of the year are printed.

Default  
7

Range  
5–32

Details

The YYMONw. format abbreviates the month's name to three characters.

Example

The example table uses the input value of 19537, which is the SAS date value that corresponds to June 28, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19537, yymon6.);</td>
<td>13JUN</td>
</tr>
<tr>
<td>select put(19537, yymon7.);</td>
<td>2013JUN</td>
</tr>
</tbody>
</table>

See Also

Formats:
- “DATEw. Format” on page 114
- “MMYYw. Format” on page 150
YYQw. Format

Writes SAS date values in the form [yy]yyQq, where Q is the separator, the year appears as either 2 or 4 digits, and q is the quarter of the year.

Categories: Date and Time
          CAS
Alignment: Right

Syntax

YYQw.

Arguments

w
  specifies the width of the output field.

  Default  6
  Range    4–32
  Interaction When w has a value of 4 or 5, the date appears with only the last two digits of the year. When w is 6 or more, the date appears with a four-digit year.

Details

The YYQw. format writes SAS date values in the form [yy]yyQq, where

[yy]yy
  is a two-digit or four-digit integer that represents the year.

Q
  is the character separator.

q
  is an integer (1, 2, 3, or 4) that represents the quarter of the year.

Example

The following examples use the input value of 19537, which is the SAS date value that corresponds to June 28, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19537,yyq4.);</td>
<td>13Q2</td>
</tr>
<tr>
<td>select put(19537,yyq5.);</td>
<td>13Q2</td>
</tr>
</tbody>
</table>
## YYQxw. Format

Writes SAS date values in the form `[yy]yy or [yy]yy-q`. The `x` in the format name is a character that represents the special character that separates the year and the quarter of the year. This character can be a hyphen (-), period (.), blank character, slash (/), colon (:), or no separator. The year can be either 2 or 4 digits.

### Formats:
- "DATEw. Format" on page 114
- "YYQxw. Format" on page 187
- "YYQRw. Format" on page 189
- "YYQRxw. Format" on page 190
- "YYQZw. Format" on page 192

### Syntax

**YYQ**\_\_\_\_w.\

### Arguments

`x`

identifies a separator or specifies that no separator appear between the year and the quarter. Valid values for `x` are any of the following:

- C
  
  separates with a colon

- D
  
  separates with a hyphen

- N
  
  indicates no separator
P
    separates with a period

S
    separates with a forward slash.

w
    specifies the width of the output field.

Default: 6
Range: 4–32

Interactions
When x is set to N, no separator is specified. The width range is then 3–32, and the default changes to 5.

When w has a value of 4 or 5, the date appears with only the last two digits of the year. When w is 6 or more, the date appears with a four-digit year.

When x has a value of N and w has a value of 3 or 4, the date appears with only the last two digits of the year. When x has a value of N and w is 5 or more, the date appears with a four-digit year.

Details
The YYQwx. format writes SAS date values in one of the following forms:

    [yy]yyq
    [yy]yyxq

where

[yy]yy
    is a two-digit or four-digit integer that represents the year.

X
    is a specified separator.

q
    is an integer (1, 2, 3, or 4) that represents the quarter of the year.

Example
The following examples use the input value of 19537, which is the SAS date value that corresponds to July 28, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19537,yyqc4.);</td>
<td>13:2</td>
</tr>
<tr>
<td>select put(19537,yyqd.);</td>
<td>2013-2</td>
</tr>
<tr>
<td>select put(19537,yyqn3.);</td>
<td>132</td>
</tr>
<tr>
<td>select put(19537,yyqp6.);</td>
<td>2013.2</td>
</tr>
</tbody>
</table>

- “YYQZw. Format” on page 192

### YYQRw. Format

Writes SAS date values in the form [yy]yyQqr, where Q is the separator, the year appears as either 2 or 4 digits, and qr is the quarter of the year expressed in roman numerals.

**Categories:** Date and Time

**CAS**

**Alignment:** Right

**Syntax**

**YYQRw.**

**Arguments**

**w**

specifies the width of the output field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
<th>Interaction</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>6–32</td>
<td>When the value of w is too small to write a four-digit year, the date appears with only the last two digits of the year.</td>
</tr>
</tbody>
</table>

**Details**

The YYQRw. format writes SAS date values in the form [yy]yyQqr, where

- `<yy>`yy
  - is a two-digit or four-digit integer that represents the year.

- Q
  - is the character separator.
is a roman numeral (I, II, III, or IV) that represents the quarter of the year.

Example

The following examples use the input value of 19537, which is the SAS date value that corresponds to June 28, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19537,yyqr6.);</td>
<td>13QII</td>
</tr>
<tr>
<td>select put(19537,yyqr7.);</td>
<td>2013QII</td>
</tr>
<tr>
<td>select put(19537,yyqr.);</td>
<td>2013QII</td>
</tr>
<tr>
<td>select put(19537,yyqr8.);</td>
<td>2013QII</td>
</tr>
<tr>
<td>select put(19537,yyqr10.);</td>
<td>2013QII</td>
</tr>
</tbody>
</table>

See Also

- "YYQRxw. Format" on page 190

YYQRxw. Format

Writes date values in the form [yy]yyqr or [yy]yy-qr. The x in the format name is a character that represents the special character that separates the year and the quarter of the year. This character can be a hyphen (-), period (.), blank character, slash (/), colon (:), or no separator. The year can be either 2 or 4 digits and qr is the quarter of the year in roman numerals.

Categories: Date and Time  
CAS

Alignment: Right

Syntax

YYQRxw.

Arguments

- x
  identifies a separator or specifies that no separator appear between the year and the quarter. Valid values for x are any of the following:
C separates with a colon
D separates with a hyphen
N indicates no separator
P separates with a period
S separates with a forward slash.

\( w \)
specifies the width of the output field.

| Default | 8 |
| Range   | 6–32 |

Interactions

- When \( x \) is set to \( N \), no separator is specified. The width range is then 5–32, and the default changes to 7.
- When the value of \( w \) is too small to write a four-digit year, the date appears with only the last two digits of the year.

Details

The YYQR\( xw \) format writes SAS date values in one of the following forms:

\[
\begin{align*}
[y]y[qr] \\
[y]y[xyqr]
\end{align*}
\]

where

- \([yy]yy\)
  is a two-digit or four-digit integer that represents the year.
- \(x\)
  is a specified separator.
- \(qr\)
  is a roman numeral (I, II, III, or IV) that represents the quarter of the year.

Example

The following examples use the input value of 19721 which is the SAS date value that corresponds to December 29, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(19721,yyqro6.);</td>
<td>13:IV</td>
</tr>
<tr>
<td>select put(19721,yyqrd.);</td>
<td>2013-IV</td>
</tr>
<tr>
<td>select put(19721,yyqrn5.);</td>
<td>13IV</td>
</tr>
</tbody>
</table>
YYQZW. Format

Writes SAS date values in the form [yy] yyqq. The year appears as 2 or 4 digits, and qq is the quarter of the year.

**Categories:**
- Date and Time
- CAS

**Alignment:**
- Right

**Syntax**

YYQZW.

**Arguments**

- **Z**
  - specifies that no separator appear between the year and the quarter.

- **W**
  - specifies the width of the output field.

**Default**

- 4

**Note**

- 6

**Details**

The YYQZW. format writes SAS date values in the form [yy]yyqq where

- **[yy]** is a two-digit or four-digit integer that represents the year.

- **Z**
  - specifies that there is no separator.

- **qq**
  - is an integer (01, 02, 03, or 04) that represents the quarter of the year.

Zw.d Format

Writers standard numeric data with leading 0s.

Categories: Numeric, CAS

Alignment: Right

Syntax

`Zw.[d]`

Arguments

- **w**
  - Specifies the width of the output field.
  - Default: 1
  - Range: 1–32
  - Tip: Allow enough space to write the value, the decimal point, and a minus sign, if necessary.

- **d**
  - Specifies the number of digits to the right of the decimal point in the numeric value.
  - Default: 0
Details

The $Zw.d$ format writes standard numeric values one digit per byte and fills in 0s to the left of the data value.

The $Zw.d$ format rounds to the nearest number that will fit in the output field. If $w.d$ is too large to fit, SAS might shift the decimal to the BEST$w$ format. The $Zw.d$ format writes negative numbers with leading minus signs. In addition, it right aligns before writing and pads the output with leading zeros.

Comparisons

The $Zw.d$ format is similar to the $w.d$ format except that $Zw.d$ pads right-aligned output with 0s instead of blanks.

Example

The following example illustrates the $Zw.d$ format:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(1350, z8.);</td>
<td>00001350</td>
</tr>
</tbody>
</table>

Overview of FedSQL Functions

A FedSQL function performs a computation on FedSQL expressions and returns either a single value or a set of values if the FedSQL expression is a column. Functions that perform a computation on a column are aggregate functions. In other SQL environments, aggregate functions are also known as set functions. Most other functions use arguments supplied by the user, but a few obtain their arguments from the operating environment.

FedSQL functions can be used in FedSQL applications or in DS2 programs where embedded FedSQL is part of a DS2 application.

For more information, see “FedSQL Expressions” on page 48 and the “SET Statement” in SAS DS2 Language Reference.

If the data types of the arguments in the function expression are not what is expected by the FedSQL function, FedSQL performs a type conversion on the arguments so that they have the appropriate data type. If the type conversion is successful, the function executes. Otherwise, an error is issued. For information, see “Type Conversions” on page 27.

Note: For the FedSQL functions that are like-named in Base SAS, these functions take DOUBLE and character arguments. FedSQL converts all numeric input, including ANSI standard date and time values, to DOUBLE. The date and time values become SAS date and time values. FedSQL converts all character input to CHAR. Character return values are NVARCHAR. However, the numeric return values remain as DOUBLE. In particular, date, time, and datetime values remain SAS date, time, and datetime values.

You can cast numeric output to a different data type by using the CAST function. For example, the SAS function INTNX returns a SAS datetime value as output. The CAST function operator :: can be used to convert the output of the INTNX function to the ANSI DATE or ANSI TIMESTAMP data type as follows:

```
select intnx('month', date'2013-01-01', 5, 'beginning'):: date
select intnx('month', date'2013-01-01', 5, 'beginning'):: timestamp
```
General Function Syntax

Aggregate Function Syntax

The syntax for an aggregate function is

\[ \text{aggregate-function (expression)} \]

\textit{aggregate-function} specifies the name of the function.

\textit{expression} specifies an expression that evaluates to a column name. The expression can include one of the following forms:

\textit{table.column}

is a qualified column that identifies the table that is being processed by the FedSQL statement followed by a period and the name of the column.

Example

\begin{verbatim}
select avg(densities.density) from densities;
\end{verbatim}

\textit{column}

is an unqualified column name that has an implicit table qualifier. The implicit table qualifier is the table that FedSQL is processing.

Example

\begin{verbatim}
select avg(density) from densities;
\end{verbatim}

\textbf{Note:} You can specify more than one argument for some aggregate functions. If you do, the Base SAS function is used and the functions can no longer be considered an aggregate function. For more information, see “Calling Base SAS Functions Instead of FedSQL Aggregate Functions” on page 207.

\textbf{Note:} Aggregate functions are currently not supported with MongoDB.

Non-Aggregate Function Syntax

The syntax of a function is

\[ \text{function (argument [ ...argument])} \]

\textit{function} specifies the name of the function.
argument can be a variable name, constant, or any FedSQL expression, including another function. The number and type of arguments that FedSQL allows are described with individual functions. Separate multiple arguments by a comma.

Examples

- `select sqrt(1500);`
- `select ifnull(AvgHigh, 0) from worldtemps;`

Using FedSQL Functions

Restrictions on Function Arguments

If the value of an argument is invalid, FedSQL sets the result to a null or missing value. Here are some common restrictions on function arguments:

- Some functions require that their arguments be restricted within a certain range. For example, the argument of the LOG function must be greater than 0.
- Most functions do not permit nulls or missing values as arguments. Exceptions include some of the descriptive statistics functions and the IFNULL function.
- In general, the allowed range of the arguments is platform-dependent, such as with the EXP function.

Using DS2 Packages in Expressions

You can invoke a DS2 package method as a function in a FedSQL SELECT statement. The syntax for the expression is shown here.

```
[catalog.] [schema.] package.method (argument-1 [,... argument-n])
```

The method parameters can be a DOUBLE, DATE, TIME, TIMESTAMP, an integer of any size, or a string.

The following restrictions apply when you use DS2 packages in expressions in FedSQL:

- The method must return a value.
- You must supply a package name.
- The types and ordering of the arguments in the FedSQL SELECT statement must match the types and ordering of the parameters in the DS2 package method.
- Package methods run from PROC FEDSQL can have only input arguments in the method.

In the following example, the method `BAR` is created in DS2 and then used in a FedSQL SELECT statement call as a function.
/* create table */
data dataset;
  x=1; y=1; z=1; output;
  x=1; y=1; z=2; output;
  x=2; y=2; z=2; output;
  x=2; y=2; z=8; output;
  x=2; y=3; z=13; output;
run;

/* DS2 code */
proc ds2;
  package pkga;
    method bar(double x, double y) returns double;
      return x*x + y*y;
    end;
  endpackage;
run;
quit;

/* fedsql code */
proc fedsql;
  select pkga.bar(1,2) as five,
       cot(radians(45)) as one,
       degrees(pi()) as one_eighty,
       power(3,4) as eighty_one,
       sign(-42) as minus1,
       sign(0) as zero,
       sign(42) as plus1;
  select * from dataset where pkga.bar(x,y) = z;
quit;

The output from the FedSQL SELECT statement would be as follows.

<table>
<thead>
<tr>
<th>FIVE</th>
<th>ONE</th>
<th>ONE_EIGHTY</th>
<th>EIGHTY_ONE</th>
<th>MINUS1</th>
<th>ZERO</th>
<th>PLUS1</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>1</td>
<td>180</td>
<td>81</td>
<td>-1</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

For more information, see “Package Method Expression” in SAS DS2 Programmer’s Guide.
Aggregate Functions

Overview of Aggregate Functions

FedSQL aggregate functions operate on all values for an expression in a table column and return a single result. If the aggregate function is processed in a GROUP BY statement, the aggregate function returns a single result for each group. Null values and SAS missing values are not considered in the operation, except for the COUNT(*) syntax of the COUNT function. The table column that you specify in the function can be any FedSQL expression that evaluates to a column name.

The following are FedSQL aggregate functions:

- "AVG Function" on page 274
- "COUNT Function" on page 365
- "CSS Function" on page 374
- "KURTOSIS Function" on page 563
- "MAX Function" on page 594
- "MIN Function" on page 599
- "NMISS Function" on page 611
- "PROBT Function" on page 707
- "RANGE Function" on page 718
- "SKEWNESS Function" on page 746
- "STD Function" on page 752
- "STDDEV Function" on page 753
- "STDERR Function" on page 754
- "STUDENTS_T Function" on page 756
- "SUM Function" on page 758
- "USS Function" on page 782
- "VARIANCE Function" on page 784

Using the table "WorldTemps" on page 1092, the following aggregate function examples operate on the AvgLow table column:

/* Get the average of the average low temperatures */
select avg(AvgLow) as AvgTemp from worldtemps;

/* Get the number of different average low temperatures */
/* and group them by the average low temperature */
select AvgLow, count(AvgLow) from worldtemps group by AvgLow;

/* Get the highest average low temperature */
select max(AvgLow) from worldtemps;
Calling Base SAS Functions Instead of FedSQL Aggregate Functions

If multiple columns are supplied as arguments to an aggregate function and there is a like-named Base SAS function, the Base SAS function is used. The statistic that is calculated for those arguments is for the current row. The function is no longer considered to be an aggregate function. Some examples are the MIN, MAX, and SUM functions.

If multiple arguments are supplied to an aggregate function and there is no like-named Base SAS function, an error is returned. An example is the AVG function.

Function Categories

Functions can be categorized by the types of values that they operate on. Each FedSQL function belongs to one of the following categories:

Aggregate
  operates on the values in a table column.

Bitwise Logical Operations
  operates on one or more bit patterns or binary numbers at the level of their individual bits.

CAS
  identifies functions that can be used on the CAS server.

Character
  operates on character SQL expressions.

Date and Time
  operates on date and time SQL expressions.

Descriptive Statistics
  operates on values that measure central tendency, variation among values, and the shape of distribution values.

Financial
  calculates financial values such as interest, periodic payments, depreciation, and prices for European options on stocks.

Mathematical
  operates on values to perform general mathematical calculations.

Probability
  returns probability calculations.

Special
  operates on null values and SAS missing values.

Trigonometric
  operates on values to perform trigonometric calculations.
Truncation
truncates numeric values and returns numeric values, often using fuzzing.

SAS Output Delivery System and FedSQL

The SAS Output Delivery System (ODS) rounds numeric output from functions that are submitted with PROC FEDSQL to eight characters by default. To display numeric output with the full precision of which FedSQL is capable, use the PUT function with the BEST16. format, as follows:

```
select PUT (beta(5,3), best16.) as Beta;
```

FEDSQL Functions by Category

<table>
<thead>
<tr>
<th>Category</th>
<th>Language Elements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregate</td>
<td>AVG Function (p. 274)</td>
<td>Returns the average of all values in a column.</td>
</tr>
<tr>
<td></td>
<td>COUNT Function (p. 365)</td>
<td>Returns the number of rows retrieved by a SELECT statement for a specified table.</td>

<td>Returns a value from the logistic cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF LOGNORMAL Distribution Function</td>
<td>(p. 318)</td>
<td>Returns a value from the lognormal cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF NEGATIVE BINOMIAL Distribution</td>
<td>Function (p. 320)</td>
<td>Returns a value from the negative binomial cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF NORMAL Distribution Function</td>
<td>(p. 321)</td>
<td>Returns a value from the normal cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF NORMALMIX Distribution Function</td>
<td>(p. 323)</td>
<td>Returns a value from the normal mixture cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF PARETO Distribution Function</td>
<td>(p. 325)</td>
<td>Returns a value from the Pareto cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF POISSON Distribution Function</td>
<td>(p. 326)</td>
<td>Returns a value from the Poisson cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF T Distribution Function</td>
<td>(p. 328)</td>
<td>Returns a value from the T cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF TWEEDIE Distribution Function</td>
<td>(p. 329)</td>
<td>Returns a value from the Tweedie cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF UNIFORM Distribution Function</td>
<td>(p. 331)</td>
<td>Returns a value from the uniform cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF WALD (Inverse Gaussian)</td>
<td>Distribution Function (p. 333)</td>
<td>Returns a value from the Wald (also known as the inverse Gaussian) cumulative probability distribution.</td>
</tr>
<tr>
<td>CDF WEIBULL Distribution Function</td>
<td>(p. 334)</td>
<td>Returns a value from the Weibull cumulative probability distribution.</td>
</tr>
<tr>
<td>CEIL Function</td>
<td>(p. 335)</td>
<td>Returns the smallest integer greater than or equal to a numeric value expression.</td>
</tr>
<tr>
<td>CEILZ Function</td>
<td>(p. 337)</td>
<td>Returns the smallest integer that is greater than or equal to the argument, using zero fuzzing.</td>
</tr>
<tr>
<td>CHARACTER_LENGTH Function</td>
<td>(p. 338)</td>
<td>Returns the number of characters in a string of any data type.</td>
</tr>
<tr>
<td>CNONCT Function</td>
<td>(p. 339)</td>
<td>Returns the noncentrality parameter from a chi-square distribution.</td>
</tr>
<tr>
<td>COALESCE Function</td>
<td>(p. 341)</td>
<td>Returns the first non-null or nonmissing value from a list of numeric arguments.</td>
</tr>
<tr>
<td>COALESCEC Function</td>
<td>(p. 342)</td>
<td>Returns the first non-null or nonmissing value from a list of character arguments.</td>

<td>CURRENT_TIME Function (p. 380)</td>
<td>Returns the current time for your time zone.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_TIME_GMT Function (p. 381)</td>
<td>Returns the current GMT time.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_TIMESTAMP Function (p. 382)</td>
<td>Returns the date and time for your time zone.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_TIMESTAMP_GMT Function (p. 382)</td>
<td>Returns the current GMT date and time.</td>
</tr>
<tr>
<td></td>
<td>CV Function (p. 383)</td>
<td>Returns the coefficient of variation.</td>
</tr>
<tr>
<td></td>
<td>DAIRY Function (p. 384)</td>
<td>Returns the derivative of the AIRY function.</td>
</tr>
<tr>
<td></td>
<td>DATDIF Function (p. 385)</td>
<td>Returns the number of days between two dates after computing the difference between the dates according to specified day count conventions.</td>
</tr>
<tr>
<td></td>
<td>DATE Function (p. 387)</td>
<td>Returns the current date as a SAS date value.</td>
</tr>
<tr>
<td></td>
<td>DATEJUL Function (p. 388)</td>
<td>Converts a Julian date to a SAS date value.</td>
</tr>
<tr>
<td></td>
<td>DATEPART Function (p. 389)</td>
<td>Returns the date as year, month, and day.</td>
</tr>
<tr>
<td></td>
<td>DATETIME Function (p. 390)</td>
<td>Returns the current date and time of day as a SAS datetime value.</td>
</tr>
<tr>
<td></td>
<td>DAY Function (p. 391)</td>
<td>Returns the numeric day of the month from a date or datetime value.</td>
</tr>
<tr>
<td></td>
<td>DEGREES Function (p. 392)</td>
<td>Returns the number of degrees for an angle in radians.</td>
</tr>
<tr>
<td></td>
<td>DEQUOTE Function (p. 393)</td>
<td>Removes matching single quotation marks from a character string that begins with a single quotation mark, and deletes all characters to the right of the closing quotation mark.</td>
</tr>
<tr>
<td></td>
<td>DEVIANCE Function (p. 396)</td>
<td>Returns the deviance based on a probability distribution.</td>
</tr>
<tr>
<td></td>
<td>DHMS Function (p. 399)</td>
<td>Returns a SAS datetime value from date, hour, minute, and second values.</td>
</tr>
<tr>
<td></td>
<td>DIGAMMA Function (p. 401)</td>
<td>Returns the value of the digamma function.</td>
</tr>
<tr>
<td></td>
<td>DUR Function (p. 402)</td>
<td>Returns the modified duration for an enumerated cash flow.</td>
</tr>
<tr>
<td></td>
<td>DURP Function (p. 403)</td>
<td>Returns the modified duration for a periodic cash flow stream, such as a bond.</td>
</tr>
<tr>
<td></td>
<td>E Function (p. 405)</td>
<td>Returns the natural logarithm, e.</td>
</tr>
<tr>
<td></td>
<td>EFFRATE Function (p. 406)</td>
<td>Returns the effective annual interest rate.</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>ERF Function (p. 407)</td>
<td>Returns the value of the (normal) error function.</td>
</tr>
<tr>
<td></td>
<td>ERFC Function (p. 409)</td>
<td>Returns the value of the complementary (normal) error function.</td>
</tr>
<tr>
<td></td>
<td>EXP Function (p. 410)</td>
<td>Returns the value of the e constant raised to a specified power.</td>
</tr>
<tr>
<td></td>
<td>FACT Function (p. 411)</td>
<td>Computes a factorial.</td>
</tr>
<tr>
<td></td>
<td>FINANCE Function (p. 412)</td>
<td>Computes financial calculations such as depreciation, maturation, accrued interest, net present value, periodic savings, and internal rates of return.</td>
</tr>
<tr>
<td></td>
<td>FINANCE ACCRINT Function (p. 416)</td>
<td>Computes the accrued interest for a security that pays periodic interest.</td>
</tr>
<tr>
<td></td>
<td>FINANCE ACCRINTM Function (p. 417)</td>
<td>Computes the accrued interest for a security that pays interest at maturity.</td>
</tr>
<tr>
<td></td>
<td>FINANCE AMORDEGRC Function (p. 419)</td>
<td>Computes the depreciation for each accounting period by using a depreciation coefficient.</td>
</tr>
<tr>
<td></td>
<td>FINANCE AMORLINC Function (p. 420)</td>
<td>Computes the depreciation for each accounting period.</td>

<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>HOUR Function (p. 508)</td>
<td>Returns the hour from a time or datetime value.</td>
<td></td>
</tr>
<tr>
<td>IBEESSEL Function (p. 510)</td>
<td>Returns the value of the modified Bessel function.</td>
<td></td>
</tr>
<tr>
<td>IFNULL Function (p. 511)</td>
<td>Checks the value of the first expression and, if it is null or a SAS missing value, returns the second expression.</td>
<td></td>
</tr>
<tr>
<td>INDEX Function (p. 512)</td>
<td>Searches a character expression for a string of characters, and returns the position of the string's first character for the first occurrence of the string.</td>
<td></td>
</tr>
<tr>
<td>INDEXC Function (p. 514)</td>
<td>Searches a character expression for specified characters and returns the position of the first occurrence of any of the characters.</td>
<td></td>
</tr>
<tr>
<td>INPUTC Function (p. 515)</td>
<td>Enables you to specify a character informat at run time.</td>
<td></td>
</tr>
<tr>
<td>INPUTN Function (p. 516)</td>
<td>Enables you to specify a numeric informat at run time.</td>
<td></td>
</tr>
<tr>
<td>INT Function (p. 517)</td>
<td>Returns the whole number, fuzzed to avoid unexpected floating-point results.</td>
<td></td>
</tr>
<tr>
<td>INTCINDEX Function (p. 519)</td>
<td>Returns the cycle index when a date, time, or timestamp interval and value are specified.</td>
<td></td>
</tr>
<tr>
<td>INTCK Function (p. 522)</td>
<td>Returns the number of interval boundaries of a given kind that lie between two SAS dates, times, or timestamp values encoded as DOUBLE.</td>
<td></td>
</tr>
<tr>
<td>INTCYCLE Function (p. 529)</td>
<td>Returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or datetime interval is specified.</td>
<td></td>
</tr>
<tr>
<td>INTFIT Function (p. 532)</td>
<td>Returns a time interval that is aligned between two dates.</td>
<td></td>
</tr>
<tr>
<td>INTGET Function (p. 533)</td>
<td>Returns a time interval based on three date or datetime values.</td>
<td></td>
</tr>
<tr>
<td>INTINDEX Function (p. 535)</td>
<td>Returns the seasonal index when a date, time, or timestamp interval and value are specified.</td>
<td></td>
</tr>
<tr>
<td>INTNX Function (p. 539)</td>
<td>Increments a SAS date, time, or datetime value encoded as a DOUBLE, and returns a SAS date, time, or datetime value encoded as a DOUBLE.</td>
<td></td>
</tr>
<tr>
<td>INTRR Function (p. 545)</td>
<td>Returns the internal rate of return as a decimal value.</td>
<td></td>
</tr>
<tr>
<td>INTSEAS Function (p. 547)</td>
<td>Returns the length of the seasonal cycle when a date, time, or datetime interval is specified.</td>
<td></td>
</tr>
<tr>
<td>INTSHIFT Function (p. 550)</td>
<td>Returns the shift interval that corresponds to the base interval.</td>
<td></td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>------------------</td>
<td>-------------</td>

<tr>
<td>INTTEST Function (p. 552)</td>
<td>Returns 1 if a time interval is valid, and returns 0 if a time interval is invalid.</td>
<td></td>
</tr>
<tr>
<td>INTZ Function (p. 554)</td>
<td>Returns the whole number portion of the argument, using zero fuzzing.</td>
<td></td>
</tr>
<tr>
<td>IPMT Function (p. 556)</td>
<td>Returns the interest payment for a given period for a constant payment loan or the periodic savings for a future balance.</td>
<td></td>
</tr>
<tr>
<td>IQR Function (p. 557)</td>
<td>Returns the interquartile range.</td>
<td></td>
</tr>
<tr>
<td>IRR Function (p. 558)</td>
<td>Returns the internal rate of return as a percentage.</td>
<td></td>
</tr>
<tr>
<td>JBESSEL Function (p. 560)</td>
<td>Returns the value of the Bessel function.</td>
<td></td>
</tr>
<tr>
<td>JULDATE Function (p. 561)</td>
<td>Returns the Julian date from a SAS date value.</td>
<td></td>
</tr>
<tr>
<td>JULDATE7 Function (p. 562)</td>
<td>Returns a seven-digit Julian date from a SAS date value.</td>
<td></td>
</tr>
<tr>
<td>KURTOSIS Function (p. 563)</td>
<td>Returns the kurtosis of all values in an expression.</td>
<td></td>
</tr>
<tr>
<td>LARGEST Function (p. 565)</td>
<td>Returns the kth largest non-null or nonmissing value.</td>
<td></td>
</tr>
<tr>
<td>LCM Function (p. 566)</td>
<td>Returns the least common multiple for a set of whole numbers.</td>
<td></td>
</tr>
<tr>
<td>LCOMB Function (p. 567)</td>
<td>Computes the logarithm of the COMB function, which is the logarithm of the number of combinations of n objects taken r at a time.</td>
<td></td>
</tr>
<tr>
<td>LEFT Function (p. 568)</td>
<td>Left aligns a character expression.</td>
<td></td>
</tr>
<tr>
<td>LFACT Function (p. 569)</td>
<td>Computes the logarithm of the FACT (factorial) function.</td>
<td></td>
</tr>
<tr>
<td>LGAMMA Function (p. 570)</td>
<td>Returns the natural logarithm of the Gamma function.</td>
<td></td>
</tr>
<tr>
<td>LOG Function (p. 571)</td>
<td>Returns the natural logarithm (base e) of a numeric value expression.</td>
<td></td>
</tr>
<tr>
<td>LOG1PX Function (p. 572)</td>
<td>Returns the log of 1 plus the argument.</td>
<td></td>
</tr>
<tr>
<td>LOG2 Function (p. 573)</td>
<td>Returns the base-2 logarithm of a numeric value expression.</td>
<td></td>
</tr>
<tr>
<td>LOG10 Function (p. 574)</td>
<td>Returns the base-10 logarithm of a numeric value expression.</td>
<td></td>
</tr>
<tr>
<td>LOGBETA Function (p. 575)</td>
<td>Returns the logarithm of the beta function.</td>
<td></td>
</tr>
<tr>
<td>LOGCDF Function (p. 576)</td>
<td>Returns the logarithm of a left cumulative distribution function.</td>
<td></td>
</tr>
<tr>
<td>LOGISTIC Function (p. 578)</td>
<td>Returns the logistic transformation of the argument.</td>
<td></td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>

<td>PMT Function</td>
<td>(p. 681)</td>
<td>Returns the periodic payment for a constant payment loan or the periodic savings for a future balance.</td>
</tr>
<tr>
<td>POISSON Function</td>
<td>(p. 683)</td>
<td>Returns the probability from a Poisson distribution.</td>
</tr>
<tr>
<td>POWER Function</td>
<td>(p. 684)</td>
<td>Returns the value of a numeric value expression raised to a specified power.</td>
</tr>
<tr>
<td>PROBBETA Function</td>
<td>(p. 685)</td>
<td>Returns the probability from a beta distribution.</td>
</tr>
<tr>
<td>PROBBNML Function</td>
<td>(p. 686)</td>
<td>Returns the probability from a binomial distribution.</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>PROBBNRM Function (p. 687)</td>
<td>Returns a probability from a bivariate normal distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBCHI Function (p. 688)</td>
<td>Returns the probability from a chi-square distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBF Function (p. 689)</td>
<td>Returns the probability from an F distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBGAM Function (p. 690)</td>
<td>Returns the probability from a gamma distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBHYPR Function (p. 691)</td>
<td>Returns the probability from a hypergeometric distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBIT Function (p. 693)</td>
<td>Returns a quantile from the standard normal distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBMC Function (p. 694)</td>
<td>Returns a probability or a quantile from various distributions for multiple comparisons of means.</td>
<td></td>
</tr>
<tr>
<td>PROBMED Function (p. 704)</td>
<td>Computes cumulative probabilities for the sample median.</td>
<td></td>
</tr>
<tr>
<td>PROBNEG Function (p. 705)</td>
<td>Returns the probability from a negative binomial distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBNORM Function (p. 706)</td>
<td>Returns the probability from the standard normal distribution.</td>
<td></td>
</tr>
<tr>
<td>PROBT Function (p. 707)</td>
<td>Returns the probability from a t distribution of the values in an expression.</td>
<td></td>
</tr>
<tr>
<td>PUT Function (p. 708)</td>
<td>Returns a value using a specified format.</td>
<td></td>
</tr>
<tr>
<td>PVP Function (p. 710)</td>
<td>Returns the present value for a periodic cash flow stream (such as a bond), with repayment of principal at maturity.</td>
<td></td>
</tr>
<tr>
<td>QTR Function (p. 712)</td>
<td>Returns the quarter of the year from a SAS date value.</td>
<td></td>
</tr>
<tr>
<td>QUANTILE Function (p. 713)</td>
<td>Returns the quantile from a distribution when you specify the left probability (CDF).</td>
<td></td>
</tr>
<tr>
<td>QUOTE Function (p. 716)</td>
<td>Adds double quotation marks to a character value.</td>
<td></td>
</tr>
<tr>
<td>RADIANS Function (p. 717)</td>
<td>Returns the number of radians converted from a numeric degree value.</td>
<td></td>
</tr>
<tr>
<td>RANGE Function (p. 718)</td>
<td>Returns the range between values in an expression.</td>
<td></td>
</tr>
<tr>
<td>RANK Function (p. 719)</td>
<td>Returns the position of a character in the ASCII collating sequence.</td>
<td></td>
</tr>
<tr>
<td>REPEAT Function (p. 720)</td>
<td>Repeats a character expression.</td>
<td></td>
</tr>
<tr>
<td>REVERSE Function (p. 721)</td>
<td>Reverses a character expression.</td>
<td></td>
</tr>
<tr>
<td>RMS Function (p. 722)</td>
<td>Returns the root mean square.</td>
<td></td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>ROUND Function (p. 723)</td>
<td>Rounds the first argument to the nearest multiple of the second argument, or to the nearest integer when the second argument is omitted.</td>
<td></td>
</tr>
<tr>
<td>ROUNDZ Function (p. 726)</td>
<td>Rounds the first argument to the nearest multiple of the second argument, using zero fuzzing.</td>
<td></td>
</tr>
<tr>
<td>SAVINGS Function (p. 729)</td>
<td>Returns the balance of a periodic savings by using variable interest rates.</td>
<td></td>
</tr>
<tr>
<td>SCAN Function (p. 731)</td>
<td>Returns the nth word from a character expression.</td>
<td></td>
</tr>
<tr>
<td>SDF Function (p. 737)</td>
<td>Returns a survival function.</td>
<td></td>
</tr>
<tr>
<td>SEC Function (p. 740)</td>
<td>Returns the secant.</td>
<td></td>
</tr>
<tr>
<td>SECOND Function (p. 741)</td>
<td>Returns the second from a time or datetime value.</td>
<td></td>
</tr>
<tr>
<td>SIGN Function (p. 743)</td>
<td>Returns a number that indicates the sign of a numeric value expression.</td>
<td></td>
</tr>
<tr>
<td>SIN Function (p. 744)</td>
<td>Returns the trigonometric sine.</td>
<td></td>
</tr>
<tr>
<td>SINH Function (p. 745)</td>
<td>Returns the hyperbolic sine.</td>
<td></td>
</tr>
<tr>
<td>SKEWNESS Function (p. 746)</td>
<td>Returns the skewness of all values in an expression.</td>
<td></td>
</tr>
<tr>
<td>SMALLEST Function (p. 747)</td>
<td>Returns the kth smallest non-null or nonmissing value.</td>
<td></td>
</tr>
<tr>
<td>SQUANTILE Function (p. 748)</td>
<td>Returns the quantile from a distribution when you specify the right probability (SDF).</td>
<td></td>
</tr>
<tr>
<td>SQRT Function (p. 751)</td>
<td>Returns the square root of a value.</td>
<td></td>
</tr>
<tr>
<td>STD Function (p. 752)</td>
<td>Returns the standard deviation.</td>
<td></td>
</tr>
<tr>
<td>STDDEV Function (p. 753)</td>
<td>Returns the statistical standard deviation of all values in an expression.</td>
<td></td>
</tr>
<tr>
<td>STDERR Function (p. 754)</td>
<td>Returns the statistical standard error of all values in an expression.</td>
<td></td>
</tr>
<tr>
<td>STUDENTS_T Function (p. 756)</td>
<td>Returns the Student's t distribution of the values in an expression.</td>
<td></td>
</tr>
<tr>
<td>SUBSTRING Function (p. 757)</td>
<td>Extracts a substring from a character string.</td>
<td></td>
</tr>
<tr>
<td>SUM Function (p. 758)</td>
<td>Returns the sum of all the values in an expression.</td>
<td></td>
</tr>
<tr>
<td>SUMABS Function (p. 760)</td>
<td>Returns the sum of the absolute values of the nonmissing arguments.</td>
<td></td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>

<tr>
<td>SYSGET Function (p. 760)</td>
<td>Returns the value of the specified operating environment variable.</td>
<td></td>
</tr>
<tr>
<td>TAN Function (p. 762)</td>
<td>Returns the tangent.</td>
<td></td>
</tr>
<tr>
<td>TANH Function (p. 763)</td>
<td>Returns the hyperbolic tangent.</td>
<td></td>
</tr>
<tr>
<td>TIMEPART Function (p. 764)</td>
<td>Returns the time as hours, minutes, and seconds.</td>
<td></td>
</tr>
<tr>
<td>TIMEVALUE Function (p. 765)</td>
<td>Returns the equivalent of a reference amount at a base date by using variable interest rates.</td>
<td></td>
</tr>
<tr>
<td>TINV Function (p. 767)</td>
<td>Returns a quantile from the t distribution.</td>
<td></td>
</tr>
<tr>
<td>TNONCT Function (p. 768)</td>
<td>Returns the value of the noncentrality parameter from the Student's t distribution.</td>
<td></td>
</tr>
<tr>
<td>TODAY Function (p. 770)</td>
<td>Returns the current date as a numeric SAS date value.</td>
<td></td>
</tr>
<tr>
<td>TRANSTRN Function (p. 771)</td>
<td>Replaces or removes all occurrences of a substring in a character string.</td>
<td></td>
</tr>
<tr>
<td>TRANWRD Function (p. 773)</td>
<td>Replaces or removes all occurrences of a substring in a character string.</td>
<td></td>
</tr>
<tr>
<td>TRIGAMMA Function (p. 775)</td>
<td>Returns the value of the trigamma function.</td>
<td></td>
</tr>
<tr>
<td>TRIM Function (p. 776)</td>
<td>Removes leading characters, trailing characters, or both from a character string.</td>
<td></td>
</tr>
<tr>
<td>TRUNC Function (p. 777)</td>
<td>Truncates a numeric value to a specified length.</td>
<td></td>
</tr>
<tr>
<td>UPCASE Function (p. 778)</td>
<td>Converts all letters in an argument to uppercase.</td>
<td></td>
</tr>
<tr>
<td>URLDECODE Function (p. 779)</td>
<td>Returns a string that was decoded using the URL escape syntax.</td>
<td></td>
</tr>
<tr>
<td>URLENCODE Function (p. 781)</td>
<td>Returns a string that was encoded using the URL escape syntax.</td>
<td></td>
</tr>
<tr>
<td>USS Function (p. 782)</td>
<td>Returns the uncorrected sum of squares of all the values in an expression.</td>
<td></td>
</tr>
<tr>
<td>VAR Function (p. 783)</td>
<td>Returns the variance.</td>
<td></td>
</tr>
<tr>
<td>VARIANCE Function (p. 784)</td>
<td>Returns the measure of the dispersion of all values in an expression.</td>
<td></td>
</tr>
<tr>
<td>VERIFY Function (p. 785)</td>
<td>Returns the position of the first character that is unique to an expression.</td>
<td></td>
</tr>
<tr>
<td>WEEK Function (p. 787)</td>
<td>Returns the week-number value.</td>
<td></td>
</tr>
<tr>
<td>Category</td>

<tr>
<td></td>
<td>HARMEANZ Function (p. 503)</td>
<td>Returns the harmonic mean, using zero fuzzing.</td>
</tr>
<tr>
<td></td>
<td>IQR Function (p. 557)</td>
<td>Returns the interquartile range.</td>
</tr>
<tr>
<td></td>
<td>KURTOSIS Function (p. 563)</td>
<td>Returns the kurtosis of all values in an expression.</td>
</tr>
<tr>
<td></td>
<td>LARGEST Function (p. 565)</td>
<td>Returns the kth largest non-null or nonmissing value.</td>
</tr>
<tr>
<td></td>
<td>MAD Function (p. 585)</td>
<td>Returns the median absolute deviation from the median.</td>
</tr>
<tr>
<td></td>
<td>MAX Function (p. 594)</td>
<td>Returns the maximum value in a column.</td>
</tr>
<tr>
<td></td>
<td>MEAN Function (p. 596)</td>
<td>Returns the arithmetic mean (average) of the non-null or nonmissing arguments.</td>
</tr>
<tr>
<td></td>
<td>MEDIAN Function (p. 597)</td>
<td>Returns the median value.</td>
</tr>
<tr>
<td></td>
<td>MIN Function (p. 599)</td>
<td>Returns the minimum value in an expression.</td>
</tr>
<tr>
<td></td>
<td>ORDINAL Function (p. 636)</td>
<td>Orders a list of values, and returns a value that is based on a position in the list.</td>
</tr>
<tr>
<td></td>
<td>PCTL Function (p. 637)</td>
<td>Returns the percentile that corresponds to the percentage.</td>
</tr>
<tr>
<td></td>
<td>PROBT Function (p. 707)</td>
<td>Returns the probability from a t distribution of the values in an expression.</td>
</tr>
<tr>
<td></td>
<td>RANGE Function (p. 718)</td>
<td>Returns the range between values in an expression.</td>
</tr>
<tr>
<td></td>
<td>RMS Function (p. 722)</td>
<td>Returns the root mean square.</td>
</tr>
<tr>
<td></td>
<td>SKEWNESS Function (p. 746)</td>
<td>Returns the skewness of all values in an expression.</td>
</tr>
<tr>
<td></td>
<td>SMALLEST Function (p. 747)</td>
<td>Returns the kth smallest non-null or nonmissing value.</td>
</tr>
<tr>
<td></td>
<td>STD Function (p. 752)</td>
<td>Returns the standard deviation.</td>
</tr>
<tr>
<td></td>
<td>STDDEV Function (p. 753)</td>
<td>Returns the statistical standard deviation of all values in an expression.</td>
</tr>
<tr>
<td></td>
<td>STDERR Function (p. 754)</td>
<td>Returns the statistical standard error of all values in an expression.</td>
</tr>
<tr>
<td></td>
<td>STUDENTS_T Function (p. 756)</td>
<td>Returns the Student's t distribution of the values in an expression.</td>
</tr>
<tr>
<td></td>
<td>SUM Function (p. 758)</td>
<td>Returns the sum of all the values in an expression.</td>
</tr>
<tr>
<td></td>
<td>SUMABS Function (p. 760)</td>
<td>Returns the sum of the absolute values of the nonmissing arguments.</td>

<tr>
<td>FINANCE AMORLINC Function (p. 420)</td>
<td>Computes the depreciation for each accounting period.</td>
<td></td>
</tr>
<tr>
<td>FINANCE COUPDAYBS Function (p. 422)</td>
<td>Computes the number of days from the beginning of the coupon period to the settlement date.</td>
<td></td>
</tr>
<tr>
<td>FINANCE COUPDAYS Function (p. 424)</td>
<td>Computes the number of days in the coupon period that contains the settlement date.</td>
<td></td>
</tr>
<tr>
<td>FINANCE COUPDAYSNC Function (p. 425)</td>
<td>Computes the number of days from the settlement date to the next coupon date.</td>
<td></td>
</tr>
<tr>
<td>FINANCE COUPNCND Function (p. 426)</td>
<td>Computes the next coupon date after the settlement date.</td>
<td></td>
</tr>
<tr>
<td>FINANCE COUPNUM Function (p. 428)</td>
<td>Computes the number of coupons that are payable between the settlement date and the maturity date.</td>
<td></td>
</tr>
<tr>
<td>FINANCE COUPPCD Function (p. 429)</td>
<td>Computes the previous coupon date before the settlement date.</td>
<td></td>
</tr>
<tr>
<td>FINANCE CUMIPMT Function (p. 430)</td>
<td>Computes the cumulative interest paid between two periods.</td>
<td></td>
</tr>
<tr>
<td>FINANCE CUMPRINC Function (p. 432)</td>
<td>Computes the cumulative principal that is paid on a loan between two periods.</td>
<td></td>
</tr>
<tr>
<td>FINANCE DB Function (p. 433)</td>
<td>Computes the depreciation of an asset for a specified period by using the fixed-declining balance method.</td>
<td></td>
</tr>
<tr>
<td>FINANCE DDB Function (p. 434)</td>
<td>Computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.</td>
<td></td>
</tr>
<tr>
<td>FINANCE DISC Function (p. 435)</td>
<td>Computes the discount rate for a security.</td>
<td></td>
</tr>
<tr>
<td>FINANCE DOLLARDE Function (p. 436)</td>
<td>Converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.</td>
<td></td>
</tr>
<tr>
<td>FINANCE DOLLARFR Function (p. 437)</td>
<td>Converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.</td>
<td></td>
</tr>
<tr>
<td>FINANCE DURATION Function (p. 438)</td>
<td>Computes the annual duration of a security with periodic interest payments.</td>
<td></td>
</tr>
<tr>
<td>FINANCE EFFECT Function (p. 439)</td>
<td>Computes the effective annual interest rate.</td>
<td></td>
</tr>
<tr>
<td>FINANCE FV Function (p. 440)</td>
<td>Computes the future value of an investment.</td>
<td></td>
</tr>
<tr>
<td>FINANCE FVSCHEDULE Function (p. 441)</td>
<td>Computes the future value of the initial principal after applying a series of compound interest rates.</td>
<td></td>
</tr>

<td></td>
<td>ERFC Function (p. 409)</td>
<td>Returns the value of the complementary (normal) error function.</td>
</tr>
<tr>
<td></td>
<td>EXP Function (p. 410)</td>
<td>Returns the value of the e constant raised to a specified power.</td>
</tr>
<tr>
<td></td>
<td>FACT Function (p. 411)</td>
<td>Computes a factorial.</td>
</tr>
<tr>
<td></td>
<td>FNONCT Function (p. 487)</td>
<td>Returns the value of the noncentrality parameter of an F distribution.</td>
</tr>
<tr>
<td></td>
<td>GAMMA Function (p. 491)</td>
<td>Returns the value of the gamma function.</td>
</tr>
<tr>
<td></td>
<td>GCD Function (p. 497)</td>
<td>Returns the greatest common divisor for a set of integers.</td>
</tr>
<tr>
<td></td>
<td>IBESSEL Function (p. 510)</td>
<td>Returns the value of the modified Bessel function.</td>
</tr>
<tr>
<td></td>
<td>JBESSEL Function (p. 560)</td>
<td>Returns the value of the Bessel function.</td>
</tr>
<tr>
<td></td>
<td>LCM Function (p. 566)</td>
<td>Returns the least common multiple for a set of whole numbers.</td>
</tr>
<tr>
<td></td>
<td>LGAMMA Function (p. 570)</td>
<td>Returns the natural logarithm of the Gamma function.</td>
</tr>
<tr>
<td></td>
<td>LOG Function (p. 571)</td>
<td>Returns the natural logarithm (base e) of a numeric value expression.</td>
</tr>
<tr>
<td></td>
<td>LOG1PX Function (p. 572)</td>
<td>Returns the log of 1 plus the argument.</td>
</tr>
<tr>
<td></td>
<td>LOG2 Function (p. 573)</td>
<td>Returns the base-2 logarithm of a numeric value expression.</td>
</tr>
<tr>
<td></td>
<td>LOG10 Function (p. 574)</td>
<td>Returns the base-10 logarithm of a numeric value expression.</td>
</tr>
<tr>
<td></td>
<td>LOGBETA Function (p. 575)</td>
<td>Returns the logarithm of the beta function.</td>
</tr>
<tr>
<td></td>
<td>LOGISTIC Function (p. 578)</td>
<td>Returns the logistic transformation of the argument.</td>
</tr>
<tr>
<td></td>
<td>MOD Function (p. 601)</td>
<td>Returns the remainder from the division of the first argument by the second argument, fuzzed to avoid most unexpected floating-point results.</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>MODZ Function (p. 603)</td>
<td>Returns the remainder from the division of the first argument by the second argument, using zero fuzzing.</td>
<td></td>

Dictionary

ABS Function

Returns the absolute value of a numeric value expression.

Categories:
- Mathematical
- CAS

Returned data type:
- The same data type as the expression

Syntax

ABS(expression)

Arguments

expression
specifies any valid SQL expression that evaluates to a numeric value.

Type
- BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT

See
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

Details

If expression is null, then the ABS function returns null. If the result is a number that does not fit into the range of the argument's data type, the ABS function fails.

Example

The following statements illustrate the ABS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select abs(-345);</td>
<td>345</td>
</tr>
<tr>
<td>select abs((3 * 50) / 5)</td>
<td>30</td>
</tr>
</tbody>
</table>
AIRY Function

Returns the value of the Airy function.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax

AIRY(x)

Arguments

x
specifies a numeric constant, variable, or expression.

Data type DOUBLE

Details

The AIRY function returns the value of the Airy function. (See a list of References.) It is the solution of the differential equation

\[ w'' - xw = 0 \]

with the conditions

\[ w(0) = \frac{1}{3^{\frac{2}{3}} \Gamma(\frac{2}{3})} \]

and

\[ w'(0) = -\frac{1}{3^{\frac{1}{3}} \Gamma(\frac{1}{3})} \]

Example

The following statements illustrate the AIRY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select airy(2.0);</td>
<td>0.034924</td>
</tr>
<tr>
<td>select airy(-2.0);</td>
<td>0.227407</td>
</tr>
</tbody>
</table>
ANYALNUM Function

Searches a character string for an alphanumeric character, and returns the first character position at which the character is found.

Categories:
- CAS
  - Character

Returned data type:
- DOUBLE

Syntax

\[ \text{ANYALNUM}(\text{expression}[\text{, start}]) \]

Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type: DOUBLE

Details

The results of the ANYALNUM function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in SAS National Language Support (NLS): Reference Guide ) and indirectly on the ENCODING and the LOCALE system options.

The ANYALNUM function searches a string for the first occurrence of any character that is a digit or an uppercase or lowercase letter. If such a character is found, ANYALNUM returns the position in the string of that character. If no such character is found, ANYALNUM returns a value of 0.

If you use only one argument, ANYALNUM begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

ANYALNUM returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of `start` is greater than the length of the string.
- The value of `start` = 0.

Comparisons

The ANYALNUM function searches a character string for an alphanumeric character. The NOTALNUM function searches a character string for a non-alphanumeric character.

Example

The following statements illustrate the ANYALNUM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select anyalnum('abc123, x');</code></td>
<td>1 (position of a)</td>
</tr>
<tr>
<td><code>select anyalnum('+abcd');</code></td>
<td>2 (position of a)</td>
</tr>
<tr>
<td><code>select anyalnum('789ab');</code></td>
<td>1 (position of 7)</td>
</tr>
<tr>
<td><code>select anyalnum('!@&amp;@start');</code></td>
<td>4 (position of s)</td>
</tr>
<tr>
<td><code>select anyalnum('!@&amp;@start1,-99');</code></td>
<td>9 (position of last alphanumeric in string)</td>
</tr>
</tbody>
</table>

- “NOTALNUM Function” on page 614

ANYALPHA Function

Searches a character string for an alphabetic character, and returns the first character position at which the character is found.

Categories: CAS
Character

Returned data type: DOUBLE
Syntax

`ANYALPHA('expression'[, start])`

Arguments

`expression`

specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See: “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

`start`

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type: DOUBLE

Details

The results of the ANYALPHA function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The ANYALPHA function searches a string for the first occurrence of any character that is an uppercase or lowercase letter. If such a character is found, ANYALPHA returns the position in the string of that character. If no such character is found, ANYALPHA returns a value of 0.

If you use only one argument, ANYALPHA begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, `start`, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of `start` is positive, the search proceeds to the right.
- If the value of `start` is negative, the search proceeds to the left.
- If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

ANYALPHA returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of `start` is greater than the length of the string.
- The value of `start` = 0.

Comparisons

The ANYALPHA function searches a character string for an alphabetic character.

The NOTALPHA function searches a character string for a non-alphabetic character.
Example

The following statements illustrate the ANYALPHA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select anyalpha('123abc456');</td>
<td>4 (position of a)</td>
</tr>
<tr>
<td>select anyalpha('abcd1234');</td>
<td>1 (position of a)</td>
</tr>
<tr>
<td>select anyalpha('12345');</td>
<td>0 (no letters)</td>
</tr>
<tr>
<td>select anyalpha('789abc456',-99);</td>
<td>6 (position of last letter in string)</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "NOTALPHA Function" on page 616

ANYDIGIT Function

Searches a character string for a digit, and returns the first character position at which the digit is found.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax

ANYDIGIT('expression', start)

Arguments

expression

specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See

- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

start

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.
Details

The ANYDIGIT function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYDIGIT function searches a string for the first occurrence of any character that is a digit. If such a character is found, ANYDIGIT returns the position in the string of that character. If no such character is found, ANYDIGIT returns a value of 0.

If you use only one argument, ANYDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

ANYDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The ANYDIGIT function searches a character string for a digit. The NOTDIGIT function searches a character string for any character that is not a digit.

Example

The following statements illustrate the ANYDIGIT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select anydigit('123abc456');</code></td>
<td>1 (position of 1)</td>
</tr>
<tr>
<td><code>select anydigit('abc456);</code></td>
<td>5 (position of 4)</td>
</tr>
<tr>
<td><code>select anydigit('abcde');</code></td>
<td>0 (no digits)</td>
</tr>
<tr>
<td><code>select anydigit('789ab',-99);</code></td>
<td>3 (position of last digit in string)</td>
</tr>
</tbody>
</table>

See Also

Functions:
ANYFIRST Function

Searches a character string for a character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax

ANYFIRST(expression[, start])

Arguments

expression

specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

start

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The ANYFIRST function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYFIRST function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7. These characters are the underscore (_) and uppercase or lowercase English letters. If such a character is found, ANYFIRST returns the position in the string of that character. If no such character is found, ANYFIRST returns a value of 0.

If you use only one argument, ANYFIRST begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
If the value of `start` is negative, the search proceeds to the left.

If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

ANYFIRST returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of `start` is greater than the length of the string.
- The value of `start` = 0.

### Comparisons

The ANYFIRST function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under `VALIDVARNAME=V7`. The NOTFIRST function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under `VALIDVARNAME=V7`.

### Example

The following statements illustrate the ANYFIRST function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select anyfirst('123aBc4D6');</code></td>
<td>4 (position of <code>a</code>)</td>
</tr>
<tr>
<td><code>select anyfirst('Bac123, x');</code></td>
<td>1 (position of <code>B</code>)</td>
</tr>
<tr>
<td><code>select anyfirst('!?;:,');</code></td>
<td>0</td>
</tr>
<tr>
<td><code>select anyfirst('1,2,3,x');</code></td>
<td>7 (position of <code>x</code>)</td>
</tr>
<tr>
<td><code>select anyfirst('x,1,2,3');</code></td>
<td>1 (position of <code>x</code>)</td>
</tr>
<tr>
<td><code>select anyfirst('x,1,2,3',-99);</code></td>
<td>1 (position of last letter)</td>
</tr>
<tr>
<td><code>select anyfirst('&amp;,x,y,z,20,!');</code></td>
<td>3 (position of <code>x</code>)</td>
</tr>
<tr>
<td><code>select anyfirst('&amp;,x,y,z,20,!',-99);</code></td>
<td>7 (position of last letter in string)</td>
</tr>
</tbody>
</table>

**Functions:**

- “NOTFIRST Function” on page 619
ANYLOWER Function

Searches a character string for a lowercase letter, and returns the first character position at which the letter is found.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax

\texttt{ANYLOWER('expression'[, start])}

Arguments

\textit{expression}
specifies any valid expression that evaluates or can be coerced to a character string.

Data type \texttt{CHAR, NCHAR, VARCHAR, NVARCHAR}

See "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

\textit{start}
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type \texttt{DOUBLE}

Details

The results of the ANYLOWER function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in \textit{SAS National Language Support (NLS): Reference Guide}) and indirectly on the \texttt{ENCODING} and the \texttt{LOCALE} system options.

The ANYLOWER function searches a string for the first occurrence of a lowercase letter. If such a character is found, ANYLOWER returns the position in the string of that character. If no such character is found, ANYLOWER returns a value of 0.

If you use only one argument, ANYLOWER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \textit{start} is positive, the search proceeds to the right.
- If the value of \textit{start} is negative, the search proceeds to the left.
If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

ANYLOWER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of `start` is greater than the length of the string.
- The value of `start` = 0.

Comparisons

The ANYLOWER function searches a character string for a lowercase letter. The NOTLOWER function searches a character string for a character that is not a lowercase letter.

Example

The following statements illustrate the ANYLOWER function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select anylower('123aBc4D6');</code></td>
<td>4 (position of a)</td>
</tr>
<tr>
<td><code>select anylower('123aBc4D6',-99);</code></td>
<td>6 (position of last lowercase letter)</td>
</tr>
<tr>
<td><code>select anylower('DAN BROWN');</code></td>
<td>0 (no lowercase letters)</td>
</tr>
</tbody>
</table>

See Also

- Functions:
  - "NOTLOWER Function" on page 621

ANYNAME Function

Searches a character string for a character that is valid in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.

Categories: CAS

Character

Returned data type: DOUBLE

Syntax

```
ANYNAME(expression,start)
```
Arguments

**expression**

specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See: "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

**start**

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type: DOUBLE

Details

The ANYNAME function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7. These characters are the underscore (_), digits, and uppercase or lowercase English letters. If such a character is found, ANYNAME returns the position in the string of that character. If no such character is found, ANYNAME returns a value of 0.

If you use only one argument, ANYNAME begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYNAME returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7. The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNAME=V7.

Example

The following statements illustrate the ANYNAME function:
ANYPUNCT Function

Searches a character string for a punctuation character, and returns the first character position at which that character is found.

Syntax

\textbf{ANYPUNCT('expression'[, start])}

Arguments

1. \textit{expression}
   
specifies any valid expression that evaluates or can be coerced to a character string.
   
   \begin{itemize}
     \item Data type: CHAR, NCHAR, VARCHAR, NVARCHAR
   \end{itemize}

2. \textit{start}
   
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

See Also

Functions:
- "NOTNAME Function" on page 623
Details

The results of the ANYPUNCT function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The ANYPUNCT function searches a string for the first occurrence of a punctuation character. If such a character is found, ANYPUNCT returns the position in the string of that character. If no such character is found, ANYPUNCT returns a value of 0.

If you use only one argument, ANYPUNCT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

ANYPUNCT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The ANYPUNCT function searches a character string for a punctuation character. The NOTPUNCT function searches a character string for a character that is not a punctuation character.

Example

The following statements illustrate the ANYPUNCT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select anypunct('abc123, x');</td>
<td>7 (position of comma)</td>
</tr>
<tr>
<td>select anypunct('!?:;,');</td>
<td>1 (position of exclamation mark)</td>
</tr>
<tr>
<td>select anypunct('!?:;, -99);</td>
<td>5 (position of last punctuation mark in string)</td>
</tr>
<tr>
<td>select anypunct('987&amp;efg');</td>
<td>4 (position of ampersand)</td>
</tr>
</tbody>
</table>
ANYSPACE Function

Searches a character string for a whitespace character (blank, horizontal and vertical tab, carriage return, line feed, and form feed), and returns the first character position at which that character is found.

Syntax

\[
\text{ANYSPACE(}'\text{expression}'[, \text{start}]\text{)}
\]

Arguments

- **expression** specifies any valid expression that evaluates or can be coerced to a character string.
  
  - Data type CHAR, NCHAR, VARCHAR, NVARCHAR
  
- **start** specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.
  
  - Data type DOUBLE

Details

The results of the ANYSPACE function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The ANYSPACE function searches a string for the first occurrence of any character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. If such a character is found, ANYSPACE returns the position in the string of that character. If no such character is found, ANYSPACE returns a value of 0.
If you use only one argument, ANYSPACE begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \textit{start} is positive, the search proceeds to the right.
- If the value of \textit{start} is negative, the search proceeds to the left.
- If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.

ANYSPACE returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \textit{start} is greater than the length of the string.
- The value of \textit{start} = 0.

Comparisons

The ANYSPACE function searches a character string for the first occurrence of a character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. The NOTSPACE function searches a character string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed.

Example

The following statements illustrate the ANYSPACE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select anyspace('abc123, x');</td>
<td>8 (position of space before x)</td>
</tr>
<tr>
<td>select anyspace('Mary Smith',-99);</td>
<td>6 (position of last space in string)</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “NOTSPACE Function” on page 626

ANYUPPER Function

Searches a character string for an uppercase letter, and returns the first character position at which the letter is found.

Categories: CAS, Character
Syntax

\texttt{ANYUPPER('expression', start)}

Arguments

\textit{expression}\hspace{1em} specifies any valid expression that evaluates or can be coerced to a character string.

- \textbf{Data type:} CHAR, NCHAR, VARCHAR, NVARCHAR
- \textbf{See:} “\texttt{<sql-expression> Expression}” on page 820
  “FedSQL Expressions” on page 48

\textit{start} \hspace{1em} specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

- \textbf{Data type:} DOUBLE

Details

The results of the ANYUPPER function depend directly on the translation table that is in effect (see “\texttt{TRANTAB= System Option}” in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The ANYUPPER function searches a string for the first occurrence of an uppercase letter. If such a character is found, ANYUPPER returns the position in the string of that character. If no such character is found, ANYUPPER returns a value of 0.

If you use only one argument, ANYUPPER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \textit{start} is positive, the search proceeds to the right.
- If the value of \textit{start} is negative, the search proceeds to the left.
- If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.

ANYUPPER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \textit{start} is greater than the length of the string.
- The value of \textit{start} = 0.
Comparisons

The ANYUPPER function searches a character string for an uppercase letter. The NOTUPPER function searches a character string for a character that is not an uppercase letter.

Example

The following statements illustrate the ANYUPPER function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select anyupper('123aBc4D6');</td>
<td>5 (position of first uppercase letter)</td>
</tr>
<tr>
<td>select anyupper('123aBc4D6',-99);</td>
<td>8 (position of last uppercase letter in string)</td>
</tr>
<tr>
<td>select anyupper('abcde');</td>
<td>0 (no uppercase letters)</td>
</tr>
</tbody>
</table>

See Also

**Functions:**

- "NOTUPPER Function" on page 628

ANYXDIGIT Function

Searches a character string for a hexadecimal character that represents a digit, and returns the first character position at which that character is found.

Categories: CAS Character

Returned data type: DOUBLE

Syntax

\[
\text{ANYXDIGIT('expression'[.[start]])}
\]

Arguments

- **expression**
  - specifies any valid expression that evaluates or can be coerced to a character string.
  - **Data type**: CHAR, NCHAR, VARCHAR, NVARCHAR
  - **See**: "<sql-expression> Expression" on page 820
The ANYXDIGIT function searches a string for the first occurrence of any character that is a digit or an uppercase or lowercase A, B, C, D, E, or F. If such a character is found, ANYXDIGIT returns the position in the string of that character. If no such character is found, ANYXDIGIT returns a value of 0.

If you use only one argument, ANYXDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \textit{start} is positive, the search proceeds to the right.
- If the value of \textit{start} is negative, the search proceeds to the left.
- If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.

ANYXDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \textit{start} is greater than the length of the string.
- The value of \textit{start} = 0.

Comparisons

The ANYXDIGIT function searches a character string for a character that is a hexadecimal character. The NOTXDIGIT function searches a character string for a character that is not a hexadecimal character.

**Example**

The following statements illustrate the ANYXDIGIT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select anyxdigit('123aBc4D6');</code></td>
<td>1 (position of 1)</td>
</tr>
<tr>
<td><code>select anyxdigit('abcd456');</code></td>
<td>1 (position of a)</td>
</tr>
<tr>
<td><code>select anyxdigit('789ab!',-99);</code></td>
<td>5 (position of b)</td>
</tr>
</tbody>
</table>
Statements | Results
---|---
select anyxdigit('&789ab!'); | 2 (position of 7)

See Also

Functions:
- "NOTXDIGIT Function" on page 630

**ARCOS Function**

Returns the arccosine in radians.

Categories: Trigonometric, CAS

Alias: ACOS

Returned data type: DOUBLE

**Syntax**

`ARCOS(expression)`

**Arguments**

*expression*

specifies any valid SQL expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Range</th>
<th>-1 to 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

**See**

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

**Details**

The ARCOS function returns the arccosine (inverse cosine) of the argument. The value that is returned is specified in radians.

**Example**

The following statements illustrate the ARCOS function:
## ARCOSH Function

Returns the inverse hyperbolic cosine.

### Syntax

\[ \text{ARCOSH}(\text{expression}) \]

### Arguments

**expression**

specifies any valid expression that evaluates to a numeric value.

- **Range**: \( \text{expression} \geq 1 \)
- **Data type**: DOUBLE

### See

- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

### Details

The ARCOSH function computes the inverse hyperbolic cosine. The ARCOSH function is mathematically defined by the following equation, where \( \text{expression} \geq 1 \).

In the equation, \( \text{expression} \) is represented by \( x \).

### Statements and Results

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select arcos(1);</td>
<td>0</td>
</tr>
<tr>
<td>select arcos(0);</td>
<td>1.570796</td>
</tr>
<tr>
<td>select arcos(-0.5);</td>
<td>2.094395</td>
</tr>
</tbody>
</table>

### See Also

---

**ARSIN Function**

Returns the arcsine in radians.

**Categories:** Trigonometric

**CAS**

**Alias:** ASIN

**Returned data type:** DOUBLE

**Syntax**

\[ \text{ARSIN}(\text{expression}) \]

**Arguments**

**expression**

specifies any valid SQL expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Range</th>
<th>–1 to 1</th>
</tr>
</thead>
</table>

**Data type** DOUBLE

**See** “<sql-expression> Expression” on page 820
Example

The following statements illustrate the ARSIN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select arsin(0);</td>
<td>0</td>
</tr>
<tr>
<td>select arsin(1);</td>
<td>1.570796</td>
</tr>
<tr>
<td>select arsin(-0.5);</td>
<td>-0.5236</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "ARCOS Function" on page 266
- "COS Function" on page 362
- "COSH Function" on page 363
- "SIN Function" on page 744

ARSINH Function

Returns the inverse hyperbolic sine.

Categories: CAS
Hyperbolic

Returned data type: DOUBLE

Syntax

`ARSINH(expression)`

Arguments

`expression` specifies any valid expression that evaluates to a numeric value.

Range: \(-\infty < x < \infty\)

Data type: DOUBLE

See "<sql-expression> Expression" on page 820
Details

The ARSINH function computes the inverse hyperbolic sine. The ARSINH function is mathematically defined by the following equation, where $-\infty < x < \infty$.

$$\text{ARSINH}(x) = \log(x + \sqrt{x^2 + 1})$$

Replace the infinity symbol with the largest double precision number that is available on your machine. In the equation, expression is represented by $x$.

Example

The following statements illustrate the ARSINH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select arsinh(5);</td>
<td>2.312438</td>
</tr>
<tr>
<td>select arsinh(-5);</td>
<td>-2.31244</td>
</tr>
</tbody>
</table>

ARTANH Function

Returns the inverse hyperbolic tangent.

Categories: CAS
            Hyperbolic

Returned data type: DOUBLE

Syntax

$$\text{ARTANH}(\text{expression})$$
Arguments

**expression**
specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Range</th>
<th>–1 &lt; <strong>expression</strong> &lt; 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

The **ARTANH** function computes the inverse hyperbolic tangent. The **ARTANH** function is mathematically defined by the following equation, where –1 < **expression** < 1. In the equation, **expression** is represented by \( x \).

\[
\text{ARTANH}(x) = \frac{1}{2} \log \left( \frac{1 + x}{1 - x} \right)
\]

Example

The following statements illustrate the **ARTANH** function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select artanh(.5);</td>
<td>0.549306</td>
</tr>
<tr>
<td>select artanh(-.5);</td>
<td>-0.54931</td>
</tr>
</tbody>
</table>

See Also

**Functions:**

- “**ARSINH Function**” on page 269
- “**ARTANH Function**” on page 270
- “**COSH Function**” on page 363
- “**SINH Function**” on page 745
- “**TANH Function**” on page 763

**ATAN Function**

Returns the arctangent in radians.

Categories: Trigonometric

CAS

Alias: **ARTAN**
Returned data type: DOUBLE

Syntax

\texttt{ATAN(\textit{expression})}

Arguments

\textit{expression}

specifies any valid SQL expression that evaluates to a numeric value.

Data type DOUBLE

See \texttt{"<sql-expression> Expression" on page 820}

\texttt{"FedSQL Expressions" on page 48}

Details

The ATAN function returns the 2-quadrant arctangent (inverse tangent) of the argument. The value that is returned is the angle (in radians) whose tangent is $x$ and whose value ranges from $-\pi/2$ to $\pi/2$. If the argument is missing, then ATAN returns a missing value.

Comparisons

The ATAN function is similar to the ATAN2 function except that ATAN2 calculates the arc tangent of the angle from the values of two arguments rather than from one argument.

Example

The following statements illustrate the ATAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{select atan(0);}</td>
<td>0</td>
</tr>
<tr>
<td>\texttt{select atan(1);}</td>
<td>0.785398</td>
</tr>
<tr>
<td>\texttt{select atan(-9.0);}</td>
<td>-1.46014</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “ATAN2 Function” on page 273
- “COT Function” on page 364
- “TAN Function” on page 762
ATAN2 Function

Returns the arctangent of the \( x \) and \( y \) coordinates of a right triangle, in radians.

**Categories:**
- Trigonometric
- CAS

**Returned data type:** DOUBLE

**Syntax**

\[
\text{ATAN2}(\text{expression-1, expression-2})
\]

**Arguments**

- **expression-1**
  - Specifies any valid SQL expression that evaluates to a numeric value.
  - \( expression-1 \) specifies the \( x \) coordinate of the end of the hypotenuse of a right triangle.
  - Data type: DOUBLE
  - See: "<sql-expression> Expression" on page 820

- **expression-2**
  - Specifies any valid SQL expression that evaluates to a numeric value.
  - \( expression-2 \) specifies the \( y \) coordinate of the end of the hypotenuse of a right triangle.
  - Data type: DOUBLE
  - See: "<sql-expression> Expression" on page 820

**Details**

The ATAN2 function returns the arctangent (inverse tangent) of two numeric variables. The result of this function is similar to the result of calculating the arctangent of \( \frac{\text{expression-1}}{\text{expression-2}} \), except that the signs of both arguments are used to determine the quadrant of the result. If either of the arguments in ATAN2 is missing, then ATAN2 returns either a null or a SAS missing value.
### Comparisons
The ATAN2 function is similar to the ATAN function except that ATAN calculates the arctangent of the angle from the value of one argument rather than from two arguments.

### Example
The following statements illustrate the ATAN2 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select atan2(-1, 0.5);</td>
<td>-1.10715</td>
</tr>
<tr>
<td>select atan2(6,8);</td>
<td>0.643501</td>
</tr>
<tr>
<td>select atan2(5,-3);</td>
<td>2.111216</td>
</tr>
</tbody>
</table>

### See Also
- "How FedSQL Processes Nulls and SAS Missing Values" on page 22

### Functions:
- “ATAN Function” on page 271
- “TAN Function” on page 762
- “TANH Function” on page 763

### AVG Function
Returns the average of all values in a column.

**Categories:**
- Aggregate
- Descriptive Statistics
- CAS

**Alias:** MEAN

**Returned data type:** DOUBLE

**Syntax**

```
AVG([DISTINCT] expression)
```

**Arguments**

`expression` specifies any valid SQL expression.
### AVG Function

**Data type**
BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT

**See**
- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48

**DISTINCT**
(optional) eliminates duplicate rows from the aggregate calculation.

**Details**

The AVG function adds the values of all the rows in the specified column and divides the result by the number of rows. Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

**Example**

**Table:** DENSITIES on page 1081

The following statements illustrate the AVG function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select avg(density) from densities;</td>
<td>172.8324</td>
</tr>
<tr>
<td>select avg(population) from densities;</td>
<td>12277544</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**

- “SUM Function” on page 758

**Clauses:**

- “SELECT Clause” on page 877
- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890
BAND Function

Returns the bitwise logical AND of two arguments.

**Categories:**
- Bitwise Logical Operations
- CAS

**Returned data type:** DOUBLE

**Syntax**

```
BAND(expression-1, expression-2)
```

**Arguments**

- `expression-1, expression-2`
  - specifies any valid expression that evaluates to a numeric value.
  - **Range:** between 0 and \((2^{32})-1\) inclusive
  - **Data type:** DOUBLE

**See**

- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48

**Example**

The following statements illustrate the BAND function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select band(9,11);</code></td>
<td>9</td>
</tr>
<tr>
<td><code>select band(15,5);</code></td>
<td>5</td>
</tr>
</tbody>
</table>

BETA Function

Returns the value of the beta function.

**Categories:**
- CAS
- Mathematical

**Returned data type:** DOUBLE
Syntax

**BETA**(*a*, *b*)

Arguments

*a*  
is the first shape parameter.  
Range  
\( a > 0 \)

Data type  
DOUBLE

*b*  
is the second shape parameter.  
Range  
\( b > 0 \)

Data type  
DOUBLE

Details

The BETA function is mathematically given by this equation:

\[
\beta(a,b) = \int_0^1 x^{a-1} (1-x)^{b-1} \, dx
\]

Note the following:

\[
\beta(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}
\]

In the previous equation, \( \Gamma(.) \) is the gamma function.

If the expression cannot be computed, BETA returns a missing value.

Example

The following statements illustrate the BETA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select beta(5,3);</td>
<td>0.00952380952381</td>
</tr>
<tr>
<td>select beta(15,45);</td>
<td>1.6710294365E-15</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “LOGBETA Function” on page 575
BETAINV Function

Returns a quantile from the beta distribution.

Categories: CAS
Quantile

Returned data type: DOUBLE

Syntax

BETAINV(p, a, b)

Arguments

p
is a numeric probability.
Range 0 ≤ p ≤ 1
Data type DOUBLE

a
is a numeric shape parameter.
Range a > 0
Data type DOUBLE

b
is a numeric shape parameter.
Range b > 0
Data type DOUBLE

Details

The BETAINV function returns the pth quantile from the beta distribution with shape parameters a and b. The probability that an observation from a beta distribution is less than or equal to the returned quantile is p.

Note: BETAINV is the inverse of the PROBBETA function.

Example

The following statement illustrates the BETAINV function:
select betainv(0.001,2,4);  
0.0101017879

See Also

Functions:

■ "PROBBETA Function" on page 685

BLACKCLPRC Function

Calculates call prices for European options on futures, based on the Black model.

Syntax

BLACKCLPRC(E, t, F, r, sigma)

Arguments

E

is a nonmissing, positive value that specifies exercise price.

Requirement Specify E and F in the same units.

Data type DOUBLE

F

is a nonmissing, positive value that specifies future price.

Requirement Specify F and E in the same units.

Data type DOUBLE

r

is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type DOUBLE
**sigma**

is a nonmissing, positive fraction that specifies the volatility (the square root of the variance of \( r \)).

Data type  DOUBLE

Details

The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. The function is based on the following relationship:

\[
\text{CALL} = e^{-rt}(FN(d_1) - EN(d_2))
\]

Arguments

\( F \)

specifies future price.

\( N \)

specifies the cumulative normal density function.

\( E \)

specifies the exercise price of the option.

\( r \)

specifies the risk-free interest rate. This is an annual rate that is expressed in terms of continuous compounding.

\( t \)

specifies the time to expiration, in years.

\[
d_1 = \left\{ \ln\left( \frac{F}{E} \right) + \left( \frac{\sigma^2}{2} \right)t \right\} \div \sigma \sqrt{t} \\
d_2 = d_1 - \sigma \sqrt{t}
\]

The following arguments apply to the preceding equation:

\( \sigma \)

specifies the volatility of the underlying asset.

\( \sigma^2 \)

specifies the variance of the rate of return.

For the special case of \( t=0 \), the following equation is true:

\[
\text{CALL} = \max((F - E), 0)
\]

For information about the basics of pricing, see “Using Pricing Functions” in SAS Functions and CALL Routines: Reference.

Comparisons

The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. These functions return a scalar value.
Example

The following statements illustrate the BLACKCLPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select blackclprc(50,.25,48,.05,.25);</td>
<td>1.55130142723117</td>
</tr>
<tr>
<td>select blackclprc(9,1/12,10,.05,.2);</td>
<td>1</td>
</tr>
</tbody>
</table>

Functions:
- “BLACKPTPRC Function” on page 281

BLACKPTPRC Function

Calculates put prices for European options on futures, based on the Black model.

Categories:
- CAS
- Financial

Returned data type: DOUBLE

Syntax

BLACKPTPRC(E, t, F, r, sigma)

Arguments

E
is a nonmissing, positive value that specifies exercise price.

Requirement Specify E and F in the same units.

Data type DOUBLE

F
is a nonmissing, positive value that specifies future price.

Requirement Specify F and E in the same units.
Data type: DOUBLE

*r* is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type: DOUBLE

**sigma**

is a nonmissing, positive fraction that specifies the volatility (the square root of the variance of *r*).

Data type: DOUBLE

Details

The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. The function is based on the following relationship:

\[
\text{PUT} = \text{CALL} + e^{-rt}(E - F)
\]

Arguments

**E**

specifies the exercise price of the option.

**r**

specifies the risk-free interest rate. This is an annual rate that is expressed in terms of continuous compounding.

**t**

specifies the time to expiration, in years.

**F**

specifies future price.

\[
d_1 = \frac{\ln\left(\frac{E}{F}\right) + \left(\frac{\sigma^2}{2}\right)t}{\sigma\sqrt{t}}
\]

\[
d_2 = d_1 - \sigma\sqrt{t}
\]

The following arguments apply to the preceding equation:

**σ**

specifies the volatility of the underlying asset.

**σ^2**

specifies the variance of the rate of return.

For the special case of *t*=0, the following equation is true:

\[
\text{PUT} = \max((E - F), 0)
\]

For information about the basics of pricing, see "Using Pricing Functions" in SAS Functions and CALL Routines: Reference.
Comparisons

The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. These functions return a scalar value.

BLKSHCLPRC Function

Calculates call prices for European options on stocks, based on the Black-Scholes model.

Categories: CAS
Financial

Returns data type: DOUBLE

Syntax

BLKSHCLPRC(E, t, S, r, sigma)

Arguments

E
is a nonmissing, positive value that specifies the exercise price.

Requirement: Specify E and S in the same units.

Data type: DOUBLE

is a nonmissing value that specifies the time to maturity, in years.
Data type: DOUBLE

S
is a nonmissing, positive value that specifies the share price.

Requirement: Specify S and E in the same units.

Data type: DOUBLE

r
is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type: DOUBLE

\( \sigma \)
is a nonmissing, positive fraction that specifies the volatility of the underlying asset.

Data type: DOUBLE

Details

The BLKSHCLPRC function calculates the call prices for European options on stocks, based on the Black-Scholes model. The function is based on the following relationship:

\[ \text{CALL} = S N(d_1) - E N(d_2) e^{-rt} \]

Arguments

S
is a nonmissing, positive value that specifies the share price.

N
specifies the cumulative normal density function.

E
is a nonmissing, positive value that specifies the exercise price of the option.

\[ d_1 = \frac{\ln \left( \frac{S}{E} \right) + \left( r + \frac{\sigma^2}{2} \right) t}{\sigma \sqrt{t}} \]
\[ d_2 = d_1 - \sigma \sqrt{t} \]

The following arguments apply to the preceding equation:

t
specifies the time to expiration, in years.

r
specifies the risk-free interest rate. This is an annual rate that is expressed in terms of continuous compounding.

\( \sigma \)
specifies the volatility (the square root of the variance).

\( \sigma^2 \)
specifies the variance of the rate of return.
For the special case of \( t=0 \), the following equation is true:

\[
\text{CALL} = \max((S - E), 0)
\]

For information about the basics of pricing, see “Using Pricing Functions” in SAS Functions and CALL Routines: Reference.

BLSHIFT Function

Returns the bitwise logical left shift of two arguments.

Categories: Bitwise Logical Operations

CAS

Returned data type: DOUBLE
Syntax

**BLSHIFT**(expression-1, expression-2)

Arguments

**expression-1**
- specifies any valid expression that evaluates to a numeric value.
- **Range**: between 0 and \(2^{32} - 1\) inclusive
- **Data type**: DOUBLE
- **See**: “<sql-expression> Expression” on page 820
  “FedSQL Expressions” on page 48

**expression-2**
- specifies any valid expression that evaluates to a numeric value.
- **Range**: 0 to 31, inclusive
- **Data type**: DOUBLE
- **See**: “<sql-expression> Expression” on page 820
  “FedSQL Expressions” on page 48

Example

The following statements illustrate the **BLSHIFT** function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select blshift(7,2);</code></td>
<td>28</td>

**BNOT Function**

Returns the bitwise logical NOT of an argument.

**Categories**: Bitwise Logical Operations

**CAS**

**Returned data type**: DOUBLE
Syntax

BNOT(expression)

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Range: between 0 and \((2^{32})-1\) inclusive

Data type: DOUBLE

See: "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Example

The following statement illustrates the BNOT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select bnot(16);</td>
<td>4.295E9</td>
</tr>
<tr>
<td>select put(bnot(16), best16.);</td>
<td>4294967279</td>
</tr>
</tbody>
</table>

BOR Function

Returns the bitwise logical OR of two arguments.

Categories: Bitwise Logical Operations

CAS

Returned data type: DOUBLE

Syntax

BOR(expression-1, expression-2)

Arguments

expression-1, expression-2

specifies any valid expression that evaluates to a numeric value.

Range: between 0 and \((2^{32})-1\) inclusive

Data type: DOUBLE
Example

The following statements illustrate the BOR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select bor(4,8);</td>
<td>12</td>
</tr>
</tbody>
</table>

BRSHIFT Function

Returns the bitwise logical right shift of two arguments.

Categories:
- Bitwise Logical Operations
- CAS

Returned data type: DOUBLE

Syntax

\[
\text{BRSHIFT}(\text{expression-1}, \text{expression-2})
\]

Arguments

**expression-1**

specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Range</th>
<th>between 0 and ((2^{32})-1) inclusive</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>See</td>

<tr>
<td></td>
<td>&quot;FedSQL Expressions&quot; on page 48</td>
</tr>
</tbody>
</table>
Example

The following statement illustrates the BRSHIFT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select brshift(64,2);</td>
<td>16</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “BLSHIFT Function” on page 287

BXOR Function

Returns the bitwise logical EXCLUSIVE OR of two arguments.

Categories:
- Bitwise Logical Operations
- CAS

Returned data type:
- DOUBLE

Syntax

\[ \text{BXOR}(\text{expression-1, expression-2}) \]

Arguments

- **expression-1, expression-2**
  - specifies any valid expression that evaluates to a numeric value.
  - Range: between 0 and \(2^{32}–1\) inclusive
  - Data type: DOUBLE

See

- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48

Example

The following statement illustrates the BXOR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select bxor(128,64);</td>
<td>192</td>
</tr>
</tbody>
</table>
**BYTE Function**

Returns one character in the ASCII or the EBCDIC collating sequence.

Categories: CAS
Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

---

**Syntax**

`BYTE(n)`

**Arguments**

`n` specifies a whole number that represents a specific ASCII or EBCDIC character.

- **Range**: 0–255
- **Data type**: DOUBLE

---

**Details**

For EBCDIC collating sequences, `n` is between 0 and 255. For ASCII collating sequences, the characters that correspond to values between 0 and 127 represent the standard character set. Other ASCII characters that correspond to values between 128 and 255 are available on certain ASCII operating environments, but the information those characters represent varies with the operating environment.

---

**Example**

The following statement illustrates the BYTE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>ASCII</th>
<th>EBCDIC</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select byte(80);</code></td>
<td>P</td>
<td>&amp;</td>
</tr>
</tbody>
</table>

---

**See Also**

- “RANK Function” on page 719
CAST Function

Converts a value from one data type to another.

Category: Special
Alias: The operator "::" can be used instead of the CAST keyword.
Returned data type: The target data type.

Syntax

\[ \text{CAST} ( \text{expression AS data-type } [(\text{length})] ) \]

Arguments

\textit{expression}

specifies any valid SQL expression.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Expression can resolve to any FedSQL data type supported by the data source.</th>
</tr>
</thead>
<tbody>
<tr>
<td>See</td>
<td>&quot;&lt;sql-expression&gt; Expression&quot; on page 820</td>
</tr>
<tr>
<td></td>
<td>&quot;FedSQL Expressions&quot; on page 48</td>
</tr>
<tr>
<td></td>
<td>Appendix 2, &quot;Data Type Reference,&quot; on page 1017</td>
</tr>
</tbody>
</table>

\textit{data-type}

Is the target data type. See “Details” for information about supported data type conversions.

<table>
<thead>
<tr>
<th>Restriction</th>
<th>The target data type must be supported by FedSQL and by the data source.</th>
</tr>
</thead>
<tbody>
<tr>
<td>See</td>
<td>“Data Types” on page 14</td>
</tr>
<tr>
<td></td>
<td>Appendix 2, &quot;Data Type Reference,&quot; on page 1017</td>
</tr>
</tbody>
</table>

\textit{length}

Is an optional integer that specifies the length of the target data type. The length argument is intended for use with character values. It is important when specifying literals. When a literal value is specified, the default value is 0, and the length needs to be at least as long as the number of characters that will be generated by the CAST.

<table>
<thead>
<tr>
<th>Restriction</th>
<th>The \textit{length} argument is not available for VARCHAR in the UTF-8 character set. A cast to VARCHAR(n) in the UTF-8 character set yields an output value containing (N\times4) bytes and as many characters as will fit in those bytes.</th>
</tr>
</thead>
</table>
Details

FedSQL performs implicit type conversions as needed for data source support. The CAST function is provided for performing explicit type conversions.

CAST expressions are permitted anywhere expressions are permitted. In addition to converting one data type to another, CAST can be used to change the length of the target type.

The following type conversions are supported:

- A character type can be converted to another character type, a numeric type, and a DATE or TIMESTAMP.

- A numeric type can be converted to CHAR, VARCHAR, or another numeric type. If the target type cannot represent the non-fractional component without truncation, an exception is raised. If the target numeric cannot represent the fractional component (scale) of the source numeric, then the source is silently truncated to fit into the target. For example, casting 123.4763 as INTEGER yields 123.

- A DATE or TIME value can be converted to a TIMESTAMP and a DOUBLE. TIMESTAMP can also be converted to a DOUBLE. If a DATE is converted to a TIMESTAMP, the TIME component of the resulting TIMESTAMP is always 00:00:00. If a TIME data value is converted to a TIMESTAMP, the DATE component is set to the value of CURRENT_DATE at the time the CAST is executed. If a TIMESTAMP is converted to a DATE, the TIME component is silently truncated. If a TIMESTAMP is converted to a TIME, the DATE component is silently truncated.

Comparisons

The CAST function permanently modifies the data type of the specified input variable. The PUT function affects the output of the query in which it is specified.

Example

Table: "CustonLine" on page 1080
Table: "Integers" on page 1085

The following statements illustrate the CAST function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cast(begintime as DATE) from custonline;</td>
<td>01SEP2013</td>
</tr>
<tr>

</tr>
<tr>
<td>select cast ('2014-04-10' as DATE);</td>
<td>10APR2014</td>
</tr>
<tr>
<td>select cast ('2014-04-10 10:56:49' as TIMESTAMP);</td>
<td>10APR2014:10:56:49</td>
</tr>
<tr>
<td>select cast ('10:56:49' as TIME);</td>
<td>10:56:49</td>
</tr>
</tbody>
</table>

CDF Function

Computes the left cumulative distribution function from various continuous and discrete probability distributions.

Categories: CAS
- Probability

Note:
The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('distribution', quantile [, parameter-1, ..., parameter-k])

Arguments

distribution
is a character constant, variable, or expression that identifies the distribution. Here are valid distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Beta</td>
<td>'BETA'</td>

</tr>
<tr>
<td>Weibull</td>
<td>'WEIBULL'</td>
</tr>
</tbody>
</table>

**Note**  
Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

*quantile*  
is a numeric constant, variable, or expression that specifies the value of the random variable.

**Data type**  
DOUBLE

*parameter-1, ⋯, parameter-k*  
are optional constants, variables, or expressions that specify the values of shape, location, or scale parameters that are appropriate for the specific distribution.
CDF BERNOUULLI Distribution Function

Returns a value from the Bernoulli cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

```
CDF('BERNOULLI', x, p)
```

Arguments

- `x`
  is a numeric constant, variable, or expression that specifies a random variable.
  
  Data type: DOUBLE

- `p`
  is a numeric constant, variable, or expression that specifies a probability of success.
  
  Range: 0 ≤ p ≤ 1
  
  Data type: DOUBLE
Details

The CDF function for the Bernoulli distribution returns the probability that an observation from a Bernoulli distribution, with probability of success equal to \( p \), is less than or equal to \( x \).

\[
CDF('BERN', x, p) = \begin{cases} 
0 & x < 0 \\
1 - p & 0 \leq x < 1 \\
1 & x \geq 1 
\end{cases}
\]

Note: There are no location or scale parameters for this distribution.

Example

The following statement illustrates the CDF Bernoulli distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('BERN', 0, .25);</td>
<td>0.75</td>
</tr>
</tbody>
</table>

CDF BETA Distribution Function

Returns a value from the beta cumulative probability distribution.

Categories: CAS, Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.
Syntax

CDF('BETA', x, a, b [l, r])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.
Data type DOUBLE

a
is a numeric constant, variable, or expression that specifies a shape parameter.
Range \( a > 0 \)
Data type DOUBLE

b
is a numeric constant, variable, or expression that specifies a shape parameter.
Range \( b > 0 \)
Data type DOUBLE

l
is a numeric constant, variable, or expression that specifies the left location parameter.
Default 0
Data type DOUBLE

r
is a numeric constant, variable, or expression that specifies the right location parameter.
Default 1
Range \( r > l \)
Data type DOUBLE

Details

The CDF function for the beta distribution returns the probability that an observation from a beta distribution, with shape parameters \( a \) and \( b \), is less than or equal to \( v \).

The following equation describes the CDF function of the beta distribution:

\[
CDF('BETA', x, a, b, l, r) = \begin{cases} 
0 & x \leq l \\
\frac{1}{\beta(a, b)} \int_{l}^{x} \frac{(v - l)^{a - 1} (r - v)^{b - 1}}{(r - l)^{a + b - 1}} dv & l < x \leq r \\
1 & x > r
\end{cases}
\]

The following relationship applies to the preceding equation:
\[
\beta(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}
\]

The following relationship applies to the preceding equation:

\[
\Gamma(a) = \int_{0}^{\infty} x^{a-1}e^{-x}dx
\]

Example

The following statement illustrates the CDF Beta distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select cdf('BETA', 0.2, 3, 4);</code></td>
<td>0.09888</td>
</tr>
</tbody>
</table>

CDF BINOMIAL Distribution Function

Returns a value from the binomial cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('BINOMIAL', \( m, p, n \))
Arguments

$m$

is a whole number, random variable that counts the number of successes.

Range $m = 0, 1, ...$

Data type DOUBLE

$p$

is a numeric constant, variable, or expression that specifies a probability of success parameter.

Range $0 \leq p \leq 1$

Data type DOUBLE

$n$

is a numeric constant, variable, or expression that specifies a whole number parameter that counts the number of independent Bernoulli trials.

Range $n = 0, 1, ...$

Data type DOUBLE

Details

The CDF function for the binomial distribution returns the probability that an observation from a binomial distribution, with parameters $p$ and $n$, is less than or equal to $m$.

\[
CDF('BINOM', m, p, n) = \begin{cases} 
0 & m < 0 \\
\sum_{j=0}^{m} \binom{n}{j} p^j (1 - p)^{n-j} & 0 \leq m \leq n \\
1 & m > n
\end{cases}
\]

Note: There are no location or scale parameters for the binomial distribution.

Example

The following statement illustrates the CDF Binomial distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('BINOM', 4, .5, 10);</td>
<td>0.376953</td>
</tr>
</tbody>
</table>

CDF CAUCHY Distribution Function

Returns a value from the Cauchy cumulative probability distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('CAUCHY', x [,.θ] [, .λ])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

θ
is a numeric constant, variable, or expression that specifies a location parameter.

Default 0
Data type DOUBLE

λ
is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1
Range λ > 0
Data type DOUBLE
Details

The CDF function for the Cauchy distribution returns the probability that an observation from a Cauchy distribution, with the location parameter \( \theta \) and the scale parameter \( \lambda \), is less than or equal to \( x \).

\[
CDF(\text{CAUCHY'}, x, \theta, \lambda) = \frac{1}{2} + \frac{1}{\pi} \tan^{-1}\left(\frac{x - \theta}{\lambda}\right)
\]

Example

The following statement illustrates the CDF Cauchy distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('CAUCHY', 2);</td>
<td>0.852416</td>
</tr>
</tbody>
</table>

CDF Chi-Square Distribution Function

Returns a value from the chi-square cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('CHISQUARE', \( x \), \( df \), \( nc \))
Arguments

\( x \) is a numeric constant, variable, or expression that specifies a random variable.

**Data type** DOUBLE

\( df \) is a numeric constant, variable, or expression that specifies a degrees of freedom parameter.

**Range** \( df > 0 \)

**Data type** DOUBLE

\( nc \) is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

**Range** \( nc \geq 0 \)

**Data type** DOUBLE

Details

The CDF function for the chi-square distribution returns the probability that an observation from a chi-square distribution, with \( df \) degrees of freedom and the noncentrality parameter \( nc \), is less than or equal to \( x \). This function accepts non-integer degrees of freedom. If \( nc \) is omitted or equal to zero, the value returned is from the central chi-square distribution. In the following equation, let \( \nu = df \) and let \( \lambda = nc \). The following equation describes the CDF function of the chi-square distribution:

\[
\text{CDF}(\text{CHISQ}', x, \nu, \lambda) = \begin{cases} 
0 & x < 0 \\
\sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \left( \frac{\lambda}{\pi} \right)^j j! P_c(x, \nu + 2j) & x \geq 0
\end{cases}
\]

In the equation, \( P_c(.,.) \) denotes the probability from the central chi-square distribution:

\[
P_c(x, a) = P_g\left(\frac{\lambda}{2}, \frac{a}{2}\right)
\]

In the equation, \( P_g(y, b) \) is the probability from the gamma distribution given by the equation:

\[
P_g(y, b) = \frac{1}{\Gamma(b)} \int_0^y e^{-\nu} \nu^{b-1} \, d\nu
\]

Example

The following statement illustrates the CDF Chi-Square distribution function:
CDF Conway-Maxwell-Poisson Distribution Function

Returns a value from the Conway-Maxwell-Poisson cumulative probability distribution.

Categories: CAS

Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('CONMAXPOI', y, λ, ν)

Arguments

y

is a numeric constant, variable, or expression that specifies a nonnegative whole number that represents counts data.

Data type: DOUBLE

λ

is similar to the mean, as in the Poisson distribution.

Data type: DOUBLE
ν is a numeric constant, variable, or expression that specifies a dispersion parameter.

Data type: DOUBLE

Details
The CDF function returns cumulative probability from 0 to y. For more information, see “Conway-Maxwell-Poisson” distribution in the PDF function on page 649.

Example
The following statement illustrates the CDF Conway-Maxwell-Poisson distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('CONMAXPOI', 5, 2.3, .4);</td>
<td>0.244541</td>
</tr>
</tbody>
</table>

CDF Exponential Distribution Function
Returns a value from the exponential cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.
Syntax

CDF('EXPONENTIAL', x [λ])

Arguments

\( x \)

is a numeric constant, variable, or expression that specifies a random variable.

| Data type | DOUBLE |

\( λ \)

is a numeric constant, variable, or expression that specifies a scale parameter.

| Default | 1 |
| Range   | \( λ > 0 \) |
| Data type | DOUBLE |

Details

The CDF function for the exponential distribution returns the probability that an observation from an exponential distribution, with the scale parameter \( λ \), is less than or equal to \( x \).

\[
CDF('EXPO', x, \lambda) = \begin{cases} 
0 & x < 0 \\
1 - e^{-\frac{x}{\lambda}} & x \geq 0 
\end{cases}
\]

Example

The following statement illustrates the CDF Exponential distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('EXPO', 1);</td>
<td>0.632121</td>
</tr>
</tbody>
</table>

CDF F Distribution Function

Returns a value from the F cumulative probability distribution.

Categories:
- CAS
  - Probability

Returned data type: DOUBLE

Note:
The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “CDF F Distribution Function” on page 308.

Syntax

CDF('F', x, ndf, ddf [, nc])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

ndf
is a numeric constant, variable, or expression that specifies a numerator degrees of freedom parameter.

Range: ndf > 0
Data type: DOUBLE

ddf
is a numeric constant, variable, or expression that specifies a denominator degrees of freedom parameter.

Range: ddf > 0
Data type: DOUBLE

nc
is a numeric constant, variable, or expression that specifies a noncentrality parameter.

Range: nc ≥ 0
Data type: DOUBLE

Details

The CDF function for the F distribution returns the probability that an observation from an F distribution, with ndf numerator degrees of freedom, ddf denominator degrees of freedom, and the noncentrality parameter nc, is less than or equal to x. This function accepts noninteger degrees of freedom for ndf and ddf. If nc is omitted
or equal to zero, the value returned is from a central $F$ distribution. In the following equation, let $\nu_1 = ndf$, let $\nu_2 = ddf$, and let $\lambda = nc$. The following equation describes the CDF function of the $F$ distribution:

$$
CDF'(F', x, \nu_1, \nu_2, \lambda) = \begin{cases} 0 & x < 0 \\
\sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\lambda^j}{j!} P_F(x, \nu_1 + 2j, \nu_2) & x \geq 0
\end{cases}
$$

In the equation, $P_F(f, u_1, u_2)$ is the probability from the central $F$ distribution with

$$
P_F(x, u_1, u_2) = P_B\left(\frac{u_1^x}{u_1^x + u_2^x}, \frac{u_1^{u_1}}{2}, \frac{u_2^{u_2}}{2}\right)
$$

and $P_B(x, a, b)$ is the probability from the standard beta distribution.

**Note:** There are no location or scale parameters for the $F$ distribution.

**Example**

The following statement illustrates the CDF $F$ distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('F', 3.32, 2, 3);</td>
<td>0.826393</td>
</tr>
</tbody>
</table>

- "QUANTILE Function" on page 713
- "SDF Function" on page 737
- "SQUANTILE Function" on page 748
Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('GAMMA', x, a [], λ)

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

a
is a numeric constant, variable, or expression that specifies a shape parameter.

Range: a > 0

Data type: DOUBLE

λ
is a numeric constant, variable, or expression that specifies a scale parameter.

Default: 1

Range: λ > 0

Data type: DOUBLE

Details

The CDF function for the gamma distribution returns the probability that an observation from a gamma distribution, with the shape parameter a and the scale parameter λ, is less than or equal to x.

\[
CDF('GAMMA', x, a, λ) = \begin{cases} 
0 & x < 0 \\
\frac{1}{\lambda^a \Gamma(a)} \int_0^x v^{a-1} e^{-\frac{v}{\lambda}} dv & x \geq 0 
\end{cases}
\]

Example

The following statement illustrates the CDF Gamma distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('GAMMA', 1, 3);</td>
<td>0.080301</td>
</tr>
</tbody>
</table>
CDF Generalized Poisson Distribution Function

Returns a value from the generalized Poisson cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('GENPOISSON', x, θ, η)

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Data type: DOUBLE

θ
is a numeric constant, variable, or expression that specifies a shape parameter.

Range: ≤5 and >0

Data type: DOUBLE

η
is a numeric constant, variable, or expression that specifies a shape parameter.

Range: ≥0 and <0.95
Data type: DOUBLE

Tip:
When \( \eta = 0 \), the distribution is the Poisson distribution with a mean and variance of \( \theta \). When \( \eta > 0 \), the mean is \( \theta \div (1 - \eta) \) and the variance is \( \theta \div (1 - \eta)^3 \).

Details:
The probability mass function for the generalized Poisson distribution follows:

\[
f(x; \theta, \eta) = \frac{(\theta + \eta x)^x - 1}{x!} e^{-\theta - \eta x}, \quad x = 0, 1, 2, ..., \quad \theta > 0, \ 0 \leq \eta < 1
\]

If \( \eta = 0 \), then the generalized Poisson distribution becomes the standard Poisson distribution with the shape parameter \( \theta \).

Example:
The following statement illustrates the CDF Generalized Poisson distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('GENPOISSON', 9, 1, .7);</td>
<td>0.906163</td>
</tr>
</tbody>
</table>

CDF GEOMETRIC Distribution Function

Returns a value from the geometric cumulative probability distribution.

Categories: CAS, Probability

Returned data type: DOUBLE
The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('GEOMETRIC', m, p)

Arguments

m
is a numeric random variable that specifies the number of failures.

Data type DOUBLE

Tip
Decimal values are rounded down if they are far away from a whole number.

p
is a numeric constant, variable, or expression that specifies a probability of success.

Range 0 ≤ p ≤ 1

Data type DOUBLE

Details

The CDF function for the geometric distribution returns the probability that an observation from a geometric distribution, with the parameter p, is less than or equal to m.

\[
CDF('GEOM', m, p) = \begin{cases} 
0 & m < 0 \\
1 - (1 - p)^{(m+1)} & m \geq 0 
\end{cases}
\]

Note: There are no location or scale parameters for this distribution.

Example

The following statement illustrates the CDF Geometric distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('GEOMETRIC', 5, .35);</td>
<td>0.924581109375</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “LOGCDF Function” on page 576
CDF HYPERGEOMETRIC Distribution Function

Returns a value from the hypergeometric cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('HYPER', x, N, R, n [, o])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Data type: DOUBLE

N
is a numeric constant, variable, or expression that specifies a population size parameter. This argument must be a whole number.

Range: N = 1, 2, ...

Data type: DOUBLE

R
is a numeric constant, variable, or expression that specifies a number of items in the category of interest. This argument must be a whole number.

Range: R = 0, 1, ..., N

Data type: DOUBLE

n
is a numeric constant, variable, or expression that specifies a sample size parameter. This argument must be a whole number.
**Range**

\[ n = 1, 2, \ldots, N \]

**Data type**

DOUBLE

\( o \)

is a numeric constant, variable, or expression that specifies an optional numeric odds ratio parameter.

**Range**

\( o > 0 \)

**Data type**

DOUBLE

**Details**

The CDF function for the hypergeometric distribution returns the probability that an observation from an extended hypergeometric distribution, with population size \( N \), number of items \( R \), sample size \( n \), and odds ratio \( o \), is less than or equal to \( x \). If \( o \) is omitted or equal to 1, the value returned is from the usual hypergeometric distribution.

\[
CDF('HYPER', x, N, R, n, o) = \\
\begin{align*}
0 & \quad x < \max(0, R + n - N) \\
\sum_{i=0}^{\min(R, n)} \binom{R}{i} \binom{N - R}{n - i} o^i & \quad \max(0, R + n - N) \leq x \leq \min(R, n) \\
1 & \quad x > \min(R, n)
\end{align*}
\]

**Example**

The following statement illustrates the CDF Hypergeometric distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('HYPER', 2, 200, 50, 10);</td>
<td>0.523673</td>
</tr>
</tbody>
</table>

CDF LAPLACE Distribution Function

Returns a value from the Laplace cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('LAPLACE', x [,θ, λ])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.
Data type DOUBLE

θ
is a numeric constant, variable, or expression that specifies a location parameter.
Default 0
Data type DOUBLE

λ
is a numeric constant, variable, or expression that specifies a scale parameter.
Default 1
Range λ > 0
Data type DOUBLE

Details

The CDF function for the Laplace distribution returns the probability that an observation from the Laplace distribution, with the location parameter θ and the scale parameter λ, is less than or equal to x.

CDF('LAPLACE', x, θ, λ) = \[
\begin{align*}
\frac{1}{2} e^{\frac{(x - \theta)}{\lambda}} & \quad x < \theta \\
1 - \frac{1}{2} e^{\frac{- (x - \theta)}{\lambda}} & \quad x \geq \theta
\end{align*}
\]
Example

The following statement illustrates the CDF Laplace distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('LAPLACE', 1);</td>
<td>0.81606</td>
</tr>
</tbody>
</table>

CDF LOGISTIC Distribution Function

Returns a value from the logistic cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('LOGISTIC', x [, θ, λ])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

θ
is a numeric constant, variable, or expression that specifies a location parameter.
$\lambda$ is a numeric constant, variable, or expression that specifies a scale parameter.

Default: 0
Data type: DOUBLE

Range: $\lambda > 0$

Data type: DOUBLE

Details

The CDF function for the Logistic distribution returns the probability that an observation from a Logistic distribution, with the location parameter $\theta$ and the scale parameter $\lambda$, is less than or equal to $x$.

$$CDF('LOGISTIC', x, \theta, \lambda) = \frac{1}{1 + e^{-\frac{x - \theta}{\lambda}}}$$

Example

The following statement illustrates the CDF Logistic distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('LOGISTIC', 1);</td>
<td>0.731059</td>
</tr>
</tbody>
</table>

CDF LOGNORMAL Distribution Function

Returns a value from the lognormal cumulative probability distribution.

Categories: CAS
The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('LOGNORMAL', x[], θ[], λ[])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

θ
is a numeric constant, variable, or expression that specifies a log scale parameter. e(θ) is a scale parameter.

Default 0

Data type DOUBLE

λ
is a numeric constant, variable, or expression that specifies a shape parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the lognormal distribution returns the probability that an observation from a lognormal distribution, with the log scale parameter θ and the shape parameter λ, is less than or equal to x.

CDF('LOGN', x, θ, λ) = \[
\begin{align*}
0 & \quad x \leq 0 \\
\frac{1}{\lambda \sqrt{2 \pi}} & \int_{-\infty}^{x} e^{-\left(\frac{y-\theta}{2\lambda}\right)^2} dy & \quad x > 0
\end{align*}
\]

Example

The following statement illustrates the CDF Lognormal distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('LOGNORMAL', 1);</td>
<td>0.5</td>
</tr>
</tbody>
</table>
CDF NEGBINOMIAL Distribution Function

Returns a value from the negative binomial cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax
CDF('NEGBINOMIAL', m, p, n)

Arguments

m
is a numeric constant, variable, or expression that specifies a random variable that counts the number of failures. This argument must be a positive whole number.

Range  
\[ m = 0, 1, ... \]

Data type  DOUBLE

p
is a numeric constant, variable, or expression that specifies a probability of success.

Range  
\[ 0 \leq p \leq 1 \]

Data type  DOUBLE

See Also

\( n \)

is a numeric constant, variable, or expression that specifies a value that counts the number of successes.

Range \( n > 0 \)

Data type DOUBLE

Details

The CDF function for the negative binomial distribution returns the probability that an observation from a negative binomial distribution, with the probability of success \( p \) and the number of successes \( n \), is less than or equal to \( m \).

\[
CDF('NEGB', m, p, n) = \begin{cases} 
0 & m < 0 \\
\sum_{j=0}^{m} \left( \binom{n + j - 1}{n - 1} (1 - p)^j p^n \right) & m \geq 0
\end{cases}
\]

Note: There are no location or scale parameters for the negative binomial distribution.

Example

The following statement illustrates the CDF Negative Binomial distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select cdf('NEGB', 1, .5, 2);</code></td>
<td>0.5</td>

CDF NORMAL Distribution Function

Returns a value from the normal cumulative probability distribution.
The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

\[ CDF('NORMAL', x, \theta, \lambda) \]

Arguments

- **x**
  is a numeric constant, variable, or expression that specifies a random variable.
  
  Data type: DOUBLE

- **\theta**
  is a numeric constant, variable, or expression that specifies a location parameter.
  
  Default: 0
  
  Data type: DOUBLE

- **\lambda**
  is a numeric constant, variable, or expression that specifies a scale parameter.
  
  Default: 1
  
  Range: \( \lambda > 0 \)
  
  Data type: DOUBLE

Details

The CDF function for the Normal distribution returns the probability that an observation from the Normal distribution, with the location parameter \( \theta \) and the scale parameter \( \lambda \), is less than or equal to \( x \).

\[
CDF('NORMAL', x, \theta, \lambda) = \frac{1}{\lambda \sqrt{2\pi}} \int_{-\infty}^{x} e^{-\frac{(v-\theta)^2}{2\lambda^2}} dv
\]

Example

The following statement illustrates the CDF Normal distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('NORMAL', 1.96);</td>
<td>0.975002</td>
</tr>
</tbody>
</table>
CDF NORMALMIX Distribution Function

Returns a value from the normal mixture cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note:
The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('NORMALMIX', x, n, p, m, s)

Arguments

\( x \)
is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

\( n \)
is a numeric constant, variable, or expression that specifies the number of mixtures.

Range \( n = 1, 2, \ldots \)

Data type DOUBLE

\( p \)
is a numeric constant, variable, or expression that specifies the \( n \) proportions, \( p_1, p_2, \ldots, p_n \), where \( \sum_{i=1}^{n} p_i = 1 \).
Range \( p = 0, 1, \ldots \)

Data type \( \text{DOUBLE} \)

\( m \)

is a numeric constant, variable, or expression that specifies the \( n \) means \( m_1, m_2, \ldots, m_n \).

Data type \( \text{DOUBLE} \)

\( s \)

is a numeric constant, variable, or expression that specifies the \( n \) standard deviations \( s_1, s_2, \ldots, s_n \).

Range \( s > 0 \)

Data type \( \text{DOUBLE} \)

**Details**

The CDF function for the Normal Mixture distribution returns the probability that an observation from a mixture of normal distribution is less than or equal to \( x \).

\[
CDF('\text{NORMALMIX}', x, n, p, m, s) = \sum_{i=1}^{i=n} p_i CDF('\text{NORMAL}', x, m_i, s_i)
\]

Weights for the Normal Mixture distribution must be nonnegative. If the sum of the weights does not equal 1, then the weights are treated as relative weights and adjusted so that the sum equals 1.

**Note:** There are no location or scale parameters for the Normal Mixture distribution.

**Example**

The following statement illustrates the CDF Normal Mixture distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('NORMALMIX', 2.3, 3, .33, .33, .34, .5, 1.5, 2.5, .79, 1.6, 4.3);</td>
<td>0.718131</td>
</tr>
</tbody>
</table>

**See Also**

CDF PARETO Distribution Function

Returns a value from the Pareto cumulative probability distribution.

Categories: CAS
            Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('PARETO', x, a [, k])

Arguments

x
    is a numeric constant, variable, or expression that specifies a random variable.
    Data type DOUBLE

a
    is a numeric constant, variable, or expression that specifies a shape parameter.
    Range a > 0
    Data type DOUBLE

k
    is a numeric constant, variable, or expression that specifies a scale parameter.
    Default 1
    Range k > 0
    Data type DOUBLE

Details

The CDF function for the Pareto distribution returns the probability that an observation from a Pareto distribution, with the shape parameter a and the scale parameter k, is less than or equal to x.
The following statement illustrates the CDF Pareto distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select cdf('PARETO', 1,1);</code></td>
<td>0</td>
</tr>
</tbody>
</table>

CDF POISSON Distribution Function

Returns a value from the Poisson cumulative probability distribution.

Categories: CAS, Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

`CDF('POISSON', n, m)`
Arguments

\( n \)

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Range \( n = 0, 1, \ldots \)

Data type \( \text{DOUBLE} \)

\( m \)

is a numeric constant, variable, or expression that specifies a mean parameter.

Range \( m > 0 \)

Data type \( \text{DOUBLE} \)

Details

The CDF function for the Poisson distribution returns the probability that an observation from a Poisson distribution, with mean \( m \), is less than or equal to \( n \).

\[
CDF('POISSON', n, m) = \begin{cases} 
0 & n < 0 \\
\sum_{i=0}^{n} e^{-m} \frac{m^i}{i!} & n \geq 0
\end{cases}
\]

Note: There are no location or scale parameters for the Poisson distribution.

Example

The following statement illustrates the CDF Poisson distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select cdf('POISSON', 2, 1);</code></td>
<td>0.919699</td>
</tr>
</tbody>
</table>

See Also

- “SDF Function” on page 737
- “SQUANTILE Function” on page 748
CDF T Distribution Function

Returns a value from the T cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

\[
\text{CDF}(T, t, df[, nc])
\]

Arguments

\(t\)

is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

\(df\)

is a numeric constant, variable, or expression that specifies the degrees of freedom.

Range: \(df > 0\)

Data type: DOUBLE

\(nc\)

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Data type: DOUBLE

Details

The CDF function for the \(T\) distribution returns the probability that an observation from a \(T\) distribution, with degrees of freedom \(df\) and the noncentrality parameter \(nc\), is less than or equal to \(x\). This function accepts noninteger degrees of freedom. If \(nc\) is omitted or equal to zero, the value returned is from the central \(T\) distribution. In the following equation, let \(\nu = df\) and let \(\delta = nc\).

\[
CDF(T', t, \nu, \delta) = \frac{1}{2^{(\nu/2) - 1}\Gamma(\nu/2)} \int_0^\infty x^{\nu/2 - 1} e^{-x/2} \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\frac{tx}{\sqrt{\nu}}} e^{-u^2} dudx
\]
Note: There are no location or scale parameters for the T distribution.

Example

The following statement illustrates the CDF T distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('T', .9, 5);</td>
<td>0.795314</td>
</tr>
</tbody>
</table>

CDF TWEEDIE Distribution Function

Returns a value from the Tweedie cumulative probability distribution.

Categories: CAS
            Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 713.

Syntax

CDF ('TWEEDIE', y, p [, μ, φ])

Arguments

y
is a numeric constant, variable, or expression that specifies a random variable.
\[ y \geq 0 \]

**Data type**: DOUBLE

**Notes**: This argument is required.

When \( p > 1 \), \( y \) is numeric. When \( p = 1 \), \( y \) is a whole number.

---

**\( p \)**

is a numeric constant, variable, or expression that specifies the power parameter.

**Range**: \( p \geq 1 \)

**Data type**: DOUBLE

**Note**: This argument is required.

---

**\( \mu \)**

is a numeric constant, variable, or expression that specifies the mean parameter.

**Default**: 1

**Range**: \( \mu > 0 \)

**Data type**: DOUBLE

---

**\( \phi \)**

is a numeric constant, variable, or expression that specifies the dispersion parameter.

**Default**: 1

**Range**: \( \phi > 0 \)

**Data type**: DOUBLE

---

**Details**

The CDF function for the Tweedie distribution returns an exponential dispersion model with variance and mean related by the equation \( \text{variance} = \phi \times \mu^p \).

\[
\int_0^\infty \sum\limits_{j=1}^{\infty} \left( \frac{y^{-j\alpha(p-1)/\alpha}}{\phi^j(1-\alpha)(2-p)^j\Gamma(-j\alpha)} \right) e^{\left\{ \frac{1}{\phi^j} \left[ \frac{\mu^{1-p-1}}{1-p} - \frac{\mu^2-p-1}{2-p} \right] \right\}} dy
\]

The following relationship applies to the preceding equation:

\[ \alpha = \frac{2-p}{1-p} \]

**Note**: The accuracy of computed Tweedie probabilities is highly dependent on the location in parameter space. Ten digits of accuracy are usually available except when \( p \) is near 2 or \( \phi \) is near 0. In that case, the accuracy might be as low as six digits.
Example

The following statement illustrates the CDF Tweedie distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('TWEEDIE', .8, 5);</td>
<td>0.591763</td>
</tr>
</tbody>
</table>

CDF UNIFORM Distribution Function

Returns a value from the uniform cumulative probability distribution.

Categories: CAS
- Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('UNIFORM', x [, l, r])

Arguments

x
- is a numeric constant, variable, or expression that specifies a random variable.
  Data type: DOUBLE
is a numeric constant, variable, or expression that specifies the left location parameter.

Default  0

Data type  DOUBLE

\( r \)
is a numeric constant, variable, or expression that specifies the right location parameter.

Default  1

Range  \( r > l \)

Data type  DOUBLE

Details

The CDF function for the uniform distribution returns the probability that an observation from a uniform distribution, with the left location parameter \( l \) and the right location parameter \( r \), is less than or equal to \( x \).

\[
CDF('UNIFORM', x, l, r) = \begin{cases} 
0 & x < l \\
\frac{x-l}{r-l} & l \leq x < r \\
1 & x \geq r 
\end{cases}
\]

Note: The default values for \( l \) and \( r \) are 0 and 1, respectively.

Example

The following statement illustrates the CDF Uniform distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('UNIFORM', 0.25);</td>
<td>0.25</td>
</tr>
</tbody>
</table>

See Also

CDF WALD (Inverse Gaussian) Distribution Function

Returns a value from the Wald (also known as the inverse Gaussian) cumulative probability distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('WALD', x, λ [, µ])
CDF('IGAUSS', x, λ [, µ])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

λ
is a numeric constant, variable, or expression that specifies a shape parameter.

Range λ > 0

Data type DOUBLE

µ
is a numeric constant, variable, or expression that specifies the mean parameter.

Default 1

Range µ > 0

Data type DOUBLE

Details

The CDF function for the Wald distribution returns the probability that an observation from a Wald distribution, with the shape parameter λ, is less than or equal to x.

Fx(x) = Φ\left(\frac{x}{\sqrt{\mu(\lambda - 1)}}\right) + e^{2\lambda/\mu}Φ\left(−\frac{x}{\sqrt{\mu(\lambda + 1)}}\right)

In the equation, Φ(.) is the standard normal cumulative distribution function. When x≤0, CDF is 0.
Example

The following statement illustrates the CDF Wald distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('WALD', 1, 2);</td>
<td>0.627698</td>
</tr>
</tbody>
</table>

CDF WEIBULL Distribution Function

Returns a value from the Weibull cumulative probability distribution.

Categories:  
- CAS
- Probability

Returned data type:  
DOUBLE

Note:  
The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 713.

Syntax

CDF('WEIBULL', x, a [, λ])

Arguments

- **x**
  - is a numeric constant, variable, or expression that specifies a random variable.
  - Data type: DOUBLE

- **a**
  - is a numeric constant, variable, or expression that specifies a shape parameter.
Range: $a > 0$

Data type: DOUBLE

$\lambda$ is a numeric constant, variable, or expression that specifies a scale parameter.

Default: 1

Range: $\lambda > 0$

Data type: DOUBLE

Details

The CDF function for the Weibull distribution returns the probability that an observation from a Weibull distribution, with the shape parameter $a$ and the scale parameter $\lambda$, is less than or equal to $x$.

$$CDF('WEIBULL', x, a, \lambda) = \begin{cases} 0 & x < 0 \\ 1 - e^{-\left(\frac{x}{\lambda}\right)^a} & x \geq 0 \end{cases}$$

Example

The following statement illustrates the CDF Weibull distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cdf('WEIBULL', 1, 2);</td>
<td>0.632121</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “LOGCDF Function” on page 576
- “LOGPDF Function” on page 579

CEIL Function

Returns the smallest integer greater than or equal to a numeric value expression.
Syntax

**CEIL(expression)**

Arguments

*expression* specifies any valid expression that evaluates to a numeric value.

Data type DECIMAL, DOUBLE, NUMERIC

See "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

If *expression* is null, then the CEILING function returns null. If the result is a number that does not fit into the range of the argument’s data type, the CEIL function fails.

If the argument is DECIMAL, the result is DECIMAL. Otherwise, the argument is converted to DOUBLE (if not so already), and the result is DOUBLE.

Comparisons

Unlike the CEILZ function, the CEIL function fuzzes the result. If the argument is within 1E-12 of an integer, the CEIL function fuzzes the result to be equal to that integer. The CEILZ function does not fuzz the result. Therefore, with the CEILZ function, you might get unexpected results.

Example

The following statements illustrate the CEIL function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select ceil(-2.4);</td>
<td>-2</td>
</tr>
<tr>
<td>select ceil(1+1.e-11);</td>
<td>2</td>
</tr>
<tr>
<td>select ceil(-1+1.e-11);</td>
<td>0</td>
</tr>
<tr>
<td>select ceil(1+1.e-13);</td>
<td>1</td>
</tr>
</tbody>
</table>
CEILZ Function

Returns the smallest integer that is greater than or equal to the argument, using zero fuzzing.

**Categories:**
- CAS
- Truncation

**Returned data type:**
DOUBLE

**Syntax**

`CEILZ(expression)`

**Arguments**

**expression**
specifies any valid expression that evaluates to a numeric value.

**Data type**
DOUBLE

**See**

- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48.

**Comparisons**

Unlike the CEIL function, the CEILZ function uses zero fuzzing. If the argument is within 1E-12 of an integer, the CEIL function fuzzes the result to be equal to that integer. The CEILZ function does not fuzz the result. Therefore, with the CEILZ function, you might get unexpected results.

**Example**

The following statements illustrate the CEILZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select ceilz(2.1);</code></td>
<td>3</td>
</tr>
<tr>
<td><code>select ceilz(3);</code></td>
<td>3</td>
</tr>
<tr>
<td>Statements</td>
<td>Results</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>select ceilz(1+1.e-11);</td>
<td>2</td>
</tr>
<tr>
<td>select ceilz(223.456);</td>
<td>224</td>
</tr>
<tr>
<td>select ceilz(-223.456);</td>
<td>-223</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “CEIL Function” on page 335
- “FLOOR Function” on page 483
- “FLOORZ Function” on page 484

CHARACTER_LENGTH Function

Returns the number of characters in a string of any data type.

Categories: Character

CAS

Alias: CHAR_LENGTH

Returned data type: BIGINT

Note: The CHARACTER_LENGTH function counts trailing blanks. If you do not want to count trailing blanks, then you must use the “TRIM Function” on page 776 to remove them.

Syntax

CHARACTER_LENGTH(expression)

Arguments

expression

specifies any valid expression.

Data type: All data types are valid.

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48
Comparisons

The CHARACTER_LENGTH function returns the number of characters in a character string, but counts a multibyte character as a single character. The OCTET_LENGTH function counts a multibyte character as multiple characters.

Example

The following statements illustrate the CHARACTER_LENGTH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select character_length('December');</td>
<td>8</td>
</tr>
<tr>
<td>select character_length('FedSQL ');</td>
<td>7</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “OCTET_LENGTH Function” on page 635

CNONCT Function

Returns the noncentrality parameter from a chi-square distribution.

Syntax

\[ \text{CNONCT}(x, df, \text{probability}) \]

Arguments

\( x \)

is a numeric random variable.

- Range: \( x \geq 0 \)
- Data type: DOUBLE

\( df \)

is a numeric degrees of freedom parameter.

- Range: \( df > 0 \)
Data type DOUBLE

**probability**
is a probability.

Range \(0 < \text{probability} < 1\)

Data type DOUBLE

### Details

The CNONCT function returns the nonnegative noncentrality parameter from a noncentral chi-square distribution whose parameters are \(x\), \(df\), and \(nc\). If \(probability\) is greater than the probability from the central chi-square distribution with the parameters \(x\) and \(df\), a root to this problem does not exist. In this case a missing value is returned. A Newton-type algorithm is used to find a nonnegative root \(nc\) of the equation

\[
P_t(x|df, nc) - \text{prob} = 0
\]

The following relationship applies to the preceding equation:

\[
P_t(x|df, nc) = e^{-nc} \sum_{j=0}^{\infty} \frac{(nc/j)^j}{j!} P_g\left(\frac{x}{2} + j\right)
\]

The following relationship applies to the preceding equation:

\[
P_g(x|a)
\]

is the probability from the gamma distribution given by

\[
P_g(x|a) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt
\]

If the algorithm fails to converge to a fixed point, a missing value is returned.

### Example

This example illustrates the CNONCT function.

```plaintext
proc ds2;
data test /overwrite=yes;
dcl double x df nc prob;
method init();
x=2;
df=4;
do nc=1 to 3 by .5;
prob=probchi(x, df, nc);
output;
end;
end;
enddata;
run;
quit;
```

```plaintext
proc fedsql;
```
select * from test;
select cnonct(x, df, prob) from test;
quit;

**Output 4.1  Content of Table “Test”**

<table>
<thead>
<tr>
<th>x</th>
<th>df</th>
<th>nc</th>
<th>prob</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>4</td>
<td>1</td>
<td>0.18611</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>1.5</td>
<td>0.155915</td>

- “TNONCT Function” on page 768

---

**COALESCE Function**

Returns the first non-null or nonmissing value from a list of numeric arguments.

**Categories:**
- CAS
- Mathematical

**Returned data type:**
- DOUBLE

**Syntax**

\[
\text{COALESCE}(\text{expression}[\ldots\text{expression}])
\]
Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Data type  DOUBLE

See  “<sql-expression> Expression” on page 820

Details

COALESCE accepts one or more numeric expressions. The COALESCE function checks the value of each expression in the order in which they are listed and returns the first non-null or nonmissing value. If only one value is listed, then the COALESCE function returns the value of that argument. If all the values of all expressions are null or missing, then the COALESCE function returns a null or a missing value depending on whether you are in ANSI mode or SAS mode. For more information, see “How FedSQL Processes Nulls and SAS Missing Values” on page 22.

Comparisons

The COALESCE function searches numeric expressions, whereas the COALESCEC function searches character expressions.

Example

The following statement illustrates the COALESCE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select COALESCE(., .A, 33, 22, 44, .);</td>
<td>33</td>
</tr>
</tbody>
</table>

See Also

Functions:

■  “COALESCEC Function” on page 342

COALESCEC Function

Returns the first non-null or nonmissing value from a list of character arguments.

Categories:
CAS
Character

Returned data type:
CHAR, NCHAR, NVARCHAR, VARCHAR
Syntax

\texttt{COALESCEC(expression[, \ldots expression])}

Arguments

\textit{expression}

\begin{itemize}
\item \texttt{specifies any valid expression that evaluates or can be coerced to a character string.}
\end{itemize}

Data type \texttt{CHAR, NCHAR, NVARCHAR, VARCHAR}

See

\begin{itemize}
\item "<sql-expression> Expression" on page 820
\item "FedSQL Expressions" on page 48.
\end{itemize}

Details

\texttt{COALESCEC} accepts one or more character expressions. The \texttt{COALESCEC} function checks the value of each expression in the order in which they are listed and returns the first non-null or nonmissing value. If only one value is listed, then the \texttt{COALESCEC} function returns the value of that expression. If all the values of all expressions are null or missing, then the \texttt{COALESCEC} function returns a null or missing value depending on whether you are in ANSI mode or SAS mode. For more information, see “How FedSQL Processes Nulls and SAS Missing Values” on page 22.

Comparisons

The \texttt{COALESCEC} function searches character expressions, whereas the \texttt{COALESCE} function searches numeric expressions.

Example

The following statements illustrate the \texttt{COALESCEC} function:

\begin{tabular}{|l|l|}
\hline
\textbf{Statements} & \textbf{Results} \\
\hline
\texttt{select coalescec('','Hello');} & Hello \\
\texttt{select coalescec('','Goodbye','Hello');} & Goodbye \\
\hline
\end{tabular}

See Also

\textbf{Functions:}

- “\texttt{COALESCE Function}” on page 341
COMB Function

Computes the number of combinations of $n$ elements taken $r$ at a time.

Categories: CAS
           Combinatorial

Returned data type: DOUBLE

Syntax

\[ \text{COMB}(n, r) \]

Arguments

$n$

is a nonnegative whole number that represents the total number of elements from which the sample is chosen.

Data type DOUBLE

$r$

is a nonnegative whole number that represents the number of chosen elements.

Restriction $r \leq n$

Data type DOUBLE

Details

The mathematical representation of the COMB function is given by the following equation:

\[
\text{COMB}(n, r) = \binom{n}{r} = \frac{n!}{r!(n - r)!}
\]

In the preceding equation, $n \geq 0$, $r \geq 0$, and $n \geq r$.

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the COMB function.

Example

The following statement illustrates the COMB function:
See Also

**Functions:**
- “FACT Function” on page 411

## COMPARE Function

Returns the position of the leftmost character by which two strings differ, or returns 0 if there is no difference.

### Syntax

`COMPARE(string-1, string-2[, modifiers])`

### Arguments

- **string-1**
  - specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.
  - **Data type:** CHAR, NCHAR, NVARCHAR, VARCHAR
  - **See:**
    - “<sql-expression> Expression” on page 820
    - “FedSQL Expressions” on page 48

- **string-2**
  - specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.
  - **Data type:** CHAR, NCHAR, NVARCHAR, VARCHAR

- **modifiers**
  - specifies a character string that can modify the action of the COMPARE function.
  - You can use one or more of the following characters as a valid modifier:
    - i or I ignores the case in `string-1` and `string-2`.
    - l or L removes leading blanks in `string-1` and `string-2` before comparing the values.
removes quotation marks from any argument that is a name literal and ignores the case of \textit{string-1} and \textit{string-2}. A name literal is a name token that is expressed as a string within quotation marks, followed by the uppercase or lowercase letter \textit{n}. Name literals enable you to use special characters (including blanks) that are not otherwise allowed in table or variable names. For \textsc{compare} to recognize a string as a name literal, the first character must be a quotation mark.

\textbf{Colon} (colon) truncates the longer of \textit{string-1} or \textit{string-2} to the length of the shorter string, or to one, whichever is greater. If you do not specify this modifier, the shorter string is padded with blanks to the same length as the longer string.

\begin{itemize}
  \item \textbf{Data type}: \textsc{char, nchar, nvarchar, varchar}
  \item \textbf{Tip}: \textsc{compare} ignores blanks that are used as modifiers.
\end{itemize}

\section*{Details}

\subsection*{The Basics}

The order in which the modifiers appear in the \textsc{compare} function is relevant.

- \textbf{``ln''} first removes leading blanks from each string, and then removes quotation marks from name literals.
- \textbf{``nl''} first removes quotation marks from name literals, and then removes leading blanks from each string.

In the \textsc{compare} function, if \textit{string-1} and \textit{string-2} do not differ, \textsc{compare} returns a value of zero. If the arguments differ, then the following apply:

- The sign of the result is negative if \textit{string-1} precedes \textit{string-2} in a sort sequence, and positive if \textit{string-1} follows \textit{string-2} in a sort sequence.
- The magnitude of the result is equal to the position of the leftmost character at which the strings differ.

\subsection*{DBCS Compatibility}

The DBCS equivalent function is \textsc{kcompare}. There are minor differences between the \textsc{compare} and \textsc{kcompare} functions. Both functions accept varying numbers of arguments, but usage of the third argument is not compatible. The following example shows the differences in the syntax:

\begin{verbatim}
\textbf{compare}(\textit{string-1}, \textit{string-2}[\textit{, modifiers}])
\textbf{kcompare}(\textit{string-1}[\textit{, position[\textit{, count}]}, \textit{string-2})
\end{verbatim}

For more information, see the "\textsc{kcompare} Function" in \textit{SAS National Language Support (NLS): Reference Guide}.

\section*{Examples:}

\subsection*{Example 1: Understanding the Order of Comparisons When Comparing Two Strings}

The following program compares two strings by using the \textsc{compare} function.
create table test(string1 CHAR(8) having informat $char8. format $char8.,
    string2 CHAR(8) having informat $char8. format $char8.,
    modifiers CHAR(8) having informat $char8. format $char8.);

insert into test (string1, string2) values ('12345678', '12345678');
insert into test (string1, string2) values ('123', 'abc');
insert into test (string1, string2) values ('abc', 'abx');
insert into test (string1, string2) values ('xyz', 'abcdef');
insert into test (string1, string2) values ('aBc', 'abc');
insert into test (string1, string2, modifiers) values ('aBc', 'AbC', 'i');
insert into test (string1, string2, modifiers) values ('   abc  ', 'abc', '  ');
insert into test (string1, string2, modifiers) values ('   abc  ', 'abc', '1');
insert into test (string1, string2, modifiers) values (' abc    ', '   abx  ', '  ');
insert into test (string1, string2, modifiers) values(' abc    ', '   abx  ', '1');

select string1, string2, modifiers, compare(string1, string2, modifiers)
from test;

Output 4.3  Results of Comparing Two Strings By Using the COMPARE Function

Example 2: Truncating Strings Using the COMPARE Function

The following program uses the : (colon) modifier to truncate strings.

create table test2 (pad1 double,
    pad2 double,
    truncate1 double,
    truncate2 double,
    blank double);

insert into test2 (pad1, pad2, truncate1, truncate2, blank) values
(  (select compare('abc','abc            ')),
  (select compare('abc','abcdef         ')),
Example 2: Truncating Strings Using the COMPARE Function
(select compare('abc','abcdef',':'));
(select compare('abcdef','abc',':'));
(select compare('', 'abc', ':'));

select * from test2;

Output 4.4  Results from Using the Colon Modifier to Truncate Strings

### COMPBL Function

Removes multiple blanks from a character string.

**Categories:**
- CAS
- Character

**Returned data type:**
CHAR, NCHAR, NVARCHAR, VARCHAR

**Syntax**

COMPBL(character-expression)

**Arguments**

**character-expression**

specifies any valid expression that evaluates or can be coerced to a character string and that specifies the character string to compress.

**Data type**

CHAR, NCHAR, NVARCHAR, VARCHAR

**See**

"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

**Details**

The COMPBL function removes multiple blanks in a character string by translating each occurrence of two or more consecutive blanks into a single blank.

**Comparisons**

The COMPRESS function removes every occurrence of the specific character from a string. If you specify a blank as the character to remove from the source string, the COMPRESS function is similar to the COMPBL function. However, the COMPRESS
function removes all blanks from the source string. The COMPBL function compresses multiple blanks to a single blank and has no effect on a single blank.

Examples:

Example 1: Removing Blanks from a String That Is Passed to the Function

The following program illustrates the COMPBL function:

```sas
data test (overwrite=yes);
  dcl char(18) string1 string2;
  method run();
    string1='125    E. Main St.';
    string2=compbl(string1);
    put string2;
  end;
enddata;
run;
```

SAS writes the following output to the log.

```
125 E. Main St.
```

Example 2

The following statements illustrate the COMPBL function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select compbl('January Status');</td>
<td>January Status</td>
</tr>
<tr>
<td>select compbl('125 E. Main St.');</td>
<td>125 E. Main St.</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “COMPRESS Function” on page 351

COMPOUND Function

Returns compound interest parameters.

Categories:  
  CAS
  Financial
Returned data type: DOUBLE

Syntax

**COMPOUND**(a, f, r, n)

Arguments

- **a**
  - specifies the initial amount.
  - Range: \( a \geq 0 \)
  - Data type: DOUBLE

- **f**
  - specifies the future amount (at the end of \( n \) periods).
  - Range: \( f \geq 0 \)
  - Data type: DOUBLE

- **r**
  - specifies the periodic interest rate expressed as a fraction.
  - Range: \( r \geq 0 \)
  - Data type: DOUBLE

- **n**
  - specifies the number of compounding periods.
  - Range: \( n \geq 0 \)
  - Data type: DOUBLE

Details

The COMPOUND function returns the missing argument in the list of four arguments from a compound interest calculation. The arguments are related by the following equation:

\[
f = a(1 + r)^n
\]

One missing argument must be provided. A compound interest parameter is then calculated from the remaining three values. No adjustment is made to convert the results to round numbers.

If \( n=0 \), then

\[
f = a
\]

and

\[(1 + r)^n\]
is equal to 1.

Note: If you choose r as your missing value, then COMPOUND returns an error.

Example
The following statement illustrates the COMPOUND function. The accumulated value of an investment of $2000 at a nominal annual interest rate of 9%, compounded monthly after 30 months, can be expressed as follows:

select compound(2000,.,0.09/12,30);

The value returned is 2502.5435276.

COMPRESS Function
Returns a character string with specified characters removed from the original string.

Categories: CAS
Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax
COMPRESS(character-expression[, character-list-expression] [, modifier(s)])

Arguments
character-expression
specifies any valid expression that evaluates to a character expression and from which specified characters will be removed.

Requirement Enclose a literal string of characters in single quotation marks.
Data type CHAR, NCHAR, NVARCHAR, VARCHAR
See “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

character-list-expression
specifies a variable or any valid expression that initializes a list of characters.
By default, the characters in this list are removed from character-expression.

Requirement Enclose a literal string of characters in single quotation marks.
Data type CHAR, NCHAR, NVARCHAR, VARCHAR
See “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48
modifier

specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COMPRESS function. Blanks are ignored. The following characters can be used as modifiers:

- a or A adds alphabetic characters to the list of characters.
- c or C adds control characters to the list of characters.
- d or D adds digits to the list of characters.
- f or F adds the underscore character and English letters to the list of characters.
- g or G adds graphic characters to the list of characters.
- h or H adds a horizontal tab to the list of characters.
- i or I ignores the case of the characters to be kept or removed.
- k or K keeps the characters in the list instead of removing them.
- l or L adds lowercase letters to the list of characters.
- n or N adds digits, the underscore character, and English letters to the list of characters.
- o or O processes the second and third arguments once rather than every time the COMPRESS function is called. Using the O modifier in the DATA step (excluding WHERE clauses), or in the SQL procedure, can make COMPRESS run much faster when you call it in a loop where the second and third arguments do not change.
- p or P adds punctuation marks to the list of characters.
- s or S adds space characters (blank, horizontal tab, vertical tab, carriage return, line feed, form feed, and NBSP ('A0'x, or 160 decimal ASCII) to the list of characters.
- t or T trims trailing blanks from the first and second arguments.
- u or U adds uppercase letters to the list of characters.
- w or W adds printable characters to the list of characters.
- x or X adds hexadecimal characters to the list of characters.

Tip If the modifier is a constant, enclose it in single quotation marks. Specify multiple constants in a single set of quotation marks. Modifier can also be expressed as a variable or an expression.

Details

The COMPRESS function allows null or missing (".") arguments. A null or missing (".") argument is treated as a string that has a length of zero. Blanks are not acceptable as shown in the following example:

```
COMPRESS(foo, null, null) /* acceptable */
COMPRESS(foo, ., .) /* acceptable */
COMPRESS(foo, , ) /* not acceptable */
```

Based on the number of arguments, the COMPRESS function works as follows:
The COMPRESS function compiles a list of characters to keep or remove, comprising the characters in the second argument plus any types of characters that are specified by the modifiers. For example, the D modifier specifies digits. Both of the following function calls remove digits from the result:

```sql
compress(source, "1234567890");
compress(source, "", "d");
```

To remove digits and plus or minus signs, you could use the following function call:

```sql
COMPRESS(source, "1234567890+-");
compress(source, "+-", "d");
```

Example

These examples show how to remove blanks, characters, lowercase letters, and space characters from a string with the COMPRESS function. The last example shows how to use COMPRESS to keep characters from a string.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select compress('AB C D ');</code></td>
<td>ABCD</td>
</tr>
<tr>
<td><code>select compress('AB C D ', 'A ');</code></td>
<td>BCD</td>
</tr>
<tr>
<td><code>select compress('123-4567-8901 e 234-5678-9012 i', 'aeiou');</code></td>
<td>123-4567-8901 234-5678-9012</td>
</tr>
<tr>
<td><code>select compress('1 2 3 4 5', ', ','s');</code></td>
<td>12345</td>
</tr>
<tr>
<td><code>select compress('Math A English B Physics A', 'ABCD', 'A&amp;M');</code></td>
<td>Math A English B Physics A</td>
</tr>
</tbody>
</table>
CONSTANT Function

Computes machine and mathematical constants.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax
CONSTANT(constant[, parameter])

Arguments
constant
is a character constant, variable, or expression that identifies the constant to be returned. Valid constants are as follows:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'E'</td>
<td>The natural base</td>
</tr>
<tr>
<td>'EULER'</td>
<td>Euler constant</td>
</tr>
<tr>
<td>'PI'</td>
<td>Pi</td>
</tr>
<tr>
<td>'EXACTINT' [, nbytes]</td>
<td>Exact integer</td>
</tr>
<tr>
<td>'BIG'</td>
<td>The largest double-precision number</td>
</tr>
<tr>
<td>'LOGBIG' [, base]</td>
<td>The log with respect to base of BIG</td>
</tr>
<tr>
<td>'SQRTBIG'</td>
<td>The square root of BIG</td>
</tr>
<tr>
<td>'SMALL'</td>
<td>The smallest double-precision number</td>
</tr>
<tr>
<td>'LOGSMALL' [, base]</td>
<td>The log with respect to base of SMALL</td>
</tr>
<tr>
<td>'SQRTSMALL'</td>
<td>The square root of SMALL</td>
</tr>
</tbody>
</table>
**CONSTANT Function**

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘MACEPS’</td>
<td>Machine precision constant</td>
</tr>
<tr>
<td>‘LOGMACEPS’</td>
<td>The log with respect to base of MACEPS</td>
</tr>
<tr>
<td>‘SQRTMACEPS’</td>
<td>The square root of MACEPS</td>
</tr>
</tbody>
</table>

**parameter**

is a numeric parameter that can be used as an optional argument with some of the constants specified in constant. When used, parameter alters the functionality of the CONSTANT function.

**Details**

**Overview**

**CAUTION**

In some operating environments, the run-time library might have limitations that prevent the use of the full range of floating-point numbers that the hardware provides. In such cases, the CONSTANT function attempts to return values that are compatible with the limitations of the run-time library. For example, if the run-time library cannot compute \( \exp(\log(\text{CONSTANT('BIG')}) \)), then \( \text{CONSTANT('LOGBIG')} \) will not return the same value as \( \log(\text{CONSTANT('BIG')}) \), but returns a value such that \( \exp(\text{CONSTANT('LOGBIG')} \) can be computed.

The Natural Base

**CONSTANT('E')**

The natural base is described by the following equation:

\[
\lim_{x \to 0} \left( 1 + \frac{x}{1} \right) \approx 2.718281828459045
\]

Euler Constant

**CONSTANT('EULER')**

Euler's constant is described by the following equation:

\[
\lim_{n \to \infty} \left\{ \sum_{j=1}^{n} \frac{1}{j} - \log(n) \right\} \approx 0.577215664901532860
\]

Pi

**CONSTANT('PI')**

Pi is the ratio between the circumference and the diameter of a circle. Many expressions exist for computing this constant. One such expression for the series is described by the following equation:

\[
4 \sum_{j=0}^{\infty} \frac{(-1)^j}{2j+1} \approx 3.14159265358979323846
\]
Exact Integer

\textbf{CONSTANT}('EXACTINT'[, \textit{nbytes}])

\textbf{Arguments}

\textit{nbytes} is a numeric value that is the number of bytes.

\begin{center}
\begin{tabular}{|l|}
\hline
\textbf{Range} & \textit{2} \leq \textit{nbytes} \leq \textit{8} \\
\hline
\textbf{Default} & 8 \\
\hline
\end{tabular}
\end{center}

The exact integer is the largest integer \(k\) such that all integers less than or equal to \(k\) in absolute value have an exact representation in a SAS numeric variable of length \textit{nbytes}. This information can be useful to know before you trim a SAS numeric variable from the default 8 bytes of storage to a lower number of bytes to save storage.

The Largest Double-Precision Number

\textbf{CONSTANT}('BIG')

This case returns the largest double-precision floating-point number (8-bytes) that is representable on your computer.

The Logarithm of BIG

\textbf{CONSTANT}('LOGBIG'[, \textit{base}])

\textbf{Arguments}

\textit{base} is a numeric value that is the base of the logarithm.

\begin{center}
\begin{tabular}{|l|}
\hline
\textbf{Default} & the natural base, \textit{E} \\
\hline
\textbf{Restriction} & The \textit{base} that you specify must be greater than the value of 1+SQRTMACEPS. \\
\hline
\end{tabular}
\end{center}

This case returns the logarithm with respect to \textit{base} of the largest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to exponentiate the given \textit{base} raised to a power less than or equal to \textbf{CONSTANT}('LOGBIG', \textit{base}) by using the power operation (***) without causing any overflows.

It is safe to exponentiate any floating-point number less than or equal to \textbf{CONSTANT}('LOGBIG') by using the exponential function, EXP, without causing any overflows.

The Square Root of BIG

\textbf{CONSTANT}('SQRTBIG')

This case returns the square root of the largest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to square any floating-point number less than or equal to \textbf{CONSTANT}('SQRTBIG') without causing any overflows.
The Smallest Double-Precision Number

**CONSTANT('SMALL')**

This case returns the smallest double-precision floating-point number (8-bytes) that is representable on your computer.

The Logarithm of SMALL

**CONSTANT('LOGSMALL'[, base])**

*Arguments*

*base*

is a numeric value that is the base of the logarithm.

*Default*

the natural base, E

*Restriction*

The base that you specify must be greater than the value of 1+SQRTMACEPS.

This case returns the logarithm with respect to base of the smallest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to exponentiate the given base raised to a power greater than or equal to CONSTANT('LOGSMALL', base) by using the power operation (**) without causing any underflows or 0.

It is safe to exponentiate any floating-point number greater than or equal to CONSTANT('LOGSMALL') by using the exponential function, EXP, without causing any underflows or 0.

The Square Root of SMALL

**CONSTANT('SQRTSMALL')**

This case returns the square root of the smallest double-precision floating-point number (8-bytes) that is representable on the computer.

It is safe to square any floating-point number greater than or equal to CONSTANT('SQRTBIG') without causing any underflows or 0.

Machine Precision

**CONSTANT('MACEPS')**

This case returns the smallest double-precision floating-point number (8-bytes) \( \varepsilon = 2^{-j} \) for some integer \( j \), such that \( 1 + \varepsilon > 1 \).

This constant is important in finite precision computations.

The Logarithm of MACEPS

**CONSTANT('LOGMACEPS'[, base])**

*Arguments*

*base*

is a numeric value that is the base of the logarithm.

*Default*

the natural base, E
Restriction  The base that you specify must be greater than the value of 1+SQRTMACEPS.

This case returns the logarithm with respect to base of CONSTANT('MACEPS').

The Square Root of MACEPS
CONSTANT('SQRTMACEPS')

This case returns the square root of CONSTANT('MACEPS').

Example

The following example uses the CONSTANT function to return values for various constants.

create table test(constant char(10), output double);
insert into test(constant, output) values ('E', (select constant('E')));
insert into test(constant, output) values ('EULER', (select constant('EULER')));
insert into test(constant, output) values ('PI', (select constant('PI')));
insert into test(constant, output) values ('EXACTINT', (select constant('EXACTINT')));
insert into test(constant, output) values ('PI', (select constant('PI')));
insert into test(constant, output) values ('BIG', (select constant('BIG')));
insert into test(constant, output) values ('LOGBIG', (select constant('LOGBIG')));
insert into test(constant, output) values ('SQRTBIG', (select constant('SQRTBIG')));
insert into test(constant, output) values ('SMALL', (select constant('SMALL')));
insert into test(constant, output) values ('LOGSMALL', (select constant('LOGSMALL')));
insert into test(constant, output) values ('SQRTSMALL', (select constant('SQRTSMALL')));
insert into test(constant, output) values ('MACEPS', (select constant('MACEPS')));
insert into test(constant, output) values ('LOGMACEPS', (select constant('LOGMACEPS')));
insert into test(constant, output) values ('SQRTMACEPS', (select constant('SQRTMACEPS')));

select * from test;
CONVX Function

Returns the convexity for an enumerated cash flow.

Categories:  
CAS
Financial

Returned data type:  
DOUBLE

Syntax

CONVX(y, f, c(1), ..., c(k))

Arguments

y
specifies the effective per-period yield-to-maturity.

Range  
0 < y < 1

Data type  
DOUBLE
Tip If you express \( y \) as a fraction, the dividend must be written as a decimal value. In DS2, integer division results in a value of zero. Zero is converted to a DOUBLE and is passed as the first argument to the CONVX function. The CONVX function returns missing when a zero is passed as the first parameter.

\( f \)

specifies the frequency of cash flows per period.

Range \( f > 0 \)

Data type DOUBLE

c(1), ... , c(k)

specifies a list of cash flows.

Data type DOUBLE

Details

The CONVX function returns the value from the following equation.

\[
C = \sum_{k=1}^{K} \frac{c(k)}{k} \frac{k(k+f)}{(1+y)^{k}}
\]

The following relationship applies to the preceding equation:

\[
P = \sum_{k=1}^{K} \frac{c(k)}{(1+y)^{k}}
\]

Example

The following statements illustrate the CONVX function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select convx(1./20,.1,.33,.44,.55,.49,.50,.22,.4,.8,.01,.36,.2,.4);</td>
<td>976.9411</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “CONVXP Function” on page 360

CONVXP Function

Returns the convexity for a periodic cash flow stream, such as a bond.
**Syntax**

\( \text{CONVXP}(A, c, n, K, k_0, y) \)

**Arguments**

- **A**
  - specifies the par value.
  - Range: \( A > 0 \)
  - Data type: \( \text{DOUBLE} \)

- **c**
  - specifies the nominal per-period coupon rate, expressed as a decimal.
  - Range: \( 0 \leq c < 1 \)
  - Data type: \( \text{DOUBLE} \)

- **n**
  - specifies the number of coupons per period.
  - Range: \( n > 0 \)
  - Data type: \( \text{DOUBLE} \)

- **K**
  - specifies the number of remaining coupons.
  - Range: \( K > 0 \)
  - Data type: \( \text{DOUBLE} \)

- **k_0**
  - specifies the time from the present date to the first coupon date, expressed in terms of the number of periods.
  - Range: \( 0 < k_0 \leq \frac{1}{n} \)
  - Data type: \( \text{DOUBLE} \)

- **y**
  - specifies the nominal per-period yield-to-maturity.
  - Range: \( y > 0 \)
  - Data type: \( \text{DOUBLE} \)
Details

The CONVXP function returns the value from the following equation.

\[
C = \frac{1}{n^2} \left( \sum_{k=1}^{K} \frac{t_k(n_k + 1)}{1 + \frac{y}{n}} \right)
\]

The following relationships apply to the preceding equation:

\[t_k = nk_0 + k - 1\]

\[c(k) = \frac{c}{n}A \text{ for } k = 1, \ldots, K - 1\]

\[c(K) = (1 + \frac{c}{n})A\]

The following relationship applies to the preceding equation:

\[P = \frac{1}{n^2} \sum_{k=1}^{K} \frac{c(k)}{1 + \frac{y}{n}}\]

Example

The following statements illustrate the CONVXP function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select convxp(1000,.01,4,14,.33/2,.08);</td>
<td>11.729</td>
</tr>
</tbody>
</table>

\textbf{COSH Function}

Returns the hyperbolic cosine in radians.

Categories: Trigonometric, CAS

Returned data type: \textbf{DOUBLE}
Syntax

\[
\text{COSH(} \text{expression} \text{)}
\]

Arguments

\textit{expression}

specifies any valid SQL expression that evaluates to a numeric value.

Data type \text{DOUBLE}

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The \text{COSH} function returns the hyperbolic cosine of the argument, given by the following equation.

\[
\cosh \text{-argument} = \frac{e^{\text{argument}} + e^{-\text{argument}}}{2}
\]

Example

The following statements illustrate the \text{COSH} function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select \text{cosh}(0);</td>
<td>1</td>
</tr>
<tr>
<td>select \text{cosh}(-5.0);</td>
<td>74.20995</td>
</tr>
<tr>
<td>select \text{cosh}(4.37);</td>
<td>39.52814</td>
</tr>
<tr>
<td>select \text{cosh}(0.5);</td>
<td>1.127626</td>
</tr>
</tbody>
</table>

\section*{COT Function}

Returns the tangent in radians.
Syntax

\[ \text{COT} (\text{expression}) \]

Arguments

\textit{expression}

specifies any valid SQL expression that evaluates to a numeric value.

Data type: DOUBLE

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Example

The following statements illustrate the COT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cot(0);</td>
<td></td>
</tr>
<tr>
<td>select cot(0.5)</td>
<td>1.830488</td>
</tr>
<tr>
<td>select cot(5.79);</td>
<td>-1.86051</td>
</tr>
<tr>
<td>select cot(1);</td>
<td>0.642093</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “ATAN Function” on page 271
- “COS Function” on page 362
- “TAN Function” on page 762
CAS

Alias: N

Returned data type: BIGINT

Syntax

Form 1: \texttt{COUNT(expression)}

Form 2: \texttt{COUNT(*)}

Form 3: \texttt{COUNT([DISTINCT] expression)}

Arguments

\textit{expression}

specifies any valid SQL expression.

\textbf{Data type} All data types are valid.

\textbf{See}

“\textless sql-expression\textgreater \ Expression” on page 820

“FedSQL Expressions” on page 48

\textit{*}

returns a count of all rows from the table, including rows that contain null values or SAS missing values.

\textbf{DISTINCT}

(optional) eliminates duplicate rows from the aggregate calculation.

Details

You use the \texttt{COUNT} function in a \texttt{SELECT} statement to return the requested number of rows in a table.

The following list describes what is returned by using the different versions of the \texttt{COUNT} function:

Form 1: \texttt{COUNT(expression)}

returns the number of rows from a table that do not have a null value.

Form 2: \texttt{COUNT(*)}

returns the number of rows in a table.

Form 3: \texttt{COUNT([DISTINCT] expression)}

returns the number of rows in \textit{expression} that have unique values. SAS missing values are included in the results. Null values are not included in the results.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the \texttt{FROM} clause or for each group that is specified in a \texttt{GROUP BY} clause. The \texttt{GROUP BY} clause groups data by a specified column or columns. When you use a \texttt{GROUP BY} clause, the aggregate function in the \texttt{SELECT} clause or in a \texttt{HAVING} clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If \texttt{GROUP BY} is omitted, then all the rows in the table or view are considered to be a single group.
Example

Table: WORLDTEMPS on page 1092

The following statements illustrate the COUNT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select count(AvgHigh) from worldtemps;</td>
<td>11</td>
</tr>
<tr>
<td>select count(*) from worldtemps;</td>
<td>12</td>
</tr>
<tr>
<td>select count(distinct AvgHigh) from worldtemps;</td>
<td>8</td>
</tr>
</tbody>
</table>

- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890

COUNTC Function

Counts the number of characters in a string that appear or do not appear in a list of characters.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax

\[
\text{COUNTC}(\text{string}, \text{charlist}[, \text{modifiers}])
\]

Arguments

\textit{string} specifies a character constant, variable, or expression in which characters are counted.

- Data type: CHAR, NCHAR, NVARCHAR, VARCHAR
- Tip: Enclose a literal string of characters in quotation marks.

\textit{charlist} specifies a character constant, variable, or expression that initializes a list of characters. COUNTC counts characters in this list, provided that you do not specify the V modifier in the \textit{modifiers} argument. If you specify the V modifier,
then all characters that are not in this list are counted. You can add more characters to the list by using other modifiers.

**Data type**  
CHAR, NCHAR, NVARCHAR, VARCHAR

**Tips**  
Enclose a literal string of characters in quotation marks.
If there are no characters in the list after processing the modifiers, COUNTC returns 0.

**Modifiers**  
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTC function. Blanks are ignored. The following characters, in uppercase or lowercase, can be used as modifiers:

- **blank**  
is ignored.
- **a or A**  
adds alphabetic characters to the list of characters.
- **b or B**  
scans *string* from right to left, instead of from left to right.
- **c or C**  
adds control characters to the list of characters.
- **d or D**  
adds digits to the list of characters.
- **f or F**  
adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.
- **g or G**  
adds graphic characters to the list of characters.
- **h or H**  
adds a horizontal tab to the list of characters.
- **i or I**  
ignores case.
- **l or L**  
adds lowercase letters to the list of characters.
- **n or N**  
adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using VALIDVARNAME=V7) to the list of characters.
- **o or O**  
processes the *charlist* and *modifier* arguments only once, at the first call to this instance of COUNTC. If you change the value of *charlist* or *modifier* in subsequent calls, the change might be ignored by COUNTC.
- **p or P**  
adds punctuation marks to the list of characters.
- **s or S**  
adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).
- **t or T**  
trims trailing blanks from *string* and *chars*. If you want to remove trailing blanks from only one character argument instead of both (or all) character arguments, use the TRIM function instead of the COUNTC function with the T modifier.
- **u or U**  
adds uppercase letters to the list of characters.
- **v or V**  
counts characters that do not appear in the list of characters. If you do not specify this modifier, then COUNTC counts characters that do appear in the list of characters.
- **w or W**  
adds printable characters to the list of characters.
- **x or X**  
adds hexadecimal characters to the list of characters.
Data type  CHAR, VARCHAR

Tip  If modifier is a constant, enclose it in quotation marks. Specify multiple constants in a single set of quotation marks.

Details

The COUNTC function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. If there are no characters in the list of characters to be counted, COUNTC returns zero.

Note: Remember that strings with a CHAR data type are always padded out with blanks to the declared length. Strings with a VARCHAR data type return the length of the actual string instead of the declared length.

Comparisons

The COUNTC function counts individual characters in a character string, whereas the COUNT function counts substrings of characters in a character string.

Example

The following example uses the COUNTC function with and without modifiers to count the number of characters in a string.

```sql
create table test(string char(24));
insert into test (string) values ('Baboons Eat Bananas');

select string,
    countc(string, 'a') as a,
    countc(string, 'b') as b,
    countc(string, 'b', 'i') as b_i,
    countc(string,'abc','i') as abc_i,
    countc(string, 'abc', 'iv') as abc_iv,
    countc(string, 'abc', 'ivt') as abc_ivt
from test;
```

Output 4.6  Results from Using the COUNTC Function with and without Modifiers

<table>
<thead>
<tr>
<th>STRING</th>
<th>A</th>
<th>B</th>
<th>B_I</th>
<th>ABC_I</th>
<th>ABC_IV</th>
<th>ABC_IVT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baboons Eat Bananas</td>
<td>5</td>
<td>1</td>
<td>3</td>
<td>8</td>
<td>16</td>
<td>11</td>
</tr>
</tbody>
</table>

Functions:

- “COUNTW Function” on page 370
- “INDEXC Function” on page 514
COUNTW Function

Counts the number of words in a character string.

Categories:
- CAS
- Character

Returned data type: DOUBLE

Syntax

\[
\text{COUNTW}(\text{string}, \text{chars}, \text{modifiers})
\]

Arguments

\textit{string}

specifies a character constant, variable, or expression in which words are counted.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

\textit{chars}

specifies an optional character constant, variable, or expression that initializes a list of characters. The characters in this list are the delimiters that separate words, provided that you do not use the K modifier in the \textit{modifier} argument. If you specify the K modifier, then all characters that are not in this list are delimiters. You can add more characters to the list by using other modifiers.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

\textit{modifiers}

specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTW function. The following characters, in uppercase or lowercase, can be used as modifiers:

- blank: is ignored.
- a or A: adds alphabetic characters to the list of characters.
- b or B: counts from right to left instead of from left to right. Right-to-left counting makes a difference only when you use the Q modifier and the string contains unbalanced quotation marks.
- c or C: adds control characters to the list of characters.
- d or D: adds digits to the list of characters.
- f or F: adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.
- g or G: adds graphic characters to the list of characters.
- h or H: adds a horizontal tab to the list of characters.
i or I  ignores the case of the characters.

k or K  causes all characters that are not in the list of characters to be treated as delimiters. If K is not specified, then all characters that are in the list of characters are treated as delimiters.

l or L  adds lowercase letters to the list of characters.

m or M  specifies that multiple consecutive delimiters, and delimiters at the beginning or end of the string argument, refer to words that have a length of zero. If the M modifier is not specified, then multiple consecutive delimiters are treated as one delimiter, and delimiters at the beginning or end of the string argument are ignored.

n or N  adds digits, an underscore, and English letters (that is, the characters that can appear after the first character in a SAS variable name using VALIDVARNAME=V7) to the list of characters.

o or O  processes the chars and modifier arguments only once, rather than every time the COUNTW function is called. Using the O modifier in the DATA step (excluding WHERE clauses), or in the SQL procedure, can make COUNTW run faster when you call it in a loop where chars and modifier arguments do not change.

p or P  adds punctuation marks to the list of characters.

q or Q  ignores delimiters that are inside substrings that are enclosed in quotation marks. If the value of string contains unmatched quotation marks, then scanning from left to right produces different words than scanning from right to left.

s or S  adds space characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed) to the list of characters.

t or T  trims trailing blanks from the string and chars arguments.

u or U  adds uppercase letters to the list of characters.

w or W  adds printable characters to the list of characters.

x or X  adds hexadecimal characters to the list of characters.

**Data type**  CHAR, VARCHAR

**Details**

**Definition of “Word”**

In the COUNTW function, “word” refers to a substring that has one of the following characteristics:

- is bounded on the left by a delimiter or the beginning of the string
- is bounded on the right by a delimiter or the end of the string
- contains no delimiters, except if you use the Q modifier and the delimiters are within substrings that have quotation marks

**Note:** The definition of “word” is the same in both the SCAN function and the COUNTW function.

Delimiter refers to any of several characters that you can specify to separate words.
Using the COUNTW Function in ASCII and EBCDIC Environments

If you use the COUNTW function with only two arguments, the default delimiters depend on whether your computer uses ASCII or EBCDIC characters.

- If your computer uses ASCII characters, then the default delimiters are as follows:
  \[ \text{blank ! $ % & ( ) * + , - . / ; < ^ |} \]

  In ASCII environments that do not contain the ^ character, the SCAN function uses the ~ character instead.

- If your computer uses EBCDIC characters, then the default delimiters are as follows:
  \[ \text{blank ! $ % & ( ) * + , - . / ; < ¬ | ¢} \]

Using Null Arguments

The COUNTW function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. Numeric arguments cannot be null.

Using the M Modifier

If you do not use the M modifier, then a word must contain at least one character. If you use the M modifier, then a word can have a length of zero. In this case, the number of words is one plus the number of delimiters in the string, not counting delimiters inside strings that are enclosed in quotation marks when you use the Q modifier.

Example

The following program shows how to use the COUNTW function with the M and P modifiers.

The explanation for the value of \(mp\) for each string is as follows:

- The period is the delimiter and the m modifier causes the period at the end to refer to a subsequent word with zero length, but still a word. So there is one word before the period and one word after the period for a total of two words.
- No delimiters, so there is only one word.
- The p modifier adds punctuation as a delimiter therefore 3 words.
- The p modifier adds punctuation, so / is a delimiter. The m modifier causes the leading / to refer to a word at beginning with zero length for a total of six words.
- The first \(\backslash\) is an escape character. The second \(\backslash\) is a delimiter, so there are six words.

```sql
proc fedsql;
drop table test;
create table test(string1 char(60) having informat $char60. format $char60.);
describe table test;

insert into test values ('The quick brown fox jumps over the lazy dog.');
insert into test values ('        Leading blanks');
insert into test values ('2+2=4');
insert into test values ('/unix/path/names/use/slashes');
```
insert into test values ('\\Windows\\Path\\Names\\Use\\Backslashes');

select string1,
countw(string1) as basic,
countw(string1, ' ') as blank,
countw(string1, '.', 'mp') as mp from test;

quit;

Note: Double backslashes are used in the Windows pathname.

Output 4.7  Results from Using the COUNTW Function with the M and P Modifiers

<table>
<thead>
<tr>
<th>STRING1</th>
<th>BASIC</th>
<th>BLANK</th>
<th>MP</th>
</tr>
</thead>
<tbody>
<tr>
<td>The quick brown fox jumps over the lazy dog.</td>
<td>9</td>
<td>9</td>
<td>2</td>
</tr>
<tr>
<td>Leading blanks</td>
<td>2</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2+2=4</td>
<td>2</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>/unix/path/names/use/slashes</td>
<td>5</td>
<td>1</td>
<td>6</td>
</tr>
<tr>
<td>\Windows\Path\Names\Use\Backslashes</td>
<td>1</td>
<td>1</td>
<td>6</td>
</tr>
</tbody>
</table>

Functions:
- “COUNTC Function” on page 367
- “SCAN Function” on page 731

CSC Function

Returns the cosecant.

Categories: CAS
Trigonometric

Returned data type: DOUBLE

Syntax

CSC(argument)
Arguments

argument specifies a numeric constant, variable, or expression and is expressed in radians.

Restriction argument cannot be 0 or a multiple of PI.

Data type DOUBLE

Comparisons

The CSC function is related to the SIN function in this way:

\[ \csc(x) = \frac{1}{\sin(x)} \]

Example

The following statements illustrate the CSC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select csc(0.5);</td>
<td>2.08583</td>
</tr>
<tr>
<td>select csc(1);</td>
<td>1.188395</td>
</tr>
<tr>
<td>csc(3.14159/3);</td>
<td>1.154701</td>
</tr>
</tbody>
</table>

Note: If you use csc(0), then the CSC function returns a missing value. This is the correct behavior.

CSS Function

Returns the corrected sum of squares of all values in an expression.

Categories: Aggregate
Descriptive Statistics
CAS

Returned data type: DOUBLE

Syntax

\[ \text{CSS}([\text{DISTINCT}] \text{ expression}) \]

Arguments

expression

specifies any valid SQL expression.

Data type DOUBLE, FLOAT, REAL

See "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

DISTINCT

(optional) eliminates duplicate rows from the aggregate calculation.

Details

The corrected sum of squares is the sum of squared deviations (differences) from the mean.

Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Comparisons

The USS function returns the uncorrected sum of squares. The CSS function returns the corrected sum of squares of all values.

Example

Table: DENSITIES on page 1081

The following statement illustrates the CSS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select css(density) from densities;</code></td>
<td>211483.1</td>
</tr>
</tbody>
</table>
CUMIPMT Function

Returns the cumulative interest paid on a loan between the start and end period.

**Categories:**
- CAS
- Financial

**Returned data type:** DOUBLE

**Syntax**

\[
\text{CUMIPMT}(rate, \text{number-of-periods}, \text{principal-amount}[, \text{start-period}][, \text{end-period}[, \text{type}]])
\]

**Arguments**

- **rate**
  - Specifies the interest rate per payment period.
  - **Data type:** DOUBLE

- **number-of-periods**
  - Specifies the number of payment periods. *Number-of-periods* must be a positive, whole number.
  - **Data type:** DOUBLE

- **principal-amount**
  - Specifies the principal amount of the loan. Zero is assumed if a missing value is specified.
  - **Data type:** DOUBLE

- **start-period**
  - Specifies the start period for the calculation.
  - **Data type:** DOUBLE

- **end-period**
  - Specifies the end period for the calculation.
Data type: DOUBLE

**type**
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if `type` is omitted or if a missing value is specified.

Data type: DOUBLE

**Example**
- The cumulative interest that is paid during the second year of a $125,000, 30-year loan with end-of-period monthly payments and a nominal annual interest rate of 9%, is computed as follows:
  ```sql
  select put(CUMIPMT(0.09/12, 360, 125000, 13, 24, 0), dollar10.2);
  ```
  This computation returns a value of $11,135.23.
- The interest that is paid on the first period of the same loan is computed in the following way:
  ```sql
  select put(CUMIPMT(0.09/12, 360, 125000, 1, 1, 0), dollar10.2);
  ```
  This computation returns a value of $937.50.

**See Also**

**Functions:**
- “CUMPRINC Function” on page 377

---

**CUMPRINC Function**

Returns the cumulative principal paid on a loan between the start and end period.

**Categories:**
- CAS
- Financial

**Returned data type:** DOUBLE

**Syntax**

\[
\text{CUMPRINC}(\text{rate}, \text{number-of-periods}, \text{principal-amount}[, \text{start-period}] [, \text{end-period}][, \text{type}])
\]

**Arguments**

- **rate**
  specifies the interest rate per payment period.
number-of-periods

specifies the number of payment periods.

Requirement: Number-of-periods must be a positive whole number.

principal-amount

specifies the principal amount of the loan.

start-period

specifies the start period for the calculation.

end-period

specifies the end period for the calculation.

type

specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if type is omitted or if a missing value is specified.

Example

- The cumulative principal that is paid during the second year of a $125,000, 30-year loan with end-of-period monthly payments and a nominal annual interest rate of 9%, is computed as follows:
  
  ```sql
  select put(CUMPRINC(0.09/12, 360, 125000, 12, 24, 0), dollar10.2);
  ```
  
  This computation returns a value of $1008.23.

- The principal that is paid on the second year of the same loan with beginning-of-period payments is computed as follows:
  
  ```sql
  select put(CUMPRINC(0.09/12, 360, 125000, 12, 24, 1), dollar10.2);
  ```
  
  This computation returns a value of $1000.73.

CV Function

Returns the coefficient of variation.

Categories: CAS
Descriptive Statistics

Returned data type: DOUBLE

Syntax

CV(expression-1, expression-2 [, ...expression-n])
Arguments

**expression**
specifies any valid expression that evaluates to a numeric value.

**Requirement** At least two arguments are required.

**Data type** DOUBLE

**See**
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

Example

The following statements illustrate the CV function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select cv(5,9,3,6);</td>
<td>43.4782608695652</td>

</tr>
</tbody>
</table>

DAIRY Function

Returns the derivative of the AIRY function.

**Categories:** CAS

Mathematical

**Returned data type:** DOUBLE

**Syntax**

DAIRY\((x)\)

**Arguments**

\(x\)

specifies a numeric constant, variable, or expression.

**Details**

The DAIRY function returns the value of the derivative of the AIRY function. (See a list of References.)
Example

The following program illustrates the DAIRY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select dairy(2.0);</td>
<td>-0.05309</td>
</tr>
<tr>
<td>select dairy(-2.0);</td>
<td>0.618259</td>
</tr>
</tbody>
</table>

DATDIF Function

Returns the number of days between two dates after computing the difference between the dates according to specified day count conventions.

Categories: CAS
Date and Time

Returned data type: DOUBLE

Syntax

DATDIF(sdate, edate, basis)

Arguments

**sdate**

specifies a SAS date value that identifies the starting date.

Data type DATE

Tip If sdate falls at the end of a month, then SAS treats the date as if it were the last day of a 30-day month.

**edate**

specifies a SAS date value that identifies the ending date.

Data type DATE

Tip If edate falls at the end of a month, then SAS treats the date as if it were the last day of a 30-day month.

**basis**

specifies a character string that represents the day count basis. The following values for basis are valid:

‘30/360’

specifies a 30-day month and a 360-day year, regardless of the actual number of calendar days in a month or year.

A security that pays interest on the last day of a month will either always make its interest payments on the last day of the month, or it will always
make its payments on the numerically same day of a month, unless that day is not a valid day of the month, such as February 30. For more information, see “Method of Calculation for Day Count Basis (30/360)” in SAS Functions and CALL Routines: Reference.

Alias  ‘360’

‘ACT/ACT’
uses the actual number of days between dates. Each month is considered to have the actual number of calendar days in that month, and each year is considered to have the actual number of calendar days in that year.

Alias  ‘Actual’

‘ACT/360’
uses the actual number of calendar days in a particular month, and 360 days as the number of days in a year, regardless of the actual number of days in a year.

Tip  ACT/360 is used for short-term securities.

‘ACT/365’
uses the actual number of calendar days in a particular month, and 365 days as the number of days in a year, regardless of the actual number of days in a year.

Tip  ACT/365 is used for short-term securities.

Data type  CHAR, NCHAR, NVARCHAR, VARCHAR

Details
The Basics
The DATDIF function has a specific meaning in the securities industry, and the method of calculation is not the same as the actual day count method. Calculations can use months and years that contain the actual number of days. Calculations can also be based on a 30-day month or a 360-day year. For more information about standard securities calculation methods, see the References section at the bottom of this function.

Note: When counting the number of days in a month, DATDIF always includes the starting date and excludes the ending date.

Method of Calculation for Day Count Basis (30/360)
To calculate the number of days between two dates, use the following formula:

\[
\text{Number of days} = [(Y2 - Y1) \times 360] + [(M2 - M1) \times 30] + (D2 - D1)
\]

Arguments
Y2
specifies the year of the later date.

Y1
specifies the year of the earlier date.
M2
specifies the month of the later date.

M1
specifies the month of the earlier date.

D2
specifies the day of the later date.

D1
specifies the day of the earlier date.

Because all months can contain only 30 days, you must adjust for the months that
do not contain 30 days. Do this before you calculate the number of days between
the two dates.

The following rules apply:

- If the security follows the End-of-Month rule, and D2 is the last day of February
  (28 days in a non-leap year, 29 days in a leap year), and D1 is the last day of
  February, then change D2 to 30.
- If the security follows the End-of-Month rule, and D1 is the last day of February,
  then change D1 to 30.
- If the value of D2 is 31 and the value of D1 is 30 or 31, then change D2 to 30.
- If the value of D1 is 31, then change D1 to 30.

Example

In the following example, DATDIF returns the actual number of days between two
dates, as well as the number of days based on a 30-day month and a 360-day year.

This FedSQL SELECT statement returns the actual number of days between two
dates:

```sql
select datdif(date'1978-10-16',date'1996-02-16', 'act/act');
```

This statement returns the number of days based on a 30-day month and a 360-day
year.

```sql
select datdif(date'1978-10-16',date'1996-02-16', '30/360');
```

The results are:

<p>| | |</p>

Securities Industry Association.
Date and Time

Alias: TODAY
Returned data type: DOUBLE

Syntax

DATE()

Without Arguments

The DATE function has no arguments.

Comparisons

The DATE function does not take any arguments. The SAS date value returned is the number of days from January 1, 1960 to the current date.

For more information about how FedSQL handles dates, see “Dates and Times in FedSQL” on page 60.

Example

The following statement illustrates the DATE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select date();</td>
<td>19611</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “TODAY Function” on page 770

DATEJUL Function

Converts a Julian date to a SAS date value.

Categories: CAS
Date and Time

Returned data type: DOUBLE
Syntax

**DATEJUL**(*julian-date*)

Arguments

*julian-date*
specifies any valid expression that evaluates to a numeric value and that represents a Julian date. A Julian date is a date in the form *yyddd* or *yyyyddd*, where *yy* or *yyyy* is a two-digit or four-digit whole number that represents the year and *ddd* is the number of the day of the year. The value of *ddd* must be between 1 and 365 (or 366 for a leap year).

**Data type**
DOUBLE

**See**
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

A SAS date value is the number of days from January 1, 1960 to a specified date. The **DATEJUL** function returns the number of days from January 1, 1960 to the Julian date specified in *julian-date*.

For more information about how dates are handled in FedSQL, see “Dates and Times in FedSQL” on page 60.

Example

The following statements illustrate the **DATEJUL** function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select datejul(11365);</td>
<td>18992</td>
</tr>
</tbody>
</table>

See Also

**Functions:**

- "JULDATE Function" on page 561

**DATEPART Function**

Returns the date as year, month, and day.

**Categories:**
Date and Time
CAS

**Returned data type:**
DATE
### Syntax

**DATEPART**(ts)

### Arguments

**ts**
- specifies the timestamp.

### Example

The following statement illustrates the DATEPART function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select datepart(timestamp '2013-09-24 14:46:58');</td>
<td>24SEP2013</td>
</tr>
<tr>
<td>select put(datepart(d), date9.) from myoracle.test;</td>
<td>24SEP2013</td>
</tr>
<tr>
<td>select put(datepart(t), time12.) from myoracle.test;</td>
<td>5:26:42</td>
</tr>
</tbody>
</table>

  - “MAKETIMESTAMP Function” on page 588
  - “TIMEPART Function” on page 764

---

### DATETIME Function

Returns the current date and time of day as a SAS datetime value.

**Categories:**
- CAS
- Date and Time

**Returned data type:**
- DOUBLE

### Syntax

**DATETIME( )**
Comparisons

The DATETIME function does not take any arguments. The SAS datetime value returned is the number of seconds from January 1, 1960 to the current date and time.

Example

The following statement illustrates the DATETIME function:

```sas
data test(overwrite=yes);
dcl double dt ;
method run();
   dt=datetime();
   put dt;
end dt;
enddata;
run;
```

SAS writes the following output to the log.

```
1863786105.136
```

Functions:
- “DATE Function” on page 387

DAY Function

Returns the numeric day of the month from a date or datetime value.

Categories: Date and Time
CAS

Returned data type: TINYINT

Syntax

```
DAY(date | datetime)
```

Arguments

`date`

specifies any valid expression that represents a date value.
Data type \textsc{DATE}

\begin{quote}
\textbf{See} \ "FedSQL Expressions" on page 48
\end{quote}

\textbf{datetime}

specifies any valid expression that represents a datetime value.

Data type \textsc{TIMESTAMP}

\begin{quote}
\textbf{See} \ "FedSQL Expressions" on page 48
\end{quote}

### Example

Table: \textsc{CUSTONLINE} on page 1080

The following statement illustrates the \textsc{DAY} function:

\begin{tabular}{|l|l|}
\hline
\textbf{Statements} & \textbf{Results} \\
\hline
\texttt{select day(endtime) from custonline;} & 1 \\
 & 2 \\
 & 15 \\
 & 1 \\
 & 1 \\
 & 2 \\
 & 16 \\
 & 1 \\
 & 1 \\
 & 15 \\
\hline
\texttt{select day(current\_time);} & 17 \\
\hline
\end{tabular}

### See Also

- “MONTH Function” on page 605
- “SECOND Function” on page 741
- “YEAR Function” on page 793

### DEGREES Function

Returns the number of degrees for an angle in radians.

\begin{tabular}{|l|l|}
\hline
\textbf{Categories:} & \textsc{Trigonometric} \\
\hline
\textsc{CAS} & \\
\hline
\end{tabular}
Returned data type: DOUBLE

Syntax

```
DEGREES(expression)
```

Arguments

- **expression**
  - specifies any valid expression that evaluates to an angle specified in radians.

Data type: BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT.

See

- "<sql-expression> Expression" on page 820

- “FedSQL Expressions” on page 48

Details

If `expression` is a null value, then the DEGREES function returns a null value. If the result is a number that does not fit into the range of a DOUBLE data type, the DEGREES function fails.

Example

The following statements illustrate the DEGREES function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select degrees(2*pi());</code></td>
<td>360</td>
</tr>
<tr>
<td><code>select degrees(pi());</code></td>
<td>180</td>
</tr>
<tr>
<td><code>select degrees(pi()/2);</code></td>
<td>90</td>
</tr>
<tr>
<td><code>select degrees(pi()/4);</code></td>
<td>45</td>
</tr>
</tbody>
</table>

See Also

- Functions:
  - “RADIANS Function” on page 717

DEQUOTE Function

Removes matching single quotation marks from a character string that begins with a single quotation mark, and deletes all characters to the right of the closing quotation mark.
Syntax

**DEQUOTE(expression)**

Arguments

*expression* specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

The value that is returned by the DEQUOTE function depends on the first character or the first two characters in *expression*:

- If the first character of *expression* is not a quotation mark, DEQUOTE returns a syntax error.
- If the first character of *expression* is a single quotation mark, the DEQUOTE function removes that single quotation mark from the result. DEQUOTE then scans *expression* from left to right, looking for more single quotation marks or double quotation marks. All paired single quotation marks are replaced with a single quotation mark. All paired double quotation marks are retained. If a double quotation mark is the second character, DEQUOTE removes the double quotation mark from the result. DEQUOTE then scans *expression* from left to right. If a matching double quotation mark is found, the text between the double quotation marks is returned. Any text to the right of the closing double quotation mark, to the end of *expression* is removed from the result. The first non-paired single quotation mark in *expression* is the closing single quotation mark and is removed. If a close parentheses follows the close single quotation mark, the function returns the dequoted string. If characters exist to the right of the close single quotation mark, the function results in a syntax error and the error is printed in the SAS log.
- If *expression* is enclosed in double quotation marks, the DEQUOTE function returns a null or missing value.
### Example

The following statements illustrate the `DEQUOTE` function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select dequote(No quotation marks);</code></td>
<td>ERROR: Syntax error at or near &quot;No&quot;</td>
</tr>
<tr>
<td><code>select dequote(No 'leading' quotation marks);</code></td>
<td>ERROR: Syntax error at or near &quot;No&quot;</td>
</tr>
<tr>
<td><code>select dequote('Single matched quotation marks are removed');</code></td>
<td>Single matched quotation marks are removed</td>
</tr>
<tr>
<td><code>select dequote(&quot;Matched double quotation marks&quot;);</code></td>
<td>ERROR: Column &quot;Matched double quotation marks&quot; not found or cannot be accessed</td>
</tr>
<tr>
<td><code>select dequote('Paired 'single' quotation marks are reduced to a single quotation mark');</code></td>
<td>Paired 'single' quotation marks are reduced to a single quotation mark</td>
</tr>
<tr>
<td><code>select dequote(' &quot;Double quotation marks&quot; within &quot;single quotation marks&quot;, with space before open quotation mark');</code></td>
<td>&quot;Double quotation marks&quot; within &quot;single quotation marks&quot;, with space before open quotation mark</td>
</tr>
<tr>
<td><code>select dequote('&quot;Double quotation marks within single quotation marks, without space before open quotation mark');</code></td>
<td>Double quotation marks within single quotation marks, without space before open quotation mark</td>
</tr>
<tr>
<td><code>select dequote('&quot;Text after closing double quotation mark&quot; is removed');</code></td>
<td>Text after closing double quotation mark</td>
</tr>
<tr>
<td><code>select dequote('No matching quotation mark);</code></td>
<td>Statement execution does not complete. Submit the following characters to complete the execution: <code>');</code></td>
</tr>
<tr>
<td><code>select dequote('Identifiers after close quotation mark' results in a syntax error);</code></td>
<td>ERROR: Syntax error at or near &quot;RESULTS&quot; }</td>
</tr>
</tbody>
</table>
DEVIANACE Function

Returns the deviance based on a probability distribution.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax

\[
\text{DEVIANACE}(\text{distribution, variable, shape-parameter(s)}[, \epsilon])
\]

Arguments

\textit{distribution}

is a character constant, variable, or expression that identifies the distribution. Valid distributions are listed in the following table:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli (p. 396)</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Binomial (p. 397)</td>
<td>'BINOMIAL'</td>
</tr>
<tr>
<td>Gamma (p. 397)</td>
<td>'GAMMA'</td>
</tr>
<tr>
<td>Inverse Gauss (Wald) (p. 398)</td>
<td>'IGAUSS'</td>
</tr>
<tr>
<td>Normal (p. 398)</td>
<td>'NORMAL'</td>
</tr>
<tr>
<td>Poisson (p. 399)</td>
<td>'POISSON'</td>
</tr>
</tbody>
</table>

\textit{variable}

is a numeric constant, variable, or expression.

\textit{shape-parameter(s)}

are one or more distribution-specific numeric parameters that characterize the shape of the distribution.

\textit{\epsilon}

is an optional numeric small value used for all of the distributions, except for the normal distribution.

Details

The Bernoulli Distribution

\[
\text{DEVIANACE('BERNOULLI', variable, p[, \epsilon])}
\]
Arguments

**variable**

is a binary numeric random variable that has the value of 1 for success and 0 for failure.

**p**

is a numeric probability of success with $\epsilon \leq p \leq 1 - \epsilon$.

**$\epsilon$**

is an optional positive numeric value that is used to bound $p$. Any value of $p$ in the interval $0 \leq p \leq \epsilon$ is replaced by $\epsilon$. Any value of $p$ in the interval $1 - \epsilon \leq p \leq 1$ is replaced by $1 - \epsilon$.

The DEVIANCE function returns the deviance from a Bernoulli distribution with a probability of success $p$, where success is defined as a random variable value of 1. The equation follows:

$$
\text{DEVIANCE('BERN', variable, } p, \epsilon) = \begin{cases} 
-2\log(1 - p) & x = 0 \\
-2\log(p) & x = 1 \\
\text{otherwise} & 
\end{cases}
$$

The Binomial Distribution

**DEVIANCE('BINO', variable, $\mu$, $n$, [\epsilon])**

Arguments

**variable**

is a numeric random variable that contains the number of successes.

Range $0 \leq \text{variable} \leq 1$

**$\mu$**

is a numeric mean parameter.

Range $n\epsilon \leq \mu \leq n(1-\epsilon)$

**$n$**

is a whole number of Bernoulli trials parameter

Range $n \geq 0$

**$\epsilon$**

is an optional positive numeric value that is used to bound $\mu$. Any value of $\mu$ in the interval $0 \leq \mu \leq n\epsilon$ is replaced by $n\epsilon$. Any value of $\mu$ in the interval $n(1 - \epsilon) \leq \mu \leq n$ is replaced by $n(1 - \epsilon)$.

The DEVIANCE function returns the deviance from a binomial distribution, with a probability of success $p$, and a number of independent Bernoulli trials $n$. The following equation describes the DEVIANCE function for the Binomial distribution, where $x$ is the random variable:

$$
\text{DEVIANCE('BINO', } x, \mu, n) = \begin{cases} 
2\log\left(\frac{\mu}{n}\right) + (n - x)\log\left(\frac{n - x}{n - \mu}\right) & 0 \leq x \leq n \\
x < 0 \\
x > n 
\end{cases}
$$

The Gamma Distribution

**DEVIANCE('GAMMA', variable, $\mu$, [\epsilon])**
Arguments

**variable**

is a numeric random variable.

Range  \( \text{variable} \geq \epsilon \)

**\( \mu \)**

is a numeric mean parameter.

Range  \( \mu \geq \epsilon \)

**\( \epsilon \)**

is an optional positive numeric value that is used to bound \( \text{variable} \) and \( \mu \). Any value of \( \text{variable} \) in the interval \( 0 \leq \text{variable} \leq \epsilon \) is replaced by \( \epsilon \). Any value of \( \mu \) in the interval \( 0 \leq \mu \leq \epsilon \) is replaced by \( \epsilon \).

The DEVIANCE function returns the deviance from a gamma distribution with a mean parameter \( \mu \). The following equation describes the DEVIANCE function for the gamma distribution, where \( x \) is the random variable:

\[
\text{DEVIANCE('GAMMA', x, \mu)} = \begin{cases} 
  x < 0 & \frac{x}{2} - \log \left( \frac{x}{\mu} \right) + \frac{x - \mu}{\mu} \\
  \geq \epsilon, \mu \geq \epsilon & 
\end{cases}
\]

The Inverse Gauss (Wald) Distribution

\[
\text{DEVIANCE('IGAUSS' | 'WALD', variable, \mu, \epsilon)}
\]

Arguments

**variable**

is a numeric random variable.

Range  \( \text{variable} \geq \epsilon \)

**\( \mu \)**

is a numeric mean parameter.

Range  \( \mu \geq \epsilon \)

**\( \epsilon \)**

is an optional positive numeric value that is used to bound \( \text{variable} \) and \( \mu \). Any value of \( \text{variable} \) in the interval \( 0 \leq \text{variable} \leq \epsilon \) is replaced by \( \epsilon \). Any value of \( \mu \) in the interval \( 0 \leq \mu \leq \epsilon \) is replaced by \( \epsilon \).

The DEVIANCE function returns the deviance from an inverse Gaussian distribution with a mean parameter \( \mu \). The following equation describes the DEVIANCE function for the inverse Gaussian distribution, where \( x \) is the random variable:

\[
\text{DEVIANCE('IGAUSS', x, \mu)} = \begin{cases} 
  x < 0 & \frac{(x - \mu)^2}{\mu^2 x} \\
  \geq \epsilon, \mu \geq \epsilon & 
\end{cases}
\]

The Normal Distribution

\[
\text{DEVIANCE('NORMAL' | 'GAUSSIAN', variable, \mu)}
\]

Arguments

**variable**

is a numeric random variable.
\[ \mu \]

is a numeric mean parameter.

The DEVIANCE function returns the deviance from a normal distribution with a mean parameter \( \mu \). The following equation describes the DEVIANCE function for the normal distribution, where \( x \) is the random variable:

\[ \text{DEVIANCE('NORMAL', x, \mu)} = (x - \mu)^2 \]

The Poisson Distribution

\[ \text{DEVIANCE('POISSON', variable, \mu[, \epsilon])} \]

Arguments

\( \textbf{variable} \)

is a numeric random variable.

Range \( \text{variable} \geq 0 \)

\( \mu \)

is a numeric mean parameter.

Range \( \mu \geq \epsilon \)

\( \epsilon \)

is an optional positive numeric value that is used to bound \( \mu \). Any value of \( \mu \) in the interval \( 0 \leq \mu \leq \epsilon \) is replaced by \( \epsilon \).

The DEVIANCE function returns the deviance from a Poisson distribution with a mean parameter \( \mu \). The following equation describes the DEVIANCE function for the Poisson distribution, where \( x \) is the random variable:

\[
\text{DEVIANCE('POISSON', x, \mu)} =
\begin{cases} 
  x < 0 & 2\left(\frac{x}{\mu}\right) - (x - \mu) \\
  x \geq 0, \mu \geq \epsilon & \text{otherwise}
\end{cases}
\]

**DHMS Function**

Returns a SAS datetime value from date, hour, minute, and second values.

Categories: CAS

Date and Time

Returned data type: DOUBLE

Syntax

**DHMS**(date, hour, minute, second)

Arguments

\( \textbf{date} \)

specifies any valid expression that represents a SAS date value.
Data type DOUBLE

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

**hour**
specifies a numeric expression that represents a whole number from 1 through 12.

Data type DOUBLE

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

**minute**
specifies a numeric expression that represents a whole number from 1 through 59.

Data type DOUBLE

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

**second**
specifies a numeric expression that represents a whole number from 1 through 59.

Data type DOUBLE

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

-----

**Details**

The DHMS function returns a numeric value that represents a SAS datetime value. This numeric value can be either positive or negative.

**Examples:**

**Example 1: Using Datetime Values**

The following program illustrates how to use the DHMS function with datetime values.

```sql
data test(overwrite=yes);
dcl double dtid dtid1 dtid2 having format datetime.;method run();
dtid=dhms(mdy(01, 03, 2018), 15, 30, 15);
put dtid;
dtid1=dhms(mdy(01, 03, 2018), 15, 30, 61);
put dtid1;
dtid2=dhms(mdy(01, 03, 2018), 15, .5, 15);
```
SAS writes the following output to the log.

<table>
<thead>
<tr>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>03JAN18:15:30:15</td>
</tr>
<tr>
<td>03JAN18:15:31:01</td>
</tr>
<tr>
<td>03JAN18:15:00:45</td>
</tr>
</tbody>
</table>

Example 2

The following statements illustrate the DHMS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select dhms(mdy(08,10,2016),5,10,15);</td>
<td>1786425015</td>
</tr>
<tr>
<td>select put(dhms(date'2016-08-10',5,10,15),datetime18.);</td>
<td>10AUG16:05:10:15</td>
</tr>
</tbody>
</table>

**DIGAMMA Function**

Returns the value of the digamma function.

**Syntax**

```
DIGAMMA(expression)
```

**Arguments**

*expression*

specifies any valid expression that evaluates to a numeric value.
Details
The DIGAMMA function returns the ratio that is given by the following equation.

\[ \Psi(x) = \frac{\Gamma'(x)}{\Gamma(x)} \]

\( \Gamma(.) \) and \( \Gamma'(.) \) denote the gamma function and its derivative, respectively. For expression > 0, the DIGAMMA function is the derivative of the lgamma function.

Example
The following statement illustrates the DIGAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select digamma(1.0);</td>
<td>-0.577215665</td>
</tr>
</tbody>
</table>

DUR Function
Returns the modified duration for an enumerated cash flow.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax
\[ \text{DUR}(y, f, c(1), ..., c(k)) \]

Arguments
\[ y \]
specifies the effective per-period yield-to-maturity, expressed as a fraction.

Range \[ y > 0 \]

Data type DOUBLE

\[ f \]
specifies the frequency of cash flows per period.
Range \( f > 0 \)

Data type \( \text{DOUBLE} \)

\( c(1), \ldots, c(k) \)
specifies a list of cash flows.

Data type \( \text{DOUBLE} \)

Details

The DUR function returns the value from the following equation.

\[
C = \sum_{k=1}^{K} \frac{c(k)}{(1 + y)^k f (1 + y)^f}
\]

The following relationship applies to the preceding equation:

\[
P = \sum_{k=1}^{K} \frac{c(k)}{(1 + y)^k f}
\]

Example

The following statement illustrates the DUR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select dur(.05,1,.33,.44,.55,.49,.50,.22,.4,.8,.01,.36,.2,.4);</td>
<td>5.284025</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “DURP Function” on page 403

DURP Function

Returns the modified duration for a periodic cash flow stream, such as a bond.

Categories: CAS, Financial

Returned data type: \( \text{DOUBLE} \)
Syntax

\textbf{DURP}(A, c, n, K, k_0, y)

Arguments

\textbf{A}
    specifies the par value.
    \begin{itemize}
    \item Range: \( A > 0 \)
    \item Data type: DOUBLE
    \end{itemize}

\textbf{c}
    specifies the nominal per-period coupon rate, expressed as a fraction.
    \begin{itemize}
    \item Range: \( 0 \leq c < 1 \)
    \item Data type: DOUBLE
    \end{itemize}

\textbf{n}
    specifies the number of coupons per period.
    \begin{itemize}
    \item Range: \( n > 0 \) and is a whole number
    \item Data type: DOUBLE
    \end{itemize}

\textbf{K}
    specifies the number of remaining coupons.
    \begin{itemize}
    \item Range: \( K > 0 \) and is a whole number
    \item Data type: DOUBLE
    \end{itemize}

\textbf{k}_0
    specifies the time from the present date to the first coupon date, expressed in terms of the number of periods.
    \begin{itemize}
    \item Range: \( 0 < k_0 \leq 1/n \)
    \item Data type: DOUBLE
    \end{itemize}

\textbf{y}
    specifies the nominal per-period yield-to-maturity, expressed as a fraction.
    \begin{itemize}
    \item Range: \( y > 0 \)
    \item Data type: DOUBLE
    \end{itemize}

Details

The DURP function returns the value from the following equation.

\[ D = \frac{1}{n} \sum_{k=1}^{K} \frac{c(k)}{(1 + \frac{1}{n})^{nk}} \]
The following relationships apply to the preceding equation:

- \( t_k = nk_0 + k - 1 \)
- \( c(k) = \frac{c}{n}A \quad \text{for} \quad k = 1, \ldots, K - 1 \)
- \( c(K) = (1 + \frac{c}{n})A \)

The following relationship applies to the preceding equation:

\[
P = \sum_{k=1}^{K} \frac{c(k)}{(1 + \frac{c}{n})^k}
\]

Example

The following statement illustrates the DURP function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select durp(1000,1/100,4,14,.33/2,.10);</td>
<td>3.331707</td>
</tr>
</tbody>
</table>

**Functions:**
- “DUR Function” on page 402

---

**E Function**

Returns the natural logarithm, e.

**Categories:**
- Mathematical
- CAS

**Returned data type:**
- DOUBLE

**Syntax**

\( E() \)

**Details**

The E function returns the value of the natural logarithm, e, 2.7182818.
Comparisons

The E function takes no argument and returns the value 2.7182818. The EXP function takes an argument and raises e to the power that is supplied by the argument.

Example

The following statement illustrates the E function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select e();</td>
<td>2.718282</td>
</tr>
</tbody>
</table>

- “LOG Function” on page 571

EFFRATE Function

Returns the effective annual interest rate.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

`EFFRATE(compounding-interval, rate)`

Arguments

- `compounding-interval` is a SAS interval. This value represents how often `rate` compounds.
  
  Data type: CHAR

- `rate` is numeric. `Rate` is a nominal annual interest rate (expressed as a percentage) that is compounded at each compounding interval.
  
  Data type: DOUBLE
Details

The EFFRATE function returns the effective annual interest rate. The function computes the effective annual interest rate that corresponds to a nominal annual interest rate.

The following details apply to the EFFRATE function:

- The values for rates must be at least –99.
- In considering a nominal interest rate and a compounding interval, if `compounding-interval` is 'CONTINUOUS', then the value that is returned by EFFRATE equals \( e^{\frac{\text{rate}}{100}} - 1 \).
  
  If `compounding-interval` is not 'CONTINUOUS', and \( m \) compounding intervals occur in a year, the value that is returned by EFFRATE equals \( (1 + \frac{\text{rate}}{100 m})^m - 1 \).
- The following values are valid for `compounding-interval`:
  - 'CONTINUOUS'
  - 'DAY'
  - 'SEMIMONTH'
  - 'MONTH'
  - 'QUARTER'
  - 'SEMIYEAR'
  - 'YEAR'
- If the interval is 'DAY', then \( m = 365 \).

Example

The following programs show how the effective rate is calculated:

- If a nominal rate is 10%, this program shows the corresponding effective rate when interest is compounded monthly.
  
  ```sql
  select EFFRATE('MONTH', 10);
  
  The effective rate is 10.4713067441296.
  
  select EFFRATE('QUARTER', 10);
  
  The effective rate is 10.3812890624999.
  ```

ERF Function

Returns the value of the (normal) error function.

Categories: CAS
Mathematical

Returned data type: DOUBLE
Syntax

ERF(expression)

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Data type  DOUBLE

See  "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

The ERF function returns the integral, given by the following:

\[
ERF(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-z^2} dz
\]

You can use the ERF function to find the probability (p) that a normally distributed random variable with mean 0 and standard deviation takes on a value less than X. For example, the quantity that is given by the following statement is equivalent to PROBNORM(X):

\[
p = 0.5 + 0.5 \cdot \text{erf}(x/\sqrt{2})
\]

Example

The following statements illustrate the ERF function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select erf(1.0);</td>
<td>0.8427007929</td>
</tr>
<tr>
<td>select erf(-1.0);</td>
<td>-0.842700793</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "ERFC Function" on page 409

ERFC Function

Returns the value of the complementary (normal) error function.

Categories:
- CAS
- Mathematical

Returned data type: DOUBLE

Syntax

ERFC(expression)

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

The ERFC function returns the complement to the ERF function (that is, $1 - \text{ERF}(\text{argument})$).

Example

The following statements illustrate the ERFC function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select erfc(1.0);</td>
<td>0.1572992071</td>
</tr>
<tr>
<td>select erfc(-1.0);</td>
<td>1.8427007929</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "ERF Function" on page 407
EXP Function

Returns the value of the e constant raised to a specified power.

Categories: Mathematical
CAS

Returned data type: DOUBLE

Syntax

EXP(expression)

Arguments

expression
specifies any valid SQL expression that evaluates to a numeric value.

Data type: BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT

See
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

The EXP function raises the constant e, which is approximately given by 2.71828, to the power that is supplied by the argument. The result is limited by the maximum value of a double decimal value on the computer.

Comparisons

The EXP function takes an argument and raises e to the power that is supplied by the argument. The E function takes no argument and returns the value 2.7182818.

Example

The following statements illustrate the EXP function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select exp(1.0);</td>
<td>2.718282</td>
</tr>
<tr>
<td>select exp(0);</td>
<td>1</td>
</tr>
</tbody>
</table>

---

**FACT Function**

**Computes a factorial.**

**Categories:**
- CAS
- Mathematical

**Returned data type:**
- DOUBLE

**Syntax**

FACT(expression)

**Arguments**

- **expression** specifies any valid expression that evaluates to a numeric value.

  **Data type**
  - DOUBLE

  **See**
  - “<sql-expression> Expression” on page 820
  - “FedSQL Expressions” on page 48

**Details**

The mathematical representation of the FACT function is given by the following equation:

\[ FACT(n) = n! \]

In this equation, \( n \geq 0 \).

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the FACT function.

**Example**

The following statement illustrates the FACT function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select fact(5);</td>
<td>120</td>
</tr>
</tbody>
</table>
FINANCE Function

Computes financial calculations such as depreciation, maturation, accrued interest, net present value, periodic savings, and internal rates of return.

Categories: CAS
Financial

Syntax

FINANCE(string-identifier, parameter–1, parameter–2, …)

Arguments

string-identifier

specifies a character constant, variable, or expression. Valid values for string-identifier are listed in the following table.

<table>
<thead>
<tr>
<th>string-identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ACCRINT'</td>
<td>computes the accrued interest for a security that pays periodic interest.</td>
</tr>
<tr>
<td>'ACCRINTM'</td>
<td>computes the accrued interest for a security that pays interest at maturity.</td>
</tr>
<tr>
<td>'AMORDEGRC'</td>
<td>computes the depreciation for each accounting period by using a depreciation coefficient.</td>
</tr>
<tr>
<td>'AMORLINC'</td>
<td>computes the depreciation for each accounting period.</td>
</tr>
<tr>
<td>'COUPDAYBS'</td>
<td>computes the number of days from the beginning of the coupon period to the settlement date.</td>
</tr>
<tr>
<td>'COUPDAYS'</td>
<td>computes the number of days in the coupon period that contains the settlement date.</td>
</tr>
<tr>
<td>'COUPDAYSNC'</td>
<td>computes the number of days from the settlement date to the next coupon date.</td>
</tr>
<tr>
<td>'COUPNCD'</td>
<td>computes the next coupon date after the settlement date.</td>
</tr>
<tr>
<td>string-identifier</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>'COUPNUM'</td>
<td>computes the number of coupons that are payable between the settlement date and the maturity date.</td>
</tr>
<tr>
<td>'COUPPCD'</td>
<td>computes the previous coupon date before the settlement date.</td>
</tr>
<tr>
<td>'CUMIPMT'</td>
<td>computes the cumulative interest that is paid between two periods.</td>
</tr>
<tr>
<td>'CUMPRINC'</td>
<td>computes the cumulative principal that is paid on a loan between two periods.</td>
</tr>
<tr>
<td>'DB'</td>
<td>computes the depreciation of an asset for a specified period by using the fixed-declining balance method.</td>
</tr>
<tr>
<td>'DDB'</td>
<td>computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.</td>
</tr>
<tr>
<td>'DISC'</td>
<td>computes the discount rate for a security.</td>
</tr>
<tr>
<td>'DOLLARDE'</td>
<td>converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.</td>
</tr>
<tr>
<td>'DOLLARFR'</td>
<td>converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.</td>
</tr>
<tr>
<td>'DURATION'</td>
<td>computes the annual duration of a security with periodic interest payments.</td>
</tr>
<tr>
<td>'EFFECT'</td>
<td>computes the effective annual interest rate.</td>
</tr>
<tr>
<td>'FV'</td>
<td>computes the future value of an investment.</td>
</tr>
<tr>
<td>'FVSCHEDULE'</td>
<td>computes the future value of an initial principal after applying a series of compound interest rates.</td>
</tr>
<tr>
<td>'INTRATE'</td>
<td>computes the interest rate for a fully invested security.</td>
</tr>
<tr>
<td>'IPMT'</td>
<td>computes the interest payment for an investment for a given period.</td>
</tr>
<tr>
<td>'IRR'</td>
<td>computes the internal rate of return for a series of cash flows.</td>
</tr>
<tr>
<td>'ISPMT'</td>
<td>calculates the interest paid during a specific period of an investment.</td>
</tr>
<tr>
<td>'MDURATION'</td>
<td>computes the Macaulay modified duration for a security with an assumed face value of $100.</td>
</tr>
<tr>
<td><strong>string-identifier</strong></td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>'MIRR'</td>
<td>computes the internal rate of return where positive and negative cash flows are financed at different rates.</td>
</tr>
<tr>
<td>'NOMINAL'</td>
<td>computes the annual nominal interest rate.</td>
</tr>
<tr>
<td>'NPER'</td>
<td>computes the number of periods for an investment.</td>
</tr>
<tr>
<td>'NPV'</td>
<td>computes the net present value of an investment based on a series of periodic cash flows and a discount rate.</td>
</tr>
<tr>
<td>'ODDFPRICE'</td>
<td>computes the price per $100 face value of a security with an odd first period.</td>
</tr>
<tr>
<td>'ODDFYIELD'</td>
<td>computes the yield of a security with an odd first period.</td>
</tr>
<tr>
<td>'ODDLPRICE'</td>
<td>computes the price per $100 face value of a security with an odd last period.</td>
</tr>
<tr>
<td>'ODDLYIELD'</td>
<td>computes the yield of a security with an odd last period.</td>
</tr>
<tr>
<td>'PMT'</td>
<td>computes the periodic payment for an annuity.</td>
</tr>
<tr>
<td>'PPMT'</td>
<td>computes the payment on the principal for an investment for a given period.</td>
</tr>
<tr>
<td>'PRICE'</td>
<td>computes the price per $100 face value of a security that pays periodic interest.</td>
</tr>
<tr>
<td>'PRICEDISC'</td>
<td>computes the price per $100 face value of a discounted security.</td>
</tr>
<tr>
<td>'PRICEMAT'</td>
<td>computes the price per $100 face value of a security that pays interest at maturity.</td>
</tr>
<tr>
<td>'PV'</td>
<td>computes the present value of an investment.</td>
</tr>
<tr>
<td>'RATE'</td>
<td>computes the interest rate per period of an annuity.</td>
</tr>
<tr>
<td>'RECEIVED'</td>
<td>computes the amount received at maturity for a fully invested security.</td>
</tr>
<tr>
<td>'SLN'</td>
<td>computes the straight-line depreciation of an asset for one period.</td>
</tr>
<tr>
<td>'SYD'</td>
<td>computes the sum-of-years digits depreciation of an asset for a specified period.</td>
</tr>
<tr>
<td>string-identifier</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>'TBILLEQ'</td>
<td>computes the bond-equivalent yield for a treasury bill.</td>
</tr>
<tr>
<td>'TBILLPRICE'</td>
<td>computes the price per $100 face value for a treasury bill.</td>
</tr>
<tr>
<td>'TBILLYIELD'</td>
<td>computes the yield for a treasury bill.</td>
</tr>
<tr>
<td>'VDB'</td>
<td>computes the depreciation of an asset for a specified or partial period by using a declining balance method.</td>
</tr>
<tr>
<td>'XIRR'</td>
<td>computes the internal rate of return for a schedule of cash flows that is not necessarily periodic.</td>
</tr>
<tr>
<td>'XNPV'</td>
<td>computes the net present value for a schedule of cash flows that is not necessarily periodic.</td>
</tr>
<tr>
<td>'YIELD'</td>
<td>computes the yield on a security that pays periodic interest.</td>
</tr>
<tr>
<td>'YIELDDISC'</td>
<td>computes the annual yield for a discounted security (for example, a treasury bill).</td>
</tr>
<tr>
<td>'YIELDMAT'</td>
<td>computes the annual yield of a security that pays interest at maturity.</td>
</tr>
</tbody>
</table>

**parameter**
specifies a parameter that is associated with each *string-identifier*. The following parameters are available:

**basis**
is an optional parameter that specifies a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

**interest-rates**
specifies rates that are provided as numeric values and not as percentages.

**dates**
specifies that all dates in the financial functions are SAS dates.
**FinancE ACCrINT Function**

Computes the accrued interest for a security that pays periodic interest.

**Categories:**
- CAS
- Financial

**Returned data type:**
- DOUBLE

**Syntax**

\[
\text{FINANCE('ACCRINT', issue, first-interest, settlement, rate, par-value, frequency, [basis]);}
\]

**Arguments**

**issue**

specifies the issue date of the security.

- **Requirement:** Issue is a SAS date.
- **Data type:** DOUBLE

**first-interest**

specifies the first interest date of the security.

- **Requirement:** First-interest is a SAS date.
- **Data type:** DOUBLE

**settlement**

specifies the settlement date.

- **Requirement:** Settlement is a SAS date.
- **Data type:** DOUBLE

**rate**

specifies the interest rate.

- **Requirement:** Rate is provided as a numeric value and not as a percentage.
- **Data type:** DOUBLE

**par-value**

specifies the par value of the security. If you omit par-value, SAS uses the value $1000.
**Data type** DOUBLE

**frequency**

specifies the number of coupon payments per year. For annual payments, \( frequency=1 \); for semiannual payments, \( frequency=2 \); for quarterly payments, \( frequency=4 \).

**Data type** DOUBLE

**basis**

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

**Data type** DOUBLE

**Example: Computing Accrued Interest: ACCRINT**

The following example computes the accrued interest for a security that pays periodic interest.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select finance('accrint', mdy(2, 28, 2016),</code></td>
<td>17.12255</td>
</tr>
<tr>
<td><code>mdy(8, 31, 2016), MDY(5, 1, 2016), 0.1, 1000,</code></td>
<td></td>
</tr>
<tr>
<td><code>2, 1);</code></td>
<td></td>
</tr>
</tbody>
</table>

**FINANCE ACCRINTM Function**

Computes the accrued interest for a security that pays interest at maturity.

Categories: CAS  
Financial

Returned data type: DOUBLE
Syntax

```
FINANCE('ACCRINTM', issue, settlement, rate, par-value, [basis]);
```

Arguments

**issue**
specifies the issue date of the security.

Requirement  *Issue* is a SAS date.

Data type  DOUBLE

**settlement**
specifies the settlement date.

Requirement  *Settlement* is a SAS date.

Data type  DOUBLE

**rate**
specifies the interest rate.

Requirement  *Rate* is provided as a numeric value and not as a percentage.

Data type  DOUBLE

**par-value**
specifies the par value of the security. If you omit *par-value*, SAS uses the value $1000.

Data type  DOUBLE

**basis**
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

Data type  DOUBLE
Example: Computing Accrued Interest: ACCRINTM

The following example computes the accrued interest for a security that pays interest at maturity.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select finance('accrintm', mdy(2, 28, 2015), mdy(8, 31, 2015), 0.1, 1000, 0);</code></td>
<td>50.55556</td>
</tr>
</tbody>
</table>

FINANCE AMORDEGRC Function

Computes the depreciation for each accounting period by using a depreciation coefficient.

<table>
<thead>
<tr>
<th>Categories</th>
<th>CAS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Financial</td>
</tr>
</tbody>
</table>

| Returned data type       | DOUBLE       |

Syntax

```plaintext
FINANCE('AMORDEGRC', cost, date-purchased, first-period, salvage, period, rate, [basis]);
```

Arguments

- **cost**
  - Specifies the initial cost of the asset.
  - Data type: DOUBLE

- **date-purchased**
  - Specifies the date of the purchase of the asset.
  - Requirement: Date-purchased is a SAS date.
  - Data type: DOUBLE

- **first-period**
  - Specifies the date of the end of the first period.
  - Requirement: First-period is a SAS date.
  - Data type: DOUBLE

- **salvage**
  - Specifies the value at the end of the depreciation (also called the salvage value of the asset).
  - Data type: DOUBLE
period
specifies the depreciation period.

Data type DOUBLE

rate
specifies the rate of depreciation.

Requirement Rate is provided as a numeric value and not as a percentage.

Data type DOUBLE

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

TIP When the first argument of the FINANCE function is AMORDEGRC and the value of basis is 2, the function returns a missing value.

Data type DOUBLE

Example: Computing Depreciation: AMORDEGRC
The following example computes the depreciation for each accounting period by using a depreciation coefficient.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select finance('amordegrc', 2400, mdy(8, 19, 2016), mdy(12, 31, 2016), 300, 1, 0.15, 1);</td>
<td>776</td>
</tr>
</tbody>
</table>

FINANCE AMORLINC Function
Computes the depreciation for each accounting period.
Syntax

```
FINANCE('AMORLINC', cost, date-purchased, first-period, salvage, period, rate, [basis]);
```

Arguments

- **cost**
  - specifies the initial cost of the asset.
  - Data type: DOUBLE

- **date-purchased**
  - specifies the date of the purchase of the asset.
  - Requirement: Date-purchased is a SAS date.
  - Data type: DOUBLE

- **first-period**
  - specifies the date of the end of the first period.
  - Requirement: First-period is a SAS date.
  - Data type: DOUBLE

- **salvage**
  - specifies the value at the end of the depreciation (also called the salvage value of the asset).
  - Data type: DOUBLE

- **period**
  - specifies the depreciation period.
  - Data type: DOUBLE

- **rate**
  - specifies the rate of depreciation.
  - Requirement: Rate is provided as a numeric value and not as a percentage.
  - Data type: DOUBLE

- **basis**
  - specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.
<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

**TIP** When the first argument of the FINANCE function is AMORLINC and the value of *basis* is 2, the function returns a missing value.

**Data type** DOUBLE

**Example: Computing Description: AMORLINC**

The following example computes the depreciation for each accounting period.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select finance('AMORLINC', 2400, mdy(9, 30, 2016), mdy(12, 31, 2016), 245, 0, 0.115, 0);</code></td>
<td>69</td>
</tr>
</tbody>
</table>

**FINANCE COUPDAYBS Function**

Computes the number of days from the beginning of the coupon period to the settlement date.

**Categories:**
- CAS
- Financial

**Returned data type:** DOUBLE

**Syntax**

`FINANCE('COUPDAYBS', settlement, maturity, frequency, [basis]);`

**Arguments**

*settlement*

specifies the settlement date of the security. The security settlement date is the date after the issue date when the security is traded to the buyer.
requirement

**Settlement** is a SAS date.

Data type: DOUBLE

**maturity**

specifies the maturity date of the security. The maturity date is the date on which the security expires.

Requirement: **Maturity** is a SAS date.

Data type: DOUBLE

**frequency**

specifies the number of coupon payments per year. For annual payments, `frequency`=1; for semiannual payments, `frequency`=2; for quarterly payments, `frequency`=4.

Data type: DOUBLE

**basis**

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

Data type: DOUBLE

Example: Computing Description: COUPDAYBS

The following example computes the number of days from the beginning of the coupon period to the settlement date.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select finance('COUPDAYBS', mdy(12,30,2013), mdy(11,29,2016), 4, 2);</code></td>
<td>31</td>
</tr>
</tbody>
</table>
FINANCE COUPDAYS Function

Computes the number of days in the coupon period that contains the settlement date.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

FINANCE('COUPDAYS', settlement, maturity, frequency, [basis]);

Arguments

settlement
specifies the settlement date.

Requirement Settlement is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement Maturity is a SAS date.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, frequency=1; for semiannual payments, frequency=2; for quarterly payments, frequency=4.

Data type DOUBLE

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>

</table>

FINANCE COUPDAYSNC Function

Computes the number of days from the settlement date to the next coupon date.

Categories:
- CAS
- Financial

Returned data type: DOUBLE

Syntax

```
FINANCE('COUPDAYSNC', settlement, maturity, frequency, [basis]);
```

Arguments

- **settlement**
  - specifies the settlement date.
  - Requirement: Settlement is a SAS date.
  - Data type: DOUBLE

- **maturity**
  - specifies the maturity date.
  - Requirement: Maturity is a SAS date.
  - Data type: DOUBLE
**frequency**  
specifies the number of coupon payments per year. For annual payments,  
\textit{frequency}=1; for semiannual payments,  
\textit{frequency}=2; for quarterly payments,  
\textit{frequency}=4.

Data type **DOUBLE**

**basis**  
specifies an optional parameter as a character or numeric value that indicates  
the type of day count basis to use.

<table>
<thead>
<tr>

**FINANCE COUPNCD Function**

Computes the next coupon date after the settlement date.

- Categories:  
  - CAS
  - Financial

- Returned data type: **DOUBLE**
**Syntax**

`FINANCE("COUPNCD", settlement, maturity, frequency, [basis]);`

**Arguments**

*settlement*

specifies the settlement date.

**Requirement** *Settlement* is a SAS date.

**Data type** DOUBLE

*maturity*

specifies the maturity date.

**Requirement** *Maturity* is a SAS date.

**Data type** DOUBLE

*frequency*

specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

**Data type** DOUBLE

*basis*

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

**Data type** DOUBLE

**Example: Computing Description: COUPNCD**

The following example computes the next coupon date after the settlement date.
**FINANCE COUPNUM Function**

Computes the number of coupons that are payable between the settlement date and the maturity date.

**Categories:**
- CAS
- Financial

**Returned data type:**
- DOUBLE

### Syntax

```sql
FINANCE('COUPNUM', settlement, maturity, frequency, [basis]);
```

### Arguments

- **settlement**
  - specifies the settlement date.
  - **Requirement:** Settlement is a SAS date.
  - **Data type:** DOUBLE

- **maturity**
  - specifies the maturity date.
  - **Requirement:** Maturity is a SAS date.
  - **Data type:** DOUBLE

- **frequency**
  - specifies the number of coupon payments per year. For annual payments, frequency=1; for semiannual payments, frequency=2; for quarterly payments, frequency=4.
  - **Data type:** DOUBLE

- **basis**
  - specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.
### FINANCE COUPNUM Function

The following example computes the number of coupons that are payable between the settlement date and the maturity date.

```
select FINANCE('COUPNUM', mdy(1, 25, 2015),
                mdy(11,15,2016), 2, 1);
4
```

### FINANCE COUPPCD Function

Computes the previous coupon date before the settlement date.

**Categories:**
- CAS
- Financial

**Returned data type:** DOUBLE

**Syntax**

```
FINANCE('COUPPCD', settlement, maturity, frequency, [basis]);
```

**Arguments**

- `settlement`
  - specifies the settlement date.
  
  **Requirement**
  - `settlement` is a SAS date.

  **Data type**
  - DOUBLE
**maturity**

specifies the maturity date.

**Requirement**  
*Maturity* is a SAS date.

**Data type**  
DOUBLE

**frequency**

specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

**Data type**  
DOUBLE

**basis**

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

</tbody>
</table>

**FINANCE CUMIPMT Function**

Computes the cumulative interest paid between two periods.
FINANCE CUMIPMT Function

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

\[
\text{FINANCE('CUMIPMT', rate, nper, pv, start-period, end-period, [type]);}
\]

Arguments

rate
specifies the interest rate.

Requirement \(Rate\) is provided as a numeric value and not as a percentage.

Data type DOUBLE

nper
specifies the total number of payment periods.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently.

Data type DOUBLE

start-period
specifies the first period in the calculation. Payment periods are numbered beginning with 1.

Data type DOUBLE

end-period
specifies the last period in the calculation.

Data type DOUBLE

type
specifies the number 0 or 1 and indicates when payments are due. If \(type\) is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the \(type\) argument or set it to 0. If payments are due at the beginning of the period, then set \(type\) to 1.

Data type DOUBLE

Example: Computing Description: CUMIPMT

The following example computes the cumulative interest that is paid between two periods.
### Statements

```
select FINANCE('CUMIPMT', 0.09, 30, 125000, 13, 24, 0);  
-94054.8
```

---

### FINANCE CUMPRINC Function

Computes the cumulative principal that is paid on a loan between two periods.

**Categories:**
- CAS
- Financial

**Returned data type:**
- DOUBLE

**Syntax**

```
FINANCE('CUMPRINC', rate, nper, pv, start-period, end-period, [type]);
```

**Arguments**

- **rate**
  - Specifies the interest rate.
  - **Requirement:** *Rate is provided as a numeric value and not as a percentage.*
  - **Data type:** DOUBLE

- **nper**
  - Specifies the total number of payment periods.
  - **Data type:** DOUBLE

- **pv**
  - Specifies the present value or the lump-sum amount that a series of future payments is worth currently.
  - **Data type:** DOUBLE

- **start-period**
  - Specifies the first period in the calculation. Payment periods are numbered beginning with 1.
  - **Data type:** DOUBLE

- **end-period**
  - Specifies the last period in the calculation.
  - **Data type:** DOUBLE
**type**
specifies the number 0 or 1 and indicates when payments are due. If type is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the type argument or set it to 0. If payments are due at the beginning of the period, then set type to 1.

Data type: DOUBLE

**Example: Computing Description: CUMPRINC**

The following example computes the cumulative principal that is paid on a loan between two periods.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('CUMPRINC', 0.09, 30, 125000, 13, 24, 0);</code></td>
<td>-51949.7</td>
</tr>
</tbody>
</table>

**FINANCE DB Function**

Computes the depreciation of an asset for a specified period by using the fixed-declining balance method.

Categories: CAS
Financial

Returned data type: DOUBLE

**Syntax**

`FINANCE('DB', cost, salvage, life, period, [month]);`

**Arguments**

*cost*
specifies the initial cost of the asset.

Data type: DOUBLE

*salvage*
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type: DOUBLE

*life*
specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).
Data type  DOUBLE

**period**
specifies the period for which you want to calculate the depreciation. *Period* must use the same time units as *life*.

Data type  DOUBLE

**month**
specifies the number of months (month is an optional numeric argument). If month is omitted, it defaults to a value of 12.

Data type  DOUBLE

Example: Computing Description: DB
The following example computes the depreciation of an asset for a specified period by using the fixed-declining balance method.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('DB', 1000000, 100000, 6, 2, 7);</td>
<td>259639.4</td>
</tr>
</tbody>
</table>

**FINANCE DDB Function**
Computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.

**Categories:** CAS  
Financial  

**Returned data type:** DOUBLE

**Syntax**

```
FINANCE('DDB', cost, salvage, life, period, [factor]);
```

**Arguments**

**cost**
specifies the initial cost of the asset.

Data type  DOUBLE

**salvage**
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type  DOUBLE
**life**

specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

*Data type*   **DOUBLE**

**period**

specifies the period for which you want to calculate the depreciation. *Period* must use the same time units as *life*.

*Data type*   **DOUBLE**

**factor**

specifies the rate at which the balance declines. If *factor* is omitted, it is assumed to be 2 (the double-declining balance method).

*Data type*   **DOUBLE**

**Example: Computing Description: DDB**

The following example computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('DDB', 2400, 300, 10*365, 1, .)</td>
<td>1.315068</td>
</tr>
</tbody>
</table>

**FINANCE DISC Function**

Computes the discount rate for a security.

- **Categories**: CAS, Financial
- **Returned data type**: DOUBLE

**Syntax**

FINANCE('DISC', *settlement*, *maturity*, *price*, *redemption*, *[basis]*)

**Arguments**

**settlement**

specifies the settlement date.

*Requirement*  *Settlement* is a SAS date.

*Data type*   **DOUBLE**
**maturity**
specifies the maturity date.

**Requirement**  
*Maturity* is a SAS date.

**Data type**  
DOUBLE

**price**
specifies the price of security per $100 face value.

**Data type**  
DOUBLE

**redemption**
specifies the amount to be received at maturity.

**Data type**  
DOUBLE

**basis**
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>

<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

**Data type**  
DOUBLE

**Example: Computing Description: DISC**
The following example computes the discount rate for a security.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('DISC', mdy(1, 25, 2007),</td>
<td>0.05242</td>
</tr>
<tr>
<td>mdy(6, 15, 2007), 97.975, 100, 1);</td>
<td></td>
</tr>
</tbody>
</table>

**FINANCE DOLLARDE Function**
Converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.

**Categories:**  
CAS
Returned data type: DOUBLE

Syntax

```plaintext
FINANCE('DOLLARDE', fractional-dollar, fraction);
```

Arguments

- `fractional-dollar` specifies the number expressed as a fraction.
  - Data type: DOUBLE
- `fraction` specifies the whole number to use in the denominator of a fraction.
  - Data type: DOUBLE

Example: Computing Description: DOLLARDE

The following example converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('DOLLARDE', 1.125, 16);</td>
<td>1.78125</td>
</tr>
</tbody>
</table>

FINANCE DOLLARFR Function

Converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.

Categories: CAS  
Financial

Returned data type: DOUBLE

Syntax

```plaintext
FINANCE('DOLLARFR', decimal-dollar, fraction);
```

Arguments

- `decimal-dollar` specifies a decimal number.
Data type DOUBLE

**fraction**
specifies the whole number to use in the denominator of a fraction.

Data type DOUBLE

**Example: Computing Description: DOLLARFR**
The following example converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('DOLLARFR', 1.125, 16);</td>
<td>1.02</td>
</tr>
</tbody>
</table>

**FINANCE DURATION Function**
Computes the annual duration of a security with periodic interest payments.

**Categories:** CAS
Financial

**Returned data type:** DOUBLE

**Syntax**
```
FINANCE('DURATION', settlement, maturity, coupon, yield, frequency, [basis]);
```

**Arguments**

**settlement**
specifies the settlement date.

**Requirement**
Settlement is a SAS date.

**Data type** DOUBLE

**maturity**
specifies the maturity date.

**Requirement**
Maturity is a SAS date.

**Data type** DOUBLE

**coupon**
specifies the annual coupon rate of the security.

**Requirement**
Coupon is provided as a numeric value and not as a percentage.
Data type: DOUBLE

**yield**
specifies the annual yield of the security.

Data type: DOUBLE

**frequency**
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type: DOUBLE

**basis**
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>

<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

Data type: DOUBLE

**Example: Computing Description: DURATION**

The following example computes the annual duration of a security with periodic interest payments.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('DURATION', mdy(1, 1, 2008), mdy(1, 1, 2016), 0.08, 0.09, 2, 1);</td>
<td>5.993775</td>
</tr>
</tbody>
</table>
Syntax

**FINANCE**('EFFECT', nominal-rate, npery);

**Arguments**

*nominal-rate*

specifies the nominal interest rate.

Data type **DOUBLE**

*npery*

specifies the number of compounding periods per year.

Data type **DOUBLE**

**Example: Computing Description: EFFECT**

The following example computes the effective annual interest rate.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('EFFECT', 0.0525, 4);</td>
<td>0.053543</td>
</tr>
</tbody>
</table>

**FINANCE FV Function**

Computes the future value of an investment.

**Categories:**

- CAS
- Financial

**Returned data type:**

**DOUBLE**

Syntax

**FINANCE**('FV', rate, nper, [payment], [present-value], [type]);

**Arguments**

*rate*

specifies the interest rate.

Requirement *Rate is provided as a numeric value and not as a percentage.*

Data type **DOUBLE**
\textit{nper} specifies the total number of payment periods.

Data type \textbf{DOUBLE}

\textit{payment} specifies the payment that is made each period; the payment cannot change over the life of the annuity. Typically, \textit{payment} contains principal and interest but no fees and taxes. If \textit{payment} is omitted, you must include the \textit{present-value} argument.

Data type \textbf{DOUBLE}

\textit{present-value} specifies the present value or the lump-sum amount that a series of future payments is worth currently. If \textit{present-value} is omitted, it is assumed to be 0 (zero), and you must include the \textit{payment} argument.

Data type \textbf{DOUBLE}

\textit{type} specifies the number 0 or 1 and indicates when payments are due. If \textit{type} is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the \textit{type} argument or set it to 0. If payments are due at the beginning of the period, then set \textit{type} to 1.

Data type \textbf{DOUBLE}

Example: Computing Description: FV

The following example computes the future value of an investment.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select finance('FV', 0.06/12, 10, -200, -500, 1);</td>
<td>2581.403</td>
</tr>
</tbody>
</table>

\textbf{FINANCE FVSCHEDULE Function}

Computes the future value of the initial principal after applying a series of compound interest rates.

Categories: \textbf{CAS} \textbf{Financial}

Returned data type: \textbf{DOUBLE}

\textbf{Syntax}

\texttt{FINANCE('FVSCHEDULE', principal, schedule-1, schedule-2 ...);}
Arguments

**principal**
specifies the present value.

Data type  **DOUBLE**

**schedule**
specifies the sequence of interest rates to apply.

Requirement  *Schedule* rates are provided as numeric values and not as percentages.

Data type  **DOUBLE**

Example: Computing Description: **FVSCHEDULE**
The following example computes the future value of the initial principal after applying a series of compound interest rates.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('FVSCHEDULE', 1, 0.09, 0.11, 0.1);</td>
<td>1.33089</td>
</tr>
</tbody>
</table>

**FINANCE INTRATE Function**
Computes the interest rate for a fully invested security.

Categories:  **CAS**
Financial

Returned data type:  **DOUBLE**

Syntax

**FINANCE('INTRATE', settlement, maturity, investment, redemption, [basis]);**

Arguments

**settlement**
specifies the settlement date.

Requirement  *Settlement* is a SAS date.

Data type  **DOUBLE**

**maturity**
specifies the maturity date.
**Requirement** | **Maturity** is a SAS date.
---|---
**Data type** | DOUBLE

**investment**
specifies the amount that is invested in the security.

**Data type** | DOUBLE

**redemption**
specifies the amount to be received at maturity.

**Data type** | DOUBLE

**basis**
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>

<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

**Data type** | DOUBLE

**Example: Computing Description: INTRATE**
The following example computes the interest rate for a fully invested security.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select finance('intrate', mdy(2, 15, 2008), mdy(5, 15, 2008), 1000000, 1014420, 2);</code></td>
<td>0.05768</td>
</tr>
</tbody>
</table>

**FINANCE IPMT Function**
Computes the interest payment for an investment for a specified period.

**Categories:**
- CAS
- Financial
Syntax

**FINANCE**('IPMT', *rate*, *period*, *nper*, *pv*, [*fv*], [*type*]);

Arguments

**rate**
specifies the interest rate.

*Requirement*  *Rate* is provided as a numeric value and not as a percentage.

*Data type*  DOUBLE

**period**
specifies the period for which you want to calculate the depreciation. *Period* must use the same units as *life*.

*Data type*  DOUBLE

**nper**
specifies the total number of payment periods.

*Data type*  DOUBLE

**pv**
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *fv* argument.

*Data type*  DOUBLE

**fv**
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

*Data type*  DOUBLE

**type**
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

- If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

*Data type*  DOUBLE

Example: Computing Description: IPMT

The following example computes the interest payment for an investment for a specified period.
FINANCE IRR Function

Computes the internal rate of return for a series of cash flows.

**Categories:**
- CAS
- Financial

**Returned data type:**
DOUBLE

**Syntax**

FINANCE('IRR', value-1, value-2, ..., value-n);

**Arguments**

- value
  - Specifies a list of numeric arguments that contain numbers for which you want to calculate the internal rate of return.

  **Data type:** DOUBLE

**Example: Computing Description: IRR**

The following example computes the internal rate of return for a series of cash flows.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('IRR', -70000, 12000, 15000, 18000, 21000, 26000);</td>
<td>0.086631</td>
</tr>
</tbody>
</table>

FINANCE ISPMT Function

Calculates the interest paid during a specific period of an investment.

**Categories:**
- CAS
- Financial

**Returned data type:**
DOUBLE

FINANCE ISPMT Function

Computes the interest paid during a specific period of an investment.

**Categories:**
- CAS
- Financial

**Returned data type:**
DOUBLE
Syntax

```
FINANCE('ISPMT', interest-rate, period, number-payments, pv);
```

Arguments

- **interest-rate**
  - Specifies the interest rate for the investment.
  - **Requirement**: *Rate* is provided as a numeric value and not as a percentage.
  - **Data type**: DOUBLE

- **period**
  - Specifies the period for which you want to calculate the interest rate. *Period* must be a value between 1 and *number-payments*.
  - **Data type**: DOUBLE

- **number-payments**
  - Specifies the number of payments for the annuity.
  - **Data type**: DOUBLE

- **pv**
  - Specifies the loan amount or present value of the payments.
  - **Data type**: DOUBLE

Example: Computing Description: ISPMT

The following example computes the interest payment for a $5,000 investment that earns 7.5% annually for two years. The interest payment is calculated for the eighth month.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('ISPMT', 0.075/12, 8, 2*12, 5000);</code></td>
<td><code>-20.8333</code></td>
</tr>
</tbody>
</table>

FINANCE MDURATION Function

Computes the Macaulay modified duration for a security with an assumed face value of $100.

- **Categories**: CAS, Financial
- **Returned data type**: DOUBLE
Syntax

\texttt{FINANCE('MDURATION', \textit{settlement}, \textit{maturity}, \textit{coupon}, \textit{yield}, \textit{frequency}, \textit{[basis]})};

Arguments

\textit{settlement} specifies the settlement date.

- \textbf{Requirement} \textit{Settlement} is a SAS date.
- \textbf{Data type} \texttt{DOUBLE}

\textit{maturity} specifies the maturity date.

- \textbf{Requirement} \textit{Maturity} is a SAS date.
- \textbf{Data type} \texttt{DOUBLE}

\textit{coupon} specifies the annual coupon rate of the security.

- \textbf{Requirement} \textit{Coupon} is provided as a numeric value and not as a percentage.
- \textbf{Data type} \texttt{DOUBLE}

\textit{yield} specifies the annual yield of the security.

- \textbf{Data type} \texttt{DOUBLE}

\textit{frequency} specifies the number of coupon payments per year. For annual payments, \textit{frequency}=1; for semiannual payments, \textit{frequency}=2; for quarterly payments, \textit{frequency}=4.

- \textbf{Data type} \texttt{DOUBLE}

\textit{basis} specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;30/360&quot;</td>
<td>US (NASD) 30/360</td>
</tr>
<tr>
<td>1</td>
<td>&quot;ACTUAL&quot;</td>
<td>Actual/actual</td>
</tr>
<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>
Example: Computing Description: MDURATION
The following example computes the Macaulay modified duration for a security with an assumed face value of $100.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('MDURATION', mdy(1, 1, 2008), mdy(1, 1, 2016), 0.08, 0.09, 2, 1);</td>
<td>5.73567</td>
</tr>
</tbody>
</table>

FINANCE MIRR Function
Computes the internal rate of return where positive and negative cash flows are financed at different rates.

Categories:
- CAS
- Financial

Returned data type: DOUBLE

Syntax

```
FINANCE('MIRR', value-1, ..., value-n, finance-rate, reinvest-rate);
```

Arguments

**value**
specifies a list of numeric arguments that contain numbers. These numbers represent a series of payments (negative values) and income (positive values) that occur at regular periods. Value must contain at least one positive value and one negative value to calculate the modified internal rate of return.

Data type: DOUBLE

**finance-rate**
specifies the interest rate that you pay on the money that is used in the cash flows.

Requirement: Finance-rate is provided as a numeric value and not as a percentage.

Data type: DOUBLE

**reinvest-rate**
specifies the interest rate that you receive on the cash flows as you reinvest them.
Reinvest-rate is provided as a numeric value and not as a percentage.

Data type: DOUBLE

Example: Computing Description: MIRR
The following example computes the internal rate of return where positive and negative cash flows are financed at different rates.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('MIRR', -1000, 3000, 4000, 5000, 0.08, 0.10);</td>
<td>1.353142</td>
</tr>
</tbody>
</table>

FINANCE NOMINAL Function
Computes the annual nominal interest rates.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

FINANCE('NOMINAL', effective-rate, npery);

Arguments

effective-rate
specifies the effective interest rate.

Requirement: Effective-rate is provided as a numeric value and not as a percentage.

Data type: DOUBLE

npery
specifies the number of compounding periods per year.

Data type: DOUBLE

Example: Computing Description: NOMINAL
The following example computes the annual nominal interest rate.
select FINANCE('NOMINAL', 0.08, 4);  
0.077706

FINANCE NPER Function
Computes the number of periods for an investment.

<table>
<thead>
<tr>
<th>Categories:</th>
<th>CAS</th>
<th>Financial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type:</td>
<td>DOUBLE</td>
<td></td>
</tr>
</tbody>
</table>

Syntax

FINANCE('NPER', rate, payment, pv, [fv], [type]);

Arguments

**rate**
specifies the interest rate.

Requirement  
*R*ate is provided as a numeric value and not as a percentage.

Data type  
DOUBLE

**payment**
specifies the payment that is made each period; the payment cannot change over the life of the annuity. Typically, *payment* contains principal and interest but no other fees or taxes. If *payment* is omitted, you must include the *pv* argument.

Data type  
DOUBLE

**pv**
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *payment* argument.

Data type  
DOUBLE

**fv**
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type  
DOUBLE

**type**
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.
If payments are due at the end of the period, then either omit the `type` argument or set it to 0. If payments are due at the beginning of the period, then set `type` to 1.

Data type: **DOUBLE**

### Example: Computing Description: NPER

The following example computes the number of periods for an investment.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('NPER', 0.08, 200, 1000, 0, 0);</code></td>
<td>-4.37198</td>
</tr>
</tbody>
</table>

---

**FINANCE NPV Function**

Computes the net present value of an investment based on a series of periodic cash flows and a discount rate.

**Categories:**
- CAS
- Financial

**Returned data type:** DOUBLE

**Syntax**

```
FINANCE('NPV', rate, value-1, [... value-n]);
```

**Arguments**

- **rate**
  - Specifies the interest rate.
  - **Requirement**: `Rate` is provided as a numeric value and not as a percentage.
  - **Data type**: DOUBLE

- **value**
  - Represents the sequence of the cash flows.
  - **Data type**: DOUBLE

### Example: Computing Description: NPV

The following example computes the net present value of an investment based on a series of periodic cash flows and a discount rate.
FINANCE ODDFPRICE Function

Computes the price of a security per $100 face value with an odd first period.

**Categories:**
- CAS
- Financial

**Returned data type:** DOUBLE

**Syntax**

```
FINANCE('ODDFPRICE', settlement, maturity, issue, first-coupon, rate, yield, redemption, frequency, [basis]);
```

**Arguments**

- **settlement**
  - specifies the settlement date.
  - **Requirement** *Settlement* is a SAS date.
  - **Data type** DOUBLE

- **maturity**
  - specifies the maturity date.
  - **Requirement** *Maturity* is a SAS date.
  - **Data type** DOUBLE

- **issue**
  - specifies the issue date of the security.
  - **Requirement** *Issue* is a SAS date.
  - **Data type** DOUBLE

- **first-coupon**
  - specifies the first coupon date of the security.
  - **Requirement** *First-coupon* is a SAS date.
  - **Data type** DOUBLE

- **rate**
  - specifies the interest rate.
Requirement 
*Rate* is provided as a numeric value and not as a percentage.

**Data type** 
DOUBLE

**yield**
specifies the annual yield of the security.

**Data type** 
DOUBLE

**redemption**
specifies the amount to be received at maturity.

**Data type** 
DOUBLE

**frequency**
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

**Data type** 
DOUBLE

**basis**
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<tr>
<td>2</td>
<td>&quot;ACT/360&quot;</td>
<td>Actual/360</td>
</tr>
<tr>
<td>3</td>
<td>&quot;ACT/365&quot;</td>
<td>Actual/365</td>
</tr>
<tr>
<td>4</td>
<td>&quot;EU30/360&quot;</td>
<td>European 30/360</td>
</tr>
</tbody>
</table>

**Data type** 
DOUBLE

**Example: Computing Description: ODDFPRICE**

The following example computes the price of a security per $100 face value with an odd first period.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('ODDFPRICE', mdy(1, 15, 93), mdy(1, 1, 98), mdy(1, 1, 93), mdy(7, 1, 94), 0.07, 0.06, 100, 2, 0);</td>
<td>103.941</td>
</tr>
</tbody>
</table>
FINANCE ODDFYIELD Function

Computes the yield of a security with an odd first period.

Categories: CAS
           Financial

Returned data type: DOUBLE

Syntax

FINANCE('ODDFYIELD', settlement, maturity, issue, first-coupon, rate, price, redemption, frequency, [basis]);

Arguments

settlement
   specifies the settlement date.
   Requirement Settlement is a SAS date.
   Data type DOUBLE

maturity
   specifies the maturity date.
   Requirement Maturity is a SAS date.
   Data type DOUBLE

issue
   specifies the issue date of the security.
   Requirement Issue is a SAS date.
   Data type DOUBLE

first-coupon
   specifies the first coupon date of the security.
   Requirement First-coupon is a SAS date.
   Data type DOUBLE

rate
   specifies the interest rate.
   Requirement Rate is provided as a numeric value and not as a percentage.
   Data type DOUBLE

price
   specifies the price of the security per $100 face value.
Data type DOUBLE

**redemption**
specifies the amount to be received at maturity.

Data type DOUBLE

**frequency**
specifies the number of coupon payments per year. For annual payments, `frequency`=1; for semiannual payments, `frequency`=2; for quarterly payments, `frequency`=4.

Data type DOUBLE

**basis**
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

Data type DOUBLE

**Example: Computing Description: ODDFYIELD**
The following example computes the interest of a yield with an odd first period.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('ODDFYIELD', mdy(1, 15, 93), mdy(1, 1, 98), mdy(1, 1, 93), mdy(7, 1, 94), 0.07, 103.94103984, 100, 2, 0);</td>
<td>0.06</td>
</tr>
</tbody>
</table>

**FINANCE ODDLPRICE Function**
Computes the price of a security per $100 face value with an odd last period.

Categories: CAS, Financial
Syntax

\texttt{FINANCE('ODDLPRICE', settlement, maturity, last-interest, rate, yield, redemption, frequency, [basis]);}

Arguments

\texttt{settlement}
  specifies the settlement date.
  Requirement \textit{Settlement} is a SAS date.
  Data type \textbf{DOUBLE}

\texttt{maturity}
  specifies the maturity date.
  Requirement \textit{Maturity} is a SAS date.
  Data type \textbf{DOUBLE}

\texttt{last-interest}
  specifies the last coupon date of the security.
  Requirement \textit{Last-interest} is a SAS date.
  Data type \textbf{DOUBLE}

\texttt{rate}
  specifies the interest rate.
  Requirement \textit{Rate} is provided as a numeric value and not as a percentage.
  Data type \textbf{DOUBLE}

\texttt{yield}
  specifies the annual yield of the security.
  Data type \textbf{DOUBLE}

\texttt{redemption}
  specifies the amount to be received at maturity.
  Data type \textbf{DOUBLE}

\texttt{frequency}
  specifies the number of coupon payments per year. For annual payments, \texttt{frequency}=1; for semiannual payments, \texttt{frequency}=2; for quarterly payments, \texttt{frequency}=4.
  Data type \textbf{DOUBLE}
**basis**
specifies an optional parameter as a character or numeric value that indicates
the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>

# FINANCE PMT Function

Computes the periodic payment of an annuity.

## Categories
- CAS
- Financial

## Returned data type
DOUBLE

## Syntax
\[
\text{FINANCE('PMT', rate, nper, pv, [fv], [type])}
\]

## Arguments

**rate**
- specifies the interest rate.
- **Requirement**: *Rate* is provided as a numeric value and not as a percentage.
- **Data type**: DOUBLE

**nper**
- specifies the total number of payment periods.
- **Data type**: DOUBLE
pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If pv is omitted, it is assumed to be 0 (zero), and you must include the fv argument.

Data type DOUBLE

fv
specifies the future value or a cash balance that you want to attain after the last payment is made. If fv is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type DOUBLE

Type
specifies the number 0 or 1 and indicates when payments are due. If type is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the type argument or set it to 0. If payments are due at the beginning of the period, then set type to 1.

Data type DOUBLE

Example: Computing Description: PMT
The following example computes the periodic payment for an annuity.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('PMT', 0.08, 5, 91, 3, 0);</td>
<td>-23.3029</td>
</tr>
</tbody>
</table>

FINANCE PPMT Function
Computes the payment on the principal for an investment for a specified period.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax
FINANCE('PPMT', rate, period, nper, pv, [fv], [type]);

Arguments
rate
specifies the interest rate.
Requirement: *Rate* is provided as a numeric value and not as a percentage.

Data type: **DOUBLE**

**period**
specifies the period.

Range: 1–*nper*

Data type: **DOUBLE**

**nper**
specifies the number of payment periods.

Data type: **DOUBLE**

**pv**
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *fv* argument.

Data type: **DOUBLE**

**fv**
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type: **DOUBLE**

**type**
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type: **DOUBLE**

Example: Computing Description: PPMT

The following example computes the payment on the principal for an investment for a specified period.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('PPMT', 0.08, 10, 10, 200000, 0, 0);</td>
<td>-27598.1</td>
</tr>
</tbody>
</table>

FINANCE PRICE Function

Computes the price of a security per $100 face value that pays periodic interest.
Syntax

\[
\text{FINANCE('PRICE', settlement, maturity, rate, yield, redemption, frequency, [basis]);}
\]

Arguments

- **settlement**
  - specifies the settlement date.
  - Requirement: Settlement is a SAS date.
  - Data type: DOUBLE

- **maturity**
  - specifies the maturity date.
  - Requirement: Maturity is a SAS date.
  - Data type: DOUBLE

- **rate**
  - specifies the interest rate.
  - Requirement: Rate is provided as a numeric value and not as a percentage.
  - Data type: DOUBLE

- **yield**
  - specifies the annual yield of the security.
  - Data type: DOUBLE

- **redemption**
  - specifies the amount to be received at maturity.
  - Data type: DOUBLE

- **frequency**
  - specifies the number of coupon payments per year. For annual payments, frequency=1; for semiannual payments, frequency=2; for quarterly payments, frequency=4.
  - Data type: DOUBLE

- **basis**
  - specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.
### FINANCE PRICEDISC Function

Computes the price of a discounted security per $100 face value.

**Categories:** CAS, Financial

**Returned data type:** DOUBLE

#### Syntax

```
FINANCE('PRICEDISC', settlement, maturity, discount, redemption, [basis]);
```

#### Arguments

- **settlement**
  - Specifies the settlement date.
  - **Requirement**: *Settlement* is a SAS date.

- **Data type**: DOUBLE
maturity
specifies the maturity date.

Requirement  
*Maturity* is a SAS date.

Data type  
DOUBLE

discount
specifies the discount rate of the security.

Requirement  
*Discount* is provided as a numeric value and not as a percentage.

Data type  
DOUBLE

redemption
specifies the amount to be received at maturity.

Data type  
DOUBLE

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>

<tr>
<td>mdy(11,15,2017), 0.0525, 100, 0);</td>
<td></td>
</tr>
</tbody>
</table>
FINANCE PRICEMAT Function

Computes the price of a security per $100 face value that pays interest at maturity.

**Categories:**
- CAS
- Financial

**Returned data type:**
- DOUBLE

**Syntax**

\[
\text{FINANCE('PRICEMAT', settlement, maturity, issue, rate, yield, [basis])};
\]

**Arguments**

- **settlement**
  - specifies the settlement date.
  - **Requirement** \( Settlement \) is a SAS date.
  - **Data type** DOUBLE

- **maturity**
  - specifies the maturity date.
  - **Requirement** \( Maturity \) is a SAS date.
  - **Data type** DOUBLE

- **issue**
  - specifies the issue date of the security.
  - **Requirement** \( Issue \) is a SAS date.
  - **Data type** DOUBLE

- **rate**
  - specifies the interest rate.
  - **Requirement** \( Rate \) is provided as a numeric value and not as a percentage.
  - **Data type** DOUBLE

- **yield**
  - specifies the annual yield of the security.
  - **Data type** DOUBLE

- **basis**
  - specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.
<table>

Data type  **DOUBLE**

**Example: Computing Description: PRICEMAT**

The following example computes the price of a security per $100 face value that pays interest at maturity.

**Statements**

```
select FINANCE('PRICEMAT', mdy(2,15,2008), mdy(4, 13, 2008), mdy(11, 11, 2007), 0.061, 0.061, 0);
```

**Results**

99.9845

---

**FINANCE PV Function**

Computes the present value of an investment.

**Categories:**

CAS
Financial

**Returned data type:**

**DOUBLE**

**Syntax**

`FINANCE('PV', rate, nper, payment, [fv], [type]);`

**Arguments**

**rate**

specifies the interest rate.

**Requirement**

*Rate* is provided as a numeric value and not as a percentage.
Data type: DOUBLE

**nper**
specifies the total number of payment periods.

Data type: DOUBLE

**payment**
specifies the payment that is made each period; the payment cannot change over the life of the annuity. Typically, payment contains principal and interest but no other fees or taxes.

Data type: DOUBLE

**fv**
specifies the future value or a cash balance that you want to attain after the last payment is made. If fv is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type: DOUBLE

**type**
specifies the number 0 or 1 and indicates when payments are due. If type is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the type argument or set it to 0. If payments are due at the beginning of the period, then set type to 1.

Data type: DOUBLE

Example: Computing Description: PV

The following example computes the present value of an investment.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('PV', 0.05, 10, 1000, 200, 0);</td>
<td>-7844.52</td>
</tr>
</tbody>
</table>

**FINANCE RATE Function**

Computes the interest rate per period of an annuity.

Categories: CAS  
Financial

Returned data type: DOUBLE
Syntax

\[ \text{FINANCE('RATE', nper, payment, pv, [fv], [type])} \]

Arguments

\textit{nper}

specifies the total number of payment periods.

Data type: \text{DOUBLE}

\textit{payment}

specifies the payment that is made each period; the payment cannot change
er over the life of the annuity. Typically, \textit{payment} contains principal and interest but
no other fees or taxes. If \textit{payment} is omitted, you must include the \textit{pv} argument.

Data type: \text{DOUBLE}

\textit{pv}

specifies the present value or the lump-sum amount that a series of future
payments is worth currently. If \textit{pv} is omitted, it is assumed to be 0 (zero), and
you must include the \textit{fv} argument.

Data type: \text{DOUBLE}

\textit{fv}

specifies the future value or a cash balance that you want to attain after the last
payment is made. If \textit{fv} is omitted, it is assumed to be 0 (for example, the future
value of a loan is 0).

Data type: \text{DOUBLE}

\textit{type}

specifies the number 0 or 1 and indicates when payments are due. If \textit{type} is
omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the \textit{type} argument
or set it to 0. If payments are due at the beginning of the period, then set \textit{type} to
1.

Data type: \text{DOUBLE}

Example: Computing Description: RATE

The following example computes the interest rate per period of an annuity.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('RATE', 4, -2481, 8000);</td>
<td>0.092148</td>
</tr>
</tbody>
</table>
FINANCE RECEIVED Function

Computes the amount that is received at maturity for a fully invested security.

Arguments

settlement
specifies the settlement date.

Requirement Settlement is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement Maturity is a SAS date.

Data type DOUBLE

investment
specifies the amount that is invested in the security.

Data type DOUBLE

discount
specifies the discount rate of the security.

Requirement Discount is provided as a numeric value and not as a percentage.

Data type DOUBLE

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</tr>
</tbody>
</table>

---

**FINANCE SLN Function**

Computes the straight-line depreciation of an asset for one period.

Categories: CAS
Financial

Returned data type: DOUBLE

**Syntax**

```
FINANCE('SLN', cost, salvage, life);
```

**Arguments**

*cost*

specifies the initial cost of the asset.

Data type: DOUBLE

*salvage*

specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type: DOUBLE
**life**

specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

Data type: **DOUBLE**

**Example: Computing Description: SLN**

The following example computes the straight-line depreciation of an asset for one period.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('SLN', 2000, 200, 11);</code></td>
<td>163.6364</td>
</tr>
</tbody>
</table>

**FINANCE SYD Function**

Computes the sum-of-years digits depreciation of an asset for a specified period.

- **Categories:** CAS, Financial

- **Returned data type:** **DOUBLE**

**Syntax**

`FINANCE('SYD', cost, salvage, life, period);`

**Arguments**

- **cost**
  - specifies the initial cost of the asset.
  - Data type: **DOUBLE**

- **salvage**
  - specifies the value at the end of the depreciation (also called the salvage value of the asset).
  - Data type: **DOUBLE**

- **life**
  - specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).
  - Data type: **DOUBLE**

- **period**
  - specifies a period in the same time units that are used for the argument `life`.  
  - Data type: **DOUBLE**
Data type DOUBLE

Example: Computing SYD Depreciation

The following example computes the sum-of-years digits depreciation of an asset for a specified period.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('SYD', 2000, 200, 11, 1);</code></td>
<td>300</td>
</tr>
</tbody>
</table>

**FINANCE TBILLEQ Function**

Computes the bond-equivalent yield for a treasury bill.

**Categories:**
- CAS
- Financial

**Returned data type:** DOUBLE

**Syntax**

```
FINANCE('TBILLEQ', settlement, maturity, discount);
```

**Arguments**

- **settlement**
  - Specifies the settlement date.
  - **Requirement:** Settlement is a SAS date.
  - **Data type:** DOUBLE

- **maturity**
  - Specifies the maturity date.
  - **Requirement:** Maturity is a SAS date.
  - **Data type:** DOUBLE

- **discount**
  - Specifies the discount rate of the security.
  - **Requirement:** Discount is provided as a numeric value and not as a percentage.
  - **Data type:** DOUBLE
Example: Computing Description: TBILLEQ
The following example computes the bond-equivalent yield for a treasury bill.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('TBILLEQ', mdy(3, 31, 2008), mdy(6, 1, 2008), 0.0914);</td>
<td>0.094151</td>
</tr>
</tbody>
</table>

FINANCE TBILLPRICE Function
Computes the price of a treasury bill per $100 face value.
Categories: CAS, Financial
Returned data type: DOUBLE

Syntax
FINANCE('TBILLPRICE', settlement, maturity, discount);

Arguments
- **settlement**
  - specifies the settlement date.
  - Requirement: Settlement is a SAS date.
  - Data type: DOUBLE

- **maturity**
  - specifies the maturity date.
  - Requirement: Maturity is a SAS date.
  - Data type: DOUBLE

- **discount**
  - specifies the discount rate of the security.
  - Requirement: Discount is provided as a numeric value and not as a percentage.
  - Data type: DOUBLE

Example: Computing Description: TBILLPRICE
The following example computes the price of a treasury bill per $100 face value.
FINANCE TBILLYIELD Function

Computes the yield for a treasury bill.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

\[
\text{FINANCE('TBILLYIELD', settlement, maturity, price)};
\]

Arguments

- **settlement**
  - specifies the settlement date.
  - Requirement: *Settlement* is a SAS date.
  - Data type: DOUBLE

- **maturity**
  - specifies the maturity date.
  - Requirement: *Maturity* is a SAS date.
  - Data type: DOUBLE

- **price**
  - specifies the price of the security per $100 face value.
  - Data type: DOUBLE

Example: Computing Description: TBILLYIELD

The following example computes the yield for a treasury bill.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('TBILLYIELD', mdy(3, 31, 2008), mdy(6, 1, 2008), 98);</code></td>
<td>0.118499</td>
</tr>
</tbody>
</table>
FINANCE VDB Function

Computes the depreciation of an asset for a specified or partial period by using a declining balance method.

Categories: CAS  
Financial

Returned data type: DOUBLE

Syntax

\[ \text{FINANCE}(\text{'VDB'}, \text{cost}, \text{salvage}, \text{life}, \text{start-period}, \text{end-period}, [\text{factor}], [\text{noswitch}]); \]

Arguments

\textit{cost} 
specifies the initial cost of the asset.

Data type DOUBLE

\textit{salvage} 
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

\textit{life} 
specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

Data type DOUBLE

\textit{start-period} 
specifies the first period in the calculation. Payment periods are numbered beginning with 1.

Data type DOUBLE

\textit{end-period} 
specifies the last period in the calculation.

Data type DOUBLE

\textit{factor} 
specifies the rate at which the balance declines. If \textit{factor} is omitted, it is assumed to be 2 (the double-declining balance method).

Data type DOUBLE
**noswitch**
specifies a logical value that determines whether to switch to straight-line
depreciation when the depreciation is greater than the declining balance
calculation. If *noswitch* is omitted, it is assumed to be 1.

Data type  **DOUBLE**

Example: Computing Description: VDB

The following example computes the depreciation of an asset for a specified or
partial period by using a declining balance method.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('VDB', 2400, 300, 10, 0, 1, 1.5);</code></td>
<td>360</td>
</tr>
</tbody>
</table>

**FINANCE XIRR Function**

Computes the internal rate of return for a schedule of cash flows that is not necessarily periodic.

Categories:  **CAS**
Financial

Returned data type:  **DOUBLE**

Syntax

```sql
FINANCE('XIRR', values, dates, [guess]);
```

Arguments

**values**
specifies a series of cash flows that corresponds to a schedule of payments in
dates. The first payment is optional and corresponds to a cost or payment that
occurs at the beginning of the investment. If the first value is a cost or payment,
it must be a negative value. All succeeding payments are discounted based on a
365-day year. The series of values must contain at least one positive value and
one negative value.

Data type  **DOUBLE**

**dates**
specifies a schedule of payment dates that corresponds to the cash flow
payments. The first payment date indicates the beginning of the schedule of
payments. All other dates must be later than this date, but they can occur in any
order.

Requirement  **Dates are SAS dates.**
**Data type**

DOUBLE

**guess**

specifies an optional number that you guess is close to the result of XIRR.

**Data type**

DOUBLE

**Example: Computing Description: XIRR**

The following example computes the internal rate of return for a schedule of cash flows that is not necessarily periodic.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select FINANCE('XIRR', -10000, 2750, 4250, 3250, 2750, mdy(1, 1, 2008), mdy(3, 1, 2008), mdy(10, 30, 2008), mdy(2, 15, 2009), mdy(4, 1, 2009), 0.1);</td>
<td>0.373363</td>
</tr>
</tbody>
</table>

**FINANCE XNPV Function**

Computes the net present value for a schedule of cash flows that is not necessarily periodic.

**Categories:**

CAS
Financial

**Returned data type:**

DOUBLE

**Syntax**

FINANCE('XNPV', rate, values, dates);

**Arguments**

**rate**

specifies the interest rate.

**Requirement**

Rate is provided as a numeric value and not as a percentage.

**Data type**

DOUBLE

**values**

specifies a series of cash flows that corresponds to a schedule of payments in dates. The first payment is optional and corresponds to a cost or payment that occurs at the beginning of the investment. If the first value is a cost or payment, it must be a negative value. All succeeding payments are discounted based on a 365-day year. The series of values must contain at least one positive value and one negative value.
Data type: DOUBLE

**dates**
specifies a schedule of payment dates that corresponds to the cash flow payments. The first payment date indicates the beginning of the schedule of payments. All other dates must be later than this date, but they can occur in any order.

**Requirement**
*Dates are SAS dates.*

Data type: DOUBLE

---

**Example: Computing Description: XNPV**

The following example computes the net present value for a schedule of cash flows that is not necessarily periodic.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select FINANCE('XNPV', .09, -10000, 2750, 4250, 3250, 2750, mdy(1, 1, 2008), mdy(3, 1, 2008), mdy(10, 30, 2008), mdy(2, 15, 2009), mdy(4, 1, 2009));</code></td>
<td>2086.648</td>
</tr>
</tbody>
</table>
**Requirement**  
*Maturity* is a SAS date.

**Data type**  
DOUBLE

**rate**  
specifies the interest rate.

**Requirement**  
*Rate* is provided as a numeric value and not as a percentage.

**Data type**  
DOUBLE

**price**  
specifies the price of the security per $100 face value.

**Data type**  
DOUBLE

**redemption**  
specifies the amount to be received at maturity.

**Data type**  
DOUBLE

**frequency**  
specifies the number of coupon payments per year. For annual payments,  
*frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments,  
*frequency*=4.

**Data type**  
DOUBLE

**basis**  
specifies an optional parameter as a character or numeric value that indicates  
the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>
<th>Day Count Method</th>
</tr>
</thead>
<tbody>

Data type: **DOUBLE**

**Example: Computing Description: YIELDDISC**

The following example computes the annual yield for a discounted security (for example, a treasury bill).

```
select FINANCE('YIELDDISC', mdy(2,15,2008),
    mdy(11, 15, 2016), 95.04287, 100, 0);
```

Results: 0.005961

**FINANCE YIELDMAT Function**

Computes the annual yield of a security that pays interest at maturity.

**Syntax**

```
FINANCE('YIELDMAT', settlement, maturity, issue, rate, price, [basis]);
```

**Arguments**

- **settlement**
  - specifies the settlement date.

  **Requirement**
  - *Settlement* is a SAS date.

  **Data type**
  - DOUBLE
maturity
specifies the maturity date.
Requirement  *Maturity* is a SAS date.
Data type  DOUBLE

issue
specifies the issue date of the security.
Requirement  *Issue* is a SAS date.
Data type  DOUBLE

rate
specifies the interest rate.
Requirement  *Rate* is provided as a numeric value and not as a percentage.
Data type  DOUBLE

price
specifies the price of the security per $100 face value.
Data type  DOUBLE

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

<table>
<thead>
<tr>
<th>Numeric Value</th>
<th>String Value</th>

<td>European 30/360</td>
</tr>
</tbody>
</table>

Data type  DOUBLE

Example: Computing Description: YIELDMAT
The following example computes the annual yield of a security that pays interest at maturity.
FLOOR Function

Returns the largest integer less than or equal to a numeric value expression.

Categories: CAS
Truncation

Returned data type: DECIMAL, DOUBLE, NUMERIC

Syntax

FLOOR(expression)

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Data type DECIMAL, DOUBLE, NUMERIC

See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

Details

If expression is within 1E-12 of an integer, the function returns that integer. If the result is a number that does not fit into the range of a DOUBLE, the FLOOR function fails.

If the argument is DECIMAL, the result is DECIMAL. Otherwise, the argument is converted to DOUBLE (if not so already), and the result is DOUBLE.

Comparisons

The FLOOR function fuzzes the results so that if the results are within 1E-12 of an integer, the FLOOR function returns that integer. The FLOORZ function uses zero fuzzing. Therefore, with the FLOORZ function, you might get unexpected results.

Example

Table: DENSITIES on page 1081
The following statement illustrates the FLOOR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select floor(1.95);</td>
<td>1</td>
</tr>
<tr>
<td>select floor(density) from densities;</td>
<td>67 306 30 323 20 383 31 309 6 247</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “CEIL Function” on page 335
- “CEILZ Function” on page 337
- “FLOORZ Function” on page 484

FLOORZ Function

Returns the largest integer that is less than or equal to the argument, using zero fuzzing.

Categories: CAS

Truncation

Returned data type: DOUBLE

Syntax

FLOORZ(expression)

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48
Comparisons

Unlike the FLOOR function, the FLOORZ function uses zero fuzzing. If the argument is within 1E-12 of an integer, the FLOOR function fuzzes the result to be equal to that integer. The FLOORZ function does not fuzz the result. Therefore, with the FLOORZ function, you might get unexpected results.

Example

Table: DENSITIES on page 1081

The following statements illustrate the FLOORZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select floorz(-2.4);</td>
<td>-3</td>
</tr>
<tr>
<td>select floorz(-1.6);</td>
<td>-2</td>
</tr>
<tr>
<td>select floorz(density) from densities;</td>
<td>67 306 30 323 323 20 383 31 309 6 247</td>
</tr>
</tbody>
</table>

FMTINFO Function

Returns information about a SAS format or informat.

Categories: CAS
Special

Restriction: This function returns information about formats that are supplied by SAS. It cannot be used for user-defined formats that are created with the FORMAT procedure.
Syntax

FMTINFO('format-name', 'information-type');

Arguments

'format-name'
specifies the name of a SAS format or informat.

Requirement  format-name must be enclosed in single quotation marks.

information-type
specifies the type of information that is returned. format-information can be one of the following values:

'CAT'
returns the function category.

'TYPE'
returns whether the format-name is a format, an informat, or both.

'DESC'
returns a short description of the format or informat.

'MIND'
returns the minimum number of digits to the right of the decimal place in the format or informat.

'MAXD'
returns the maximum number of digits to the right of the decimal place in the format or informat.

'DEFAULT'
returns the default number of digits to the right of the decimal place in the format or informat.

'MINW'
returns the minimum width value of the format or informat.

'MAXW'
returns the maximum width value of the format or informat.

'_DEFAULT'
returns the default width value of the format or informat.

Restriction  You can specify only one information-type argument.

Requirement information-type must be enclosed in single quotation marks.

Details

The FMTINFO function returns information about a format or informat. You can return information about a format or informat’s category, the type of language element, a description of the language element, and the minimum, maximum, and default decimal and width values.

You cannot specify multiple arguments with the FMTINFO function.

The FMTINFO function returns a character string for all data values, including the numeric value arguments MIND, MAXD, DEFD, MINW, MAXW, and DEFW.
Example

The following example returns information about the DATE format.

```sql
select fmtinfo('date','type') as ftype,
       fmtinfo('date','cat') as fcat,
       fmtinfo('date','desc') as fdesc,
       fmtinfo('date','mind') as fmind,
       fmtinfo('date','maxd') as fmaxd,
       fmtinfo('date','defd') as fdefd,
       fmtinfo('date','minw') as fminw,
       fmtinfo('date','maxw') as fmaxw,
       fmtinfo('date','defw') as fdefw;
```

**Output 4.8  Result of FMTINFO Query on DATE Format**

<table>
<thead>

</tr>
</tbody>
</table>

**FNONCT Function**

Returns the value of the noncentrality parameter of an F distribution.

- **Categories:** CAS Mathematical
- **Returned data type:** DOUBLE

**Syntax**

```
FNONCT(x, ndf, ddf, probability)
```

**Arguments**

- **x**
  - is a numeric random variable.
  - Range: $x \geq 0$
  - Data type: DOUBLE
- **ndf**
  - is a numeric numerator degree of freedom parameter.
  - Range: $ndf > 0$
  - Data type: DOUBLE
- **ddf**
  - is a numeric denominator degree of freedom parameter.
Range  $ddf > 0$

Data type  DOUBLE

**probability**

is a probability.

Range  $0 < probability < 1$

Data type  DOUBLE

Details

The FNONCT function returns the nonnegative noncentrality parameter from a noncentral $F$ distribution whose parameters are $x$, $ndf$, $ddf$, and $nc$. If $probability$ is greater than the probability from the central $F$ distribution whose parameters are $x$, $ndf$, and $ddf$, a root to this problem does not exist. In this case a missing value is returned. A Newton-type algorithm is used to find a nonnegative root $nc$ of the equation

$$P_f(x|ndf, ddf, nc) - prob = 0$$

The following relationship applies to the preceding equation:

$$P_f(x|ndf, ddf, nc) = e^{\frac{-nc}{2}} \sum_{j=0}^{\infty} \left(\frac{nc}{2}\right)^j I\left(\frac{ndf}{2} + j, \frac{ddf}{2}ight)$$

In the equation, $I(\ldots)$ is the probability from the beta distribution that is given by the following equation:

$$I_x(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a + b)} \int_0^x t^{a-1}(1 - t)^{b-1} dt$$

If the algorithm fails to converge to a fixed point, a missing value is returned.

Example

The following example computes the noncentrality parameter from the $F$ distribution.

```plaintext
proc ds2;
  data test /overwrite=yes;
    dcl double x df ddf nc prob;
    method init();
      x=2;
      df=4;
      ddf=5;
      do nc=1 to 3 by .5;
         prob=probf(x, df, ddf, nc);
         output;
      end;
    enddata;
run;
quit;
```
proc print data=test;
run;

proc fedsql;
  select * from test;
  select fnonct(x, df, ddf, prob) from test;
quit;

Output 4.9  Contents of Table Test

- “TNONCT Function” on page 768

FUZZ Function

Returns the nearest whole number if the argument is within 1E-12 of that number.

Categories: CAS
Truncation

Returned data type: DOUBLE
Syntax

**FUZZ**(*expression*)

Arguments

*expression*

specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

The FUZZ function returns the nearest whole number if the expression is within 1E-12 of the number (that is, if the absolute difference between the whole number and argument is less than 1E-12). Otherwise, the expression is returned.

Example

The following statement illustrates the FUZZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select fuzz(5.99999999);</code></td>
<td>5.99999999</td>
</tr>
</tbody>
</table>

**GAMINV Function**

Returns a quantile from the gamma distribution.

Categories:

CAS

Quantile

Returned data type: DOUBLE

Syntax

**GAMINV**(p, a)

Arguments

*p*

specifies any valid expression that evaluates to a numeric probability.

Range: 0 ≤ p < 1
Data type DOUBLE

See "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

\( a \)
specifies any valid expression that evaluates to a numeric shape parameter.

Range \( a > 0 \)

Data type DOUBLE

See "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details
The GAMINV function returns the \( p \)th quantile from the gamma distribution, with shape parameter \( a \). The probability that a row from a gamma distribution is less than or equal to the returned quantile is \( p \).

Note: GAMINV is the inverse of the PROBGAM function.

Example
The following statements illustrate the GAMINV function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select gaminv(0.5, 9);</td>
<td>8.6689513844</td>
</tr>
<tr>
<td>select gaminv(0.1, 2.1);</td>
<td>0.5841912369</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "PROBGAM Function" on page 690

GAMMA Function
Returns the value of the gamma function.

Categories: CAS
Mathematical
Returned data type: DOUBLE

Syntax

\[
\text{GAMMA}(\text{expression})
\]

Arguments

\textit{expression}

specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Restriction</th>
<th>Nonpositive integers are invalid.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>See</td>
<td>“&lt;sql-expression&gt; Expression” on page 820</td>
</tr>
<tr>
<td></td>
<td>“FedSQL Expressions” on page 48</td>
</tr>
</tbody>
</table>

Details

The GAMMA function returns the integral, which is given by the following equation.

\[
\text{GAMMA}(x) = \int_{0}^{\infty} t^{x-1} e^{-t} \, dt.
\]

For positive integers, GAMMA(x) is (x − 1)!. This function is commonly denoted by \( \Gamma(x) \).

Example

The following statement illustrates the GAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{select gamma(6);}</td>
<td>120</td>
</tr>
</tbody>
</table>

GARKHCLPRC Function

Calculates call prices for European options on stocks, based on the Garman-Kohlhagen model.

Categories: CAS, Financial

Returned data type: DOUBLE
Syntax

GARKHCLPRC(\(E, t, S, R_d, R_f, \sigma\))

Arguments

\(E\)

is a nonmissing, positive value that specifies the exercise price.

Requirement Specify \(E\) and \(S\) in the same units.

Data type DOUBLE

\(t\)

is a nonmissing value that specifies the time to maturity.

Data type DOUBLE

\(S\)

is a nonmissing, positive value that specifies the spot currency price.

Requirement Specify \(S\) and \(E\) in the same units.

Data type DOUBLE

\(R_d\)

is a nonmissing, positive fraction that specifies the risk-free domestic interest rate for period \(t\).

Requirement Specify a value for \(R_d\) for the same time period as the unit of \(t\).

Data type DOUBLE

\(R_f\)

is a nonmissing, positive fraction that specifies the risk-free foreign interest rate for period \(t\).

Requirement Specify a value for \(R_f\) for the same time period as the unit of \(t\).

Data type DOUBLE

\(\sigma\)

is a nonmissing, positive fraction that specifies the volatility of the currency rate.

Requirement Specify a value for \(\sigma\) for the same time period as the unit of \(t\).

Data type DOUBLE

Details

The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. The function is based on the following relationship:

\[
\text{CALL} = SN(d_1)(e^{-R_f t}) - EN(d_2)(e^{-R_d t})
\]

Arguments
\[ d_1 = \frac{\ln(S/E) + (R_d - R_f + \frac{\sigma^2}{2})}{\sigma \sqrt{t}} \]
\[ d_2 = d_1 - \sigma \sqrt{t} \]

The following arguments apply to the preceding equation:

- \( \sigma \) specifies the volatility of the underlying asset.
- \( \sigma^2 \) specifies the variance of the rate of return.

For the special case of \( t = 0 \), the following equation is true:

\[ \text{CALL} = \max((S - E), 0) \]

For information about the basics of pricing, see "Using Pricing Functions" in SAS Functions and CALL Routines: Reference.

### Comparisons

The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. These functions return a scalar value.

### Example

The following statements illustrate the GARKHCLPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select garkhclprc(40, .5, 38, .06, .04, .2);</td>
<td>1.449425</td>
</tr>
<tr>
<td>select garkhclprc(19, .25, 20, .05, .03, .09);</td>
<td>1.130421</td>
</tr>
</tbody>
</table>
GARKHPTPRC Function

Calculates put prices for European options on stocks, based on the Garman-Kohlhagen model.

Returned data type: DOUBLE

Syntax

GARKHPTPRC(E, t, S, R_d, R_f, sigma)

Arguments

- **E**
  
is a nonmissing, positive value that specifies the exercise price.

  Requirement: Specify E and S in the same units.

  Data type: DOUBLE

- **t**
  
is a nonmissing value that specifies the time to maturity, in years.

  Data type: DOUBLE

- **S**
  
is a nonmissing, positive value that specifies the spot currency price.

  Requirement: Specify S and E in the same units.

  Data type: DOUBLE

- **R_d**
  
is a nonmissing, positive fraction that specifies the risk-free domestic interest rate for period t.

  Requirement: Specify a value for R_d for the same time period as the unit of t.

  Data type: DOUBLE

- **R_f**
  
is a nonmissing, positive fraction that specifies the risk-free foreign interest rate for period t.
Requirement: Specify a value for $R_t$ for the same time period as the unit of $t$.

**Data type:** DOUBLE

**$\sigma$** is a nonmissing, positive fraction that specifies the volatility of the currency rate.

**Data type:** DOUBLE

### Details

The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. The function is based on the following relationship:

$$\text{PUT} = \text{CALL} - S(e^{-R_f t}) + E(e^{-R_f t})$$

### Arguments

- **$S$** specifies the spot currency price.
- **$E$** specifies the exercise price of the option.
- **$t$** specifies the time to expiration, in years.
- **$R_d$** specifies the risk-free domestic interest rate for period $t$.
- **$R_f$** specifies the risk-free foreign interest rate for period $t$.

$$d_1 = \frac{\ln(S/E) + (R_d - R_f + \frac{\sigma^2}{2})t}{\sigma \sqrt{t}}$$

$$d_2 = d_1 - \sigma \sqrt{t}$$

The following arguments apply to the preceding equation:

- **$\sigma$** specifies the volatility of the underlying asset.
- **$\sigma^2$** specifies the variance of the rate of return.

For the special case of $t=0$, the following equation is true:

$$\text{PUT} = \max(E - S, 0)$$

For information about the basics of pricing, see “Using Pricing Functions” in SAS Functions and CALL Routines: Reference.

### Comparisons

The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. The GARKHCLPRC function
calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. These functions return a scalar value.

Example

The following statements illustrate the GARKHPTPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select garkhptprc(50, .7, 55, .05, .04, .2);</td>
<td>1.405088</td>
</tr>
<tr>

GCD Function

Returns the greatest common divisor for a set of integers.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax

GCD(expression-1, expression-2 [, ...expression-n])

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Requirement
At least two arguments are required.

Data type
DOUBLE

See
- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48
Details

The GCD (greatest common divisor) function returns the greatest common divisor of one or more integers. For example, the greatest common divisor for 30 and 42 is 6. The greatest common divisor is also called the highest common factor.

Example

The following statements illustrate the GCD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select gcd(5,15);</td>
<td>5</td>
</tr>
<tr>
<td>select gcd(36,45);</td>
<td>9</td>
</tr>
</tbody>
</table>

Functions:

- “LCM Function” on page 566

GEOMEAN Function

Returns the geometric mean.

Categories: CAS

Descriptive Statistics

Returned data type: DOUBLE

Syntax

GEOMEAN(expression [, ...expression])

Arguments

expression

is any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48
Details

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If any argument is zero, then the geometric mean is zero. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the geometric mean of the non-null or nonmissing values.

Let \( n \) be the number of arguments with non-null or nonmissing values, and let \( x_1, x_2, \ldots, x_n \) be the values of those arguments. The geometric mean is the \( n^{th} \) root of the product of the values:

\[
\sqrt[n]{x_1 \times x_2 \times \cdots \times x_n}
\]

Equivalently, the geometric mean is shown in this equation.

\[
\exp\left(\frac{\log(x_1) + \log(x_2) + \cdots + \log(x_n)}{n}\right)
\]

Floating-point arithmetic often produces tiny numerical errors. Some computations that result in zero when exact arithmetic is used might result in a tiny nonzero value when floating-point arithmetic is used. Therefore, GEOMEAN fuzzes the values of arguments that are approximately zero. When the value of one argument is extremely small relative to the largest argument, the former argument is treated as zero. If you do not want SAS to fuzz the extremely small values, then use the GEOMEANZ function.

Comparisons

The MEAN function returns the arithmetic mean (average), and the HARMEAN function returns the harmonic mean, whereas the GEOMEAN function returns the geometric mean of the non-null or nonmissing values. Unlike GEOMEANZ, GEOMEAN fuzzes the values of the arguments that are approximately zero.

Example

The following statements illustrate the GEOMEAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select geomean(1,2,2,4);</td>
<td>2</td>
</tr>
<tr>
<td>select geomean(.,2,4,8);</td>
<td>4</td>
</tr>
</tbody>
</table>

HARMEAN Function

Returns the harmonic mean.

Categories:
- CAS
- Descriptive Statistics

Returned data type: DOUBLE

Syntax

HARMEAN(expression [ , ...expression])

Arguments

eexpression
specifies any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See
- "<sql-expression> Expression” on page 820
- "FedSQL Expressions” on page 48

Details

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If all the arguments are null
or missing values, then the result is a null or missing value. Otherwise, the result is the harmonic mean of the non-null or nonmissing values.

If any argument is zero, then the harmonic mean is zero. Otherwise, the harmonic mean is the reciprocal of the arithmetic mean of the reciprocals of the values.

Let \( n \) be the number of arguments with non-null or nonmissing values, and let \( x_1, x_2, \ldots, x_n \) be the values of those arguments. The harmonic mean is shown in this equation.

\[
\frac{1}{\frac{1}{x_1} + \frac{1}{x_2} + \cdots + \frac{1}{x_n}}
\]

Floating-point arithmetic often produces tiny numerical errors. Some computations that result in zero when exact arithmetic is used might result in a tiny nonzero value when floating-point arithmetic is used. Therefore, HARMEAN fuzzes the values of arguments that are approximately zero. When the value of one argument is extremely small relative to the largest argument, the former argument is treated as zero. If you do not want SAS to fuzz the extremely small values, then use the HARMEANZ function.

HMS Function

Returns a SAS time value from hour, minute, and second values.

Categories: CAS
            Date and Time

Returned data type: DOUBLE

Syntax

HMS(hour, minute, second)

Arguments

hour

specifies a numeric expression that represents a whole number from 1 through 12.

Data type: DOUBLE

See

"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

minute

specifies a numeric expression that represents a whole number from 1 through 59.
**HOLIDAY Function**

Returns a SAS date value of a specified holiday for a specified year.

**HOLIDAY Function**

Returns a SAS date value of a specified holiday for a specified year.

**Data type** DOUBLE

**See**
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

**second**

specifies a numeric expression that represents a whole number from 1 through 59.

**Data type** DOUBLE

**See**
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

**Details**

The HMS function returns a numeric value that represents a SAS time value. A SAS time value is a number that represents the number of seconds since midnight of the current day.

**Example**

The following statements illustrate the HMS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select hms(12,45,10);</td>

**Data type**  

**CHAR**

**year**  

is a numeric constant, variable, or expression that specifies a four-digit year. If you use a two-digit year, then you must specify the YEARCUTOFF= system option.

**Data type**  

**DOUBLE**

**Details**  

The HOLIDAY function computes the date on which a specific holiday occurs in a specified year. Only certain common U.S. and Canadian holidays are defined for use with this function. (See “Holiday Values and Their Descriptions” in SAS Functions and CALL Routines: Reference for a list of valid holidays.)

The definition of many holidays has changed over the years. In the U.S., Executive Order 11582, issued on February 11, 1971, fixed the observance of many U.S. federal holidays.
The current holiday definition is extended indefinitely into the past and future, although many holidays have a fixed date at which they were established. Some holidays have not had a consistent definition in the past.

The HOLIDAY function returns a SAS date value. To convert the SAS date value to a calendar date, use any valid SAS date format, such as the DATE9. format.

Comparisons

In some cases, the HOLIDAY function and the NWKDOM function return the same result. For example, the statement `holiday('thanksgiving', 2012);` returns the same value as `nwkdom(4, 5, 11, 2012);`.

In other cases, the HOLIDAY function and the MDY function return the same result. For example, the statement `holiday('christmas', 2012);` returns the same value as `mdy(12, 25, 2012);`.

Example

The following statements illustrate the HOLIDAY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(holiday('thanksgiving', 2013), date.);</code></td>
<td><code>28NOV2013</code></td>
</tr>
<tr>
<td><code>select put(holiday('boxing', 2013), date.);</code></td>
<td><code>26DEC2013</code></td>
</tr>
<tr>
<td><code>select put(holiday('easter', 2013), date.);</code></td>
<td><code>31MAR2013</code></td>
</tr>
<tr>
<td><code>select put(holiday('canada', 2013), date.);</code></td>
<td><code>01JUL2013</code></td>
</tr>
<tr>
<td><code>select put(holiday('fathers', 2013), date.);</code></td>
<td><code>16JUN2013</code></td>
</tr>
<tr>
<td><code>select put(holiday('valentines', 2013), date.);</code></td>
<td><code>14FEB2013</code></td>
</tr>
<tr>
<td><code>select put(holiday('victoria', 2013), date.);</code></td>
<td><code>20MAY2013</code></td>
</tr>
</tbody>
</table>

HOUR Function

Returns the hour from a time or datetime value.

Categories: Date and Time

CAS
Syntax

\texttt{HOUR(} \textit{time} \texttt{[datetime])}

Arguments

\textit{time}

specifies any valid expression that represents a time value.

Data type \hspace{1em} \textsc{time}  \hspace{1em} \textsc{time}  \hspace{1em} \textsc{TIME}

See \textit{“FedSQL Expressions” on page 48}

\textit{datetime}

specifies any valid expression that represents a datetime value.

Data type \hspace{1em} \textsc{datetime}  \hspace{1em} \textsc{datetime}  \hspace{1em} \textsc{TIMESTAMP}

See \textit{“FedSQL Expressions” on page 48}

Example

Table: \textsc{custonline} on page 1080

The following statement illustrates the \textit{HOUR} function:

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Statements} & \textbf{Results} \\
\hline
\texttt{select hour(endtime) from custonline;} & 10  \\
& 22  \\
& 19  \\
& 12  \\
& 12  \\
& 16  \\
& 15  \\
& 11  \\
& 10  \\
& 9  \\
\texttt{select hour(current_time);} & 14  \\
\hline
\end{tabular}
\end{table}

\end{itemize}
IBESSEL Function

Returns the value of the modified Bessel function.

Categories: CAS Mathematical

Returned data type: DOUBLE

Syntax

IBESSEL(nu, x, kode)

Arguments

nu
 specifies a numeric constant, variable, or expression.

Range $\nu \geq 0$

Data type DOUBLE

x
 specifies a numeric constant, variable, or expression.

Range $x \geq 0$

Data type DOUBLE

kode
 is a numeric constant, variable, or expression that specifies a nonnegative whole number.

Data type DOUBLE

Details

The IBESSEL function returns the value of the modified Bessel function of order $\nu$ evaluated at $x$ (Abramowitz, Stegun 1964; Amos, Daniel, Weston 1977). When $kode$ equals 0, the Bessel function is returned. Otherwise, the value of the following function is returned:

$$e^{-x}I_{\nu}(x)$$

Example

The following statements illustrate the IBESSEL function:
### Statements

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select ibessel(2, 2, 0);</code></td>
<td>0.688948</td>
</tr>
<tr>
<td><code>select ibessel(2, 2, 1);</code></td>
<td>0.091239</td>
</tr>
</tbody>
</table>

## IFNULL Function

Checks the value of the first expression and, if it is null or a SAS missing value, returns the second expression.

**Categories:**
- Special
- CAS

**Returned data type:**
Any data type, depending on the context

### Syntax

**IFNULL**(expression-1, expression-2)

### Arguments

**expression**
- specifies any valid expression.

**Data type**
All data types are valid.

**See**
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

### Details

The IFNULL function returns the first expression if it is not null. You can use the IFNULL function to replace a null or SAS missing value value with another value.

### Comparisons

The NULLIF expression compares two expressions and returns a null value if the two expressions are equal. The IFNULL function checks the value of the first expression and if it is null, returns the second expression; otherwise, returns the first expression.
Example

Table: WORLD_CITY_COORDS on page 1089

In the table WORLDTEMPS, the city for China in the last row contains a missing value.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select ifnull(AvgHigh, 0) as &quot;AvgHigh: 0 indicates null/missing&quot; from worldtems;</td>
<td>AvgHigh: 0 indicates null/missing</td>
</tr>
<tr>
<td></td>
<td>90</td>
</tr>
<tr>
<td></td>
<td>70</td>
</tr>
<tr>
<td></td>
<td>86</td>
</tr>
<tr>
<td></td>
<td>90</td>
</tr>
<tr>
<td></td>
<td>97</td>
</tr>
<tr>
<td></td>
<td>83</td>
</tr>
<tr>
<td></td>
<td>76</td>
</tr>
<tr>
<td></td>
<td>89</td>
</tr>
<tr>
<td></td>
<td>90</td>
</tr>
<tr>
<td></td>
<td>89</td>
</tr>
<tr>
<td></td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>78</td>
</tr>
</tbody>
</table>

Expressions:
- “NULLIF Expression” on page 818

INDEX Function

Searches a character expression for a string of characters, and returns the position of the string's first character for the first occurrence of the string.

Categories: CAS, Character

Returned data type: INTEGER

Syntax

INDEX(target-expression, search-expression)

Arguments

target-expression

specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR
search-expression
specifies any valid expression that evaluates or can be coerced to a character string that is used to search for in target-expression.

Tip
Enclose a literal string of characters in single quotation marks.

Details
The INDEX function searches target-expression, from left to right, for the first occurrence of the string specified in search-expression, and returns the position in target-expression of the string's first character. If the string is not found in target-expression, INDEX returns a value of 0. If there are multiple occurrences of the string, INDEX returns only the position of the first occurrence.

Note: When either the target-expression or the search-expression has a length of 0, the INDEX function returns a value of 0. It should also be noted that an undeclared VARCHAR variable has a length of 0.

Comparisons
The VERIFY function returns the position of the first character in target-expression that does not contain search-expression where the INDEX function returns the position of the first occurrence of search-expression that is present in target-expression.

Example
The following statement illustrates the INDEX statement:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select index('aabb','ab');</code></td>
<td>2</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "INDEXC Function" on page 514
- "VERIFY Function" on page 785
INDEXC Function

Searches a character expression for specified characters and returns the position of the first occurrence of any of the characters.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax

INDEXC(target-expression, search-expression[, …search-expression])

Arguments

target-expression
specifies any valid expression that evaluates or can be coerced to a character string that is searched.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

search-expression
specifies the characters to search for in target-expression.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip Enclose a literal string of characters in single quotation marks.

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

The INDEXC function searches target-expression, from left to right, for the first occurrence of any character present in the search expressions and returns the position in target-expression of that character. If none of the characters in the search expressions are found in target-expression, INDEXC returns a value of 0.

Comparisons

The INDEXC function searches for the first occurrence of any individual character that is present within the search expression, whereas the INDEX function searches for the first occurrence of the search expression as a pattern.
Example

The following statement illustrates the INDEXC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select indexc('aabb','ab');</td>
<td>1</td>
</tr>
</tbody>
</table>

Functions:

- “INDEX Function” on page 512

INPUTC Function

Enables you to specify a character informat at run time.

Categories:
- CAS
- Special

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INPUTC(source, informat[, w])

Arguments

source

specifies a character constant, variable, or expression to which you want to apply the informat.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

informat

is a character constant, variable, or expression that contains the character informat that you want to apply to source.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

w

specifies any valid expression that evaluates to a numeric width to apply to the informat.

Interaction

If you specify a width here, it overrides any width specification in the informat.

Data type: DOUBLE
Details
If the INPUTC function returns a value to a variable that has not yet been assigned a length, by default the variable length is determined by the length of the first argument.

Comparisons
The INPUTN function enables you to specify a numeric informat at run time.

Example
The following statements illustrate the INPUTC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select inputc('positive', '$upcase15.');</td>
<td>POSITIVE</td>
</tr>
<tr>
<td>select inputc('positive', '$upcase15.', 3);</td>
<td>POS</td>
</tr>
</tbody>
</table>

See Also

**Functions:**
- “INPUTN Function” on page 516
- "PUT Function” on page 708

**INPUTN Function**
Enables you to specify a numeric informat at run time.

<table>
<thead>
<tr>
<th>Categories:</th>
<th>CAS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Special</td>
<td></td>
</tr>
</tbody>
</table>

| Returned data type: | DOUBLE |

**Syntax**

\[
\text{INPUTN}(\text{source, informat[, w[, d]]})
\]

**Arguments**

- **source**
  - specifies a character constant, variable, or expression to which you want to apply the informat.
  - Data type: CHAR
**informat**

is a character constant, variable, or expression that contains the numeric informat that you want to apply to *source*.

Data type **CHAR**

*w*

is a numeric constant, variable, or expression that specifies a width to apply to the informat.

Interaction

If you specify a width here, it overrides any width specification in the informat.

Data type **DOUBLE**

*d*

is a numeric constant, variable, or expression that specifies the number of decimal places to use.

Interaction

If you specify a number here, it overrides any decimal-place specification in the informat.

Data type **DOUBLE**

**Comparisons**

The INPUTC function enables you to specify a character informat at run time. Using the PUT function is faster because you specify the informat at compile time.

**Example**

The following statement illustrates the INPUTN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select inputn('20,000.00', 'comma10.2')</td>
<td>20000</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- "INPUTC Function" on page 515
- "PUT Function" on page 708

**INT Function**

Returns the whole number, fuzzed to avoid unexpected floating-point results.

Categories: CAS
            Truncation
Returned data type: DOUBLE

Syntax

\[\text{INT}(\text{expression})\]

Arguments

\textit{expression}

specifies any expression that evaluates to a numeric value.

Data type: DOUBLE

See

"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

In FedSQL, INT is a reserved word. To use the function, you must specify the function name as a delimited identifier.

The INT function returns the whole number portion of the argument (truncates the decimal portion). If the argument's value is within 1E-12 of a whole number, the function results in that whole number. If the value of \textit{expression} is positive, the INT function has the same result as the FLOOR function. If the value of \textit{expression} is negative, the INT function has the same result as the CEIL function.

Comparisons

Unlike the INTZ function, the INT function fuzzes the result. If the argument is within 1E-12 of a whole number, the INT function fuzzes the result to be equal to that whole number. The INTZ function does not fuzz the result. Therefore, with the INTZ function, you might get unexpected results.

Example

The following statements illustrate the INT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select &quot;int&quot;(2.6);</td>
<td>2</td>
</tr>
<tr>
<td>select &quot;int&quot;(-2.4);</td>
<td>-2</td>
</tr>
<tr>
<td>select &quot;int&quot;(1+1.3-11);</td>
<td>-8</td>
</tr>
<tr>
<td>select &quot;int&quot;(-1.6);</td>
<td>-1</td>
</tr>
</tbody>
</table>

- “MODZ Function” on page 603
- “ROUND Function” on page 723

INTCINDEX Function

Returns the cycle index when a date, time, or timestamp interval and value are specified.

Categories: CAS
Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

INTCINDEX({interval[multiple][shift-index]}, date-time-value)

Arguments

interval
specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note
The possible values of interval are listed in “Intervals Used with Date and Time Functions” in SAS Formats and Informats: Reference.

Tip
Interval can appear in uppercase or lowercase.

Example
YEAR specifies year-based intervals.

multiple
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE
See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in SAS Functions and CALL Routines: Reference for more information.

Example

YEAR2 specifies a two-year, or biennial, interval type.

**shift-index**

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

**Restrictions**

The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

**Data type**

DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in SAS Functions and CALL Routines: Reference for more information.

Example

YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

date-time-value

specifies a date, time, or timestamp value that represents a time period of a specified interval.

**Data type**

DOUBLE

Details

The Basics

The INTCINDEX function returns the index of the seasonal cycle when you specify an interval and a DATE, TIME, or TIMESTAMP value. For example, if the interval is MONTH, each observation in the data corresponds to a particular month. Monthly data is considered to be periodic for a one-year period. A year contains 12 months, so the number of intervals (months) in a seasonal cycle (year) is 12. WEEK is the seasonal cycle for an interval that is equal to DAY. This example returns a value of 36 because September 1, 2013, is the sixth day of the 35th week of the year.

```
select intcindex('day', date'2013-09-01');
```

For more information about working with date and time intervals, see "Date and Time Intervals" in SAS Functions and CALL Routines: Reference.
The INTCINDEX function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For a list of these intervals, see “Retail Calendar Intervals: ISO 8601 Compliant” in SAS Language Reference: Concepts.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

\[ \text{interval[\{multiple\}[.\{shift-index\}] \] } \]

For more information, see “Arguments” on page 519.

Comparisons

The INTCINDEX function returns the cycle index, whereas the INTINDEX function returns the seasonal index.

In this example, the INTCINDEX function returns the week of the year.

```sql
select intcindex('day', date'2013-04-04');
```

In this example, the INTINDEX function returns the day of the week.

```sql
select intindex('day', date'2013-04-04');
```

In this example, the INTCINDEX function returns the hour of the day.

```sql
select intcindex('minute', timestamp'2012-09-01 00:00:00');
```

In this example, the INTINDEX function returns the minute of the hour.

```sql
select intindex('minute', timestamp'2012-09-01 00:00:00');
```

In the example `intseas(intcycle('interval'))`, the INTSEAS function returns the maximum number that could be returned by `intcindex('interval', date)`.

Example

The following statements illustrate the INTCINDEX function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select intcindex('dtqtr', timestamp'2013-05-23 05:03:01');</code></td>
<td>1</td>
</tr>
<tr>
<td><code>select intcindex('tenday', date'2013-12-13');</code></td>
<td>1</td>
</tr>
<tr>
<td><code>select intcindex('minute', time'23:13:02');</code></td>
<td>24</td>
</tr>
<tr>
<td><code>select intcindex('semimonth', timestamp'2013-05-05 10:54:03');</code></td>
<td>1</td>
</tr>
</tbody>
</table>
INTCK Function

Returns the number of interval boundaries of a given kind that lie between two SAS dates, times, or timestamp values encoded as DOUBLE.

**Syntax**

```
INTCK(interval[multiple][.shift-index], start-date, end-date[, 'method'])
INTCK(start-date, end-date[, 'method'])
```

**Arguments**

**interval**

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

**Data type** CHAR, NCHAR, NVARCHAR, VARCHAR

**Note**

The possible values of *interval* are listed in "Intervals Used with Date and Time Functions" in *SAS Formats and Informats: Reference*.

**Tip**

*Interval* can appear in uppercase or lowercase.

**Example**

YEAR specifies year-based intervals.

**multiple**

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

**Data type** DOUBLE

**See**

"Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.
Example: YEAR2 specifies a two-year, or biennial, interval type.

**shift-index**

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

**Restrictions**

The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

**Data type** DOUBLE

**See** "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in SAS Functions and CALL Routines: Reference for more information.

Example: YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

**start-date**

specifies an expression that represents the starting SAS date, time, or timestamp value.

**Data type** DOUBLE

**end-date**

specifies an expression that represents the ending SAS date, time, or timestamp value.

**Data type** DOUBLE

**'method'**

specifies that intervals are counted using either a discrete or a continuous method.

You must enclose method in quotation marks. Method can be one of these values:

**CONTINUOUS**

specifies that continuous time is measured. The interval is shifted based on the starting date.

For example, the distance in months between January 15, 2013, and February 15, 2013, is one month.

**Alias** C or CONT
DISCRETE specifies that discrete time is measured. The discrete method counts interval boundaries (for example, end of month).

The default discrete method is useful to sort time series observations into bins for processing. For example, daily data can be accumulated to monthly data for processing as a monthly series.

For the DISCRETE method, the distance in months between January 31, 2013, and February 1, 2013, is one month.

Alias D or DISC

Default DISCRETE

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[multiple][.shift-index]

For more information, see “Arguments” on page 522.

Calendar Interval Calculations

All values within a discrete time interval are interpreted as being equivalent. This means that the dates of January 1, 2013 and January 15, 2013 are equivalent when you specify a monthly interval. Both of these dates represent the interval that begins on January 1, 2013 and ends on January 31, 2013. You can use the date for the beginning of the interval (January 1, 2013) or the date for the end of the interval (January 31, 2013) to identify the interval. These dates represent all of the dates within the monthly interval.

In the following example, the start-date (Jan. 14, 2013) is equivalent to the first quarter of 2013.

select intck('qtr', date'2013-01-14', date'2013-09-02');

The end-date (September 2, 2013) is equivalent to the third quarter of 2013. The interval count, that is, the number of times the beginning of an interval is reached in moving from the start-date to the end-date is 2.

The INTCK function using the default discrete method counts the number of times the beginning of an interval is reached in moving from the first date to the second. It does not count the number of complete intervals between two dates:

- The following example returns 0, because the two dates are within the same month.
  
  select intck('month', date'2013-01-01', date'2013-01-31');

- The following example returns 1, because the two dates lie in different months that are one month apart.
select intck('month', date'2013-01-31', date'2013-02-01');

The following example returns –1 because the first date is in a later discrete interval than the second date. (INTCK returns a negative value whenever the first date is later than the second date and the two dates are not in the same discrete interval.)

select intck('month', date'2013-02-01', date'2013-01-31');

Using the discrete method, WEEK intervals are determined by the number of Sundays, the default first day of the week, that occur between the start-date and the end-date, and not by how many seven-day periods fall between those dates. To count the number of seven-day periods between start-date and end-date, use the continuous method.

Both the multiple and the shift-index arguments are optional and default to 1. For example, YEAR, YEAR1, YEAR.1, and YEAR1.1 are all equivalent ways of specifying ordinary calendar years.

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Functions and CALL Routines: Reference.

Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. For more information, see "Retail Calendar Intervals: ISO 8601 Compliant" in SAS Formats and Informats: Reference.

Example

The following statements illustrate the INTCK function:
In the second example, INTCK returns a value of 1 even though only one day has elapsed. This result is returned because the interval from December 31, 2012, to January 1, 2013, contains the starting point for the YEAR interval. However, in the third example, a value of 0 is returned even though 364 days have elapsed. This result occurs because the period between January 1, 2013, and December 31, 2013, does not contain the starting point for the interval.

In the fourth example, SAS returns a value of 6 because the period of January 1, 2010, through January 1, 2013, contains six semiyearly intervals. (Note that if the ending date were December 31, 2012, SAS would count five intervals.) In the fifth example, SAS returns a value of 6 because there are six two-week intervals beginning on a first Monday during the period of January 7, 2013, through April 1, 2013. In the sixth example, SAS returns the value 27. That indicates that beginning with January 1, 2013, and counting only Saturdays as weekend days through February 1, 2013, the period contains 27 weekdays. The last example specifies the number of years that have elapsed between the specified dates (10).

INTCYCLE Function

Returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or datetime interval is specified.

Categories: CAS
              Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

```
INTCYCLE(interval[multiple][.shift-index][, seasonality])
```

Arguments

**interval**

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of `interval` are listed in “Intervals Used with Date and Time Functions” in SAS Formats and Informats: Reference.

Tip Interval can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

**multiple**

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See “Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in SAS Functions and CALL Routines: Reference for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

**shift-index**

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.
If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type

DOUBLE

See

“Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in SAS Functions and CALL Routines: Reference for more information.

Example

YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

seasonality

specifies a numeric value.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

Default

52

Data type

DOUBLE, CHAR, NCHAR, NVARCHAR, VARCHAR

Example

The seasonality argument in the following example

INTCYCLE('MONTH', 3);

causes the function call to return the value QTR. The function call

INTCYCLE('MONTH');

does not have a seasonality argument and returns the value YEAR.

Details

The Basics

The INTCYCLE function returns the interval of the seasonal cycle, depending on a date, time, or datetime interval. For example, INTCYCLE('MONTH'); returns the value YEAR because the months from January through December constitute a yearly cycle. INTCYCLE('DAY'); returns the value WEEK because the days from Sunday through Saturday constitute a weekly cycle.

For information about multipliers and shift indexes, see “Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in SAS Functions and CALL Routines: Reference. For information about how intervals are calculated, see “Commonly Used Time Intervals” in SAS Functions and CALL Routines: Reference.

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Functions and CALL Routines: Reference.

The INTCYCLE function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Retail Calendar Intervals: ISO 8601 Compliant” in SAS Functions and CALL Routines: Reference.
Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

`interval[multiple][.shift-index]`

For more information, see "Arguments" on page 529.

Seasonality

Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTCYCLE function uses the concept of seasonality and returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or datetime interval is specified. For more information about seasonality and using the forecasting methods in PROC FORECAST, see the SAS/ETS User's Guide.

Example

The following statements illustrate the INTCYCLE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intcycle('year');</td>
<td>YEAR</td>
</tr>
<tr>
<td>select intcycle('qtr');</td>
<td>YEAR</td>
</tr>
<tr>
<td>select intcycle('month', 3);</td>
<td>QTR</td>
</tr>
<tr>
<td>select intcycle('month');</td>
<td>YEAR</td>
</tr>
<tr>
<td>select intcycle('weekday');</td>
<td>WEEK</td>
</tr>
<tr>
<td>select intcycle('weekday', 5);</td>
<td>WEEK</td>
</tr>
<tr>
<td>select intcycle('day');</td>
<td>WEEK</td>
</tr>
<tr>
<td>select intcycle('day', 10);</td>
<td>TENDAY</td>
</tr>
<tr>
<td>intcycle('day', 10);</td>
<td>DTMNUTE</td>
</tr>
</tbody>
</table>
INTFIT Function

Returns a time interval that is aligned between two dates.

Categories: CAS
Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INTFIT(expression-1, expression-2, 'type')

Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string and that represents a SAS date or datetime value.

Data type DOUBLE

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

'type'
specifies whether the arguments are SAS date values, datetime values, or a row.
The following values for type are valid:

d specifies that expression-1 and expression-2 are date values.
dt specifies that expression-1 and expression-2 are datetime values.
obs specifies that expression-1 and expression-2 are rows.

Details

The INTFIT function returns the most likely time interval based on two dates, datetime values, or rows that have been aligned within an interval. INTFIT assumes that the alignment value is SAME, which specifies that the date is aligned to the same calendar date with the corresponding interval increment. For more information about the alignment argument, see "INTNX Function" in SAS Functions and CALL Routines: Reference.

If the arguments that are used with INTFIT are rows, you can determine the cycle of an occurrence by using row numbers. In the following example, the first two arguments of INTFIT are row numbers, and the type argument is obs. If Jason used the gym the first time and the 25th time that a researcher recorded data, you could
determine the interval by using the following statement: interval=intfit(1, 25, 'obs');. In this case, the value of interval is OBS24.2.

For information about time series, see the SAS/ETS 9.3 User’s Guide.

The INTFIT function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Retail Calendar Intervals: ISO 8601 Compliant” in SAS Formats and Informats: Reference.

Example

The following statement illustrates the INTFIT function. This example shows the interval aligned between two dates.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intfit(date'2013-08-01', date'2013-09-01', 'd');</td>
<td>month</td>
</tr>
</tbody>
</table>

INTGET Function

Returns a time interval based on three date or datetime values.

Categories: CAS
            Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INTGET(date-1, date-2, date-3)

Argument

date
specifies any valid expression that evaluates to a SAS date or datetime value.

Data type    DOUBLE

See

“<sql-expression> Expression” on page 820
Details

INTGET Function Intervals

The INTGET function returns a time interval based on three date or datetime values. The function first determines all possible intervals between the first two dates, and then determines all possible intervals between the second and third dates. If the intervals are the same, INTGET returns that interval. If the intervals for the first and second dates differ, and the intervals for the second and third dates differ, INTGET compares the intervals. If one interval is a multiple of the other, then INTGET returns the smaller of the two intervals. Otherwise, INTGET returns a missing value.

INTGET works best with dates generated by the INTNX function whose alignment value is BEGIN.

In the following example, INTGET returns the interval DAY2:

```sql
select intget(date'2000-03-01', date'2000-03-03', date'2000-03-09');
```

The interval between the first and second dates is DAY2, because the number of days between March 1, 2000, and March 3, 2000, is two. The interval between the second and third dates is DAY6, because the number of days between March 3, 2000, and March 9, 2000, is six. DAY6 is a multiple of DAY2. INTGET returns the smaller of the two intervals.

In the following example, INTGET returns the interval MONTH4:

```sql
select intget(date'2000-01-01', date'2000-05-01', date'2001-05-01');
```

The interval between the first two dates is MONTH4, because the number of months between January 1, 2000, and May 1, 2000, is four. The interval between the second and third dates is YEAR. INTGET determines that YEAR is a multiple of MONTH4 (there are three MONTH4 intervals in YEAR), and returns the smaller of the two intervals.

In the following example, INTGET returns a missing value:

```sql
select intget(date'2006-01-01', date'2006-04-01', date'2006-12-01');
```

The interval between the first two dates is MONTH3, and the interval between the second and third dates is MONTH8. INTGET determines that MONTH8 is not a multiple of MONTH3, and returns a missing value.

The intervals that are returned are valid SAS intervals, including multiples of the intervals and shift intervals. Valid SAS intervals are listed in “Intervals Used with Date and Time Functions” in SAS Formats and Informats: Reference.

Note: If INTGET cannot determine a matching interval, then the function returns a missing value. No message is written to the SAS log.

Retail Calendar Intervals

The INTGET function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Retail Calendar Intervals: ISO 8601 Compliant” in SAS Formats and Informats: Reference.
Example

The following statements illustrate the INTGET function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intget(date'2013-01-01', date'2014-01-01', date'2014-05-01');</td>
<td>MONTH4</td>
</tr>
<tr>
<td>select intget(date'2012-02-29', date'2014-02-28', date'2016-02-29');</td>
<td>YEAR2.2</td>
</tr>
<tr>
<td>select intget(date'2013-02-01', date'2013-02-16', date'2013-03-01');</td>
<td>SEMIMONTH</td>
</tr>
<tr>
<td>select intget(date'2013-01-02', date'2014-02-02', date'2015-03-02');</td>
<td>MONTH13.13</td>
</tr>
<tr>
<td>select intget(date'2013-02-10', date'2013-02-19', date'2013-02-28');</td>
<td>DAY9.5</td>
</tr>
<tr>
<td>select intget(timestamp'2014-04-01 01:03:00.0000', timestamp'2014-04-01 01:04:00.0000', timestamp'2014-04-01 01:05:00.0000');</td>
<td>MINUTE</td>
</tr>
</tbody>
</table>

Functions:
- “INTFIT Function” on page 532
- “INTNX Function” on page 539

INTINDEX Function

Returns the seasonal index when a date, time, or timestamp interval and value are specified.

Categories: CAS
Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

\[ \text{INTINDEX}((\text{interval}\,[\text{multiple}]\,[\text{shift-index}]), \text{date-value}, \text{seasonality}) \]
Arguments

**interval**

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of *interval* are listed in "Intervals Used with Date and Time Functions" in SAS Formats and Informats: Reference.

Tip Interval can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

**multiple**

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in SAS Functions and CALL Routines: Reference for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

**shift-index**

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in SAS Functions and CALL Routines: Reference for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

**date-value**

specifies a date, time, or timestamp value that represents a time period of the given interval.
Data type DOUBLE

seasonality
specifies a number or a cycle.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

Data type DOUBLE, CHAR, NCHAR, NVARCHAR, VARCHAR

Example
In this example, the following functions produce the same result.

INTINDEX('MONTH', sasdate, 3);
INTINDEX('MONTH', sasdate, 'QTR');

Seasonality in the first example is a number (the number of months), and in the second example seasonality is a cycle (QTR).

Details
The Basics

The INTINDEX function returns the seasonal index when you supply an interval and an appropriate date, time, or timestamp value. The seasonal index is a number that represents the position of the date, time, or timestamp value in the seasonal cycle of the specified interval. This example returns a value of 12 because there are 12 months in a yearly cycle and December is the 12th month of the year.

select intindex('month', date'2012-12-01');

In the following examples, INTINDEX returns the same value (1) because both statements have dates that occur in the first quarter of the year 2013.

select intindex('qtr', date'2013-01-01');
select intindex('qtr', date'2013-03-01');

The following example returns a value of 6 because daily data is weekly periodic and December 7, 2012, is a Friday, the sixth day of the week.

select intindex('day', date'2012-12-07');

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[multiple][.shift-index]

For more information, see "Arguments" on page 536.

How Interval and Date-Time-Value Are Related

sasdate=to_double(date'2012-12-07');
x=intindex('day', sasdate);
put x;
To correctly identify the seasonal index, the interval should agree with the date, time, or timestamp value. For example, `intindex('month', date'2012-12-01');` returns a value of 12 because there are 12 months in a yearly interval and December is the 12th month of the year. The MONTH interval requires a SAS date value. The following example, returns a value of 6 because there are seven days in a weekly interval and December 7, 2012, is a Friday, the sixth day of the week.

`select intget('day', date'2012-12-07');`

The DAY interval requires a SAS date value.

This example returns a missing value because the QTR interval expects the date to be a SAS date value rather than a TIMESTAMP value.

`select intindex('qtr', timestamp'2013-01-01 00:00:00');`

This example returns a value of 12. The DTMONTH interval requires a TIMESTAMP value.

`select intindex('dtmonth', timestamp'2013-12-01 00:00:00');`

For more information about working with date and time intervals, see "Date and Time Intervals" in SAS Functions and CALL Routines: Reference.

Retail Calendar Intervals

The INTINDEX function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Retail Calendar Intervals: ISO 8601 Compliant" in SAS Functions and CALL Routines: Reference.

Seasonality

Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTINDEX function uses the concept of seasonality and returns the seasonal index when a date, time, or timestamp interval and value are specified. For more information about seasonality and using the forecasting methods in PROC FORECAST, see the SAS/ETS User's Guide.

Comparisons

The INTINDEX function returns the seasonal index whereas the INTCINDEX function returns the cycle index.

In the following example, the INTINDEX function returns 5 because April 4, 2013 is on a Thursday, the fifth day of the week.

`select intindex('day', date'2013-04-04');`

Using the same date, the INTCINDEX function returns 14 because April 4, 2013 is the 14th week of the year.

`select intcindex('day', date'2013-04-04');`

In this example, the INTINDEX function returns the minute of the hour.

`select intindex('minute', timestamp'2012-09-01 06:05:04');`

Using the same date and time, the INTCINDEX function returns the hour of the day.
select intcindex('minute', timestamp'2012-09-01 06:05:04');

In the example intseas('interval'); INTSEAS returns the maximum number that could be returned by intindex('interval', date);

Example

The following statements illustrate the INTINDEX function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intindex('qtr', date'2013-08-14');</td>
<td>3</td>
</tr>
<tr>
<td>select intindex('dtqtr', timestamp'2013-12-23 15:09:19');</td>
<td>4</td>
</tr>
<tr>
<td>select intindex('hour', time'09:05:15');</td>
<td>10</td>
</tr>
<tr>
<td>select intindex('month', date '2013-02-26');</td>
<td>2</td>
</tr>
<tr>
<td>select intindex('dtmonth', timestamp'2013-05-28 05:15:00');</td>
<td>5</td>
</tr>
<tr>
<td>select intindex('week', date '2013-09-09');</td>
<td>37</td>
</tr>
<tr>
<td>select intindex('tenday', date '2013-04-16');</td>
<td>11</td>
</tr>
</tbody>
</table>

- SAS/ETS User’s Guide

INTNX Function

Increments a SAS date, time, or datetime value encoded as a DOUBLE, and returns a SAS date, time, or datetime value encoded as a DOUBLE.

Categories: CAS
Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: DOUBLE
Syntax

\texttt{INTNX([interval][multiple][.shift-index]), start-from, increment[, 'alignment']})

\texttt{INTNX(start-from, increment[, 'alignment'])}

Arguments

\textit{interval}

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type \texttt{CHAR, NCHAR, NVARCHAR, VARCHAR}

Note

The possible values of \textit{interval} are listed in “Intervals Used with Date and Time Functions” in \textit{SAS Formats and Informats: Reference}.

Tip

\textit{Interval} can appear in uppercase or lowercase.

Example

YEAR specifies year-based intervals.

\textit{multiple}

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type \texttt{DOUBLE}

See

“Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in \textit{SAS Functions and CALL Routines: Reference} for more information.

Example

YEAR2 specifies a two-year, or biennial, interval type.

\textit{shift-index}

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions

The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type \texttt{DOUBLE}

See

“Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in \textit{SAS Functions and CALL Routines: Reference} for more information.
Example
YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

*start-from*

specifies an expression that represents a SAS date, time, or datetime value encoded as a DOUBLE and that identifies a starting point.

Data type: DOUBLE

*increment*

specifies a negative, positive, or zero whole number that represents the number of date, time, or datetime intervals. *Increment* is the number of intervals to shift the value of *start-from*.

Data type: DOUBLE

*alignment*

controls the position of SAS dates within the interval. You must enclose *alignment* in quotation marks. *Alignment* can be one of these values:

- **BEGINNING**
  - specifies that the returned date or datetime value is aligned to the beginning of the interval.
  - Alias: B

- **MIDDLE**
  - specifies that the returned date or datetime value is aligned to the midpoint of the interval, which is the average of the beginning and ending alignment values.
  - Alias: M

- **END**
  - specifies that the returned date or datetime value is aligned to the end of the interval.
  - Alias: E

- **SAME**
  - specifies that the date that is returned has the same alignment as the input date.
  - Aliases: S

  **SAMEDAY**

See **“SAME Alignment” on page 542**

Default: BEGINNING

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See **“Aligning SAS Date Output within Its Intervals” on page 542**
The Basics

The INTNX function increments a date, time, or datetime value by intervals such as DAY, WEEK, QTR, and MINUTE, or a custom interval that you define. The increment is based on a starting date, time, or datetime value, and on the number of time intervals that you specify.

The INTNX function returns the SAS date value for the beginning date, time, or datetime value of the interval that you specify in the `start-from` argument. (To convert the date value to a calendar date, use any valid DS2 date format, such as the DATE9. format.) The following example shows how to determine the date of the start of the week that is six weeks from the week of October 17, 2011.

```sql
select put(intnx('week', date'2011-10-17', 6), date9.);
```

INTNX returns the value 27NOV2011.

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Functions and CALL Routines: Reference.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

```
interval[multiple][.shift-index]
```

For more information, see “Arguments” on page 540.

Aligning SAS Date Output within Its Intervals

SAS date values are typically aligned with the beginning of the time interval that is specified with the `interval` argument.

You can use the optional `alignment` argument to specify the alignment of the date that is returned. The values BEGINNING, MIDDLE, or END align the date to the beginning, middle, or end of the interval, respectively.

SAME Alignment

If you use the SAME value of the `alignment` argument, then INTNX returns the same calendar date after computing the interval increment that you specified. The same calendar date is aligned based on the interval's shift period, not the interval. To view the valid shift periods, see “Intervals by Category” on page 525.

Most of the values of the shift period are equal to their corresponding intervals. The exceptions are the intervals WEEK, WEEKDAY, QTR, SEMIYEAR, YEAR, and their DT counterparts. WEEK and WEEKDAY intervals have a shift period of DAYS; and QTR, SEMIYEAR, and YEAR intervals have a shift period of MONTH. For example, when you use SAME alignment with YEAR, the result is same-day alignment based on MONTH, the interval's shift period. The result is not aligned to the same day of the YEAR interval. If you specify a multiple interval, then the default shift interval is based on the interval, and not on the multiple interval.

When you use SAME alignment for QTR, SEMIYEAR, and YEAR intervals, the computed date is the same number of months from the beginning of the interval as
the input date. The day of the month matches as closely as possible. Because not all months have the same number of days, it is not always possible to match the day of the month.

For more information about shift periods, see "Intervals by Category" on page 525.

Alignment Intervals

Use the SAME value of the alignment argument if you want to base the alignment of the computed date on the alignment of the input date.

```sql
/*** returns 22MAR2011 ***/
select put(intnx('week', date'2011-03-15', 1, 'same'), date9.);

/*** returns 15MAR2016 ***/
select put(intnx('year', date'2011-03-15', 5, 'same'), date9.);
```

Adjusting Dates

The INTNX function automatically adjusts for the date if the date in the interval that is incremented does not exist. Here is an example:

```sql
/*** returns 15AUG2011 ***/
select put(intnx('month', date'2011-03-15', 5, 'same'), date9.);

/*** returns 28FEB2014 ***/
select put(intnx('year', date'2012-02-29', 2, 'same'), date9.);

/*** returns 30SEP2011 ***/
select put(intnx('month', date'2011-08-31', 1, 'same'), date9.);

/*** returns 01MAR2012 (the 1st day of the 3rd month of the year) ***/
select put(intnx('year', date'2011-03-01', 1, 'same'), date9.);

/*** returns 29FEB2012 (the 60th day of the year) ***/
select put(intnx('year', date'2011-03-01', 1, 'same', 'day'), date9.);
```

In the following example, the INTNX function returns the value 01JAN2014, which is the beginning of the year two years from the starting date (29FEB2012).

```sql
select put(intnx('year', date'2012-02-29', 2), date9.);
```

In this example, the INTNX function returns the value 28FEB2014. In this case, the starting date begins in the year 2012, the year is two years later (2014), the month is the same (February), and the date is the 28th, because that is the closest date to the 29th in February 2014.

```sql
select put(intnx('year', date'2012-02-29', 2, 'same'), date9.);
```

Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. For more information, see "Retail Calendar Intervals: ISO 8601 Compliant" in SAS Formats and Informats: Reference.
Examples:

Example 1: Using the INTNX Function

The following statements illustrate the INTNX function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intnx('year', date'2013-02-05', 3);</td>
<td>20454</td>
</tr>
<tr>
<td>select put(intnx('year', date'2013-02-05', 3), date7.);</td>
<td>01Jan16</td>
</tr>
<tr>
<td>select intnx('month', date'2013-01-05', 0);</td>
<td>19359</td>
</tr>
<tr>
<td>select put(intnx('month', date'2013-01-05', 0), date7.);</td>
<td>01JAN13</td>
</tr>
<tr>
<td>select intnx('semiyear', date'2013-01-01', 1);</td>
<td>19540</td>
</tr>
<tr>
<td>select put(intnx('semiyear', date'2013-01-01', 1), date7.);</td>
<td>01JUL13</td>
</tr>
<tr>
<td>select intnx('month2', date'2012-08-01', -1);</td>
<td>19114</td>
</tr>
<tr>
<td>select put(intnx('month2', date'2012-08-01', -1), date7.);</td>
<td>01MAY12</td>
</tr>
<tr>
<td>select intnx('semimonth2.2', date'2013-04-01', 4);</td>
<td>19555</td>
</tr>
<tr>
<td>select put(intnx('semimonth2.2', date'2013-04-01', 4), date7.);</td>
<td>16JUL13</td>
</tr>
</tbody>
</table>

Example 2: Using the ALIGNMENT Argument

The following examples show the results of advancing a date by using the optional alignment argument.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intnx('month', date'2013-01-01', 5, 'beginning');</td>
<td>19510</td>
</tr>
<tr>
<td>select put(intnx('month', date'2013-01-01', 5, 'beginning'), date7.);</td>
<td>01JUN13</td>
</tr>
<tr>
<td>select intnx('month', date'2013-01-01', 5, 'middle');</td>
<td>19524</td>
</tr>
<tr>
<td>select put(intnx('month', date'2013-01-01', 5, 'middle'), date7.);</td>
<td>15JUN13</td>
</tr>
<tr>
<td>select intnx('month', date'2013-01-01', 5, 'end');</td>
<td>19539</td>
</tr>
<tr>
<td>select put(intnx('month', date'2013-01-01', 5, 'end'), date7.);</td>
<td>30JUN13</td>
</tr>
<tr>
<td>select intnx('month', date'2013-01-01', 5, 'sameday');</td>
<td>19510</td>
</tr>
<tr>
<td>select put(intnx('month', date'2013-01-01', 5, 'sameday'), date7.);</td>
<td>01JUN13</td>
</tr>
<tr>
<td>select intnx('month', date'2013-03-15', 5, 'same');</td>
<td>19585</td>
</tr>
<tr>
<td>select put(intnx('month', date'2013-03-15', 5, 'same'), date7.);</td>
<td>15AUG13</td>
</tr>
</tbody>
</table>
INTRR Function

Returns the internal rate of return as a decimal value.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

INTRR(freq, c0, c1[... , cn])

Arguments

freq
is numeric, the number of payments over a specified base period of time that is associated with the desired internal rate of return.

Range: freq > 0
Data type: DOUBLE
Tip: The case freq = 0 is a flag to allow continuous compounding.

c0, c1[... , cn]
are numeric, the optional cash payments.

Data type: DOUBLE

Details

The INTRR function returns the internal rate of return over a specified base period of time for the set of cash payments c0, c1, ..., cn. The time intervals between any two consecutive payments are assumed to be equal. The argument freq > 0 describes the number of payments that occur over the specified base period of time.

The number of notes issued from each instance is limited.

The internal rate of return is the interest rate such that the sequence of payments has a 0 net present value. (See the “NPV Function” on page 632.) It is given by the following equation.
\[
    r = \begin{cases} 
    \frac{1}{freq} - 1 & freq > 0 \\
    -\log(x) & freq = 0 
    \end{cases}
\]

In this equation, \( x \) is the real root of the polynomial.

\[
    \sum_{i=0}^{n} c_i x^i = 0
\]

In the case of multiple roots, one real root is returned and a warning is issued concerning the non-uniqueness of the returned internal rate of return. Depending on the value of payments, a root for the equation does not always exist. In that case, a missing value is returned.

Missing values in the payments are treated as 0 values. When \( freq > 0 \), the computed rate of return is the effective rate over the specified base period. To compute a quarterly internal rate of return (the base period is three months) with monthly payments, set \( freq \) to 3.

If \( freq \) is 0, continuous compounding is assumed and the base period is the time interval between two consecutive payments. The computed internal rate of return is the nominal rate of return over the base period. To compute with continuous compounding and monthly payments, set \( freq \) to 0. The computed internal rate of return is a monthly rate.

Comparisons

The IRR function is identical to INTRR, except for in the IRR function, the internal rate of return is a percentage.

Example

For an initial outlay of $400 and expected payments of $100, $200, and $300 over the following three years, the annual internal rate of return can be calculated as follows:

```sql
select intrr(1,-400,100,200,300);
```

```
0.19437709962747
```

SAS writes the following output to the log.

```
0.1943770996
```

Functions:

- "IRR Function" on page 558
INTSEAS Function

Returns the length of the seasonal cycle when a date, time, or datetime interval is specified.

Categories: CAS
Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

\[
\text{INTSEAS}((\text{interval}\text{[}\text{multiple}\text{[.shift-index]}\text{[, seasonality]}])
\]

Arguments

**interval**

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of interval are listed in “Intervals Used with Date and Time Functions” in SAS Formats and Informats: Reference.

Tip Interval can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

**multiple**

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See “Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in SAS Functions and CALL Routines: Reference for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

**shift-index**

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.
If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See “Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in SAS Functions and CALL Routines: Reference for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

seasonality specifies a numeric value.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

Default 52

Data type DOUBLE, CHAR, NCHAR, NVARCHAR, VARCHAR

Example The seasonality argument in the following example

\[
\text{INTSEAS('MONTH', 'qtr');}
\]

causes the function call to return the value 3. The function call

\[
\text{INTSEAS('MONTH');}
\]

does not have a seasonality argument and returns the value 12.

Details

The Basics

The INTSEAS function returns the number of intervals in a seasonal cycle. For example, when the interval for a time series is described as monthly, then many procedures use the option INTERVAL=MONTH. Each observation in the data then corresponds to a particular month. Monthly data is considered to be periodic for a one-year period. A year contains 12 months, so the number of intervals (months) in a seasonal cycle (year) is 12.

Quarterly data is also considered to be periodic for a one-year period. A year contains four quarters, so the number of intervals in a seasonal cycle is four.

The periodicity is not always one year. For example, INTERVAL=DAY is considered to have a period of one week. Because there are seven days in a week, the number of intervals in the seasonal cycle is seven.

For more information about working with date and time intervals, see “Date and Time Intervals” in SAS Functions and CALL Routines: Reference.
Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

\[ \text{interval}[\text{multiple}][.\text{shift-index}] \]

For more information, see “Arguments” on page 547.

Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. For more information, see “Retail Calendar Intervals: ISO 8601 Compliant” in SAS Formats and Informats: Reference.

Seasonality

Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTSEAS function uses the concept of seasonality and returns the length of the seasonal cycle when a date, time, or datetime interval is specified. For more information about seasonality and forecasting, see the SAS/ETS User's Guide.

Example

The following statements illustrate the INTCYCLE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intseas('year');</td>
<td>1</td>
</tr>
<tr>
<td>select intseas('semiyear');</td>
<td>2</td>
</tr>
<tr>
<td>select intseas('quarter');</td>
<td>4</td>
</tr>
<tr>
<td>select intseas('month');</td>
<td>12</td>
</tr>
<tr>
<td>select intseas('semimonth');</td>
<td>24</td>
</tr>
<tr>
<td>select intseas('tenday');</td>
<td>36</td>
</tr>
<tr>
<td>select intseas('week');</td>
<td>52</td>
</tr>
<tr>
<td>select intseas('weekday');</td>
<td>5</td>
</tr>
<tr>
<td>select intseas('hour');</td>
<td>24</td>
</tr>
</tbody>
</table>
### INTSHIFT Function

*Returns the shift interval that corresponds to the base interval.*

**Categories:** CAS  
**Date and Time**

**Restriction:** FedSQL does not support custom date or time intervals.

**Returned data type:** CHAR, NCHAR, NVARCHAR, VARCHAR

#### Syntax

```sql
INTSHIFT(interval[multiple][.shift-index])
```

#### Arguments

- **interval**
  
  specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

  **Data type**  
  CHAR, NCHAR, NVARCHAR, VARCHAR

- **Note**

  The possible values of `interval` are listed in “Intervals Used with Date and Time Functions” in SAS Formats and Informats: Reference.
Tip  *Interval* can appear in uppercase or lowercase.

**Example** YEAR specifies yearly intervals.

**multiple**
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

**Data type** DOUBLE

**See** “Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in *SAS Functions and CALL Routines: Reference* for more information.

**Example** YEAR2 consists of two-year, or biennial, periods.

**shift-index**
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

**Restrictions** The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

**Data type** DOUBLE

**See** “Incrementing Dates and Times By Using Multipliers and By Shifting Intervals” in *SAS Functions and CALL Routines: Reference* for more information.

**Example** YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

**Details**

**The Basics**

The **INTSHIFT** function returns the shift interval that corresponds to the base interval. For custom intervals, the value that is returned is the base custom interval name. **INTSHIFT** ignores multiples of the interval and interval shifts.

The **INTSHIFT** function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Retail Calendar Intervals: ISO 8601 Compliant” in *SAS Formats and Informats: Reference*. 
Intervals
Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[multiple][.shift-index]

For more information, see “Arguments” on page 550.

Example
The following statements illustrate the INTSHIFT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intshift('year');</td>
<td>MONTH</td>
</tr>
<tr>
<td>select intshift('dtyear');</td>
<td>DTMONTH</td>
</tr>
<tr>
<td>select intshift('minute');</td>
<td>DTMINUTE</td>
</tr>
<tr>
<td>select intshift('weekdays');</td>
<td>WEEKDAY</td>
</tr>
<tr>
<td>select intshift('weekday5.4');</td>
<td>WEEKDAY</td>
</tr>
<tr>
<td>select intshift('qtr');</td>
<td>MONTH</td>
</tr>
<tr>
<td>select intshift('dttoday');</td>
<td>DTTENOUR</td>
</tr>
</tbody>
</table>

INTTTEST Function
Returns 1 if a time interval is valid, and returns 0 if a time interval is invalid.

Categories: CAS
Date and Time

Restriction: FedSQL does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

INTTTEST(interval[multiple][.shift-index])
Arguments

interval
specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of interval are listed in "Intervals Used with Date and Time Functions" in SAS Formats and Informats: Reference.

Tip Interval can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

multiple
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in SAS Functions and CALL Routines: Reference for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in SAS Functions and CALL Routines: Reference for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.
Details

The Basics

The INTTEST function checks for a valid interval name. This function is useful when checking for valid values of multiple and shift-index. For more information about multipliers and shift indexes, see “Multiunit Intervals” in SAS Language Reference: Concepts.

The INTTEST function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see “Retail Calendar Intervals: ISO 8601 Compliant” in SAS Formats and Informats: Reference.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

\[ \text{interval}[\text{multiple}][.\text{shift-index}] \]

For more information, see “Arguments” on page 553.

Example

In the following examples, SAS returns a value of 1 if the interval argument is valid, and 0 if the interval argument is invalid.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select inttest('month');</td>
<td>1</td>
</tr>
<tr>
<td>select inttest('week6.13');</td>
<td>1</td>
</tr>
<tr>
<td>select inttest('tenday');</td>
<td>1</td>
</tr>
<tr>
<td>select inttest('twoweeks');</td>
<td>0</td>
</tr>
<tr>
<td>select inttest('hour2.2');</td>
<td>1</td>
</tr>
</tbody>
</table>

INTZ Function

Returns the whole number portion of the argument, using zero fuzzing.

Categories: CAS
Truncation

Returned data type: DOUBLE
Syntax

**INTZ**(expression)

Arguments

**expression**

specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The following rules apply:

- If the value of the argument is an exact whole number, INTZ returns that whole number.
- If the argument is positive and not a whole number, INTZ returns the largest whole number that is less than the argument.
- If the argument is negative and not a whole number, INTZ returns the smallest whole number that is greater than the argument.

Comparisons

Unlike the INT function, the INTZ function uses zero fuzzing. If the argument is within 1E-12 of a whole number, the INT function fuzzes the result to be equal to that whole number. The INTZ function does not fuzz the result. Therefore, with the INTZ function, you might get unexpected results.

Example

The following statements illustrate the INTZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select intz('2.1');</td>
<td>2</td>
</tr>
<tr>
<td>select intz(-2.4);</td>
<td>-2</td>
</tr>
<tr>
<td>select intz(1+1.e11);</td>
<td>1E11</td>
</tr>
<tr>
<td>select intz(-1.6);</td>
<td>-1</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “CEIL Function” on page 335
IPMT Function

Returns the interest payment for a given period for a constant payment loan or the periodic savings for a future balance.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

\[ \text{IPMT}(rate, \text{period}, \text{number-of-periods}, \text{principal-amount}[, \text{future-amount}][, \text{type}]) \]

Arguments

rate
specifies the interest rate per payment period.

Data type \text{DOUBLE}

period
specifies the payment period for which the interest payment is computed.

Requirement \text{Period} must be a positive whole number that is less than or equal to the value of number-of-periods.

Data type \text{INTEGER}

number-of-periods
specifies the number of payment periods.

Requirement \text{Number-of-periods} must be a positive whole number.

Data type \text{INTEGER}

principal-amount
specifies the principal amount of the loan.

Data type \text{DOUBLE}
**Note**

Zero is assumed if a missing value is specified.

**future-amount**

specifies the future amount.

**Data type**

DOUBLE

**Notes**

*Future-amount* can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of periodic savings.

Zero is assumed if *future-amount* is omitted or if a missing value is specified.

**type**

specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments.

**Data type**

INTEGER

**Note**

0 is assumed if *type* is omitted or if a missing value is specified.

**Example**

The interest payment on the first periodic payment of an $8,000 loan, where the nominal annual interest rate is 10% and the end-of-period monthly payments are 36, is computed as follows:

```
select ipmt(0.1/12, 1, 36, 8000);
```

66.6666666666666

SAS writes the following output to the log.

66.66667

If the same loan has beginning-of-period payments, then the interest payment can be computed as follows:

- `select ipmt(0.1/12, 1, 36, 8000, 0, 1);`
  
  This computation returns a value of 0.

- `select ipmt(0.1, 3, 3, 8000);`
  
  This computation returns a value of 292.4471.

- `select ipmt(0.09/12, 359, 360, 125000, 0, 1);`
  
  This computation returns a value of 14.80757.

---

**IQR Function**

Returns the interquartile range.

**Categories:**

CAS

Descriptive Statistics
Returned data type: DOUBLE

Syntax

\[ \text{IQR}(\text{expression} [, \ldots \text{expression}]) \]

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See

“\textless sql-expression\textgreater  Expression” on page 820

“FedSQL Expressions” on page 48

Details

If all arguments have null or missing values, the result is a null or missing value depending on whether you are in ANSI mode or SAS mode. For more information, see “How FedSQL Processes Nulls and SAS Missing Values” on page 22.

Otherwise, the result is the interquartile range of the non-null or nonmissing values. The formula for the interquartile range is the same as the one that is used in the Base SAS UNIVARIATE procedure. For more information, see Base SAS Procedures Guide: Statistical Procedures.

Example

The following statement illustrates the IQR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select iqr(2,4,1,3,999999);</td>
<td>2</td>
</tr>
</tbody>
</table>

IRR Function

Returns the internal rate of return as a percentage.

Categories: CAS
Returned data type: 

Financial

DOUBLE

Syntax

\texttt{IRR(freq, c1, c2 [\ldots, cn])}

Arguments

\texttt{freq}

is numeric, the number of payments over a specified base period of time that is associated with the desired internal rate of return.

Range \quad freq > 0.

Data type \quad DOUBLE

Tip
The case \texttt{freq = 0} is a flag to allow continuous compounding.

\texttt{c1, c2[\ldots, cn]}

are numeric, the optional cash payments.

Requirement \quad At minimum, two cash payment values are required.

Data type \quad DOUBLE

Details

The \texttt{IRR} function returns the internal rate of return over a specified base period of time for the set of cash payments \texttt{c1, c2, \ldots, cn}. The time intervals between any two consecutive payments are assumed to be equal. The argument \texttt{freq > 0} describes the number of payments that occur over the specified base period of time. The number of notes issued from each instance is limited.

Comparisons

The \texttt{IRR} function is identical to \texttt{INTRR}, except that in the \texttt{IRR} function, the internal rate of return is a percentage.

Example

For an initial outlay of $400 and expected payments of $100, $200, and $300 over the following three years, the annual internal rate of return as a percentage can be expressed by the following program:

\begin{verbatim}
  select irr(1,-400,100,200,300);
\end{verbatim}

The value that is returned is 19.437709963.

Functions:
JBESSEL Function

Returns the value of the Bessel function.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax

JBESSEL(nu, x)

Arguments

nu
specifies a numeric constant, variable, or expression.
Range \( nu \geq 0 \)

x
specifies a numeric constant, variable, or expression.
Range \( x \geq 0 \)

Details

The JBESSEL function returns the value of the Bessel function of order \( nu \) evaluated at \( x \) (For more information, see Abramowitz and Stegun 1964; Amos, Daniel, and Weston 1977).

Example

The following statements illustrate the JBESSEL function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select jbessel(2, 2);</td>
<td>0.352834</td>
</tr>
</tbody>
</table>

Functions:

- "IBESSEL Function" on page 510
JULDATE Function

Returns the Julian date from a SAS date value.

Categories: CAS
Date and Time

Returned data type: DOUBLE

Syntax

JULDATE(date)

Arguments

date

specifies any valid expression that represents a SAS date value.

Data type: DOUBLE

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

A SAS date value is a number that represents the number of days from January 1, 1960 to a specific date. The JULDATE function converts a SAS date value to a Julian date. If date falls within the 100-year span defined by the system option YEARCUTOFF=, the result has three, four or five digits: In a five-digit result, the first two digits represent the year, and the next three digits represent the day of the year (1 to 365, or 1 to 366 for leap years). As leading zeros are dropped from the result, the year portion of a Julian date can be omitted (for years ending in 00) or it can have only one digit (for years ending 01–09). Otherwise, the result has seven digits: the first four digits represent the year, and the next three digits represent the day of the year.

For years that end between 00–09, you can format the five-digit Julian date by using the Z5. format.

For more information about how FedSQL handles dates, see "Dates and Times in FedSQL" on page 60.

Comparisons

The function JULDATE7 is similar to JULDATE except that JULDATE7 always returns a four-digit year. Thus, JULDATE7 is year 2000 compliant because it eliminates the need to consider the implications of a two-digit year.
Example

The following statements illustrate the JULDATE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select juldate(mdy(12,31,2013));</td>
<td>7365</td>
</tr>
<tr>
<td>select put(juldate(mdy(12,31,2013)),z5.);</td>
<td>07365</td>
</tr>
<tr>
<td>select juldate(mdy(9,1,1999));</td>
<td>99244</td>
</tr>
<tr>
<td>select juldate(mdy(7,1,1886));</td>
<td>1886182</td>
</tr>
</tbody>
</table>

JULDATE7 Function

Returns a seven-digit Julian date from a SAS date value.

Categories: CAS
Date and Time

Returned data type: DOUBLE

Syntax

JULDATE7(date)

Arguments

*date*

specifies any valid expression that represents a SAS date value.

Data type: DOUBLE

See

"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48
Details
A SAS date value is a number that represents the number of days from January 1, 1960 to a specific date. The JULDATE7 function returns a seven-digit Julian date from a SAS date value. The first four digits represent the year, and the next three digits represent the day of the year.

For more information about how FedSQL handles dates, see “Dates and Times in FedSQL” on page 60.

Comparisons
The function JULDATE7 is similar to JULDATE except that JULDATE7 always returns a four-digit year. Thus, JULDATE7 is year 2000 compliant because it eliminates the need to consider the implications of a two-digit year.

Example
The following statements illustrate the JULDATE7 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select juldate7(mdy(12,31,2006));</td>
<td>2007365</td>

KURTOSIS Function
Returns the kurtosis of all values in an expression.

Categories: Aggregate
Description Statistics
CAS

Returned data type: DOUBLE

Syntax
\[
\text{KURTOSIS([DISTINCT] expression)}
\]
Arguments

**expression**
specifies any valid SQL expression.

| Data type | DOUBLE |

See

"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

**DISTINCT**
(optional) eliminates duplicate rows from the aggregate calculation.

Details

*Kurtosis* is primarily a measure of the heaviness of the tails of a distribution. Large values of kurtosis indicate that the distribution has heavy tails.

Null values and SAS missing values are ignored and are not included in the computation.

At least four nonnull or nonmissing arguments are required. Otherwise, the function returns a null value. If all nonnull or nonmissing arguments have equal values, the kurtosis is mathematically undefined and the KURTOSIS function returns a null value.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Example

Table: *WORLDTEMPS* on page 1092

The following statement illustrates the KURTOSIS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select kurtosis(AvgLow) from worldtemps;</td>
<td>-0.87431</td>
</tr>
</tbody>
</table>

LARGEST Function

Returns the kth largest non-null or nonmissing value.

Categories: CAS
Descriptive Statistics

Returned data type: DOUBLE

Syntax

LARGEST(k, expression [, expression])

Arguments

k
specifies any valid expression that evaluates to a numeric value that represents the largest value to return. For example, if k is 2, the LARGEST function returns the second largest value from the list of expressions.

Data type DOUBLE

See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

expression
specifies any valid expression that evaluates to a numeric value and that is to be searched.

Data type DOUBLE

See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

Details

If k is null or missing, less than zero, or greater than the number of values, the result is a null or missing value. Otherwise, if k is greater than the number of non-null or nonmissing values, the result is a null or missing value.

Example

The following statements illustrate the LARGEST function:
## LCM Function

Returns the least common multiple for a set of whole numbers.

**Categories:**
- CAS
- Mathematical

**Returned data type:**
DOUBLE

### Syntax

\[
\text{LCM}(\text{expression-1, expression-2 [..expression-n]})
\]

### Arguments

**expression**

specifies any valid expression that evaluates to a whole number.

**Requirement**

At least two arguments are required.

**Data type**

DOUBLE

**Note**

If any expression evaluates to zero, an error occurs and a missing value is returned.

### See Also

- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48
Details
The least common multiple is the smallest number that two or more numbers divide into evenly.

Example
The following statements illustrate the LCM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select lcm(1,5,3,0);</td>
<td></td>
</tr>
<tr>
<td>select lcm(25,70,85,130);</td>
<td>77350</td>
</tr>
<tr>
<td>select lcm(33,78);</td>
<td>858</td>
</tr>
</tbody>
</table>

LCOMB Function
Computes the logarithm of the COMB function, which is the logarithm of the number of combinations of $n$ objects taken $r$ at a time.

Categories: CAS
           Combinatorial

Returned data type: DOUBLE

Syntax
LCOMB($n$, $r$)

Arguments

$n$
is a nonnegative whole number that represents the total number of elements from which the sample is chosen.

$r$
is a nonnegative whole number that represents the number of chosen elements.

Restriction $r \leq n$
Comparisons
The LCOMB function computes the logarithm of the COMB function.

Example
The following statements illustrate the LCOMB function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select lcomb(5000, 500);</td>
<td>1621.441</td>
</tr>
<tr>
<td>select lcomb(100, 10);</td>
<td>30.48232</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “COMB Function” on page 344

LEFT Function
Left aligns a character expression.

Categories: CAS, Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

LEFT(expression)

Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details
LEFT returns a character string with leading blanks moved to the end of the value.
Example

The following statements illustrate the LEFT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select left('   END-OF-YEAR');</td>
<td>END-OF-YEAR</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "COMPRESS Function" on page 351

LFACT Function

Computes the logarithm of the FACT (factorial) function.

Categories: CAS
Combinatorial

Returned data type: DOUBLE

Syntax

LFACT(n)

Arguments

n
is a whole number that represents the total number of elements from which the sample is chosen.

Details

The LFACT function computes the logarithm of the FACT function.

Example

The following statements illustrate the LFACT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select lfact(5000);</td>
<td>37591.14</td>
</tr>
</tbody>
</table>
LGAMMA Function

Returns the natural logarithm of the Gamma function.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax

LGAMMA(expression)

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: Must be a positive number.

Data type: DOUBLE

See

“<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

Example

The following statements illustrate the LGAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select lgamma(2);</td>
<td>0</td>
</tr>
<tr>
<td>select lgamma(1.5);</td>
<td>-0.120782238</td>
</tr>
</tbody>
</table>
LOG Function

Returns the natural logarithm (base e) of a numeric value expression.

Categories:
- Mathematical
- CAS

Returned data type:
- DOUBLE

Syntax

```
LOG(expression)
```

Arguments

- **expression**
  - specifies any valid SQL expression that evaluates to a numeric value.
    - Data type: DOUBLE
    - See: "<sql-expression> Expression" on page 820
    - "FedSQL Expressions" on page 48

Example

The following statements illustrate the LOG function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select log(1.0);</td>
<td>0</td>
</tr>
<tr>
<td>select log(10.0);</td>
<td>2.302585</td>
</tr>
</tbody>
</table>

LOG1PX Function

Returns the log of 1 plus the argument.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax

LOG1PX(x)

Arguments

x
specifies a numeric variable, constant, or expression.

Data type DOUBLE

Details

The LOG1PX function computes the log of 1 plus the argument. The LOG1PX function is mathematically defined by the following equation, where –1 < x:

\[ \text{LOG1PX}(x) = \log(1 + x) \]

When x is close to 0, LOG1PX(x) can be more accurate than \( \log(1 + x) \).

Example

The following statements illustrate the LOG1PX function. The first example computes the log of 1 plus the value 0.5. The second computes the value of X by using the LOG1PX function and the value of Y by using the LOG function. The PUT function applies the HEX16. format to show the full precision of which FedSQL is capable.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select log1px(0.5);</td>
<td>0.405465</td>
</tr>
<tr>
<td>select put(log1px(1.e-5), hex16.) as x, put(log(1+1.e-5), hex16.) as y;</td>
<td>x=3EE4F8AE9AB7317 y=3EE4F8AE9AF0A25</td>
</tr>
</tbody>
</table>

See Also

Functions:
LOG2 Function

Returns the base-2 logarithm of a numeric value expression.

Categories:
Mathematical
CAS

Returned data type:
DOUBLE

Syntax

LOG2(expression)

Arguments

expression
specifies any valid SQL expression that evaluates to a numeric value.

Data type
DOUBLE

See
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Example

The following statements illustrate the LOG2 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select log2(8.0);</td>
<td>3</td>
</tr>
<tr>
<td>select log2(4);</td>
<td>2</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "LOG Function" on page 571
- "LOG10 Function" on page 574
LOG10 Function

Returns the base-10 logarithm of a numeric value expression.

Categories: Mathematical
CAS

Returned data type: DOUBLE

Syntax

LOG10(expression)

Arguments

expression specifies any valid SQL expression that evaluates to a numeric value.

Data type DOUBLE

See

"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Example

The following statements illustrate the LOG10 function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select log10(1.0);</td>
<td>0</td>
</tr>
<tr>
<td>select log10(10.0);</td>
<td>1</td>
</tr>
<tr>
<td>select log10(100.0);</td>
<td>2</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "LOG Function" on page 571
- "LOG2 Function" on page 573
LOGBETA Function

Returns the logarithm of the beta function.

Categories:
- CAS
- Mathematical

Returned data type: DOUBLE

Syntax

\textbf{LOGBETA}(a, b)

Arguments

\(a\)

is the first shape parameter, where \(a > 0\).

Data type: DOUBLE

\(b\)

is the second shape parameter, where \(b > 0\).

Data type: DOUBLE

Details

The \textbf{LOGBETA} function is mathematically given by the equation

\[
\log(\beta(a, b)) = \log(\Gamma(a)) + \log(\Gamma(b)) - \log(\Gamma(a + b))
\]

In the equation, \(\Gamma(\cdot)\) is the gamma function.

If the expression cannot be computed, \textbf{LOGBETA} returns a missing value.

Example

The following statement illustrates the \textbf{LOGBETA} function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select logbeta(5,3);</td>
<td>-4.6539603501575</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “\textit{BETA Function}” on page 276
LOGCDF Function

Returns the logarithm of a left cumulative distribution function.

Categories:
CAS
Probability

See:
“CDF Function” on page 295

Syntax

\[
\text{LOGCDF('distribution', quantile [, parameter-1, ..., parameter-k])}
\]

Arguments

distribution
is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the LOGCDF distribution functions are identical to those of the corresponding CDF distribution functions.

Here are valid distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Beta</td>
<td>'BETA'</td>
</tr>
<tr>

</tbody>
</table>
### Distribution | Argument
---|---
Laplace | 'LAPLACE'
Logistic | 'LOGISTIC'
Lognormal | 'LOGNORMAL'
Negative binomial | 'NEGBINOMIAL'
Normal | 'NORMAL' | 'GAUSS'
Normal mixture | 'NORMALMIX'
Pareto | 'PARETO'
Poisson | 'POISSON'
T | 'T'
Tweedie | 'TWEEDIE'
Uniform | 'UNIFORM'
Wald (inverse Gaussian) | 'WALD' | 'IGAUSS'
Weibull | 'WEIBULL'

**Note:** Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

**quantile**

is a numeric variable, constant, or expression that specifies the value of a random variable.

**Data type** DOUBLE

**parameter-1, ..., parameter-k**

are optional shape, location, or scale parameters appropriate for the specific distribution.

**Data type** DOUBLE

**Details**

The LOGCDF function computes the logarithm of a left cumulative distribution function (logarithm of the left side) from various continuous and discrete distributions. For more information, see the individual distributions in the table above.
LOGISTIC Function

Returns the logistic transformation of the argument.

Categories: CAS
Mathematical

Syntax

LOGISTIC(argument)

Arguments

argument
is a numeric variable, constant, or expression that specifies the value of a numeric random variable. When argument is a missing or null value, the LOGISTIC function returns a missing or null value.

Details

The LOGISTIC function returns the logistic transformation of an argument. It is typically used to convert a log odds value to a value on the probability scale. The function is mathematically expressed by the following equation:

\[
\text{logistic} = \frac{e^x}{1 + e^x}
\]

If the argument contains a missing value, then the LOGISTIC function returns a missing or null value.

Example

The following statement illustrates the LOGISTIC function:
LOGPDF Function

Computes the logarithm of the probability density (mass) function from various continuous and discrete distributions.

Categories: CAS
Probability

Alias: LOGPMF

See: “PDF Function” on page 639

Syntax

\[
\text{LOGPDF}(\text{'distribution'}, \text{quantile}, \text{parameter-1}, ..., \text{parameter-k})
\]

Arguments

distribution

is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the LOGPDF distribution functions are identical to those of the corresponding PDF distribution functions.

Here are valid distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Beta</td>

</table>
**LOWCASE Function**

Converting all letters in a character expression to lowercase.

**Categories:**
- CAS
- Character
Alias: LOWER
Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

LOWCASE(expression)

Arguments

expression specifies any valid expression that evaluates or can be coerced to a character string.

Requirement Literal character expressions must be enclosed in single quotation marks.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

The LOWCASE function copies a character expression, converts all uppercase letters to lowercase letters, and returns the altered value as a result.

Comparisons

The UPCASE function converts all letters in an argument to uppercase letters. The LOWCASE function converts all letters in an argument to lowercase letters.

Example

The following statement illustrates the LOWCASE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select lowcase('INTRODUCTION');</td>
<td>introduction</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "UPCASE Function" on page 778
MAD Function
Returns the median absolute deviation from the median.

Syntax
\[ \text{MAD(expression-1[, ...expression-n])} \]

Arguments
- \( \text{expression} \)
  - specifies any valid expression that evaluates to a numeric value of which the median absolute deviation from the median is to be computed.

Data type: DOUBLE

Details
If all arguments have missing or null values, the result is a missing or null value. Otherwise, the result is the median absolute deviation from the median of the nonmissing or non-null values. The formula for the median is the same as the one that is used in the UNIVARIATE procedure. For more information, see Base SAS Procedures Guide: Statistical Procedures.

Example
The following statement illustrates the MAD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select mad(2, 4, 1, 3, 5, 999999);</td>
<td>1.5</td>
</tr>
</tbody>
</table>

- "PCTL Function" on page 637
MAKEDATE Function

Returns the date as year, month, and day.

Categories: Date and Time
            CAS

Returned data type: DATE

Syntax

MAKEDATE(y, m, d)

Arguments

y specifies the year.

m specifies the month.

d specifies the day.

Example

The following statements illustrates the MAKEDATE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select makedate(2013, 10, 30);</td>
<td>30OCT2013</td>
</tr>
<tr>
<td>select makedate(y, m, d) from adate;</td>
<td>30OCT2013</td>
</tr>
</tbody>
</table>

Functions:

- “DATEPART Function” on page 389
- “MAKETIME Function” on page 587
- “MAKETIMESTAMP Function” on page 588
- “TIMEPART Function” on page 764
MAKETIME Function

Returns the time as hours, minutes, and seconds.

Categories: Date and Time
CAS

Returned data type: TIME

Syntax

MAKETIME\( (h, m, s) \)

Arguments

\( h \)
- specifies the hour.

\( m \)
- specifies the minute.

\( s \)
- specifies the second.

Example

The following statement illustrates the MAKETIME function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select maketime(15,39,10);</td>
<td>15:39:10</td>
</tr>
<tr>
<td>select maketime(h, mn, s) from adate;</td>
<td>15:39:10</td>
</tr>
</tbody>
</table>

- “MAKETIMESTAMP Function” on page 588
- “TIMEPART Function” on page 764
MAKETIMESTAMP Function

Returns the timestamp.

Categories:
Date and Time
CAS

Returned data type:
timestamp

Syntax

MAKETIMESTAMP\(d,t\)
MAKETIMESTAMP\(y,m,d,h,m,s\)

Arguments

\(d,t\)
\(d\)
specifies the date.
\(t\)
specifies the time.

\(y,m,d,h,m,s\)
\(y\)
specifies the year.
\(m\)
specifies the month.
\(d\)
specifies the day.
\(h\)
specifies the hours.
\(m\)
specifies the minutes.
\(s\)
specifies the seconds.

Example

The following statements illustrate the MAKETIMESTAMP function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select maketimestamp(date '2013-10-30', time '10:39:10');</td>
<td>30OCT2013:10:39:10</td>
</tr>
<tr>
<td>select maketimestamp(2013,10,30,13,39,10);</td>
<td>30OCT2013:13:39:10</td>
</tr>
</tbody>
</table>
select maketimestamp(makedate(2013, 10, 30),
maketime(13, 39, 10));

30OCT2013:13:39:10

MARGRCLPRC Function

Calculates call prices for European options on stocks, based on the Margrabe model.

Categories:
- CAS
- Financial

Returned data type:
- DOUBLE

Syntax

MARGRCLPRC\((X_1, t, X_2, \sigma_1, \sigma_2, \rho_{12})\)

Arguments

\(X_1\)
- is a nonmissing, positive value that specifies the price of the first asset.

Requirement
- Specify \(X_1\) and \(X_2\) in the same units.

Data type
- DOUBLE

\(t\)
- is a nonmissing value that specifies the time to expiration, in years.

Data type
- DOUBLE

\(X_2\)
- is a nonmissing, positive value that specifies the price of the second asset.

Requirement
- Specify \(X_2\) and \(X_1\) in the same units.

Data type
- DOUBLE
\(\sigma_1\)

is a nonmissing, positive fraction that specifies the volatility of the first asset.

Data type \(\text{DOUBLE}\)

\(\sigma_2\)

is a nonmissing, positive fraction that specifies the volatility of the second asset.

Data type \(\text{DOUBLE}\)

\(\rho_{12}\)

specifies the correlation between the first and second assets, \(\rho_{x_1,x_2}\).

Range between \(-1\) and \(1\)

Data type \(\text{DOUBLE}\)

Details

The `MARGRCLPRC` function calculates the call price for European options on stocks, based on the Margrabe model. The function is based on the following relationship:

\[
\text{CALL} = X_1 N(d_1) - X_2 N(d_2)
\]

Arguments

\(X_1\)

specifies the price of the first asset.

\(X_2\)

specifies the price of the second asset.

\(N\)

specifies the cumulative normal density function.

\[
d_1 = \frac{\ln\left(\frac{X_1}{X_2}\right) + \frac{\sigma_{x_1}^2 t}{2}}{\sigma_{x_1} \sqrt{t}}
\]

\[
d_2 = d_1 - \sigma_{x_1} \sqrt{t}
\]

\[
\sigma^2 = \sigma_{x_1}^2 + \sigma_{x_2}^2 - 2\rho_{x_1,x_2} \sigma_{x_1} \sigma_{x_2}
\]

The following arguments apply to the preceding equation:

\(t\)

specifies the time to expiration.

\(\sigma_{x_1}^2\)

specifies the variance of the first asset.

\(\sigma_{x_2}^2\)

specifies the variance of the second asset.

\(\sigma_{x_1}\)

specifies the volatility of the first asset.

\(\sigma_{x_2}\)

specifies the volatility of the second asset.
\rho_{X_1,X_2}

specifies the correlation between the first and second assets.

For the special case of \( t=0 \), the following equation is true:

\[
\text{CALL} = \max((X_1 - X_2), 0)
\]

**Note:** This function assumes that there are no dividends from the two assets.

For information about the basics of pricing, see “Using Pricing Functions” in *SAS Functions and CALL Routines: Reference*.

### Comparisons

The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. These functions return a scalar value.

### Example

The following statements illustrate the MARGRCLPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select margrclprc(15, .5, 13, .06, .05, 1);</td>
<td>2</td>
</tr>
<tr>
<td>select margrclprc(2, .25, 1, .3, .2, 1);</td>
<td>1</td>
</tr>
</tbody>
</table>

### See Also

**Functions:**
- "MARGRPTPRC Function" on page 591

---

### MARGRPTPRC Function

Calculates put prices for European options on stocks, based on the Margrabe model.

**Categories:**
- CAS
- Financial

**Returned data type:**
- DOUBLE

**Syntax**

\[
\text{MARGRPTPRC}(X_1, t, X_2, \text{sigma}1, \text{sigma}2, \text{rho}12)
\]
Arguments

\( X_1 \)

is a nonmissing, positive value that specifies the price of the first asset.

Requirement  Specify \( X_1 \) and \( X_2 \) in the same units.

Data type  DOUBLE

\( t \)

is a nonmissing value that specifies the time to expiration, in years.

Data type  DOUBLE

\( X_2 \)

is a nonmissing, positive value that specifies the price of the second asset.

Requirement  Specify \( X_2 \) and \( X_1 \) in the same units.

Data type  DOUBLE

\( \sigma_1 \)

is a nonmissing, positive fraction that specifies the volatility of the first asset.

Data type  DOUBLE

\( \sigma_2 \)

is a nonmissing, positive fraction that specifies the volatility of the second asset.

Data type  DOUBLE

\( \rho_{12} \)

specifies the correlation between the first and second assets, \( \rho_{X_1X_2} \).

Range  between –1 and 1

Data type  DOUBLE

Details

The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. The function is based on the following relationship:

\[
\text{PUT} = X_2 N(p_{d1}) - X_1 N(p_{d2})
\]

Arguments

\( X_1 \)

specifies the price of the first asset.

\( X_2 \)

specifies the price of the second asset.

\( N \)

specifies the cumulative normal density function.
The following arguments apply to the preceding equation:

\( t \)

is a nonmissing value that specifies the time to expiration, in years.

\( \sigma_{\text{x1}}^2 \)

specifies the variance of the first asset.

\( \sigma_{\text{x2}}^2 \)

specifies the variance of the second asset.

\( \sigma_{\text{x1}} \)

specifies the volatility of the first asset.

\( \sigma_{\text{x2}} \)

specifies the volatility of the second asset.

\( \rho_{\text{x1, x2}} \)

specifies the correlation between the first and second assets.

To view the corresponding CALL relationship, see the "MARGRCLPRC Function" on page 589.

For the special case of \( t=0 \), the following equation is true:

\[
\text{PUT} = \max(X_2 - X_1, 0)
\]

Note: This function assumes that there are no dividends from the two assets.

For information about the basics of pricing, see “Using Pricing Functions” in SAS Functions and CALL Routines: Reference.

Comparisons

The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. These functions return a scalar value.

Example

The following statements illustrate the MARGRPTPRC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select margrptprc(2, .25, 3, .06, .2, 1);</td>
<td>1.0000000000973</td>
</tr>
<tr>
<td>select margrptprc(3, .25, 4, .05, .3, 1);</td>
<td>1.00157624907712</td>
</tr>
</tbody>
</table>
MAX Function

Returns the maximum value in a column.

Categories:  
- Aggregate  
- Descriptive Statistics  
- CAS

Returned data type:  
The same data type as the expression

Syntax

\[ \text{MAX}([\text{DISTINCT}] \, \text{expression}) \]

Arguments

**expression**
- specifies any valid SQL expression.

Data type  
- All data types are supported.

See  
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

**DISTINCT**  
- (optional) eliminates duplicate rows from the aggregate calculation.

Details

The MAX function ignores null values and SAS missing values.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Comparisons

The MIN function returns the minimum value in a column. The MAX function returns the maximum value in a column.
Example

Table: DENSITIES on page 1081

The following statement illustrates the MAX function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select max(population) from densities;</td>
<td>34248705</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “MIN Function” on page 599

SELECT Statement Clauses:
- “SELECT Clause” on page 877
- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890

MDY Function

Returns a SAS date value from month, day, and year values.

Categories: CAS
            Date and Time

Returned data type: DOUBLE

Syntax

MDY(month, day, year)

Arguments

month

specifies a numeric expression that represents a whole number from 1 through 12.

Data type DOUBLE

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

day

specifies a numeric expression that represents a whole number from 1 through 31.
Data type DOUBLE

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

**year**

specifies a numeric expression that represents a two-digit or four-digit year. The YEARCUTOFF= system option defines the year value for two-digit dates.

Data type DOUBLE

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

**Example**

The following statements illustrate the MDY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(mdy(8,27,12),date7.);</td>
<td>27AUG12</td>
</tr>
<tr>
<td>select put(mdy(8,27,90),date7.);</td>
<td>27AUG90</td>
</tr>
</tbody>
</table>

**See Also**

**Concepts:**

**Functions:**
- “DAY Function” on page 391
- “MONTH Function” on page 605
- “YEAR Function” on page 793

---

**MEAN Function**

Returns the arithmetic mean (average) of the non-null or nonmissing arguments.

| Categories: | CAS
|-------------|-------------|
|             | Descriptive Statistics

| Returned data type: | DOUBLE |
Syntax

**MEAN**(expression-1[, ...expression-n])

Arguments

**expression**
specifies any valid expression that evaluates to a numeric value.

**Requirement**
At least one non-null or nonmissing argument is required. Otherwise, the function returns a null or missing value.

**Data type**
DOUBLE

**See**
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Comparisons

The GEOMEAN function returns the geometric mean, the HARMEAN function returns the harmonic mean, whereas the MEAN function returns the arithmetic mean (average).

Example

The following statements illustrate the MEAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select mean(2,...,6);</td>
<td>4</td>
</tr>
<tr>
<td>select mean(1,2,3,2);</td>
<td>2</td>
</tr>
</tbody>
</table>

See Also

**Functions:**
- "GEOMEAN Function" on page 498
- "GEOMEANZ Function" on page 500
- "HARMEAN Function" on page 501
- "HARMEANZ Function" on page 503
- "MEDIAN Function" on page 597

**MEDIAN Function**

Returns the median value.

Categories: CAS
Descriptive Statistics

Returned data type: DOUBLE

Syntax

\texttt{MEDIAN(}\texttt{expression-1[, \ldots, expression-n ]})

Arguments

\texttt{expression}
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See \texttt{“<sql-expression> Expression” on page 820}
\texttt{“FedSQL Expressions” on page 48}

Details

The \texttt{MEDIAN} function returns the median of the nonmissing or nonnull values. If all arguments have missing or null values, the result is a missing or null value.

\texttt{Note:} The formula that is used in the \texttt{MEDIAN} function is the same as the formula that is used in \texttt{PROC UNIVARIATE} in Base SAS Procedures Guide: Statistical Procedures. For more information, see \texttt{SAS Elementary Statistics Procedures}.

Comparisons

The \texttt{MEDIAN} function returns the median of nonmissing or nonnull values, whereas the \texttt{MEAN} function returns the arithmetic mean (average).

Example

The following statements illustrate the \texttt{MEDIAN} function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select median(2, 4, 1, 3);</td>
<td>2.5</td>
</tr>
<tr>
<td>select median(5, 8, 0, 3, 4);</td>
<td>4</td>
</tr>
</tbody>
</table>

See Also

Functions:

- \texttt{“MEAN Function” on page 596}
MIN Function

Returns the minimum value in an expression.

Categories:  
- Aggregate
- Descriptive Statistics
- CAS

Returned data type:  
The same data type as the expression

Syntax  

\[ \text{MIN}([\text{DISTINCT}] \text{ expression}) \]

Arguments  

\textit{expression}  
specifies any valid SQL expression.

Data type  
All data types are supported.

See  
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

\textbf{DISTINCT}  
(optional) eliminates duplicate rows from the aggregate calculation.

Details  
The MIN function ignores null values and SAS missing values.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Comparisons  
The MAX function returns the maximum value in a column. The MIN function returns the minimum value in a column.

Example  
Table: DENSITIES on page 1081

The following statement illustrates the MIN function.
MINUTE Function

Returns the minute from a time or datetime value.

Syntax

\[ \text{MINUTE}(\text{time} | \text{datetime}) \]

Arguments

time

specifies any valid expression that represents a time value.

Data type \( \text{TIME} \)

See

“Overview of Expressions and Predicates” on page 801

datetime

specifies any valid expression that represents a datetime value.

Data type \( \text{TIMESTAMP} \)

See

“Overview of Expressions and Predicates” on page 801

Example

Table: CUSTONLINE on page 1080
The following statement illustrates the MINUTE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select minute(endtime) from custonline;</td>
<td>5 21 4 25 47 6 5 15 35 6</td>
</tr>
<tr>
<td>select minute(current_time);</td>
<td>16</td>
</tr>
<tr>
<td>select minute(localtimestamp);</td>
<td>16</td>
</tr>
</tbody>
</table>

See Also
- "Dates and Times in FedSQL" on page 60

Functions:
- "DAY Function" on page 391
- "HOUR Function" on page 508
- "MONTH Function" on page 605
- "SECOND Function" on page 741
- "YEAR Function" on page 793

MOD Function

Returns the remainder from the division of the first argument by the second argument, fuzzed to avoid most unexpected floating-point results.

<table>
<thead>
<tr>
<th>Categories</th>
<th>CAS</th>
<th>Mathematical</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned data type</td>
<td>DOUBLE</td>
<td></td>
</tr>
</tbody>
</table>

Syntax

MOD(dividend-expression, divisor-expression)
Arguments

**dividend-expression**
specifies a dividend that is any valid expression that evaluates to a numeric value.

Data type  DOUBLE

See  “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

**divisor-expression**
specifies a divisor that is any valid expression that evaluates to a numeric value.

Restriction  **divisor-expression** cannot be 0

Data type  DOUBLE

See  “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

Details

The MOD function returns the remainder from the division of **dividend-expression** by **divisor-expression**. When the result is nonzero, the result has the same sign as the first argument. The sign of the second argument is ignored.

The computation that is performed by the MOD function is exact if both of the following conditions are true:

- Both arguments are exact integers.
- All integers that are less than either argument have exact 8-byte floating-point representations.

If either of the above conditions is not true, a small amount of numerical error can occur in the floating-point computation. In this case, the following occurs.

- MOD returns zero if the remainder is very close to zero or very close to the value of the second argument.
- MOD returns a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more. In this case, SAS also writes an error message to the log.

Comparisons

Here are some comparisons between the MOD and MODZ functions:

- The MOD function performs extra computations, called fuzzing, to return an exact zero when the result would otherwise differ from zero because of numerical error.
- The MODZ function performs no fuzzing.
- Both the MOD and MODZ functions return a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more.
Example

The following statements illustrate the MOD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select mod(10,3);</td>
<td>1</td>
</tr>
<tr>
<td>select mod(.35,-1);</td>
<td>0.05</td>
</tr>
<tr>
<td>select mod(17,3);</td>
<td>2</td>
</tr>
<tr>
<td>select mod(.3,-.9);</td>
<td>0.3</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "MODZ Function" on page 603
- "INTZ Function" on page 554

MODZ Function

Returns the remainder from the division of the first argument by the second argument, using zero fuzzing.

Categories: CAS

Mathematical

Returned data type: DOUBLE

Syntax

MODZ(dividend-expression, divisor-expression)

Arguments

*dividend-expression*

specifies a dividend that is any valid expression that evaluates to a numeric value.

Data type: DOUBLE

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

*divisor-expression*

specifies a divisor that is any valid expression that evaluates to a numeric value.
Restriction: divisor-expression cannot be 0

Data type: DOUBLE

See: 
“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The MODZ function returns the remainder from the division of dividend-expression by divisor-expression. When the result is nonzero, the result has the same sign as the first argument. The sign of the second argument is ignored.

The computation that is performed by the MODZ function is exact if both of the following conditions are true:

- Both arguments are exact integers.
- All integers that are less than either argument have exact 8-byte floating-point representation.

If either of the above conditions is not true, a small amount of numerical error can occur in the floating-point computation. For example, when you use exact arithmetic and the result is zero, MODZ might return a very small positive value or a value slightly less than the second argument.

Comparisons

Here are some comparisons between the MODZ and MOD functions:

- The MODZ function performs no fuzzing.
- The MOD function performs fuzzing, to return an exact zero when the result would otherwise differ from zero because of numerical error.
- Both the MODZ and MOD functions return a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more.

Examples:

Example 1

The following statements illustrate the MOD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select mod(10,3);</td>
<td>1</td>
</tr>
<tr>
<td>select mod(.35,-.1);</td>
<td>0.05</td>
</tr>
<tr>
<td>select mod(17,3);</td>
<td>2</td>
</tr>
<tr>
<td>select mod(.3,-.9);</td>
<td>0.3</td>
</tr>
</tbody>
</table>
Example 2

The following statements illustrate the MODZ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select modz(10,3);</td>
<td>1</td>
</tr>
<tr>
<td>select modz(.35,-.1);</td>
<td>0.05</td>
</tr>
<tr>
<td>select modz(17,3);</td>
<td>2</td>
</tr>
<tr>
<td>select modz(.3,-.9);</td>
<td>0.3</td>
</tr>
</tbody>
</table>

See Also

**Functions:**
- "INTZ Function" on page 554
- "MOD Function" on page 601

MONTH Function

Returns the numeric month from a date or datetime value.

**Categories:** Date and Time
CAS

**Returned data type:** TINYINT

**Syntax**

MONTH(*date | datetime*)

**Arguments**

*date*
specifies any valid expression that represents a date value.

Data type DATE

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

*datetime*
specifies any valid expression that represents a datetime value.

Data type TIMESTAMP
Example

Table: CUSTONLINE on page 1080

The following statement illustrates the MONTH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select month(endtime) from custonline;</td>
<td>9</td>
</tr>
<tr>
<td></td>
<td>10</td>
</tr>
<tr>
<td></td>
<td>10</td>
</tr>
<tr>
<td></td>
<td>11</td>
</tr>
<tr>
<td></td>
<td>12</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>3</td>
</tr>
<tr>
<td>select month(current_time);</td>
<td>10</td>
</tr>
</tbody>
</table>

- “YEAR Function” on page 793

MORT Function

Returns amortization parameters.

Categories: CAS
            Financial

Returned data type: DOUBLE
Syntax

\texttt{MORT(a, p, r, n)}

Arguments

\textit{a}

specifies any valid expression that evaluates to the initial amount.

Data type \texttt{DOUBLE}

See \small{
"<sql-expression> Expression" on page 820 \par
"FedSQL Expressions" on page 48
}

\textit{p}

specifies any valid expression that evaluates to the periodic payment.

Data type \texttt{DOUBLE}

See \small{
"<sql-expression> Expression" on page 820 \par
"FedSQL Expressions" on page 48
}

\textit{r}

specifies any valid expression that evaluates to the periodic interest rate that is expressed as a fraction.

Data type \texttt{DOUBLE}

See \small{
"<sql-expression> Expression" on page 820 \par
"FedSQL Expressions" on page 48
}

\textit{n}

specifies any valid expression that evaluates to the number of compounding periods.

Range \quad \textit{n} \geq 0

Data type \texttt{DOUBLE}

See \small{
"<sql-expression> Expression" on page 820 \par
"FedSQL Expressions" on page 48
}

Details

Calculating Results

The MORT function returns the missing argument in the list of four arguments from an amortization calculation with a fixed interest rate that is compounded each period. The arguments are related by the following equation:

\[ p = \frac{ar(1 + r)^n}{(1 + r)^n - 1} \]
One missing argument must be provided. The value is then calculated from the remaining three. No adjustment is made to convert the results to round numbers.

Restrictions in Calculating Results
The MORT function returns an invalid argument note to the SAS log and sets _ERROR_ to 1 if one of the following argument combinations is true:

- rate < -1 or n < 0
- principal <= 0 or payment <= 0 or n <= 0
- principal <= 0 or payment <= 0 or rate <= -1
- principal * rate > payment
- principal > payment * n

Example
In the following program, an amount of $50,000 is borrowed for 30 years at an annual interest rate of 10% compounded monthly.

```
select mort(50000, . , .10/12, 30*12);
```

The value that is returned is 438.79 (rounded). The second argument is set to missing, which indicates that the periodic payment is to be calculated. The 10% nominal annual rate has been converted to a monthly rate of 0.10/12. The rate is the fractional (not the percentage) interest rate per compounding period. The 30 years are converted to 360 months.

---

### N Function

Returns the number of non-null or nonmissing numeric values.

**Categories:**
- CAS
- Special

**Returned data type:**
- INTEGER

**Syntax**

```
N(expression [, …expression])
```

**Arguments**

- `expression`
  - specifies any valid expression that evaluates to a numeric value.

**Requirement**
- At least one argument is required.

**Data type**
- DECIMAL, DOUBLE, NUMERIC

**See**
- “<sql-expression> Expression” on page 820
Details
Null values are converted to missing values and are counted as missing values.

Comparisons
The N function counts non-null and nonmissing values, whereas the NMISS function counts missing values. The N function requires numeric arguments.

Example
The following statements illustrate the N function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select n(1,0,,2,5,..);</td>
<td>4</td>
</tr>
<tr>
<td>select n(1,2);</td>
<td>2</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “NMISS Function” on page 611.

NETPV Function
Returns the net present value as a percent.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax
\[ \text{NETPV}(r, \text{freq}, c0, c1, \ldots, cn) \]

Arguments
\[ r \]
is numeric, the interest rate over a specified base period of time expressed as a fraction.

Range \( r \geq 0 \)
Data type DOUBLE

freq
is numeric, the number of payments during the base period of time that is specified with the rate \( r \).

Range \( freq > 0 \)

Data type DOUBLE

Note The case \( freq = 0 \) is a flag to allow continuous discounting.

c_0, c_1, ..., c_n
are numeric cash flows that represent cash outlays (payments) or cash inflows (income) occurring at times 0, 1, ...n. These cash flows are assumed to be equally spaced, beginning-of-period values. Negative values represent payments, positive values represent income, and values of 0 represent no cash flow at a given time. The \( c_0 \) argument and the \( c_1 \) argument are required.

Details

The NETPV function returns the net present value at time 0 for the set of cash payments \( c_0, c_1, ..., c_n \), with a rate \( r \) over a specified base period of time. The argument \( freq > 0 \) describes the number of payments that occur over the specified base period of time.

The net present value is given by the equation:

\[
NETPV(r, freq, c_0, c_1, ..., c_n) = \sum_{i=0}^{n} c_i x^i
\]

The following relationship applies to the preceding equation:

\[
x = \begin{cases} \frac{1}{(1+r)^{(1/freq)}} & \text{if } freq > 0 \\ e^{-r} & \text{if } freq = 0 \end{cases}
\]

Missing values in the payments are treated as 0 values. When \( freq > 0 \), the rate \( r \) is the effective rate over the specified base period. To compute with a quarterly rate (the base period is three months) of 4% with monthly cash payments, set \( freq \) to 3 and set \( r \) to .04.

If \( freq \) is 0, continuous discounting is assumed. The base period is the time interval between two consecutive payments, and the rate \( r \) is a nominal rate.

To compute with a nominal annual interest rate of 11% discounted continuously with monthly payments, set \( freq \) to 0 and set \( r \) to .11/12.

Example

For an initial investment of $500 that returns biannual payments of $200, $300, and $400 over the succeeding 6 years and an annual discount rate of 10%, the net present value of the investment can be expressed as follows:

```sql
SELECT netpv(.10,.5,-500,200,300,400);
```
The value that is returned is 95.982864829.

Functions:
- “NPV Function” on page 632

NMISS Function

Returns the number of null values or SAS missing values in an expression.

Categories: Aggregate  
Scalar  
CAS

Syntax

Aggregate:

NMISS([DISTINCT] expression)

Scalar:

NMISS(expression[, ...expression])

Arguments

expression (aggregate)

specifies a SQL expression that evaluates to a character column.

Data type: CHAR  
Returned data type: BIGINT

expression (scalar)

specifies a SQL expression that evaluates to a numeric value. Multiple expressions must be separated by commas.

Data type: DECIMAL, DOUBLE, NUMERIC  
Returned data type: INTEGER

See
- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48

DISTINCT

(optional) eliminates duplicate rows from the aggregate calculation.

Details

NMISS returns the number of null or SAS missing values. When FedSQL is run in ANSI mode, ANSI null values are converted to SAS missing values.
When used as an aggregate function, NMISS returns the number of null or missing values found in a single character column. You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

When used as a scalar function, NMISS returns the number of null or missing values among the specified expression(s).

Comparisons

The NMISS function returns the number of null or SAS missing values. The N function returns the number of non-null and non-missing values.

Examples:

Example 1: Aggregate Operation

Table: WORLDTEMPS on page 1092

The following statement illustrates the use of NMISS as an aggregate function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select nmiss(AvgHigh) from worldtemps;</td>
<td>1</td>
</tr>
</tbody>
</table>

Example 2: Scalar Operation

The following statement illustrates the use of NMISS as a scalar function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select nmiss(1,2,.,3,.);</td>
<td>2</td>
</tr>
</tbody>
</table>

- "How FedSQL Processes Nulls and SAS Missing Values" on page 22

Functions:

- "N Function" on page 608

SELECT Statement Clauses:

- "SELECT Clause" on page 877
- "GROUP BY Clause" on page 889
**NOMRATE Function**

Returns the nominal annual interest rate.

**Syntax**

\[
\text{NOMRATE}(\text{compounding-interval}, \text{rate})
\]

**Arguments**

- **compounding-interval**
  - is a SAS interval. This value represents how often the returned value is compounded.
  - Data type: CHAR

- **rate**
  - is numeric. Rate is the effective annual interest rate (expressed as a percentage) that is compounded at each interval.
  - Data type: DOUBLE

**Details**

The NOMRATE function returns the nominal annual interest rate. NOMRATE computes the nominal annual interest rate that corresponds to an effective annual interest rate.

The following details apply to the NOMRATE function:

- The values for rates must be at least –99.
- In considering an effective interest rate and a compounding interval, if \( \text{compounding-interval} \) is ‘CONTINUOUS’, then the value that is returned by NOMRATE equals \( \log_e(1+\text{rate}/100) \).
  
  If \( \text{compounding-interval} \) is not ‘CONTINUOUS’, and \( m \) intervals occur in a year, the value that is returned by NOMRATE equals the following:

\[
m \left( 1 + \frac{\text{rate}}{100} \right)^\frac{1}{m} - 1
\]

- The following values are valid for \( \text{compounding-interval} \):
  - ‘CONTINUOUS’
  - ‘DAY’
'SEMIMONTH'
'MONTH'
'QUARTER'
'SEMIYEAR'
'YEAR'

If the interval is 'DAY', then $m=365$.

Example

If an effective rate is 10% when compounded monthly, the corresponding nominal rate can be expressed as follows:

```sql
SELECT NOMRATE('MONTH', 10);
```

effective_rate1=9.56896851468451

If an effective rate is 10% when compounded quarterly, the corresponding nominal rate can be expressed as follows:

```sql
SELECT NOMRATE('QUARTER', 10);
```

effective_rate2=9.64547563377804

**NOTALNUM Function**

Searches a character string for a non-alphanumeric character, and returns the first character position at which the character is found.

**Categories:**
CAS

**Character type:**
DOUBLE

**Syntax:**

```
NOTALNUM('expression'[, start])
```

**Arguments**

*expression*

specifies any valid expression that evaluates or can be coerced to a character string.

**Data type**
CHAR, NCHAR, VARCHAR, NVARCHAR

**See**
“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48
**NOTALNUM Function**

**start**

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type  **DOUBLE**

**Details**

The results of the NOTALNUM function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in SAS National Language Support (NLS): Reference Guide) and indirectly on the **ENCODING** and the **LOCALE** system options.

The NOTALNUM function searches a string for the first occurrence of any character that is not a digit or an uppercase or lowercase letter. If such a character is found, NOTALNUM returns the position in the string of that character. If no such character is found, NOTALNUM returns a value of 0.

If you use only one argument, NOTALNUM begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, **start**, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of **start** is positive, the search proceeds to the right.
- If the value of **start** is negative, the search proceeds to the left.
- If the value of **start** is less than the negative length of the string, the search begins at the end of the string.

NOTALNUM returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of **start** is greater than the length of the string.
- The value of **start** = 0.

**Comparisons**

The NOTALNUM function searches a character string for a non-alphanumeric character. The ANYALNUM function searches a character string for an alphanumeric character.

**Example**

The following statements illustrate the NOTALNUM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select notalnum('abc123, x');</td>
<td>7 (position of comma)</td>
</tr>
<tr>
<td>select notalnum('+abcd');</td>
<td>1 (position of plus sign)</td>
</tr>
<tr>
<td>select notalnum('789ab');</td>
<td>0</td>
</tr>
<tr>
<td>select notalnum('<a href="mailto:mynname@gmail.com">mynname@gmail.com</a>');</td>
<td>7 (position of @)</td>
</tr>
</tbody>
</table>
See Also

Functions:
- "ANYALNUM Function" on page 249

Notalpha Function

Searches a character string for a nonalphabetic character, and returns the first character position at which the character is found.

Syntax

\[ \text{Notalpha('expression'[, start])} \]

Arguments

expression  
specifies any valid expression that evaluates or can be coerced to a character string.

Data type  
CHAR, NCHAR, VARCHAR, NVARCHAR

See  
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

start  
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type  
DOUBLE
Details

The results of the NOTALPHA function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTALPHA function searches a string for the first occurrence of any character that is not an uppercase or lowercase letter. If such a character is found, NOTALPHA returns the position in the string of that character. If no such character is found, NOTALPHA returns a value of 0.

If you use only one argument, NOTALPHA begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTALPHA returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The NOTALPHA function searches a character string for a nonalphabetic character. The ANYALPHA function searches a character string for an alphabetic character.

Example

The following statements illustrate the NOTALPHA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select notalpha('123abc456');</td>
<td>1 (position of 1)</td>
</tr>
<tr>
<td>select notalpha('abcd1234');</td>
<td>5 (position of 1)</td>
</tr>
<tr>
<td>select notalpha('abcd');</td>
<td>0</td>
</tr>
<tr>
<td>select notalpha('789abc456','-99');</td>
<td>9 (position of 6)</td>
</tr>
<tr>
<td>select notalpha('abc$123');</td>
<td>4 (position of dollar sign)</td>
</tr>
</tbody>
</table>

Functions:
NOTDIGIT Function

Searches a character string for any character that is not a digit, and returns the first character position at which that character is found.

Categories:
- CAS
- Character

Returned data type: DOUBLE

Syntax

NOTDIGIT('expression'[, start])

Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type: DOUBLE

Details

The results of the NOTDIGIT function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTDIGIT function searches a string for the first occurrence of any character that is not a digit. If such a character is found, NOTDIGIT returns the position in the string of that character. If no such character is found, NOTDIGIT returns a value of 0.

If you use only one argument, NOTDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of `start` is negative, the search proceeds to the left.
- If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

`NOTDIGIT` returns a value of zero when one of the following is true:
- The character that you are searching for is not found.
- The value of `start` is greater than the length of the string.
- The value of `start` = 0.

**Comparisons**

The `NOTDIGIT` function searches a character string for any character that is not a digit. The `ANYDIGIT` function searches a character string for a digit.

**Example**

The following statements illustrate the `NOTDIGIT` function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select notdigit('123abc456');</code></td>
<td>4 (position of a)</td>
</tr>
<tr>
<td><code>select notdigit('1234');</code></td>
<td>0</td>
</tr>
<tr>
<td><code>select notdigit('123abc456','-99');</code></td>
<td>6 (position of last non-digit in string)</td>
</tr>
<tr>
<td><code>select notdigit('$12,300');</code></td>
<td>1 (position of dollar sign)</td>
</tr>
<tr>
<td><code>select notdigit('$12,300', -99);</code></td>
<td>4 (position of comma)</td>
</tr>
</tbody>
</table>

---

**NOTFIRST Function**

Searches a character string for an invalid first character in a SAS variable name under `VALIDVARNAME=V7`, and returns the first character position at which that character is found.

Categories: CAS, Character

Returned data type: DOUBLE
Syntax

\textbf{NOTFIRST}(\textit{expression}[\textit{start}])

Arguments

\textit{expression}

specifies any valid expression that evaluates or can be coerced to a character string.

Data type \quad \textbf{CHAR, NCHAR, VARCHAR, NVARCHAR}

See \quad “\textless sql-expression\textgreater \ Expression” on page 820

“FedSQL Expressions” on page 48

\textit{start}

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type \quad \textbf{DOUBLE}

Details

The \textbf{NOTFIRST} function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The \textbf{NOTFIRST} function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under VALIDVARNAME=V7. These characters are any except the underscore (_), and uppercase or lowercase English letters. If such a character is found, \textbf{NOTFIRST} returns the position in the string of that character. If no such character is found, \textbf{NOTFIRST} returns a value of 0.

If you use only one argument, \textbf{NOTFIRST} begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \textit{start}, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \textit{start} is positive, the search proceeds to the right.
- If the value of \textit{start} is negative, the search proceeds to the left.
- If the value of \textit{start} is less than the negative length of the string, the search begins at the end of the string.

\textbf{NOTFIRST} returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \textit{start} is greater than the length of the string.
- The value of \textit{start} = 0.

Comparisons

The \textbf{NOTFIRST} function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under VALIDVARNAME=V7. The \textbf{ANYFIRST} function searches a string for the first
occurrence of any character that is valid as the first character in a SAS variable
name under VALIDVARNAME=V7.

Example
The following statements illustrate the NOTFIRST function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select notfirst('123aBC4D6');</td>
<td>1 (position of 1)</td>
</tr>
<tr>
<td>select notfirst('123aBC4D6',-99);</td>
<td>9 (position of 6)</td>
</tr>
<tr>
<td>select notfirst('Bac123, x');</td>
<td>4 (position of 1)</td>
</tr>
<tr>
<td>select notfirst('x,&amp;,y,z,20,!');</td>
<td>2 (position of ampersand)</td>
</tr>
<tr>
<td>select notfirst('x,&amp;,y,z,20,!',-99);</td>
<td>12 (position of exclamation mark)</td>
</tr>
</tbody>
</table>

NOTLOWER Function

Searches a character string for a character that is not a lowercase letter, and returns the first character position at which that character is found.

Categories: CAS

Character

Returned data type: DOUBLE

Syntax

NOTLOWER(expression[, start])

Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR
**NOTLOWER function**

The NOTLOWER function searches a string for the first occurrence of any character that is not a lowercase letter. If such a character is found, NOTLOWER returns the position in the string of that character. If no such character is found, NOTLOWER returns a value of 0.

If you use only one argument, NOTLOWER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, `start`, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of `start` is positive, the search proceeds to the right.
- If the value of `start` is negative, the search proceeds to the left.
- If the value of `start` is less than the negative length of the string, the search begins at the end of the string.

NOTLOWER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of `start` is greater than the length of the string.
- The value of `start` = 0.

**Comparisons**

The NOTLOWER function searches a character string for a character that is not a lowercase letter. The ANYLOWER function searches a character string for a lowercase letter.

**Example**

The following statements illustrate the NOTLOWER function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select notlower('123aBc4D6');</code></td>
<td>1 (position of 1)</td>
</tr>
<tr>
<td><code>select notlower('123aBc4D6',-99);</code></td>
<td>9 (position of 6)</td>
</tr>
</tbody>
</table>
### NOTNAME Function

Searches a character string for an invalid character in a SAS variable name under `VALIDVARNAME=V7`, and returns the first character position at which that character is found.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select notlower('DAN BROWN');</code></td>
<td>1 (position of D)</td>
</tr>
<tr>
<td><code>select notlower('dan brown');</code></td>
<td>4 (position of space)</td>
</tr>
<tr>
<td><code>select notlower('mr. dan brown');</code></td>
<td>3 (position of period)</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- "ANYLOWER Function" on page 256

**Syntax**

```
NOTNAME('expression'[, start])
```

**Arguments**

- **expression** specifies any valid expression that evaluates or can be coerced to a character string.
  - **Data type**: CHAR, NCHAR, VARCHAR, NVARCHAR
  - **See**: "<sql-expression> Expression" on page 820
    - "FedSQL Expressions" on page 48

- **start** specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.
  - **Data type**: DOUBLE
Details

The NOTNAME function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNAME=V7. These characters are any except underscore (_), digits, and uppercase or lowercase English letters. If such a character is found, NOTNAME returns the position in the string of that character. If no such character is found, NOTNAME returns a value of 0.

If you use only one argument, NOTNAME begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTNAME returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNAME=V7. The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7.

Example

The following statements illustrate the NOTNAME function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select notname('&lt;&amp;abc!&gt;');</td>
<td>1 (position of angle bracket)</td>
</tr>
<tr>
<td>select notname('&amp;abc!&gt;');</td>
<td>1 (position of ampersand)</td>
</tr>
<tr>
<td>select notname('abc!&gt;');</td>
<td>4 (position of exclamation mark)</td>
</tr>
<tr>
<td>select notname('789!&gt;');</td>
<td>4 (position of exclamation mark)</td>
</tr>
<tr>
<td>select notname('abc!&gt;', -99);</td>
<td>5 (position of angle bracket)</td>
</tr>
</tbody>
</table>
NOTPUNCT Function

Searches a character string for a character that is not a punctuation character, and returns the first character position at which that character is found.

Categories: CAS Character

Returned data type: DOUBLE

Syntax

NOTPUNCT('expression'[, start])

Arguments

expression
  specifies any valid expression that evaluates or can be coerced to a character string.

Data type  CHAR, NCHAR, VARCHAR, NVARCHAR

See
  "<sql-expression> Expression" on page 820
  "FedSQL Expressions" on page 48

start
  specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type  DOUBLE

Details

The results of the NOTPUNCT function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTPUNCT function searches a string for the first occurrence of a character that is not a punctuation character. If such a character is found, NOTPUNCT returns the position in the string of that character. If no such character is found, NOTPUNCT returns a value of 0.
If you use only one argument, NOTPUNCT begins the search at the beginning of
the string. If you use two arguments, the absolute value of the second argument,
start, specifies the position at which to begin the search. The direction in which to
search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search
  begins at the end of the string.

NOTPUNCT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

Comparisons

The NOTPUNCT function searches a character string for a character that is not a
punctuation character. The ANYPUNCT function searches a character string for a
punctuation character.

Example

The following statements illustrate the NOTPUNCT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select notpunct('abc123, x');</td>
<td>1 (position of a)</td>
</tr>
<tr>
<td>select notpunct('!??:,');</td>
<td>0</td>
</tr>
<tr>
<td>select notpunct('987&amp;efg');</td>
<td>1 (position of 9)</td>
</tr>
</tbody>
</table>

Functions:

- "ANYPUNCT Function" on page 259

NOTSPACE Function

Searches a character string for a character that is not a whitespace character (blank, horizontal and
vertical tab, carriage return, line feed, and form feed), and returns the first character position at which that
character is found.

Categories: CAS

Character
Syntax

**NOTSPACE**('[expression]', [start])

Arguments

*expression*

specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See: "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

*start*

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type: DOUBLE

Details

The results of the NOTSPACE function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTSPACE function searches a string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. If such a character is found, NOTSPACE returns the position in the string of that character. If no such character is found, NOTSPACE returns a value of 0.

If you use only one argument, NOTSPACE begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTSPACE returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.
Comparisons

The NOTSPACE function searches a character string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. The ANYSPACE function searches a character string for the first occurrence of a character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed.

Example

The following statements illustrate the NOTSPACE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select notspace('abc123, x');</td>
<td>1 (position of a)</td>
</tr>
<tr>
<td>select notspace('Ma ry Smith');</td>
<td>1 (position of M)</td>
</tr>
<tr>
<td>select notspace('Ma ry Smith',-99);</td>
<td>11 (position of h)</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "ANYSPACE Function" on page 261

NOTUPPER Function

Searches a character string for a character that is not an uppercase letter, and returns the first character position at which that character is found.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax

NOTUPPER('expression'[, start])

Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See
- "<sql-expression> Expression" on page 820
**FedSQL Expressions** on page 48

**start**

specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type  **DOUBLE**

---

**Details**

The results of the NOTUPPER function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in SAS National Language Support (NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTUPPER function searches a string for the first occurrence of a character that is not an uppercase letter. If such a character is found, NOTUPPER returns the position in the string of that character. If no such character is found, NOTUPPER returns a value of 0.

If you use only one argument, NOTUPPER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, start, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of start is positive, the search proceeds to the right.
- If the value of start is negative, the search proceeds to the left.
- If the value of start is less than the negative length of the string, the search begins at the end of the string.

NOTUPPER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of start is greater than the length of the string.
- The value of start = 0.

**Comparisons**

The NOTUPPER function searches a character string for a character that is not an uppercase letter. The ANYUPPER function searches a character string for an uppercase letter.

**Example**

The following statements illustrate the NOTUPPER function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select notupper('aBc4D');</td>
<td>1 (position of a)</td>
</tr>
<tr>
<td>select notupper('aBc4D', -99);</td>
<td>4 (position of 4)</td>
</tr>
<tr>
<td>select notupper('123aBc4D6');</td>
<td>1 (position of 1)</td>
</tr>
<tr>
<td>Statements</td>
<td>Results</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>select notupper('123aBc4D6', 5);</td>
<td>6 (position of c)</td>
</tr>
<tr>
<td>select notupper('123aBc4D6', -5);</td>
<td>4 (position of a)</td>
</tr>
<tr>
<td>select notupper('ABCDE');</td>
<td>0</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “ANYUPPER Function” on page 262

NOTXDIGIT Function

Searches a character string for a character that is not a hexadecimal character, and returns the first character position at which that character is found.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax

NOTXDIGIT('expression'[, start])

Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type: DOUBLE
Details

The NOTXDIGIT function searches a string for the first occurrence of any character that is not a digit or an uppercase or lowercase A, B, C, D, E, or F. If such a character is found, NOTXDIGIT returns the position in the string of that character. If no such character is found, NOTXDIGIT returns a value of 0.

If you use only one argument, NOTXDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, \( \text{start} \), specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of \( \text{start} \) is positive, the search proceeds to the right.
- If the value of \( \text{start} \) is negative, the search proceeds to the left.
- If the value of \( \text{start} \) is less than the negative length of the string, the search begins at the end of the string.

NOTXDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of \( \text{start} \) is greater than the length of the string.
- The value of \( \text{start} = 0 \).

Comparisons

The NOTXDIGIT function searches a character string for a character that is not a hexadecimal character. The ANYXDIGIT function searches a character string for a character that is a hexadecimal character.

Example

The following statements illustrate the NOTXDIGIT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select notxdigit('123aBC4D6');</code></td>
<td>0 (no special characters)</td>
</tr>
<tr>
<td><code>select notxdigit('abcd056');</code></td>
<td>0 (no special characters)</td>
</tr>
<tr>
<td><code>select notxdigit('789ab!','-99');</code></td>
<td>6 (position of exclamation mark)</td>
</tr>
<tr>
<td><code>select notxdigit('&amp;789ab!');</code></td>
<td>1 (position of ampersand)</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "ANYXDIGIT Function" on page 264
**NPV Function**

Returns the net present value with the rate expressed as a percentage.

**Categories:**
- CAS
- Financial

**Returned data type:**
- DOUBLE

**Syntax**

\[ \text{NPV}(r, \text{freq}, c_0, c_1, \ldots, c_n) \]

**Arguments**

- **r**
  - is numeric, the interest rate over a specified base period of time expressed as a percentage.
  - Data type: DOUBLE

- **freq**
  - is numeric, the number of payments during the base period of time specified with the rate \( r \).
  - Range: \( freq > 0 \)
  - Data type: DOUBLE

  **Note**
  - The case \( freq = 0 \) is a flag to allow continuous discounting.

- **c_0, c_1, \ldots, c_n**
  - are numeric cash flows that represent cash outlays (payments) or cash inflows (income) occurring at times 0, 1, ...n. These cash flows are assumed to be equally spaced, beginning-of-period values. Negative values represent payments, positive values represent income, and values of 0 represent no cash flow at a given time. The \( c_0 \) argument and the \( c_1 \) argument are required.
  - Data type: DOUBLE

**Comparisons**

The NPV function is identical to NETPV, except that the \( r \) argument is provided as a percentage.

**Example**

The following statement illustrates the NPV function:
Statements | Results
---|---
select npv(1,2,3,4,5,6,7,8); | 32.50727639

See Also

Functions:

- "NETPV Function" on page 609

NWKDOM Function

Returns the date for the nth occurrence of a weekday for the specified month and year.

Categories:

- CAS
- Date and Time

Returned data type: DOUBLE

Syntax

\[
\text{NWKDOM}(n, \text{weekday}, \text{month}, \text{year})
\]

Arguments

\(n\)

- specifies the numeric week of the month that contains the specified day.
- Range: 1–5
- Data type: DOUBLE
- Tip: \(N=5\) indicates that the specified day occurs in the last week of that month. Sometimes \(n=4\) and \(n=5\) produce the same results.

weekday

- specifies the number that corresponds to the day of the week.
- Range: 1–7
- Data type: DOUBLE
- Tip: Sunday is considered the first day of the week and has a weekday value of 1.

month

- specifies the number that corresponds to the month of the year.
- Range: 1–12
Data type DOUBLE

**year**
specifies a four-digit calendar year.

Data type DOUBLE

Details

The NWKDOM function returns a SAS date value for the \( n \)th weekday of the month and year that you specify. Use any valid SAS date format, such as the DATE9. format, to display a calendar date. You can specify \( n=5 \) for the last occurrence of a particular weekday in the month.

Sometimes \( n=5 \) and \( n=4 \) produce the same result. These results occur when there are only four occurrences of the requested weekday in the month. For example, if the month of January begins on a Sunday, there are five occurrences of Sunday, Monday, and Tuesday, but only four occurrences of Wednesday, Thursday, Friday, and Saturday. In this case, specifying \( n=5 \) or \( n=4 \) for Wednesday, Thursday, Friday, or Saturday produces the same result.

If the year is not a leap year, February has 28 days and there are four occurrences of each day of the week. In this case, \( n=5 \) and \( n=4 \) produce the same results for every day.

Comparisons

In the NWKDOM function, the value for **weekday** corresponds to the numeric day of the week beginning on Sunday. This value is the same value that is used in the WEEKDAY function, where Sunday = 1, and so on. The value for **month** corresponds to the numeric month of the year beginning in January. This value is the same value that is used in the MONTH function, where January = 1, and so on.

You can use the NWKDOM function to calculate events that are not defined by the HOLIDAY function. For example, if a university always schedules graduation on the first Saturday in June, then you can use the following statement to calculate the date:

```
UnivGrad = nwkdom(1, 7, 6, year);
```

Examples:

**Example 1: Returning Date Values**

The following statements illustrate the use of the NWKDOM function to return the date for specific occurrences of a weekday for a specified month and year. The examples apply the WEEKDATX. format to display the output SAS date values in a readable format.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(nwkdom(3, 2, 5, 2012), weekdatx.);</td>
<td>Monday, 21 May 2012</td>
</tr>
<tr>
<td>select put(nwkdom(4, 4, 11, 2012), weekdatx.);</td>
<td>Wednesday, 28 November 2012</td>
</tr>
<tr>
<td>Statements</td>
<td>Results</td>
</tr>
<tr>
<td>------------</td>
<td>---------</td>
</tr>
<tr>
<td>select put(nwkdom(4, 7, 11, 2012), weekdatx.);</td>
<td>Saturday, 24 November 2012</td>
</tr>
<tr>
<td>select put(nwkdom(1, 1, 1, 2013), weekdatx.);</td>
<td>Sunday, 6 January 2013</td>
</tr>
<tr>
<td>select put(nwkdom(2, 3, 9, 2012), weekdatx.);</td>
<td>Tuesday, 11 September 2012</td>
</tr>
<tr>
<td>select put(nwkdom(5, 5, 12, 2012), weekdatx.);</td>
<td>Thursday, 27 December 2012</td>
</tr>
</tbody>
</table>

Example 2: Returning a Date

The following statement illustrates the use of the NWKDOM function to return the date of the last Monday in May. The DATE9. format is applied to display the date value.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(nwkdom(5, 2, 5, 2012), date9.);</td>
<td>28MAY2012</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “HOLIDAY Function” on page 505
- “INTNX Function” on page 539
- “WEEKDAY Function” on page 790

OCTET_LENGTH Function

Returns the number of bytes in a string of any data type.

Categories: Character, CAS

Returned data type: BIGINT

Syntax

```
OCTET_LENGTH(expression)
```

Arguments

- `expression` specifies any valid expression.
Data type
All data types are valid.

See
“<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

Details
The OCTET_LENGTH function counts a multibyte character as multiple characters. For example, if the specified string contains 6 two-byte characters, the OCTET_LENGTH function returns a value of 12.

If the character string is a bit string, the OCTET_LENGTH function returns the number of bytes it takes to hold the number of bits.

Comparisons
The CHARACTER_LENGTH function also returns the number of characters in a character string, but counts a multibyte character as a single character. The OCTET_LENGTH function counts a multibyte character as multiple characters.

Example
The following statements illustrate the OCTECT_LENGTH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select octect_length('December');</td>
<td>8</td>
</tr>
<tr>
<td>select octet_length(B'0100011100');</td>
<td>2</td>
</tr>
<tr>
<td>select octet_length(x'FEA364BEA234');</td>
<td>6</td>
</tr>
<tr>
<td>select octet_length('FedSQL ');</td>
<td>18</td>
</tr>
</tbody>
</table>

See Also

Functions:
- "CHARACTER_LENGTH Function" on page 338

ORDINAL Function
Orders a list of values, and returns a value that is based on a position in the list.

Categories: CAS
Descriptive Statistics

Returned data type: DOUBLE
Syntax

**ORDINAL**(position, expression-1, expression-2 [ , …expression-n])

Arguments

*position*

specifies a whole number that is less than or equal to the number of elements in the list of arguments.

**Requirement**

*position* must be a positive number.

**Data type**

DOUBLE

*expression*

specifies any valid expression that evaluates to a numeric value.

**Requirement**

At least two arguments are required.

**Data type**

DOUBLE

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The ORDINAL function sorts the list and returns the argument in the list that is specified by *position*. Missing values are sorted low and are placed before any numeric values.

Comparisons

The ORDINAL function counts both null, missing, non-null, and nonmissing values, whereas the SMALLEST function counts only non-null and nonmissing values.

Example

The following statement illustrates the ORDINAL function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select ordinal(4,1,2,3,-4,5,6,7);</td>
<td>3</td>
</tr>
</tbody>
</table>

PCTL Function

Returns the percentile that corresponds to the percentage.

Categories: CAS
Descriptive Statistics

Returned data type: DOUBLE

Syntax

\[ \text{PCTL}[n](\text{percentage}, \text{expression}[,...\text{expression}]) \]

Arguments

\( n \)

is a digit from 1 to 5 that specifies the definition of the percentile to be computed.

Default: definition 5

Data type: DOUBLE

\( \text{percentage} \)

specifies the percentile to be computed.

Data type: DOUBLE

Tip: \( \text{percentage} \) is numeric where, \( 0 \leq \text{percentage} \leq 100 \).

\( \text{expression} \)

specifies any valid expression that evaluates to a numeric value, whose value is computed in the percentile calculation.

Data type: DOUBLE

See: “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The PCTL function returns the percentile of the non-null or nonmissing values corresponding to the percentage. If \( \text{percentage} \) is null or missing, less than zero, or greater than 100, the PCTL function generates an error message.

Example

The following statements illustrate the PCTL function:

<table>
<thead>
<tr>
<th>Description</th>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower quartile</td>
<td>select pctl(25,2,4,1,3);</td>
<td>1.5</td>
</tr>
<tr>
<td>Percentile definition two</td>
<td>select pctl2(25,2,4,1,3);</td>
<td>1</td>
</tr>
<tr>
<td>Description</td>
<td>Statement</td>
<td>Result</td>
</tr>
<tr>
<td>------------------------------</td>
<td>----------------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>Lower tertile</td>
<td>select pctl(100/3,2,4,1,3);</td>
<td>2</td>
</tr>
<tr>
<td>Percentile definition three</td>
<td>select pctl3(100/3,2,4,1,3);</td>
<td>2</td>
</tr>
<tr>
<td>Median</td>
<td>select pctl(50,2,4,1,3);</td>
<td>2.5</td>
</tr>
<tr>
<td>Upper tertile</td>
<td>select pctl(200/3,2,4,1,3);</td>
<td>3</td>
</tr>
<tr>
<td>Upper quartile</td>
<td>select pctl(75,2,4,1,3);</td>
<td>3.5</td>
</tr>
</tbody>
</table>

**PDF Function**

Returns a value from a probability density (mass) distribution.

**Categories:**

- CAS
- Probability

**Alias:**

PMF

**Data type:**

DOUBLE

**Syntax**

PDF('distribution', quantile [, parameter-1, ..., parameter-k])

**Arguments**

- **distribution**
  - is a character constant, variable, or expression that identifies the distribution. Here are valid distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Beta</td>
<td>'BETA'</td>
</tr>
<tr>

<td>'UNIFORM'</td>
</tr>
<tr>
<td>Wald (inverse Gaussian)</td>
<td>'WALD'</td>
</tr>
<tr>
<td>Weibull</td>
<td>'WEIBULL'</td>
</tr>
</tbody>
</table>

**Note**: Except for T, F, and NORMALMIX, you can identify any distribution by its first four characters.

**quantile**

is a numeric constant, variable, or expression that specifies the value of the random variable.

**Data type**: `DOUBLE`

**parameter-1, ..., parameter-k**

are optional numeric constants, variables, or expressions that specify the values of `shape`, `location`, or `scale` parameters that are appropriate for the specific distribution.
Data type  DOUBLE

---

**PDF BERNOULLI Distribution Function**

Returns a value from the Bernoulli probability density (mass) distribution.

Categories: CAS
- Probability

Alias: PMF

Returned data type: DOUBLE

**Syntax**

PDF (‘BERNOULLI', x, p)

**Arguments**

\( x \)
- is a numeric constant, variable, or expression that specifies a random variable.
- Data type  DOUBLE

\( p \)
- is a numeric constant, variable, or expression that specifies the probability of success.
- Range  \( 0 \leq p \leq 1 \)
Data type  DOUBLE

Details
The PDF function for the Bernoulli distribution returns the probability density function with the probability of success equal to \( p \). The PDF function is evaluated at the value \( x \).

\[
PDF('BERN', x, p) = \begin{cases} 
0 & x < 0 \\
1 - p & x = 0 \\
0 & 0 < x < 1 \\
p & x = 1 \\
0 & x > 1 
\end{cases}
\]

Note: There are no location or scale parameters for this distribution.

Example
The following statement illustrates the PDF Bernoulli distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select pdf('BERN', 0, .25);</code></td>
<td>0.75</td>
</tr>
</tbody>
</table>

See Also

PDF BETA Distribution Function
Returns a value from the beta probability density (mass) distribution.

Categories:  CAS
Probability

Alias:  PMF
Syntax

\[
\text{PDF ('BETA', } x, a, b[, l, r])
\]

Arguments

\(x\)

is a numeric constant, variable, or expression that specifies a random variable.

Data type \(\text{DOUBLE}\)

\(a\)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range \(a > 0\)

Data type \(\text{DOUBLE}\)

\(b\)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range \(b > 0\)

Data type \(\text{DOUBLE}\)

\(l\)

is a numeric constant, variable, or expression that specifies the left location parameter.

Default \(0\)

Data type \(\text{DOUBLE}\)

\(r\)

is a numeric constant, variable, or expression that specifies the right location parameter.

Default \(1\)

Range \(r > l\)

Data type \(\text{DOUBLE}\)

Details

The PDF function for the beta distribution returns the probability density function with the shape parameters \(a\) and \(b\). The PDF function is evaluated at the value \(x\).

\[
\text{PDF('BETA', } x, a, b, l, r) = \begin{cases} 
0 & x < l \\
\frac{1}{\beta(a,b)} \frac{(x-l)^{a-1}(r-x)^{b-1}}{(r-l)^{a+b-1}} & l \leq x \leq r \\
0 & x > r
\end{cases}
\]
Note: The quantity $\frac{x-l}{r-l}$ is forced to be $\epsilon \leq \frac{x-l}{r-l} \leq 1 - 2\epsilon$.

Example

The following statement illustrates the PDF Beta distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select pdf('BETA', 0.2, 3, 4);</code></td>
<td>1.2288</td>
</tr>
</tbody>
</table>

**PDF BINOMIAL Distribution Function**

Returns a value from the binomial probability density (mass) distribution.

**Categories:**
- CAS
- Probability

**Alias:**
- PMF

**Returned data type:**
- DOUBLE

**Syntax**

`PDF('BINOMIAL', m, p, n)`

**Arguments**

- `m` is a random variable that counts the number of successes. This argument must be a whole number.
PDF BINOMIAL Distribution Function

- **Range**: \( m=0, 1, \ldots \)
- **Data type**: DOUBLE

**p**
- is a numeric constant, variable, or expression that specifies the probability of success.
- **Range**: \( 0 \leq p \leq 1 \)
- **Data type**: DOUBLE

**n**
- is a parameter that counts the number of independent Bernoulli trials. This argument must be a whole number.
- **Range**: \( n=0, 1, \ldots \)
- **Data type**: DOUBLE

**Details**

The PDF function for the binomial distribution returns the probability density function with the parameters \( p \) and \( n \). The PDF function is evaluated at the value \( m \).

\[
\text{PDF('BINOM', m, p, n)} = \begin{cases} 
0 & m < 0 \\
\binom{n}{m} p^m (1-p)^{n-m} & 0 \leq m \leq n \\
0 & m > n 
\end{cases}
\]

**Note:** There are no location or scale parameters for the binomial distribution.

**Example**

The following statement illustrates the PDF Binomial distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('BINOM', 4, .5, 10);</td>
<td>0.205078</td>

PDF CAUCHY Distribution Function

Returns a value from the Cauchy probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('CAUCHY', x [, θ, λ])

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

θ
is a numeric constant, variable, or expression that specifies a location parameter.

Default: 0
Data type: DOUBLE

λ
is a numeric constant, variable, or expression that specifies a scale parameter.

Default: 1
Range: λ > 0
Data type: DOUBLE

Details

The PDF function for the Cauchy distribution returns the probability density function with the location parameter θ and the scale parameter λ. The PDF function is evaluated at the value x.

PDF('CAUCHY', x, θ, λ) = \frac{1}{\pi} \left( \frac{\lambda}{\lambda^2 + (x - \theta)^2} \right)
Example
The following statement illustrates the PDF Cauchy distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('CAUCHY', 2);</td>
<td>0.063662</td>
</tr>
</tbody>
</table>

PDF Chi-Square Distribution Function

Returns a value from the chi-square probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

`PDF('CHISQUARE', x, df [, nc])`

Arguments

- `x` is a numeric constant, variable, or expression that specifies a random variable.
  Data type: DOUBLE

- `df` is a numeric constant, variable, or expression that specifies the degrees of freedom.
Range \( \text{df} > 0 \)

Data type \( \text{DOUBLE} \)

**nc**

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Range \( \text{nc} \geq 0 \)

Data type \( \text{DOUBLE} \)

**Details**

The PDF function for the chi-square distribution returns the probability density function of a chi-square distribution, with \( \text{df} \) degrees of freedom and the noncentrality parameter \( \text{nc} \). The PDF function is evaluated at the value \( x \). This function accepts noninteger degrees of freedom. If \( \text{nc} \) is omitted or equal to zero, the value returned is from the central chi-square distribution.

\[
PDF(\text{'CHISQ'}, x, \nu, \lambda) = \begin{cases} 
  0 & x < 0 \\
  \sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\lambda^j}{j!} p_c(x, \nu + 2j) & x \geq 0
\end{cases}
\]

In this equation, \( p_c(.,.) \) denotes the density from the central chi-square distribution:

\[
p_c(x, a) = \frac{1}{2} p_g(\frac{x}{2}, \frac{a}{2})
\]

In this equation, \( p_g(y, b) \) is the density from the gamma distribution:

\[
p_g(y, b) = \frac{1}{\Gamma(b)} e^{-y} y^{b-1}
\]

**Example**

The following statement illustrates the PDF Chi-Square distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('CHISQ', 11.264, 11);</td>
<td>0.081686</td>
</tr>
</tbody>
</table>

PDF Conway-Maxwell-Poisson Distribution Function

Returns a value from the Conway-Maxwell-Poisson probability density (mass) distribution.

Categories: CAS Probability
Alias: PMF
Returned data type: DOUBLE

Syntax

```
PDF('CONMAXPOI', y, λ, ν)
```

Arguments

- **y**
  - is a numeric constant, variable, or expression that specifies a nonnegative, whole number representing a count.
  - Data type: DOUBLE

- **λ**
  - is a numeric constant, variable, or expression that specifies a location parameter, similar to the Poisson mean parameter.
  - Data type: DOUBLE

- **ν**
  - is a numeric constant, variable, or expression that specifies a dispersion parameter.
  - Data type: DOUBLE

Details

The Conway-Maxwell-Poisson (CMP) distribution is a generalization of the Poisson distribution that enables you to model underdispersed and overdispersed data. The CMP distribution is defined according to this equation:

\[
P(Y = y ; \lambda, \nu) = \frac{1}{Z(\lambda, \nu)} \frac{\lambda^y}{y!\nu^y} \quad y = 0, 1, 2, ...
\]

The normalization factor is expressed by this equation:

\[
Z(\lambda, \nu) = \sum_{n=0}^{\infty} \frac{\lambda^n}{(n!)^\nu}
\]
\( \lambda \) and \( \nu \) are nonnegative and not simultaneously zero.

The additional parameter, \( \nu \), allows for flexibility in modeling the tail behavior of the distribution. If \( \nu=1 \), the ratio is equal to the rate of decay of the Poisson distribution. If \( \nu<1 \), the rate of decay decreases, which enables you to model processes that have longer tails than the Poisson distribution (overdispersed data). If \( \nu>1 \), the rate of decay increases in a nonlinear manner, thus shortening the tail of the distribution (underdispersed data).

There are several special cases of the Conway-Maxwell-Poisson distribution. If \( \lambda<1 \) and \( \nu\to\infty \), the Conway-Maxwell-Poisson distribution results in the Bernoulli distribution. In this case, the data can take only the values 0 and 1, which represent an extreme underdispersion. If \( \nu=1 \), the Poisson distribution is recovered with its equidispersion property. When \( \nu=0 \) and \( \lambda<1 \), the normalization factor is convergent and forms this geometric series:

\[
Z(\lambda, 0) = \frac{1}{1-\lambda}
\]

The probability density function is represented by this equation:

\[
P(Y = y; \lambda, \nu = 0) = (1 - \lambda)^{\lambda^y}
\]

The geometric distribution represents a case of severe overdispersion.

**Mean, Variance, and Dispersion for the Conway-Maxwell-Poisson Model**

The mean and variance of the Conway-Maxwell-Poisson distribution are defined by these equations:

\[
E[Y] = \frac{\partial \ln Z}{\partial \ln \lambda}
\]

\[
V[Y] = \frac{\partial^2 \ln Z}{\partial^2 \ln \lambda}
\]

The Conway-Maxwell-Poisson distribution does not have closed-form expressions for its moments in terms of parameters \( \lambda \) and \( \nu \). However, the moments can be approximated. (For more information about the Conway-Maxwell-Poisson distribution and discrete data, see the References section that is located at the end of this function.) Use asymptotic expressions for \( Z \) to derive \( E(Y) \) and \( V(Y) \) as these equations show:

\[
E[Y] \approx \lambda^{1/\nu} + \frac{1}{2\nu} - \frac{1}{2}
\]

\[
V[Y] \approx \frac{1}{\nu} \lambda^{1/\nu}
\]

In the Conway-Maxwell-Poisson model, the summation of infinite series is evaluated using a logarithmic expansion. (For more information about the Conway-Maxwell-Poisson distribution and discrete data, see the References section that is located at the end of this function.) The mean and variance are calculated as follows for the Conway-Maxwell-Poisson model:

\[
E(Y) = \frac{1}{Z(\lambda, \nu)} \sum_{j=0}^{\infty} \frac{j^2 \lambda^j}{(j!)^\nu}
\]

\[
V(Y) = \frac{1}{Z(\lambda, \nu)} \sum_{j=0}^{\infty} \frac{j^2 \lambda^j}{(j!)^\nu} - E(Y)^2
\]
The dispersion is defined as follows:

\[ D(Y) = \frac{V(Y)}{E(Y)} \]

**Example**

The following statement illustrates the PDF Conway-Maxwell-Poisson distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>

---

**PDF EXPONENTIAL Distribution Function**

Returns a value from the exponential probability density (mass) distribution.

**Categories:**
- CAS
  - Probability

**Alias:**
- PMF

**Returned data type:**
- DOUBLE

**Syntax**

`PDF ('EXPONENTIAL', x [, λ])`

**Arguments**

- `x`
  - is a numeric constant, variable, or expression that specifies a random variable.
Data type DOUBLE

$\lambda$

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range $\lambda > 0$

Data type DOUBLE

Details

The PDF function for the exponential distribution returns the probability density function of an exponential distribution, with the scale parameter $\lambda$. The PDF function is evaluated at the value $x$.

$$PDF('EXPO', x, \lambda) = \begin{cases} 0 & x < 0 \\ \frac{1}{\lambda} \exp\left(-\frac{x}{\lambda}\right) & x \geq 0 \end{cases}$$

Example

The following statement illustrates the PDF Exponential distribution function:

```
select pdf('EXPO', 1);
```

Results

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('EXPO', 1);</td>
<td>0.367879</td>
</tr>
</tbody>
</table>

PDF F Distribution Function

Returns a value from the F probability density (mass) distribution.

Categories: CAS

Probability
Syntax

\[ PDF \left( \text{'}F\text{', }x, \text{ndf}, \text{ddf} [, \text{nc}] \right) \]

Arguments

\( x \)

is a numeric constant, variable, or expression that specifies a random variable.

Data type \( \text{DOUBLE} \)

\( \text{ndf} \)

is a numeric constant, variable, or expression that specifies the numerator degrees of freedom.

Range \( \text{ndf} > 0 \)

Data type \( \text{DOUBLE} \)

\( \text{ddf} \)

is a numeric constant, variable, or expression that specifies the denominator degrees of freedom.

Range \( \text{ddf} > 0 \)

Data type \( \text{DOUBLE} \)

\( \text{nc} \)

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Range \( \text{nc} \geq 0 \)

Data type \( \text{DOUBLE} \)

Details

The PDF function for the \( F \) distribution returns the probability density function of an \( F \) distribution, with \( \text{ndf} \) numerator degrees of freedom, \( \text{ddf} \) denominator degrees of freedom, and the noncentrality parameter \( \text{nc} \). The PDF function is evaluated at the value \( x \). This PDF function accepts noninteger degrees of freedom for \( \text{ndf} \) and \( \text{ddf} \). If \( \text{nc} \) is omitted or equal to zero, the value returned is from a central \( F \) distribution. In the following equation, let \( \nu_1 = \text{ndf} \), let \( \nu_2 = \text{ddf} \), and let \( \lambda = \text{nc} \). This equation describes the PDF function for the \( F \) distribution:

\[
PDF\left(\text{'}F\text{', }x, \nu_1, \nu_2, \lambda\right) = \begin{cases} 
0 & x < 0 \\
\sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\lambda^j}{j!} \cdot p_f(\nu_1 + 2j, \nu_2) & x \geq 0
\end{cases}
\]

In the equation, \( p_f(f, u_1, u_2) \) is the density from the central \( F \) distribution:
\[ p_f(f, u_1, u_2) = \frac{u_1^2 f^{u_1 - 1} (1 + f)^{-u_1 - 1} \Gamma(u_2 + u_1)}{u_2 \Gamma(u_2) [1 + f]^2} \]

In the equation, \( p_B(x, a, b) \) is the density from the standard beta distribution.

**Note:** There are no location or scale parameters for the F distribution.

**Example**

The following statement illustrates the PDF F distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('F', 3.32, 2, 3);</td>
<td>0.054027</td>
</tr>
</tbody>
</table>

**PDF GAMMA Distribution Function**

Returns a value from the gamma probability density (mass) distribution.

**Categories:** CAS
- Probability

**Alias:** PMF

**Returned data type:** DOUBLE

**Syntax**

\( \text{PDF} ('\text{GAMMA}', x, a \ [, \lambda]) \)
Arguments

\( x \)

is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

\( a \)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range: \( a > 0 \)

Data type: DOUBLE

\( \lambda \)

is a numeric constant, variable, or expression that specifies a scale parameter.

Default: 1

Range: \( \lambda > 0 \)

Data type: DOUBLE

Details

The PDF function for the gamma distribution returns the probability density function of a gamma distribution, with the shape parameter \( a \) and the scale parameter \( \lambda \). The PDF function is evaluated at the value \( x \).

\[
PDF('GAMMA', x, a, \lambda) = \begin{cases} 
0 & x < 0 \\
\frac{1}{\lambda^a \Gamma(a)} x^{a-1} \exp\left(-\frac{x}{\lambda}\right) & x \geq 0
\end{cases}
\]

Example

The following statement illustrates the PDF Gamma distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('GAMMA', 1, 3);</td>
<td>0.18394</td>
</tr>
</tbody>
</table>

PDF Generalized Poisson Distribution Function

Returns a value from the generalized Poisson probability density (mass) distribution.

Categories:
- CAS
- Probability

Alias:
- PMF

Returned data type:
- DOUBLE

Syntax

PDF ('GENPOISSON', x, θ, η)

Arguments

x
- is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.
- Data type: DOUBLE

θ
- is a numeric constant, variable, or expression that specifies a shape parameter.
- Range: <10^6 and >0
- Data type: DOUBLE

η
- is a numeric constant, variable, or expression that specifies a shape parameter.
- Range: ≥0 and <0.95
- Data type: DOUBLE

Tip
- When η = 0, the distribution is the Poisson distribution with a mean and variance of θ. When η > 0, the mean is θ / (1 − η) and the variance is θ / (1 − η)^3.

Details

Here is the probability mass function for the generalized Poisson distribution:

\[ f(x; θ, η) = \theta(\theta + ηx)^{x-1}e^{-θ - ηx/x!}, \quad x = 0, 1, 2, ..., \quad θ > 0, \quad 0 ≤ η < 1 \]

Example

The following statement illustrates the PDF Generalized Poisson distribution function:
PDF GEOMETRIC Distribution Function

Returns a value from the geometric probability density (mass) distribution.

Categories: CAS  Probability
Alias: PMF
Returned data type: DOUBLE

Syntax

PDF ('GEOMETRIC', m, p)

Arguments

m is a numeric constant, variable, or expression that specifies the number of failures before the first success.

Range  \( m \geq 0 \)

Data type DOUBLE

p is a numeric constant, variable, or expression that specifies a probability of success.

Range  \( 0 \leq p \leq 1 \)
PDF Hypergeometric Distribution Function

Returns a value from a hypergeometric probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE
Syntax

**PDF (')HYPER', x, N, R, n [, o])**

Arguments

- **x**
  - is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.
  - Data type: **DOUBLE**

- **N**
  - is a numeric constant, variable, or expression that specifies a population size parameter. This argument must be a whole number.
  - Range: **N=1, 2, ...**
  - Data type: **DOUBLE**

- **R**
  - is a numeric constant, variable, or expression that specifies the number of items in the category of interest. This argument must be a whole number.
  - Range: **R=0, 1, ..., N**
  - Data type: **DOUBLE**

- **n**
  - is a numeric constant, variable, or expression that specifies a sample size parameter. This argument must be a whole number.
  - Range: **n=1, 2, ..., N**
  - Data type: **DOUBLE**

- **o**
  - is a numeric constant, variable, or expression that specifies an optional odds ratio parameter.
  - Range: **o > 0**
  - Data type: **DOUBLE**

Details

The PDF function for the hypergeometric distribution returns the probability density function of an extended hypergeometric distribution, with population size **N**, number of items **R**, sample size **n**, and odds ratio **o**. The PDF function is evaluated at the value **x**. If **o** is omitted or equal to 1, the value returned is from the usual hypergeometric distribution.
PDF \( \left( \text{HYPER}', x, N, R, n, o \right) = \)

\[
\begin{cases}
0 & x < \max(0, R + n - N) \\
\frac{\binom{R}{x} \binom{N-R}{n-x} x^x}{\sum_{j=\max(0, R + n - N)}^{\min(R, n)} \binom{R}{j} \binom{N-R}{n-j} j^j} & \max(0, R + n - N) \leq x \leq \min(R, n) \\
0 & x > \min(R, n)
\end{cases}
\]

Example

The following statement illustrates the PDF Hypergeometric distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select pdf('HYPER', 2, 200, 50, 10);</code></td>
<td><code>0.286851</code></td>

PDF LAPLACE Distribution Function

Returns a value from the Laplace probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

`PDF ("LAPLACE", x [, \theta, \lambda])`
Arguments

\( x \)

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

\( \theta \)

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

\( \lambda \)

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range \( \lambda > 0 \)

Data type DOUBLE

Details

The PDF function for the Laplace distribution returns the probability density function of the Laplace distribution, with the location parameter \( \theta \) and the scale parameter \( \lambda \). The PDF function is evaluated at the value \( x \).

\[
PDF('LAPLACE', x, \theta, \lambda) = \frac{1}{2\lambda}exp\left(-\frac{|x-\theta|}{\lambda}\right)
\]

Example

The following statement illustrates the PDF Laplace distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('LAPLACE', 1);</td>
<td>0.18394</td>

PDF LOGISTIC Distribution Function

Returns a value from the logistic probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('LOGISTIC', x, θ, λ)

Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

θ
is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ
is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The PDF function for the logistic distribution returns the probability density function of a logistic distribution, with the location parameter θ and the scale parameter λ. The PDF function is evaluated at the value x.

\[
PDF('LOGISTIC', x, θ, λ) = \frac{\exp\left(-\frac{x - θ}{λ}\right)}{λ\left(1 + \exp\left(-\frac{x - θ}{λ}\right)\right)^2}
\]

Example

The following statement illustrates the PDF Logistic distribution function:
PDF LOGNORMAL Distribution Function

Returns a value from the lognormal probability density (mass) distribution.

**Categories:** CAS

**Alias:** Probability

**Returned data type:** DOUBLE

**Syntax**

\[
\text{PDF ('LOGNORMAL', } x, \theta, \lambda)\]

**Arguments**

- \(x\) is a numeric constant, variable, or expression that specifies a random variable.
  
  **Data type:** DOUBLE

- \(\theta\) is a numeric constant, variable, or expression that specifies a log scale parameter. \(\exp(\theta)\) is a scale parameter.
  
  **Default:** 0
  
  **Data type:** DOUBLE
λ is a numeric constant, variable, or expression that specifies a shape parameter.

Default 1
Range $\lambda > 0$
Data type DOUBLE

Details
The PDF function for the lognormal distribution returns the probability density function of a lognormal distribution, with the log scale parameter $\theta$ and the shape parameter $\lambda$. The PDF function is evaluated at the value $x$.

$$PDF('LOGN', x, \theta, \lambda) = \begin{cases} 0 & x \leq 0 \\ \frac{1}{\lambda \sqrt{2\pi}} \exp \left( -\frac{(\log(x) - \theta)^2}{2\lambda^2} \right) & x > 0 \end{cases}$$

Example
The following statement illustrates the PDF Lognormal distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('LOGNORMAL', 1);</td>
<td>0.398942</td>
</tr>

PDF NEGBINOMIAL Distribution Function

Returns the value from the negative binomial probability density (mass) distribution.

Categories: CAS Probability
Alias: PMF
Syntax

**PDF('NEGBinomial', m, p, n)**

Arguments

**m**

is a numeric constant, variable, or expression that specifies a random variable that counts the number of failures. This argument must be a positive, whole number.

Range: \( m=0, 1, ... \)

Data type: **DOUBLE**

**p**

is a numeric constant, variable, or expression that specifies a probability of success.

Range: \( 0 \leq p \leq 1 \)

Data type: **DOUBLE**

**n**

is a numeric constant, variable, or expression that specifies a value that counts the number of successes.

Range: \( n>0 \)

Data type: **DOUBLE**

Details

The PDF function for the negative binomial distribution returns the probability density function of a negative binomial distribution, with probability of success \( p \) and number of successes \( n \). The PDF function is evaluated at the value \( m \).

\[
PDF('NEGB', m, p, n) = \begin{cases} 
0 & m < 0 \\
\binom{n + m - 1}{n - 1} p^n (1 - p)^m & m \geq 0 
\end{cases}
\]

Note: There are no location or scale parameters for the negative binomial distribution.

Example

The following statement illustrates the PDF Negative Binomial distribution function:
PDF NORMAL Distribution Function

Returns a value from the normal probability density (mass) distribution.

Categories: CAS Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF('NORMAL', x [, \theta, \lambda])

Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

\theta

is a numeric constant, variable, or expression that specifies a location parameter.

Default: 0

Data type: DOUBLE

\lambda

is a numeric constant, variable, or expression that specifies a scale parameter.

Default: 1

- “SQUANTILE Function” on page 748

PDF NORMALMIX Distribution Function
Returns a value from the normal mixture probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE
Syntax

\[
\text{PDF('NORMALMIX', } \ x, \ n, \ p_1, \ p_2, \ldots, \ p_n, \ m_1, \ m_2, \ldots, \ m_n, \ s_1, \ s_2, \ldots, \ s_n) \]

Arguments

\(x\)

is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

\(n\)

is a numeric constant, variable, or expression that specifies the number of mixtures. This argument must be a whole number.

Range: \(n=1, 2, \ldots\)

Data type: DOUBLE

\(p_i\)

is a list of numeric constants, variables, or expressions that specifies the \(n\) proportions, \(p_1, p_2, \ldots, p_n\), where \(\sum_{i=1}^{n} p_i = 1\).

Range: \(p=0, 1, \ldots\)

Data type: DOUBLE

\(m_i\)

is a list of numeric constants, variables, or expressions that specifies the \(n\) means \(m_1, m_2, \ldots, m_n\).

\(s_i\)

is a list of numeric constants, variables, or expressions that specifies the \(n\) standard deviations \(s_1, s_2, \ldots, s_n\).

Range: \(s > 0\)

Data type: DOUBLE

Details

The PDF function for the Normal Mixture distribution returns the probability that an observation from a mixture of normal distributions is less than or equal to \(x\).

\[
PDF('NORMALMIX', x, n, \ p, \ m, s) = \sum_{i=1}^{n} p_i \cdot PDF('NORMAL', x, m_i, s_i)
\]

Weights for the Normal Mixture distribution must be nonnegative. If the sum of the weights does not equal 1, then the weights are treated as relative weights and adjusted so that the sum equals 1.

Note: There are no location or scale parameters for the Normal Mixture distribution.
Example

The following statement illustrates the PDF Normal Mixture distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('NORMALMIX',2.3, 3, .33, .33, .34, .5, 1.5, 2.5, .79, 1.6, 4.3);</td>
<td>0.116554</td>
</tr>
</tbody>
</table>

PDF PARETO Distribution Function

Returns a value from the Pareto probability density (mass) distribution.

<table>
<thead>
<tr>
<th>Categories</th>
<th>CAS</th>
<th>Probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias:</td>
<td>PMF</td>
<td>Returned data type: DOUBLE</td>
</tr>
</tbody>
</table>

Syntax

PDF ('PARETO', x, a [, k])

Arguments

x

is a numeric constant, variable, or expression that specifies a numeric random variable.

Data type: DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.
Details

The PDF function for the Pareto distribution returns the probability density function of a Pareto distribution, with the shape parameter $a$ and the scale parameter $k$. The PDF function is evaluated at the value $x$.

\[
PDF(\text{`PARETO'}, x, a, k) = \begin{cases} 
0 & x < k \\
\frac{a}{k^a + 1} & x \geq k
\end{cases}
\]

Example

The following statement illustrates the PDF Pareto distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select pdf('PARETO', 1, 1);</code></td>
<td>1</td>
</tr>
</tbody>
</table>

PDF POISSON Distribution Function

Returns a value from the Poisson probability density (mass) distribution.
Syntax

PDF ('POISSON', \( n, m \))

Arguments

\( n \)

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Range \( n = 0, 1, ... \)

Data type DOUBLE

\( m \)

is a numeric constant, variable, or expression that specifies a mean parameter.

Range \( m > 0 \)

Data type DOUBLE

Details

The PDF function for the Poisson distribution returns the probability density function of a Poisson distribution, with mean \( m \). The PDF function is evaluated at the value \( n \).

\[
PDF('POISSON', n, m) = \begin{cases} 
0 & n < 0 \\
\frac{e^{-m}m^n}{n!} & n \geq 0 
\end{cases}
\]

Note: There are no location or scale parameters for the Poisson distribution.

Example

The following statement illustrates the PDF Poisson distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('POISSON', 2, 1);</td>
<td>0.18394</td>
</tr>
</tbody>
</table>

PDF T Distribution Function

Returns a value from the T probability density (mass) distribution.

Categories: CAS

Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('T', t, df [, nc])

Arguments

\( t \)

is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

\( df \)

is a numeric constant, variable, or expression that specifies the degrees of freedom.

Range: \( df > 0 \)

Data type: DOUBLE

\( nc \)

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Data type: DOUBLE
Details

The PDF function for the *T* distribution returns the probability density function of a *T* distribution, with degrees of freedom *df* and the noncentrality parameter *nc*. The PDF function is evaluated at the value *x*. This PDF function accepts noninteger degrees of freedom. If *nc* is omitted or equal to zero, the value returned is from the central *T* distribution. In this equation, let \( \nu = df \) and let \( \delta = nc \).

\[
PDF(T; \nu, \nu, \delta) = \frac{1}{2^\frac{\nu}{2} \Gamma\left(\frac{\nu}{2}\right)} \int_{0}^{\infty} x^{\nu - 1} e^{-\frac{1}{2} x^2} e^{-\frac{1}{2} \nu x^2 (\nu - \delta)} x^{\nu} \, dx
\]

Note: There are no location or scale parameters for the *T* distribution.

Example

The following statement illustrates the PDF *T* distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('T',.9,5);</td>
<td>0.24194</td>
</tr>
</tbody>
</table>

PDF TWEEDIE Distribution Function

Returns a value from the Tweedie probability density (mass) distribution.
Syntax

**PDF ("TWEEDIE", \(y, p \{\mu, \varphi\}\))**

Arguments

\(y\)
- is a numeric constant, variable, or expression that specifies a random variable.
- Range: \(y \geq 0\)
- Data type: DOUBLE
- Notes: This argument is required. When \(y > 1\), \(y\) is numeric. When \(p = 1\), \(y\) is a whole number.

\(p\)
- is a numeric constant, variable, or expression that specifies the power parameter.
- Range: \(p \geq 1\)
- Data type: DOUBLE
- Note: This argument is required.

\(\mu\)
- is a numeric constant, variable, or expression that specifies the mean parameter.
- Default: 1
- Range: \(\mu > 0\)
- Data type: DOUBLE

\(\varphi\)
- is a numeric constant, variable, or expression that specifies the dispersion parameter.
- Default: 1
- Range: \(\varphi > 0\)
- Data type: DOUBLE

Details

The PDF function for the Tweedie distribution returns an exponential dispersion model with variance and mean related by the equation $\text{variance} = \varphi \cdot \mu^p$.

$$
\frac{1}{\varphi} \sum_{j=1}^{\infty} \frac{1}{\Gamma(-\alpha)} \left( \gamma^{1-p}(\gamma - 1)^{\mu - 1} \right)^{\mu - 1} \exp \left( \frac{1}{\varphi} \left( \frac{\mu^{1-p-1} - 1}{1-p} - \frac{\mu^{2-p-1}}{2-p} \right) \right)
$$

The following relationship applies to the preceding equation:

$$
\alpha = \frac{2-p}{1-p}
$$
Note: The accuracy of computed Tweedie probabilities is highly dependent on the location in parameter space. Ten digits of accuracy are usually available except when $p$ is near 2 or $\phi$ is near 0. In either of these cases, the accuracy might be as low as six digits.

Note: To avoid issues with numerical data, $\mu$ and $\Phi$ cannot be less than the constant SQRTMACEPS.

Example

The following statement illustrates the PDF Tweedie distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('TWEEDIE', .8, 5);</td>
<td>0.742291</td>
</tr>
</tbody>
</table>

PDF UNIFORM Distribution Function

Returns a value from the uniform probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF('UNIFORM', x[, l, r])
Arguments

\( x \)

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

\( l \)

is a numeric constant, variable, or expression that specifies the left location parameter.

Default 0

Data type DOUBLE

\( r \)

is a numeric constant, variable, or expression that specifies the right location parameter.

Default 1

Range \( r > l \)

Data type DOUBLE

Details

The PDF function for the uniform distribution returns the probability density function of a uniform distribution, with the left location parameter \( l \) and the right location parameter \( r \). The PDF function is evaluated at the value \( x \).

\[
PDF('UNIFORM', x, l, r) = \begin{cases} 
0 & x < l \\
\frac{1}{r-l} & l \leq x \leq r \\
0 & x > r 
\end{cases}
\]

Example

The following statement illustrates the PDF Uniform distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('UNIFORM', 0.25);</td>
<td>1</td>
</tr>
</tbody>
</table>

PDF Wald (Inverse Gaussian) Distribution Function

Returns a value from the Wald (also known as the inverse Gaussian) probability density (mass) distribution.

Categories:
- CAS
- Probability

Alias:
- PMF

Returned data type:
- Double

Syntax

\[
\text{PDF ('WALD', } x, \lambda [, \mu]) \\
\text{PDF ('IGAUSS', } x, \lambda [, \mu])
\]

Arguments

\(x\)
- is a numeric constant, variable, or expression that specifies a random variable.

\(\lambda\)
- is a numeric constant, variable, or expression that specifies a shape parameter.

Range: \(\lambda > 0\)

\(\mu\)
- is a numeric constant, variable, or expression that specifies the mean parameter.

Default: 1

Range: \(\mu > 0\)

Details

The PDF function for the Wald distribution returns the probability density function of a Wald distribution, with the shape parameter \(\lambda\), which is evaluated at the value \(x\).

\[
f(x(x)) = \left[\frac{\lambda}{2\pi x^3}\right]^{1/2} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\}, \quad x > 0
\]

Example

The following statement illustrates the PDF Wald distribution function:
PDF WEIBULL Distribution Function

Returns a value from the Weibull probability density (mass) distribution.

Categories: CAS
Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

\[
\text{PDF}('\text{WEIBULL}', x, a [, \lambda])
\]

Arguments

\(x\)

is a numeric constant, variable, or expression that specifies a random variable.

Data type: DOUBLE

\(a\)

is a numeric constant, variable, or expression that specifies a shape parameter.

Range: \(a > 0\)

Data type: DOUBLE
\( \lambda \) is a numeric constant, variable, or expression that specifies a scale parameter.

- **Default**: 1
- **Range**: \( \lambda > 0 \)
- **Data type**: DOUBLE

**Details**

The PDF function for the Weibull distribution returns the probability density function of a Weibull distribution, with the shape parameter \( a \) and the scale parameter \( \lambda \). The PDF function is evaluated at the value \( x \).

\[
PDF(\text{WEIBULL}', x, a, \lambda) = \begin{cases} 
0 & x < 0 \\
\exp\left(-\left(\frac{x}{\lambda}\right)^a\right)^{a-1} & x \geq 0
\end{cases}
\]

**Example**

The following statement illustrates the PDF Weibull distribution function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pdf('WEIBULL', 1, 2);</td>
<td>0.735759</td>
</tr>
</tbody>
</table>

**PERM Function**

Computes the number of permutations of \( n \) items that are taken \( r \) at a time.

**Categories:**

- CAS
- Combinatorial
Syntax

\[ \text{PERM}(n[, r]) \]

Arguments

\( n \)

specifies any valid expression that represents the total number of elements from which the sample is chosen.

Data type: DOUBLE

See: "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

\( r \)

Specifies any valid expression that represents the number of chosen elements.

Restriction: \( r \leq n \)

Data type: DOUBLE

Note: If \( r \) is omitted, the function returns the factorial of \( n \).

See: "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

The mathematical representation of the PERM function is given by the following equation:

\[ \text{PERM}(n, r) = \frac{n!}{(n - r)!} \]

with \( n \geq 0, r \geq 0, \) and \( n \geq r \).

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the PERM function.

Example

The following statements illustrate the PERM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select perm(5, 1);</td>
<td>5</td>
</tr>
<tr>
<td>select perm(5);</td>
<td>120</td>
</tr>
</tbody>
</table>
PI Function

Returns the constant value of PI as a floating-point value.

Categories: Mathematical, CAS

Returned data type: DOUBLE

Syntax

PI()

Details

The value of PI is 3.141593.

Example

The following statement illustrates the PI function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pi();</td>
<td>3.141593</td>
</tr>
</tbody>
</table>

PMT Function

Returns the periodic payment for a constant payment loan or the periodic savings for a future balance.

Categories: CAS, Financial
Returned data type: DOUBLE

Syntax

\[ \text{PMT}(\text{rate}, \text{number-of-periods}, \text{principal-amount}[, \text{future-amount}[[, \text{type}]]]) \]

Arguments

\textit{rate}

specifies the interest rate per payment period.

Data type DOUBLE

\textit{number-of-periods}

specifies the number of payment periods.

Requirement \textit{Number-of-periods} must be a positive whole number.

Data type DOUBLE

\textit{principal-amount}

specifies the principal amount of the loan. Zero is assumed if a null or missing value is specified.

Data type DOUBLE

\textit{future-amount}

specifies the future amount. \textit{Future-amount} can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of periodic savings. Zero is assumed if \textit{future-amount} is omitted or if a missing value is specified.

Data type DOUBLE

\textit{type}

specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if \textit{type} is omitted or if a null or missing value is specified.

Data type DOUBLE

Example

- The monthly payment for a $10,000 loan with a nominal annual interest rate of 8% and 10 end-of-month payments can be computed in the following ways:

  \[
  \text{select PMT}(0.08/12., 10, 10000, 0, 0);
  \]

  \[
  \text{select PMT}(0.08/12., 10, 10000);
  \]

  1037.03208935915

  These computations return a value of 1037.032.

- If the same loan has beginning-of-period payments, then payment can be computed as follows:
The payment for a $5,000 loan earning a 12% nominal annual interest rate that is to be paid back in five monthly payments is computed as follows:

```sql
select PMT(.08/12., 10, 10000, 0, 1);
```

This computation returns a value of 1030.164.

- The payment for monthly periodic savings that accrue more than 18 years at a 6% nominal annual interest rate and that accumulate $50,000 at the end of the 18 years is computed as follows:

```sql
select PMT(0.06/12., 216, 0, 50000, 0);
```

This computation returns a value of -129.081.

**POISSON Function**

Returns the probability from a Poisson distribution.

<table>
<thead>
<tr>
<th>Categories:</th>
<th>CAS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probability</td>
<td></td>
</tr>
</tbody>
</table>

| Returned data type: | DOUBLE |

**Syntax**

`POISSON(m, n)`

**Arguments**

- **m**
  - Specifies any valid expression that evaluates to a numeric mean parameter.
  - Range: $m \geq 0$
  - Data type: DOUBLE
  - See: "<sql-expression> Expression" on page 820
  - "FedSQL Expressions" on page 48

- **n**
  - Specifies any valid expression that evaluates to a random variable.
  - Range: $n \geq 0$
  - Data type: DOUBLE
Details

The POISSON function returns the probability that an observation from a Poisson distribution, with mean \( m \), is less than or equal to \( n \). To compute the probability that an observation is equal to a given value, \( n \), compute the difference of two probabilities from the Poisson distribution for \( n \) and \( n-1 \).

Example

The following statement illustrates the POISSON function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select poisson(1, 2);</code></td>
<td>0.9196986029</td>
</tr>
</tbody>
</table>

POWER Function

Returns the value of a numeric value expression raised to a specified power.

Categories: Mathematical

CAS

Returned data type: DOUBLE

Syntax

\[
\text{POWER}(\text{numeric-expression}, \text{power-numeric-expression})
\]

Required Arguments

- **numeric-expression**
  - specifies any valid SQL expression that evaluates to a numeric value.
  - Data type: BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

- **power-numeric-expression**
  - specifies any valid SQL expression that evaluates to a numeric value. This argument is the power value.
Details

If *numeric-expression* is a null or missing value, then the POWER function returns a null or missing value. If the result is a number that does not fit into the range of a DOUBLE, the POWER function fails.

Example

Table: DENSITIES on page 1081

The following statements illustrate the POWER function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select power(5*3, 2);</td>
<td>225</td>
</tr>
<tr>
<td>select name from densities where squaremiles &gt;= power(density,2);</td>
<td>Afghanistan, Algeria, Angola, Argentina, Australia</td>
</tr>
</tbody>
</table>

**PROBBETA Function**

Returns the probability from a beta distribution.

**Categories:**

- CAS
- Probability

**Returned data type:**

DOUBLE

**Syntax**

**PROBBETA**(*x*, *a*, *b*)

**Arguments**

- **x**
  - is a numeric random variable.
  - Range: $0 \leq x \leq 1$
  - Data type: DOUBLE

- **a**
  - is a numeric shape parameter.
  - Range: $a > 0$
  - Data type: DOUBLE
Details
The PROBBETA function returns the probability that an observation from a beta distribution, with shape parameters $a$ and $b$, is less than or equal to $x$.

Example
The following statement illustrates the PROBBETA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select probbeta(.2,3,4);</code></td>
<td>0.09888</td>
</tr>
</tbody>
</table>

PROBBNML Function
Returns the probability from a binomial distribution.

Syntax
`PROBBNML(p, n, m)`

Arguments

$p$
- is a numeric probability of success parameter.
- Range: $0 \leq p \leq 1$
- Data type: DOUBLE

$n$
- is the number of independent Bernoulli trials parameter. This argument must be a whole number.
- Range: $n > 0$
- Data type: DOUBLE
is the number of successes random variable. This argument must be a whole number.

Range \[ 0 \leq m \leq n \]

Data type DOUBLE

Details

The PROBBNML function returns the probability that an observation from a binomial distribution, with probability of success \( p \), number of trials \( n \), and number of successes \( m \), is less than or equal to \( m \). To compute the probability that an observation is equal to a given value \( m \), compute the difference of two probabilities from the binomial distribution for \( m \) and \( m-1 \) successes.

Example

The following statement illustrates the PROBBNML function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probbnml(0.5,10,4);</td>
<td>0.376953125</td>
</tr>
</tbody>
</table>

PROBNNRM Function

Returns a probability from a bivariate normal distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Syntax

\[
\text{PROBNNRM}(x, y, r)
\]

Arguments

\( x \)

specifies a numeric constant, variable, or expression.

Data type DOUBLE

\( y \)

specifies a numeric constant, variable, or expression.

Data type DOUBLE
\( r \)

is a numeric correlation coefficient.

Range \(-1 \leq r \leq 1\)

Data type DOUBLE

Details

The PROBBNRM function returns the probability that an observation \((X, Y)\) from a standardized bivariate normal distribution with mean 0, variance 1, and a correlation coefficient \(r\), is less than or equal to \((x, y)\). That is, it returns the probability that \(X \leq x\) and \(Y \leq y\). The following equation describes the PROBBNRM function, where \(u\) and \(v\) represent the random variables \(x\) and \(y\), respectively:

\[
\text{PROBBNRM}(x, y, r) = \frac{1}{2 \pi \sqrt{1 - r^2}} \int_{-\infty}^{x} \int_{-\infty}^{y} \exp \left( -\frac{u^2 - 2ruv + v^2}{2(1 - r^2)} \right) dv \, du
\]

Example

The following statement illustrates the PROBBNRM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probbnrm(.4, -.3, .2);</td>
<td>0.27831833451902</td>
</tr>
</tbody>
</table>

PROBCHI Function

Returns the probability from a chi-square distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Syntax

\[
\text{PROBCHI}(x, df[, nc])
\]

Arguments

\(x\)

is a numeric random variable.

Range \(x \geq 0\)

Data type DOUBLE
**df**

is a numeric degrees of freedom parameter.

Range  

\[ df > 0 \]

Data type  

DOUBLE

**nc**

is an optional numeric noncentrality parameter.

Range  

\[ nc \geq 0 \]

Data type  

DOUBLE

**Details**

The PROBCHI function returns the probability that an observation from a chi-square distribution, with degrees of freedom \( df \) and noncentrality parameter \( nc \), is less than or equal to \( x \). This function accepts a noninteger degrees of freedom parameter \( df \). If the optional parameter \( nc \) is not specified or has the value 0, the value returned is from the central chi-square distribution.

**Example**

The following statement illustrates the PROBCHI function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probchi(11.264,11);</td>
<td>0.5785813293173</td>
</tr>
</tbody>
</table>

**PROBF Function**

Returns the probability from an \( F \) distribution.

Categories:  

CAS

Probability

Returned data type:  

DOUBLE

**Syntax**

\[ \text{PROBF}(x, \text{ndf}, \text{ddf}, [\text{nc}]) \]

**Arguments**

\( x \)

is a numeric random variable.

Range  

\( x \geq 0 \)
Data type: DOUBLE

\( ndf \)

is a numeric numerator degrees of freedom parameter.

Range: \( ndf > 0 \)

Data type: DOUBLE

\( ddf \)

is a numeric denominator degrees of freedom parameter.

Range: \( ddf > 0 \)

Data type: DOUBLE

\( nc \)

is an optional numeric noncentrality parameter.

Range: \( nc \geq 0 \)

Data type: DOUBLE

Details

The PROBF function returns the probability that an observation from an \( F \) distribution, with numerator degrees of freedom \( ndf \), denominator degrees of freedom \( ddf \), and noncentrality parameter \( nc \), is less than or equal to \( x \). The PROBF function accepts noninteger degrees of freedom parameters \( ndf \) and \( ddf \). If the optional parameter \( nc \) is not specified or has the value 0, the value returned is from the central \( F \) distribution.

The significance level for an \( F \) test statistic is given by the following equation.

\[ p = \frac{1 - \text{probf}(x, ndf, ddf)}{1} \]

Example

The following statement illustrates the PROBF function:

<table>

PROBGAM Function

Returns the probability from a gamma distribution.

Categories:

- CAS
- Probability

Returned data type: DOUBLE
Syntax
PRGAMGAM(x, a)

Arguments
x
is a numeric random variable.
Range x ≥ 0
Data type DOUBLE

a
is a numeric shape parameter.
Data type DOUBLE

Details
The PROBAM function returns the probability that an observation from a gamma distribution, with shape parameter a, is less than or equal to x.

Example
The following statement illustrates the PROBAM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probam(1,3);</td>
<td>0.0803013971</td>
</tr>
</tbody>
</table>

PROBHPR Function
Returns the probability from a hypergeometric distribution.

Categories:
CAS
Probability

Returned data type:
DOUBLE

Syntax
PROBHPR(N, K, n, x[, r])
Arguments

\( N \)

is a population size parameter. This argument must be a whole number.
- Range: \( N \geq 1 \)
- Data type: DOUBLE

\( K \)

is the number of items in the category of interest parameter. This argument must be a whole number.
- Range: \( 0 \leq K \leq N \)
- Data type: DOUBLE

\( n \)

is the sample size parameter. This argument must be a whole number.
- Range: \( 0 \leq n \leq N \)
- Data type: DOUBLE

\( x \)

is the random variable. This argument must be a whole number.
- Range: \( \max(0, K + n - N) \leq x \leq \min(K, n) \)

\( r \)

is a numeric odds ratio parameter.
- Range: \( r \geq 0 \)
- Data type: DOUBLE

Details

The PROBHYPR function returns the probability that an observation from an extended hypergeometric distribution, with population size \( N \), number of items \( K \), sample size \( n \), and odds ratio \( r \), is less than or equal to \( x \). If the optional parameter \( r \) is not specified or is set to 1, the value returned is from the usual hypergeometric distribution.

Example

The following statement illustrates the PROBHYPR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probhypr(200,50,10,2);</td>
<td>0.5236734081</td>
</tr>
</tbody>
</table>
**PROBIT Function**

Returns a quantile from the standard normal distribution.

**Syntax**

\[ \text{PROBIT}(p) \]

**Arguments**

- \( p \) is a numeric probability.
- \( 0 < p < 1 \)

**Details**

The PROBIT function returns the \( p \)th quantile from the standard normal distribution. The probability that an observation from the standard normal distribution is less than or equal to the returned quantile is \( p \).

**CAUTION**

The result could be truncated to lie between -8.222 and 7.941.

**Note:** PROBIT is the inverse of the PROBNORM function.

**Example**

The following statements illustrate the PROBIT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select probit(.025);</code></td>
<td>-1.959963985</td>

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

\textit{q}

is the quantile from the distribution.

Data type: DOUBLE

\textit{prob}

is the left probability from the distribution.

Data type: DOUBLE

Restriction
- Either \textit{q} or \textit{prob} can be specified, but not both.
Data type  DOUBLE

**df**

is the degrees of freedom.

Note: A missing value is interpreted as an infinite value.

**nparms**

is the number of treatments.

Data type  DOUBLE

Note  For DUNNETT1 and DUNNETT2, the control group is not counted.

**parameters**

is a set of **nparms** parameters that must be specified to handle the case of unequal sample sizes. The meaning of **parameters** depends on the value of **distribution**. If **parameters** is not specified, equal sample sizes are assumed, which is usually the case for a null hypothesis.

Data type  CHAR, NCHAR, NVARCHAR, VARCHAR

Details

Overview

The PROBMC function returns the probability or the quantile from various distributions with finite and infinite degrees of freedom for the variance estimate.

The **prob** argument is the probability that the random variable is less than \( q \). Therefore, \( p \)-values can be computed as \( 1 - \text{prob} \). For example, to compute the critical value for a 5% significance level, set \( \text{prob} = 0.95 \). The precision of the computed probability is \( O(10^{-8}) \) (absolute error); the precision of computed quantile is \( O(10^{-5}) \).

Note: The studentized range is not computed for finite degrees of freedom and unequal sample sizes.

Note: Williams’ test is computed only for equal sample sizes.

Formulas and Parameters

The equations listed here define expressions that are used in equations that relate the probability, \( \text{prob} \), and the quantile, \( q \), for different distributions and different situations within each distribution. For these equations, let \( \nu \) be the degrees of freedom, \( df \).

\[
d\mu_\nu(x) = \frac{\nu^\frac{\nu}{2}}{\Gamma\left(\frac{\nu}{2}\right)} x^{\nu-1} e^{-\frac{\nu x^2}{2}} dx
\]

\[
\phi(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}
\]
\[ \Phi(x) = \int_{-\infty}^{x} \phi(u) du \]

Computing the Analysis of Means

Analysis of Means (ANOM) applies to data that is organized as \( k \) (Gaussian) samples, the \( i \)th sample being of size \( n_i \). Let \( I = \sqrt{-1} \). The distribution function \([1, 2, 3, 4, 5]\) is the CDF for the maximum absolute of a \( k \)-dimensional multivariate \( \mathbf{T} \) vector, with \( \nu \) degrees of freedom, and an associated correlation matrix \( \rho_{ij} = \alpha_i \alpha_j \).

This equation can be written as follows.

\[
\text{prob} = r(|t_1| < h, |t_2| < h, ..., |t_k| < h) = \int_{0}^{\infty} \prod_{j=0}^{k} g(s_h, y, \alpha_j) \phi(y) dy d\mu_v(s) \]

The following relationship applies to the preceding equation:

\[
g(s_h, y, \alpha_j) = \Phi \left( \frac{s_h - y \alpha_j}{\sqrt{1 + \alpha_j^2}} \right) - \Phi \left( \frac{-s_h - y \alpha_j}{\sqrt{1 + \alpha_j^2}} \right) \]

In this equation, \( \Gamma() \), \( \phi() \), and \( \Phi() \), are the gamma function, the density, and the CDF from the standard normal distribution, respectively.

For \( \nu = \infty \), the distribution reduces to this equation.

\[
\text{prob} = r(|t_1| < h, |t_2| < h, ..., |t_k| < h) = \int_{0}^{\infty} \prod_{j=0}^{k} f(h, y, \rho) \phi(y) dy \]

The following relationship applies to the preceding equation:

\[
g(h, y, \alpha_j) = \Phi \left( \frac{h - y \alpha_j}{\sqrt{1 + \alpha_j^2}} \right) - \Phi \left( \frac{-h - y \alpha_j}{\sqrt{1 + \alpha_j^2}} \right) \]

For the balanced case, the distribution reduces to the following equation:

\[
r(|t_1| < h, |t_2| < h, ..., |t_n| < h) = \int_{0}^{\infty} f(h, y, \rho)^n \phi(y) dy \]

The following relationships apply to the preceding equation:

\[
f(h, y, \rho) = \Phi \left( \frac{h - y \sqrt{n}}{\sqrt{1 + \rho}} \right) - \Phi \left( \frac{-h - y \sqrt{n}}{\sqrt{1 + \rho}} \right) \]

Here is the syntax for this distribution:

\[ x = \text{probmc('anom', q, p, nu, n[, alpha_1, ..., alpha_n])}; \]

**Arguments**

\( x \)

is a numeric value with the returned result.

\( q \)

is a numeric value that denotes the quantile.
\( p \)
is a numeric value that denotes the probability. One of \( p \) and \( q \) must be missing.

\( nu \)
is a numeric value that denotes the degrees of freedom.

\( n \)
is a numeric value that denotes the number of samples.

\( \alpha_i, i = 1, ..., k \)
are optional numeric values denoting the alpha values from the first equation of this distribution. See "Computing the Analysis of Means" on page 696.

Many-One \( t \)-Statistics: Dunnett's One-Sided Test

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with finite degrees of freedom. The parameters are \( \lambda_1, ..., \lambda_k \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( v \). The equation follows:

\[
\text{prob} = \int_0^{\infty} \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \Phi\left( \frac{\lambda_i y + q x}{\sqrt{1 - \lambda_i^2}} \right) dy \, du_x(x)
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed (\( \lambda = \frac{1}{\sqrt{2}} \)), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( v \). The equation follows:

\[
\text{prob} = \int_0^{\infty} \int_{-\infty}^{\infty} \phi(y) \Phi\left( y + \sqrt{2} q \right)^k dy \, du_x(x)
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with infinite degrees of freedom. The parameters are \( \lambda_1, ..., \lambda_k \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
\text{prob} = \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \Phi\left( \frac{\lambda_i y + q x}{\sqrt{1 - \lambda_i^2}} \right) dy
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with infinite degrees of freedom. No parameters are passed (\( \lambda = \frac{1}{\sqrt{2}} \)), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
\text{prob} = \int_{-\infty}^{\infty} \phi(y) \Phi\left( y + \sqrt{2} q \right)^k dy
\]

Many-One \( t \)-Statistics: Dunnett's Two-sided Test

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with finite degrees of freedom. The parameters are \( \lambda_1, ..., \lambda_k \), the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( v \). The equation follows:

\[
\text{prob} = \int_0^{\infty} \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \left[ \Phi\left( \frac{\lambda_i y + q x}{\sqrt{1 - \lambda_i^2}} \right) - \Phi\left( \frac{\lambda_i y - q x}{\sqrt{1 - \lambda_i^2}} \right) \right] dy \, du_x(x)
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed, the value of \( nparms \) is set to \( k \), and the value of \( df \) is set to \( v \). The equation follows:
This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with infinite degrees of freedom. The parameters are \( \lambda_1, \ldots, \lambda_k \), the value of \( n_{\text{parms}} \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
\text{prob} = \int_0^\infty \int_{-\infty}^{\infty} \phi(y) \Phi(y + \sqrt{2qx}) - \Phi(y - \sqrt{2qx}) \, dy \, du(x)
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with infinite degrees of freedom. No parameters are passed, the value of \( n_{\text{parms}} \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
\text{prob} = \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \Phi\left(\frac{2y + q}{\lambda_i}\right) - \Phi\left(\frac{2y - q}{\lambda_i}\right) \, dy
\]

Computing the Partitioned Range

\( \text{RANGE} \) applies to the distribution of the studentized range for \( n \) group means. \( \text{PARTRANGE} \) applies to the distribution of the partitioned studentized range. Let the \( n \) groups be partitioned into \( k \) subsets of size \( n_1 + \ldots + n_k = n \). Then the partitioned range is the maximum of the studentized ranges in the respective subsets. The studentization factor is the same in all cases.

\[
\text{prob} = \int_0^\infty \prod_{i=1}^{k} \left( \int_{-\infty}^{\infty} k\phi(y)(\Phi(y) - \Phi(qx))^k - 1 \, dy \right)^{n_i} \, d\mu(x)
\]

Here is the syntax for this distribution:

\[
x = \text{probmc}(\text{partrange}, q, p, nu, k, n_1, \ldots, n_k);
\]

Arguments

- \( x \) is a numeric value with the returned result (either the probability or the quantile).
- \( q \) is a numeric value that denotes the quantile.
- \( p \) is a numeric value that denotes the quantile. One of \( p \) and \( q \) must be missing.
- \( \text{nu} \) is a numeric value that denotes the probability. One of \( p \) and \( q \) must be missing.
- \( \text{k} \) is a numeric value that denotes the number of groups.
- \( n_i, i=1,\ldots,k \) are optional numeric values that denote the \( n \) values from the equation in this distribution. See "Computing the Partitioned Range" on page 698.

The Studentized Range

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed, the value of \( n_{\text{parms}} \) is set to \( k \), and the value of \( df \) is set to \( v \). The equation follows:
\[
prob = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} k \phi(y) \left[ \Phi(y) - \Phi(y - qx) \right] dy \text{du}_{\nu}(x)
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with infinite degrees of freedom. The parameters are \( \sigma_1, ..., \sigma_k \), the value of \( \text{npars} \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
prob = \int_{-\infty}^{\infty} \sum_{j=1}^{k} \left\{ \prod_{i=1}^{k} \left[ \Phi\left(\frac{y}{\sigma_i}\right) - \Phi\left(\frac{y-q}{\sigma_i}\right) \right] \right\} \phi\left(\frac{y}{\sigma_j}\right) dy
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with infinite degrees of freedom. No parameters are passed, the value of \( \text{npars} \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
prob = \int_{-\infty}^{\infty} k \phi(y) \left[ \Phi(y) - \Phi(y - q) \right] dy
\]

The Studentized Maximum Modulus

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with finite degrees of freedom. The parameters are \( \sigma_1, ..., \sigma_k \), the value of \( \text{npars} \) is set to \( k \), and the value of \( df \) is set to \( \nu \). The equation follows:

\[
prob = \int_{0}^{\infty} \prod_{i=1}^{k} 2 \phi\left(\frac{qx}{\sigma_i}\right) - 1 \text{du}_{\nu}(x)
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed, the value of \( \text{npars} \) is set to \( k \), and the value of \( df \) is set to \( \nu \). The equation follows:

\[
prob = \int_{0}^{\infty} \left[ 2 \Phi(qx) - 1 \right]^k d\mu_{\nu}(x)
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the unequal case with finite degrees of freedom. The parameters are \( \sigma_1, ..., \sigma_k \), the value of \( \text{npars} \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
prob = \prod_{i=1}^{k} 2 \phi\left(\frac{q}{\sigma_i}\right) - 1
\]

This case relates the probability, \( \text{prob} \), and the quantile, \( q \), for the equal case with finite degrees of freedom. No parameters are passed, the value of \( \text{npars} \) is set to \( k \), and the value of \( df \) is set to missing. The equation follows:

\[
prob = \left[ 2 \Phi(q) - 1 \right]^k
\]

Williams' Test

PROBMC computes the probabilities or quantiles from the distribution defined in Williams (1971, 1972). See "References" in SAS Functions and CALL Routines: Reference. The need for the Williams' Test arises when you compare the dose treatment means with a control mean to determine the lowest effective dose of treatment.

Note: Williams' Test is computed only for equal sample sizes.

Let \( X_1, X_2, ..., X_k \) be identical independent \( \text{N}(0,1) \) random variables. Let \( Y_k \) denote their average given by the following equation.
It is required to compute the distribution of the following value.

\( (Y_k - Z)/S \)

**Arguments**

- **Y<sub>k</sub>**
  - is as defined previously.

- **Z**
  - is an \( N(0,1) \) independent random variable.

- **S**
  - is such that \( \frac{1}{2} \nu S^2 \) is a \( \chi^2 \) variable with \( v \) degrees of freedom.

As described in Williams (1971), the full computation is extremely lengthy, and is carried out in three stages. See “References” in *SAS Functions and CALL Routines: Reference*.

1. Compute the distribution of \( Y_k \). It is the fundamental (expensive) part of this operation and it can be used to find both the density and the probability of \( Y_k \). Let \( U_i \) be defined in this equation.

\[
U_i = \frac{X_1 + X_2 + \ldots + X_i}{i}, \quad i = 1, 2, \ldots, k
\]

You can write a recursive expression for the probability of \( Y_k > d \). The value of \( d \) can be any real number.

\[
\Pr(Y_k > d) = \Pr(U_1 > d) + \Pr(U_2 > d, U_1 < d) + \Pr(U_3 > d, U_2 < d, U_1 < d) + \ldots + \Pr(U_k > d, U_{k-1} < d, \ldots, U_1 < d) = \Pr(Y_{k-1} > d) + \Pr(X_k + (k-1)U_{k-1} > kd)
\]

To compute this probability, start from an \( N(0,1) \) density function.

\[
D(U_1 = x) = \phi(x)
\]

And recursively compute the convolution.

\[
D(U_k = x, U_{k-1} < d, \ldots, U_1 < d) = \int_{-\infty}^{d} D(U_{k-1} = y, U_{k-2} < d, \ldots, U_1 < d)(k-1)\phi(kx - (k-1)y)dy
\]

From this sequential convolution, it is possible to compute all the elements of the recursive equation for \( \Pr(Y_k < d) \), shown previously.

2. Compute the distribution of \( Y_k - Z \). This computation involves another convolution to compute the probability.

\[
\Pr((Y_k - Z) > d) = \int_{-\infty}^{\infty} \Pr(Y_k > \sqrt{2d} + y)\phi(y)dy
\]
3 Compute the distribution of \((Y_k - Z)/S\). This computation involves another convolution to compute the probability.

\[
\Pr((Y_k - Z) > ts) = \int_0^\infty \Pr((Y_k - Z) > ty)d\mu_v(y)
\]

The third stage is not needed when \(v = \infty\). Due to the complexity of the operations, this lengthy algorithm is replaced by a much faster one when \(k \leq 15\) for both finite and infinite degrees of freedom \(v\). For \(k \geq 16\), the lengthy computation is carried out. It is extremely expensive and very slow due to the complexity of the algorithm.

Comparisons

The MEANS statement in the GLM Procedure of SAS/STAT Software computes the following tests:

- Dunnett's one-sided test
- Dunnett's two-sided test
- Studentized Range

Examples:

Example 1: Computing the Analysis of Means

The following statements illustrate computing the analysis of means with the PROBMC function:

```sas
select probmc('anom',.,0.9,.,20) as q1,
    probmc('anom',.,0.9,20,5,0.1,0.1,0.1,0.1) as q2,
    probmc('anom',.,0.9,20,5,0.5,0.5,0.5,0.5) as q3,
    probmc('anom',.,0.9,20,5,0.1,0.2,0.3,0.4,0.5) as q4;
quit;
```

**Output 4.11 Results of Computing the Analysis of Means**

<table>
<thead>
<tr>
<th>Q1</th>
<th>Q2</th>
<th>Q3</th>
<th>Q4</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.789506</td>
<td>2.454996</td>
<td>2.454996</td>
<td>2.453232</td>
</tr>
</tbody>
</table>

Example 2: Computing the Partitioned Range

The following statements illustrate computing the partitioned range with the PROBMC function:

```sas
select probmc('partrange',.,0.9,.,4,3,4,5,6) as q1,
    probmc('partrange',.,0.9,12,4,3,4,5,6) as q2;
quit;
```
Example 3: Computing Williams' Test

In the following program, a substance has been tested at seven levels in a randomized block design of eight blocks. The observed treatment means are as follows:

<table>
<thead>
<tr>
<th>Treatment</th>
<th>Mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>$X_0$</td>
<td>10.4</td>
</tr>
<tr>
<td>$X_1$</td>
<td>9.9</td>
</tr>
<tr>
<td>$X_2$</td>
<td>10.0</td>
</tr>
<tr>
<td>$X_3$</td>
<td>10.6</td>
</tr>
<tr>
<td>$X_4$</td>
<td>11.4</td>
</tr>
<tr>
<td>$X_5$</td>
<td>11.9</td>
</tr>
<tr>
<td>$X_6$</td>
<td>11.7</td>
</tr>
</tbody>
</table>

The mean square, with $(7 – 1)(8 – 1) = 42$ degrees of freedom, is $s^2 = 1.16$.

Determine the maximum likelihood estimates $M_i$ through the averaging process.

- Because $X_0 > X_1$, form $X_{0,1} = (X_0 + X_1)/2 = 10.15$.
- Because $X_{0,1} > X_2$, form $X_{0,1,2} = (X_0 + X_1 + X_2)/3 = (2X_0 + X_2)/3 = 10.1$.
- $X_{0,1,2} < X_3 < X_4 < X_5$
- Because $X_5 > X_0$, form $X_{5,6} = (X_5 + X_6)/2 = 11.8$.

Now the order restriction is satisfied.

The maximum likelihood estimates under the alternative hypothesis are:

- $M_0 = M_1 = M_2 = X_{0,1,2} = 10.1$
- $M_3 = X_3 = 10.6$
- $M_4 = X_4 = 11.4$
- $M_5 = M_6 = X_{5,6} = 11.8$

Now compute $t = (11.8 - 10.4)/\sqrt{1.16/8} = 2.60$, and the probability that corresponds to $k = 6$, $\nu = 42$, and $t = 2.60$ is .9924467341, which shows strong evidence that there is a response to the substance.
data _null_;

Returned data type: DOUBLE

Syntax

PROB MED \((n, x)\)

Arguments

\(n\)

specifies the sample size.

Data type DOUBLE

\(x\)

is the point of interest. That is, the PROB MED function calculates the probability that the median is less than or equal to \(x\).

Data type DOUBLE

Details

The PROB MED function computes the probability that the sample median is less than or equal to \(x\) for a sample of \(n\) independent, standard normal random variables (mean 0, variance 1).

Let \(n\) represent the sample size, and \(x_{(i)}\) represents the \(i\)th order statistic. Then, when \(n\) is odd, the function makes the following calculation:

\[
\Pr \left[ X_{(n+1)/2} \leq x \right] = I_{\Phi(x)} \left( \frac{n+1}{2}, \frac{n+1}{2} \right)
\]

The following equations refer to the preceding equation:

\[
I_p(a, b) = \frac{1}{B(a, b)} \int_0^1 t^{a-1} (1-t)^{b-1} dt
\]

In the equation \(B(a, b) = \Gamma(a)\Gamma(b)/\Gamma(a + b), \Gamma(.)\) is the gamma function. If \(n\) is even, the PROB MED function performs the following calculation:

\[
\Pr \left[ \frac{X_{(n/2)} + X_{(n/2 + 1)}}{2} \leq x \right] =
\]

\[
\frac{2}{B\left(\frac{2n}{2} \frac{n}{2}\right)} \int_{-\infty}^{x} \left[ (1 - \Phi(u))^{n/2} - (1 - \Phi(2x - u))^{n/2} \right] \Phi(u)^{(n/2) - 1} \phi(u) du
\]
In this equation, \( B(n/2, n/2) = \frac{[\Gamma(n/2)]^2}{\Gamma(n)} \), and \( \Phi(.) \) and \( \phi(.) \) are the standard normal cumulative distribution function and density function, respectively.

Example

The following statement illustrates the PROBME function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probmed(5,-0.1);</td>
<td>0.425638</td>
</tr>
</tbody>
</table>

References

**PROBNEGB Function**

Returns the probability from a negative binomial distribution.

**Categories:** CAS

**Probability**

**Returned data type:** DOUBLE

**Syntax**

\[
\text{PROBNEGB}(p, n, m)
\]

**Arguments**

\( p \)

\( p \) is a numeric probability of success parameter.

- **Range:** \( 0 \leq p \leq 1 \)
- **Data type:** DOUBLE

\( n \)

\( n \) is the number of successes parameter. This argument must be a whole number.

- **Range:** \( n \geq 1 \)
- **Data type:** DOUBLE

\( m \)

\( m \) is the random variable, the number of failures. This argument must be a positive, whole number.
Range $m \geq 0$

Data type DOUBLE

Details
The PROBNEGB function returns the probability that an observation from a negative binomial distribution, with probability of success $p$ and number of successes $n$, is less than or equal to $m$.

To compute the probability that an observation is equal to a given value $m$, compute the difference of two probabilities from the negative binomial distribution for $m$ and $m-1$.

Example
The following statement illustrates the PROBNEGB function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probnegb(0.5,2,1);</td>
<td>0.5</td>
</tr>
</tbody>
</table>

PROBNORM Function
Returns the probability from the standard normal distribution.

Categories: CAS
Probability

Returned data type: DOUBLE

Syntax
PROBNORM($x$)

Arguments
$x$
is a numeric random variable.

Data type DOUBLE

Details
The PROBNORM function returns the probability that an observation from the standard normal distribution is less than or equal to $x$. 
Note: PROBNORM is the inverse of the PROBIT function.

Example
The following statement illustrates the PROBNORM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select probnorm(1.96);</code></td>
<td>0.9750021049</td>
</tr>
</tbody>
</table>

PROBT Function
Returns the probability from a t distribution of the values in an expression.

Categories:
- Aggregate
- Descriptive Statistics
- CAS

Returned data type: DOUBLE

Syntax
`PROBT([DISTINCT] expression)`

Arguments
`expression`
specifies any valid SQL expression.

Data type: DOUBLE

See
- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48

DISTINCT
(optional) eliminates duplicate rows from the aggregate calculation.

Details
The PROBT function returns the probability that an observation from a Student's t distribution, with degrees of freedom \( n-1 \) and noncentrality parameter \( nc \) equal to 0, is less than or equal to \( expression \).

The significance level of a two-tailed t test is given by this code line.

\[
p = (1 - \text{probt(abs(x), df)})^2;
\]
You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Comparisons

The STUDENTS_T function returns the Student's t-distribution. The PROBT function returns the probability that the Student's t-distribution is less than or equal to a given value.

Example

Table: DENSITIES

The following statements illustrate the PROBT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select probt(density) from densities;</td>
<td>0.006068</td>
</tr>
<tr>
<td>select probt(population) from densities;</td>
<td>0.009722</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “STUDENTS_T Function” on page 756

SELECT Statement Clauses:
- “SELECT Clause” on page 877
- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890

PUT Function

Returns a value using a specified format.

Categories: Special

CAS

Returned data type: NVARCHAR VARBINARY BINARY
Syntax

**PUT**(*source, format*)

Arguments

**source**
identifies the variable or constant whose value you want to reformat.

Data type  A data type that is supported by the format argument

**format.**
contains the SAS or FedSQL format that you want applied to the variable or constant that is specified in the source.

To override the default alignment, you can add an alignment specification to a format:

-L
left aligns the value

-C
centers the value

-R
right aligns the value

Restriction  The format must be the same type as the value of *source*

Details

The PUT function affects the output of the query in which it is specified. It temporarily modifies the data type of the specified input variable.

The result of the PUT function is always a character string. If the source is numeric, the resulting string is right-aligned. If the source is character, the result is left-aligned.

Use PUT to format constants and to output stored data in a different format. Use PUT to convert a numeric value to a character value. For more information, see “How to Format Output with the PUT Function” on page 81.

Comparisons

The CAST function permanently modifies the data type of the specified input variable. The PUT function affects the output of the query in which it is specified.

Example

Table: WORLDTEMPS on page 1092

The following statement illustrates the PUT function.

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select put(0.6666666667, fract8.);</code></td>
<td>2/3</td>
</tr>
</tbody>
</table>
### Statement

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(date(), date());</td>
<td>19SEP13</td>
</tr>
<tr>
<td>select put(AvgLow, 4.1) from worldtemps;</td>
<td>45.0</td>
</tr>
<tr>
<td></td>
<td>33.0</td>
</tr>
<tr>

“How to Format Output with the PUT Function” on page 81

---

**PVP Function**

Returns the present value for a periodic cash flow stream (such as a bond), with repayment of principal at maturity.

**Categories:**

- CAS
- Financial

**Returned data type:**

**DOUBLE**

### Syntax

\[
PVP(A, c, n, K, k_0, y)
\]

### Arguments

**\( A \)**

- Specifies the par value.
- **Range:** \( A > 0 \)
- **Data type:** DOUBLE

**\( c \)**

- Specifies the nominal per-year coupon rate, expressed as a fraction.
- **Range:** \( 0 \leq c < 1 \)
- **Data type:** DOUBLE
\( n \) specifies the number of coupons per year.

- **Range**: \( n > 0 \)
- **Data type**: DOUBLE

\( K \) specifies the number of remaining coupons.

- **Range**: \( K > 0 \)
- **Data type**: DOUBLE

\( k_0 \) specifies the time from the present date to the first coupon date, expressed in terms of the number of years.

- **Range**: \( 0 < k_0 \leq \frac{1}{n} \)
- **Data type**: DOUBLE

\( y \) specifies the nominal per-year yield-to-maturity, expressed as a fraction.

- **Range**: \( y > 0 \)
- **Data type**: DOUBLE

**Details**

The PVP function is based on the following relationship:

\[
P = \sum_{k=1}^{K} \frac{c(k)}{(1 + \frac{y}{n})^k}
\]

The following relationships apply to the preceding equation:

- \( t_k = nk_0 + k - 1 \)
- \( c(k) = \frac{e}{n} for k = 1, \ldots, K - 1 \)
- \( c(K) = (1 + \frac{e}{n})A \)

**Example**

The following statement illustrates the PVP function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select pvp(1000,.01,4,14,.33/2,.10);</td>
<td>743.1676</td>
</tr>
</tbody>
</table>
QTR Function

Returns the quarter of the year from a SAS date value.

Categories: CAS
Date and Time

Returned data type: DOUBLE

Syntax

\texttt{QTR(date)}

Arguments

date

specifies any valid expression that represents a SAS date value.

Data type: DOUBLE

See

"\texttt{<sql-expression> Expression} on page 820"

"FedSQL Expressions" on page 48

Details

The QTR function returns a value of 1, 2, 3, or 4 from a SAS date value to indicate the quarter of the year in which a date value falls.

For more information about how FedSQL handles date and time values, see "Dates and Times in FedSQL" on page 60.

Example

The following statements illustrate the QTR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select qtr(16983);</td>
<td>3</td>
</tr>
<tr>
<td>select qtr(17075);</td>
<td>4</td>
</tr>
</tbody>
</table>

Functions:

- “YYQ Function” on page 799
QUANTILE Function

Returns the quantile from a distribution when you specify the left probability (CDF).

Categories:
- CAS
  - Quantile

Returned data type:
- Double

See:
- “CDF Function” on page 295

Syntax

QUANTILE('distribution', probability, parameter-1, ..., parameter-k)

Arguments

distribution

is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the QUANTILE distribution functions are identical to those of the corresponding CDF distribution functions.

Here are valid distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Beta</td>
<td>'BETA'</td>

<td>'TWEEDIE'</td>
</tr>
<tr>
<td>Uniform</td>
<td>'UNIFORM'</td>
</tr>
<tr>
<td>Wald (inverse Gaussian)</td>
<td>'WALD'</td>
</tr>
<tr>
<td>Weibull</td>
<td>'WEIBULL'</td>
</tr>
</tbody>
</table>

**Note:** Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

**probability**

is a numeric constant, variable, or expression that specifies the value of a random variable.

**parameter-1, ..., parameter-k**

are optional shape, location, or scale parameters appropriate for the specific distribution.

### Details

The QUANTILE function computes the quantile from the specified continuous or discrete distribution, based on the probability value that is provided. For more information, see the individual distributions noted in the table above.

The Conway-Maxwell-Poisson distribution for the QUANTILE function returns the counts value $y$ that is the largest whole number whose CDF value is less than or equal to $p$. The syntax for the Conway-Maxwell-Poisson distribution in the QUANTILE function has the following form:
**QUANTILE**('CONMAXPOI', \(p, \lambda, \nu\))

\(p\)

is a real number between 0 and 1, inclusively.

\(\lambda\)

is similar to the mean, as in the Poisson distribution.

\(\nu\)

is a dispersion parameter.

For more information, see “Conway-Maxwell-Poisson” distribution in the PDF function on page 649.

**Example**

The following statements illustrate the QUANTILE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select quantile('BERN', 0.75, 0.25);</td>
<td>0</td>
</tr>
<tr>
<td>select quantile('BETA', 0.1, 3, 4);</td>
<td>0.200909</td>
</tr>
<tr>
<td>select quantile('BINOM', 0.4, 0.5, 10);</td>
<td>5</td>
</tr>
<tr>
<td>select quantile('CAUCHY', 0.85);</td>
<td>1.962611</td>
</tr>
<tr>
<td>select quantile('CHISQ', 0.6, 11);</td>
<td>11.52983</td>
</tr>
<tr>
<td>select quantile('CONMAXPOI', 0.2, 2.3, 0.4);</td>
<td>5</td>
</tr>
<tr>
<td>select quantile('EXPO', 0.6);</td>
<td>0.916291</td>
</tr>
<tr>
<td>select quantile('F', 0.8, 2, 3);</td>
<td>2.886027</td>
</tr>
<tr>
<td>select quantile('GAMMA', 0.4, 3);</td>
<td>2.285077</td>
</tr>
<tr>
<td>select quantile('GENPOISSON', 0.9, 1, 0.7);</td>
<td>9</td>
</tr>
<tr>
<td>select quantile('HYPER', 0.5, 200, 50, 10);</td>
<td>2</td>
</tr>
<tr>
<td>select quantile('LAPLACE', 0.8);</td>
<td>0.916291</td>
</tr>
<tr>
<td>select quantile('LOGISTIC', 0.7);</td>
<td>0.847298</td>
</tr>
<tr>
<td>select quantile('LOGNORMAL', 0.5);</td>
<td>1</td>
</tr>
<tr>
<td>select quantile('NEGB', 0.5, 0.5, 2);</td>
<td>1</td>
</tr>
<tr>
<td>select quantile('NORMAL', 0.975);</td>
<td>1.959964</td>
</tr>
<tr>
<td>select quantile('NORMALMIX', 0.5, 1, 0.2, 1.1, 0.1);</td>
<td>1.1</td>
</tr>
<tr>
<td>select quantile('PARETO', 0.01, 1);</td>
<td>1.010101</td>
</tr>
</tbody>
</table>
## QUOTE Function

Adds double quotation marks to a character value.

### Categories:
- CAS
- Character

### Returned data type:
- CHAR, NCHAR, NVARCHAR, VARCHAR

### Syntax

`QUOTE(expression)`

### Arguments

**expression**
specifies any valid expression that evaluates or can be coerced to a character string.

---

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select quantile('POISSON', .9, 1);</code></td>
<td>2</td>
</tr>
<tr>
<td><code>select quantile('T', .8, 5);</code></td>
<td>0.919544</td>
</tr>
<tr>
<td><code>select quantile('TWEEDIE', .8, 5);</code></td>
<td>1.26112</td>
</tr>
<tr>
<td><code>select quantile('UNIFORM', 0.25);</code></td>
<td>0.25</td>
</tr>
<tr>
<td><code>select quantile('WALD', .6, 2);</code></td>
<td>0.952621</td>
</tr>
<tr>
<td><code>select quantile('WEIBULL', .6, 2);</code></td>
<td>0.957231</td>
</tr>
</tbody>
</table>

### See Also

**Functions:**

- “PDF Function” on page 639
- “SDF Function” on page 737
- “SQUANTILE Function” on page 748
Details

The QUOTE function adds double quotation marks, the default character, to a character value. If double quotation marks are found within the argument, they are doubled in the output.

The length of the receiving variable must be long enough to contain the argument (including trailing blanks), leading and trailing quotation marks, and any embedded quotation marks that are doubled. For example, if the argument is ABC followed by three trailing blanks, then the receiving variable must have a length of at least eight to hold “ABC###”. (The character # represents a blank space.) If the receiving field is not long enough, the QUOTE function returns a blank string, and writes an invalid argument note to the SAS log.

A string of characters enclosed in double quotation marks is a DS2 identifier and not a character constant. The double quotation marks become part of the identifier. Quoted identifiers cannot be used to create column names in an output table.

Example

The following statements illustrate the QUOTE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select quote('A&quot;B');</td>
<td>&quot;A&quot;&quot;B&quot;</td>
</tr>
<tr>
<td>select quote('A''B');</td>
<td>&quot;A'B&quot;</td>
</tr>
<tr>
<td>select quote('Paul''s Catering Service');</td>
<td>&quot;Paul's Catering Service&quot;</td>
</tr>
</tbody>
</table>

RADIANS Function

Returns the number of radians converted from a numeric degree value.

Categories: Trigonometric
            CAS

Returned data type: DOUBLE

Syntax

RADIANS(expression)
Arguments

expression
specifies any valid SQL expression that evaluates to a numeric value.

Data type \[\text{BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT}\]

See
“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Example

The following statement illustrate the RADIANS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select radians(360);</code></td>
<td>6.283185</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “DEGREES Function” on page 392

RANGE Function

Returns the range between values in an expression.

Categories:
- Aggregate
- Descriptive Statistics
- CAS

Returned data type: the same type as the expression

Syntax

\[
\text{RANGE}[\text{[DISTINCT]} ~ \text{expression}]
\]

Arguments

expression
specifies any valid SQL expression.

Data type \[\text{BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT}\]

See
“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48
DISTINCT
(optional) eliminates duplicate rows from the aggregate calculation.

Details
The RANGE function returns the difference between the largest and the smallest values in the specified expression. The RANGE function ignores null values and SAS missing values.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Example
Table: WORLDTEMPS on page 1092
The following statement illustrates the RANGE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select range(AvgHigh) from worldtemps;</td>
<td>27</td>
</tr>
</tbody>
</table>

See Also

SELECT Statement Clauses:
- “SELECT Clause” on page 877
- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890

RANK Function
Returns the position of a character in the ASCII collating sequence.

Categories: CAS
Character

Returned data type: DOUBLE

Syntax
\[ \text{RANK}(\text{expression}) \]
Arguments

**expression**
specifies any valid expression that evaluates or can be coerced to a character string.

**Data type** CHAR, NCHAR, NVARCHAR, VARCHAR

**See**
"&lt;sql-expression&gt; Expression" on page 820
"FedSQL Expressions" on page 48

Details

The RANK function returns a whole number that represents the position of the character in the ASCII collating sequence. When more than one character is specified, the RANK function returns the position in the ASCII collating sequence for the first character.

**Note:** Any program that uses the RANK function with characters above ASCII 127 is not portable. (The hexadecimal notation is '7F'x.) The program is not portable because these characters are national characters and they vary from country to country.

Example

The following statement illustrates the RANK function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ASCII</td>
</tr>
<tr>
<td>select 'rank'('A');</td>
<td>65</td>
</tr>
</tbody>
</table>

**Note:** RANK is a FedSQL reserved word. The RANK function must be specified as a delimited identifier.

See Also

**Functions:**

- "BYTE Function" on page 292

---

**REPEAT Function**

Repeats a character expression.

**Categories:** CAS
**REPEAT Function**

Reverses a character expression.

**Syntax**

\[ \text{REPEAT}(\text{expression}, \text{n}) \]

**Arguments**

*expression*

specifies any valid expression that evaluates or can be coerced to a character string.

*Data type*

CHAR, NCHAR, NVARCHAR, VARCHAR

*See*

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

*n*

specifies the number of times to repeat *expression*.

*Restriction*

\( n \) must be greater than or equal to 0.

*Data type*

BIGINT, DOUBLE

**Details**

The REPEAT function returns a character value consisting of the first argument repeated \( n \) times. Thus, the first argument appears \( n+1 \) times in the result.

**Example**

The following statement illustrates the REPEAT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select repeat('ONE',2);</code></td>
<td>ONEONEONE</td>
</tr>
</tbody>
</table>
Syntax

REVERSE(expression)

Arguments

expression

specifies any valid expression that evaluates or can be coerced to a character string.

Data type

CHAR, NCHAR, NVARCHAR, VARCHAR

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The REVERSE function returns a character value with the last character in the expression is the first character in the result, the next-to-last character in the expression is the second character in the result, and so on.

Note: Trailing blanks in the expression become leading blanks in the result.

Example

The following statement illustrates the REVERSE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>------</td>
</tr>
<tr>
<td>select reverse('xyz ');</td>
<td>zyx</td>
</tr>
</tbody>
</table>

RMS Function

Returns the root mean square.

Categories:

CAS
Descriptive Statistics

Returned data type:

DOUBLE

Syntax

RMS(expression [, ...expression])
Arguments

**expression**
specifies any valid expression that evaluates to a numeric value.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The root mean square is the square root of the arithmetic mean of the squares of the values. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the root mean square of the non-null or nonmissing values.

Let \( n \) be the number of arguments with non-null or nonmissing values, and let \( x_1, x_2, \ldots, x_n \) be the values of those arguments. The root mean square is calculated as follows.

\[
\sqrt{\frac{x_1^2 + x_2^2 + \ldots + x_n^2}{n}}
\]

Example

The following statements illustrate the RMS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select rms(1,7);</td>
<td>5</td>
</tr>
<tr>
<td>select rms(.,1,5,11);</td>
<td>7</td>
</tr>
</tbody>
</table>

ROUND Function

Rounds the first argument to the nearest multiple of the second argument, or to the nearest integer when the second argument is omitted.

Categories: CAS

Truncation

| Returned data type: | DOUBLE |

Syntax

ROUND(expression [, rounding-unit])
Arguments

expression
specifies any valid expression that evaluates to a numeric value, to be rounded.

Data type DOUBLE

See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

rounding-unit
specifies a positive numeric expression that specifies the rounding unit.

Data type DOUBLE

See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

Details

Basic Concepts

The ROUND function rounds the first argument to a value that is very close to a multiple of the second argument. The results might not be an exact multiple of the second argument.

Differences between Binary and Decimal Arithmetic

Computers use binary arithmetic with finite precision. If you work with numbers that do not have an exact binary representation, computers often produce results that differ slightly from the results that are produced with decimal arithmetic.

For example, the decimal values 0.1 and 0.3 do not have exact binary representations. In decimal arithmetic, 3*0.1 is exactly equal to 0.3, but this equality is not true in binary arithmetic.

The Effects of Rounding

Rounding by definition finds an exact multiple of the rounding unit that is closest to the value to be rounded. For example, 0.33 rounded to the nearest tenth equals 3*0.1 or 0.3 in decimal arithmetic. In binary arithmetic, 0.33 rounded to the nearest tenth equals 3*0.1, and not 0.3, because 0.3 is not an exact multiple of one tenth in binary arithmetic.

The ROUND function returns the value that is based on decimal arithmetic, even though this value is sometimes not the exact, mathematically correct result. In the example \texttt{ROUND(0.33, 0.1)}, \texttt{ROUND} returns 0.3 and not 3*0.1.

Testing for Approximate Equality

You should not use the ROUND function as a general method to test for approximate equality. Two numbers that differ only in the least significant bit can round to different values if one number rounds down and the other number rounds up. Testing for approximate equality depends on how the numbers have been computed. If both numbers are computed to high relative precision, you could test for approximate equality by using the ABS and the MAX functions.
Producing Expected Results

In general, \( \text{ROUND}(\text{expression}, \text{rounding-unit}) \) produces the result that you expect from decimal arithmetic if the result has no more than nine significant digits and any of the following conditions are true:

- The rounding unit is an integer.
- The rounding unit is a power of 10 greater than or equal to 1e-15. \(^1\)
- The result that you expect from decimal arithmetic has no more than four decimal places.

For example:

\[
\begin{align*}
\text{select round(1234.56789,100);} & \quad \text{Result: 1200} \\
\text{select round(1234.56789,10);} & \quad \text{Result: 1230} \\
\text{select round(1234.56789,1);} & \quad \text{Result: 1235} \\
\text{select round(1234.56789,.1);} & \quad \text{Result: 1234.6} \\
\text{select round(1234.56789,.01);} & \quad \text{Result: 1234.57} \\
\text{select round(1234.56789,.001);} & \quad \text{Result: 1234.568} \\
\text{select round(1234.56789,.0001);} & \quad \text{Result: 1234.5679} \\
\text{select round(1234.56789,.00001);} & \quad \text{Result: 1234.56789} \\
\text{select round(1234.56789,.000001);} & \quad \text{Result: 1234.5432} \\
\text{select round(1234.56789,.0000001);} & \quad \text{Result: 1234.54321} \\
\end{align*}
\]

When the Rounding Unit Is the Reciprocal of an Integer

When the rounding unit is the reciprocal of an integer \(^2\), the ROUND function computes the result by dividing by the integer. Therefore, you can safely compare the result from ROUND with the ratio of two integers, but not with a multiple of the rounding unit.

Computing Results in Special Cases

The ROUND function computes the result by multiplying an integer by the rounding unit when all of the following conditions are true:

- The rounding unit is not an integer.
- The rounding unit is not a power of 10.
- The rounding unit is not the reciprocal of an integer.
- The result that you expect from decimal arithmetic has no more than four decimal places.

For example:

\[
\text{select round(1234.56789,.1111) - 11111*.1111;}
\]

Returns the value 0 (zero).

---

1. If the rounding unit is less than one, ROUND treats it as a power of 10 if the reciprocal of the rounding unit differs from a power of 10 in at most the three or four least significant bits.
2. ROUND treats the rounding unit as a reciprocal of an integer if the reciprocal of the rounding unit differs from an integer in at most the three or four least significant bits.
Computing Results When the Value Is Halfway between Multiples of the Rounding Unit

When the value to be rounded is approximately halfway between two multiples of the rounding unit, the ROUND function rounds up the absolute value and restores the original sign.

Example

The following statement illustrates the ROUND function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select round(9.5,10);</td>
<td>10</td>
</tr>
</tbody>
</table>

ROUNDZ Function

Rounds the first argument to the nearest multiple of the second argument, using zero fuzzing.

Categories: CAS, Truncation

Returned data type: DOUBLE

Syntax

ROUNDZ(expression [, rounding-unit])

Arguments

expression

specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See

“<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48
**rounding-unit**
specifies any valid expression that evaluates to a numeric expression and that specifies the rounding unit.

<table>
<thead>
<tr>
<th>Default</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirement</td>
<td>Only positive values are valid.</td>
</tr>
<tr>
<td>Data type</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

See “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

**Details**

The ROUNDZ function rounds the first argument to the nearest multiple of the second argument.

**Comparisons**

The ROUNDZ function is the same as the ROUND function with these exceptions:

- ROUNDZ returns an even multiple when the first argument is exactly halfway between the two nearest multiples of the second argument. ROUND returns the multiple with the larger absolute value when the first argument is approximately halfway between the two nearest multiples.

- When the rounding unit is less than one and not the reciprocal of an integer, the result that is returned by ROUNDZ might not agree exactly with the result from decimal arithmetic. ROUND does not fuzz the result. ROUND performs extra computations, called fuzzing, to try to make the result agree with decimal arithmetic.

**Example: Sample Output from the ROUNDZ Function**

The following statements illustrate the ROUNDZ function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select put(roundz(223.456, 1), 9.5);</td>
<td>223.00000</td>
</tr>
<tr>
<td>select put(roundz(223.456, .01), 9.5);</td>
<td>223.46000</td>
</tr>
<tr>
<td>select put(roundz(223.456, 100), 9.5);</td>
<td>200.00000</td>
</tr>
<tr>
<td>select put(roundz(223.456, .3), 9.5);</td>
<td>223.50000</td>
</tr>
</tbody>
</table>

**Functions:**

- “ROUND Function” on page 723
SAVING Function

Returns the future value of a periodic saving.

Category: Financial

Restriction: This function is not supported on the CAS server.

Returned data type: DOUBLE

Syntax

SAVING(\(f, p, r, n\))

Arguments

\(f\)
is numeric, the future amount (at the end of \(n\) periods).

Range \(f \geq 0\)

Data type DOUBLE

\(p\)
is numeric, the fixed periodic payment.

Range \(p \geq 0\)

Data type DOUBLE

\(r\)
is numeric, the periodic interest rate expressed as a decimal.

Range \(r \geq 0\)

Data type DOUBLE

\(n\)
is an integer, the number of compounding periods.

Range \(n \geq 0\)

Data type DOUBLE

Details

The SAVING function returns the missing argument in the list of four arguments from a periodic saving. The arguments are related by the following equation:

\[ f = \frac{p(1 + r)(1 + r)^n - 1}{r} \]
One missing argument must be provided. It is then calculated from the remaining three. No adjustment is made to convert the results to round numbers.

Example

A savings account pays a 5% nominal annual interest rate, compounded monthly. For a monthly deposit of $100, the number of payments that are needed to accumulate at least $12,000, can be expressed as follows:

```sql
select saving(12000, 100, .05/12, .);
```

The value that is returned is 97.18 months. The fourth argument is set to missing, which indicates that the number of payments is to be calculated. The 5% nominal annual rate is converted to a monthly rate of 0.05/12. The rate is the fractional (not the percentage) interest rate per compounding period.

See Also

Functions:
- “SAVINGS Function” on page 729

SAVINGS Function

Returns the balance of a periodic savings by using variable interest rates.

Categories: CAS
Financial

Returned data type: DOUBLE

Syntax

```sql
SAVINGS(base-date, initial-deposit-date, deposit-amount, deposit-number, deposit-interval, compounding-interval, date-1, rate-1[, …date-n, rate-n])
```

Arguments

- **base-date**
  - specifies the value that is returned is the balance of the savings at the base date.
  - Requirement: *Base-date* is a SAS date.
  - Data type: DOUBLE

- **initial-deposit-date**
  - specifies the date of the first deposit. Subsequent deposits are at the beginning of subsequent deposit intervals.
  - Requirement: *Initial-deposit-date* is a SAS date.
Data type DOUBLE

**deposit-amount**
specifies the value of each deposit. All deposits are assumed constant.

Data type DOUBLE

**deposit-number**
specifies the number of deposits.

Data type DOUBLE

**deposit-interval**
specifies the frequency at which deposits are made.

Requirement *Deposit-interval* is a SAS interval.

Data type CHAR

**compounding-interval**
specifies the compounding interval.

Requirement *Compounding-interval* is a SAS interval.

Data type CHAR

**date**
specifies the time at which *rate* takes effect. Each date is paired with a rate.

Requirement *Date* is a SAS date.

Data type DOUBLE

**rate**
specifies the interest rate as numeric percentage that starts on *date*. Each rate is paired with a date.

Data type DOUBLE

Details

The following details apply to the SAVINGS function:

- The values for rates must be between –99 and 120.
- *Deposit-interval* cannot be ’CONTINUOUS’.
- The list of date-rate pairs does not need to be in chronological order.
- When multiple rate changes occur on a single date, the SAVINGS function applies only the final rate that is listed for that date.
- Simple interest is applied for partial periods.
- There must be a valid date-rate pair whose date is at or prior to both the *initial-deposit-date* and the *base-date*. 
Example

- If you deposit $300 monthly for two years into an account that compounds quarterly at an annual rate of 4%, the balance of the account after five years can be expressed as follows:

  ```
  select savings(date'2005-01-01', date'2000-01-01',
                 300, 24, 'month', 'qtr', date'2000-01-01', 4.00);
  ```

  The following line is written to the SAS log.

  8458.794159

- If the interest rate increases by a quarter-point each year, then the balance of the account could be expressed as follows:

  ```
  select savings(date'2005-01-01', date'2000-01-01',
                 300, 24, 'month', 'qtr', date'2000-01-01', 4.00, date'2001-01-01', 4.25,
                 date'2002-01-01', 4.50, date'2003-01-01', 4.75, date'2004-01-01', 5.0);
  ```

  The following line is written to the SAS log.

  8665.5059376

- To determine the balance after one year of deposits, the following program sets amount_base3 to the desired balance:

  ```
  select savings(date'2001-01-01', date'2000-01-01',
                 300, 24, 'month', 'qtr', date'2000-01-01', 4);
  ```

  The following line is written to the SAS log.

  3978.69037121739

The SAVINGS function ignores deposits after the base date, so the deposits after the reference date do not affect the value that is returned.

  - "SAVING Function" on page 728

---

**SCAN Function**

Returns the n th word from a character expression.

Categories: CAS
  Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

**Syntax**

```
SCAN(expression, n [, delimiters[, modifier]])
```
Arguments

**expression**
specifies any valid expression that evaluates or can be coerced to a character string.

Data type  CHAR, NCHAR, NVARCHAR, VARCHAR

See  “<sql-expression> Expression” on page 820
     “FedSQL Expressions” on page 48

**n**
is a nonzero numeric expression that specifies the number of the word in the character expression that you want SCAN to select. The following rules apply:

- If **n** is positive, SCAN counts words from left to right in the character string.
- If **n** is negative, SCAN counts words from right to left in the character string.
- If **n** is greater than the number of words in **expression**, SCAN returns a blank value.

**delimiters**
specifies any valid expression that evaluates or can be coerced to a character string and that SCAN uses as word separators in the expression.

Default

Requirement  If **delimiter** is a constant, enclose **delimiter** in single quotation marks.

Interactions  ASCII default delimiters are: blank ! $ % & ( ) * + , – . / ; < |. In environments without the ^ character, SCAN uses the ~ character instead.

EBCDIC default delimiters are: blank ! $ % & ( ) * + , – . / ; < ¬ | ¢.

Specifying a modifier can change the characters in **delimiter**. For example, if you specify the K modifier in the **modifier** argument, all characters that are not in **delimiter** are used as delimiters.

Data type  CHAR, NCHAR, NVARCHAR, VARCHAR

Tip  You can add more characters to **delimiter** by using other modifiers.

See  “Using Default Delimiters in ASCII and EBCDIC Environments” on page 734
     “<sql-expression> Expression” on page 820
     “FedSQL Expressions” on page 48

**modifier**
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the SCAN function. Blanks are ignored. Use the following characters as modifiers:

- a or A    adds alphabetic characters to the list of characters.
b or B  scans backward from right to left instead of from left to right, regardless of the sign of the count argument.

c or C  adds control characters to the list of characters.

d or D  adds digits to the list of characters.

f or F  adds an underscore and English letters to the list of characters.

g or G  adds graphic characters to the list of characters. Graphic characters are characters that, when printed, produce an image on paper.

h or H  adds a horizontal tab to the list of characters.

i or I  ignores the case of the characters.

k or K  causes all characters that are not in the list of characters to be treated as delimiters. That is, if K is specified, characters that are in the list of characters are kept in the returned value rather than being omitted because they are delimiters. If K is not specified, then all characters that are in the list of characters are treated as delimiters.

l or L  adds lowercase letters to the list of characters.

m or M  specifies that multiple consecutive delimiters, and delimiters at the beginning or end of the string argument, refer to words that have a length of zero. If the M modifier is not specified, then multiple consecutive delimiters are treated as one delimiter, and delimiters at the beginning or end of the string argument are ignored.

n or N  adds digits, an underscore, and English letters to the list of characters.

o or O  processes the charlist and modifier arguments only once, rather than every time the SCAN function is called. Using the O modifier in the DATA step (excluding WHERE clauses), or in the SQL procedure can make SCAN run faster when you call it in a loop where the character-list and modifier arguments do not change. The O modifier applies separately to each instance of the SCAN function in your SAS code, and does not cause all instances of the SCAN function to use the same delimiters and modifiers.

p or P  adds punctuation marks to the list of characters.

q or Q  ignores delimiters that are inside substrings that are enclosed in quotation marks. If the value of the string argument contains unmatched quotation marks, then scanning from left to right produces different words than scanning from right to left.

r or R  removes leading and trailing blanks from the word that SCAN returns. If you specify the Q and R modifiers, the SCAN function first removes leading and trailing blanks from the word. Then, if the word begins with a quotation mark, SCAN also removes one layer of quotation marks from the word.

s or S  adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).

t or T  trims trailing blanks from the string and charlist arguments. If you want to remove trailing blanks from only one character argument instead of both character arguments, use the TRIM function instead of the SCAN function with the T modifier.
u or U adds uppercase letters to the list of characters.
w or W adds printable (writable) characters to the list of characters.
x or X adds hexadecimal characters to the list of characters.

Restriction This argument is supported only in SAS Viya and on the CAS server.

Tip If the modifier argument is a character constant, enclose the argument in quotation marks. Specify multiple modifiers in a single set of quotation marks. A modifier argument can also be expressed as a character variable or expression.

Details

Definitions of “Delimiter” and “Word”

A delimiter is any of several characters that are used to separate words. You can specify the delimiters in the delimiter and modifier arguments.

If you specify the Q modifier, delimiters inside substrings that are enclosed in quotation marks are ignored.

In the SCAN function, “word” refers to a substring that has all of these characteristics:

- It is bounded on the left by a delimiter or the beginning of the string.
- It is bounded on the right by a delimiter or the end of the string.
- It contains no delimiters.

A word can have a length of zero if there are delimiters at the beginning or end of the string, or if the string contains two or more consecutive delimiters. However, the SCAN function ignores words that have a length of zero unless you specify the M modifier.

Note: The definition of “word” is the same in the SCAN and COUNTW functions.

Using Default Delimiters in ASCII and EBCDIC Environments

If you use the SCAN function with only two arguments, then the default delimiters depend on whether your computer uses ASCII or EBCDIC characters.

- If your computer uses ASCII characters, the default delimiters are as follows:
  
  blank ! $ % & ( ) * + , - . / ; < ^ | 
  
  In ASCII environments that do not contain the ^ character, the SCAN function uses the ~ character instead.

- If your computer uses EBCDIC characters, then the default delimiters are as follows:
  
  blank ! $ % & ( ) * + , - . / ; < ¬ | ¢ 
  
  If you use the modifier argument without specifying any characters as delimiters, then the only delimiters that are used are delimiters that are defined by the modifier argument. In this case, the lists of default delimiters for ASCII and EBCDIC environments are not used. In other words, modifiers add to the list of delimiters that
are explicitly specified by the *delimiter* argument. Modifiers do not add to the list of default modifiers.

**The Length of the Result**

Leading delimiters before the first word in the expression do not affect SCAN. If there are two or more contiguous delimiters, SCAN treats them as one.

The minimum length of the word that is returned by the SCAN function depends on whether the M modifier is specified. See “Using the SCAN Function with the M Modifier” on page 735. See also “Using the SCAN Function without the M Modifier” on page 735.

**Using the SCAN Function with the M Modifier**

If you specify the M modifier, the number of words in a string is defined as one plus the number of delimiters in the string. However, if you specify the Q modifier, delimiters that are inside quotation marks are ignored.

If you specify the M modifier, the SCAN function returns a word with a length of zero if one of these conditions is true:

- The string begins with a delimiter and you request the first word.
- The string ends with a delimiter and you request the last word.
- The string contains two consecutive delimiters and you request the word that is between the two delimiters.

**Using the SCAN Function without the M Modifier**

If you do not specify the M modifier, the number of words in a string is defined as the number of maximal substrings of consecutive non-delimiters. However, if you specify the Q modifier, delimiters that are inside quotation marks are ignored.

If you do not specify the M modifier, the SCAN function acts in these ways:

- It ignores delimiters at the beginning or end of the string.
- It treats two or more consecutive delimiters as if they were a single delimiter.

If the string contains no characters other than delimiters, or if you specify a count that is greater in absolute value than the number of words in the string, then the SCAN function returns one of the following items:

- a single blank when you call the SCAN function from a DATA step
- a string with a length of zero when you call the SCAN function from the macro processor

**Using Null Arguments**

The SCAN function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. Numeric arguments cannot be null.

**Processing SBCS and DBCS Data**

The SCAN function is designed to process SBCS data, but it can also process DBCS data. Here are the criteria:
If `expression` is not declared as VARCHAR and you are processing single-byte data, then SCAN processes SBCS.

If `string` is declared as VARCHAR and you are processing multibyte data, then SCAN processes DBCS.

Examples:

Example 1: Finding Substrings of Digits by Using the D and K Modifiers

This example finds substrings of digits. The character-list argument is null. Consequently, the list of characters is initially empty. The D modifier adds digits to the list of characters. The K modifier treats all characters that are not in the list as delimiters. Therefore, all characters except digits are delimiters.

```
proc ds2;
data test(keep=(count digits) overwrite=yes);
dcl char(25) string digits;
dcl double count;
method run();
  string='Call (800) 555-1234 now!';
do until(digits=' ');
count+1;
digits=scan(string, count, '', 'dko');
  output;
end;
end;
enddata;
run;
quit;
```

```
Obs digits count
1  800   1
2  666   2
3  1234  3
4      4
```

Example 2: Basic SCAN Function Usage

The following statements illustrate the SCAN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select scan('ABC.DEF(X=Y)', 3);</code></td>
<td>X=Y</td>
</tr>
<tr>
<td><code>select scan('ABC.DEF(X=Y)', -3);</code></td>
<td>ABC</td>
</tr>
</tbody>
</table>
SDF Function

Returns a survival function.

Categories: CAS
Probability

See: “CDF Function” on page 295

Syntax

SDF('distribution', quantile, parameter-1, ..., parameter-k)

Arguments

distribution
is a character string that identifies the distribution.

Note: The arguments for each of the SDF distribution functions are identical to those of the corresponding CDF distribution functions.

Here are valid distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Beta</td>
<td>'BETA'</td>
</tr>
<tr>
<td>Binomial</td>
<td>'BINOMIAL'</td>
</tr>
<tr>
<td>Cauchy</td>
<td>'CAUCHY'</td>
</tr>
<tr>
<td>Chi-Square</td>
<td>'CHISQUARE'</td>
</tr>
<tr>
<td>Conway-Maxwell-Poisson</td>
<td>'CONMAXPOI'</td>
</tr>
<tr>
<td>Exponential</td>
<td>'EXPONENTIAL'</td>
</tr>
<tr>
<td>F</td>
<td>'F'</td>
</tr>
<tr>
<td>Gamma</td>

<td>'UNIFORM'</td>
</tr>
<tr>
<td>Wald (inverse Gaussian)</td>
<td>'WALD'</td>
</tr>
<tr>
<td>Weibull</td>
<td>'WEIBULL'</td>
</tr>
</tbody>
</table>

**Note**  
Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

**quantile**  
is a numeric constant, variable, or expression that specifies the value of a random variable.  
**Data type** DOUBLE

**parameter-1, ..., parameter-k**  
are optional *shape*, *location*, or *scale* parameters appropriate for the specific distribution.  
**Data type** DOUBLE

**Details**  
The SDF function computes the survival function (upper tail) from various continuous and discrete distributions. For more information, see the individual distributions listed in the table above.

The SDF function for the Conway-Maxwell-Poisson distribution has the following form:
\[ \text{SDF('CONMAXPOI',y,\lambda,\nu)} \]

\( y \)

is a nonnegative, whole number that represents counts data.

\( \lambda \)

is similar to the mean, as in the Poisson distribution.

\( \nu \)

is a dispersion parameter.

The SDF function returns the probability that the counts value is greater than \( y \).

For more information, see “Conway-Maxwell-Poisson” distribution in the PDF function on page 649.

Example

The following statements illustrate the SDF function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select sdf('BERN', 0, .25);</td>
<td>0.25</td>
</tr>
<tr>
<td>select sdf('BETA', 0.2, 3, 4);</td>
<td>0.90112</td>
</tr>
<tr>
<td>select sdf('BINOM', 4, .5, 10);</td>
<td>0.623047</td>
</tr>
<tr>
<td>select sdf('CAUCHY', 2);</td>
<td>0.147584</td>
</tr>
<tr>
<td>select sdf('CHISQ', 11.264, 11);</td>
<td>0.421419</td>
</tr>
<tr>
<td>select sdf('CONMAXPOI', 12, 2.3, .4);</td>
<td>0.197051</td>
</tr>
<tr>
<td>select sdf('EXPO', 1);</td>
<td>0.367879</td>
</tr>
<tr>
<td>select sdf('F', 3.32, 2,3);</td>
<td>0.173607</td>
</tr>
<tr>

SEC Function
Returns the secant.

Categories: CAS
Trigonometric

Returned data type: DOUBLE

Syntax
SEC(expression)
Arguments

**expression**

specifies any valid expression that evaluates to a numeric value that expressed in radians.

**Restriction**

expression cannot be an odd multiple of Pi/2.

**See**

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Comparisons

The SEC function is related to the COS function:

\[ \sec(x) = \frac{1}{\cos(x)} \]

Example

The following statements illustrate the SEC function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select sec(0.5);</td>
<td>1.139494</td>
</tr>
<tr>
<td>select sec(0);</td>
<td>1</td>
</tr>
<tr>
<td>select sec(3.14159/3);</td>
<td>1.999997</td>
</tr>
</tbody>
</table>

- “SIN Function” on page 744
- “TAN Function” on page 762

SECOND Function

Returns the second from a time or datetime value.

**Categories:** Date and Time

**CAS:**

**Returned data type:**

DOUBLE
Syntax
SECOND(time | datetime)

Arguments

time
specifies any valid expression that represents a time value.

Data type TIME

See “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

datetime
specifies any valid expression that represents a datetime value.

Data type TIMESTAMP

See “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Example
Table: CUSTONLINE on page 1080

The following statement illustrates the SECOND function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select second(endtime) from custonline;</td>
<td>1.253</td>
</tr>
<tr>
<td></td>
<td>9.421</td>
</tr>
<tr>
<td></td>
<td>55.746</td>
</tr>
<tr>
<td></td>
<td>9.398</td>
</tr>
<tr>
<td></td>
<td>45.221</td>
</tr>
<tr>
<td></td>
<td>15.766</td>
</tr>
<tr>
<td></td>
<td>56.288</td>
</tr>
<tr>
<td></td>
<td>33.955</td>
</tr>
<tr>
<td></td>
<td>27.908</td>

SIGN Function

Returns a number that indicates the sign of a numeric value expression.

Categories: Mathematical
            CAS

Returned data type: TINYINT

Note: This function is not supported on Teradata 14.0. and later.

Syntax

**SIGN**(expression)

Arguments

*expression* specifies any valid SQL expression that evaluates to a numeric value.

Data type: BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT

See

“,sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The SIGN function returns the following values:

-1
   if *expression* < 0

0
   if *expression* = 0

1
   if *expression* > 0

Example

The following statements illustrate the SIGN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT SIGN(-5);</code></td>
<td>-1</td>
</tr>
<tr>
<td><code>SELECT SIGN(5);</code></td>
<td>1</td>
</tr>
</tbody>
</table>
SIN Function

Returns the trigonometric sine.

Categories:  
- Trigonometric  
- CAS

Returned data type:  
DOUBLE

Syntax

SIN(expression)

Arguments

expression  
specifies any valid SQL expression that evaluates to a numeric value.

Data type  
DOUBLE

See  
"<sql-expression> Expression" on page 820  
"FedSQL Expressions" on page 48

Example

The following statements illustrate the SIN function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select sin(25.6);</td>
<td>0.450441</td>
</tr>
<tr>
<td>select sin(5);</td>
<td>-0.95892</td>
</tr>
</tbody>
</table>

See Also

Functions:

SINH Function

Returns the hyperbolic sine.

Categories:
- Trigonometric
- CAS

Returned data type:
- DOUBLE

Syntax

SINH(expression)

Arguments

expression

specifies any valid SQL expression that evaluates to a numeric value.

Data type

DOUBLE

See

"<sql-expression> Expression" on page 820

“FedSQL Expressions” on page 48

Details

The SINH function returns the hyperbolic sine of the argument, which is given by the following equation.

\[ \sinh(x) = \frac{e^x - e^{-x}}{2} \]

Example

The following statements illustrate the SINH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select sinh(0);</td>
<td>0</td>
</tr>
<tr>
<td>select sinh(1);</td>
<td>1.175201</td>
</tr>
<tr>
<td>select sinh(-1.0);</td>
<td>-1.1752</td>
</tr>
</tbody>
</table>

Functions:
SKEWNESS Function

Returns the skewness of all values in an expression.

Syntax

```sql
SKEWNESS([DISTINCT] expression)
```

Arguments

- **expression**: specifies any valid SQL expression.

Interaction

At least three valid values are required in the column to perform the calculation. Otherwise the function returns a null value.

Data type

- **DOUBLE**

See

- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48

**DISTINCT**

(optional) eliminates duplicate rows from the aggregate calculation.

Details

*Skewness* is a measure of the tendency of the deviations from the mean to be larger in one direction than in the other. A positive value for skewness indicates that the data is skewed to the right. A negative value indicates that the data is skewed to the left.

Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each
group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Example

Table: **WORLDTEMPS** on page 1092

The following statement illustrates the SKEWNESS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select skewness(AvgHigh) from worldtemps;</td>
<td>-0.69811</td>
</tr>
</tbody>
</table>

See Also

**Functions:**
- “STDDEV Function” on page 753

**SELECT Statement Clauses:**
- “SELECT Clause” on page 877
- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890

---

**SMALLEST Function**

Returns the \( k \)th smallest non-null or nonmissing value.

**Categories:**
- CAS
- Descriptive Statistics

**Returned data type:** DOUBLE

**Syntax**

**SMALLEST**(\( k \), expression \[,...expression\])

**Arguments**

\( k \)

specifies any valid expression that evaluates to a numeric value to return.

**Data type** DOUBLE

**See**
- “<sql-expression> Expression” on page 820
- “FedSQL Expressions” on page 48
expression

specifies any valid expression that evaluates to a numeric value to be processed.

<table>
<thead>
<tr>
<th>Data type</th>
<th>DOUBLE</th>
</tr>
</thead>
</table>

See

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

If \( k \) is null or missing, less than zero, or greater than the number of values, the result is a null or missing value.

Comparisons

The SMALLEST function differs from the ORDINAL function in that SMALLEST ignores null and missing values, but ORDINAL counts null and missing values.

Example

The following statements illustrate the SMALLEST function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select smallest(1, 456, 789, .Q, 123);</td>
<td>123</td>
</tr>
<tr>
<td>select smallest(2, 456, 789, .Q, 123);</td>
<td>456</td>
</tr>
<tr>
<td>select smallest(3, 456, 789, .Q, 123);</td>
<td>789</td>
</tr>
<tr>
<td>select smallest(4, 456, 789, .Q, 123);</td>
<td>.</td>
</tr>
</tbody>
</table>

SQUANTILE Function

Returns the quantile from a distribution when you specify the right probability (SDF).

Categories: CAS

Quantile
SQUANTILE Function

Restriction: This function is not supported on the CAS server.

Returned data type: DOUBLE

See: “SDF Function” on page 737

Syntax

SQUANTILE('distribution', probability, parameter-1, ..., parameter-k)

Arguments

distribution

is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the SQUANTILE Distribution functions are identical to those of the corresponding CDF Distribution functions.

Here are valid distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bernoulli</td>
<td>'BERNOULLI'</td>
</tr>
<tr>
<td>Beta</td>
<td>'BETA'</td>
</tr>
<tr>
<td>Binomial</td>
<td>'BINOMIAL'</td>
</tr>
<tr>
<td>Cauchy</td>
<td>'CAUCHY'</td>
</tr>
<tr>
<td>Chi-Square</td>
<td>'CHISQUARE'</td>
</tr>
<tr>
<td>Conway-Maxwell-Poisson</td>
<td>'CONMAXPOI'</td>
</tr>
<tr>
<td>Exponential</td>
<td>'EXPONENTIAL'</td>
</tr>
<tr>
<td>F</td>

<td>'HYPERGEOMETRIC'</td>
</tr>
<tr>
<td>Laplace</td>
<td>'LAPLACE'</td>
</tr>
<tr>
<td>Logistic</td>
<td>'LOGISTIC'</td>
</tr>
</tbody>
</table>
### Distribution

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lognormal</td>
<td>'LOGNORMAL'</td>
</tr>
<tr>
<td>Negative binomial</td>
<td>'NEGBINOMIAL'</td>
</tr>
<tr>
<td>Normal</td>
<td>'NORMAL'</td>
</tr>
<tr>
<td>Normal mixture</td>
<td>'NORMALMIX'</td>
</tr>
<tr>
<td>Pareto</td>
<td>'PARETO'</td>
</tr>
<tr>
<td>Poisson</td>
<td>'POISSON'</td>
</tr>
<tr>
<td>T</td>
<td>'T'</td>
</tr>
<tr>
<td>Tweedie</td>
<td>'TWEEDIE'</td>
</tr>
<tr>
<td>Uniform</td>
<td>'UNIFORM'</td>
</tr>
<tr>
<td>Wald (inverse Gaussian)</td>
<td>'WALD'</td>
</tr>
<tr>
<td>Weibull</td>
<td>'WEIBULL'</td>
</tr>
</tbody>
</table>

**Note:** Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

**probability**

is a numeric constant, variable, or expression that specifies the value of a random variable.

**Data type**  DOUBLE

**parameter-1, …, parameter-k**

are optional *shape*, *location*, or *scale* parameters that are appropriate for the specific distribution.

**Data type**  DOUBLE

### Details

The SQUANTILE function computes the quantile from the specified continuous or discrete distribution, based on the probability value that is provided. For more information, see the individual distributions noted in the table above.

The Conway-Maxwell-Poisson distribution of the SQUANTILE function returns the counts value $y$ that is the smallest, whole number whose SDF value is less than $p$.

The syntax for the Conway-Maxwell-Poisson distribution in the SQUANTILE function has the following form:

$$\text{SQUANTILE}('\text{CONMAXPOI}', p, \lambda, v)$$
\( p \)

is a real number between 0 and 1, inclusively.

\( \lambda \)

is similar to the mean, as in the Poisson distribution.

\( \nu \)

is a dispersion parameter.

For more information, see "Conway-Maxwell-Poisson" distribution in the PDF function on page 649.

Example

The following statement illustrates the SQUANTILE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select squantile('logistic', 1.e-20);</td>
<td>46.0517</td>
</tr>
<tr>
<td>select squantile('conmaxpoi',.2,.4,.4);</td>
<td>12</td>
</tr>
</tbody>
</table>

SQRT Function

Returns the square root of a value.

Categories: Mathematical

CAS

Returned data type: DOUBLE

Syntax

\[ \text{SQRT}(\text{expression}) \]
Arguments

expression
specifies any SQL valid expression that evaluates to a nonnegative numeric value.

Data type: DOUBLE

See
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Example
The following statements illustrate the SQRT function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select sqrt(36);</td>
<td>6</td>
</tr>
<tr>
<td>select sqrt(25);</td>
<td>5</td>
</tr>
<tr>
<td>select sqrt(4.4);</td>
<td>2.097618</td>
</tr>
</tbody>
</table>

STD Function
Returns the standard deviation.

Categories:
CAS
Descriptive Statistics

Returned data type: DOUBLE

Syntax
STD(expression-1, expression-2 [, ...expression-n])

Arguments
expression
specifies any valid expression that evaluates to a numeric value.

Requirement
At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

Data type: DOUBLE

See
"<sql-expression> Expression" on page 820
Example

The following statements illustrate the STD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select std(2,6);</td>
<td>2.82842712474619</td>
</tr>
<tr>
<td>select std(2,6,);</td>
<td>2.82842714274619</td>
</tr>
<tr>
<td>select std(2,4,6,3,1);</td>
<td>1.92353840616714</td>
</tr>
</tbody>
</table>

STDDEV Function

Returns the statistical standard deviation of all values in an expression.

Categories: Aggregate
Descriptive Statistics
CAS

Alias: STD

Returned data type: DOUBLE

Syntax

```
STDDEV([DISTINCT] expression)
```

Arguments

**expression**

specifies any valid SQL expression.

**Interaction**

At least two valid values are required in the column to perform the calculation. Otherwise the function returns a null value.

**Data type**

DOUBLE

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

**DISTINCT**

(optional) eliminates duplicate rows from the aggregate calculation.
Details

The standard deviation is calculated as the square root of the variance.

Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Example

Table: WORLDTEMPS on page 1092

The following statement illustrates the STDDEV function:

| Statements                                      | Results  
|------------------------------------------------|----------
| select stddev(AvgHigh) from worldtemps;       | 7.811414 |

STDERR Function

Returns the statistical standard error of all values in an expression.

Categories: Aggregate
Descriptive Statistics
CAS

Returned data type: DOUBLE
Syntax

\texttt{STDERR([DISTINCT] \textit{expression})}

Arguments

\textit{expression}

specifies any valid SQL expression.

Interaction

At least two valid values are required in the column to perform the calculation. Otherwise the function returns a null value.

Data type

DOUBLE

 DISTINCT

(optional) eliminates duplicate rows from the aggregate calculation.

Details

Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Example

Table: WORLDTEMPS on page 1092

The following statement illustrates the STDERR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select \texttt{stderr(AvgHigh)} from worldtemps;</td>
<td>2.35523</td>
</tr>
</tbody>
</table>

STUDENTS_T Function

Returns the Student's t distribution of the values in an expression.

Categories: Aggregate
Descriptive Statistics
CAS

Alias: T

Returned data type: DOUBLE

Syntax

STUDENTS_T([DISTINCT] expression)

Arguments

expression specifies any valid SQL expression.

Data type DOUBLE

See

"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

DISTINCT optionally eliminates duplicate rows from the aggregate calculation.

Details

The STUDENTS_T function returns the probability for the Student's t distribution with n-1 degrees of freedom and a central distribution (nc=0).

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Comparisons

The STUDENTS_T function returns the Student's t distribution. The PROBT function returns the probability that the Student's t distribution is less than or equal to a given value.
Example

The following statements illustrate the STUDENTS_T function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select students_t(density) from densities;</td>
<td>3.565402</td>
</tr>
<tr>
<td>select students_t(population) from densities;</td>
<td>3.267438</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “PROBT Function” on page 707

SELECT Statement Clauses:

- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890

SUBSTRING Function

Extracts a substring from a character string.

Categories: Character

CAS

Returned data type: VARCHAR NVARCHAR

Syntax

SUBSTRING(`character-string` FROM `position` [FOR `length`])

Arguments

`character-string`
- specifies any valid expression that evaluates to a character string. `character-string` is the source string that is searched for a substring.
  
  Data type  CHAR, VARCHAR, NVARCHAR

`position`
- specifies the beginning character position.
Interaction  If position is larger than the length of the source string, FedSQL returns a null value. For example, if you ask for a substring starting at character five but the source string is only four characters long, you get a null result.

Data type  INTEGER

length  specifies the length of the substring to extract.

Interaction  If length is zero, a negative value, or larger than the length of the expression that remains in string after position, FedSQL extracts the remainder of the expression.

Data type  INTEGER

Tip  If you omit length, FedSQL extracts the remainder of the expression.

Details  The SUBSTRING function returns a portion of an expression that you specify in character-string. The portion begins with the character that you specify by position, and is the number of characters that you specify in length.

Example  Table: AFEWORDS on page 1078

The following statement illustrates the SUBSTRING function.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select substring(word2 from 2 for 3);</td>
<td>HER</td>
</tr>
<tr>
<td></td>
<td>HIN</td>
</tr>
<tr>
<td></td>
<td>ODY</td>
</tr>
</tbody>
</table>

See Also  Functions:

- “TRIM Function” on page 776

SUM Function  Returns the sum of all the values in an expression.

Categories:  Aggregate
Descriptive Statistics
CAS
Syntax

\[ \text{SUM}([\text{DISTINCT}] \text{ expression}) \]

Arguments

\textit{expression}

specifies any valid SQL expression.

\begin{itemize}
\item \textbf{Requirement}: The result of the \text{SUM} function must be within the range of the data type.
\item \textbf{Data type}: BIGINT, DOUBLE, FLOAT, INTEGER, REAL, SMALLINT, TINYINT
\item \textbf{See}:
\begin{itemize}
\item "<sql-expression> Expression" on page 820
\item "FedSQL Expressions" on page 48
\end{itemize}
\end{itemize}

\textit{DISTINCT}

(optional) eliminates duplicate rows from the aggregate calculation.

Details

Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Example

Table: DENSITIES on page 1081

The following statements illustrate the \text{SUM} function:

\begin{center}
\begin{tabular}{l|c}
\hline
\textbf{Statements} & \textbf{Results} \\
\hline
select \text{sum(density)} from densities; & 1728.324 \\
select \text{sum(population)} from densities; & 1.2278E8 \\
\hline
\end{tabular}
\end{center}

See Also

\textbf{SELECT Statement Clauses}:
SUMABS Function

Returns the sum of the absolute values of the nonmissing arguments.

Categories:
- CAS
- Descriptive Statistics

Returned data type: DOUBLE

Syntax

```
SUMABS(value-1[, ... value-n])
```

Arguments

value

specifies any valid expression that evaluates to a numeric value.

Data type: DOUBLE

Details

If all arguments have null or missing values, then the result is a null or missing value. Otherwise, the result is the sum of the absolute values of the nonmissing values.

Example

The following statements illustrate the SUMABS function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select sumabs(1,-2,0,3,.q,-4);</td>
<td>10</td>
</tr>
<tr>
<td>select sumabs(1,3,4,3,1);</td>
<td>12</td>
</tr>
</tbody>
</table>

SYSGET Function

Returns the value of the specified operating environment variable.

Categories: CAS
Special Restriction: This function is supported in CAS only for users with administrative-level capabilities.

Syntax
Windows and UNIX:
SYSGET('environment-variable')

z/OS:
SYSGET(operating-environment-variable)

Arguments

environment-variable is a character constant, variable, or expression with a value that is the name of an environment variable under Windows and UNIX.

Requirement This argument must be enclosed in single quotation marks.

operating-environment-variable is a character constant, variable, or expression with a value that is the name of a simulated environment variable under z/OS.

Details
General Information
The SYSGET function returns the value of an environment variable as a character string. For example, this statement returns the value of the HOME environment variable under UNIX:

```select sysget('HOME');```

If the SYSGET function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 200.

SYSGET Specifics under UNIX
The case of the value that you supply in the environment-variable argument must agree with the case of the variable that is stored in the UNIX operating environment.

SYSGET Specifics under z/OS
z/OS does not have native environment variables, but SAS supports three types of simulated environment variables that SYSGET can access.

- variables that have been created through the SET system option
- variables that have been defined in a TKMVSENV file
- under TSO, variables in the calling REXX exec or CLIST

SYSGET searches for the specified operating-environment-variable in each of these three locations, in the order specified in the preceding list. If the specified variable is not found in any of the locations, then the error message NOTE: Invalid argument to the function SYSGET is generated, and _ERROR_ is set to 1.
Names of TKMVSENV variables are case-sensitive, but names of SET, REXX, and CLIST variables are not case-sensitive.

**Example: Obtain Environment Variable Values under Windows**

This example obtains the value of the PATH environment variable in the Windows environment:

```sql
SELECT SYSGET('PATH');
```

The following line is written to the SAS log:

```
C:\WINDOWS\system32;C:\WINDOWS;C:\WINDOWS\System32\Wbem;C:\WINDOWS\System32\WindowsPowerShell\v1.0\;C:\Program Files\SASHome\SASFoundation\9.4\ets\sasexe;C:\Program Files\SASHome\Secure\ccme4;C:\Program Files\SASHome\x86\Secure\ccme4;C:\Program Files (x86)\PRISM;
```

---

**TAN Function**

Returns the tangent.

**Categories:** Trigonometric

**CAS:**

**Returned data type:** DOUBLE

---

**Syntax**

```
TAN(expression)
```

**Arguments**

`expression`

specifies any valid SQL expression that evaluates to a numeric value.

**Restriction**

`expression` cannot be an odd multiple of \( \pi / 2 \)

**Requirement**

The expression must evaluate to a value in radians.

**Data type**

DOUBLE

**See**

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

---

**Example**

The following statements illustrate the TAN function:
<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select tan(0.5);</td>
<td>0.546302</td>
</tr>
<tr>
<td>select tan(3.14159/3);</td>
<td>1.732047</td>
</tr>
</tbody>
</table>

- “SIN Function” on page 744
- “TANH Function” on page 763

TANH Function

Returns the hyperbolic tangent.

Categories: Trigonometric, CAS

Returned data type: DOUBLE

Syntax

TANH(expression)

Arguments

- **expression**
  - specifies any valid SQL expression that evaluates to a numeric value.
  - **Restriction**: expression cannot be an odd multiple of π/2
  - **Data type**: DOUBLE
  - See
    - “<sql-expression> Expression” on page 820
    - “FedSQL Expressions” on page 48
Details

The TANH function returns the hyperbolic tangent of the argument, which is given by the following equation.

\[
\frac{e^{\text{argument}} - e^{-\text{argument}}}{e^{\text{argument}} + e^{-\text{argument}}}
\]

Example

The following statements are examples of the TANH function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select tanh(0);</td>
<td>0</td>
</tr>
<tr>
<td>select tanh(0.5);</td>
<td>0.462117</td>
</tr>
<tr>
<td>select tanh(-0.5);</td>
<td>-0.46212</td>
</tr>
</tbody>
</table>

See Also

- “TAN Function” on page 762

TIMEPART Function

Returns the time as hours, minutes, and seconds.

Syntax

TIMEPART(t)

Arguments

\(t\)

specifies the timestamp.
Example

The following statement illustrates the TIMEPART function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select timepart('2013-10-30 15:39:10');</td>
<td>15:39:10</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “DATEPART Function” on page 389
- “MAKEDATE Function” on page 586
- “MAKETIME Function” on page 587
- “MAKETIMESTAMP Function” on page 588

TIMEVALUE Function

Returns the equivalent of a reference amount at a base date by using variable interest rates.

**Categories:**
- CAS
- Financial

**Returned data type:**
- DOUBLE

**Syntax**

```
TIMEVALUE(base-date, reference-date, reference-amount, compounding-interval, date-1, rate-1[. . .date-n, rate-n])
```

**Arguments**

- **base-date**
  - specifies the time value of the reference-amount at the base-date.
  - **Requirement**: Base-date is a SAS date.
  - **Data type**: DOUBLE

- **reference-date**
  - specifies the date of reference-amount.
  - **Requirement**: Reference-date is a SAS date.
  - **Data type**: DOUBLE

- **reference-amount**
  - specifies the amount at the reference-date.
Data type DOUBLE

**compounding-interval**
specifies the compounding interval.

**Requirement** *Compounding-interval* is a SAS interval.

Data type CHAR

**date**
specifies the time at which *rate* takes effect. Each date is paired with a rate.

**Requirement** *Date* is a SAS date.

Data type DOUBLE

**rate**
specifies the interest rate as numeric percentage that starts on *date*. Each rate is paired with a date.

Data type DOUBLE

---

**Details**

The following details apply to the TIMEVALUE function:

- The values for rates must be between –99 and 120.
- The list of date-rate pairs does not need to be sorted by date.
- When multiple rate changes occur on a single date, the TIMEVALUE function applies only the final rate that is listed for that date.
- Simple interest is applied for partial periods.
- There must be a valid date-rate pair whose date is at or prior to both the *reference-date* and the *base-date*.

---

**Example**

- You can express the accumulated value of an investment of $1,000 at a nominal interest rate of 10% compounded monthly for one year as the following:

```sql
SELECT timevalue('2001-01-01', '2000-01-01', 1000, 'month', '2000-01-01', 10);
```

1104.71306744129

- If the interest rate jumps to 20% halfway through the year, the resulting calculation would be as follows:

```sql
```

1160.63657783831

- The date-rate pairs do not need to be sorted by date. This flexibility allows *amount_base2* and *amount_base3* to assume the same value:

```sql
```

766
TINV Function

Returns a quantile from the t distribution.

Categories: CAS
Quantile

Returned data type: DOUBLE

Syntax

TINV(p, df, nc)

Arguments

p
specifies any valid expression that evaluates to a numeric probability.

Range 0 < p < 1
Data type DOUBLE
See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

df
specifies any valid expression that evaluates to a numeric degrees of freedom parameter.

Range df > 0
Data type DOUBLE
See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

nc
specifies any valid expression that evaluates to a numeric noncentrality parameter.

Data type DOUBLE
See “<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48
Details

The TINV function returns the $p^{th}$ quantile from the Student's $t$ distribution with degrees of freedom $df$ and a noncentrality parameter $nc$. The probability that an observation from a $t$ distribution is less than or equal to the returned quantile is $p$.

TINV accepts a noninteger degree of freedom parameter $df$. If the optional parameter $nc$ is not specified or is 0, the quantile from the central $t$ distribution is returned.

CAUTION

For large values of $nc$, the algorithm can fail. In that case, a missing value is returned.

Comparisons

TINV is the inverse of the PROBT function.

Example

The following statements illustrate the TINV function:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>select tinv(.95, 2);</td>
<td>2.9199855804</td>
</tr>
<tr>
<td>select tinv(.95, 2.5, 3)</td>
<td>11.033833625</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “PROBT Function” on page 707

TNONCT Function

Returns the value of the noncentrality parameter from the Student's $t$ distribution.

Categories: CAS

Mathematical

Returned data type: DOUBLE

Syntax

TNONCT($x$, $df$, $prob$)
Arguments

\( x \)

is a numeric random variable.

Data type  \textbf{DOUBLE}

\( df \)

is a numeric degrees of freedom parameter.

Range  \( df > 0 \)

Data type  \textbf{DOUBLE}

\( prob \)

is a probability.

Range  \( 0 < prob < 1 \)

Data type  \textbf{DOUBLE}

Details

The TNONCT function returns the nonnegative noncentrality parameter from a noncentral \( t \) distribution whose parameters are \( x \), \( df \), and \( nc \). A Newton-type algorithm is used to find a root \( nc \) of the equation

\[
P_t(x\mid df, nc) - prob = 0
\]

The following relationship applies to the preceding equation:

\[
P_t(x\mid df, nc) = \frac{1}{\Gamma(df/2)} \int_0^\infty v^{df/2} - 1 e^{-v} \int_{-\infty}^{\sqrt{2v}} e^{-(u-nc)^2/2} du dv
\]

If the algorithm fails to converge to a fixed point, a missing value is returned.

Example

The following example computes the noncentrality parameter from the \( t \) distribution.

```plaintext
proc ds2;
  data test /overwrite=yes;
    dcl double x df nc prob;
    method init();
      x=2;
      df=4;
      do nc=1 to 3 by .5;
        prob=probt(x, df, nc);
        output;
      end;
    end;
  enddata;
run;
quit;

proc print data=test;
```

run;
proc fedsql;
    select tnonct(x, df, prob) from test;
quit;

Output 4.13  Contents of Table Test

<table>
<thead>
<tr>
<th>Obs</th>
<th>x</th>
<th>df</th>
<th>nc</th>
<th>prob</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>4</td>
<td>1.0</td>
<td>0.76457</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>4</td>
<td>1.5</td>
<td>0.61893</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>4</td>
<td>2.0</td>
<td>0.45567</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>4</td>
<td>2.5</td>
<td>0.30115</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>4</td>
<td>3.0</td>
<td>0.17702</td>
</tr>
</tbody>
</table>

Output 4.14  Result of TNONCT Function on Table Test

See Also

Functions:
- “CNONCT Function” on page 339
- “FNONCT Function” on page 487

TODAY Function

Returns the current date as a numeric SAS date value.

Categories:  
CAS  
Date and Time

Returned data type:  
DOUBLE

Syntax

TODAY( )
Details

The TODAY function does not take any arguments. It produces the current date in the form of a SAS date value, which is the number of days since January 1, 1960.

For more information about how FedSQL handles dates, see “Dates and Times in FedSQL” on page 60.

Example

The following statement illustrates the TODAY function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select today();</td>
<td>19612</td>
</tr>
<tr>
<td>select put(td,date.);</td>
<td>11SEP13</td>
</tr>
</tbody>
</table>

TRANSTRN Function

Replaces or removes all occurrences of a substring in a character string.

Categories: CAS Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

TRANSTRN(source-expression, target-expression, replacement-expression)

Arguments

source-expression

specifies any valid expression that evaluates or can be coerced to a character string and whose characters you want to translate.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See “<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

target-expression

specifies any valid expression that evaluates or can be coerced to a character string and whose characters are searched for in source-expression.

Requirement The length for target-expression must be greater than zero.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR
replacement-expression
  specifies any valid expression that evaluates or can be coerced to a character
  string and that replaces target-expression.

Data type  CHAR, NCHAR, NVARCHAR, VARCHAR

See
  “<sql-expression> Expression” on page 820
  “FedSQL Expressions” on page 48

Details
  The TRANSTRN function replaces or removes all occurrences of a given substring
  within a character string. The TRANSTRN function does not remove trailing blanks
  in the target-expression string and the replacement-expression string. To remove all
  occurrences of target, specify replacement-expression as TRIMN("").

Comparisons
  The TRANWRD function differs from the TRANSTRN function because TRANSTRN
  allows the replacement string to have a length of zero. TRANWRD uses a single
  blank instead when the replacement string has a length of zero.

  The TRANSLATE function converts every occurrence of a user-supplied character
  to another character. TRANSLATE can scan for more than one character in a single
  call. In doing this scan, however, TRANSLATE searches for every occurrence of any
  of the individual characters within a string. That is, if any letter (or character) in the
  target string is found in the source string, it is replaced with the corresponding letter
  (or character) in the replacement string.

  The TRANSTRN function differs from TRANSLATE in that TRANSTRN scans for
  substrings and replaces those substrings with a second substring.

Example
  The following statements illustrate how to use the TRANSTRN function to replace
  occurrences of a word and to manipulate spaces.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select transtrn('Mrs. Joan Smith', 'Mrs.', 'Ms.');</td>
<td>Ms. Joan Smith</td>
</tr>
<tr>
<td>select transtrn('Miss Alice Cooper', 'Miss', 'Ms.');</td>
<td>Ms. Alice Cooper</td>
</tr>
<tr>
<td>select transtrn('CATFISH', 'FISH', 'NIP');</td>
<td>CATNIP</td>
</tr>
<tr>
<td>select '*'</td>
<td></td>
</tr>
</tbody>
</table>
TRANWRD Function

Replaces or removes all occurrences of a substring in a character string.

Categories:
- CAS
- Character

Returned data type:
- CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

TRANWRD(source-expression, target-expression, replacement-expression)

Arguments

source-expression
specifies any valid expression that evaluates or can be coerced to a character string whose characters you want to replace.

Data type
- CHAR, NCHAR, NVARCHAR, VARCHAR

See
- "<sql-expression> Expression" on page 820
- “FedSQL Expressions” on page 48

target-expression
specifies any valid expression that evaluates or can be coerced to a character string and that is searched for in source-expression.

Requirement
- The length of the target-expression must be greater than zero.

Data type
- CHAR, NCHAR, NVARCHAR, VARCHAR

See
- "<sql-expression> Expression" on page 820
- “FedSQL Expressions” on page 48
**replacement-expression**

specifies any valid expression that evaluates or can be coerced to a character string and that replaces target-expression.

**Data type**

CHAR, NCHAR, NVARCHAR, VARCHAR

**See**

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

**Details**

The TRANWRD function replaces or removes all occurrences of a given substring (or a pattern of characters) within a character string. The TRANWRD function does not remove trailing blanks in the target-expression string and the replacement-expression string.

**Comparisons**

The TRANWRD function differs from the TRANSTRN function because TRANSTRN allows the replacement string to have a length of zero. TRANWRD uses a single blank instead when the replacement string has a length of zero.

The TRANSLATE function converts every occurrence of a user-supplied character to another character. TRANSLATE can scan for more than one character in a single call. In doing this, however, TRANSLATE searches for every occurrence of any of the individual characters within a string. That is, if any letter (or character) in the target string is found in the source string, it is replaced with the corresponding letter (or character) in the replacement string.

The TRANWRD function differs from TRANSLATE in that it scans for substrings (or patterns of characters) and replaces those substrings with a second substring (or pattern of characters).

**Example**

The following statements illustrate replacing occurrences of a substring using the TRANWRD function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select tranwrd('Whatever you so, so it with all your might. -P.T. Barnum','so','do');</td>
<td>Whatever you do, do it with all your might. -P.T. Barnum</td>
</tr>
<tr>
<td>select tranwrd('Believe and act as if it were impossible to pail. -Charles F. Kettering','pail','fail');</td>
<td>Believe and act as if it were impossible to fail. -Charles F. Kettering</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**

- “TRANSTRN Function” on page 771
TRIGAMMA Function

Returns the value of the trigamma function.

Categories: CAS
Mathematical

Returned data type: DOUBLE

Syntax

TRIGAMMA(expression)

Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Restriction
Nonpositive integers are invalid.

Data type
DOUBLE

See
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

The TRIGAMMA function returns the derivative of the digamma function. For expression > 0, the TRIGAMMA function is the second derivative of the lgamma function.

Example

The following statement illustrates the TRIGAMMA function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select trigamma(3);</td>
<td>0.394934</td>
</tr>
</tbody>
</table>

See Also

Functions:

- “DIGAMMA Function” on page 401
- “LGAMMA Function” on page 570
TRIM Function

Removes leading characters, trailing characters, or both from a character string.

Categories:  
Character  
CAS

Returned data type:  
VARCHAR NVARCHAR

Syntax

\[
\text{TRIM([BOTH | LEADING | TRAILING] [trim-character] FROM column)}
\]

Arguments

**BOTH | LEADING | TRAILING**  
specifies whether to remove the leading characters, the trailing characters, or both.

Default  
BOTH

**trim-character**  
specifies one character to remove from column. Enclose a literal character in single quotation marks. If trim-character is not specified, the TRIM function trims all blank spaces, not just one character.

Default  
Blank

Data type  
CHAR, VARCHAR, NVARCHAR

**column**  
is any valid expression that evaluates to a column name.

Details

The TRIM function is useful for trimming character strings of blanks or other characters before they are concatenated.

Example

Table: AFEWWORDS on page 1078

The following statements illustrate the TRIM function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
</table>
| select trim(word1) from afewwords; | *some/  
*every*  
*no* |
TRUNC Function

Truncates a numeric value to a specified length.

Categories:  
- CAS
- Truncation

Returned data type:  
- DOUBLE

Syntax

\[
\text{TRUNC}(\text{expression}, \text{length-expression})
\]

Arguments

- **expression**  
  Specifies any valid expression that evaluates to a numeric value.
  - Data type: DOUBLE
  - See: "<sql-expression> Expression" on page 820
  - "FedSQL Expressions" on page 48

- **length-expression**  
  Specifies any valid expression that evaluates to a numeric value.
  - Range: 3–8
  - Data type: DOUBLE

See Also

Functions:

- “SUBSTRING Function” on page 757
Details

The TRUNC function truncates a full-length numeric expression (stored as a DOUBLE) to a smaller number of bytes, as specified in length-expression and pads the truncated bytes with 0s. The truncation and subsequent expansion duplicate the effect of storing numbers in less than full length and then reading them.

Example

The following statements illustrate the TRUNC function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select trunc(3.1,3);</td>
<td>3.099609375</td>
</tr>
<tr>
<td>select trunc(3.1,4);</td>
<td>3.0999984741</td>
</tr>
<tr>
<td>select trunc(3.1,5);</td>
<td>3.099999994</td>
</tr>
<tr>
<td>select trunc(3.1,6);</td>
<td>3.1</td>
</tr>
<tr>
<td>select trunc(3.1,7);</td>
<td>3.1</td>
</tr>
<tr>
<td>select trunc(3.1,8);</td>
<td>3.1</td>
</tr>
</tbody>
</table>

UPCASE Function

Converts all letters in an argument to uppercase.

Categories: CAS
Character

Alias: UPPER

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

```sql
UPCASE(expression)
```

Arguments

expression

specifies any valid expression that evaluates or can be coerced to a character string.

Data type

CHAR, NCHAR

See

“<sql-expression> Expression” on page 820
Details
The UPCASE function copies a character expression, converts all lowercase letters to uppercase letters, and returns the altered value as a result.

Comparisons
The LOWCASE function converts all letters in an argument to lowercase letters. The UPCASE function converts all letters in an argument to uppercase letters.

Example
The following statement illustrates the UPCASE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select upcase('John B. Smith');</td>
<td>JOHN B. SMITH</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “LOWCASE Function” on page 583

URLDECODE Function
Returns a string that was decoded using the URL escape syntax.

Categories: CAS
            Web Tools

Syntax
URLDECODE(expression)

Arguments
expression specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR
Details

The Basics

The URL escape syntax is used to hide characters that might otherwise be significant when used in a URL.

A URL escape sequence can be one of the following:

- a plus sign, which is replaced by a blank.
- a sequence of three characters beginning with a percent sign and followed by two hexadecimal characters, which is replaced by a single character that has the specified hexadecimal value.

_expression_ can be decoded using either SAS session encoding or UTF-8 encoding.

Operating Environment Information: In operating environments that use EBCDIC, SAS performs an extra translation step after it recognizes an escape sequence. The specified character is assumed to be an ASCII encoding. SAS uses the transport-to-local translation table to convert this character to an EBCDIC character in operating environments that use EBCDIC. For more information, see the TRANTAB option.

Character Verification

The URLDECODE and URLENCODE functions do not verify that the bytes that are produced by the escape sequences are valid characters based on the encoding.

Length of Returned Variable

If the URLDECODE function returns a value to a variable that has not previously been assigned a length, then that variable is given the length of the argument.

Example

The following statements illustrate the URLDECODE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select urldecode('abc+def');</td>
<td>abc def</td>
</tr>
<tr>
<td>select urldecode('why%3F');</td>
<td>why?</td>
</tr>
<tr>
<td>select urldecode('%41%42%43%23%31');</td>
<td>ABC#1</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "URLENCODE Function" on page 781
URLENCODE Function

Returns a string that was encoded using the URL escape syntax.

Categories: CAS
Web Tools

Syntax

\texttt{URLENCODE(expression)}

Arguments

\texttt{expression}

specifies any valid expression that evaluates or can be coerced to a character string.

Data type \hspace{0.5cm} \texttt{CHAR, NCHAR, NVARCHAR, VARCHAR}

Details

The Basics

\textit{expression} can be encoded using either SAS session encoding or UTF-8 encoding.

The URLENCODE function encodes characters that might otherwise be significant when used in a URL. This function encodes all characters except for the following:

- all alphanumeric characters
- dollar sign ($)
- hyphen (-)
- underscore ( _ )
- at sign (@)
- period (.)
- exclamation point (!)
- asterisk (*)
- open parenthesis ( ( ) and close parenthesis ( )
- comma (,)

\textbf{Note:} The encoded string might be longer than the original string. Ensure that you consider the additional length when you use this function.

Character Verification

The URLDECODE and URLENCODE functions do not verify that the bytes that are produced by the escape sequences are valid characters based on the encoding.
Example

The following statement illustrates the URLENCODE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select urlencode('abc def');</code></td>
<td><code>abc%20def</code></td>
</tr>
</tbody>
</table>

Functions:

- "URLDECODE Function" on page 779

USS Function

Returns the uncorrected sum of squares of all the values in an expression.

Categories: Aggregate
Descriptive Statistics
CAS

Returned data type: DOUBLE

Syntax

```
USS([DISTINCT] expression)
```

Arguments

- `expression` specifies any valid SQL expression.

  Data type: DOUBLE

See

- "<sql-expression> Expression" on page 820
- “FedSQL Expressions” on page 48

DISTINCT

(optional) eliminates duplicate rows from the aggregate calculation.

Details

Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or
columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Comparisons

The CSS function returns the corrected sum of squares of all values. The USS function returns the uncorrected sum of squares.

Example

Table: DENSITIES on page 1081

The following statements illustrate the USS function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select uss(density) from densities;</td>
<td>510190</td>
</tr>
<tr>
<td>select uss(population) from densities;</td>
<td>2.82E15</td>
</tr>
</tbody>
</table>

See Also

Functions:
- “CSS Function” on page 374

SELECT Statement Clauses:
- “SELECT Clause” on page 877
- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890

VAR Function

Returns the variance.

Categories: CAS
Descriptive Statistics

Returned data type: DOUBLE

Syntax

**VAR(expression-1, expression-2 [ , ...expression-n])**
Arguments

expression
specifies any valid expression that evaluates to a numeric value. The argument list can consist of a variable list.

Requirement
At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

Data type
DOUBLE

See
“<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

Example

The following statements illustrate the VAR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select var(4,2,3.5,6);</td>
<td>2.7291666667</td>
</tr>
<tr>
<td>select var(4,6,.);</td>
<td>2</td>
</tr>
</tbody>
</table>

VARIANCE Function

Returns the measure of the dispersion of all values in an expression.

Syntax

VARIANCE([[DISTINCT] expression])

Arguments

expression
specifies any valid SQL expression.

Interaction
At least two values are required to perform the calculation. Otherwise the function returns a null value.

Data type
DOUBLE
DISTINCT
(optional) eliminates duplicate rows from the aggregate calculation.

Details
Null values and SAS missing values are ignored and are not included in the computation.

You can use an aggregate function to produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. The GROUP BY clause groups data by a specified column or columns. When you use a GROUP BY clause, the aggregate function in the SELECT clause or in a HAVING clause instructs FedSQL in how to summarize the data for each group. FedSQL calculates the aggregate function separately for each group. If GROUP BY is omitted, then all the rows in the table or view are considered to be a single group.

Example
Table: DENSITIES on page 1081

The following statements illustrate the VARIANCE function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select variance(density) from densities;</code></td>
<td>23498.12</td>
</tr>
<tr>
<td><code>select variance(population) from densities;</code></td>
<td>1.412E14</td>
</tr>
</tbody>
</table>

  - “HAVING Clause” on page 890

VERIFY Function

Returns the position of the first character that is unique to an expression.

Categories: CAS
Returned data type:

DOUBLE

Syntax

VERIFY(target-expression, search-expression)

Arguments

**target-expression**
specifies any valid expression that evaluates or can be coerced to a character string that is to be searched.

**Requirement**
Literal character strings must be enclosed in single quotation marks.

**Data type**
CHAR, NCHAR, NVARCHAR, VARCHAR

**See**
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

**search-expression**
specifies any valid expression that evaluates or can be coerced to a character string.

**Requirement**
Literal character strings must be enclosed in single quotation marks.

**Data type**
CHAR, NCHAR, NVARCHAR, VARCHAR

**See**
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

The VERIFY function returns the position of the first character in target-expression that is not present in search-expression. If there are no characters in target-expression that are unique from those in search-expression, VERIFY returns a 0.

Comparisons

The INDEX function returns the position of the first occurrence of search-expression that is present in target-expression where the VERIFY function returns the position of the first character in target-expression that does not contain search-expression.

Example

The following statement illustrates the VERIFY function:
WEEK Function

Returns the week-number value.

Categories: CAS
Date and Time

Returned data type: DOUBLE

Syntax

\[
\text{WEEK([sas-date], ['descriptor'])}
\]

Arguments

\textit{sas-date}

specifies the SAS date value. If the \textit{sas-date} argument is not specified, the WEEK function returns the week-number value of the current date.

Data type DOUBLE

\textit{descriptor}

specifies the value of the descriptor. The following descriptors can be specified in uppercase or lowercase characters.

\textit{U}

specifies the number-of-the-week within the year. Sunday is considered the first day of the week. The number-of-the-week value is represented as a decimal number in the range 0–53. Week 53 has no special meaning. The value of \text{week('31dec2013'd, 'u')} is 53. \textit{U} is the default value.

Tip The \textit{U} and \textit{W} descriptors are similar, except that the \textit{U} descriptor considers Sunday as the first day of the week, and the \textit{W} descriptor considers Monday as the first day of the week.

See “The U Descriptor” on page 788

\textit{V}

specifies the number-of-the-week whose value is represented as a decimal number in the range 1–53. Monday is considered the first day of the week.
and week 1 of the year is the week that includes both January 4 and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year.

See “The V Descriptor” on page 788

\(W\)

specifies the number-of-the-week within the year. Monday is considered the first day of the week. The number-of-the-week value is represented as a decimal number in the range 0–53. Week 53 has no special meaning. The value of week('31dec2013'd, 'w') is 53.

Tip The U and W descriptors are similar except that the U descriptor considers Sunday as the first day of the week, and the W descriptor considers Monday as the first day of the week.

See “The W Descriptor” on page 789

Default U

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note If you specify a descriptor other than U, V, or W, a note is written to the SAS log to indicate that the argument is invalid. The function returns NULL.

Details

The Basics

The WEEK function reads a SAS date value and returns the week number. The WEEK function is not dependent on locale, and uses only the Gregorian calendar in its computations.

The U Descriptor

The WEEK function with the U descriptor reads a SAS date value and returns the number of the week within the year. The number-of-the-week value is represented as a decimal number in the range 0–53, with a leading zero and maximum value of 53. Week 0 means that the first day of the week occurs in the preceding year. The fifth week of the year is represented as 05.

Sunday is considered the first day of the week. For example, the value of week('01jan2013'd, 'u') is 0.

The V Descriptor

The WEEK function with the V descriptor reads a SAS date value and returns the week number. The number-of-the-week is represented as a decimal number in the range 01–53. The decimal number has a leading zero and a maximum value of 53. Weeks begin on a Monday, and week 1 of the year is the week that includes both January 4 and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year. In the following example, 01jan2014 and 31dec2013 occur in the same week. The first day (Monday) of that week is 30dec2013. Therefore, week('01jan2014'd, 'v') and week('30dec2013'd, 'v') both return a value of 53. This means that both dates occur in week 53 of the year 2013.
The W Descriptor

The WEEK function with the W descriptor reads a SAS date value and returns the number of the week within the year. The number-of-the-week value is represented as a decimal number in the range 0–53, with a leading zero and maximum value of 53. Week 0 means that the first day of the week occurs in the preceding year. The fifth week of the year would be represented as 05.

Monday is considered the first day of the week. Therefore, the value of `week('30dec2013'd, 'w')` is 1.

Comparisons of Descriptors

U is the default descriptor. Its range is 0-53, and the first day of the week is Sunday. The V descriptor has a range of 1-53 and the first day of the week is Monday. The W descriptor has a range of 0-53 and the first day of the week is Monday.

The following list describes the descriptors and an associated week:

- **Week 0:**
  - U indicates the days in the current Gregorian year before week 1.
  - V does not apply.
  - W indicates the days in the current Gregorian year before week 1.

- **Week 1:**
  - U begins on the first Sunday in a Gregorian year.
  - V begins on the Monday between December 29 of the previous Gregorian year and January 4 of the current Gregorian year. The first ISO week can span the previous and current Gregorian years.
  - W begins on the first Monday in a Gregorian year.

- **End of Year Weeks:**
  - U specifies that the last week (52 or 53) in the year can contain less than 7 days. A Sunday to Saturday period that spans 2 consecutive Gregorian years is designated as 52 and 0 or 53 and 0.
  - V specifies that the last week (52 or 53) of the ISO year contains 7 days. However, the last week of the ISO year can span the current Gregorian and next Gregorian year.
  - W specifies that the last week (52 or 53) in the year can contain less than 7 days. A Monday to Sunday period that spans two consecutive Gregorian years is designated as 52 and 0 or 53 and 0.

Example

The following statements illustrate the values of the U, V, and W descriptors for the date August 16, 2013.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select week(date'2013-08-16', 'u');</code></td>
<td>32</td>
</tr>
<tr>
<td><code>select week(date'2013-08-16', 'v');</code></td>
<td>33</td>
</tr>
</tbody>
</table>
WEEKDAY Function

From a SAS date value, returns a whole number that corresponds to the day of the week.

**Syntax**

\[ \text{WEEKDAY}(\text{expression}) \]

**Arguments**

*expression*

specifies any valid expression that represents a SAS date value.

**Data type** DOUBLE

**See**

"<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

**Details**

The WEEKDAY function produces a whole number that represents the day of the week, where 1 = Sunday, 2 = Monday, ..., 7 = Saturday.

For information about how FedSQL handles date and times values, see "Dates and Times in FedSQL" on page 60.
Example

The following statement illustrates the WEEKDAY function when the current day is Sunday:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>select weekday(today());</code></td>
<td>1</td>
</tr>
</tbody>
</table>

WHICHC Function

Returns the first position of a character string from a list of character strings.

Categories:
- CAS
- Character

Returned data type: DOUBLE

Syntax

```
WHICHC(search-expression, expression-list-item-1, expression-list-item-2 [...expression-list-item-n])
```

Arguments

**search-expression**
- specifies any valid expression that evaluates or can be coerced to a character string that is compared with a list of character string expressions.
  - Requirement: Literal character strings must be enclosed in single quotation marks.
  - Data type: CHAR, NCHAR, NVARCHAR, VARCHAR
  - See: `<sql-expression> Expression` on page 820
  - See: “FedSQL Expressions” on page 48

**expression-list-item**
- specifies any valid expression that evaluates or can be coerced to a character string and that is a member of a list of character string expressions.
  - Requirements:
    - Literal character strings must be enclosed in single quotation marks.
    - At least two expressions are required in the list.
  - Data type: CHAR, NCHAR, NVARCHAR, VARCHAR
  - See: `<sql-expression> Expression` on page 820
Details
The WHICHC function searches the character expression list, from left to right, for the first expression that matches the search expression. If a match is found, WHICHC returns its position in the expression list. If none of the expressions match the search expression, WHICHC returns a value of 0.

Example
In the following example, 'Spain' appears twice in the list. The WHICHC function returns the first position of 'Spain' in the list:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select whichc('Spain', 'Denmark', 'Germany', 'Austria', 'Spain', 'China', 'Egypt', 'Spain', 'France');</td>
<td>4</td>
</tr>
</tbody>
</table>

See Also

Functions:

- "WHICHN Function" on page 792

WHICHN Function
Returns the first position of a number from a list of numbers.

Categories: CAS Mathematical
Returned data type: DOUBLE

Syntax
WHICHN(search-expression, expression-list-item-1, expression-list-item-2 [, ...expression-list-item-n])

Arguments
search-expression
specifies any valid expression that evaluates to a number and that is compared with a list of numeric expressions.

Data type: DOUBLE
**expression-list-item**
specifies any valid expression that evaluates to a number and is part of a list.

**Requirement**
At least two expressions are required in the list.

**Data type**
DOUBLE

**See**
“<sql-expression> Expression” on page 820
“FedSQL Expressions” on page 48

**Details**
The WHICHN function searches the numeric expression list, from left to right, for the first expression that matches the search expression. If a match is found, WHICHN returns its position in the expression list. If none of the expressions match the search expression, WHICHN returns a value of 0. Arguments for the WHICHN functions can be any numeric data type.

**Example**
In the following example, 4.5 appears two times in the list. The WHICHN function returns the first position of 4.5 in the list.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select whichn(4.5, 7.3, 8.6, 4.5, 4.5, 2.1, 6.4);</td>
<td>3</td>
</tr>
</tbody>
</table>

**See Also**

**Functions:**
- "WHICHC Function" on page 791

---

**YEAR Function**
Returns the year from a date or datetime value.

**Categories:**
Date and Time
CAS

**Returned data type:**
SMALLINT
Syntax

YEAR(\textit{date} \mid \textit{datetime})

Arguments

\textit{date} specifies any valid expression that represents a date value.

Data type DATE

See “\textless sql-expression\textgreater Expression” on page 820

“FedSQL Expressions” on page 48

\textit{datetime} specifies any valid expression that represents a datetime value.

Data type TIMESTAMP

See “\textless sql-expression\textgreater Expression” on page 820

“FedSQL Expressions” on page 48

Example

Table: CUSTOMLINE on page 1080

The following statement illustrates the YEAR function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
</table>
| select year\{(endtime)\} from customline; | 2012  
| | 2012  
| | 2012  
| | 2012  
| | 2012  
| | 2012  
| | 2013  
| | 2013  
| | 2013  
| | 2013  
| | 2013  |
| select year\{(current\_time)\}; | 2013 |

See Also

“Dates and Times in FedSQL” on page 60

Functions:

“DAY Function” on page 391

“HOUR Function” on page 508

“MINUTE Function” on page 600
YIELDP Function

Returns the yield-to-maturity for a periodic cash flow stream, such as a bond.

Categories:

- CAS
- Financial

Returned data type: DOUBLE

Syntax

\[
\text{YIELDP}(A, c, n, K, k_0, p)
\]

Arguments

- **A** specifies the face value.
  - Range: \( A > 0 \)
  - Data type: DOUBLE

- **c** specifies the nominal annual coupon rate, expressed as a fraction.
  - Range: \( 0 \leq c < 1 \)
  - Data type: DOUBLE

- **n** specifies the number of coupons per year.
  - Range: \( n > 0 \)
  - Data type: DOUBLE

- **K** specifies the number of remaining coupons from settlement date to maturity.
  - Range: \( K > 0 \)
  - Data type: DOUBLE

- **k_0** specifies the time from settlement date to the next coupon as a fraction of the annual basis.
  - Range: \( 0 < k_0 \leq \frac{1}{n} \)
Details

The YIELDP function is based on the following relationship:

\[ P = \sum_{k=1}^{K} c(k) \frac{1}{(1 + \frac{y}{n})^t_k} \]

The following relationships apply to the preceding equation:

- \( t_k = nk_0 + k - 1 \)
- \( c(k) = \frac{c}{n}A \) for \( k = 1, ..., K - 1 \)
- \( c(K) = (1 + \frac{c}{n})A \)

The YIELDP function solves for \( y \).

Example

In the following example, the YIELDP function returns the yield-to-maturity of a bond that has a face value of 1000, an annual coupon rate of 0.01, 4 coupons per year, and 14 remaining coupons. The time from settlement date to next coupon date is 0.165, and the price with accrued interest is 800. The value returned is 0.077503.

```sql
select yieldp(1000, .01, 4, 14, .165, 800);
```

YRDIF Function

Returns the difference in years between two dates according to specified day count conventions; returns a person’s age.

Categories: CAS

Date and Time

Returned data type: DOUBLE

Syntax

\[ \text{YRDIF}(\text{start-date}, \text{end-date}[\text{, basis}]) \]
Arguments

**start-date**
specifies a SAS date value that identifies the starting date.

Data type  DOUBLE

**end-date**
specifies a SAS date value that identifies the ending date.

Data type  DOUBLE

**basis**
identifies a character constant or variable that describes how SAS calculates a date difference or a person’s age. The following character strings are valid:

'30/360'
specifies a 30-day month and a 360-day year in calculating the number of years. Each month is considered to have 30 days, and each year 360 days, regardless of the actual number of days in each month or year.

Alias  '360'
Tip    If either date falls at the end of a month, it is treated as if it were the last day of a 30-day month.

'ACT/ACT'
uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days that fall in 365-day years divided by 365 plus the number of days that fall in 366-day years divided by 366.

Alias  'Actual'

'ACT/360'
uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days divided by 360, regardless of the actual number of days in each year.

'ACT/365'
uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days divided by 365, regardless of the actual number of days in each year.

'AGE'
specifies that a person’s age will be computed.

If you do not specify a third argument, AGE becomes the default value for **basis**.

Data type  CHAR, NCHAR, NVARCHAR, VARCHAR

YRDIF Function 797
Details

Using YRDIF in Financial Applications

The Basics

The YRDIF function can be used in calculating interest for fixed income securities when the third argument, basis, is present. YRDIF returns the difference between two dates according to specified day count conventions.

Calculations That Use ACT/AKT Basis

In YRDIF calculations that use the ACT/AKT basis, both a 365-day year and 366-day year are taken into account. For example, if n365 equals the number of days between the start and end dates in a 365-day year, and n366 equals the number of days between the start and end dates in a 366-day year, the YRDIF calculation is computed as YRDIF=n365/365.0 + n366/366.0. This calculation corresponds to the commonly understood ACT/AKT day count basis that is documented in the financial literature. The values for basis also includes 30/360, ACT/360, and ACT/365. Each has well-defined meanings that must be conformed to in calculating interest payments for specific financial instruments.

Computing a Person’s Age

The YRDIF function can compute a person’s age. The first two arguments, start-date and end-date, are required. If the value of basis is AGE, then YRDIF computes the age. The age computation takes into account leap years. No other values for basis are valid when computing a person’s age.

Examples:

Example 1: Calculating a Difference in Years Based on Basis

In the following example, YRDIF returns the difference in years between two dates based on each of the ACT options for basis.

```sql
select yrdif(date'1998-10-16', date'2010-02-06', '30/360') as y30360,
       yrdif(date'1998-10-16', date'2010-02-06', 'ACT/AKT') as yactact,
       yrdif(date'1998-10-16', date'2010-02-06', 'ACT/360') as yact360,
       yrdif(date'1998-10-16', date'2010-02-06', 'ACT/365') as yact365;
quit;
```

Output 4.15  Output from ACT Calculations

<table>
<thead>
<tr>
<th>Y30360</th>
<th>YACTACT</th>
<th>YACT360</th>
<th>YACT365</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.30556</td>
<td>11.30959</td>
<td>11.475</td>
<td>11.31781</td>
</tr>
</tbody>
</table>

Example 2: Calculating a Person’s Age

You can calculate a person’s age by using the AGE option in the basis argument of the YRDIF function as follows:

```sql
select yrdif(date'1998-10-16', date'2010-02-16', 'AGE');
```

SAS returns the value 11.33699.
YYQ Function

Returns a SAS date value from year and quarter year values.

Categories:
- CAS
- Date and Time

Returned data type: DOUBLE

Syntax

\[ \text{YYQ}(\text{year}, \text{quarter}) \]

Arguments

\text{year}

specifies any valid expression that evaluates to a two-digit or four-digit whole number that represents the year.

Data type: DOUBLE

Interaction

The YEARCUTOFF= system option defines the year value for two-digit dates.

\text{quarter}

specifies the quarter of the year (1, 2, 3, or 4).

Data type: DOUBLE

See

- "<sql-expression> Expression" on page 820
- "FedSQL Expressions" on page 48
Details
The YYQ function returns a SAS date value that corresponds to the first day of the specified quarter. If either *year* or *quarter* is null or missing, or if the quarter value is not valid, the result is a null or missing value.

Example
The following statements illustrate the YYQ function:

<table>
<thead>
<tr>
<th>Statements</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>select yyq(2006,3);</td>
<td>16983</td>
</tr>
<tr>
<td>select put(yyq(2006,3), date7.);</td>
<td>01JUL06</td>
</tr>
<tr>
<td>select put(yyq(2006,3), date9.);</td>
<td>01JUL2006</td>
</tr>
<tr>
<td>select yyq(2006,4);</td>
<td>17075</td>
</tr>
<tr>
<td>select put(yyq(2006,4), date9.);</td>
<td>01OCT2006</td>
</tr>
</tbody>
</table>

Overview of Expressions and Predicates

Expressions are combinations of symbols and operators that FedSQL evaluates and then returns a single value. Expressions can be as simple as a single constant or column or as complex as multiple expressions joined by an operator.

This chapter focuses on three conditional expressions, CASE, COALESCE, and NULLIF, and on <sql-expression>, a generic expression that defines all other types of expressions.

Predicates specify conditions that evaluate to either true, false, or unknown. They are used most often in WHERE and HAVING clauses and in the FROM clause in join conditions.
Dictionary

BETWEEN Predicate

Selects rows where column values are within a range of values.

Syntax

```
expression [NOT] BETWEEN expression AND expression
```

Arguments

- `expression`
  - specifies any valid SQL expression.

See  "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

The BETWEEN predicate specifies a range of column values to select using these criteria:

- The SQL expressions must be of compatible data types.
- Because a BETWEEN condition evaluates the boundary values as a range, it is not necessary to specify the smaller quantity first.
- You can use the NOT logical operator to exclude a range of numbers. For example, you can use NOT to eliminate customer numbers between 1 and 15 (inclusive) so that you can retrieve data on more recently acquired customers.

Example

```
select * from invtry
where invtry.name
    between 'A' and 'Mzzz';
```

See Also

Expressions:

- "<sql-expression> Expression" on page 820
CASE Expression

Selects result values that satisfy search conditions and value comparisons.

Syntax

```
CASE [case-expression]
  WHEN when-expression THEN result-expression
  ...
  [WHEN when-expression THEN result-expression]
  [ELSE result-expression]
END
```

Arguments

- **case-expression**
  specifies any valid SQL expression that evaluates to a table column whose values are compared to when-expression.

  See  "<sql-expression> Expression" on page 820

  "FedSQL Expressions" on page 48

- **when-expression**
  specifies any valid SQL search condition expression or a value expression.

  - When case-expression is not specified, when-expression is a search condition expression that evaluates to true or false.
  
    See  "<sql-expression> Expression" on page 820

  - When case-expression is specified, when-expression is an SQL value expression that is compared to case-expression and that evaluates to true or false.

  See  "<sql-expression> Expression" on page 820

- **result-expression**
  specifies an SQL expression that evaluates to a value.

  See  "<sql-expression> Expression" on page 820

Details

The CASE expression selects values if certain conditions are met. The case-expression argument returns a single value that is conditionally evaluated for each row of a table. Use the WHEN-THEN clauses to execute a CASE expression for some, but not all of the rows in the table that is being queried or created. The optional ELSE expression gives an alternative action if no THEN expression is executed.

When you omit case-expression, when-expression is evaluated as a Boolean (true or false) value. If when-expression returns a nonzero, non-null result, then the
WHEN clause is true. If case-expression is specified, then it is compared with when-expression for equality. If case-expression equals when-expression, then the WHEN clause is true.

If the when-expression is true for the row that is being executed, then the result-expression that follows THEN is executed. If when-expression is false, then FedSQL evaluates the next when-expression until they are all evaluated. If every when-expression is false, then FedSQL executes the ELSE expression, and its result becomes the CASE expression’s result. If no ELSE expression is present and every when-expression is false, then the result of the CASE expression is null.

You can use a CASE expression as an item in the SELECT clause and as either operand in an SQL expression.

Comparisons

The COALESCE expression and the NULLIF expression are variations of the CASE expression.

The following CASE expression and COALESCE expression are equivalent:

```sql
case
  when value1 is not null then value1
  when value2 is not null then value2
  else value3
end
coalesce(value1, value2, value3)
```

The following CASE expression and NULLIF expression are equivalent:

```sql
case
  when value1 = -1 then null
  else value1
end
nullif(value1, -1);
```

Examples:

Example 1: The CASE Expression Using A Search Condition

Table: WORLDTEMPS on page 1092

```sql
select AvgLow,
  case
    when AvgLow < 32 then AvgLow + 2
    when ((AvgLow < 60) and (AvgLow > 32)) then AvgLow + 5
    when AvgLow > 60 then AvgLow + 10
    else AvgLow
  end
as Adjusted from worldtemps;
```

SAS creates the follow table:
Output 5.1  CASE Using a Search Condition

Example 2: The CASE Expression Using a Value

Table: WORLDTEMPS on page 1092

```sql
select Country,
  case Country
    when 'Algeria' then 'Africa'
    when 'Nigeria' then 'Africa'
    when 'Netherlands' then 'Europe'
    when 'Spain' then 'Europe'
    when 'Switzerland' then 'Europe'
    when 'China' then 'Asia'
    when 'India' then 'Asia'
    when 'Venezuela' then 'South America'
    else 'Unknown'
  end as Continent
from worldtemps;
```

SAS creates the following table:

<table>
<thead>
<tr>
<th>avglow</th>
<th>ADJUSTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>50</td>
</tr>
<tr>
<td>33</td>
<td>38</td>
</tr>
<tr>
<td>17</td>
<td>19</td>
</tr>
<tr>
<td>56</td>
<td>61</td>
</tr>
<tr>
<td>57</td>
<td>62</td>
</tr>
<tr>
<td>28</td>
<td>30</td>
</tr>
<tr>
<td>51</td>
<td>56</td>
</tr>
<tr>
<td>75</td>
<td>85</td>
</tr>
<tr>
<td>36</td>
<td>41</td>
</tr>
<tr>
<td>33</td>
<td>38</td>
</tr>
<tr>
<td>25</td>
<td>27</td>
</tr>
</tbody>
</table>
COALESCE Expression

Returns the first non-null value from a list of columns.

Restriction:

SAS data sets, SPD Engine data sets, and SPD Server tables process null values as a blank string.

Syntax

\[ \text{COALESCE}(\text{expression} \ [\ldots\text{expression}]) \]
Arguments

**expression**
specifies any valid SQL expression.

See "<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

COALESCE accepts one or more SQL expressions of the same data type. The COALESCE expression checks the value of each SQL expression in the order in which it is listed and returns the first non-null value. If only one SQL expression is listed, the COALESCE expression returns the value of that SQL expression. If all the values of all arguments are null, the COALESCE expression returns a null value.

In some SQL DBMSs, the COALESCE expression is called the IFNULL expression.

**Note:** If your query contains a large number of COALESCE expressions, it might be more efficient to use a natural join instead. For more information, see "Natural Joins" on page 887.

Comparisons

The COALESCE expression is a variation of the CASE expression. For example, these two sets of code are equivalent,

```sql
coalesce(value1, value2, value3)
case
  when value1 is not null
    then value1
  when value2 is not null
    then value2
  else value3
end;
```

See Also

**Expressions:**
- "CASE Expression" on page 803

DISTINCT Predicate

Specifies that only unique rows are selected as input or output.
Syntax

Form 1: \[ \text{aggregate-function} \ (\text{DISTINCT} \ \text{expression}); \]

Form 2: \[ \text{SELECT} \ \text{DISTINCT} \ <\text{select-list}> \ \text{FROM} \ <\text{table-expression}>; \]

Arguments

\textit{aggregate-function} 

can be any aggregate function.

\textit{expression} 

specifies any valid SQL expression.

See "\textless sql-expression\textgreater Expression" on page 820

"FedSQL Expressions" on page 48

\textit{SELECT <select-list> FROM <table-expression>}

is a query that retrieves rows from a table.

See For more information about using the DISTINCT predicate in the SELECT statement, see the "SELECT Clause" on page 877.

Details

Both forms of the DISTINCT predicate perform a form of duplicate elimination. Use of the DISTINCT keyword with an aggregate function causes FedSQL to only provide unique values as input to the aggregate calculation. Use of SELECT DISTINCT causes FedSQL to only return unique rows in the query’s result set.

Note: Two null values are \textit{not} considered distinct.

Example

\[- \text{select count}(\text{distinct avghigh}) \ \text{from} \ \text{worldtemps}; \]

\[- \text{select distinct c1.employee, firstname, salary} \]
\[- \quad \text{from} \ \text{company as c1;} \]

See Also

Statements:

Functions:

- “AVG Function” on page 274
- “COUNT Function” on page 365
- “CSS Function” on page 374
- “KURTOSIS Function” on page 563
- “MAX Function” on page 594
EXISTS Predicate
Tests whether a subquery returns one or more rows.

Syntax

\[
\text{[NOT] EXISTS (select-statement)}
\]

Arguments

\textit{select-statement}

specifies a subquery with the SELECT statement.

See \textit{“SELECT Statement” on page 874}

Details

The EXISTS predicate is an operator whose right operand is a subquery. The result of an EXISTS predicate is true if the subquery resolves to at least one row. The result of a NOT EXISTS predicate is true if the subquery evaluates to zero rows.

Example

The following query subsets PAYROLL based on the criteria in the subquery. If the value for STAFF.IDNUM is on the same row as the value CT in STAFF, then the matching IDNUM in PAYROLL is included in the output. Thus, the query returns all the employees from PAYROLL who live in CT.

\begin{verbatim}
select *
from payroll p
where exists (select * from staff s
where p.idnumber=s.idnum and state='CT');
\end{verbatim}
See Also

**Statements:**

- "SELECT Statement" on page 874

---

### IN Predicate

Tests set membership.

**Syntax**

```
expression [NOT] IN (select-statement | constant [, ...constant])
```

**Arguments**

- **expression**
  - specifies any valid SQL expression.
    - See "<sql-expression> Expression" on page 820
    - "FedSQL Expressions" on page 48
  - **select-statement**
    - specifies a subquery with the SELECT statement.
      - See "SELECT Statement" on page 874
  - **constant**
    - specifies a number or a quoted character string (or other special notation) that indicates a fixed value. Constants are also called *literals*.

**Details**

The IN predicate tests whether the column value that is returned by the SQL expression on the left is a member of the set (of constants or values returned by the query expression) on the right. The IN condition is true if the value of the operand on the left is in the set of values that are defined by the operand on the right.

The NOT IN predicate negates the returned value.

**Example**

**Table:** WORLDTEMPS on page 1092

```sql
select city, country
from worldtemps
  where avghigh in (90, 97);
```

SAS creates the following table:
IS FALSE Predicate

Tests for a false value.

Syntax

(expression) IS [NOT] FALSE

Arguments

expression

specifies any valid SQL expression.

See "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

IS FALSE is a predicate that tests for a false value. IS FALSE is used in the WHERE, ON, and HAVING clauses. The IS FALSE predicate resolves to true if the result of the SQL expression is false and resolves to false if it is true.

Comparisons

The IS TRUE predicate tests for true values.

Example

Table: WORLD_CITYCOORDS on page 1089

select city
    from worldcitycoords
    where (latitude = 40) is false;

SAS creates the following table:
IS MISSING Predicate

Tests for a SAS missing value in a SAS native data store.

Syntax

```
expression IS [NOT] MISSING
```

Arguments

- `expression` specifies any valid SQL expression.

See

- "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48
Details

IS MISSING is a predicate that tests for a SAS missing value. IS MISSING is used in the WHERE, ON, and HAVING clauses. The IS MISSING predicate resolves to true if the result of the SQL expression is a SAS missing value and resolves to false if it is not a SAS missing value.

The IS MISSING predicate is valid only in use with SAS native data stores. Only DOUBLE and CHAR data types support missing values.

Comparisons

The IS NULL predicate tests for null values.

Example

Table: WORLD_CITY_COORDS on page 1089

```sql
select *
from worldcitycoords
where city is missing;
```

SAS creates the following table:

**Output 5.5  IS MISSING Example Output Table**

<table>
<thead>
<tr>
<th>city</th>
<th>country</th>
<th>latitude</th>
<th>longitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>China</td>
<td></td>
<td>40</td>
<td>116</td>
</tr>
</tbody>
</table>

---

**IS NULL Predicate**

Tests for a null value.

**Syntax**

```
expression IS [NOT] NULL
```

**Arguments**

- `expression` specifies any valid SQL expression.
Details

IS NULL is a predicate that tests for a null value. IS NULL is used in the WHERE, ON, and HAVING clauses. The IS NULL predicate resolves to true if the result of the SQL expression is null and resolves to false if it is not null.

Comparisons

The IS MISSING predicate tests for SAS missing values in SAS native data stores.

Example

Table: WORLD_CITYCOORDS on page 1089

```sql
select city
from worldcitycoords
where latitude is not null;
```

SAS creates the following table:

**Output 5.6  IS NULL Example Output Table**

<table>
<thead>
<tr>
<th>city</th>
</tr>
</thead>
<tbody>
<tr>
<td>Algiers</td>
</tr>
<tr>
<td>Shanghai</td>
</tr>
<tr>
<td>Hong Kong</td>
</tr>
<tr>
<td>Bombay</td>
</tr>
<tr>
<td>Calcutta</td>
</tr>
<tr>
<td>Amsterdam</td>
</tr>
<tr>
<td>Lagos</td>
</tr>
<tr>
<td>Madrid</td>
</tr>
<tr>
<td>Zurich</td>
</tr>
<tr>
<td>Caracas</td>
</tr>
</tbody>
</table>

**Predicates:**
- "IS MISSING Predicate" on page 812
- `<search-condition>` in the “SELECT Statement” on page 874

---

IS TRUE Predicate

Tests for a true value.

**Syntax**

\[(expression) \text{ IS [NOT]} \text{ TRUE}\]

**Arguments**

*expression*

specifies any valid SQL expression.

See "<sql-expression> Expression" on page 820

“FedSQL Expressions” on page 48

**Details**

IS TRUE is a predicate that tests for a true value. IS TRUE is used in the WHERE, ON, and HAVING clauses. The IS TRUE predicate resolves to true if the result of the SQL expression is true and resolves to false if it is false.

**Comparisons**

The IS FALSE predicate tests for false values.

**Example**

Table: WORLD_CITYCOORDS on page 1089

```sql
select city
from world_citycoords
where (latitude = 40) is true;
```

SAS creates the following table:
IS UNKNOWN Predicate

Tests for an unknown value.

Syntax

expression IS [NOT] UNKNOWN

Arguments

expression

specifies any valid SQL expression.

See  "<sql-expression> Expression" on page 820

"FedSQL Expressions" on page 48

Details

IS UNKNOWN is a predicate that tests for an unknown value. IS UNKNOWN is used in the WHERE, ON, and HAVING clauses. The IS UNKNOWN predicate resolves to true if the result of the SQL expression is unknown and resolves to false if it is a valid value.

See Also

Predicates:

- “IS FALSE Predicate” on page 811
- “IS TRUE Predicate” on page 815
LIKE Predicate
Tests for a matching pattern.

Syntax

\[ \text{expression} \ [\text{NOT}] \ \text{LIKE} \ \text{expression} \]

Arguments

\text{expression}

specifies any valid SQL expression that is either a character string type or a binary string type.

Tip
The SQL expression on the right side of the syntax, that is the pattern, is most likely to be a literal.

See
"<sql-expression> Expression" on page 820
"FedSQL Expressions" on page 48

Details

Overview of the LIKE Predicate

The LIKE predicate selects rows by comparing character strings with a pattern-matching specification. It resolves to true and displays the matched string or strings if the left operand matches the pattern that is specified by the right operand.

Escape characters are not supported.

Note: If no rows are returned, the result is a null value.

Patterns for Searching

Patterns include three classes of characters:

- underscore (_)
  matches any single character.

- percent sign (%)
  matches any sequence of zero or more characters.

- any other character
  matches that character.

These patterns can appear before, after, or on both sides of characters that you want to match. The LIKE condition is case-sensitive.

The following list uses these values: Smith, Smooth, Smothers, Smart, and Smuggle.
'Sm\%'  
matches Smith, Smooth, Smothers, Smart, Smuggle.

'\%th'  
matches Smith, Smooth.

'S__gg\%'  
matches Smuggle.

'S_o'  
matches a three-letter word, so it has no matches here.

'S_o\%'  
matches Smooth, Smothers.

'S\%th'  
matches Smith, Smooth.

'M'  
matches the single, uppercase character m only, so it has no matches here.

Searching for Mixed-Case Strings
To search for mixed-case strings, use the UPPER function to make all the names uppercase before entering the LIKE condition:

\text{upper(name) like 'SM\%';}

\textbf{Note:} When you are using the \% character, be aware of the effect of trailing blanks. You might have to use the TRIM function to remove trailing blanks in order to match values.

Example

Table: DENSITIES on page 1081

\text{select name, population  
from densities  
where name like 'Al\%';}

See Also

\textbf{Functions:}

\begin{itemize}
  \item "TRIM Function" on page 776
\end{itemize}

\textbf{NULLIF Expression}

Returns a null value if the two specified expressions are equal; otherwise, returns the first expression.

\textbf{Restriction:} The BASE file format processes a null value as DOUBLE values in some situations and as a blank string in other situations. For more information, see "How FedSQL Processes Nulls and SAS Missing Values" on page 22.
Syntax

**NULLIF**(expression-1, expression-2)

Arguments

*expression*

specifies any valid SQL expression.

Data type  
All data types are valid.

See

“<sql-expression> Expression” on page 820

“FedSQL Expressions” on page 48

Details

The NULLIF expression compares two SQL expressions and, if they are equal, returns a null value. The NULLIF expression enables you to replace a missing or inapplicable value with a null value and to use SQL's behavior for null values.

Comparisons

The NULLIF expression is a shorthand syntax for a special CASE expression. For example, if a student misses a test, a -1 is entered in the GRADES table. To replace this -1 with a null value, you could use the following CASE code.

```sql
update grades
set testscore =
CASE
  when testscore = '-1' then null
  ELSE testscore
END;
```

The following code uses the shorter NULLIF expression.

```sql
update grades
set testscore = NULLIF(testscore, '-1');
```

The IFNULL function compares two SQL expressions and returns the second SQL expression if the first SQL expression is a null value. The NULLIF expression compares two SQL expressions and returns a null value if the two SQL expressions are equal.

Example

Table: **WORLDCITYCOORDS** on page 1089

```sql
missingLong= '.L';
update worldcitycoords
set longitude = nullif(missingLong, '.');
select city
  from worldcitycoords
  where Longitude='L';
```

### `<sql-expression>` Expression

Produces a single value from a combination of symbols and operators or predicates.

#### Syntax

```
<sql-expression>::=
  constant
  | [alias] column
  | function
  | (scalar-subquery)
  | (<sql-expression>)
  | <sql-expression> {operator | predicate} <sql-expression>
```

#### Arguments

**constant**
- is a number, a quoted character string, or a datetime value that represents a single, specific data value.

**alias**
- is the alias that is assigned to a table by using the AS keyword in the FROM clause of a SELECT statement.

**column**
- is the name of a column.

**function**
- is a SAS or aggregate function.

  See “FedSQL Functions” on page 195

**scalar-subquery**
- is a subquery that returns a single value.

**operator**
- is a symbol that specifies an action that is performed on one or more expressions. The following table shows valid operators. An expression can also contain the CASE or COALESCE expressions. For more information, see “CASE Expression” on page 803 or “COALESCE Expression” on page 806.
Table 5.1  Valid Operators

<table>
<thead>
<tr>
<th>Operator</th>

- "IS NULL Predicate" on page 813
- "IS TRUE Predicate" on page 815
- "IS UNKNOWN Predicate" on page 816
- "LIKE Predicate" on page 817
Details

Overview of `<sql-expression>`

Simple expressions can be a single constant, column name, or function. Complex expressions are two or more simple expressions that are joined by an operator or predicate.

Functions in Expressions

An expression can contain a SAS function or an aggregate function. SAS functions perform a computation or system manipulation on one or more arguments and return a value. Aggregate functions produce a statistical summary of data in the entire table that is listed in the FROM clause or for each group that is specified in a GROUP BY clause. If GROUP BY is omitted, then all the rows in the table are considered to be a single group. Aggregate functions reduce all the values in each row or column in a table to one summarizing or aggregate value. For example, the sum (one value) of a column results from the addition of all the values in the column.

Subqueries in Expressions

FedSQL allows a scalar subquery (contained in parentheses) at any point in an expression where a simple column value or constant can be used. In this case, a subquery must return a single value (that is, one row with only one column).

Order of Evaluation

The operators and predicates that are shown in the following table are listed in the order in which they are evaluated.

<table>
<thead>
<tr>
<th>Grou</th>

</tr>
</tbody>
</table>

SAS missing values and null values always appear as the smallest value in the collating sequence.
You can use parentheses to group values or to nest mathematical expressions. Parentheses make expressions easier to read and can also be used to change the order of evaluation of the operators. Evaluating expressions with parentheses begins at the deepest level of parentheses and moves outward. For example, SAS evaluates $A+B\times C$ as $A+(B\times C)$, although you can add parentheses to make it evaluate as $(A+B)\times C$ for a different result.

See Also

Statements:
- “SELECT Statement” on page 874
- “FedSQL Expressions” on page 48
Definition of an Informat

An informat is an instruction that determines how values are read into a column. For example, the following value contains a dollar sign and commas:

$1,000,000

To remove the dollar sign ($) and commas (,) before storing the numeric value 1000000 in a variable, read this value with the COMMA11. informat.

General Informat Syntax

FedSQL informats have the following syntax:

[$]informat[w],[d]

Arguments

$  
indicates a character informat; its absence indicates a numeric informat.

informat  
names the informat. The informat is a SAS informat or a user-defined informat that was previously defined with the INVALUE statement in PROC FORMAT. For more information on user-defined informats, see PROC FORMAT in Base SAS Procedures Guide.
specifies the informat width, which for most informats is the number of columns in the input data.

d  
specifies an optional decimal scaling factor in the numeric informats. SAS divides the input data by 10 to the power of d.

Note: Even though SAS can read up to 31 decimal places when you specify some numeric informats, floating-point numbers with more than 12 decimal places might lose precision because of the limitations of the eight-byte, floating-point representation used by most computers.

Informats always contain a period (.) as a part of the name. If you omit the w and the d values from the informat, SAS uses default values. If the data contains decimal points, SAS ignores the d value and reads the number of decimal places that are actually in the input data.

For more information about how informats work and a complete list of informats, see *SAS Formats and Informats: Reference*.

---

**How Informats Are Used in FedSQL**

Informats are informational and do not operate on your data at run time in the FedSQL environment. The client application is responsible for using the informat to convert the raw data when the table is returned to the application.

Note: If the informat that is stored in the FedSQL environment is invalid, an error occurs only when the invalid informat is used in the client application.
An informat is applied by the client application. Here, the Base SAS session validates and applies the informat when a SAS procedure uses the data.

However, in FedSQL, you can store and retrieve informat names. The informat name is associated with a column—either temporarily for the duration of an operation or permanently—by storing the informat as a metadata attribute on the column. The metadata then can be retrieved for subsequent operations.

FedSQL supports SAS informats as follows.

- Both informats supplied by SAS and user-defined informats can be associated with a column. For information about how to create your own informat in SAS, see PROC FORMAT in Base SAS Procedures Guide.

  Note: To create and access user-defined informats, a Base SAS session must be available in order to access the SAS catalog file that stores the SAS informat definitions.

- Only the SAS data sets, SPD Engine data sets, and SPD Server tables support storing and retrieving an informat with a column.
- Informats can be associated with all data types, but all data types are converted to either CHAR or DOUBLE.
- You can associate SAS informats with a column by using the HAVING clause of the FedSQL CREATE TABLE or the SET clause of the FedSQL ALTER TABLE statement. For more information, see “How to Specify Informats in FedSQL” on page 828.

For more information and a complete list of informats that are supplied by SAS, see the section on informats in SAS Formats and Informats: Reference.
How to Specify Informats in FedSQL

In FedSQL, specify informats as an attribute in the HAVING clause of the CREATE TABLE statement. For example, in the following statement, the column X is declared with the IEEE8.2 format and the BITS5.2 informat.

```
create table a (x double having format ieee8.2 informat bits5.2 label 'foo');
```

Validation of FedSQL Informats

Informats are not validated by a data source or applied to a column until execution time.

When a table is created using FedSQL, no validation occurs.

When metadata for a column is requested, the informat name is returned without validation.

FedSQL Informat Example

```
create table y (x double having label 'price' format $5. informat $charzb4.3);
```
Overview of Statements

A FedSQL statement is a series of items that can include keywords, identifiers, special characters, and operators. All FedSQL statements end with a semicolon.

There are five categories of statements:

- data definition
  - statements that are used to create, modify, and delete tables and views.

- data control
  - statements that are used to control transactions with the database.

- data manipulation
  - statements that are used to add, update, and delete data.

- data retrieval
  - statements that are used to retrieve data, or retrieve information about a data table or a SQL view.
**FedSQL Statements by Category**

<table>
<thead>
<tr>
<th>Category</th>
<th>Language Elements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Control</td>
<td>BEGIN Statement (p. 836)</td>
<td>Marks the beginning of a transaction that comprises multiple statements.</td>
</tr>
<tr>
<td></td>
<td>COMMIT Statement (p. 837)</td>
<td>Makes changes that have been performed since the start of a transaction a permanent part of the database.</td>
</tr>
<tr>
<td></td>
<td>ROLLBACK Statement (p. 873)</td>
<td>Rolls back transaction changes to the beginning of the transaction.</td>
</tr>
<tr>
<td>Data Definition</td>
<td>ALTER TABLE Statement (p. 831)</td>
<td>Adds or drops table columns and modifies column definitions.</td>
</tr>
<tr>
<td></td>
<td>CREATE INDEX Statement (p. 838)</td>
<td>Creates an index on columns in a specified table.</td>
</tr>
<tr>
<td></td>
<td>CREATE TABLE Statement (p. 840)</td>
<td>Creates a new table.</td>
</tr>
<tr>
<td></td>
<td>CREATE VIEW Statement (p. 858)</td>
<td>Creates a view of data from one or more tables or other views.</td>
</tr>
<tr>
<td></td>
<td>DESCRIBE TABLE Statement (p. 861)</td>
<td>Retrieves SQL from a table and returns a result set.</td>
</tr>
<tr>
<td></td>
<td>DESCRIBE VIEW Statement (p. 863)</td>
<td>Retrieves SQL from a view and returns a result set.</td>
</tr>
<tr>
<td></td>
<td>DROP INDEX Statement (p. 864)</td>
<td>Removes the specified index from a table.</td>
</tr>
<tr>
<td></td>
<td>DROP TABLE Statement (p. 865)</td>
<td>Removes a table from the database.</td>
</tr>
<tr>
<td></td>
<td>DROP VIEW Statement (p. 867)</td>
<td>Removes a view from the database.</td>
</tr>
<tr>
<td></td>
<td>SELECT Statement (p. 874)</td>
<td>Retrieves columns and rows of data from tables.</td>
</tr>
<tr>
<td>Data Manipulation</td>
<td>DELETE Statement (p. 859)</td>
<td>Deletes rows from a table.</td>
</tr>
<tr>
<td></td>
<td>INSERT Statement (p. 870)</td>
<td>Adds rows to a specified table.</td>
</tr>
<tr>
<td></td>
<td>SELECT Statement (p. 874)</td>
<td>Retrieves columns and rows of data from tables.</td>
</tr>
</tbody>
</table>
## ALTER TABLE Statement

Adds or drops table columns and modifies column definitions.

**Category:** Data Definition

**Restrictions:**
This statement is not supported in FedSQL programs that run in CAS.

Constraint syntax is defined by the data source. The constraint syntax that is provided here is a general syntax. For complete constraint syntax, see the documentation for your data source.

**Data source:**
SAS data set, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Spark, Teradata, Vertica

**Note:**
Braces in the syntax convention indicate a syntax grouping. The escape character ( \ ) before a brace indicates that the brace is required in the syntax. Table options must be contained by braces ( { } ).

### Syntax

```
ALTER TABLE table [(OPTIONS SAS-table-option=value [, ...SAS-table-option=value] ])
   ADD COLUMN <column-definition> [, ...<column-definition>]
| ADD CONSTRAINT <table-constraint>
| ALTER [COLUMN] <column-definition> [, ...<column-definition> ]
| DROP COLUMN column [, ...column] [FORCE]
| DROP CONSTRAINT constraint [, ...constraint]
| RENAME TO table
```
| RENAME column TO column |

<column-definition>::=
  column data-type [<column-constraint>] [ SET DEFAULT value | DROP DEFAULT ]

<column-constraint>::=
  CONSTRAINT constraint
  { CHECK (search-condition)
    | PRIMARY KEY
    | UNIQUE
    | NOT NULL }

<table-constraint>::=
  CONSTRAINT constraint
  { CHECK (search-condition)
    | PRIMARY KEY (column [, …column])
    | UNIQUE (column [, …column])
    | <referential-constraint> }
  [<constraint-check-time>]

<referential-constraint>::=
  FOREIGN KEY (referencing-column [, … referencing-column])
    REFERENCES referenced-table (referenced-column [, …referenced-column])
    [<referential-trigger-action>]

<referential-trigger-action>::=
  { [ ON UPDATE <referential-action> [ON DELETE <referential-action>]] } |
  { [ ON DELETE <referential-action> [ON UPDATE <referential-action>]] }

<referential-action>::=
  CASCADE | SET NULL | SET DEFAULT | RESTRICT | NO ACTION

<constraint-check-time>::=
  { DEFERRABLE [INITIALLY DEFERRED | INITIALLY IMMEDIATE] }
  | { [INITIALLY DEFERRED | INITIALLY IMMEDIATE] DEFERRABLE }
  | INITIALLY DEFERRED
  | { NOT DEFERRABLE [INITIALLY IMMEDIATE] }
  | { [INITIALLY IMMEDIATE] NOT DEFERRABLE }

Arguments

**table**
specifies a table to modify. **table** can be specified in one of these forms:
- catalog.schema.table-name
- schema.table-name
- catalog.table-name
- table-name
catalog
is an implementation of the ANSI SQL standard for an SQL catalog. The
catalog is a data container object that groups logically related schemas. It is
the first-level (top) grouping mechanism in a data organization hierarchy that
is used along with a schema to provide a means of qualifying names. A
catalog is a metadata object in a SAS Metadata Repository.

schema
is an implementation of the ANSI SQL standard for an SQL schema. The
schema is a data container object that groups files such as tables and views
and other objects that are supported by a data source such as stored
procedures. The schema provides a grouping object that is used along with a
catalog to provide a means of qualifying names.

table-name
is the name of the table.

Restriction
You cannot alter an MDS table while it is referenced in another
transaction or statement. If a request fails, make sure other users
are no longer using the table or have disconnected.

Requirement
Table naming conventions are based on the data source. When
more than one data source is involved, the maximum length of a
table name is determined by the maximum length that is supported
by all of the data sources and FedSQL. For example, if your data
sources are a SAS data set that has a maximum of 32 characters
and MySQL that has a maximum of 64 characters, the maximum
length of a table name is 32 characters. For more information, see
the documentation for your data source.

{OPTIONS SAS-table-option=value [, ...SAS-table-option=value ]}
specifies one or more table options and their respective values to apply to the
table.

Requirement
The OPTION argument and all table options must be enclosed in
braces ( { } ).

See
"FedSQL Statement Table Options" on page 907

column
specifies the name of a column in a table.

Requirement
Each column in a table must be unique.

ADD COLUMN <column-definition> [, ...<column-definition>]
specifies to add a column to a table.

Data source
Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum,
HAWQ, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MySQL,
Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Spark,
Teradata, Vertica

See
column on page 833 and "<column-definition> Arguments" on page
843 in the CREATE TABLE statement

Example
"Adding and Deleting Columns" on page 835

ADD CONSTRAINT <table-constraint>
specifies to add an integrity constraint to one or more columns.
Data source SAS data set, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, Microsoft SQL Server, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata, Vertica

Note Constraint validation and enforcement is performed by the data source. You should be familiar with data source’s requirements before adding or dropping an integrity constraint.

See "<column-constraint> and <table-constraint> Arguments" on page 852 in the CREATE TABLE statement

Example "Adding and Deleting Constraints" on page 835

**ALTER [COLUMN] <column-definition> [,...<column-definition>]** specifies to modify the definition of one or more columns.

Data source Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP IQ, Teradata, Vertica

See "<column-definition> Arguments" on page 843 in the CREATE TABLE statement

Example "Altering Column Definitions" on page 835

**DROP COLUMN column [,...column] [FORCE]** specifies to delete the specified column from the table. When FORCE is specified, the column is dropped from the table without error processing. Use the FORCE keyword only when you are certain that dropping the column without error processing will not negatively affect the table.

Data source Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, Hive, JDBC, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata, Vertica

See "column" on page 833

**DROP CONSTRAINT constraint [,...constraint]** specifies to delete an integrity constraint.

**constraint** specifies the name of the constraint to drop.

Data source SAS data set, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, Microsoft SQL Server, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata, Vertica

**RENAME** changes the specified table or column name to a new name. The new name follows the TO keyword.

Data source Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, MDS, Microsoft SQL Server, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata, Vertica
Arguments

See “Arguments” on page 843 in the CREATE TABLE statement.

<column-constraint> and <table-constraint> Arguments

See “<column-constraint> and <table-constraint> Arguments” on page 852 in the CREATE TABLE statement.

Details

Adding and Deleting Columns

To add a column to a table, use the ALTER TABLE statement with the ADD COLUMN clause. By using the ADD COLUMN clause, you name the column and define the column attributes, such as the column data type, a default value, and a label for the column.

```
alter table personal_info add column em_num char(16);
```

To delete a column, you need to specify only the column name.

```
alter table personal_info drop em_num;
```

Adding and Deleting Constraints

You can define a constraint on a column that is added with the ADD COLUMN clause in all data sources that support integrity constraints as follows:

```
alter table mytest add y char(5) constraint c2 unique;
```

Exceptions are SAP HANA and Vertica. For these data sources, you must add the column first, and then add the constraint with ADD CONSTRAINT. In addition, for Vertica you must specify a constraint name when adding a UNIQUE constraint with the ALTER TABLE statement.

By using the ADD CONSTRAINT clause, you can add a constraint for a table, or you can add or modify a constraint for one or more existing columns. The following code adds a primary key constraint to a table with ALTER TABLE.

```
alter table customers add constraint pkey primary key(custid);
```

The following code adds a CHECK constraint to an existing column.

```
alter table mytest add constraint chk check (col1 < 5);
```

You delete a constraint by using the DROP CONSTRAINT clause. The following code is an example of deleting a constraint from a SAS data set. The code deletes a primary key constraint that was defined at table creation. When they are defined at table creation, primary keys in a SAS data set are created with the default name _pk0001_.

```
alter table customers drop constraint _pk0001_;
```

When you add or modify constraints, you must know the constraint syntax that the data source supports. Constraint validation is performed by the data source.

Altering Column Definitions

To alter a column definition, use the ALTER TABLE statement with the ALTER clause.
alter table personal_info alter country set default 'UK';
This example drops a default value from a column.
alter table personal_info alter country drop default;
This example renames a column.
alter table sales rename column y to customers;

Comparisons
You use the ALTER TABLE statement to alter a table after it has been created. Use the CREATE TABLE statement to create a table.

See Also
- “How to Store, Change, Delete, and Use Stored Formats ” on page 80

Statements:
- “CREATE TABLE Statement” on page 840
- “DROP INDEX Statement” on page 864

BEGIN Statement
Marks the beginning of a transaction that comprises multiple statements.
Category: Data Control
Restrictions: This statement is not supported in FedSQL programs that run in CAS.
The BEGIN statement has an effect only when autocommit functionality is off.
Data source: Greenplum, HAWQ, MDS, Microsoft SQL Server, MySQL, ODBC, Oracle, SAP HANA, SAP IQ, Teradata, Vertica

Syntax
BEGIN [TRANSACTION];

Details
The BEGIN statement marks a point at which the data is logically and physically consistent. If errors are encountered during a transaction, the user can roll back all changes to the data to this last known state of consistency.

When you use FedSQL processing, this statement is not really necessary. By default, autocommit functionality is on, which means that all updates are committed immediately after each request is submitted, and no rollback is possible. A transaction is effectively started with each update. The BEGIN statement is provided to enable you to mark the beginning of a transaction that comprises multiple statements.
See the server administration documentation for information about how to turn off autocommit functionality. For example, see *SAS Federation Server: Administrator’s Guide* for the appropriate connection option to the FedSQL driver. For the FEDSQL procedure, see *Base SAS Procedures Guide*.

See Also

**Statements:**
- “COMMIT Statement” on page 837
- “ROLLBACK Statement” on page 873

---

**COMMIT Statement**

Makes changes that have been performed since the start of a transaction a permanent part of the database.

**Category:** Data Control

**Restrictions:**
- This statement is not supported in FedSQL programs that run in CAS.
- The COMMIT statement has an effect only when autocommit functionality is off.

**Data source:**
- Greenplum, HAWQ, MDS, Microsoft SQL Server, MySQL, ODBC, Oracle, SAP HANA, SAP IQ, Teradata, Vertica

**Syntax**

**COMMIT** [TRANSACTION];

**Details**

When your program has completed all of the statements in the transaction, you must explicitly terminate the transaction using COMMIT or ROLLBACK. You use a COMMIT statement to make the changes to the database permanent.

You cannot roll back the changes to the database after the COMMIT statement is executed.

**Note:** The COMMIT statement has an effect only when autocommit functionality is off. In most data sources, autocommit functionality is on by default. Refer to the server administration documentation for information about how to turn off autocommit functionality. For example, see the *SAS Federation Server: Administrator’s Guide* for the appropriate connection option to the FedSQL driver. For the FEDSQL procedure, see the *Base SAS Procedures Guide*.

**Comparisons**

The ROLLBACK statement causes all the uncommitted changes that were made by the transaction to be rolled back to the start of the transaction or to the point that is marked by the BEGIN statement. The COMMIT statement takes all the data
changes that have been performed since the start of the transaction and makes them a permanent part of the database.

See Also

Statements:

- “BEGIN Statement” on page 836
- “ROLLBACK Statement” on page 873

CREATE INDEX Statement

Creates an index on columns in a specified table.

Category: Data Definition

Restriction: This statement is not supported in FedSQL programs that run in CAS.

Data source: SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, JDBC, MDS, Microsoft SQL Server, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata

Syntax

```sql
CREATE [UNIQUE] INDEX index ON table (column [ASCENDING | DESCENDING |][, ...column]);
```

Arguments

**UNIQUE**

creates a unique index on a table.

**index**

specifies the name of the index.

**Restriction**

For SAS data sets – If you are creating an index on one column only, then index must be the same as column. If you are creating an index on more than one column, then index cannot be the same as any column in the table.

**table**

specifies the name of the table that contains the column or columns to be indexed.

**column**

specifies the name of the column to which the index applies. Specify two or more column names to create a composite index.

**Tip** If you search two or more columns as a unit or if you have queries that involve only specific columns, use composite indexes.
ASCENDING

Rows are sorted from the smallest value to the largest value. This is the default value.

Alias  ASC

Note  This option is not valid for Base data sets, SPD Engine data sets, and SPD Server tables.

DESCENDING

Rows are sorted from the largest value to the smallest value.

Alias  DESC

Note  This option is not valid for Base data sets, SPD Engine data sets, and SPD Server tables.

Details

Overview of Table Indexes

An index stores both the values of a table's columns and a system of directions that enable access to rows in that table by index value. Defining an index on a column or set of columns enables SAS, under certain circumstances, to locate rows in a table more quickly and efficiently. Indexes enable SAS to execute the following classes of queries more efficiently:

- comparisons against a column that is indexed
- an IN subquery where the column in the inner subquery is indexed
- correlated subqueries, where the column being compared with the correlated reference is indexed
- join-queries, where the join-expression is an equals comparison and all the columns in the join-expression are indexed in one of the tables being joined

SAS maintains indexes for all changes to the table, whether the changes originate from FedSQL or from some other source. Therefore, if you alter a column's definition or update its values, then the same index continues to be defined for it. However, if an indexed column in a table is dropped, then the index on it is also dropped.

You can create simple or composite indexes. A simple index is created on one column in a table. A simple index must have the same name as that column. A composite index is one index name that is defined for two or more columns. The columns can be specified in any order, and they can have different data types. A composite index name cannot match the name of any column in the table. If you drop a composite index, then the index is dropped for all the columns that are named in that composite index.

Only the table owner can create an index on a table.

When you create an index, you must know the syntax that the data source supports. Index validation is performed by the data source. FedSQL provides the DBCREATE_INDEX_OPTS= table option to enable you to specify data source-specific index parameters for ODBC databases.
UNIQUE Keyword

The UNIQUE keyword causes SAS to reject any change to a table that would cause more than one row to have the same index value. Unique indexes guarantee that data in one column, or in a composite group of columns, remain unique for every row in a table. A unique index can be defined for a column that includes null or SAS missing values if each row has a unique index value.

See Also

Statements:
- "DROP INDEX Statement" on page 864

Table Options:
- "DBCREATE_INDEX_OPTS= Table Option" on page 950

CREATE TABLE Statement

Creates a new table.

Category: Data Definition

Restrictions: You cannot overwrite an existing table. You must drop the table by using the DROP TABLE statement and re-create the table with the CREATE TABLE statement.

The full functionality of the CREATE TABLE statement is not supported in FedSQL programs that run in CAS. For CAS information, see “CREATE TABLE Statement” in SAS Viya: FedSQL Programming for SAS Cloud Analytic Services.

Constraint syntax is defined by the data source. The constraint syntax provided here is a general syntax. For complete constraint syntax, see the documentation for your data source. The SPD Engine and SPD Server data sources do not support integrity constraints.

Notes: Braces in the syntax convention indicate a syntax grouping. The escape character ( \ ) before a brace indicates that the brace is required in the syntax. Table options must be contained by braces ( { } ).

MongoDB tables are not relational tables and differ from relational tables in significant ways. See information about MongoDB in SAS/ACCESS for Nonrelational Databases: Reference before creating tables in MongoDB.

When creating a table, Salesforce automatically generates a Name column. If you specify a Name column, the column is ignored. If you must add a column named Name, specify the USE_NATIVE_NAMES= option in the Salesforce connection and qualify the column name as follows: Name_c. Columns in Salesforce tables might not be created in the order that they were defined. However, the resulting order is preserved in subsequent executions of FedSQL statements on the tables.

Data source: SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB, MySQL, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP HANA, SAP IQ, Spark, Teradata, Vertica
Syntax

**CREATE TABLE** `{table | _NULL_}"

```
[{
  OPTIONS SAS-table-option=value
  [...SAS-table-option=value] 
}]
```

```
  | ( <column-definition> [, ...<column-definition> | <table-constraint>])
  | AS query-expression
  ;
```

```
<column-definition>::=
  column data-type [<column-constraint>] [DEFAULT value]
  [HAVING [FORMAT format][INFORMAT informat][LABEL 'label']]
```

```
<column-constraint>::=
  CONSTRAINT constraint
  { CHECK (search-condition)
  | PRIMARY KEY
  | UNIQUE
  | NOT NULL }
```

```
<table-constraint>::=
  CONSTRAINT constraint
  { CHECK (search-condition)
  | PRIMARY KEY (column [, ...column])
  | UNIQUE (column [, ...column])
  | <referential-constraint> }
  [<constraint-check-time>]
```

```
<referential-constraint>::=
  FOREIGN KEY (referencing-column [, ...referencing-column])
    REFERENCES referenced-table (referenced-column [, ...referenced-column])
    [<referential-trigger-action>]
```

```
<referential-trigger-action>::=
  { ON UPDATE <referential-action> [ON DELETE <referential-action>] } 
  | { ON DELETE <referential-action> [ON UPDATE <referential-action>] }
```

```
<referential-action>::=
  CASCADE | SET NULL | SET DEFAULT | RESTRICT | NO ACTION
```

```
<constraint-check-time>::=
  { DEFERRABLE [INITIALLY DEFERRED | INITIALLY IMMEDIATE] }
  | { [INITIALLY DEFERRED | INITIALLY IMMEDIATE] DEFERRABLE }
  | INITIALLY DEFERRED
  | { NOT DEFERRABLE [INITIALLY IMMEDIATE] }
  | { [INITIALLY IMMEDIATE] NOT DEFERRABLE }
```

Arguments

*table*

specifies a name for the table. *table* can be one of these forms

- `catalog.schema.table-name`
schema.table-name

catalog.table-name

**catalog**

is an implementation of the ANSI SQL standard for an SQL catalog. The catalog is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

**schema**

is an implementation of the ANSI SQL standard for an SQL schema. The schema is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

**table-name**

is the name of the table.

**Restriction**

Table names for Hive and HDMD tables should not begin with an underscore (_). In HDFS, a name that starts with _ is a hidden system file. Additionally, table names for HDMD tables should not contain \( a : (colon) \), \( a / \) (forward slash), or \( a \ \backslash \) (backslash). They can include \( a . \) (period). Table names for Hive tables should not contain \( a . \) (period), \( a : (colon) \), \( a / \) (forward slash), or \( a \ \backslash \) (backslash).

**Requirement**

Table naming conventions are based on the data source. When more than one data source is involved, the maximum length of a table name is determined by the maximum length that is supported by all of the data sources and FedSQL. For example, if your data sources are a SAS data set that has a maximum of 32 characters and MySQL that has a maximum of 64 characters, the maximum length of a table name is 32 characters. For more information, see the documentation for your data source.

**Interaction**

For data sources that do not support schema, such as SAS data sets, SPD Engine data sets, and SPD Server tables, use the form catalog.table-name.

**Note**

Three-level table names are supported in Hive 0.14 and later. When creating or accessing tables in earlier Hive releases, use the two-level form catalog.table-name. Support for SQL-standard three-level table names for Hive tables was added in SAS 9.4M4.

_**NULL**_

specifies to test the performance of creating a table using the AS query-expression clause. FedSQL creates the table internally as if it were to be saved, writing the normal progress messages. The table creation appears to be successful. Once the query expression is complete, the table is discarded.

**Interaction**

A SELECT select-list FROM _**NULL**_ statement returns an error.

{**OPTIONS SAS-table-option=value [ ... SAS-table-option=value ]**}

specifies one or more table options and their respective values to apply to the table.
The OPTION argument and all table options must be enclosed in braces ({}).

See "FedSQL Statement Table Options" on page 907

**AS query-expression**

specifies to create a new table from an existing table by selecting rows from the existing table using a query expression. The column attributes, such as formats and labels, are copied from the existing table to the new table.

query-expression

specifies the SELECT statement that retrieves information from an existing table to use in creating a new table.

The number of columns used in the SELECT statement must equal the number of columns in the table.

See

"Creating and Populating Tables from a Query Expression" on page 856

"Query Expressions and Subqueries" on page 48

"SELECT Statement" on page 874

**Data source**

SAS data set, SPD Engine data set, SPD Server table, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, JDBC, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, SAP HANA, SAP IQ, Spark, Teradata, Vertica

**<column-definition> Arguments**

**column**

specifies the name of the column. The column name is either a local or schema qualified name, using one of these forms:

- `schema.column-name`
- `column-name`

**schema**

is an implementation of the ANSI SQL standard for an SQL schema. The schema is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

**column-name**

is the name of the column.

**Restrictions**

For SAS data sets, SPD Engine data sets, and SPD Server tables, the column name cannot be longer than 32 characters.

Hive does not permit a . (period) or a : (colon) within a column name.

**Requirement**

When more than one data source is involved, the maximum length of a column name is determined by the maximum length that is supported by all of the data sources and FedSQL. For example, if your data sources are a SAS data set that has a maximum of 32
characters and MySQL that has a maximum of 64 characters, the maximum length of a column name is 32 characters. Each column in a table must be unique.

See
For column name requirements, see the documentation for your data source.

data-type
specifies the type of data that the column can store. If the column definition is for a SAS data set, an SPD Engine data set, or an SPD Server table and the data type is other than CHAR or DOUBLE, FedSQL converts character data types to a CHAR and numeric data types to DOUBLE. FedSQL supports the following table data types:

**BIGINT**
stores a large signed, exact whole number.

<table>
<thead>
<tr>
<th>Range</th>
<th>Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Spark, Teradata, Vertica</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>DB2 under UNIX and PC, Hive, JDBC, MDS, Microsoft SQL Server, ODBC, SAP HANA, SAP IQ, Spark, Vertica</td>
</tr>
<tr>
<td>Storage size</td>
<td>8 bytes</td>
</tr>
</tbody>
</table>

**BINARY(n)**
stores varying-length binary data.

\( n \)
specifies the maximum number of bytes that can be used to store the binary data. The number of bytes that are used to store the binary data is the number of bytes that are necessary to represent the binary data, up to \( n \) bytes.

<table>
<thead>
<tr>
<th>Range</th>
<th>DB2 under UNIX and PC, Hive, JDBC, MDS, Microsoft SQL Server, ODBC, SAP HANA, SAP IQ, Spark, Vertica</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>DB2 under UNIX and PC, Hive, JDBC, MDS, Microsoft SQL Server, ODBC, SAP HANA, SAP IQ, Spark, Vertica</td>
</tr>
<tr>
<td>Storage size</td>
<td>up to ( n ) bytes</td>
</tr>
</tbody>
</table>

**CHAR(n)** [CHARACTER SET "character-set-identifier"]
stores a fixed-length character string.

\( n \)
specifies the number of bytes that are used to store the character string. If the character string is less than \( n \) bytes, the value is right-padded with spaces.

CHARACTER SET "character-set-identifier"
specifies character set encoding information for CHAR data types.

Default

Restriction
SAS data sets, SPD Engine data sets, SPD Server tables, Hive, Impala, JDBC, MongoDB, Salesforce, and Spark do not support the use of CHARACTER SET "character-set-identifier". You can specify an encoding value for SAS data sets with the "ENCODING= Table Option" on page 954.
Hive, Impala, MongoDB, Salesforce, and Spark character columns are stored as UTF-8.

Alias CHARACTER(n)

Requirements n must be specified.

In Salesforce, n must be less than or equal to 255 characters. If a value greater than 255 is specified, the column is created as VARCHAR(n).

Data source SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, DB2 under UNIX and PC, Greenplum, HAWQ, Hive, HDMD, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB, MySQL, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP HANA, Spark, Teradata, Vertica

Storage size n bytes

DATE stores a date value in the format yyyy-mm-dd.

<table>
<thead>
<tr>
<th>Date Element</th>
<th>Description</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>yyyy</td>
<td>a four-digit year</td>
<td>0001 – 9999</td>
</tr>
<tr>
<td>mm</td>
<td>a two-digit month</td>
<td>01 – 12</td>
</tr>
<tr>
<td>dd</td>
<td>a two-digit day</td>
<td>00 – 31</td>
</tr>
</tbody>
</table>

Requirement Input values must be specified as a DATE constant. For more information, see “FedSQL Date, Time, and Datetime Constants” on page 60.

Data source SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Salesforce, Spark, Teradata, Vertica

Storage size 8 bytes

DECIMAL stores a signed, fixed-point decimal number.

Alias NUMERIC

Data source Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, JDBC, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP HANA, SAP IQ, Spark, Teradata, Vertica
DOUBLE
stores a signed, approximate, floating point number.

Alias
DOUBLE PRECISION

Data source
SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Salesforce, Teradata, Vertica

Storage size
8 bytes

FLOAT(p)
stores a signed, approximate, single-precision or double-precision, floating point number. The user-specified precision determines whether the data type stores a single precision or double precision number. If the specified precision is equal to or greater than 25, the value is stored as a double precision number, which is a DOUBLE. If the specified precision is less than 25, the value is stored as a single precision number, which is a REAL.

p specifies the maximum number of digits in the floating point number.

Data source
SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, Microsoft SQL Server, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Spark, Teradata, Vertica

Storage size
4 bytes

Tip
If p is not specified, a DOUBLE is used.

INTEGER
stores an exact whole number.

Range
-2,147,483,648 to 2,147,483,647

Data source
SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Salesforce, Spark, Teradata, Vertica

Storage size
4 bytes

NCHAR(n)
stores a fixed-length character string by using the Unicode national character set.

n specifies the maximum number of multibyte characters that are used to store the character string. If the character string is less than n characters, the value is right-padded with spaces.
<table>
<thead>
<tr>
<th>Requirement</th>
<th>Data source</th>
<th>Storage size</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMERIC</td>
<td>stores a signed, fixed-point decimal number.</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>Alias</td>
<td>Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, JDBC, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP HANA, SAP IQ, Spark, Teradata, Vertica</td>
<td>8 bytes</td>
</tr>
<tr>
<td>NVARCHAR(n)</td>
<td>stores a varying-length multibyte character string by using the Unicode national character set.</td>
<td>4 bytes</td>
</tr>
<tr>
<td>REAL</td>
<td>stores a signed, approximate, single-precision, floating-point number.</td>
<td>4 bytes</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>stores a small signed, exact whole number.</td>
<td>-32,768 to 32,767</td>

</table>
**Data source**

SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MySQL, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP HANA, SAP IQ, Spark, Teradata, Vertica

**Storage size**

2 bytes

**TIME(p)**

stores a time value with seconds precision.

Time values are in the following form: 

\[ hh:mm:ss[.nnnnnn] \]

<table>
<thead>
<tr>
<th>Time Element</th>
<th>Description</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>hh</td>
<td>a two-digit hour</td>
<td>00 – 23</td>
</tr>
<tr>
<td>mm</td>
<td>a two-digit minute</td>
<td>00 – 59</td>
</tr>
<tr>
<td>ss</td>
<td>a two-digit second</td>
<td>00 – 61</td>
</tr>
<tr>
<td>nnnnnn</td>
<td>up to six digits to indicate a fraction of a second</td>
<td>0 – 999999</td>
</tr>
</tbody>
</table>

*p* specifies 0–6 digits to use for the precision of a fraction of a second.

**Requirement**

Input values must be specified as a TIME constant. For more information, see “FedSQL Date, Time, and Datetime Constants” on page 60.

**Data source**

SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, MySQL, Netezza, Microsoft SQL Server, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Salesforce, Spark, Teradata, Vertica

**Storage size**

8 bytes

**TIMESTAMP(p)**

stores both the date and time value with seconds precision.

Date and time values are in the following form: 

\[ yyyy-mm-dd hh:mm:ss[.nnnnnn] \]

<table>
<thead>
<tr>
<th>Time Element</th>
<th>Description</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>yyyy</td>
<td>a four-digit year</td>
<td>0001–9999</td>
</tr>
<tr>
<td>mm</td>
<td>a two-digit month</td>
<td>01–12</td>
</tr>
</tbody>
</table>

**Date Components**
<table>
<thead>
<tr>
<th>Time Element</th>
<th>Description</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd</td>
<td>a two-digit day</td>
<td>01- 31</td>
</tr>
</tbody>
</table>

**Time Components**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>hh</td>
<td>a two-digit hour</td>
<td>00 – 23</td>
</tr>
<tr>
<td>mm</td>
<td>a two-digit minute</td>
<td>00 – 59</td>
</tr>
<tr>
<td>ss</td>
<td>a two-digit second</td>
<td>00 – 61</td>
</tr>
<tr>
<td>nnnnnn</td>
<td>up to six digits to indicate a fraction of a second</td>
<td>0 – 999999</td>
</tr>
</tbody>
</table>

\[ p \] specifies 0–6 digits to use for the precision of a fraction of a second.

**Alias** DATE_TIME

**Requirement** Input values must be specified as a TIMESTAMP constant. For more information, see “FedSQL Date, Time, and Datetime Constants” on page 60.

**Data source** SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Salesforce, Spark, Teradata, Vertica

**Storage size** 8 bytes

**TINYINT**

stores a very small signed exact, whole number.

**Range** -128 to 127

**Data source** SAS data set, SPD Engine data set, SPD Server table, HDMD, Hive, Impala, JDBC, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, Salesforce, SAP HANA, SAP IQ, Spark, Teradata, Vertica

**Storage size** 1 byte

**VARBINARY(n)**

stores varying-length binary data.

\[ n \]
specifies the maximum number of bytes that can be used to store the binary data. The number of bytes that are used to store the binary data is the number of bytes that are necessary to represent the binary data, up to \( n \) bytes.
VARCHAR(n) [CHARACTER SET "character-set-identifier"]
stores a varying-length character string.

\[ n \]
specifies the number of multibyte characters that are used to store the
class character string. The number of bytes that are stored is the actual number
of multibyte characters, up to \( n \) characters.

[CHARACTER SET "character-set-identifier"]
specifies character set encoding information for CHAR data types.

Default
The default encoding depends on your operating system and locale.

Restriction
Hive, JDBC, MongoDB, Salesforce, and Spark do not support
the use of CHARACTER SET "character-set-identifier". Hive,
JDBC, MongoDB, Salesforce, and Spark VARCHAR columns
are stored as UTF-8. See Table A2.11 on page 1035 for more
information about Hive support for VARCHAR columns.

See
"LOCALE= Values for PAPERSIZE and DFLANG, Options" in

DEFAULT value
for each row that is added to the table, specifies a value for the column that is
assumed when no other value is entered for that column.

value
specifies the default value.

Requirement
value must be in the range of the specified data type.
HAVING [FORMAT format][INFORMAT informat][LABEL 'label']
specifies a clause that is used to associate a format, informat, or label with the column.

**FORMAT format**
specifies a SAS data format that is stored as column metadata. The format is not applied to the column data until execution time.

format specifies a valid SAS data format. If the format is a format other than a FedSQL or DS2 format, it must be a valid format for the Base SAS.

See "FedSQL Formats" on page 77

“DS2 Formats” in SAS DS2 Language Reference

“Dictionary of Formats” in SAS Formats and Informats: Reference

**Restriction** Formats that are created by PROC FORMAT cannot be stored as column metadata.

**Note** When you create a table, you can associate a SAS data format with a column. The format is not validated or applied to the column until execution time, such as in a PUT function. If the format is applied to the column in a Base SAS environment, any format can be stored with the column. If the format is applied to the column in the FedSQL environment, the format must be a valid FedSQL or DS2 format.

**INFORMAT informat**
specifies a SAS data informat that is stored as column metadata. The informat is not applied to the column data. No validation is done on the informat; it is only informational.

informat specifies a SAS data informat.

See Chapter 6, “FedSQL Informats,” on page 825

“Dictionary of Informats” in SAS Formats and Informats: Reference

**LABEL ‘text-string’**
specifies a text string to use as an alternate column heading that appears in place of the column name in a query expression result.

**Range** 1 - 255 characters

**Restriction** A label can be created only with the CREATE TABLE statement and it cannot be used in a query expression operation.

**Requirement** text-string must be enclosed in either double or single quotation marks. If text-string contains a single quotation mark, enclose text-string in double quotation marks.

**Data source** SAS data set, SPD Engine data set, SPD Server table
<column-constraint> and <table-constraint> Arguments

**CONSTRAINT**
- begins a column constraint or a table constraint.

**Data source**
- SAS data set, DB2 under UNIX and PC, MDS, Microsoft SQL Server, MongoDB, MySQL, ODBC, Oracle, SAP HANA, Teradata, Vertica

**constraint**
- specifies a name to identify the constraint.

**See**
- For constraint name requirements, see the documentation for your data source.

**CHECK(search-condition)**
- specifies a condition for values in the column or table. `search-condition` is a valid FedSQL expression that resolves to a Boolean value. If `search-condition` is false, no changes are made to the table.

**Restrictions**
- For a SAS data set, the search condition cannot contain FedSQL functions.

**Data source**
- SAS data set, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, Microsoft SQL Server, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata, Vertica

**See**
- “FedSQL Expressions” on page 48

**PRIMARY KEY**
- specifies that, for each row in the table, the value in the column can be used to uniquely identify its respective row in the table. It is a value that does not change. A primary key cannot have a null value.

**Data source**
- SAS data set, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, Microsoft SQL Server, MongoDB, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata, Vertica

**Note**
- See SAS/ACCESS for Nonrelational Databases: Reference for information about how PRIMARY KEY constraints are used in MongoDB.

**PRIMARY KEY (column [, ...column])**
- specifies that, for each row in the table, the values for all of the columns specified are used to uniquely identify its respective row in the table. A primary key cannot have a null value and it must be unique for each row in the column. It is a value that does not change.

**Data source**
- SAS data set, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, Microsoft SQL Server, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata, Vertica

**UNIQUE**
- specifies that no two rows in the column can have the same value. A null value is allowed unless you specify NOT NULL.
**Data source**

SAS data set, Amazon Redshift, DB2 under UNIX and PC, MDS, Microsoft SQL Server, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, Teradata, Vertica

**Note**

For Vertica, see the vendor documentation for information about how the UNIQUE constraint is enforced.

**UNIQUE(column [, ...column])**

specifies that no two rows in any of the specified columns can have the same value. A null value is allowed unless you specify NOT NULL.

**NOT NULL**

specifies that a null value is not valid in any row for the specified column.

**FOREIGN KEY (referencing-column [, ...referencing column]) REFERENCES referenced-table (referenced-column [, ...referenced-column <referential-trigger-action>])**

specifies the clause that relates columns in table to columns in another table through the values for those columns. Foreign keys must always include enough columns to uniquely identify a row in the referenced table. Foreign key constraints help ensure the integrity of related data in multiple tables.

**FOREIGN KEY**

begins the clause that identifies one or more columns in table that relate to columns in another table.

**referencing-column**

specifies the columns in table that relate to columns in another table.

**REFERENCES**

begins the clause that identifies the columns in another table.

**referenced-table**

specifies the table whose columns relate to columns in table.

**referenced-column**

specifies one or more columns in the referenced table that relate to the columns in table.

**CREATE TABLE Statement**

853
<referential-trigger-action>
specifies the action to take in the referenced table when columns in table are updated or deleted.

ON UPDATE <referential-action>
specifies the clause for the action to take when a column in table is updated.

ON DELETE <referential-action>
specifies the clause for the action to take when a column in table is deleted.

<referential-action>
specifies the action to take when a column in table is updated or deleted.

CASCADE
ON UPDATE, specifies to update all rows in table that reference an updated value in the referenced table. ON DELETE, removes all rows in table that reference the deleted rows in the referenced table.

SET NULL
specifies to set the referenced columns to a null value.

SET DEFAULT
specifies to set the referenced columns to their default value.

RESTRICT
specifies that if the referential constraint is not satisfied at any time while the FedSQL statement is processing, no action is taken and the update or deletion fails.

NO ACTION
specifies that if the referential constraint is not satisfied at the end of the FedSQL statement, no action is taken and the update or deletion fails.

<constraint-check-time>
specifies when the constraint is checked:

DEFERRABLE

NOT DEFERRABLE
specifies whether the constraint violation check can be performed after the transaction completes or if it must be checked at the end of each FedSQL statement. If DEFERRABLE is specified, the constraint check can occur at the end of the transaction. If NOT DEFERRABLE is specified, the constraint must be checked when the FedSQL statement terminates. Specifying DEFERRABLE is useful when more than one statement is necessary to complete a transaction.

Default DEFERRABLE

INITIALLY DEFERRED
specifies that the constraint violation check is deferred, by default, at the beginning of each transaction and it does not occur until the end of a transaction.

INITIALLY IMMEDIATE
specifies that the constraint violation check occurs at the end of each FedSQL statement.
Details

Overview of the CREATE TABLE Statement

The CREATE TABLE statement enables you to create tables by defining table columns or by selecting columns from an existing table using a query expression. SAS provides extensions to the CREATE TABLE statement to support SAS data sources.

SAS Extensions for the CREATE TABLE Statement to Support SAS Data Sources

SAS extensions for the CREATE TABLE statement using FedSQL enable you to assign formats and informats to columns and add a label to a column.

SAS Formats

You can specify that the column data is stored and retrieved as a SAS formatted value by using the HAVING FORMAT clause. If the data type is not either CHAR or DOUBLE, it is converted to either CHAR or DOUBLE.

For example, to store the date in the format \textit{ddmmmyy}, where \textit{dd} is a two-digit year, \textit{mmm} is a three-digit month, and \textit{yy} is a two-digit year, the column definition would specify DOUBLE as the data type and \texttt{FORMAT='DATE7.'}. November 1, 2012 would be stored as 01Nov12. Your column definition might look like the following:

\begin{verbatim}
  saleenddate double not null having format date7.;
\end{verbatim}

In comparison, a column that stores date information using the DATE data type stores the date in the format \texttt{yyyy-mm-dd}. November 1, 2012 would be stored as 2012-11-01.

SAS Informats

SAS and user-defined informats can be stored and retrieved with the column data by using the HAVING INFORMAT clause. The informat is not applied to the data; it is information only. The client application is responsible for applying the informat to the data. Informats can be associated with all data types, but all data types will be converted to either CHAR or DOUBLE.

\begin{verbatim}
  saledates double having informat anydtdate14.;
\end{verbatim}

For more information about SAS informats, see Chapter 6, \textit{“FedSQL Informats,”} on page 825.

Column Labels

A label is a descriptive, quoted, text string that is displayed in query expression results instead of the column name. You specify a label by using the LABEL argument in the HAVING clause:

\begin{verbatim}
  saleenddate double not null having label 'Last Day of Sale';
\end{verbatim}

A label cannot be used in a query expression operation.

Defining Columns for a Table

When you define columns for a table, the column name and the data type are required. All other column definition arguments are optional. For column naming conventions, see the documentation for your data source. FedSQL reserved words cannot be used as column names. For a list of FedSQL reserved words, see \textit{“FedSQL Reserved Words”} on page 71.
You can add an unspecified number of columns to a table by separating each column definition with a comma. Enclose the complete group of column definitions in parenthesis. The following CREATE TABLE statement creates the Customers table:

```
cREATE TABLE customers
(CUSTID double unique, 
  name char(16), 
  address char(64), 
  city char(16), 
  state char(2), 
  country char(16), 
  phone char(16), 
  initorder date having label 'Initial Order'
);
```

Each column definition names the column and assigns a data type. The CUSTID column contains the UNIQUE integrity constraint, which is used to uniquely identify a table row. The INITORDER column is of the DATE data type. If the code is used to create a SAS data set, an SPD engine data set, or an SPD Server table, note the following result. When the column is displayed, the label Initial Order is used instead of the column name initorder. For other data sources, the label is ignored.

You can add rows to the table by using the INSERT statement. The INSERT statement enables you to specify values for each of the table columns defined with the CREATE TABLE statement. For more information, see the "INSERT Statement" on page 870.

Creating and Populating Tables from a Query Expression

When you create a table using a query expression, you add rows to the table as the table is created. You use a SELECT statement to retrieve data from an existing table to create the new table. The number of columns in the CREATE TABLE statement column definition must equal the number of columns that are returned by the SELECT statement. If no column names are specified in the CREATE TABLE statement, the columns and default values that are returned by the SELECT statement are used in the new table.

This CREATE TABLE statement creates a new table that is based on only three columns from the CorpData table:

```
CREATE TABLE spainEmails
AS SELECT name, emailid, lastPurchaseDate FROM corpdata WHERE country='Spain';
```

The following CREATE TABLE statement selects all columns from the CorpData table:

```
CREATE TABLE spain
AS SELECT * FROM corpdata WHERE country='Spain';
```

You can test the performance of a query expression before creating a table by using a table name of _NULL_ for the query expression, as in this example:

```
CREATE TABLE _null_ AS SELECT * FROM corpdata WHERE country='Spain';
```

FedSQL performs normal processing to create the table and the table appears to be created. The table is discarded when the query is complete.
Data Sources

When defining data types using the FedSQL language, in order for data to be stored, the defined data type must be available for data storage in that data source. Although FedSQL provides support for several data types, the data types that can be defined for a particular table depend on the data source. Each data source does not necessarily support all of the FedSQL data types.

In addition, data sources support variations of the standard SQL data types. That means that a data type that you specify might default to a different data type that might also have different attributes in the underlying data source. This is done when a data source does not natively support a specific data type, but data values of a similar data type can be converted without data loss. For example, to support the INTEGER data type, a SAS data set defaults the data type definition to SAS numeric, which is a DOUBLE. For details about data source implementation for each data type such as data source-dependent attributes, see Appendix 2, “Data Type Reference,” on page 1017.

Integrity Constraints

Integrity constraints are a set of data validation rules that you can specify to preserve the validity and consistency of your data. Integrity constraints that are specified in the CREATE TABLE statement are passed through to the data source. When a transaction modifies the table, the data source enforces integrity constraints.

A column constraint is a constraint that is defined for one column. A table constraint defines a constraint for two or more columns.

The following statements create SAS data sets using integrity constraints:

- Create a Products table using the product ID as the primary key; no two product IDs can identify the same product, and the product cannot be a null value. Check constraints at the end of a transaction:
  
  ```sql
  create table products (prodid double primary key, 
  product char(8) unique not null initially deferred);
  ```

- Create a Sales table with totals in US dollars, and include the country:
  
  ```sql
  create table sales (prodid double, 
  custid double primary key, 
  totals double having format dollar10., 
  country char(30) not null);
  ```

- Create a SAS data set for customer credit card information. Customers are uniquely identified by their name and customer number.
  
  ```sql
  create table custcredit (name char(30), 
  custNum double, 
  ccType char(15) having label 'Credit Card Type', 
  ccNum char(20) having label 'Credit Card Number', 
  ccExp date having label 'Expiration Date', 
  CONSTRAINT ccconst primary key(name, CustNum));
  ```

When FedSQL encounters a DATE data type for a SAS data set, it does a type conversion from DATE to DOUBLE and assigns the DATE9. format to the column.

For information about constraints, see the documentation for your data source.
CREATE VIEW Statement

Creates a view of data from one or more tables or other views.

Category: Data Definition

Restriction: This statement is not supported in FedSQL programs that run in CAS.

Data source: SAS data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MySQL, Netezza, ODBC, Oracle, PostgreSQL, SAP HANA, Spark, Terdata, Vertica

Syntax

CREATE VIEW view [SECURITY security-type] AS query-expression;

Arguments

SECURITY security-type
specifies the type of security that will be enforced for the view. security-type can be one of the following values.

DEFINER
specifies that the view is run with the schema owner’s credentials.

INVOKER
specifies that the view is run with the invoking user’s credentials.

Default
If SECURITY is not used, security for the view defaults to INVOKER.

Restriction
Security is available only with SAS Federation Server. The SECURITY security-type argument is ignored in a FedSQL request that is not directed to SAS Federation Server. For more information about the security available through SAS Federation Server, see the documentation for SAS Federation Server.

view
specifies the name of the view being created.

Requirement
The view name must be different from any other view, table, or index in the same database.

query-expression
specifies the SELECT statement that retrieves the information from an existing table that is used to create the view.
Details

Overview of the CREATE VIEW Statement

A view is a definition of a virtual table that is formed by a query expression against one or more tables or other views. A view contains no data. The view definition is stored as metadata and consists of the view name, possibly the name of the columns in the view, and the query expression that is used to derive its rows.

If an underlying table or view in a view is deleted, SAS returns an error message when the view is executed. If the underlying table or view is changed, the view might have to be re-created.

Access to Views

To create a view, you must have CREATE VIEW privilege. As the view owner, you have all privileges for the view, including the ability to grant privileges to other users.
To execute a view, the user must have SELECT privilege on the tables and views that are referenced in the view.

SELECT Statement Restrictions

The SELECT statement cannot include an ORDER BY clause.

FedSQL Views and the SAS PRINT Procedure

The SAS PRINT procedure prints information about the structure of a FedSQL view. The procedure does not print the data in a FedSQL view.

See Also

Statements:
- “CREATE TABLE Statement” on page 840
- “DESCRIBE VIEW Statement” on page 863
- “DROP VIEW Statement” on page 867
- “SELECT Statement” on page 874

DELETE Statement

Deletes rows from a table.

Category: Data Manipulation

Restriction: This statement is not supported in FedSQL programs that run in CAS.
Syntax

DELETE FROM table [WHERE <search-condition>];

Arguments

table
specifies the table from which you are deleting rows.

Restriction
If row-level permissions are in effect for the table, you cannot delete rows from the table. Row-level security is available only with SAS Federation Server. See the SAS Federation Server documentation for more information.

Tip
You can use ‘.*’ after the table name for compatibility with Microsoft Access tables.

WHERE <search-condition>
specifies any valid WHERE clause used to limit the number of rows that are deleted.

Tip
You can use parameter arrays in the WHERE statement.

Note
FedSQL does not currently support the use of subqueries as inner queries for writing to MongoDB.

See
WHERE clause in the “SELECT Statement” on page 874

Details

The DELETE statement deletes the rows that satisfy the WHERE clause from the specified table. If you do not use a WHERE clause, all rows are deleted.

Comparisons

The DROP TABLE statement removes the table from the database completely, including the table structure. The DELETE statement deletes only the rows (data) in a table.

Statements:
- “DROP TABLE Statement” on page 865
- “INSERT Statement” on page 870
- “UPDATE Statement” on page 904
DESCRIBE TABLE Statement

Retrieves SQL from a table and returns a result set.

Categories:
- Data Definition
- Data Retrieval

Restriction:
- This statement is not supported in FedSQL programs that run in CAS.

Data source:
- All

Syntax

DESCRIBE TABLE [catalog.][schema.] table;

Arguments

- catalog
  - specifies the catalog that contains the table.

- schema
  - specifies the schema that contains the table.

- table
  - specifies the name of the table.

Details

The DESCRIBE TABLE statement writes a CREATE TABLE statement to the SAS log for the specified table, regardless of how the table was originally created (for example, with another programming language). The column definitions returned by the DESCRIBE TABLE statement show the column’s native data type. If indexes are defined on columns in the table, then CREATE INDEX statements for those indexes are written to the SAS log. The CREATE TABLE statement also includes any integrity constraints that are defined for the specified table. For SAS data sets, primary key integrity constraints are described by a CREATE UNIQUE INDEX statement. Foreign key variables that reference a primary key constraint are not displayed as part of the primary key constraint’s DESCRIBE TABLE output.

The FedSQL language supports most of the data types used by the data sources that it supports, but not all. Refer to Appendix 2, “Data Type Reference,” on page 1017 for a listing of the data types that FedSQL supports for each data source. If you have a need to create a table with a data type that FedSQL does not support directly, use the EXECUTE statement to make the request.

The DESCRIBE TABLE statement is not supported for FedSQL DICTIONARY tables.

Examples:

Example 1: Information Returned for a SAS Data Set

Consider a SAS data set created with the SAS DATA step:
data myfiles.employees;
  input IdNum $4. +2 LName $11. FName $11. JobCode $3. +1 Salary 5. +1 Phone $12.;

The DESCRIBE TABLE statement writes the following information to the SAS log:

describe table myfiles.employees;

Example 2: Information Returned for a Supported Data Type
Consider an Oracle table created by using FedSQL with the following statement:

CREATE TABLE ORACLE.FOO1 (COL1 INTEGER, COL2 VARCHAR(10);

Oracle does not support the INTEGER data type. The FedSQL language converts the INTEGER data type to Oracle’s NUMBER data type when writing data to Oracle.

DESCRIBE TABLE oracle.foo1;

Example 3: Information Returned For A Data Type For Which FedSQL Has Limited Support
Consider a DB2 table created with the following statement by using the DB2 driver natively:

CREATE TABLE dlfoo1 (col1 CLOB);

FedSQL has limited support for the CLOB data type. It does not currently allow creation of columns of the CLOB data type, but it does have some support for reading CLOB columns. The DESCRIBE TABLE statement writes the following information to the SAS log:

DESCRIBE TABLE dlfoo1;

Example 4: Information Returned for Teradata
Consider a Teradata table created by using FedSQL:

create table x.customer (item_name char(30), cost decimal(10,2), delivered date);
The DESCRIBE TABLE statement returns a CREATE TABLE statement that describes the columns in the table. It also returns a CREATE INDEX statement, although an index was not explicitly defined. The index is a FedSQL abstraction. Do not use it to re-create the table.

describe table x.customer;

```sql
CREATE TABLE X."dmvdq1".CUSTOMER (
    ITEM_NAME CHAR(60) DEFAULT NULL,
    COST DECIMAL DEFAULT NULL,
    DELIVERED DATE DEFAULT NULL
);
CREATE INDEX NONAME1 ON X."dmvdq1".CUSTOMER(ITEM_NAME);```

See Also

Statements:
- “CREATE TABLE Statement” on page 840

DESCRIBE VIEW Statement

Retrieves SQL from a view and returns a result set.

Categories: Data Definition  Data Retrieval

Restrictions: This statement is not supported in FedSQL programs that run in CAS.
This statement is not supported for SAS data views created with the SAS DATA step or PROC SQL.

Data source: SQL-based data sources that support views.

Syntax

```
DESCRIBE VIEW ["catalog"]["schema"]"view"
DESCRIBE VIEW XML ["catalog"]["schema"]"view"
```

Arguments

catalog
    specifies the catalog that contains the view.

schema
    specifies the schema that contains the view.

view
    specifies the name of the view.
Details

Use DESCRIBE VIEW to retrieve standard SQL text from a FedSQL or DBMS view. Use DESCRIBE VIEW XML to retrieve SQL from a view as XML. This eliminates the need to implement an SQL parser on the client.

You must have ALTER VIEW privilege to run DESCRIBE VIEW on a secured view.

See Also

Statements:

- “CREATE VIEW Statement” on page 858

DROP INDEX Statement

Removes the specified index from a table.

Category: Data Definition

Restriction: This statement is not supported in FedSQL programs that run in CAS.

Data source: SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, JDBC, MDS, Microsoft SQL Server, MySQL, ODBC, Oracle, PostgreSQL, SAP HANA, SAP IQ, Teradata

Syntax

```
DROP INDEX index [FROM table] [FORCE];
```

Arguments

**index**

specifies the name of the index to be removed.

**FROM table**

specifies the name of the table where the index resides.

Requirements

For a SAS data set, SPD Engine data set, SPD Server table, and MDS table, you must include the FROM table syntax in order to specify the name of the table where the index resides.

For all data sources, you must include the FROM table syntax if you connected to the data source using a data source name (DSN) that has SAS security enabled.

**FORCE**

specifies that the index is removed without error processing. Use the FORCE keyword only when you are certain that removing the index without error processing will not negatively affect the table.
Details

If you drop a composite index, then the index is removed for all the columns that are named in that index.

---

Note: The DROP INDEX statement does not apply to indexes that were created by using the PRIMARY KEY or UNIQUE constraints of either the CREATE TABLE or ALTER TABLE statements, respectively. To remove those indexes, you must first remove the constraint by using the ALTER TABLE statement.

---

See Also

Statements:
- “ALTER TABLE Statement” on page 831
- “CREATE INDEX Statement” on page 838

---

DROP TABLE Statement

Removes a table from the database.

Category: Data Definition

Restriction: The DROP TABLE statement behaves differently in CAS. For CAS information, see “DROP TABLE Statement” in SAS Viya: FedSQL Programming for SAS Cloud Analytic Services.

Data source: SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB, MySQL, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP HANA, SAP IQ, Spark, Teradata, Vertica

Syntax

```sql
DROP TABLE table [FORCE];
```

Arguments

- `table` specifies the name of the table to be removed.

Restrictions

You cannot alter or drop an MDS table while it is referenced in another transaction or statement. If a request fails, make sure other users are no longer using the table or have disconnected.

You cannot drop a MongoDB table that has a child table. To remove a MongoDB table that has a child table, you must drop the child table first.

- `FORCE` specifies that the table is dropped without error processing.
Details

The DROP TABLE statement removes a table definition and all the table’s data, metadata, and indexes.

If you use the DELETE statement to remove all the rows in a table, the table still exists until it is removed with the DROP TABLE statement.

You cannot use the DROP TABLE statement to remove a table that is referenced by a foreign key constraint. You must drop the foreign key constraint first, and then remove the table.

If you remove a table with indexed columns, then all the indexes are automatically removed. If you drop a composite index, then the index is removed for all the columns that are named in that index.

When specifying the DROP TABLE statement in the same submission as a CREATE TABLE statement, specify the FORCE option in the DROP TABLE statement. The DROP TABLE statement writes messages to the log when the specified table cannot be found. These messages can interfere with the CREATE TABLE statement. The FORCE option suppresses these messages so that the CREATE TABLE request can succeed.

Teradata users: See Appendix 8, “Usage Notes,” on page 1137.

Comparisons

The DELETE statement deletes only the rows (data) in a table. The DROP TABLE statement removes the table from the database completely, including the table structure.

Examples:

Example 1: Drop a Table

```
proc fedsql;
drop table mytable;
quit;
```

Example 2: Drop a Table and Create a Table at the Same Time

```
proc fedsql;
drop table mytable force;
create table mytable (col1 integer, col2 char(5));
quit;
```

See Also

Statements:

- “CREATE TABLE Statement” on page 840
- “DELETE Statement” on page 859
DROP VIEW Statement

Removes a view from the database.

Syntax

```
DROP VIEW view [FORCE];
```

Arguments

`view`

specifies the name of the view to be removed.

`FORCE`

specifies that the view is removed without error processing.

Details

A view can be considered a virtual table. The view is formed by running a query expression against one or more tables. Dropping a view does not change any data in the database. Only the metadata that is associated with the view is deleted.

Any view on a dropped table can be dropped explicitly by using the DROP VIEW statement.

Comparisons

The DROP TABLE statement removes a table from the database. The DROP VIEW statement removes a view from the database.

- “DROP TABLE Statement” on page 865
EXECUTE Statement

Sends a DBMS-specific statement to a DBMS that FedSQL supports.

Category: FedSQL Pass-through

Restriction: This statement is not supported in FedSQL programs that run in CAS.

Data source: Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, JDBC, MySQL, Microsoft SQL Server, MongoDB, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP HANA, SAP IQ, Spark, Teradata, Vertica

See: “Data Source Connection” on page 6
“FedSQL Explicit Pass-Through Facility” on page 70
SQL documentation for your DBMS

Syntax

EXECUTE(native-syntax) BY catalog;

Arguments

native-syntax specifies a native query that can be run on the catalog’s driver. The EXECUTE statement accepts statements that produce a result set, as well as statements that do not produce a result set.

Restriction: PROC FEDSQL does not support native syntax that contains embedded bare semicolons. You can, however, use the FedSQL language processor to run these statements.

Note: The SQL statement might be case-sensitive, depending on your data source, and it is passed to the data source exactly as you enter it.

catalog specifies the name of a catalog in the existing FedSQL connection.

Details

General Use

The EXECUTE statement is the only way that FedSQL provides to submit native SQL statements that do not produce a result set to a DBMS. Native SQL can be used in the following statements: DDLs, UPDATE, SELECT, and bulk loads.

Use with HDMD

A native connection for HDMD is a FedSQL connection.

Use with MongoDB

MongoDB is not an SQL-based data source. In order to read and write data from MongoDB, SAS/ACCESS software generates a relational schema. By default, this
schema exists in memory, but the schema can be stored. You can use the EXECUTE statement to submit a REFRESH command to generate and overwrite a stored MongoDB schema with a new schema.

Use this command to update a stored schema only when database changes, such as additions and deletions of collections or columns, are made by a means other than SAS. When you add new collections with the CREATE TABLE statement or delete collections with the DROP TABLE statement, do not use this command. Structural changes made with SAS are instantly saved to the schema when the SCHEMA_COLLECTION= option is set in the database connection.

The REFRESH command is submitted from a SAS session as follows:

```sas
proc fedsql;
   execute (refresh) by libref;
quit;
```

Execution of the REFRESH command is an administrative task and should be performed only by the system administrator. REFRESH forces a scan of the current MongoDB database collections and updates the current schema (whether in memory or saved by name) accordingly. This overwrites any manual changes that might have been made directly to a stored schema, so this command should be used with care.

For more information about MongoDB schemas, see “Working with Schemas for MongoDB Data” in SAS/ACCESS for Nonrelational Databases: Reference.

You can also use FedSQL explicit pass-through to submit JSON-style MongoDB commands to query, create, and update MongoDB collections. For supported syntax, see information about MongoDB in SAS/ACCESS for Nonrelational Databases: Reference.

Examples:

Example 1: Using EXECUTE to Create and Drop a Table in Saphana

```sas
execute(create table t_blob (col1 blob)) by saphana;
execute(drop table t_blob) by saphana;
```

Example 2: Using EXECUTE to Produce a Result Set in Oracle

```sas
execute(select i, rank() over (order by j) rank from table_a ) by oracle;
```

INSERT Statement

Adds rows to a specified table.

Syntax

Form 1:  
`INSERT INTO table`  
  `{VALUES (value | NULL [, ...value | NULL])};`

Form 2:  
`INSERT INTO table`  
  `{ (column [, ...column]) VALUES (value | NULL [, ...value | NULL]) };`

Form 3:  
`INSERT INTO table`  
  `{ (column [, ...column]) [query-expression] };`

Arguments

`table`

specifies the name of a table into which you are inserting rows.

Restriction  
If row-level permissions are in effect for the table, you cannot insert rows into the table. Row-level security is available only with SAS Federation Server. For more information about row-level security, see the SAS Federation Server documentation.

`value`

specifies a data value to insert into the table.

Restriction  
There must be one value for each column in the table or for each column in the column list (column).
Requirement  If columns are specified in the column list (column), the data values list should be in the same order as the column list.

Tip  You can use parameter arrays in the INSERT statement.

column  specifies the column into which you are inserting data.

Tip  You can specify more than one column. The columns do not have to be in the same order as they appear in the table as long as the order of the column list and the data values list match one another.

<query-expression>  specifies any valid query expression that returns rows and where the number of columns in each row is the same as the number of items to be inserted.

See  “SELECT Statement” on page 874

Details

Form 1: INSERT Statement without Column Names

This form of the INSERT statement that uses the VALUES clause without specifying column names can be used to insert lists of values into a table. You specify a value for each column in the table. One row is inserted for each VALUES clause. The order of the values in the VALUES clause should match the order of the columns in the table.

The following code fragment shows how the INSERT statement could be used with the VALUES clause to insert data values into the Customers table that was created in “CREATE TABLE Statement” on page 840. The Customers table has columns CustId, Name, Address, City, State, Country, PhoneNumber, and InitOrder.

```sql
insert into customers values (1, 'Peter Frank', '300 Rock Lane', 'Boulder', 'CO', 'United States', '3039564321', date '2012-01-14');
insert into customers values (2, 'Jim Stewart', '1500 Lapis Lane', 'Little Rock', 'AR', 'United States', '8705553978', date '2012-03-20');
insert into customers values (3, 'Janet Chien', '75 Jujitsu', 'Nagasaki', '', 'Japan', '01181956879932', date '2012-06-07');
insert into customers values (4, 'Qing Ziao', '10111 Karaje', 'Tokyo', '', 'Japan', '0118136774351', date '2012-10-12');
insert into customers values (5, 'Humberto Sertu', '876 Avenida Blanca', 'Buenos Aires', '', 'Argentina', '01154118435029', date '2012-12-15');
```

These statements add data values to the Sales table that was created in the “CREATE TABLE Statement” on page 840. The Sales table has columns ProdID, CustId, Totals, and Country.

```sql
insert into sales values (3234, 1, 189400, 'United States');
insert into sales values (1424, 3, 555789, 'Japan');
insert into sales values (3421, 4, 781183, 'Japan');
insert into sales values (3421, 2, 2789654, 'United States');
insert into sales values (3975, 5, 899453, 'Argentina');
```

Note that character values are enclosed in quotation marks.
Form 2: INSERT Statement with Column Names

This form of the INSERT statement that uses the VALUES clause with specific column names can also be used to insert lists of values into a table. You give values for the columns specified in the list of column names. The column names do not have to be in the same order as they appear in the table, but the order of the values in the VALUES clause must match the order of the column names in the INSERT column list. One row is inserted for each VALUES clause.

In the following code fragment, column names are used to add values to the Products table that was created in the “CREATE TABLE Statement” on page 840.

```sql
insert into products (prodid, product) values (1424, 'Rice');
insert into products (prodid, product) values (3421, 'Corn');
insert into products (prodid, product) values (3234, 'Wheat');
insert into products (prodid, product) values (3485, 'Oat');
```

The column list enables you to add a row that contains values for specified columns. If you do not specify the column list, values for every column in the table must be provided by the VALUES clause.

Form 3: INSERT Statement with a Query Expression

This form of the INSERT statement uses a query expression that inserts rows that were selected from another table or tables. The order of the values returned by the query expression should match the order of the columns that are specified in the list of column names. All the rows that are returned by the query expression are inserted into the table. The following restrictions should be noted when you use this form of the INSERT statement.

- If you do not specify the column list, values for every column in the table must be provided by the query expression.
- If you do not specify all columns in the column list, a null value is inserted for each column that is not listed.
- If the data type of the column that is being added does not match the data type of the column in the table, an automatic type conversion is attempted.

Here is an example of an INSERT statement that contains a query expression.

```sql
insert into coldtemps select * from worldtemps
where AvgLow >=40;
```

This example queries an existing table WorldTemps and inserts the rows that are returned by the query into a new table, ColdTemps. The ColdTemps table has the same column names and data types as the WorldTemps table. The rows that are inserted into table ColdTemps include countries from the table WorldTemps that have an average low temperature less than or equal to 40 degrees. For information about table WorldTemps, see “WorldTemps” on page 1092.

Inserting Date, Time, and Timestamp Values

For information about inserting date, time, and timestamp values, see “Dates and Times in FedSQL” on page 60.
Comparisons
The DELETE statement enables you to delete rows from a table. The UPDATE statement enables you to change rows in a table. The INSERT statement enables you to insert new rows into a table.

ROLLBACK Statement
Rolls back transaction changes to the beginning of the transaction.

Category: Data Control
Restrictions: This statement is not supported in FedSQL programs that run in CAS. The ROLLBACK statement has an effect only when autocommit functionality is off.
Data source: Greenplum, HAWQ, MDS, Microsoft SQL Server, MySQL, ODBC, Oracle, SAP HANA, SAP IQ, Teradata, Vertica

Syntax
ROLLBACK [TRANSACTION];

Details
When your program has completed all of the statements in the transaction, you must explicitly terminate the transaction using COMMIT or ROLLBACK. You use a ROLLBACK statement to roll back, or undo, the changes that have been made since the start of the transaction.

You cannot roll back the changes to the database after a COMMIT statement is executed.

The ROLLBACK statement has an effect only when autocommit functionality is off. For most data sources, autocommit functionality is on by default. See the server administration documentation for information about how to turn off autocommit functionality. For example, see SAS Federation Server: Administrator’s Guide for the appropriate connection option to the FedSQL driver. For the FEDSQL procedure, see Base SAS Procedures Guide.

Comparisons
The COMMIT statement takes all the changes that have been performed since the start of the transaction and makes them a permanent part of the database. The
ROLLBACK statement causes all the changes that were made by the transaction to be rolled back to the start of the transaction.

## SELECT Statement

Retrieves columns and rows of data from tables.

**Categories:**
- Data Definition
- Data Manipulation
- Data Retrieval

**Restriction:**
The full functionality of the SELECT statement is not supported in FedSQL programs that run in CAS. For CAS information, see "SELECT Statement" in SAS Viya: FedSQL Programming for SAS Cloud Analytic Services.

**Data source:**
- SAS data set, SPD Engine data set, SPD Server table, Amazon Redshift, Aster, DB2 under UNIX and PC, Greenplum, HAWQ, HDMD, Hive, Impala, JDBC, MDS, Microsoft SQL Server, MongoDB on Linux for x64, MySQL, Netezza, ODBC, Oracle, PostgreSQL, Salesforce, SAP, SAP HANA, SAP IQ, Spark, Teradata, Vertica

---

### Syntax

The main clauses of the SELECT statement can be summarized as follows.

**SELECT** <select-list>

| FROM <table-specification> |
| [WHERE <search-condition>] |
| [GROUP BY <grouping-column>] |
| [HAVING <search-condition>] |
| [ORDER BY <sort-specification>] |
| [LIMIT {count | ALL}] |
| [OFFSET number] |

;  

The detailed syntax of the SELECT statement is as follows.

<query-expression>

| [ORDER BY <sort-specification> [, ...<sort-specification>]]; |

<query-expression>::=

{<query-specification> | <query-expression>}

{UNION | EXCEPT | INTERSECT} {{ALL}[CORRESPONDING [BY (column[, ... column])]]} {<query-specification> | <query-expression>
SELECT [ALL | DISTINCT] <select-list> <table-expression>

<select-list>::=
  *
  | column [AS column-alias]
  | expression [AS column-alias]
  | table.*
  | table-alias.*
  | table.column [AS column-alias]

<table-expression>::=
  FROM <table-specification> [, ...<table-specification>]
  [WHERE <search-condition>]
  [GROUP BY <grouping-column> [, ...<grouping-column>]]
  [HAVING <search-condition>]

<table-specification>::=
  table [AS alias]
  | CONNECTION TO catalog (<native-syntax>) [AS table-alias]
  | (<query-specification>) [AS alias]
  | <joined-table>

<joined-table>::=
  <cross-join>
  | <qualified-join>
  | <natural-join>
  <cross-join>::=
    <table-specification> CROSS JOIN <table-specification>
  <qualified-join>::=
    <table-specification> [<join-type>] JOIN <table-specification> <join-specification>
  <natural-join>::=
    <table-specification> NATURAL [<join-type>] JOIN <table-specification>
  <join-type>::=
    INNER
    | LEFT [OUTER]
    | RIGHT [OUTER]
    | FULL [OUTER]
  <join-specification>::=
    ON <search-condition>
    | USING (column [, ...column])

<search-condition>::=
{
  [NOT] {<sql-expression> | (<search-condition>)}
  {[AND | OR] [NOT] {<sql-expression> | (<search-condition>)}}
}
[... [NOT] {<sql-expression> | (<search-condition>)}
  {[AND | OR] [NOT] {<sql-expression> | (<search-condition>)}}]
<sql-expression>::=  
expression \{operator | predicate\} expression

<sort-specification>::=  
\{order-by-expression [ASC | DESC]] [, …order-by-expression [ASC | DESC]]

<grouping-column>::=  
column [, …column]
| column-position-number
| <sql-expression>

Arguments

See the following sections for syntax argument descriptions.

- “SELECT Clause” on page 877
- “FROM Clause” on page 878
- “WHERE Clause” on page 888
- “GROUP BY Clause” on page 889
- “HAVING Clause” on page 890
- “ORDER BY Clause” on page 891
- “LIMIT Clause” on page 896
- “OFFSET Clause” on page 896
- “UNION Operator” on page 897
- “EXCEPT Operator” on page 899
- “INTERSECT Operator” on page 900

Details

Overview

The SELECT statement can be used in two ways.

- The single row SELECT statement, which can be executed by itself, returns only one row. For example:
  
  ```sql
  select 42;
  select 42 as x;
  ```

  The first code fragment returns a single column that contains the value 42. The column is named “column”. The second code fragment returns a similar column. However, the column is named “x”.

- A query specification begins with the SELECT keyword (called a SELECT clause) and cannot be used by itself. It reads column values from one or more tables and enables you to define conditions for the data that will be returned from the tables. It must be used as a part of another SQL statement and can return more than one row. A query specification creates a virtual table. For example:
  
  ```sql
  select column(s)
  from table(s)
  where condition(s);
  ```
The order of clauses in the SELECT statement is important. The optional clauses can be omitted but, when used, they must appear in the appropriate order. A SELECT statement can be specified within a SELECT statement (called a subquery). The ORDER BY, OFFSET, and LIMIT clauses can be used only on the outermost SELECT of a SELECT statement.

A view can be specified in the SELECT statement wherever a table can be specified. FedSQL supports native DBMS views and FedSQL views. It does not support PROC SQL views.

Note: There is no limit on the number of tables that you can reference in a FedSQL query. However, queries with a large number of table references can cause performance issues.

**SELECT Clause**

**Description**

Lists the columns that will appear in a virtual result set.

**Syntax**

```
SELECT [ALL | DISTINCT] <select-list>

<select-list>::= *
  | column [AS column-alias]
  | <query-specification>
  | <sql-expression> [AS column-alias]
  | table.*
  | table-alias.*
  | table.column [AS column-alias]
```

**Arguments**

**ALL**

includes all rows, including duplicate rows in the result set.

**DISTINCT**

eliminates duplicate rows in the result set.

**<select-list>**

specifies the columns to be selected for the result set.

* selects all columns in the table that is listed in the FROM clause.

**column-alias**

assigns a temporary, alternate name to the column.

**column [AS column-alias]**

selects a single column. When [AS column-alias] is specified, assigns the column alias to the column.

**<query-specification>**

specifies an embedded SELECT subquery.

See “Overview of Subqueries” on page 52
<sql-expression> [AS column-alias]
derives a column name from an expression.

See  "<sql-expression> Expression" on page 820

table.*
selects all columns in the table.

table-alias.*
selects all columns in the table.

See  “Table Aliases” on page 880

table.column [AS column-alias]
selects a single column from the specified table.

Asterisk (*) Notation
The asterisk (*) represents all columns of the table or tables that are listed in the FROM clause. When an asterisk is not prefixed with a table name, all the columns from all tables in the FROM clause are included; when it is prefixed (for example, table.* or table-alias.*), all the columns from only that table are included.

Column Aliases
A column alias is a temporary, alternate name for a column. Aliases are specified in the SELECT clause to name or rename columns in the result set in order to be clearer or easier to read. Aliases are often used to name a column that is the result of an arithmetic expression or summary function. An alias is one word only.

The keyword AS is required to distinguish a column alias from other column names.

Column aliases are optional, and each column name in the SELECT clause can have an alias. After you assign an alias to a column, you can use the alias to refer to that column in other clauses.

FROM Clause
Description
(Optional) specifies source tables.

Syntax
FROM <table-specification> [, ...<table-specification>]
<table-specification>::=

  table [AS table-alias]
  | CONNECTION TO catalog (<native-syntax>) [AS alias]
  | (query-specification) [AS alias]
  | <joined-table>

<joined-table>::=

  <cross-join>
  | <qualified-join>
  | <natural-join>

<cross-join>::=

  <table-specification> CROSS JOIN <table-specification>
<qualified-join>::=
  <table-specification> [<join-type>] JOIN <table-specification> <join-specification>

<natural-join>::=
  <table-specification> NATURAL [<join-type>] JOIN <table-specification>

<join-type>::=
  INNER
  | LEFT [OUTER]
  | RIGHT [OUTER]
  | FULL [OUTER]

<join-specification>::=
  ON <search-condition>
  | USING (column [, …column])

Arguments

**CONNECTION TO catalog (<native-syntax>) [[AS] alias]**

specifies data from a DBMS catalog by using the SQL pass-through facility. You can use SQL syntax that the DBMS understands, even if that syntax is not valid in FedSQL. For more information, see “FedSQL Explicit Pass-Through Facility” on page 70.

**CROSS JOIN**

defines a join that is the Cartesian product of two tables.

See  “Cross Joins” on page 883

**JOIN**

defines a join that enables you to filter the data by using a search condition or by using specific columns.

See  “Qualified Joins” on page 883

**NATURAL JOIN**

defines a join that selects rows from two tables that have equal values in columns that share the same name and the same type.

See  “Natural Joins” on page 887

(**query-specification**) [AS alias]

specifies an embedded SELECT subquery that functions as an in-line view. alias defines a temporary name for the in-line view and is required. An in-line view saves you a programming step. Rather than creating a view and referring to it in another query, you can specify the view in-line in the FROM clause.

See  “Overview of Subqueries” on page 52

**table**

specifies the name of a table. The name can be in any of the forms described for “table” on page 841.

**table-alias**

specifies a temporary, alternate name for table. The AS keyword is optional.
INNER
specifies that only the subset of rows from the first table that matches rows from the second table are returned. Unmatched rows from both tables are discarded.

LEFT [OUTER]
specifies that matching rows and rows from the first table that do not match any row in the second table are returned.

RIGHT [OUTER]
specifies that matching rows and rows from the second table that do not match any row in the first table are returned.

FULL [OUTER]
specifies that all matching and unmatching rows from the first and second table are returned.

column
specifies the name of a column.

ON <search-condition>
specifies a condition join used to match rows from one table to another. If the search condition is satisfied, the matching rows are added to the result set.

See "<search-condition>" on page 902

USING (column[,...,column])
specifies which columns to use in an inner or outer join.

See "ON and USING Clauses" on page 887

Overview
The FROM clause enables you to specify source tables. You can reference tables by specifying their table name, by submitting a query to a DBMS, by specifying an embedded SELECT subquery, or by specifying a join.

Table Aliases
A table alias is a temporary, alternate name for a table. Table aliases are used in joins to distinguish the columns of one table from those in the other table or tables and can make a query easier to read by abbreviating the table names. A table name or alias must be prefixed to a column name when you are joining tables that have matching column names. Column names in reflexive joins (joining a table with itself) must be prefixed with a table alias in order to distinguish which copy of the table the column comes from. A table alias cannot be given an alias.

Joined Tables
When multiple table specifications are listed in the FROM clause, they are processed to form one table. The result set contains data from each contributing table. These queries are referred to as joins. Joins do not alter the original table.

Conceptually, when two tables are specified, each row of table A is matched with all the rows of table B to produce an internal or intermediate table. The number of rows in the intermediate table (Cartesian) is equal to the product of the number of rows in each of the source tables. The intermediate table becomes the input to the rest of the query in which some of its rows can be eliminated by the WHERE, ON, or USING clause or summarized by a function.

For an overview of FedSQL join operations, see "Join Operations" on page 31.
Specifying the Rows to Be Returned

The WHERE, ON, and USING clauses contain the conditions under which the rows in the Cartesian product are kept or eliminated in the result set. WHERE is used to select rows from inner joins. ON is used to select rows from inner or outer joins. USING is used to select specific columns to be included in the join. The condition is evaluated for each row from each table in the intermediate table described in “Joined Tables” on page 880. The row is considered to be a match if the result of the expression is true (a nonzero, nonmissing, or null value) for that row.

Simple Joins

The most basic type of join is simply a list of multiple tables, separated by commas, in the FROM clause of a SELECT statement. The following query joins the two tables GrainProducts and Sales that are shown in Appendix 4, “Tables Used in Examples,” on page 1077.

/* FedSQL code for simple join */
title 'Simple Join - GrainProducts and Sales';
select * from grainproducts, sales;
Joining tables in this way returns the *Cartesian* product of the tables. Each row from the first table is combined with every row of the second table. The number of rows in the result set is equal to the number of rows in the first table multiplied by the number of rows in the second table.

The Cartesian product of a simple join can result in large, meaningless tables. You can subset a simple join by using a WHERE clause. This type of simple join is known as an *equijoin*. The following query subsets the previous table by matching the ID columns and creates the table shown in *Output 7.61 on page 883*.

```sql
/* FedSQL code for equijoin */
title 'Equijoin - GrainProducts and Sales';
select * from grainproducts, sales
where grainproducts.prodid=sales.prodid;
```

In an equijoin, the comparison has to be an equality comparison. Multiple match criteria (not shown here) can be specified by using the AND operator. When multiple match criteria are specified, only rows meeting all of the equality tests are returned.
Cross Joins

The cross join functions the same as a simple join; it returns the product of two tables. Like a Cartesian product, a cross join's output can be limited by a WHERE clause.

The following queries produce the same result.

```sql
select * from grainproducts, sales;
select * from grainproducts cross join sales;
```

**Note:** Do not use an ON clause with a cross join. An ON clause causes a cross join to fail. However, you can use a WHERE clause to subset the output.

Qualified Joins

Qualified joins provide an easier way to control which rows appear in the result set. You can also further subset the result set with the ON or USING clause.

The two types of qualified joins are inner and outer.

Inner Joins

*Figure 7.1  Inner Join Diagram*

An *inner join* returns a result set for all the rows in one table that have one or more matching rows in another table. Using the GrainProducts and Sales tables, the following query matches the product ID columns of the two tables and creates the result set shown in *Output 7.62 on page 884*.

```sql
/* FedSQL code for inner join */
title 'Inner Join - GrainProducts and Sales';
select *
from grainproducts inner join sales
on grainproducts.prodid=sales.prodid;
```
You can use the ON or USING clause instead of the WHERE clause to specify the column or columns on which you are joining the tables. However, you can continue to use the WHERE clause to subset the query result.

Note that an inner join with an ON or USING clause can provide the same functionality as listing tables in the FROM clause and specifying join columns with a WHERE clause (an equijoin). For example, these two sets of code use the inner join construction.

```
select *
from grainproducts inner join sales
  on grainproducts.prodid=sales.prodid;
```

```
select *
from grainproducts inner join sales
  using (prodid);
```

This code produces the same output as the previous code but uses the inner join construction.

```
select *
from grainproducts, sales
  where grainproducts.prodid=sales.prodid;
```

Outer Joins

*Outer joins* are inner joins that have been augmented with rows from one table that do not match with any row from the other table in the join. The result set includes rows that match and rows that do not match from the join's source tables. Nonmatching rows have null or missing values in the columns from the unmatched table. You can use the ON or USING clause instead of the WHERE clause to specify the column or columns on which you are joining the tables. However, you can continue to use the WHERE clause to subset the query result.

The three types of outer joins are left, right, and full.

Left Outer Joins

*Figure 7.2  Left Outer Join Diagram*
A left outer join lists matching rows and rows from the first table listed in the FROM clause that do not match any row in the second table listed in the FROM clause. Using the GrainProducts and Sales tables, the following code creates a table with matching rows from the GrainProducts and Sales tables and the unmatched rows from the GrainProducts table. Note that missing values are shown for Sales table data in the unmatched row from the GrainProducts table.

```
/* FedSQL code for left outer join */
title 'Left Outer Join - GrainProducts and Sales';
select *
from grainproducts left outer join sales
  on grainproducts.prodid=sales.prodid;
```

Output 7.4  Left Outer Join - GrainProducts and Sales Table

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>PRODID</th>
<th>CUSTID</th>
<th>TOTALS</th>
<th>COUNTRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>3234</td>
<td>Wheat</td>
<td>3234</td>
<td>1</td>
<td>$189,400</td>
<td>United States</td>
</tr>
<tr>
<td>1424</td>
<td>Rice</td>
<td>1424</td>
<td>3</td>
<td>$555,789</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3421</td>
<td>4</td>
<td>$781,183</td>
<td>Japan</td>
</tr>
<tr>
<td>3421</td>
<td>Corn</td>
<td>3421</td>
<td>2</td>
<td>$2,789,654</td>
<td>United States</td>
</tr>
<tr>
<td>3485</td>
<td>Oat</td>
<td>.</td>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

Right Outer Joins

Figure 7.3  Right Outer Join Diagram

A right outer join lists matching rows and rows from the second table listed in the FROM clause that do not match any row in the first table listed in the FROM clause. Using the GrainProducts and Sales tables, the following code creates a table with matching rows from the GrainProducts and Sales tables and the unmatched rows from the Sales table. Note that missing values are shown for GrainProducts table data in the unmatched row from the Sales table.

```
/* FedSQL code for right outer join */
title 'Right Outer Join - GrainProducts and Sales';
select *
from grainproducts right outer join sales
  on grainproducts.prodid=sales.prodid;
```
A full outer join combines the left outer join and the right outer join. The result set contains both the matching and unmatching rows from the left and right tables. Using the GrainProducts and Sales tables, the following code creates a table with matching rows from the GrainProducts and Sales tables and the unmatched rows from the GrainProducts and Sales tables. Note that missing values are shown for data in the unmatched rows.

```sql
/* FedSQL code for full outer join */
title 'Full Outer Join - GrainProducts and Sales';
select *
from grainproducts full outer join sales
    on grainproducts.prodid=sales.prodid;
```

### Output 7.6  Full Outer Join - GrainProducts and Sales Table

<table>
<thead>
<tr>
<th>PRODID</th>
<th>PRODUCT</th>
<th>PRODID</th>
<th>CUSTID</th>
<th>TOTALS</th>
<th>COUNTRY</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
ON and USING Clauses

You can use an ON clause with an expression that specifies a condition on which the join is based. The conditional expression can contain any predicate, although column names and comparison operators are most often used. The ON clause with an inner join is equivalent to a WHERE clause. The ON clause with an outer join (left, right, or full) is different from a WHERE clause. The ON clause with an outer join filters the rows and then includes the nonmatched rows with the null or missing values.

You can use a USING clause to specify one of two columns to include in the result set.

The difference between the ON clause and the USING clause is that you can use any conditional expression with the ON clause. The USING clause always implies an equality between the column names. For example, this ON clause eliminates United States from the results table.

/* FedSQL code for inner join with on clause */
title 'Inner Join - GrainProducts and Sales Outside US';
select *
    from grainproducts inner join sales
    on sales.country <> 'United States'
    AND grainproducts.prodid=sales.prodid;

Output 7.7  Inner Join - GrainProducts and Sales outside the US

Natural Joins

A natural join selects rows from two tables that have equal values in columns that share the same name and the same type. An error results if two columns have the same name but different types. You can perform an inner, left, right, or full natural join. If join-type is omitted when specifying a natural join, then INNER is implied. If like columns are not found, then a cross join is performed. You can use a WHERE clause to limit the output.

Using the GrainProducts and Sales tables, the following code performs a natural left outer join.

/* FedSQL code for natural left outer join */
title 'Natural Left Outer Join - GrainProducts and Sales';
select *
    from grainproducts natural left outer join sales;
Notice that the \textit{prodid} column appears only once in the result set.

\textbf{Note:} Do not use an ON clause with a natural join. An ON clause causes a natural join to fail. When using a natural join, an ON clause is implied, matching all like columns.

\textbf{WHERE Clause}

\textbf{Description}
Subsets the result set based on the specified search conditions.

\textbf{Syntax}
\texttt{WHERE <search-condition>}

\textbf{Arguments}
\texttt{<search-condition>}
specifies the conditions for the rows returned by the \texttt{WHERE} clause.

See "<search-condition>" on page 902

\textbf{Details}
The \texttt{WHERE} clause requires a search condition (one or more expressions separated by an operand or predicate) that specifies which rows are chosen for inclusion in the result set. When a condition is met (that is, the condition resolves to true), those rows are displayed in the result set. Otherwise, no rows are displayed.

\textbf{Note:} You cannot use aggregate functions that specify only one column. For example, you cannot use the following code.

\begin{verbatim}
where max(inventory1)>10000;
\end{verbatim}

However, you can use this \texttt{WHERE} clause.

\begin{verbatim}
where max(inventory1, inventory2)>10000;
\end{verbatim}
Note: If a column contains REAL or DOUBLE values, avoid using a WHERE clause with the = and the <> operators. REAL and DOUBLE values are approximate numeric data types and can give inaccurate results when used in a WHERE clause with the = and the <> operators. You should limit REAL and DOUBLE columns to comparisons with the > or < operator.

GROUP BY Clause

Description

Specifies how to group the data for summarizing.

Syntax

GROUP BY <grouping-column> [, ...<grouping-column>]
<grouping-column>::=
    column [, ...column]
| column-position-number
| <sql-expression>

Arguments

column
    specifies the name of a column or a column alias.

column-position-number
    specifies a nonnegative integer that equates to a column position.

<sql-expression>
    specifies a valid SQL expression.

See "<sql-expression> Expression" on page 820

Details

The GROUP BY clause groups data by a specified column or columns.

If the column or columns on which you are grouping contain missing or null values in some rows, SAS collects all the rows with missing or null values in the grouping columns into a single group.

You can specify more than one grouping column to get more detailed reports. If more than one grouping column is specified, then the first one determines the major grouping.

Integers can be substituted for column names in the GROUP BY clause. For example, if the grouping column is 2, then the results are grouped by values in the second column. Note that if you use a floating-point value (for example, 2.3) instead of an integer, then FedSQL ignores the decimal portion.

You can group the output by the values that are returned by an expression. For example, if X is a numeric variable, then the output of the following is grouped by the values of X.

```sql
select x, sum(y)
from table1
  group by x;
```
Similarly, if \( Y \) is a character variable, then the output of the following is grouped by the values of \( Y \).

\[
\text{select } \text{sum}(x), y \\
\quad \text{from table1} \\
\quad \text{group by } y;
\]

When you use a GROUP BY clause, you can also use an aggregate function in the SELECT clause or in a HAVING clause to instruct SAS in how to summarize the data for each group. When you use a GROUP BY clause without an aggregate function, SAS treats the GROUP BY clause as if it were an ORDER BY clause.

You can use the ORDER BY clause to specify the order in which rows are displayed in the result set. If you do not specify the ORDER BY clause, groups returned by the GROUP BY clause are not in any particular order.

**Note:** For an SPD Engine data set, utility files are used for certain operations that need extra space. The GROUP BY clause requires a utility file and the SPDEUTILLOC= system option allocates space for that utility file. For more information, see *SAS Scalable Performance Data Engine: Reference*.

**Note:** FedSQL GROUP BY syntax does not support remerging of summary statistics. The select list in a GROUP BY query can reference only grouping columns and aggregate functions. If you specify a column in the SELECT list that is not specified in the GROUP BY clause, you get this error: *column name must be grouped or used in an aggregate function.*

---

**TIP** In FedSQL, the results of an analysis can be integrated with other columns from the data by using a subquery. Specify the analysis in the subquery and then select the rest of the row based on the results of the subquery.

Here is an example of using a subquery to remerge data. The request uses a subquery to identify the oldest employee of each gender in a payroll table, and then it references the subquery in an outer query. Note that the subquery \( t \) is referenced in both the SELECT list and in the join condition.

\[
\text{select} \\
\quad \text{from} \\
\quad (\text{select Gender, min(Birth) as min_birth} \\
\quad \text{from sql.payroll} \\
\quad \text{group by Gender} \\
\quad ) \text{ as } t \\
\quad \text{inner join sql.payroll as p on p.Gender=\text{\textasciitilde}gender and p.Birth=\text{\textasciitilde}.min_birth;} \\
\text{quit;}
\]

For more information, see “Rewriting a GROUP BY Remerge Query in FedSQL” on page 1114.

**HAVING Clause**

**Description**

Subsets grouped data based on specified search conditions.
Syntax
HAVING <search-condition>

Arguments

<search-condition>
specifies the conditions for the rows returned by the HAVING clause.

See “<search-condition>” on page 902

Details
The HAVING clause requires a search condition (one or more expressions separated by an operand or predicate) that specifies which rows are chosen for inclusion in the result set. A HAVING clause evaluates as either true or false for each group in a query. You can use a HAVING clause with a GROUP BY clause to filter grouped data. The HAVING clause affects groups in a way that is similar to how a WHERE clause affects individual rows.

Queries that contain a HAVING clause usually also contain a GROUP BY clause, an aggregate function, or both. When you use a HAVING clause without a GROUP BY clause, SAS treats the HAVING clause as if it were a WHERE clause.

Table 7.1 Differences between the HAVING Clause and WHERE Clause

<table>
<thead>
<tr>
<th>HAVING clause attributes</th>
<th>WHERE clause attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>typically used to specify conditions for including or excluding groups of rows from a table</td>
<td>used to specify conditions for including or excluding individual rows from a table</td>
</tr>
<tr>
<td>must follow the GROUP BY clause in a query, if used with a GROUP BY clause</td>
<td>must precede the GROUP BY clause in a query, if used with a GROUP BY clause</td>
</tr>
<tr>
<td>affected by a GROUP BY clause; when there is no GROUP BY clause, the HAVING clause is treated like a WHERE clause</td>
<td>not affected by a GROUP BY clause</td>
</tr>
<tr>
<td>processed after the GROUP BY clause and any aggregate functions</td>
<td>processed before a GROUP BY clause, if there is one, and before any aggregate functions</td>
</tr>
</tbody>
</table>

ORDER BY Clause
Description
Specifies the order in which rows are returned in a result set.

Syntax
ORDER BY <sort-specification> [, ...<sort-specification>];
<sort-specification>::=

{order-by-expression [ASC | DESC]} [, ...order-by-expression [ASC | DESC]]
| {order-by-expression [COLLATE collating-sequence-options]}
| [, …order-by-expression [COLLATE collating-sequence-options]]

Arguments

**order-by-expression**
specifies a column on which to sort. The sort column can be one of the following.

*column*
specifies the name of a column or a column alias.

*column-position-number*
specifies a nonnegative integer that equates to a column position.

*<sql-expression>*
specifies any valid SQL expression.

See "<sql-expression> Expression" on page 820

**ASC**
orders the data in ascending order. This is the default order; if ASC or DESC are not specified, the data is ordered in ascending order.

**DESC**
orders the data in descending order.

**COLLATE collating-sequence-options**
specifies linguistic collation, which sorts characters according to rules of the specified language. The rules and default collating sequence options are based on the language specified in the current locale setting. The implementation is provided by the International Components for Unicode (ICU) library and produces results that are largely compatible with the Unicode Collation Algorithms (UCA).

The *collating-sequence-options* argument can be one of the following values:

DANISH | FINNISH | ITALIAN | NORWEGIAN | POLISH | SPANISH | SWEDISH
sorts characters according to the language specified.

**LINGUISTIC [collating-rules]**
collating-rules can be one of the following values:

**ALTERNATE_HANDLING=SHIFTED**
controls the handling of variable characters like spaces, punctuation, and symbols. When this option is not specified (using the default value NON_IGNORABLE), differences among these variable characters are of the same importance as differences among letters. If the ALTERNATE_HANDLING option is specified, these variable characters are of minor importance.

Default NON_IGNORABLE

Tip
The SHIFTED value is often used in combination with STRENGTH= set to Quaternary. In such a case, spaces, punctuation, and symbols are considered when comparing strings, but only if all other aspects of the strings (base letters, accents, and case) are identical.

**CASE_FIRST=**
specify order of uppercase and lowercase letters. This argument is valid for only TERTIARY, QUATERNARY, or IDENTICAL levels. The following table provides the values and information for the CASE_FIRST argument:
**Table 7.2**  **CASE-FIRST= Values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPPER</td>
<td>Sorts uppercase letters first, then the lowercase letters.</td>
</tr>
<tr>
<td>LOWER</td>
<td>Sorts lowercase letters first, then the uppercase letters.</td>
</tr>
</tbody>
</table>

**COLLATION=**
The following table lists the available COLLATION= values. If you do not select a collation value, then the user’s locale-default collation is selected.

**Table 7.3**  **COLLATION= Values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIG5HAN</td>
<td>specifies Pinyin ordering for Latin and specifies big5 charset ordering for Chinese, Japanese, and Korean characters.</td>
</tr>
<tr>
<td>DIRECT</td>
<td>specifies a Hindi variant.</td>
</tr>
<tr>
<td>GB2312HAN</td>
<td>specifies Pinyin ordering for Latin and specifies gb2312han charset ordering for Chinese, Japanese, and Korean characters.</td>
</tr>
<tr>
<td>PHONEBOOK</td>
<td>specifies a telephone-book style for ordering of characters. Select PHONEBOOK only with the German language.</td>
</tr>
<tr>
<td>PINYIN</td>
<td>specifies an ordering for Chinese, Japanese, and Korean characters based on character-by-character transliteration into Pinyin. This ordering is typically used with simplified Chinese.</td>
</tr>
<tr>
<td>POSIX</td>
<td>is the Portable Operating System Interface. This option specifies a &quot;C&quot; locale ordering of characters.</td>
</tr>
<tr>
<td>STROKE</td>
<td>specifies a nonalphabetic writing style ordering of characters. Select STROKE with Chinese, Japanese, Korean, or Vietnamese languages. This ordering is typically used with Traditional Chinese.</td>
</tr>
<tr>
<td>TRADITIONAL</td>
<td>specifies a traditional style for ordering of characters. For example, select TRADITIONAL with the Spanish language.</td>
</tr>
</tbody>
</table>

**LOCALE= locale_name**
specifies the locale name in the form of a POSIX name(for example, ja_JP). For more information, see *SAS National Language Support (NLS): Reference Guide*
**NUMERIC_COLLATION=**
orders integer values within the text by the numeric value instead of characters used to represent the numbers.

**Table 7.4  **NUMERIC_COLLATION= Values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ON</td>
<td>Order numbers by the numeric value. For example, &quot;8 Main St.&quot; would sort before &quot;45 Main St.&quot;.</td>
</tr>
<tr>
<td>OFF</td>
<td>Order numbers by the character value. For example, &quot;45 Main St.&quot; would sort before &quot;8 Main St.&quot;.</td>
</tr>
</tbody>
</table>

Default OFF

**STRENGTH=**
The value of strength is related to the collation level. There are five collation-level values. The following table provides information about the five levels. The default value for strength is related to the locale.

**Table 7.5  **STRENGTH= Values

<table>
<thead>
<tr>
<th>Value</th>
<th>Type of Collation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY or 1</td>
<td>PRIMARY specifies differences between base characters (for example, &quot;a&quot; &lt; &quot;b&quot;).</td>
<td>It is the strongest difference. For example, dictionaries are divided into different sections by base character.</td>
</tr>
<tr>
<td>SECONDARY or 2</td>
<td>Accents in the characters are considered secondary differences (for example, &quot;as&quot; &lt; &quot;às&quot; &lt; &quot;at&quot;).</td>
<td>A secondary difference is ignored when there is a primary difference anywhere in the strings. Other differences between letters can also be considered secondary differences, depending on the language.</td>
</tr>
<tr>
<td>TERTIARY or 3</td>
<td>Upper and lowercase differences in characters are distinguished at the tertiary level (for example, &quot;ao&quot; &lt; &quot;Ào&quot; &lt; &quot;aò&quot;).</td>
<td>A tertiary difference is ignored when there is a primary or secondary difference anywhere in the strings. Another example is the difference between large and small Kana.</td>
</tr>
<tr>
<td>Alias</td>
<td>LEVEL=</td>
<td></td>
</tr>
<tr>
<td>-------</td>
<td>--------</td>
<td></td>
</tr>
</tbody>
</table>

| Restriction | Linguistic collation is not supported on platforms VMS on Itanium (VMI) or 64-bit Windows on Itanium (W64). |
| Tip | The collating-rules must be enclosed in parentheses. More than one collating rule can be specified. |
| See | "ICU Licence: ICU 1.8.1–ICU 57 and ICU4J 1.3.1–ICU4J 57” on page 1139. |

Refer to http://www.unicode.org for the Unicode Collation Algorithm (UCA) specification.

### Details

The ORDER BY clause sorts the result of a query expression according to the order specified in that query. When this clause is used, the default ordering sequence is ascending, from the lowest value to the highest.

If an ORDER BY clause is omitted, then a particular order to the output rows, such as the order in which the rows are encountered in the queried table, cannot be guaranteed. Without an ORDER BY clause, the order of the output rows is determined by the internal processing of FedSQL, the default collating sequence of SAS, and your operating environment. Therefore, if you want your result set to appear in a particular order, then use the ORDER BY clause.

If more than one order-by-expression is specified (separated by commas), then the first one determines the major sort order.

Integers can be substituted for column names in the ORDER BY clause. For example, if the order-by-expression is 2, then the results are ordered by values in
the second column. Note that if you use a floating-point value (for example, 2.3) instead of an integer, then FedSQL issues an error message.

In the ORDER BY clause, you can specify any column of a table that is specified in the FROM clause of a query expression, regardless of whether that column has been included in the query's SELECT clause. However, if SELECT DISTINCT is specified, or if the SELECT statement contains a UNION set operator, the sort column must appear in the query's SELECT clause.

Note: SAS missing values or null values are treated as the lowest possible values.

Note: For an SPD Engine data set, utility files are used for certain operations that need extra space. The ORDER BY clause requires a utility file and the Base SAS UTILLOC system option allocates space for that utility file. For more information, see SAS Scalable Performance Data Engine: Reference.

LIMIT Clause
Description
Specifies the number of rows that the SELECT statement returns.

Syntax
LIMIT {count | ALL}

Arguments
count
specifies the number of rows that the SELECT statement returns.

Tip count can be an integer or any simple expression that resolves to an integer value.

ALL
specifies that all rows are returned.

Details
The LIMIT clause can be used alone or in conjunction with the OFFSET clause. The OFFSET clause specifies the number of rows to skip before the SELECT statement starts to return rows.

Note: When you use the LIMIT clause, it is recommended that you use an ORDER BY clause to create an ordered sequence. Otherwise, you can get an unpredictable subset of a query's rows.

OFFSET Clause
Description
Specifies the number of rows to skip before the SELECT statement starts to return rows.
Syntax
OFFSET number

Arguments
number
  specifies the number of rows to skip.

  Tip  number can be an integer or any simple expression that resolves to an integer value.

Details
The OFFSET clause can be used alone or in conjunction with the LIMIT clause. The OFFSET clause specifies the number of rows to skip before the SELECT statement starts to return rows.

Note: When you use the OFFSET clause, it is recommended that you use an ORDER BY clause to create an ordered sequence. Otherwise, you get an unpredictable subset of a query's rows.

UNION Operator
Description
Combines the result of two queries into a single result set.

Syntax
{<query-specification> | <query-expression>}  UNION  
  {  
    [ALL] [CORRESPONDING [BY (column[, ...column])]]  
  }  <query-specification> | <query-expression>

Arguments
<query-specification> | <query-expression>
  specifies one or more SELECT statements that produce a virtual result set.

  See  “SELECT Statement” on page 874

  “Overview of Subqueries” on page 52

UNION
  specifies that multiple result sets are combined and returned as a single result set.

ALL
  (optional) specifies that all rows, including duplicates, are included in the result set.
CORRESPONDING
(optional) specifies to combine columns in the result set by column name or column list.

BY (column[, ... column])
(optional) specifies that only these columns be included in the result set. Columns are identified by column name.

Requirement The column names must exist in both input tables.

Details
The UNION set operator produces a result set that contains all the unique rows that result from two queries. That is, the result set contains rows that are produced by the first query and the second query (and any optional subsequent queries that are separated by a UNION operator). The UNION set operator automatically eliminates duplicate rows from its result sets. The optional ALL keyword can preserve the duplicate rows, reduce the execution by one step, and thereby improve the query’s performance. Use it when you want to display all the rows resulting from the query, rather than just the unique rows.

Columns are appended by position in the tables by default, regardless of the column names. However, the data type of the corresponding columns must match or be of a corresponding data type where length is the only differentiator, or the union does not occur. That is, CHAR can be merged with CHAR or VARCHAR, and INTEGER can be merged with BIGINT, INTEGER, SMALLINT, or TINYINT. However, CHAR or INTEGER cannot be merged with DOUBLE.

When columns of different lengths are merged, the length of the longer column is used. For example, if one column is CHAR(4) and the corresponding column is CHAR(10), then CHAR(10) is used.

The optional CORRESPONDING keyword causes FedSQL to match columns by column name instead of by position. The name matching is not case-sensitive. Formats are ignored unless they originate in the first query. Any columns that have non-matching column names are ignored. Use the CORRESPONDING keyword when the columns that you want to match have the same column name but exist in different positions in the input tables.

CORRESPONDING without a column list forms a result set that contains all columns that have the same name. The BY keyword restricts the columns that are returned to those whose names are specified in the column list. Columns that are not specified in the column list are dropped, even if the original queries specify SELECT *. Use the BY keyword to specify just one or more of the columns from both queries to be included in the result set.

The names of the columns in the result set are the names of the columns from the first query expression or query-specification unless a column (such as an expression) has no name in the first query expression or query-specification. Then, the name used depends on whether the SELECT statement result set is being returned to the client, or whether the SELECT statement is part of a CREATE TABLE AS statement. When the SELECT statement result set is being returned to the client, the name of an unnamed column in the result table is “column”. Unnamed columns in a CREATE TABLE AS statement are given generated names. The generated names are _expr_1, _expr_2, and so on.

See Also

"Query Expressions and Subqueries" on page 48
EXCEPT Operator

Description

Combines the results of two queries into a single result set that contains only rows that are unique to the first query.

Syntax

```
{<query-specification> | <query-expression>}

EXCEPT

{ [ALL][CORRESPONDING [BY (column [, ...column])]]

}<query-specification> | <query-expression>
```

Arguments

`<query-specification> | <query-expression>` specifies one or more SELECT statements that produce a virtual result set.

See “SELECT Statement” on page 874

“Overview of Subqueries” on page 52

EXCEPT

specifies that multiple result sets are combined and only those rows that are in the first result set and not in the second result set are included.

ALL

(optional) specifies that all rows, including duplicates, are included in the result set.

CORRESPONDING

(optional) specifies to combine columns in the result set by column name or column list.

BY (column[, ...column])

(optional) specifies that only these columns be included in the result set. Columns are identified by column name.

Requirement

The column names must exist in both input tables.

Details

The EXCEPT set operator produces a result set that includes rows that exist in the results of the first query, except those that also exist in the results of the second query. Use the EXCEPT operator to identify results that are unique to the first query. If the intermediate result from the first query has at least one occurrence of a row that is not in the intermediate result of the second query, then that row (from the first query) is included in the result set.

The EXCEPT set operator automatically eliminates duplicate rows from its result sets. The optional ALL keyword can preserve the duplicate rows, reduce the execution by one step, and thereby improve the query's performance. Use it when you want to display all the rows resulting from the query, rather than just the unique rows.
Columns are evaluated based on their position in the input tables by default, regardless of the column names. However, the data type of the corresponding columns must match or be of a corresponding data type where length is the only differentiator; otherwise, the comparison does not occur. That is, CHAR can be evaluated against CHAR or VARCHAR, and INTEGER can be evaluated against BIGINT, INTEGER, SMALLINT, or TINYINT. However, CHAR or INTEGER cannot be evaluated against DOUBLE.

When columns of different lengths are merged, the length of the longer column is used.

The optional CORRESPONDING keyword causes FedSQL to match columns by column name instead of by position. The name matching is not case-sensitive. The column names display in the order that they are returned in the first query. Formats are ignored unless they originate in the first query. Any columns that have non-matching names are ignored. Use the CORRESPONDING keyword when the columns that you want to match have the same column name but exist in different positions in the input tables.

CORRESPONDING without a column list forms a result set that contains all columns that have the same name. The BY keyword restricts the columns that are returned to those whose names are specified in the column list. Columns that are not specified in the column list are dropped, even if the original queries specify SELECT *. Use the BY keyword to return only one or more columns from both queries in the result set.

The names of the columns in the result set are the names of the columns from the first query-expression or query-specification unless a column (such as an expression) has no name in the first query expression or query-specification. In such a case, the name of that column in the result set is "column".

See Also

"Query Expressions and Subqueries" on page 48

INTERSECT Operator

Description

Combines the result of two queries into a single result set that contains only rows that are common to the queries.

Syntax

```
{ <query-specification> | <query-expression> }
INTERSECT
{ [ALL][CORRESPONDING [BY (column [, …column])]] }
{ <query-specification> | <query-expression> }
```

Arguments

```
<query-specification> | <query-expression>
```

specifies one or more SELECT statements that produces a virtual table.

See “SELECT Statement” on page 874
INTERSECT
   specifies that multiple result sets are combined and only those rows that are
   common to the result sets are included.

ALL
   (optional) specifies that all rows, including duplicates, are included in the result
   set.

CORRESPONDING
   (optional) specifies to combine columns in the result set by column name or
   column list.

   BY (column[, ...column])
      (optional) specifies that only these columns be included in the result set.
      Columns are identified by column name.

   Requirement   The column names must exist in both input tables.

Details
The INTERSECT operator produces a result set that has rows that are common to
two queries.

The INTERSECT set operator automatically eliminates duplicate rows from its result
sets. The optional ALL keyword is available to preserve the duplicate rows, reduce
the execution by one step, and thereby improve the query's performance. Use it
when you want to display all the rows resulting from the query, rather than just the
unique rows.

Columns are evaluated based on their position in the input tables by default,
regardless of the column names. However, the data type of the corresponding
columns must match or be of a corresponding data type where length is the only
differentiator, or the comparison does not occur. That is, CHAR can be evaluated
against CHAR or VARCHAR, and INTEGER can be evaluated against BIGINT,
INTEGER, SMALLINT, or TINYINT. However, CHAR or INTEGER cannot be
evaluated against DOUBLE.

When columns of different lengths are merged, the length of the longer column is
used.

The optional CORRESPONDING keyword causes FedSQL to match columns by
column name instead of by position. The name matching is not case-sensitive. The
column names display in the order that they are returned in the first query. Formats
are ignored unless they originate in the first query. Any columns that have non-
matching names are ignored. Use the CORRESPONDING keyword when the
columns that you want to match have the same column name but exist in different
positions in the input tables.

CORRESPONDING without a column list forms a result set that contains all
columns that have the same name. The BY keyword restricts the columns that are
returned to those whose names are specified in the column list. Columns that are
not specified in the column list are dropped, even if the original queries specify
SELECT *. Use the BY keyword to return only one or more columns from both
queries in the result set.

The names of the columns in the result set are the names of the columns from the
first query-expression or query-specification unless a column (such as an
expression) has no name in the first query expression or query-specification. In such a case, the name of that column in the result set is “column”.

“Query Expressions and Subqueries” on page 48

<search-condition>

Description
Is a combination of one or more operators and predicates that specifies which rows are chosen for inclusion in the result set.

Syntax
<search-condition>::=
{  
[NOT] {<sql-expression> | (<search-condition>)}  
[(AND | OR) NOT] {<sql-expression> | (<search-condition>))}  
}
[ , ...[NOT] {<sql-expression> | (<search-condition>)}  
[(AND | OR) NOT] {<sql-expression> | (<search-condition>))}]

<sql-expression>::=
expression {operator | predicate} expression

Arguments

NOT
negates a Boolean condition. This table outlines the outcomes when you compare true and false values using the NOT operator.

Table 7.6 Truth Table for the NOT Operator

<table>
<thead>
<tr>
<th>NOT</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

AND
combines two conditions by finding observations that satisfy both conditions. This table outlines the outcomes when you compare TRUE and FALSE values using the AND operator.

Table 7.7 Truth Table for the AND Operator

<table>
<thead>
<tr>
<th>AND</th>
<th>True</th>
<th>False</th>
<th>Unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>True</td>
<td>False</td>
<td>Unknown</td>
</tr>
</tbody>
</table>
**AND**

<table>
<thead>
<tr>
<th></th>
<th>True</th>
<th>False</th>
<th>Unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td>False</td>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>Unknown</td>
<td>Unknown</td>
<td>False</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

**OR**

combines two conditions by finding observations that satisfy either condition or both. This table outlines the outcomes when you compare TRUE and FALSE values using the OR operator.

Table 7.8  Truth Table for the OR Operator

<table>
<thead>
<tr>
<th>OR</th>
<th>True</th>
<th>False</th>
<th>Unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>True</td>

<td>True</td>
</tr>
<tr>
<td>False</td>
<td>True</td>
<td>False</td>
<td>Unknown</td>
</tr>
<tr>
<td>Unknown</td>
<td>True</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

**<sql-expression>**

specifies any valid SQL expression.

See  “<sql-expression> Expression” on page 820

**Details**

The search condition specifies which rows are returned in a result set for a SELECT statement. Within the SELECT statement, the search condition is used in the WHERE clause, the HAVING clause, and the ON clause with joins.

The order of precedence for the logical operators is NOT, AND, and then OR, but you can override the order by using parentheses. Everything within the parentheses is evaluated first to yield a single value before that value can be used by any operator outside of the parentheses.

There can be precision issues when REAL values are involved in a search condition. To avoid these issues, it is recommended that you define or create a cast for the value in the condition. In other words, wherever the value is used in the original query, force a cast with this syntax.

CAST (value AS type)

Here are some examples:

```sql
select * from test where x = cast (1.0e20 as real);
select cast (1.0e20 as real) from test;
select cast (col1 as real) from test;
```

**Note:** The search condition is also used with the “UPDATE Statement” on page 904 and the “DELETE Statement” on page 859. For the UPDATE statement, the search specification specifies which rows are updated. For the DELETE statement, the search specification specifies which rows are deleted.
UPDATE Statement

Modifies a column’s values in existing rows of a table.

Syntax

```
UPDATE table
{
    SET column=<sql-expression> [, …column=<sql-expression>]
    | column=value-expression [, …column=value-expression]
}
[WHERE <sql-expression> | value-expression];
```

Arguments

table
specifies a table name.

Restriction: A Teradata table must have a primary key defined to be updated with the UPDATE statement.

column
specifies a column name.

<sql-expression>
specifies any valid SQL expression.

Note: FedSQL does not currently support the use of subqueries as inner queries for writing to MongoDB.

See: "<sql-expression> Expression" on page 820
The UPDATE statement changes the values in all or part of an existing row in a table.

The SET clause specifies which columns to modify and the values to assign them. Columns that are not SET retain their previous values. In the SET clause, a column reference on the left side of the equal sign can also appear as part of the expression on the right side of the equal sign. The SET clause uses the current value of the column in the expression. For example, you could use this expression to give employees a $1,000 holiday bonus.

```sql
update payroll set salary = salary + 1000;
```

The WHERE clause enables you to choose which rows to update. If you omit the WHERE clause, then all the rows are updated. When you use a WHERE clause, only the rows that meet the WHERE clause condition are updated.

**Note:** If row-level permissions are in effect for the table, you cannot update rows in the table. Row-level security is available only with SAS Federation Server. For more information about row-level security, see the SAS Federation Server documentation.

The DELETE statement enables you to delete rows from a table. The INSERT statement enables you to insert new rows into a table. The UPDATE statement enables you to change rows in a table.

Overview of Statement Table Options

About FedSQL Statement Table Options

FedSQL statement table options specify actions that apply only to the table with which they appear. They enable you to perform operations such as specifying a password for a SAS file and renaming columns.

You can specify table options in a FedSQL statement in which you specify a table name, such as the CREATE TABLE, ALTER TABLE, or SELECT statement.

Restrictions

The availability and behavior of FedSQL statement options are data-source specific.

How Table Options Interact with Other Types of Options

Many types of options share the same name and have the same function. For example, you can compress a SAS data set by specifying the COMPRESS= table option as a connection string option and as a FedSQL statement table option.

When more than one type of option with the same function is specified, the software follows the following order of precedence:

1. FedSQL statement table option
2. data source connection string option
For example, if a connection string includes COMPRESS=NO, and a FedSQL statement includes the table option COMPRESS=YES, then the table option overrides the connection string specification for the named table.

If you are submitting FedSQL statements in a Base SAS session, the following order of precedence applies:

1  FedSQL statement option
2  LIBNAME statement option
3  data source connection string option
4  system option

That is, FedSQL statement table options override a LIBNAME statement option, which overrides a data source connection string option.

FedSQL Statement Table Option Syntax

Specify a FedSQL statement table option immediately after the table name, within braces (that is, { }) and including the keyword OPTIONS. To specify several table options, separate them with spaces or commas.

CAUTION
While specifying the syntax for table options, you cannot have a space between the left brace { and the OPTIONS keyword. A space results in a syntax error. For example, this statement is correct:

```sql
create table temp {options dbcreate_table_opts='primary index(b)'}
(a int, b int);
```

The following statement, however, is incorrect and results in an error message:

```sql
create table temp { options dbcreate_table_opts='primary index(b)'}
(a int, b int);
```

```sql
{OPTIONS option-1=value [... option-n=value]}
```

These examples show table options in FedSQL statements:

```sql
create table salary {options encrypt=yes read=green};

select * from salary {options read=green};
```

Understanding BULKLOAD Table Options

Table options that are related to bulk loading are available only when the FedSQL language processes the call, as opposed to when the driver uses the native SQL language. The FedSQL language processor is used over native SQL to process
requests that create tables or insert data from multiple data sources. In order for the
table options to be enforced, the data source that supports them must be specified
in the CREATE TABLE or INSERT INTO part of the query. The FedSQL language
processor is also used to process CREATE TABLE and INSERT statements for a
single data source when the requests specify a SAS function.

Bulk loading is initiated with the BULKLOAD= table option. Data source-specific
bulk-loading table options are specified in the BULKOPTS= table option.

FedSQL Statement Table Options by Data Source

The following table lists the table options that are supported in FedSQL programs by
the data source that supports them. The options are listed alphabetically for each
data source.

<table>

## Dictionary

### ALTER= Table Option

Assigns an ALTER password to a data set that prevents users from replacing or deleting the file, and enables access to a Read- or Write-protected file.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SAS data set, SPD Engine data set

**Note:** Check your log after this operation to ensure that the password values are not visible. For more information, see “Blotting Passwords and Encryption Key Values” in SAS Language Reference: Concepts.

### Syntax

`ALTER= alter-password`

### Arguments

- **alter-password**
  - specifies a password.

  **Restriction**  
  `alter-password` must be a valid SAS name.
Details

The ALTER= table option applies only to a SAS data set or an SPD Engine data set. You can use this option to assign a password or to access a Read-protected, Write-protected, or alter-protected file. When you replace a data set that is protected with an ALTER password, the new data set inherits the ALTER password.

Note: A SAS password does not control access to a SAS file beyond the SAS system. You should use the operating system-supplied utilities and file-system security controls to control access to SAS files outside of SAS.

ASYNCINDEX= Table Option

Specifies to create indexes in parallel when creating multiple indexes on an SPD Engine data set.

Valid in: CREATE INDEX Statement
Category: User Control of Index Usage
Restriction: This table option is not supported on the CAS server.
Data source: SPD Engine data set

Syntax

ASYNCINDEX= YES | NO

Arguments

YES
creates the indexes in parallel (asynchronously).

NO
creates one index at a time (synchronously). This is the default value.

Details

The SPD Engine can create multiple indexes for a data set at the same time. The SPD Engine spawns a single thread for each index created, and then processes the threads simultaneously. Although creating indexes in parallel is much faster than creating one index at a time, the default for this option is NO. Parallel creation requires additional utility work space and additional memory, which might not be available. If the index creation fails due to insufficient resources, you can do one of the following:

- set the SAS system option to MEMSIZE=0
- increase the size of the utility file space using the SPDEUTILLOC= system option

You increase the memory space that is used for index sorting using the SPDEINDEXSORTSIZE= system option. If you specify to create indexes in parallel, specify a large-enough space using the SPDEUTILLOC= system option.
BL_ALLOW_READ_ACCESS= Table Option

Specifies that the original table data is still visible to readers during bulk load.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945

Data source: DB2 under UNIX and PC

Syntax

BL_ALLOW_READ_ACCESS= YES | NO

Arguments

YES

specifies that the original (unchanged) data in the table is still visible to readers while bulk load is in progress.

NO

specifies that readers cannot view the original data in the table while bulk load is in progress. This is the default value.

Details

For more information about using this option, see the SQUU_ALLOW_READ_ACCESS parameter in IBM DB2 Universal Database Data Movement Utilities Guide and Reference.

Table Options:

- “BULKLOAD= Table Option” on page 943

BL_COPY_LOCATION= Table Option

Specifies the directory to which DB2 saves a copy of the loaded data.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945

Data source: DB2 under UNIX and PC
Syntax

**BL_COPY_LOCATION**= *pathname*

Arguments

*pathname*  
specifies the path where the loaded data is copied.

Table Options:
- "BL_RECOVERABLE= Table Option" on page 936
- "BULKLOAD= Table Option" on page 943

---

**BL_CPU_PARALLELISM= Table Option**

Specifies the number of processes or threads to use when building table objects.

<table>
<thead>
<tr>
<th>Category</th>
<th>Bulk Loading</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restriction</td>
<td>This table option is not supported on the CAS server.</td>
</tr>
<tr>
<td>Requirement</td>
<td>Must be specified within the “BULKOPTS= Table Option” on page 945</td>
</tr>
<tr>
<td>Data source</td>
<td>DB2 under UNIX and PC</td>
</tr>
</tbody>
</table>

Syntax

**BL_CPU_PARALLELISM**= *number-of-processes-or-threads*

Arguments

*number-of-processes-or-threads*  
specifies the number of processes or threads that the load utility uses to parse, convert, and format data records when building table objects.

Details

This option exploits intrapartition parallelism and significantly improves load performance. It is particularly useful when loading presorted data, because record order in the source data is preserved.

The maximum number that is allowed is 30. If the value is 0 or has not been specified, the load utility selects an intelligent default. This default is based on the number of available CPUs on the system at run time. If there is insufficient memory to support the specified value, the utility adjusts the value.

When **BL_CPU_PARALLELISM** is greater than 1, the flushing operations are asynchronous, permitting the loader to exploit the CPU. If tables include either LOB or LONG VARCHAR data, parallelism is not supported. The value is set to 1, regardless of the number of system CPUs or the specified value.
Although use of this parameter is not restricted to symmetric multiprocessor (SMP) hardware, you might not obtain any discernible performance benefit from using it in non-SMP environments.

For more information about using BL_CPU_PARALLELISM=, see the CPU_PARALLELISM parameter in *IBM DB2 Universal Database Data Movement Utilities Guide and Reference*.

Table Options:

- “BL_DATA_BUFFER_SIZE= Table Option” on page 926
- “BL_DISK_PARALLELISM= Table Option” on page 928
- “BULKLOAD= Table Option” on page 943

---

**BL_DATA_BUFFER_SIZE= Table Option**

Specifies the total amount of memory to allocate for the bulk load utility to use as a buffer for transferring data.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945

Data source: DB2 under UNIX and PC

Syntax

```
BL_DATA_BUFFER_SIZE= buffer-size
```

Arguments

**buffer-size**

specifies the total amount of memory (in 4KB pages) that is allocated for the bulk load utility to use as buffered space for transferring data within the utility. This setting does not consider the degree of parallelism that is available.

Details

If you specify a value that is less than the algorithmic minimum, the minimum required resource is used and no warning is returned. This memory is allocated directly from the utility heap, the size of which you can modify through the util_heap_sz database configuration parameter. If you do not specify a value, the utility calculates an intelligent default at run time. The calculation is based on a percentage of the free space that is available in the utility heap at the time of instantiation of the loader, as well as some characteristics of the table.

It is recommended that the buffer be several extents in size. An *extent* is the unit of movement for data within DB2, and the extent size can be one or more 4KB pages.
The DATA BUFFER parameter is useful when you are working with large objects (LOBs) because it reduces input and output waiting time. The data buffer is allocated from the utility heap. Depending on the amount of storage that is available on your system, you should consider allocating more memory for use by the DB2 utilities. You can modify the database configuration parameter util_heap_sz accordingly. The default value for the Utility Heap Size configuration parameter is 5,000 4KB pages. Because load is one of several utilities that use memory from the utility heap, it is recommended that no more than 50% of the pages that are defined by this parameter be made available for the load utility.

For more information about using this option, see the DATA BUFFER parameter in IBM DB2 Universal Database Data Movement Utilities Guide and Reference.

- “BL_DISK_PARALLELISM= Table Option” on page 928
- “BULKLOAD= Table Option” on page 943

BL_DEFAULT_DIR= Table Option

Specifies the location where bulk load creates all intermediate files.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945

Data source: Oracle

Syntax

BL_DEFAULT_DIR= host-specific-directory-path

Arguments

host-specific-directory-path

specifies the host-specific directory path where intermediate bulk-load files are created. The default is the current directory.

Details

The value that you specify for this option is prepended to the filename. Be sure to provide the complete, host-specific directory path, including the file and directory separator character to accommodate all platforms.
BL_DISK_PARALLELISM= Table Option

Specifies the number of processes or threads to use when writing data to disk.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
Data source: DB2 under UNIX and PC

Syntax

```
BL_DISK_PARALLELISM= number-of-processes-or-threads
```

Arguments

`number-of-processes-or-threads`

specifies the number of processes or threads that the load utility uses to write data records to the table-space containers.

Details

This option exploits the available containers when it loads data and significantly improves load performance.

The maximum number that is allowed is the greater of four times the BL_CPU_PARALLELISM value, which the load utility actually uses, or 50. By default, BL_DISK_PARALLELISM is equal to the sum of the table-space containers on all table spaces that contain objects for the table that is being loaded except where this value exceeds the maximum number that is allowed.

If you do not specify a value, the utility selects an intelligent default that is based on the number of table-space containers and the characteristics of the table.

For more information about using this option, see the DISK_PARALLELISM parameter in *IBM DB2 Universal Database Data Movement Utilities Guide and Reference*.

- “BL_CPU_PARALLELISM= Table Option” on page 925
- “BULKLOAD= Table Option” on page 943
## BL_ERRORS= Table Option

Specifies that, after the indicated number of errors is received, the load should stop.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** Oracle

### Syntax

```
BL_ERRORS= number
```

### Arguments

- **number**
  - Specifies the number of errors that should be received before the load stops. The default is 1000000 errors.

### See Also

- **Table Options:**
  - “BULKLOAD= Table Option” on page 943

## BL_EXCEPTION= Table Option

Specifies the exception table into which rows in error are copied.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** DB2 under UNIX and PC

### Syntax

```
BL_EXCEPTION= exception-table-name
```

### Arguments

- **exception-table-name**
  - Specifies the exception table into which rows in error are copied.
Details

Any row that is in violation of a unique index or a primary key index is copied. DATALINK exceptions are also captured in the exception table. If you specify an unqualified table name, the table is qualified with the CURRENT SCHEMA. Information that is written to the exception table is not written to the dump file. In a partitioned database environment, you must define an exception table for those partitions on which the loading table is defined. However, the dump file contains rows that cannot be loaded because they are not valid or contain syntax errors.

For more information about using this option, see the FOR EXCEPTION parameter in IBM DB2 Universal Database Data Movement Utilities Guide and Reference. For more information about the load exception table, see the load exception table topics in IBM DB2 Universal Database Data Movement Utilities Guide and Reference and IBM DB2 Universal Database SQL Reference, Volume 1.

See Also

Table Options:
- “BULKLOAD= Table Option” on page 943

BL_INDEXING_MODE= Table Option

Specifies which scheme the DB2 load utility should use for index maintenance.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
Data source: DB2 under UNIX and PC

Syntax

BL_INDEXING_MODE= AUTOSELECT | REBUILD | INCREMENTAL | DEFERRED

Arguments

AUTOSELECT
  specifies that the load utility automatically decides between REBUILD or INCREMENTAL mode.

REBUILD
  specifies that all indexes are rebuilt.

INCREMENTAL
  specifies that indexes are extended with new data.

DEFERRED
  specifies that the load utility does not attempt index creation. Indexes are marked as needing a refresh.
Details
For more information about using the values for this option, see IBM DB2 Universal Database Data Movement Utilities Guide and Reference.

See Also
Table Options:
- “BLLOAD= Table Option” on page 943

BL_LOAD= Table Option
Specifies that, after the indicated number of rows is loaded, the load should stop.

Category:        Bulk Loading
Restriction:     This table option is not supported on the CAS server.
Requirement:     Must be specified within the “BULKOPTS= Table Option” on page 945
Data source:     Oracle

Syntax
BL_LOAD= number-of-rows

Arguments
number-of-rows specifies the number of rows that should be loaded. The first rows from the table will be loaded. The default is to load all rows.

See Also
Table Options:
- “BLLOAD= Table Option” on page 943

BL_LOAD_REPLACE= Table Option
Specifies whether DB2 appends or replaces rows during bulk loading.

Category:        Bulk Loading
Restriction:     This table option is not supported on the CAS server.
Requirement:     Must be specified within the “BULKOPTS= Table Option” on page 945
Data source:     DB2 under UNIX and PC
Syntax

`BL_LOAD_REPLACE= NO | YES`

Arguments

**NO**
specifies that the CLI LOAD interface appends new rows of data to the DB2 table. This is the default value.

**YES**
specifies that the CLI LOAD interface replaces the existing data in the table.

See Also

Table Options:

- “BULKLOAD= Table Option” on page 943

---

**BL_LOG= Table Option**

Identifies a log file that contains information such as statistics and error information for a bulk load.

**Category:** Bulk Loading  
**Restriction:** This table option is not supported on the CAS server.  
**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945  
**Data source:** DB2 under UNIX and PC, Oracle

Syntax

`BL_LOG= "path-and-log-file-name"`

Arguments

**path-and-log-file-name**
is a file to which information about the loading process is written. The default path and log filename is DBMS-specific.

Details

When the DBMS bulk load facility is invoked, it creates a log file. The contents of the log file are DBMS-specific. The BL_ prefix distinguishes this log file from the one created by the SAS log. If the BL_LOG= table option is specified with the same path and filename as an existing log, the new log replaces the existing log.

If the BL_LOG= table option is not specified, the log file is deleted automatically after a successful operation.
Example

The BL_LOG= table option is specified within the BL_BULKOPTS= table option:

```
bulkload=yes; bulkopts=(bl_log="c:\temp\bulkload.log");
```

See Also

**Table Options:**
- “BULKLOAD= Table Option” on page 943

---

**BL_LOGFILE= Table Option**

Specifies the filename for the bulk load log file.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** Oracle

**Syntax**

```
BL_LOGFILE='log-file-name'
```

**Arguments**

- **log-file-name**
  - specifies a name for the bulk load log file. The default is a generated filename that has the template `BL_TablenameUniquenumber`.

See Also

**Table Options:**
- “BULKLOAD= Table Option” on page 943

---

**BL_OPTIONS= Table Option**

Passes options to the DBMS bulk load facility, affecting how it loads and processes data.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** DB2 under UNIX and PC
Syntax
BL_OPTIONS= 'option [ …option ]'

Arguments
option
specifies a valid DB2 option. By default, no options are passed.

Details
The BL_OPTIONS= table option enables you to pass options to the DBMS bulk load facility when it is invoked, thereby affecting how data is loaded and processed. You must separate multiple options with commas and enclose the entire string of options in single quotation marks.

This option passes DB2 file type modifiers to DB2 LOAD or IMPORT commands to affect how data is loaded and processed. Not all DB2 file type modifiers are appropriate for all situations. You can specify one or more DB2 file type modifiers with .IXF files. For a list of file type modifiers, see the description of the LOAD and IMPORT utilities in DB2 Data Movement Utilities Guide and Reference.

Example
This option is specified within the BULKOPTS= table option:

```
bulkload=yes; bulkopts=(bl_options='option1, option2');
```

See Also

Table Options:
- “BULKLOAD= Table Option” on page 943

---

**BL_PARALLEL Table Option**

Specifies whether to perform a parallel bulk load.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945

**Data source:** Oracle

**Syntax**

BL_PARALLEL= YES | NO
Arguments

**YES**
specifies that a parallel load should be performed.

**NO**
specifies that a parallel load is not performed. That is the default behavior.

See Also

**Table Options:**

- “BULKLOAD= Table Option” on page 943

---

### BL_PORT_MAX= Table Option

Sets the highest available port number for concurrent uploads.

**Category:** Bulk Loading  
**Restriction:** This table option is not supported on the CAS server.  
**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945  
**Data source:** DB2 under UNIX and PC

**Syntax**

```plaintext
BL_PORT_MAX= integer
```

**Arguments**

**integer**
specifies a positive integer that represents the highest available port number for concurrent uploads.

See Also

**Table Options:**

- “BULKLOAD= Table Option” on page 943

---

### BL_PORT_MIN= Table Option

Sets the lowest available port number for concurrent uploads.

**Category:** Bulk Loading  
**Restriction:** This table option is not supported on the CAS server.  
**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
Syntax

BL_PORT_MIN= integer

Arguments

integer specifies a positive integer that represents the lowest available port number for concurrent uploads.

See Also

Table Options:
- "BULKLOAD= Table Option" on page 943

---

BL_RECOVERABLE= Table Option

Specifies whether the LOAD process is recoverable.

Syntax

BL_RECOVERABLE= YES | NO

Arguments

YES specifies that the LOAD process is recoverable. For DB2, YES also specifies that BL_COPY_LOCATION= should specify the copy location for the data.

NO specifies that the LOAD process is not recoverable.

Details

DB2 under UNIX and PC Hosts: The default is NO.

Oracle: The default is YES. Set this option to NO to improve direct load performance. Specifying NO adds the UNRECOVERABLE keyword before the LOAD keyword in the control file.
Be aware that an unrecoverable load does not log loaded data into the redo log file. Therefore, media recovery is disabled for the loaded table. For more information about the implications of using the UNRECOVERABLE parameter in Oracle, see your Oracle utilities documentation.

See Also

Table Options:
- “BL_COPY_LOCATION= Table Option” on page 924
- “BULKLOAD= Table Option” on page 943

BL_REMOTE_FILE= Table Option

Specifies the base filename and location of DB2 LOAD temporary files.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
Data source: DB2 under UNIX and PC

Syntax

BL_REMOTE_FILE= pathname-and-base-filename

Arguments

pathname-and-base-filename
specifies the full pathname and base filename to which DB2 appends extensions (such as .log, .msg and .dat files) to create temporary files during load operations. By default, BL_<table>_<unique-ID> is the form of the base filename.

  table
  specifies the table name.

  unique-ID
  specifies a number that prevents collisions in the event of two or more simultaneous bulk loads of a particular table. The table driver generates this number.

Details

When you specify this option, the DB2 LOAD command is used (instead of the IMPORT command).

For pathname, specify a location on a DB2 server that is accessed exclusively by a single DB2 server instance, and for which the instance owner has Read and Write permissions. Make sure that each LOAD command is associated with a unique pathname-and-base-filename value.
See Also

**Table Options:**
- “BULKLOAD= Table Option” on page 943

---

**BL_SKIP= Table Option**

Specifies to skip the indicated number of rows before starting the bulk load.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** Oracle

**Syntax**

**BL_SKIP=** *number-of-rows*

**Arguments**

*number-of-rows*

specifies the number of rows to skip before beginning the load. The default is 0, which means that no records are skipped.

See Also

**Table Options:**
- “BULKLOAD= Table Option” on page 943

---

**BL_SKIP_INDEX_MAINTENANCE= Table Option**

Specifies whether to perform index maintenance on the bulk load.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** Oracle

**Syntax**

**BL_SKIP_INDEX_MAINTENANCE=** **YES | NO**
Arguments

YES
specifies to stop index maintenance on the load. This causes the index partitions that would have had index keys added to them to be marked Index Unusable. The index segment is inconsistent with the data it indexes. Index segments that are not affected by the load retain the Index Unusable state that they had prior to the load.

NO
specifies that index maintenance is performed on the load. This is the default value.

See Also

Table Options:
- “BULKLOAD= Table Option” on page 943

BL_SKIP_UNUSABLE_INDEXES= Table Option

Specifies whether to skip index entries that are in an unusable state and continue with the bulk load.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
Data source: Oracle

Syntax

BL_SKIP_UNUSABLE_INDEXES= YES | NO

Arguments

YES
specifies that the unusable index entry should be skipped. This is the default value.

NO
specifies that the unusable index entry should not be skipped.

Details

If an index in an Index Unusable state is encountered, by default, it is skipped and the load operation continues. This allows the SQL*Loader to load a table with indexes that are in an unusable state before beginning the load. Indexes that are not in an unusable state at load time are maintained by the SQL*Loader. Indexes that are in an unusable state at load time are not maintained and remain in an unusable state at load completion.
If this bulk load option is not specified, the default value is specified in the Oracle database configuration parameter, SKIP_UNUSABLE_INDEXES. This value is specified in the initialization parameter file. The BL_SKIP_UNUSABLE_INDEXES bulk load table option overrides the value of the SKIP_UNUSABLE_INDEXES configuration parameter in the initialization parameter file.

Table Options:

- “BULKLOAD= Table Option” on page 943

---

**BL_WARNING_COUNT= Table Option**

Specifies the maximum number of row warnings to allow before the load fails.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945

**Data source:** DB2 under UNIX and PC

**Syntax**

```
BL_WARNING_COUNT= number-of-warnings
```

**Arguments**

`number-of-warnings`

specifies the maximum number of row warnings to allow before the load fails.

**Details**

To specify this option, you must first set BULKLOAD=YES and also specify a value for BL_REMOTE_FILE=.

Use this option to limit the maximum number of rows that generate warnings. See the log file for information about why the rows generated warnings.

Table Options:

- “BLREMOTE_FILE= Table Option” on page 937
- “BULKLOAD= Table Option” on page 943
**BUFNO= Table Option**

Specifies the number of buffers to be allocated for processing a SAS data set.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SAS data set

### Syntax

\[ \text{BUFNO=} n \mid nK \mid \text{hexX} \mid \text{MIN} \mid \text{MAX} \]

### Arguments

- **\( n \mid nK \)**
  - Specifies the number of buffers in multiples of 1 (bytes); 1,024 (kilobytes). For example, a value of 8 specifies 8 buffers, and a value of 1K specifies 1,024 buffers.
  - **Requirement:** \( K \) must be uppercased.

- **\( \text{hexX} \)**
  - Specifies the number of buffers as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by an \( X \). For example, the value 2dX sets the number of buffers to 45 buffers.
  - **Requirement:** \( X \) must be uppercased.

- **MIN**
  - Sets the minimum number of buffers to 0, which causes SAS to use the minimum optimal value for the operating environment. This is the default value.

- **MAX**
  - Sets the number of buffers to the maximum possible number in your operating environment, up to the largest four-byte, signed integer. The largest four-byte, signed integer is \( 2^{31} - 1 \), or approximately 2 billion.

### Details

The buffer number is not a permanent attribute of the data set; it is valid only for the current operation.

The BUFNO= table option applies to SAS data sets that are opened for input, output, or update.

A larger number of buffers can speed up execution time by limiting the number of input and output (I/O) operations that are required for a particular SAS data set. However, the improvement in execution time comes at the expense of increased memory consumption.

To reduce I/O operations on a small data set as well as speed execution time, allocate one buffer for each page of data to be processed. This technique is most effective if you read the same observations several times during processing.
BUFSIZE= Table Option

Specifies the size of a permanent buffer page for an output SAS data set.

Category: Table Control

Restrictions: This table option is not supported on the CAS server.
Use with output data sets only.

Data source: SAS data set

Syntax

\[ \text{BUFSIZE}= n \mid nK \mid nM \mid nG \mid \text{hexX} \mid \text{MIN} \mid \text{MAX} \]

Arguments

\[ n \mid nK \mid nM \mid nG \]

specifies the page size in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). For example, a value of 8 specifies a page size of 8 bytes, and a value of 4k specifies a page size of 4096 bytes.

Requirement \( K, M, \text{ and } G \) must be uppercased.

\[ \text{hexX} \]

specifies the page size as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by an X. For example, the value 2dx sets the page size to 45 bytes.

Requirement \( X \) must be uppercased.

\[ \text{MIN} \]

sets the minimum number of buffers to 0, which causes SAS to use the minimum optimal value for the operating environment.

\[ \text{MAX} \]

sets the page size to the maximum possible number in your operating environment, up to the largest four-byte, signed integer. The largest four-byte, signed integer is \( 2^{31} - 1 \), or approximately 2 billion bytes.

Details

The page size is the amount of data that can be transferred for a single I/O operation to one buffer. The page size is a permanent attribute of the data set and is used when the data set is processed.

A larger page size can speed up execution time by reducing the number of times SAS has to read from or write to the storage medium. However, the improvement in execution time comes at the cost of increased memory consumption.

To change the page size, copy the data set and either specify a new page or use the SAS default. To reset the page size to the default value in your operating environment, specify BUFSIZE=0.
Operating Environment Information: The default value for the BUFSIZE= table option is determined by your operating environment and is set to optimize sequential access. To improve performance for direct (random) access, you should change the value for BUFSIZE=.

BULKLOAD= Table Option
Determines whether SAS uses a DBMS facility to insert data into a DBMS table.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Interaction: Used in conjunction with "BULKOPTS= Table Option" on page 945.
Data source: DB2 under UNIX and PC, Google BigQuery, Impala, MDS, Oracle, Teradata

Syntax
BULKLOAD= YES | NO

Arguments
YES
- calls a DBMS-specific bulk-load facility in order to insert or append rows to a DBMS table.

NO
- does not call the DBMS-specific bulk-load facility. This is the default value.

Details
Overview
Using BULKLOAD=YES is the fastest way to insert rows into a DBMS table.

You can specify data source-specific options in the BULKOPTS= table option (BL_BULKOPTS= for Oracle). BULKOPTS= functions as a container for the data source-specific options. For more information, see "BULKOPTS= Table Option" on page 945.

When the BULKLOAD= table option is not set, a simple multi-row insert SQL scheme is used to insert data rows.

Usage Notes
Google BigQuery

There are two ways to set bulk-loading options for Google BigQuery in a SAS session:
- in the LIBNAME statement for the BIGQUERY engine. When bulk-loading options are set in the LIBNAME statement, they are automatically propagated to the FEDSQL procedure. Bulk-loading options that are specified this way apply to all Insert operations in the SAS session.
by specifying the BULKLOAD=YES and BULKOPTS=(options) table options. The table option settings override the LIBNAME option settings. See “Bulk Loading for Google BigQuery” in SAS/ACCESS for Relational Databases: Reference for valid Google BigQuery bulk-load options.

The first method applies only to Google BigQuery. Bulk loading for other FedSQL data sources is requested by using the table options.

Impala

Bulk loading to the Impala server can be accomplished in two ways: you can use the WebHDFS interface to Hadoop to push data to HDFS, or you can configure a required set of Hadoop JAR files. Both approaches require Hadoop configuration files needed by SAS to be in one location and available to the client machine. To use WebHDFS, you must additionally set the SAS_HADOOP_RESTFUL= environment variable to 1. To use Java, you must make the Hadoop JAR location known to the client machine and ensure that the SAS_HADOOP_RESTFUL= environment variable is not set to 1 (or TRUE or YES).

Specifying BULKLOAD=YES causes two CREATE TABLE statements to be issued to the Impala server. One creates the target Impala table. The other creates a temporary table. SAS uses WebHDFS to upload table data to the HDFS /tmp directory. The resulting file is a UTF-8 delimited text file. SAS issues a LOAD DATA statement to move the data file from the /tmp directory to the temporary table, and then issues an INSERT INTO statement that copies and transforms the text data from the temporary table to the target table. The temporary table is then deleted from HDFS.

MDS

BULKLOAD= is available for insert operations only. When the BULKLOAD= table option is set, newly inserted rows are committed immediately and become visible to existing transactions. When the BULKLOAD= table option is not set, newly inserted rows are not visible until the existing transactions are committed or rolled back.

Teradata

Specifying BULKLOAD=YES invokes the Teradata Parallel Transporter (TPT) API protocol driver. The default TPT operator is the Stream operator. Use the BULKOPTS= table option to specify a different TPT operator.

Example

```
create table mylib.myexample {options BULKLOAD=YES
   BULKOPTS=(BL_DELETE_DATAFILE=NO)}(col1 float);
```

See Also

Concepts:

- “FedSQL Statement Table Options by Data Source” on page 911

Table Options:

- “BULKOPTS= Table Option” on page 945
BULKOPTS= Table Option

Provides a container for bulk-loading options.

Category: Bulk Loading
Alias: In Oracle, this option has the name BL_BULKOPTS=
Restriction: This table option is not supported on the CAS server.
Requirement: BULKLOAD=YES must be set in order to use BULKOPTS=
Data source: DB2 under UNIX and PC, Google BigQuery, Impala, Oracle, Teradata

Syntax

BULKOPTS= (option[ ...option])

Arguments

option[ ...option]
  specifies one or more bulk load table options separated by spaces.

Details

To specify BULKOPTS= table option, you must first specify BULKLOAD=YES. For more information, see “BULKLOAD= Table Option” on page 943.

The BULKOPTS= table option is a container option that is required in order to specify other bulk load table options.

Bulk load options are data source-specific. See “FedSQL Statement Table Options by Data Source” on page 911 for a list of the options that can be specified in this container for each data source.

Google BigQuery users: FedSQL supports the same bulk-load options as the SAS/ACCESS to Google BigQuery LIBNAME engine. See “Bulk Loading for Google BigQuery” in SAS/ACCESS for Relational Databases: Reference for valid options.

Examples:

Example 1

The following example uses the BULKLOAD=YES and BULKOPTS= table options to submit bulk-loading options to DB2 under UNIX and PC:

```
BULKLOAD=YES BULKOPTS=(BL_LOG='c:\temp\bulkload.log' BL_LOAD_REPLACE=yes BL_OPTIONS='ERRORS=999, LOAD=2000');
```

Example 2

The following example uses the BULKLOAD=YES and BL_BULKOPTS= options to submit bulk-loading options to Oracle:

```
BULKLOAD=YES BL_BULKOPTS=(BL_DEFAULT_DIR='C:\mylogs' BL_LOGFILE='novemberdatalog' BL_ERRORS=999)
```
Example 3

The following example uses the BULKLOAD=YES and BULKOPTS= options to submit bulk-loading options to Teradata. The Teradata Parallel Transporter (TPT) is used to load data into Teradata tables when BULKLOAD=YES. The TPT job uses the Stream operator by default. In the example below, the TD_TPT_OPER= table option specifies to use the Load operator instead, among other things.

BULKLOAD=YES  BULKOPTS=(TD_TPT_OPER=LOAD  
TD_ERROR_LIMIT=1  
TD_TRACE_OUTPUT=tpttrace  
TD_TRACE_LEVEL=TD_OPER_ALL  
TD_MAX_SESSIONS=8  
TD_TRACE_LEVEL_INF=TD_OPER_ALL)

Example 4

The following example uses the BULKLOAD=YES and BULKOPTS= options to submit bulk-loading options to Impala. The bulk load request will use WebHDFS to load the data to HDFS. Note that the SAS_HADOOP_RESTFUL= environment variable must also be set to 1 for the request to succeed.

BULKLOAD=YES  BULKOPTS=(USER=HDFS  
PASS="hdfs-pwd"  
CONFIG="my-config-path")

Example 5

The following example uses the BULKLOAD=YES and BULKOPTS= options to submit bulk-load options to Google BigQuery. The Google BigQuery loader client application is used to move data from the client to the Google BigQuery database. Valid bulk-load options are documented in “Bulk Loading Data in Google BigQuery” in SAS/ACCESS for Relational Databases: Reference.

BULKLOAD=YES  BULKOPTS=(BL_DELETE_DATA_FILE=NO;BL_DEFAULT_DIR='/u/myid/temp')

Table Options:
- “TD_TPT_OPER= Table Option” on page 998
- “CONFIG= Table Option” on page 948

COMPRESS= Table Option

Specifies how rows are compressed in a new output data set or table.

Category: Table Control

Restrictions: This table option is not supported on the CAS server. Use with output tables only.

Data source: SAS data set, SPD Engine data set, SPD Server table

Syntax

COMPRESS= NO | YES | CHAR | BINARY
Arguments

**CHAR | YES**
specifies that the rows in a newly created table are compressed (variable length records). SAS data sets are compressed by using Run Length Encoding (RLE). RLE compresses rows by reducing repeated consecutive characters (including blanks) to two-byte or three-byte representations. SPD Engine data sets are compressed by using the run length compression algorithm SPDSRLC2. SPD Server tables are compressed by using the run-length compression algorithm SPDSRLLC.

**Alias**
ON (SPD Engine data set only)

**Tip**
Use this compression algorithm for character data.

**BINARY**
specifies that the rows in a newly created data set or table are compressed by SAS using Ross Data Compression (RDC). RDC combines run-length encoding and sliding-window compression to compress the file. SPD Engine data sets are compressed by the SPD Engine by using SPDSRDC.

**Tip**
This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (numeric variables). Because the compression function operates on a single record at a time, the record length needs to be several hundred bytes or larger for effective compression.

**NO**
specifies that the rows in a newly created table are uncompressed (fixed-length records).

Details

Compressing a table is a process that reduces the number of bytes required to represent each row. Advantages of compressing a table include reduced storage requirements for the table and fewer I/O operations necessary to read or write to the data during processing. However, more CPU resources are required to read a compressed table (because of the overhead of uncompressing each row). Also, there are situations where the resulting file size might increase rather than decrease.

Use the COMPRESS= table option to compress an individual table. Specify the option for an output table only—that is, a table name on the CREATE TABLE statement.

---

**Note:** In SPD Engine data sets and SPD Server tables, encryption and compression are mutually exclusive. You cannot specify encryption for a compressed SPD Engine data set or SPD Server table. You cannot compress an encrypted SPD Engine data set or SPD Server table.

---

After a table is compressed, the setting is a permanent attribute of the table, which means that to change the setting, you must re-create the table. That is, to uncompress a table, you must drop the table by using the DROP TABLE statement and re-create the table with the CREATE TABLE statement and the COMPRESS=NO option.
When you specify COMPRESS= to compress an SPD Engine data set or SPD Server table, the table drivers compress, by blocks, the table as it is created. To specify the size of the compressed blocks, use the “IOBLOCKSIZE= Table Option” on page 966.

The SPD Engine table driver also supports the PADCOMPRESS= table option when creating or updating the SPD Engine data set. The PADCOMPRESS= option enables you to add padding to the newly compressed blocks. See the “PADCOMPRESS= Table Option” on page 971.

Comparisons
The COMPRESS= table option overrides the COMPRESS= connection string option.

SAS data sets only: When you create a compressed table, you can also specify the REUSE=YES table option in order to track and reuse space. With REUSE=YES, new rows are inserted in space freed when other rows are updated or deleted. When the default REUSE=NO is in effect, new rows are appended to the existing table.

See Also

Table Options:

- “ENCRYPT= Table Option” on page 955
- “POINTOBS= Table Option” on page 975
- “IOBLOCKSIZE= Table Option” on page 966
- “PADCOMPRESS= Table Option” on page 971
- “REUSE= Table Option” on page 979

CONFIG= Table Option

Specifies a file or pathname for Hadoop configuration path resolution.

Category: Bulk Loading

Alias: CFG=, HD_CONFIG=, CONFIGDIR=, CFGDIR=, HD_CONFIGDIR=

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945.

Data source: Impala

Syntax

\texttt{CONFIG=configuration-path}
Arguments

"configuration-path"

specifies the name of a single file or a directory that contains Hadoop configuration information that is required by SAS on your machine. If this option is not specified, SAS searches for the value in the SAS_HADOOP_CONFIG_PATH environment variable.

Details

The SAS_HADOOP_CONFIG_PATH environment variable can list multiple directories (defined similarly to a PATH variable) to search for configuration information. Use the CONFIG= option when you want to use a specific configuration file or to search a specific directory for configuration information.

See Also

Table Options:
- "BULKLOAD= Table Option" on page 943

DATAFILE= Table Option

Specifies an alternate name and location for the temporary HDFS file.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945.
Data source: Impala

Syntax

DATAFILE= "filename"

Arguments

"filename"

specifies the full pathname to a file. When this option is not specified, the default pathname for the temporary file is "/tmp/bl_tablename_unixtimeval.dat".

See Also

Table Options:
- "BULKLOAD= Table Option" on page 943
**DBCREATE_INDEX_OPTS= Table Option**

Allows DBMS-specific options to be added to the CREATE INDEX statement.

**Category:** Index Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** Microsoft SQL Server, ODBC

**Syntax**

```
DBCREATE_INDEX_OPTS= 'DBMS-SQL-clauses'
```

**Arguments**

**DBMS-SQL-clauses**

specifies one or more DBMS-specific clauses that can be appended to the end of an SQL CREATE INDEX statement.

**Details**

This option enables you to add DBMS-specific clauses to the end of the CREATE INDEX statement. The interface passes the CREATE INDEX statement and its clauses to the DBMS, which executes the statement and creates the DBMS index.

**Example**

In the following example, a Hive index is created with the value of the DBCREATE_INDEX_OPTS= "as 'compact' with deferred rebuild" option appended to the CREATE INDEX statement:

```
create index "COL1_1A03" on "TKTS002_1A03"{options DBCREATE_INDEX_OPTS="as 'compact' with deferred rebuild"}("COL1")
```

The following CREATE INDEX statement is passed to the DBMS in order to create the index:

```
create index 'COL1_1A03' on table 'TKTS002_1A03'('COL1') as 'compact' with deferred rebuild
```
Syntax

**DBCREATE_TABLE_OPTS= 'DBMS-SQL-clauses'**

Arguments

**DBMS-SQL-options**

specifies one or more DBMS-specific options that can be appended to the end of an SQL CREATE TABLE statement.

Details

This option enables you to add DBMS-specific options to the end of the CREATE TABLE statement. The interface passes the CREATE TABLE statement and its options to the DBMS, which executes the statement and creates the DBMS table.

The availability and behavior of FedSQL statement options are data-source specific. If DBCREATE_TABLE_OPTS= options are used in a statement other than CREATE TABLE, those options might be ignored.

Examples:

**Example 1: Google BigQuery**

In the following example, the Google BigQuery table TEMP is created with the description “table created by SAS” appended to the CREATE TABLE statement:

```sql
create table a."my_dataset".temp {option dbcreate_table_opts='options (description="table created by SAS")'}(col1 char(8));
```

The following CREATE TABLE statement is sent to the DBMS:

```sql
create table `my_project`.`my_dataset`.`TEMP` (`COL1` STRING)  
options  (description="table created by SAS")
```

**Example 2: Greenplum**

In the following example, the Greenplum table TEMP is created with the value of the DBCREATE_TABLE_OPTS='DISTRIBUTED BY ("B")' option appended to the CREATE TABLE statement:

```sql
create table temp {options dbcreate_table_opts='distributed by ("b")'}
(a int, b int);
```

The following CREATE TABLE statement is passed to the DBMS in order to create the table:

```sql
create table temp (a int, b int) distributed by ("b")
```

**Example 3: HAWQ**

In the following example, the HAWQ table TEMP is created with the value of the DBCREATE_TABLE_OPTS='DISTRIBUTED BY ("A")' option appended to the CREATE TABLE statement:
create table temp {options DBCREATE_TABLE_OPTS='DISTRIBUTED by ("A")'}(a int, b int);

The following CREATE TABLE statement is passed to the DBMS in order to create the table:

create table temp {options DBCREATE_TABLE_OPTS='DISTRIBUTED by ("A")'}(a int, b int);

Example 4: Hive

In the following example, the Hive table TEMP is created with the value of the DBCREATE_TABLE_OPTS='PARTITIONED BY ("col1")' option appended to the CREATE TABLE statement:

create table temp {options DBCREATE_TABLE_OPTS='PARTITIONED BY (col1 int)'} (col1 int, col2 int);

The following CREATE TABLE statement is passed to the DBMS in order to create the table:

create table `temp` (`COL2` int) PARTITIONED BY (col1 int)

In Hive, beginning in **9.4M5**, you can use DBCREATE_TABLE_OPTS= in combination with these related table options: PRE_TABLE_OPTS= and POST_TABLE_OPTS=. For usage information, see “PRE_TABLE_OPTS= Table Option” on page 977 and “POST_TABLE_OPTS= Table Option” on page 976. Beginning in 9.4M5, you can also use the alias POST_STMT_OPTS= instead of DBCREATE_TABLE_OPTS=. Do not specify POST_STMT_OPTS= and DBCREATE_TABLE_OPTS= in the same statement. Specifying both names in the same statement results in an error.

Example 5: MySQL

In the following example, the MySQL table TEMP is created with the value of the DBCREATE_TABLE_OPTS='PARTITIONING KEY (x) USING HASHING' option appended to the CREATE TABLE statement:

create table temp {option dbcreate_table_opts='partitioning key (x) using hashing'}

(x double);

The following CREATE TABLE statement is passed to the DBMS in order to create the table:

create table temp (x double) partitioning key (x) using hashing;

Example 6: Netezza

In the following example, the Netezza table TEMP is created with the value of the DBCREATE_TABLE_OPTS='DISTRIBUTE ON (b)' option appended to the CREATE TABLE statement:

create table temp {options dbcreate_table_opts='distribute on (b)'}

(a int, b int);

The following CREATE TABLE statement is passed to the DBMS in order to create the table:

create table temp (A int, B int) distribute on (b)
Example 7: Oracle

In the following example, the Oracle table TEMP is created with the value of the
DBCREATE_TABLE_OPTS='NOLOGGING' option appended to the CREATE
TABLE statement:

create table temp{options dbcreate_table_opts='nologging'}
(a int, b int)

The following CREATE TABLE statement is passed to the DBMS in order to create
the table:

create table temp (*a* number (10) , "b" number (10) ) nologging

Example 8: SAP HANA

In the following example, the SAP HANA table TEMP is created with the value of the
DBCREATE_TABLE_OPTS='PARTITION BY RANGE' option appended to the
CREATE TABLE statement:

create table temp {options table_type=column dbcreate_table_opts="partition by range (x)
(partition 1 <= values < 10, partition others)"}
(x int, y int);

The following CREATE TABLE statement is passed to the DBMS in order to create
the table:

create column table temp (x int, y int) partition by range (x)
(partition 1 <= values < 10, partition others)

Example 9: Spark

In the following example, the Spark table TEMP is created with the value of the
DBCREATE_TABLE_OPTS='PARTITIONED BY ("B")' option appended to the
CREATE TABLE statement:

create table temp {options dbcreate_table_opts='PARTITIONED by (b int)'}
(a int, b int);

The following CREATE TABLE statement is passed to the DBMS in order to create
the table:

create table temp (a int) PARTITIONED by (b int)

Example 10: Teradata

In the following example, the Teradata table TEMP is created with the value of the
DBCREATE_TABLE_OPTS='PRIMARY INDEX (B)' option appended to the
CREATE TABLE statement:

create table temp {options dbcreate_table_opts='primary index(b)'}
(a int, b int);

The following CREATE TABLE statement is passed to the DBMS in order to create
the table:

create table temp (a int, b int) primary index(b)
ENCODING= Table Option

Specifies the encoding to use when creating a SAS data set.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SAS data set

**Syntax**

```
ENCODING=encoding-value
```

**Arguments**

- **encoding-value** specifies an encoding value.

**Details**

SAS data sets are created with the session encoding by default. You can specify a different encoding for a new table by using the `ENCODING=` table option. `ENCODING=` is supported for input only. You cannot change the encoding of an existing table temporarily by specifying `ENCODING=` in the `SELECT` statement. Likewise, you cannot change the encoding of an existing table permanently by specifying it in the `UPDATE` statement.

Specify the `ENCODING=` table option in the `CREATE TABLE` statement before the columns are defined. Here is an example:

```
create table test {options encoding=ebcdic1145} (x char(8));
```

The `ENCODING=` table option is not supported with `CREATE TABLE AS`. If you specify the table option with `CREATE TABLE AS`, you get an error. The requested table will be created, but it will use the session encoding. However, if you use `CREATE TABLE AS` to insert an existing table that has an encoding specified into a new table that has no encoding specified, then the new table will have the encoding of the inserted table. For example, the following request creates table Test2 with the encoding `ebcdic1145 Spain (EBCDIC)`, which is the encoding used by table Test.

```
create table test2 as select * from test;
```
ENCRYPT= Table Option

Specifies whether to encrypt an output SAS data set.

Category: Table Control

Restrictions:
- Use with output tables only.
- This table option is not supported on the CAS server.
- In SPD Engine data sets, this table option cannot be used with COMPRESS=.

Data source: SAS data set, SPD Engine data set, SPD Server table

Syntax

ENCRYPT= | "AES" or "AES2"

Arguments

AES or AES2
encrypts the file using AES (Advanced Encryption Standard) algorithm. AES provides encryption by using SAS/SECURE software, which is included with Base SAS software. You must specify the ENCRYPTKEY= table option when you are using ENCRYPT=AES or ENCRYPT=AES2, or have a recorded key in a metadata-bound library. For more information, see “ENCRYPTKEY= Table Option” on page 957.

Restriction
SPD Engine and SPD Server do not support AES2 encryption.

Note
AES2 encryption is supported beginning with SAS 9.4M5.

CAUTION
Record all ENCRYPTKEY= values when you are using ENCRYPT=AES or ENCRYPT=AES2. If you forget to record the ENCRYPTKEY= value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= value. The following note is written to the log:

Note: If you lose or forget the ENCRYPTKEY= value, there will be no way to open the file or recover the data.

NO

does not encrypt the data set.

YES

crypts the data set using the SASProprietary algorithm. This encryption method uses passwords that are stored in the data set. At a minimum, you must specify the READ= or the PW= table option at the same time that you specify ENCRYPT=YES. For more information, see “Example: Using the ENCRYPT=YES Option” on page 956.

Note
Because the encryption method uses passwords, you cannot change any password on an encrypted file without re-creating the table.
CAUTION  Record all passwords when using ENCRYPT=YES. If you forget the passwords, you cannot reset them. This is a time-consuming and resource-intensive process.

Details

When you use ENCRYPT=YES, the following rules apply:

- If the data file is encrypted, all associated indexes are also encrypted, except for SPD Server tables. SPD Server does not encrypt table indexes or metadata. Only table row data are encrypted.
- In order to copy an encrypted data file, the output engine must support encryption. Otherwise, the data file is not copied.
- You cannot use PROC CPORT on SAS Proprietary encrypted data files.

When you use ENCRYPT=AES or ENCRYPT=AES2, the following rules apply:

- You must have SAS/SECURE software.
- You must use the ENCRYPTKEY= table option when encrypting a table.
- You must use the ENCRYPTKEY= table option to enable decryption.
- A data set encrypted with AES encryption can be decrypted only by engines that support AES encryption.
- You cannot change the ENCRYPTKEY= value on an AES encrypted data file without re-creating the data file. The AUTHLIB procedure must be used to change the recorded key of a metadata-bound library.
- In Base SAS, data files with referential integrity constraints can use AES encryption. All primary key and foreign key data files must use the same encryption key that opens all referencing foreign key and primary key data files.

If a default Base SAS data set with AES2 encryption is copied to create a new SPD Engine data set or SPD Server table, the encryption converts to AES. A warning is written to the log.

For more information about the encryption provided by SAS, see *Encryption in SAS*.

Example: Using the ENCRYPT=YES Option

This example creates an encrypted data set using the SASProprietary algorithm:

```sql
create table myfiles.salary {option encrypt=yes read=green}
  (name char(15),
   yrsal double,
   bonuspct double);
insert into myfiles.salary {option read=green} values ('Muriel', 34567, 3.2);
insert into myfiles.salary {option read=green} values ('Bjorn', 74644, 2.5);
insert into myfiles.salary {option read=green} values ('Freda', 38755, 4.1);
insert into myfiles.salary {option read=green} values ('Benny', 29855, 3.5);
insert into myfiles.salary {option read=green} values ('Agnetha', 70998, 4.1);
```

To retrieve data from the data set, you must specify the Read password:

```sql
select * from myfiles.salary {option read=green};
```

Table Options:
- "ENCRYPTKEY= Table Option" on page 957
- "PW= Table Option" on page 978
- "READ= Table Option Table Option" on page 979

ENCRYPTKEY= Table Option

Specifies a key value for AES and AES2 encryption.

<table>
<thead>
<tr>
<th>Category:</th>
<th>Table Control</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restrictions:</td>
<td>Use only with AES and AES2 encrypted data files.</td>
</tr>
<tr>
<td></td>
<td>This table option is not supported on the CAS server.</td>
</tr>
<tr>
<td>Data source:</td>
<td>SAS data set, SPD Engine data set, SPD Server table</td>
</tr>
<tr>
<td>Note:</td>
<td>Check your log after this operation to ensure that the encrypt key values are not visible.</td>
</tr>
<tr>
<td></td>
<td>For more information, see “Blotting Passwords and Encryption Key Values” in SAS Language Reference: Concepts.</td>
</tr>
</tbody>
</table>

Syntax

```
ENCRYPTKEY= [ ] ['key-value' [ ' ]]  
```

Syntax Description

`key-value`

assigns an encrypt key value. You must specify the ENCRYPTKEY= table option when you are using ENCRYPT=AES or ENCRYPT=AES2, unless you are creating a data set in a metadata-bound library with a recorded key. The key value can be up to 64 bytes long. The ENCRYPTKEY= value can be created with or without quotation marks using the following rules:

**no quotation marks**

- alphanumeric characters and underscores only
- up to 64 bytes
- uppercase and lowercase letters
- must start with a letter
- cannot include blank spaces
- is not case-sensitive

**Example**  
```
encryptkey=key_value_1234
```

**single quotation marks**

- alphanumeric, special, and DBCS characters
- up to 64 bytes
- uppercase and lowercase letters
- can include blank spaces, but cannot contain all blanks
- is case-sensitive

Example  
```plaintext
encryptkey='key-value'
encryptkey='1234*#mykey'
```

double quotation marks
- alphanumeric, special, and DBCS characters
- up to 64 bytes
- uppercase and lowercase letters
- enables macro resolution
- can include blank spaces, but cannot contain all blanks
- is case-sensitive

Example  
```plaintext
encryptkey="key-value"
encryptkey="1234*#mykey"
```

Note  
When the ENCRYPTKEY= key value uses DBCS characters, the 64-byte limit applies to the character string after it has been transcoded to UTF-8 encoding. You can use the following DATA step to calculate the length in bytes of a key value in DBCS:

```plaintext
data _null_
  key=length(unicode("key-value","UTF8"));
  put "key length=" key;
run;
```

Details

**CAUTION**

**Record the key value.** If you forget the ENCRYPTKEY= key value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value because the key value is not stored with the data set. The following warning is written to the log:

```
WARNING: If you lose or forget the ENCRYPTKEY= value, there
will be not be any way to open the file or recover the data.
```

You must use the ENCRYPTKEY= option when you are creating or accessing a SAS file with AES or AES2 encryption.

The ENCRYPTKEY= table option does not protect the file from deletion or replacement. Encrypted data sets can be deleted by using any of the following scenarios without having to specify an ENCRYPTKEY= key value:

- the KILL option in PROC DATASETS
- the DROP statement in PROC SQL
- the DELETE statement in PROC DATASETS or the DELETE procedure
- the DROP TABLE statement in FedSQL
The ENCRYPTKEY= option prevents access to the contents of the file only. To protect the file from deletion or replacement, the file must also contain an ALTER= password.

The following DATASETS procedure statements require you to specify the ENCRYPTKEY= key value when working with protected files: AGE, AUDIT, APPEND, CHANGE, CONTENTS, MODIFY, REBUILD, and REPAIR statements.

```sas
append base=name data=name(encryptkey=key-value);
run;
```

The option can be specified either in parentheses after the name of the SAS data file or after a forward slash.

It is possible to use a macro variable as the ENCRYPTKEY= key value. When you specify a macro variable for the ENCRYPTKEY= key value, you must enclose the macro variable in double quotation marks. If you do not use the double quotation marks, unpredictable results can occur. The following example defines a macro variable and uses the macro variable as the ENCRYPTKEY= key value:

```sas
%let secret=myvalue;
create table myschema.dsname {options encrypt=aes encryptkey="&secret"};
```

The following example uses the COPY statement from the DATASETS procedure and the SELECT statement:

```sas
copy in=OldLib out=NewLib;
select salary(encryptkey=key-value);
run;
```

The option can be specified either in parentheses after the name of the table or after a forward slash.

**CAUTION**

When using referential integrity constraints, all primary key and foreign key tables that reference each other must use the same encryption key. For more information, see the topic on encryption and integrity constraints in *SAS Language Reference: Concepts*.

You cannot change the key value on an AES-encrypted data file without re-creating the data file. The AUTHLIB procedure must be used to change the recorded key of a metadata-bound library.

**Example: Using the ENCRYPTKEY= Option**

This example uses the ENCRYPT=AES option to encrypt a SAS data set:

```sas
create table myfiles.salary {options encrypt=aes encryptkey="1234*#mykey"} (
  name char(15),
  yrsal double,
  bonuspct double);
insert into myfiles.salary {option encryptkey="1234*#mykey"} values ('Muriel', 34567, 3.2);
insert into myfiles.salary {option encryptkey="1234*#mykey"} values ('Bjorn', 74644, 2.5);
insert into myfiles.salary {option encryptkey="1234*#mykey"} values ('Freda', 38755, 4.1);
insert into myfiles.salary {option encryptkey="1234*#mykey"} values ('Benny', 29855, 3.5);
insert into myfiles.salary {option encryptkey="1234*#mykey"} values ('Agnetha', 70998, 4.1);
```
To retrieve data from the data set, you must specify the ENCRYPTKEY= option and the password:

```
select * from myfiles.salary {option encryptkey="1234*#mykey"};
```

**Table Options:**
- “ENCRYPT= Table Option” on page 955

---

**ENDOBS= Table Option**

Specifies the end observation number in a user-defined range of observations to be processed.

- **Valid in:** SELECT statement
- **Category:** Observation Control
- **Restrictions:** This table option is not supported on the CAS server.
  - Use with input data sets only
- **Interaction:** Use in conjunction with STARTOBS= table option
- **Data source:** SPD Engine data set, SPD Server table

**Syntax**

```
ENDOBS= n
```

**Arguments**

- `n` is the number of the end observation.

**Details**

The software processes all of the observations in the entire data set unless you specify a range of observations with the STARTOBS= or ENDOBS= options. If the STARTOBS= option is used without the ENDOBS= option, the implied value of ENDOBS= is the end of the data set. When both options are used together, the value of ENDOBS= must be greater than the value of STARTOBS=.

In contrast to the Base SAS software options FIRSTOBS= and OBS=, the STARTOBS= and ENDOBS= SPD Server options can be used for WHERE clause processing in addition to table input operations. When ENDOBS= is used in a WHERE expression, the ENDOBS= value represents the last observation to process, rather than the number of observations to return.

**Example**

The following code shows how the ENDOBS= table option is specified in the FedSQL SELECT statement:
select * from spdslib.table1(startobs=3 endobs=4);

See Also

Table Options:
- “STARTOBS= Table Option” on page 980

EXTENDOBSCOUNTER= Table Option

Specifies whether to extend the maximum observation count in a new output SAS data set.

Valid in: CREATE TABLE statement
Category: Table Control
Alias: EOC=
Default: YES
Restriction: This table option is not supported on the CAS server.
Data source: SAS data set

Syntax
EXTENDOBSCOUNTER=YES | NO

Arguments

YES
requests an enhanced file format in a newly created SAS data set that counts observations beyond the 32-bit limitation. Although this SAS data set is created for an operating environment that stores the number of observations with a 32-bit integer, the data set behaves like a 64-bit file with respect to counters. This is the default value.

Restrictions
EXTENDOBSCOUNTER=YES is valid only for an output SAS data set whose internal data representation stores the observation count as a 32-bit integer. EXTENDOBSCOUNTER= is ignored for SAS data sets with a 64-bit integer.

A SAS data set that is created with an extended observation count is incompatible with releases prior to SAS 9.3.

NO
specifies that the maximum observation count in a newly created SAS data file is determined by the long integer size for the operating environment. In operating environments with a 32-bit integer, the maximum number is $2^{31}-1$ or approximately two billion observations (2,147,483,647). In operating environments with a 64-bit integer, the maximum number is $2^{63}-1$ or approximately 9.2 quintillion observations.
Details

Historically, Base SAS had a limitation in which up to approximately two billion observations could be counted and fully supported for operating environments with a 32-bit long integer. The EXTENDOBSCOUNTER= table option extends the limit to match that of operating environments with a 64-bit long integer. EXTENDOBSCOUNTER=NO is provided for backward compatibility.

GP_DISTRIBUTED_BY= Table Option

Specifies the distribution key for the table being created.

Category: Table Control
Alias: DISTRIBUTED_BY=
Restriction: This table option is not supported on the CAS server.
Data source: Greenplum, HAWQ

Syntax

GP_DISTRIBUTED_BY= ‘DISTRIBUTED BY (column[, …column])
| DISTRIBUTED RANDOMLY’

Arguments

DISTRIBUTED BY (column, [ …column] )
specifies one or more DBMS column names to use as the distribution key.

DISTRIBUTED RANDOMLY
specifies to determine the column or set of columns to use to distribute table rows across database segments. This is known as round-robin distribution.

Details

DISTRIBUTED BY uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you might choose DISTRIBUTED RANDOMLY, which sends the data round-robin to the segment instances. If a value is not supplied, then hash distribution is chosen using the primary key (if the table has one) or the first eligible column of the table as the distribution key.

DISTRIBUTED_BY can be submitted as shown above or within the DBCREATE_TABLE_OPTS= table option. Here is an example of how it is specified in DBCREATE_TABLE_OPTS=:

dbcreate_table_opts='distributed by ("b")'

See Also

Table Options:
- “DBCREATE_TABLE_OPTS= Table Option” on page 950
IDXNAME= Table Option

Directs SAS to use a specific index to match the conditions of a WHERE clause.

Category: User Control of SAS Index Usage

Restrictions:
- This table option is not supported on the CAS server.
- Use with input data sets only
- Cannot be used with the IDXWHERE= table option

Data source: SAS data set

Syntax

IDXNAME= index-name

Arguments

index-name

specifies the name (up to 32 characters) of a simple or composite index for the SAS data set. SAS does not attempt to determine whether the specified index is the best one or whether a sequential search might be more resource efficient.

Interaction

The specification is not a permanent attribute of the data set and is valid only for the current use of the data set.

Details

By default, to satisfy the conditions of a WHERE clause for an indexed SAS data set, SAS identifies zero or more candidate indexes that could be used to optimize the WHERE clause. From the list of candidate indexes, SAS selects the one that it determines will provide the best performance, or rejects all of the indexes if a sequential pass of the data is expected to be more efficient.

Because the index that SAS selects might not always provide the best optimization, you can direct SAS to use one of the candidate indexes by specifying the IDXNAME= table option. If you specify an index that SAS does not identify as a candidate index, then IDXNAME= table option does not process the request. That is, IDXNAME= does not allow you to specify an index that would produce incorrect results.

Comparisons

The IDXWHERE= table option enables you to override the SAS decision about whether to use an index.

Example

This example uses the IDXNAME= table option to direct SAS to use a specific index to optimize the WHERE clause. SAS then disregards the possibility that a sequential search of the data set might be more resource efficient and does not attempt to
determine whether the specified index is the best one. (Note that the EMPNUM index was not created with the NOMISS option.)

```sql
create table mydata.empnew
    as select * from mydata.employee {option idxname=empnum}
    where empnum < 2000;
```

See Also

**Table options**

- “IDXWHERE= Table Option” on page 964

## IDXWHERE= Table Option

Specifies whether SAS uses an index search or a sequential search to match the conditions of a WHERE clause.

**Syntax**

```none
IDXWHERE= YES | NO
```

**Arguments**

- **YES**
  - tells SAS to choose the best index to optimize a WHERE clause, and to disregard the possibility that a sequential search of the data set might be more resource-efficient. This is the default value.

- **NO**
  - tells SAS to ignore all indexes and satisfy the conditions of a WHERE clause with a sequential search of the data set.

**Notes**

- You cannot use the IDXWHERE= table option to override the use of an index to process a BY statement.

- You cannot use the WHERENOINDEX= table option when IDXWHERE=NO is used.

### Details

By default, to satisfy the conditions of a WHERE clause for an indexed data set, the software decides whether to use an index or to read the data set sequentially. The
software estimates the relative efficiency and chooses the method that is more efficient.

You might need to override the software's decision by specifying the IDXWHERE= table option because the decision is based on general rules that occasionally might not produce the best results. That is, by specifying the IDXWHERE= table option, you are able to determine the processing method.

---

**Note:** The specification is not a permanent attribute of the data set and is valid only for the current use of the data set.

---

### Comparisons

The IDXNAME= table option (which is supported only for SAS data sets) enables you to direct SAS to use a specific index.

The WHERENOINDEX= table option enables you to specify a list of indexes to exclude when making WHERE expression evaluations.

### Examples:

#### Example 1: Specifying Index Usage

This example uses the IDXWHERE= table option to tell SAS to decide which index is the best to optimize the WHERE clause. SAS then disregards the possibility that a sequential search of the data set might be more resource-efficient:

```sql
create table mydata.empnew
  as select * from mydata.employee {option idxwhere=yes}
  where empnum < 2000;
```

#### Example 2: Specifying No Index Usage

This example uses the IDXWHERE= table option to tell SAS to ignore any index and to satisfy the conditions of the WHERE clause with a sequential search of the data set:

```sql
create table mydata.empnew
  as select * from mydata.employee {option idxwhere=no}
  where empnum < 2000;
```

### See Also

**Table options:**

- “IDXNAME= Table Option” on page 963
- “WHERENOINDEX= Table Option” on page 1006
**IOBLOCKSIZE= Table Option**

Specifies the number of rows in a block to be used in an I/O operation.

- **Category:** Table Control
- **Restriction:** This table option is not supported on the CAS server.
- **Data source:** SPD Engine data set, SPD Server table

### Syntax

```
IOBLOCKSIZE= n
```

### Arguments

- **n** specifies the size of the block in bytes. The default value is smallest block size supported by the data source.

### Details

The software reads and stores rows in the table in blocks. IOBLOCKSIZE= is useful on compressed or encrypted tables. The software does not use IOBLOCKSIZE= on noncompressed or nonencrypted tables.

For tables that you compress or encrypt, the IOBLOCKSIZE= specification determines the number of rows to include in the block. The specification applies to block compression as well as data I/O to and from disk. The IOBLOCKSIZE= value affects the table's organization on disk.

When using compression or encryption, specify an IOBLOCKSIZE= value that complements how the data is to be accessed, sequentially or randomly. Sequential access or operations requiring full table scans favor a large block size. In contrast, random access favors a smaller block size. On SPD Engine, a large block size would be 131,072 bytes. The smallest allowed value is 32,768 bytes. For SPD Server, a large block size is 64,000 bytes. The smallest allowed value is 8,000 bytes.

### See Also

**Table Options:**

- “COMPRESS= Table Option” on page 946
- “ENCRYPT= Table Option” on page 955
- “PADCOMPRESS= Table Option” on page 971
KMS_PATH= Table Option

Specifies the location of a key file resource within a project.

Category: Table Access
Alias: KMS_FILE=
Restriction: This table option is not supported on the CAS server.
Data source: Google BigQuery
Note: Support for this option was added in the November 2019 release of SAS/ACCESS.
Example: kms_path="/u/BigQuery/projFiles/filename"

Syntax

KMS_PATH="path-and-filename"

Arguments

"path-and-filename"
    specifies the path to the key file resource within a project.

See Also

Table Options:
- "LOCATION= Table Option" on page 968

LABEL= Table Option

Specifies a label for a table.

Category: Table Control
Restriction: This table option is not supported in the CAS server.
Data source: SAS data set, SPD Engine data set

Syntax

LABEL='label'

Arguments

'label'
    specifies a text string of up to 256 characters.
Requirement

For SAS data sets and SPD Engine data sets, if the text contains single quotation marks, use double quotation marks around the label. Or, use two single quotation marks in the label text and enclose the string in single quotation marks. To remove a label from a data set, assign a label that is equal to a blank that is enclosed in quotation marks.

Details

The labels specified with the LABEL= table option are stored as part of the table’s metadata; however, the information is not used by FedSQL. That is, once stored, the label cannot be displayed. The label can be viewed with the SAS CONTENTS procedure.

You can use the LABEL= table option on both input and output tables. When you use the LABEL= table option on input tables, it assigns a label for the file for the duration of the operation. When this is specified for an output table, the label becomes a permanent part of that file.

A label assigned to a table remains associated with that table when you update a table in place, such as when you use the APPEND procedure or the MODIFY statement. However, a label is lost if you use a table with a previously assigned label to create a new table with the CREATE TABLE statement. For example, a label previously assigned to table ONE is lost when you create the new output table ONE in this CREATE TABLE statement:

```
create table one as select * from one;
```

Example

These examples assign labels to SAS data sets:

```
create table tst {option label='1976 W2 Info, Hourly'} (col1 char(4), col2 double);
create table tst1 {option label="Hillside's Daily Account"} as select * from tst;
create table tst2 {option label='Peter''s List'}(col1 char(20), col2 char(20));
```

LOCATION= Table Option

Specifies the location of the data set.

Category: Table Access

Restriction: This table option is not supported in the CAS server.

Data source: Google BigQuery

Note: Support for this option was added in the November 2019 release of SAS/ACCESS.

Syntax

```
LOCATION='value'
```
Argument

'value'

specifies the location of the data set. For valid values, see https://cloud.google.com/bigquery/docs/locations.

Details

If LOCATION= is not specified, BigQuery determines the location.

Examples:

Example 1
This setting specifies the location for the United States:

LOCATION='US'

Example 2
This setting specifies the location for the European Union:

LOCATION='EU'

See Also

Table Options:
- “KMS_PATH= Table Option” on page 967

---

LOCKTABLE= Table Option

Places shared or exclusive locks on tables.

Category: Table Control

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set

Syntax

LOCKTABLE=

Arguments

SHARE
locks a table in shared mode, allowing other users or processes to read data from the tables, but preventing users from updating data.

EXCLUSIVE
locks a table exclusively, preventing other users from accessing any table that you open.
Details
You can lock tables only if you are the owner or have been granted the necessary privilege.

If you access the BASE table driver through PROC FEDSQL, the default value for the LOCKTABLE option is EXCLUSIVE. However, if you access the BASE table driver through a SAS Federation Server, or if you run your program locally with the SAS Federation Server LIBNAME engine, the default value for the LOCKTABLE option is SHARE.

---

**ORHINTS= Table Option**

Specifies Oracle hints to pass to Oracle from FedSQL.

**Valid in:** DELETE statement, INSERT statement, SELECT statement, UPDATE statement  
**Category:** Data Control  
**Restriction:** This table option is not supported on the CAS server.  
**Data source:** Oracle

**Syntax**

\[
\text{ORHINTS}='/* \text{Oracle-hint} */'
\]

**Arguments**

**Oracle-hint**  
specifies an Oracle hint for the FedSQL language processor to pass to the DBMS as part of a query. If you do not specify a hint, FedSQL does not send any hints to Oracle. For more information, see *SAS Federation Server: Administrator's Guide.*

**Details**

The ORHINTS= table option is used in conjunction with the DRIVER_TRACE= and DRIVER_TRACEFILE= data source connection options. PROC FEDSQL and PROC DS2 do not support use of data source connection options.

**Example: Using the ORHINTS= Option**

These examples show how to specify ORHINTS=:

```
select * from test{options orhints='/* dummy hint */'} ;
update test{options orhints='/* dummy hint */'} set c1=1;
insert into test{options orhints='/* dummy hint */'} values (100);
delete from test{options orhints='/* dummy hint */'} ;
```
ORNUMERIC= Table Option

Specifies how numbers read from or inserted into the Oracle NUMBER column are treated.

Category: Table Control
Default: YES
Restriction: This table option is not supported on the CAS server.
Data source: Oracle
Data type: DECIMAL, NUMERIC

Syntax

ORNUMERIC=YES | NO

Arguments

NO
Indicates that the numbers are treated as TKTS_DOUBLE values. They might not have precision beyond 14 digits.

YES
Indicates that non-integer values with explicit precision are treated as TKTS_NUMERIC values. This is the default setting.

Details

This option defaults to YES so that a NUMBER column with precision or scale is described as TKTS_NUMERIC. This option can be specified as both a connection option and a table option. When specified as both connection and table option, the table option value overrides the connection option.

PADCOMPRESS= Table Option

Specifies the number of bytes to add to compressed blocks in an SPD Engine data set that is opened for OUTPUT or UPDATE.

Category: Table Control
Restriction: This table option is not supported on the CAS server.
Data source: SPD Engine data set

Syntax

PADCOMPRESS= n
Arguments

\( n \)

specifies the number of bytes to add. The default number is 0 (zero).

Details

Compressed SPD Engine data sets occupy blocks of space on the disk. The size of a block is derived from the IOBLOCKSIZE= table option that is specified when the data set is created. When the data set is updated, a new block fragment might need to be created to hold the update. More updates might then create new fragments, which, in turn, increases the number of I/O operations needed to read a data set.

By increasing the block padding in certain situations where many updates to the data set are expected, fragmentation can be kept to a minimum. However, adding padding can waste space if you do not update the data set.

You must weigh the cost of padding all compression blocks against the cost of possible fragmentation of some compression blocks.

Specifying the PADCOMPRESS= table option when you create or update a data set adds space to all of the blocks as they are written back to the disk. The PADCOMPRESS= setting is not retained in the data set's metadata.

See Also

Table Options:

- “COMPRESS= Table Option” on page 946
- “IOBLOCKSIZE= Table Option” on page 966

PARTSIZE= Table Option

Specifies the size of the table partitions.

Valid in: CREATE TABLE statement
Category: Table Control
Restriction: This table option is not supported on the CAS server.
Data source: SPD Engine data set, SPD Server table

Syntax

\[ \text{PARTSIZE} = n \]

Arguments

\( n \)

specifies the size of the partition.

Requirements  
The size can be specified in megabytes, gigabytes, and terabytes. If \( n \) is specified without M, G, or T, the default is megabytes. For
example, PARTSIZE=128 is the same as PARTSIZE=128M. For SPD Engine data sets, the default value is 128 megabytes. The maximum value is 8,796,093,022,207 megabytes. For SPD Server tables, the default value is the setting of the MINPARTSIZE= server option. If the MINPARTSIZE= server option is not set, the default is 16 megabytes.

When creating an SPD Engine data set, if the row length is greater than 65K, you might find that the PARTSIZE= that you specify and the actual partition size do not match. To get these numbers to match, specify a PARTSIZE= that is a multiple of 32 and the row length.

Details

For more information, see “PARTSIZE= Data Set Option in SAS Scalable Performance Data Engine: Reference and “PARTSIZE= Table Option” in SAS Scalable Performance Data Server: User’s Guide, as appropriate.

PARTITION_KEY= Table Option

Specifies the column name to use as the partition key for creating fact tables.

Category: Table Control
Restriction: This table option is not supported on the CAS server.
Data source: Aster

Syntax

PARTITION_KEY= "column-name"

Arguments

column-name
  specifies the name of the column, in quotation marks.

Details

Aster uses two table types: dimension and fact. To create a fact table in Aster without error, you must set the PARTITION_KEY= table option.

PASSWORD= Table Option

Specifies the password for the HDFS user.

Category: Bulk Loading
Alias: PASS=, PWD=
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945.
Interaction: Used in conjunction with “USER= Table Option” on page 1005.
Data source: Impala

Syntax

```
PASSWORD="value"
```

Arguments

"value"

specifies the password for the HDFS user.

See Also

Table Options:

- “BULKLOAD= Table Option” on page 943
- “USER= Table Option” on page 1005

---

**PICKLIST= Table Option**

Specifies the picklist to use for the bulk-loading operation.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945.
Data source: Impala

Syntax

```
PICKLIST="filename"
```

Arguments

"filename"

specifies the full pathname to a text file that contains the Hadoop picklist.

Default

When this table option is omitted, the file “hadoopbasics/hadoopwrapr.txt” is used.

Details

Use the PICKLIST= option when you want to override the default picklist of “hadoopbasics/hadoopwrapr.txt”.
POINTOBS= Table Option

Specifies whether SAS creates compressed data sets whose observations can be randomly accessed or sequentially accessed.

Category: Table Control

Restrictions: This table option is not supported on the CAS server.
Use with output tables only.

Interaction: Used with COMPRESS= table option

Data source: SAS data set

Syntax

POINTOBS= YES | NO

Syntax Description

YES
causes the FedSQL language to produce a compressed data set that might be randomly accessed by observation number. This is the default.

Here are examples of accessing data directly by observation number:

- the POINT= option of the MODIFY and SET statements in the DATA step
- going directly to a specific observation number with PROC FSEDIT.

TIP Specifying POINTOBS=YES does not affect the efficiency of retrieving information from a data set. It does increase CPU usage by approximately 10% when creating a compressed data set and when updating or adding information to it.

NO
suppresses the ability to randomly access observations in a compressed data set by observation number.

TIP Specifying POINTOBS=NO is desirable for applications where the ability to point directly to an observation by number within a compressed data set is not important. If you do not need to access data by observation number, then you can improve performance by approximately 10% by specifying POINTOBS=NO:

- when creating a compressed data set
when updating or adding observations to it

Details
Note that REUSE=YES takes precedence over POINTOBS=YES. For example:
create table test{options compress=yes pointobs=yes reuse=yes};
This example code results in a data set that has POINTOBS=NO. Because POINTOBS=YES is the default when you use compression, REUSE=YES causes POINTOBS= to change to NO.

See Also

Table Options:
- “COMPRESS= Table Option” on page 946
- “REUSE= Table Option” on page 979

POST_TABLE_OPTS= Table Option
Allows database-specific options to be placed after the table name in the CREATE TABLE statement.
Category: Table Control
Default: None
Restriction: This table option is not supported on the CAS server.
Data source: Hive, Spark
Note: This option is available beginning with SAS 9.4M5.
See: "DBCREATE_TABLE_OPTS= Table Option" on page 950
"PRE_TABLE_OPTS= Table Option" on page 977

Syntax
POST_TABLE_OPTS="DBMS-SQL-options"

Required Argument
"DBMS-SQL-options"
specifies additional database-specific options to be placed after the table name in a CREATE TABLE statement. You can use single or double quotation marks around the DBMS value.

Details
You can use the POST_TABLE_OPTS= table option alone or with these related table options: PRE_TABLE_OPTS= and POST_STMT_OPTS=.
POST_STMT_OPTS= is an alias for DBCREATE_TABLE_OPTS=. For example, you can supply database options according to these templates:

create table dblib.test{OPTIONS post_table_opts="external"} col1(int);

create table dblib.test{options pre_table_opts="external"
    post_table_opts="stored as orc"} col1(int);

create table dblib.test{options pre_table_opts="external"
    post_table_opts="stored as"
    post_stmt_options="orc"} col1(int);

When all three table options are specified together, they are processed as follows:

CREATE [PRE_TABLE_OPTIONS] TABLE test (col1 int) [POST_TABLE_OPTS] [POST_STMT_OPTS/DBCREATE_TABLE_OPTS]

---

**PRE_TABLE_OPTS= Table Option**

Allows database-specific options to be placed before the table name in the CREATE TABLE statement.

- **Category:** Table Control
- **Default:** None
- **Restriction:** This table option is not supported in the CAS server.
- **Data source:** Hive, Spark
- **Note:** This option is available beginning with **SAS 9.4M5**.
- **See:**
  - “DBCREATE_TABLE_OPTS= Table Option” on page 950
  - “POST_TABLE_OPTS= Table Option” on page 976

**Syntax**

`PRE_TABLE_OPTS= "DBMS-SQL-options"`

**Required Argument**

`"DBMS-SQL-options"`

specifies additional database-specific options to be placed before the table name in a CREATE TABLE statement. You can use single or double quotation marks around the DBMS value.

**Details**

You can use the PRE_TABLE_OPTS= table option alone or with these related table options: POST_TABLE_OPTS= and POST_STMT_OPTS=. POST_STMT_OPTS= is an alias for DBCREATE_TABLE_OPTS=. For example, you can supply database options according to these templates:

create table dblib.test{OPTIONS pre_table_opts="external"} col1(int);

create table dblib.test{OPTIONS pre_table_opts="external"}
When all three table options are specified together, they are processed as follows:

```sql
CREATE [PRE_TABLE_OPTIONS] TABLE test (col1 int) [POST_TABLE_OPTS] [POST_STMT_OPTS/DBCREATE_TABLE_OPTS]
```

---

**PW= Table Option**

Assigns a READ, WRITE, and ALTER password to a SAS data set or an SPD Engine data set and enables access to the password-protected file. Specifies a key value for accessing an encrypted SPD Server table.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SAS data set, SPD Engine data set, SPD Server table

**Note:** Check your log after this operation to ensure that the password values are not visible. For more information, see “Blotting Passwords and Encryption Key Values” in SAS Language Reference: Concepts.

**Syntax**

```
PW= password | key-value
```

**Arguments**

- `password`
  - must be a valid SAS name.

- `key-value`
  - must be a valid SAS name.

**Details**

The PW= table option applies to a SAS data set, an SPD Engine data set, and an SPD Server table. For a SAS data set and SPD Engine data set, you can use this option to assign a password to the data set or to access a password-protected data set. When a data set that is protected by a password is replaced, the new data set inherits the password.

---

**Note:** A SAS password does not control access to a SAS file beyond the SAS system. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside of SAS.

---

For SPD Server tables, you can use the PW= option to access an SPD Server table that is already encrypted. The PW= option enables access to table files that are protected by the SAS proprietary encryption algorithm.
Examples:

Example 1: Assigning a Password or Encryption Key with PW=
```sql
create table myfiles.mytable {options pw=green}{column1 double};
```

Example 2: Specifying a Password or Encryption Key with PW=
```sql
select * from myfiles.mytable {option pw=green};
```

**READ= Table Option**

Assigns a READ password to a SAS file that prevents users from reading the file, unless they enter the password.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SAS data set, SPD Engine data set

**Note:** Check your log after this operation to ensure that the password values are not visible. For more information, see “Blotting Passwords and Encryption Key Values” in SAS Language Reference: Concepts.

**Syntax**

```sql
READ= read-password
```

**Arguments**

`read-password`

must be a valid SAS name.

**Details**

The READ= option applies only to a SAS data set or an SPD Engine data set. You can use this option to assign a password or to access a Read-protected file.

```
Note: A SAS password does not control access to a SAS file beyond SAS. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.
```

**REUSE= Table Option**

Specifies whether new rows can be written to freed space in a compressed SAS data set.

**Category:** Table Control

**Restrictions:** This table option is not supported on the CAS server.
Syntax

**REUSE= NO | YES**

Arguments

**NO**

does not track and reuse space in a compressed SAS data set. New rows are appended to the existing data set. Specifying NO results in less efficient data storage if you delete or update many rows in the data set.

**YES**

tracks and reuses space in a compressed SAS data set. New rows are inserted in the space that is freed when other rows are updated or deleted.

If you plan to use operations that add rows to the end of a compressed data set, use REUSE=NO. REUSE=YES causes new rows to be added wherever there is space in the file, not necessarily at the end of the file.

Details

By default, new rows are appended to an existing compressed data set. If you want to track and reuse free space by deleting or updating other rows, use the REUSE= table option when you create a compressed SAS data set.

The REUSE= table option has meaning only when you are creating a new data set with the COMPRESS=YES option. Using the REUSE= table option when you are accessing an existing SAS data set has no effect.

See Also

**Table Options:**

- "COMPRESS= Table Option" on page 946
- "POINTOBS= Table Option" on page 975

---

**STARTOBS= Table Option**

Specifies the starting row number in a user-defined range of rows to be processed.

Valid in: SELECT statement

Category: Observation Control

Restrictions: This table option is not supported on the CAS server.

Use with input data sets only

Data source: SPD Engine data set, SPD Server tables
Syntax

**STARTOBS=** \( n \)

Arguments

\( n \)

is the number of the starting row.

Details

The software processes the entire data set unless you specify a range of rows with the \textsc{STARTOBS=} and \textsc{ENDOBS=} options. If the \textsc{ENDOBS=} option is used without the \textsc{STARTOBS=} option, the implied value of \textsc{STARTOBS=} is 1. When both options are used together, the value of \textsc{STARTOBS=} must be less than the value of \textsc{ENDOBS=}.

In contrast to the Base SAS software options \textsc{FIRSTOBS=} and \textsc{OBS=}, the \textsc{STARTOBS=} and \textsc{ENDOBS=} options can be used for WHERE clause processing in addition to table input operations. When \textsc{STARTOBS=} is used in a WHERE expression, the \textsc{STARTOBS=} value represents the first row on which to apply the WHERE expression.

Example

The following code shows how the \textsc{STARTOBS=} table option is specified in the FedSQL SELECT statement:

```sql
select * from spdslib.table1(startobs=3 endobs=4);
```

See Also

- **Table Options:**
  - “\textsc{ENDOBS=} Table Option” on page 960

---

### TABLE\_TYPE= Table Option

Specifies the type of table storage FedSQL will use when creating tables in SAP HANA.

- **Valid in:** CREATE TABLE statement
- **Category:** Data Access
- **Restriction:** This table option is not supported on the CAS server.
- **Interactions:** GLOBAL and GLOBAL TEMPORARY have the same behavior
  LOCAL and LOCAL TEMPORARY have the same behavior
- **Data source:** SAP HANA

Syntax

**TABLE\_TYPE=** [COLUMN] [GLOBAL] [GLOBAL TEMPORARY] [LOCAL]
[LOCAL TEMPORARY] [ROW]

Arguments

COLUMN
creates a table using column-based storage in SAP HANA.

GLOBAL | GLOBAL TEMPORARY
creates a global, temporary table in SAP HANA. The tables are globally available; however, the data is visible only in the current session.

LOCAL | LOCAL TEMPORARY
creates a local, temporary table in SAP HANA. The table definition and data are visible only in the current session.

ROW
creates a table using row-based storage in SAP HANA.

Details

The SAP HANA TABLE_TYPE= option is available as a connection option and as a table option. If neither are specified, tables that are created in SAP HANA follow the SAP HANA default for row or column store.

See Also

Table Options:

- “DBCREATE_TABLE_OPTS= Table Option” on page 950

TD_BUFFER_MODE= Table Option

Specifies whether the LOAD method is used.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945

Data source: Teradata

Syntax

TD_BUFFER_MODE= YES | NO

Arguments

YES
enables the bulk load feature. This option must be set to YES for the bulk load feature to work.

NO
disables the bulk load feature. This is the default value.
See Also

**Table Options:**
- “BULKLOAD= Table Option” on page 943

---

**TD_CHECKPOINT= Table Option**

Specifies when the TPT operation issues a checkpoint or savepoint to the database.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** Teradata

**Syntax**

```
TD_CHECKPOINT= number
```

**Arguments**

- **number**
  - Specifies the number of rows after which the TPT operation issues a checkpoint or savepoint to the database. The default is 0, which means no checkpoint is taken. All rows are saved at the end of the job.

---

**TD_DATA_ENCRYPTION= Table Option**

Activates data encryption.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945
- **Data source:** Teradata

**Syntax**

```
TD_DATA_ENCRYPTION= ON | OFF
```

**Arguments**

- **ON**
  - Encrypts all SQL requests, responses, and data.
- **OFF**
  - No encryption occurs. This is the default setting.
TD_DROP_ERROR_TABLE= Table Option

Drops the log table at the end of the job, whether the job was completed successfully or not.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
Data source: Teradata

Syntax

TD_DROP_ERROR_TABLE= YES | NO

Arguments

YES
specifies to drop the error tables at the end of the job, whether the job was completed successfully or not.

NO
keeps error tables that contain errors after the job is complete. Error tables that are empty after successful completion are deleted. This is the default setting.

See Also

Table Options:

“BULKLOAD= Table Option” on page 943

TD_DROP_LOG_TABLE= Table Option

Drops the log table at the end of the job, whether the job completed successfully or not.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
Data source: Teradata
**Syntax**

**TD_DROP_LOG_TABLE** = YES | NO

**Arguments**

**YES**  
specifies to drop the log table at the end of the job, whether the job is completed successfully or not.

**NO**  
keeps log tables for jobs that were not completed successfully. This is the default setting.

---

**TD_DROP_WORK_TABLE** = Table Option

Drops the work table at the end of the job, whether the job was completed successfully or not.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified within the “**BULKOPTS** = Table Option” on page 945

**Data source:** Teradata

**Syntax**

**TD_DROP_WORK_TABLE** = YES | NO

**Arguments**

**YES**  
specifies to drop the work table at the end of the job, whether the job was completed successfully or not.

**NO**  
keeps work tables for jobs that were not completed successfully. This is the default setting.

---

**TD_ERROR_LIMIT** = Table Option

Specifies the maximum number of records that can be stored in an error table.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified within the “**BULKOPTS** = Table Option” on page 945

**Data source:** Teradata
Syntax

TD_ERROR_LIMIT= number-of-records

Arguments

number-of-records
specifies the maximum number of records that can be stored in an error table before the Load, Stream, or Update operator job is terminated. By default, the ErrorLimit value is unlimited. The number of records must be greater than zero.

Details

The ErrorLimit specification applies to each instance of an operator job. Specifying an invalid value terminates the job.

See Also

Table Options:

- “BULKLOAD= Table Option” on page 943

TD_ERROR_TABLE_1= Table Option

Specifies a name for the first error table.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKLOAD= Table Option” on page 943

Data source: Teradata

Syntax

TD_ERROR_TABLE_1= name-of-table

Arguments

name-of-table
specifies a name for the error table. The default name for ErrorTable1 is tname_ET, where tname is the name of the target table. Table names exceeding 27 characters are truncated to accommodate the three-character suffix. Therefore, you might want to specify a name for the table that will not be truncated. When truncation occurs, a message is written to the log.

Restriction The name of an existing table cannot be used, unless you are restarting a paused job.
Details

ErrorTable1 contains records that were rejected during the acquisition phase of a Load, Stream, or Update operator job because of the following:

- Data conversion errors
- Constraint violations
- Access Module Processor (AMP) configuration changes.

The error table is created in the default user (logon) database, optionally qualified with a schema, unless the TD_LOGDB= table option is used to specify a different location for utility tables.

Error tables that contain errors are retained at the end of a job. Specify the TD_DROP_ERROR_TABLE= table option if you do not want to retain them.

For information about the error table format and the procedure to correct errors, see Teradata Parallel Transporter Reference.

See Also

Table Options:

- “BULKLOAD= Table Option” on page 943
- “TD_DROP_ERROR_TABLE= Table Option” on page 984
- “TD_LOGDB= Table Option” on page 990

TD_ERROR_TABLE_2= Table Option

Specifies a name for the second error table.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
Data source: Teradata

Syntax

TD_ERROR_TABLE_2= name-of-table

Arguments

name-of-table

specifies a name for the error table. The default name for ErrorTable2 is tname_UV, where tname is the name of the target table. Table names exceeding 27 characters are truncated to accommodate the three-character suffix. Therefore, you might want to specify a name for the table that will not be truncated. When truncation occurs, a message is written to the log.
Restrictions

This option is provided for the Load and Update operators. It is ignored by the Stream operator.

The name of an existing table cannot be used, unless you are restarting a paused job.

Details

ErrorTable2 contains records that violated the unique primary index constraint. This type of error occurs during the application phase of a Load or Update operator job.

The error table is created in the default user (logon) database, optionally qualified with a schema, unless the TD_LOGDB= table option is used to specify a different location for utility tables.

For information about the error table format and the procedure to correct errors, see Teradata Parallel Transporter Reference.

See Also

Table Options:

- "BULKLOAD= Table Option" on page 943
- "TD_LOGDB= Table Option" on page 990

TD_LOG_MECH_TYPE= Table Option

Specifies the logon mechanism for a bulk load.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the "BULKOPTS= Table Option" on page 945

Data source: Teradata

Syntax

TD_LOG_MECH_TYPE= mechanism

Arguments

mechanism

specifies the logon authentication mechanism. Currently, the valid value is LDAP.

Requirement

The driver requires an 8-character input value. To submit, pad the value with four spaces as follows:

TD_LOG_MECH_TYPE="LDAP    "

Details

If the user connected via LDAP with the UID connection option, there is no reason to use this option. Use TD_LOG_MECH_TYPE= and TD_LOG_MECH_DATA= to allow LDAP authentication for TPT if the user did not specify LDAP authentication for UID in the connect string. You can also use this option with TD_LOG_MECH_DATA= to override the LDAP ID specified in the UID option with a different LDAP ID.

See Also

Table Options:

- "BULKLOAD= Table Option" on page 943

TD_LOG_MECH_DATA= Table Option

Specifies additional data for the logon mechanism.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the "BULKOPTS= Table Option" on page 945

Data source: Teradata

Syntax

TD_LOG_MECH_DATA="string"

Arguments

string

used in conjunction with the TD_LOG_MECH_TYPE= table option, specifies credentials for authentication. Currently, only LDAP credentials are accepted. The credentials must be in the following form:

TD_LOG_MECH_DATA="authcid=value password=value realm=value"

See Also

Table Options:

- "BULKLOAD= Table Option" on page 943
- "TD_LOG_MECH_TYPE= Table Option" on page 988
TD_LOG_TABLE= Table Option

Specifies the name of the restart log table.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945

Data source: Teradata

Syntax

TD_LOG_TABLE= name-of-table

Arguments

name-of-table

specifies the name of the restart log table for the Load, Stream, and Update operators. The restart log table contains restart information. The default name for the restart log table is tname_RS, where tname is the name of the target table. Table names exceeding 30 characters are truncated to accommodate the three-character suffix. Therefore, you might want to specify a name for the table that will not be truncated. When truncation occurs, a message is written to the log.

Details

The restart log table is created in the user's default (logon) database, unless the TD_LOGDB= table option is used to specify a different location.

See Also

Table Options:

- “BULKLOAD= Table Option” on page 943
- “TD_DROP_LOG_TABLE= Table Option” on page 984
- “TD_LOGDB= Table Option” on page 990
- “TD_WORKING_DB= Table Option” on page 1002

TD_LOGDB= Table Option

Specifies the database where the TPT utility tables are created.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPTS= Table Option” on page 945
**TD_LOGDB= Table Option**

**Syntax**

**TD_LOGDB= database-name**

**Arguments**

*database-name*

specifies the name of the database where the utility tables are to be created. If this option is not specified, the utility tables are created in the specified SCHEMA. If SCHEMA is not specified, the tables are created in the default user (logon) database. The utility tables include ErrorTable1, ErrorTable2, the restart log table, and the work table.

**See Also**

Table Options:
- “BULKLOAD= Table Option” on page 943

---

**TD_MAX_SESSIONS= Table Option**

Specifies the maximum number of logon sessions that TPT can acquire for a job.

**Data source:** Teradata

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945

**Syntax**

**TD_MAX_SESSIONS= integer**

**Arguments**

*integer*

specifies the maximum number of logon sessions that the Teradata Parallel Transporter can acquire for an operator job. The default value is four sessions, if a value is not specified. The maximum value cannot be more than the number of AMPs available. See your Teradata documentation for details.

**Details**

The TD_MAX_SESSIONS= value must be greater than zero. Specifying a value less than 1 causes the job to terminate.
See Also

Table Options:
- "BULKLOAD= Table Option" on page 943

---

**TD_MIN_SESSIONS= Table Option**

Specifies the minimum number of sessions for TPT to acquire before a job starts.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the "BULKOPTS= Table Option" on page 945
- **Data source:** Teradata

**Syntax**

**TD_MIN_SESSIONS=** integer

**Arguments**

INTEGER

specifies the minimum number of sessions required for TPT to start a job. The number is applied to the Load, Stream, and Update operators. The default is one session.

**Details**

The TD_MIN_SESSIONS= value must be greater than zero and less than or equal to the maximum number of sessions. Specifying a value less than 1 causes the active operator to terminate.

Table Options:
- "BULKLOAD= Table Option" on page 943

---

**TD_NOTIFY_LEVEL= Table Option**

Specifies the level at which log events are recorded.

- **Category:** Bulk Loading
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified with the "BULKOPTS= Table Option" on page 945
Syntax

**TD_NOTIFY_LEVEL=** *level*

Arguments

*level*

Specifies the level at which events are reported. Valid settings are any of the following:

- **OFF**: No notification of events is provided (the default value).
- **LOW**: Initialize, CLIv2/DBS error, Exit events only
- **MEDIUM**: All events except Err1 and Err2
- **HIGH**: All events.

Details

If you set **TD_NOTIFY_LEVEL=**, set **TD_NOTIFY_METHOD=** to indicate how you want the events reported.

See Also

- **Table Options**:
  - “**TD_NOTIFY_METHOD= Table Option**” on page 993

---

**TD_NOTIFY_METHOD= Table Option**

Specifies the method for reporting events.

**Category**: Bulk Loading

**Restriction**: This table option is not supported on the CAS server.

**Requirement**: Must be specified with the “**BULKOPTS= Table Option**” on page 945

**Data source**: Teradata

Syntax

**TD_NOTIFY_METHOD=** *method*

Arguments

*method*

specifies the notify method to be used for reporting events. Valid settings are any of the following:
NONE  No notification of events is provided (the default value)

MSG   Sends events to a log. On Windows, the events are sent to an
      EventLog that can be viewed using the Event Viewer. On UNIX, the
      destination of events is specified in the /etc/syslog.conf file.

EXIT  Sends events to a user-defined notify exit routine.

Details

If you set `TD_NOTIFY_METHOD=`, set `TD_NOTIFY_LEVEL=` to indicate the types
of events that you want reported.

See Also

Table Options:

- "TD_NOTIFY_LEVEL= Table Option" on page 992
- "TD_NOTIFY_STRING= Table Option" on page 994

---

**TD_NOTIFY_STRING= Table Option**

Defines a string that precedes all messages sent to the system log.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified with the "BULKOPTS= Table Option" on page 945

**Data source:** Teradata

**Syntax**

`TD_NOTIFY_STRING= string`

**Arguments**

*string*

Is an optional, user-specified string that precedes all messages that are sent to
the system log. This string is also sent to the user-defined notify exit routine. If
the NotifyMethod is MSG, the maximum length is 16 bytes. If the NotifyMethod is
EXIT, the maximum length is 80 bytes.

See Also

Table Options:

- "TD_NOTIFY_METHOD= Table Option" on page 993
**TD_PACK= Table Option**

Specifies the number of statements to pack into a multistatement request.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945

**Data source:** Teradata

**Syntax**

`TD_PACK= number`

**Arguments**

`number`

Specifies the number of statements to pack into a multistatement request. The default number is 20. The maximum number of statements allowed is 600.

**Restriction**

This option is ignored by the Load and Update operators.

---

**See Also**

**Table Options:**

- “TD_PACK_MAXIMUM= Table Option” on page 995

---

**TD_PACK_MAXIMUM= Table Option**

Lets the Stream operator determine the pack factor for the current Stream job.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified within the “BULKOPTS= Table Option” on page 945

**Data source:** Teradata

**Syntax**

`TD_PACK_MAXIMUM= YES | NO`
Arguments

YES
triggers the Stream operator to dynamically determine the maximum pack factor for the current Stream job.

Restriction: This option is ignored by the Load and Update operators.

NO
loads the number of statements indicated by the TD_PACK= option for multistatement requests.

See Also

Table Options:

- "TD_PACK= Table Option" on page 995

TD_PAUSE_ACQ= Table Option
Forces a pause between the acquisition phase and the application phase of a load job.

Category: Bulk Loading
Restriction: This table option is not supported on the CAS server.
Requirement: Must be specified with the "BULKOPTS= Table Option" on page 945
Data source: Teradata

Syntax

TD_PAUSE_ACQ= YES | NO

Arguments

YES
specifies to pause the load job after the acquisition phase and skip the application phase.

Restriction: This option is provided for the Load and Update operators. It is ignored by the Stream operator.

NO
distributes all of the rows that were sent to the Teradata database during the acquisition phase to their final destination on the AMPs. This is the default value.

TD_SESSION_QUERY_BAND= Table Option
Passes a string of user-specified name=value pairs for use by the TPT session.
Syntax

**TD_SESSION_QUERY_BAND**= *string*

Arguments

*string*

specifies one or more query band expressions for use by each TPT session generated for the job or process. The bands are specified as name=value pairs.

Details

The bands are passed to the database for use by the server for load balancing. They are also used as trigger mechanisms by Teradata Multi-System Manager or TASM (Teradata Active System Management).

---

**TD_TENACITY_HOURS**= Table Option

Specifies the amount of time the TPT operator continues trying to log on to the Teradata database.

Syntax

**TD_TENACITY_HOURS**= *integer*

Arguments

*integer*

specifies the number of hours the TPT operator should attempt to log on to the Teradata database, when the maximum number of server utility slots are already occupied by other jobs. The default value is 0 (zero), meaning the operator does not try again and the job fails. It is recommended that you set a value when the Load and Update operators are used.

See Also

Table Options:
TD_TENACITY_SLEEP= Table Option

Specifies the amount of time the TPT operator pauses, before retrying to log on to the Teradata database.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the “BULKOPT= Table Option” on page 945

Data source: Teradata

Syntax

TD_TENACITY_SLEEP= integer

Arguments

integer specifies the number of minutes that the TPT operator pauses before retrying a job. This option is activated only when TD_TENACITY_HOURS= is set to a value. The default is six minutes.

Details

The TD_TENACITY_SLEEP= value must be greater than zero. If you specify a value of less than 1, the TPT operator responds with an error message and terminates the job.

See Also

Table Options:

- “BULKLOAD= Table Option” on page 943

TD_TPT_OPER= Table Option

Specifies the load operator that is used by the Teradata Parallel Transporter.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified with the “BULKOPTS= Table Option” on page 945

Data source: Teradata
Syntax

TD_TPT_OPER= operator

Arguments

operator

Specifies the load operator that the Teradata Parallel Transporter (TPT) uses to load data. Valid values are LOAD, STREAM, or UPDATE.

LOAD specifies the Load operator, which inserts into an empty table. This is the fastest of the load operators.

STREAM specifies the Stream operator. It can be used to insert rows into empty Teradata tables or append to existing tables. The Stream operator is used by default when the TD_TPT_OPER= table option is not specified.

UPDATE specifies the Update operator, which inserts into existing tables. The Update operator is faster than the Stream operator.

Details

When BULKLOAD=YES is specified, the Teradata Parallel Transporter (TPT) is used to load data. TPT jobs are run using operators. These are discrete object-oriented modules that perform specific extraction, loading, and updating processes.

To obtain the best performance when the Update operator is used, it is recommended that you drop all unique secondary indexes, foreign key references, and join indexes onto target tables before the load.

The Teradata server supports a maximum of 16 concurrent utility slots. The Stream operator does not take up a utility slot. The Load and Update operators do take up a slot.

See Also

Table Options:

- “BULKLOAD= Table Option” on page 943
- “TD_PAUSE_ACQ= Table Option” on page 996

TD_TRACE_LEVEL= Table Option

TD_TRACE_LEVEL_INF= Table Option

Specifies the trace levels for driver tracing. TD_TRACE_LEVEL sets the primary trace level. TD_TRACE_LEVEL_INF sets the secondary trace level.

Category: Bulk Loading

Restriction: This table option is not supported on the CAS server.
Syntax

TD_TRACE_LEVEL= trace-level

Arguments

trace-level

specifies the type of diagnostic messages written by each instance of the driver to an external log file. The diagnostic trace function provides more detailed information (including the version number) in the log file to aid in problem tracking and diagnosis. The following trace levels are available:

- **TD_OFF**: disables driver tracing. TD_OFF is the default setting for both driver tracing and infrastructure tracing. No external log file is produced unless this default is changed. Specifying TD_OFF for both driver tracing and infrastructure tracing is the same as disabling tracing.

- **TD_OPER**: activates the tracing function for driver-specific activities. The absence of any value for the PauseAcq attribute means that the Update driver job executes both the acquisition phase and the application phase without pausing. This distributes all of the rows that were sent to the Teradata database during the acquisition phase to their final destination on the AMPs.

- **TD_OPER_CLI**: activates the tracing function for CLIv2-related activities (interaction with the Teradata database).

- **TD_OPER_NOTIFY**: activates the tracing function for activities related to the Notify feature.

- **TD_OPER_OPCOMMON**: activates the tracing function for activities involving the opcommon library.

- **TD_OPER_ALL**: activates the tracing function for all of the tracing activities.

Details

If the trace level is set to any value other than TD_OFF, an external log file is created for each instance of the driver.

The trace levels for infrastructure tracing should be used only when you are directed to by Teradata support. TD_OFF, which disables infrastructure tracing, should always be specified.

See Also

Table Options:
### TD_TRACE_OUTPUT= Table Option

Specifies the name of the external file used for trace messages.

<table>
<thead>
<tr>
<th>Category</th>
<th>Bulk Loading</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restriction</td>
<td>This table option is not supported on the CAS server.</td>
</tr>
<tr>
<td>Requirement</td>
<td>Must be specified within the “BULKOPTS= Table Option” on page 945</td>
</tr>
<tr>
<td>Data source</td>
<td>Teradata</td>
</tr>
</tbody>
</table>

#### Syntax

```
TD_TRACE_OUTPUT= filename
```

#### Arguments

- `filename` specifies the name of the external file to use for tracing. If a file with the specified name already exists, then the existing file is overwritten. The new filename is created with the name of the driver and a time stamp.

#### See Also

- **Table Options:** [“BULKLOAD= Table Option” on page 943](#)

### TD_WORK_TABLE= Table Option

Specifies a name for the TPT Work table.

<table>
<thead>
<tr>
<th>Category</th>
<th>Bulk Loading</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restriction</td>
<td>This table option is not supported on the CAS server.</td>
</tr>
<tr>
<td>Requirement</td>
<td>Must be specified with the “BULKOPTS= Table Option” on page 945</td>
</tr>
<tr>
<td>Data source</td>
<td>Teradata</td>
</tr>
</tbody>
</table>

#### Syntax

```
TD_WORK_TABLE= name-of-table
```

---
Arguments

**name-of-table**

specifies a name for the TPT Work table. The default name for the table is `ttname_WT`, where `ttname` is the name of the target table. Table names exceeding 27 characters are truncated to accommodate the three-character suffix. Therefore, you might want to specify a name for the table that will not be truncated. When truncation occurs, a message is written to the log.

**Restriction**
This option is provided for the Update operator. It is ignored by the Load and Stream operators.

Details

The Work table is created in the default user (logon) database, optionally qualified with a schema, unless the TD_LOGDB= table option is used to specify a different location for utility tables.

See Also

**Table Options:**

- “BULKLOAD= Table Option” on page 943
- “TD_DROP_WORK_TABLE= Table Option” on page 985
- “TD_LOGDB= Table Option” on page 990

---

**TD_WORKING_DB= Table Option**

Specifies the database where the insert table is to be created.

**Category:** Bulk Loading

**Restriction:** This table option is not supported on the CAS server.

**Requirement:** Must be specified with the “BULKOPTS= Table Option” on page 945

**Data source:** Teradata

**Syntax**

```
TD_WORKING_DB= database-name
```

**Arguments**

**database-name**

specifies a database name. If this option is not specified, the table is created in the specified SCHEMA. If SCHEMA is not specified, the table is created in the default user (logon) database.
See Also

**Table Options:**
- “BULKLOAD= Table Option” on page 943

---

### THREADNUM= Table Option

Specifies the maximum number of I/O threads the SPD Engine can spawn for processing an SPD Engine data set.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SPD Engine data set

**Syntax**

```
THREADNUM= n
```

**Arguments**

`n`

specifies the number of threads. The default is the value of the SPDEMAXTHREADS= system option, if set. Otherwise, the default is two times the number of CPUs on your computer.

**Details**

THREADNUM= enables you to specify the maximum number of I/O threads that the SPD Engine spawns for processing an SPD Engine data set. The THREADNUM= value applies to any of the following SPD Engine I/O processing:

- WHERE expression processing
- parallel index creation
- I/O requested by thread-enabled applications

Adjusting THREADNUM= enables the system administrator to adjust the level of CPU resources the SPD Engine can use for any process. For example, in a 64-bit processor system, setting THREADNUM=4 limits the process to, at most, four CPUs, thereby enabling greater throughput for other users or applications.

When THREADNUM= is greater than 1, parallel processing is likely to occur. Therefore, physical order might not be retained in the output. Setting THREADNUM=1 means that no parallel processing occurs.

You can also use this option to explore scalability for WHERE expression evaluations.

SPDEMAXTHREADS=, a configurable system option, imposes an upper limit on the consumption of system resources and therefore constrains the THREADNUM= value.
**TYPE= Table Option**

Specifies the data set type for a specially structured SAS data set.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SAS data set, SPD Engine data set

**Syntax**

```
TYPE= data-set-type
```

**Arguments**

`data-set-type`

specifies the special type of the data set.

**Details**

Use the TYPE= table option to create a special data set in the proper format or to identify the special type of the data set.

Most data sets do not have a specified type. However, there are several specially structured data sets that are used by some SAS/STAT procedures. These SAS data sets contain special columns and rows, and they are usually created by SAS statistical procedures. Because most of the special data sets are used with SAS/STAT software, they are described in SAS/STAT User’s Guide.

Other values are available in other SAS software products and are described in the appropriate documentation.

---

**UNIQUESAVE= Table Option**

Specifies to save observations with nonunique key values (the rejected observations) to a separate data set when inserting observations into data sets with unique indexes.

**Valid in:** INSERT statement

**Category:** User Control of SAS Index Usage

**Restriction:** This table option is not supported on the CAS server.

**Interaction:** Used in conjunction with SPDSUSDS= automatic macro variable

**Data source:** SPD Engine data set

**Syntax**

```
UNIQUESAVE= YES | NO
```
Arguments

**YES**
writes rejected observations to a separate, system-created table that can be accessed by a reference to the macro variable SPDSUSDS=.

**NO**
does not write rejected observations to a separate table (that is, ignores nonunique key values).

Details
When observations are inserted into a data set that has a unique index, the rejected observations are ignored. With UNIQUESAVE=YES, the rejected observations are saved to a separate data set whose name is stored in the macro variable SPDSUSDS. You can specify the macro variable in place of the data set name to identify the rejected observations.

---

**USER= Table Option**

Specifies the HDFS user name.

- **Category:** Bulk Loading
- **Alias:** USERID=, UID=
- **Restriction:** This table option is not supported on the CAS server.
- **Requirement:** Must be specified within the "BULKOPTS= Table Option" on page 945.
- **Interaction:** (Optional) Use with "PASSWORD= Table Option" on page 973.
- **Data source:** Impala

**Syntax**

```
USER=HDFS-user
```

**Arguments**

**HDFS-user**
specifies the name that represents the HDFS user. Quotation marks around the value are optional, unless the name contains spaces.

**Example**

```
BULKLOAD=YES BULKOPTS=(USER=HADOOP PWD="hdfs-password" CFG="config-path")
```

**See Also**

- "BULKLOAD= Table Option" on page 943
- "PASSWORD= Table Option" on page 973
**WHEREINOINDEX= Table Option**

Specifies a list of indexes to exclude when making WHERE expression evaluations.

**Category:** User Control of SAS Index Usage

**Restrictions:**
- This table option is not supported on the CAS server.
- Cannot be used with IDXWHERE=NO

**Data source:** SPD Engine data set

**Syntax**

```plaintext
WHEREINOINDEX= (name1 name2...)
```

**Arguments**

`(name1 name2...)`

specifies a list of index names that you want to exclude from use.

**See Also**

Table Options:
- “IDXWHERE= Table Option” on page 964

---

**WRITE= Table Option Table Option**

Assigns a WRITE password to a SAS file that prevents users from writing to the file or that enables access to a Write-protected file.

**Category:** Table Control

**Restriction:** This table option is not supported on the CAS server.

**Data source:** SAS data set, SPD Engine data set

**Note:** Check your log after this operation to ensure that the password values are not visible. For more information, see “Blotting Passwords and Encryption Key Values” in SAS Language Reference: Concepts.

**Syntax**

```plaintext
WRITE= write-password
```

**Arguments**

`write-password`

must be a valid SAS name.
Details

You can use this option to assign a password or to access a write-protected file.

**Note:** A SAS password does not control access to a SAS file beyond SAS. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.
FedSQL does not provide any options that affect the processing of an entire SAS program or interactive SAS session from the time the option is specified until it is changed. Nor does FedSQL support SAS system options, with the exception of certain SAS invocation options. These SAS system options are described, where applicable, in this documentation.

Resolving FedSQL Errors

Types of Errors

FedSQL writes errors to the SAS log when it is unable to complete a request. Most errors can be categorized as follows:

Usage errors
Usage errors arise because of incorrect or invalid requests. FedSQL usage errors are typically caused by syntax, semantic, or logic errors. Syntax and semantic errors are detected at compile time and prevent compilation of a FedSQL statement. A FedSQL statement that successfully compiles might still contain logic errors that surface at execution time.

Resource errors
Resource errors arise when resource service requests cannot be fulfilled. Various conditions lead to a resource service request failure. For example, the resource could be inaccessible, a resource threshold could be reached, or you could lack authorization to access the resource.

How to Resolve FedSQL Errors

To resolve errors:

1. Check the SAS log for error messages. These messages might help you understand the source of the problem or provide ideas to help you resolve the error.
Here is an example that shows what the problem is. In this instance, a usage error occurred. The messages indicate that a problem occurred in the compilation phase and was either a syntax error or access violation. The problem was encountered at the word DRIP. In this instance, a review of the code showed that the word was encountered where a table option was expected. A quick check of the documentation shows that FedSQL does not support a DRIP table option. It does support a DROP= table option.

ERROR: Compilation error.
ERROR: Syntax error or access violation DRIP

2 In the SAS log, focus on the earliest error messages first. Sometimes a single problem leads to a cascade of failures and resolving the first error can also resolve subsequent errors.

3 If an error message indicates a resource error, check with your system administrator to monitor system resources. Examples of system resources include memory usage and disk space. If system resources are low, look for ways to increase resources or consider ways that your application could use them more efficiently.

Here is an example that shows a resource error. The message indicates a memory threshold was reached.

ERROR: Memory allocation failed.

4 If you have been unable to resolve the error using the previous three steps, contact SAS Technical Support. Here is a list of information you will need to supply: Four tips to remember when you contact SAS Technical Support.

If the SAS log contains any error messages with internal error codes, provide the codes to your SAS Technical Support representative. Internal error codes are hexadecimal numbers that can help SAS more quickly determine the source of the problem. Here is an example of an error message with an internal error code.

ERROR: FedSQL internal error code 0xEC8C8B7C049FD. Refer to FedSQL documentation for resolving errors.

Additional Information to Provide Technical Support for FedSQL Requests Submitted to a SAS Library

Beginning with SAS Viya 3.5, FedSQL supports a _DIAG option that can be used to gather additional information for SAS Technical Support. Your SAS Technical Support representative will request this information from you when you encounter an internal error. The messages returned by the _DIAG option are intended for FedSQL developers and will not make sense to you.

Add the _DIAG option to the FedSQL request that failed. The following code shows how to add the option to the FedSQL procedure. The _DIAG option is specified as a procedure option.

proc fedsql _diag;
...FedSQL statements...
quit;

Other information that is helpful to provide to Technical Support includes the following:
- the number of tables involved in the failed request
- the number of columns and rows in each input table
- the data types used
- the data sources involved in the request
- the LIBNAME statement or connection string used to make the data source connection or connections

Data Types for SAS Data Sets

The following table lists the data type support for a SAS data set. The BINARY and VARBINARY data types are not supported for data definition. For some data type definitions, the data type is mapped to CHAR, which is a Base SAS character data type, or DOUBLE, which is a Base SAS numeric data type. For data source-specific information about the SAS numeric and SAS character data types, see SAS Language Reference: Concepts. Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to SAS Data Sets in SAS Cloud Analytic Services: User’s Guide.

</tr>
<tr>
<td>TINYINT^2</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>VARCHAR(n)</td>
<td>CHAR(n)</td>
<td>Fixed-length character string. Note: Cannot contain ANSI SQL null values.</td>
<td>CHAR(n)</td>
</tr>
</tbody>
</table>

1. The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.
2. Do not apply date and time SAS formats to a numeric data type. For date and time values, use the DATE, TIME, or TIMESTAMP data types.
3. Because the values are stored as a double precision, floating-point number, you can use the values in arithmetic expressions.
4. UTF-8 is an MBCS encoding. Depending on the operating environment, UTF-8 characters are of varying width, from one to four bytes. The value for \(n\), which is the maximum number of multibyte characters to store, is multiplied by the maximum length for the operating environment. Note that when you are transcoding, such as from UTF-8 to WLatin2, the variable lengths (in bytes) might not be sufficient to hold the values, and the result is character data truncation.
Data Types for SPD Engine Data Sets

The following table lists the data type support for an SPD Engine data set.

The BINARY, DECIMAL, NUMERIC, NCHAR, NVARCHAR, and VARBINARY data types are not supported for data type definition.

For some data type definitions, the data type is mapped to CHAR, which is a Base SAS character data type, or DOUBLE, which is a Base SAS numeric data type. For data source-specific information about the SAS numeric and SAS character data types, see *SAS Language Reference: Concepts*.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to SPD Engine Files in *SAS Cloud Analytic Services: User’s Guide*.

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>SPD Data Set Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT¹</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number. Note: There is potential for loss of precision.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>CHAR((n))</td>
<td>CHAR((n))</td>
<td>Fixed-length character string. Note: Cannot contain ANSI SQL null values.</td>
<td>CHAR((n))</td>
</tr>
<tr>
<td>DATE ²</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number. By default, applies the DATE9 SAS format.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>DOUBLE¹</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>FLOAT((p))¹</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>INTEGER¹</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>Data Type Definition Keyword</td>
<td>SPD Data Set Data Type</td>
<td>Description</td>
<td>Data Type Returned</td>
</tr>
<tr>
<td>------------------------------</td>
<td>------------------------</td>
<td>-------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>REAL¹</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>SMALLINT¹</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>TIME(p)²</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number. By default, applies the TIME8 SAS format.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>TIMESTAMP(p)²</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number. By default, applies the DATETIME19.2 SAS format.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>TINYINT¹</td>
<td>DOUBLE</td>
<td>64-bit double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>VARCHAR(n)</td>
<td>CHAR(n)</td>
<td>Fixed-length character string. Note: Cannot contain ANSI SQL null values.</td>
<td>CHAR(n)</td>
</tr>
</tbody>
</table>

¹ Do not apply date and time SAS formats to a numeric data type. For date and time values, use DATE, TIME, or TIMESTAMP data types.

² Because the values are stored as double precision, floating-point numbers, you can use the values in arithmetic expressions.

---

**Data Types for SPD Server Tables**

The following table lists the data type support for an SPD Server table.

The BINARY, DECIMAL, NUMERIC, NCHAR, NVARCHAR, and VARBINARY data types are not supported for data type definition.

For some data type definitions, the data type is mapped to CHAR, which is a Base SAS character data type, or DOUBLE, which is a Base SAS numeric data type. For data source-specific information about the SAS numeric and SAS character data types, see *SAS Language Reference: Concepts*.

---

**Note:** This data source is not supported on the CAS server.

### Data Types for Amazon Redshift

The following table lists the data type support for an Amazon Redshift database.

The BINARY, TINYINT, and VARBINARY data types are not supported for data type definition.

For data source-specific information about Redshift data types, see the Amazon Redshift database documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Amazon Redshift in *SAS Cloud Analytic Services: User’s Guide*.

#### Table A7.4  Mapping of FedSQL Data Types to Data Types Used by Amazon Redshift

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>Amazon Redshift Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>BIGINT</td>
<td>Signed eight-byte integer.</td>
<td>BIGINT</td>
</tr>
<tr>
<td>Data Type Definition Keyword</td>
<td>Amazon Redshift Data Type</td>
<td>Description</td>
<td>Data Type Returned</td>
</tr>
<tr>

<td>NUMERIC(p,s)</td>
<td>DECIMAL, NUMERIC</td>
<td>Signed, fixed-point decimal number.</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>DOUBLE PRECISION</td>
<td>Signed, double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>FLOAT(p)</td>
<td>FLOAT</td>
<td>Signed, single precision or double precision, floating-point number.</td>
<td>FLOAT(p)</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INTEGER</td>
<td>Regular signed, exact whole number.</td>
<td>INTEGER</td>
</tr>
<tr>
<td>NCHAR</td>
<td>NCHAR</td>
<td>Fixed-length Unicode character string.</td>
<td>CHAR</td>
</tr>
<tr>
<td>NVARCHAR</td>
<td>NVARCHAR</td>
<td>Varying length Unicode character string.</td>
<td>VARCHAR</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL</td>
<td>Signed, single precision floating-point number.</td>
<td>REAL</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>SMALLINT</td>
<td>Small signed, exact whole number.</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>TIME(p)</td>
<td>TIME</td>
<td>Time value.</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>TIMESTAMP(p)</td>
<td>TIMESTAMP</td>
<td>Date and time value.</td>
<td>TIMESTAMP(p)</td>
</tr>
<tr>
<td>2</td>
<td>TIMESTAMPZ</td>
<td>Date and time value with time zone.</td>
<td>2</td>
</tr>
<tr>
<td>VARCHAR(n)</td>
<td>VARCHAR</td>
<td>Varying-length character string.</td>
<td>VARCHAR(n)</td>
</tr>
</tbody>
</table>

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined.
The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Amazon Redshift data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 Amazon Redshift does not support the TIME(p) data type. When you define a column of type TIME, a column of type TIMESTAMP is created instead.

4 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

Data Types for Aster

The following table lists the data type support for an Aster database.

The NCHAR, NVARCHAR, and TINYINT data types are not supported for data type definition.

For data source-specific information about Aster database data types, see the Aster database documentation.

Note: This data source is not supported on the CAS server.

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>Aster Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>BIGINT</td>
<td>Large signed, exact whole number.</td>
<td>BIGINT</td>
</tr>
<tr>
<td>BINARY(n)</td>
<td>BYTEA</td>
<td>Varying-length binary string.</td>
<td>BINARY(n)</td>
</tr>
<tr>
<td>1</td>
<td>BOOL</td>
<td>One byte integral data type that can contain values 0, 1, or NULL.</td>
<td>1</td>
</tr>
<tr>
<td>CHAR(n)</td>
<td>CHAR(n)</td>
<td>Fixed-length character string.</td>
<td>CHAR(n)</td>
</tr>
<tr>
<td>DATE</td>
<td>DATE</td>
<td>Date values.</td>
<td>DATE</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NUMERIC(p,s)</td>
<td>NUMERIC(p,s)</td>
<td>Signed, fixed-point decimal number.</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>FLOAT(p)</td>
<td>Signed, double precision, floating-point number.</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

Table A7.5  Mapping of FedSQL Data Types to Data Types Used by Aster
<table>
<thead>

1. The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2. The DB2 data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3. In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

### Data Types for Google BigQuery

The following table lists the data type support for a Google BigQuery project. SAS/ACCESS to Google BigQuery uses the GoLang BiqQuery API to communicate with Google BigQuery.

The FedSQL DECIMAL/NUMERIC(p,s) data type is not supported for data type definition.

The Google BigQuery NUMERIC, ARRAY, STRUCT, and GEOGRAPHY data types are not supported.

For data source-specific information about Google BigQuery data types, see the Google BigQuery documentation.
Note: This data source is supported on the CAS server. See SAS Data Connector for Google BigQuery documentation for information about data type support in the CAS server.

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>

</tr>
<tr>
<td>VARCHAR(n)</td>
<td>STRING</td>
<td>Varying-length Unicode character string.</td>
<td></td>
</tr>
</tbody>
</table>

1. The BigQuery data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.
2. Length is determined by the MAX_BINARY_LEN= connection option. If MAX_BINARY_LEN= is not set, the default length is 2,000 bytes. MAX_BINARY_LEN= can be set in the SAS/ACCESS to Google BigQuery LIBNAME statement or as a data source connection option in the PROC FEDSQL and PROC DS2 CONN= string. For more information, see the procedure documentation in *Base SAS Procedures Guide*.
3. Length is determined by the MAX_CHAR_LEN= connection option. If MAX_CHAR_LEN= is not set, the default length is 2,000 characters. MAX_CHAR_LEN= can be set in the SAS/ACCESS to Google BigQuery LIBNAME statement or as a data source connection option in the PROC FEDSQL and PROC DS2 CONN= string. For more information, see the procedure documentation in *Base SAS Procedures Guide*.

### Data Types for Greenplum

The following table lists the data type support for a Greenplum database.

The BINARY, NCHAR, NVARCHAR, and TINYINT data types are not supported for data type definition.

For data source-specific information about Greenplum data types, see the Greenplum database documentation.

**Note:** This data source is not supported on the CAS server.
### Table A7.8  Mapping of FedSQL Data Types to Data Types Used by Greenplum

<table>
<thead>
<tr>

<td>Varying-length binary string.</td>
<td>VARBINARY(n)</td>
</tr>
<tr>
<td>VARCHAR(n)</td>
<td>VARCHAR(n)</td>
<td>Varying-length character string.</td>
<td>VARCHAR(n)</td>
</tr>
</tbody>
</table>

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 Due to the ODBC-style interface that is used to communicate with the Greenplum server, fractional seconds are lost in the data transfer from server to client.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.
Data Types for HAWQ

The following table lists the data type support for a HAWQ database.

The BINARY, NCHAR, NVARCHAR, and TINYINT data types are not supported for data type definition.

For data source-specific information about HAWQ data types, see the HAWQ database documentation.

Note: This data source is not supported on the CAS server.

<table>

<td>Date value.</td>
<td>DATE</td>
</tr>
<tr>
<td>DECIMAL/NUMERIC(p,s)</td>
<td>DECIMAL</td>
<td>A fixed-point decimal number, with 38 digits precision.</td>
<td>DECIMAL(p,s)</td>
</tr>
</tbody>
</table>

---

1. The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2. Due to the ODBC-style interface that is used to communicate with the HAWQ server, fractional seconds are lost in the data transfer from server to client.

3. In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.
<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>HDMD Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
</table>
| DOUBLE                      | DOUBLE        | A signed, approximate, double-precision, floating-point number.  
Note: Supports SAS missing values | DOUBLE |
| FLOAT                       | DOUBLE        | A signed, approximate, double-precision, floating-point number.  
Note: Supports SAS missing values | DOUBLE |
| INTEGER                     | INTEGER       | A regular size signed, exact whole number, with a precision of 10 digits. The range of integers is -2,147,483,647 to 2,147,483,647. | INTEGER |
| REAL                        | REAL          | A signed, approximate, single-precision, floating-point number.  
Note: Supports SAS missing values | REAL |
| SMALLINT                    | SMALLINT      | A small signed, exact whole number, with a precision of five digits. The range of integers is -32,767 to 32,767. | SMALLINT |
| TIME(p)                     | TIME[(p)]     | Time value with optional precision. | TIME[(p)] |
| TIMESTAMP(p)                | TIMESTAMP[(p)] | Date and time value with optional precision. | TIMESTAMP[(p)] |
| TINYINT                     | TINYINT       | A very small signed, exact whole number, with a precision of three digits. The range of integers is -127 to 127. | TINYINT |
| VARCHAR(n)                  | VARCHAR(n)    | Varying-length character string data. | VARCHAR(n) |

1 The DECIMAL data type is handled as double precision.
The following table lists the data type support for Hive. Hive database requirements can vary, depending on your SAS software release. See the system requirements for your SAS 9.4 Foundation software for information about SAS 9.4 database requirements. The requirements are listed for “SAS/ACCESS Interface to Hadoop”.

The NCHAR and NVARCHAR data types are not available for data definition. The VARBINARY data type is available for data definition beginning with SAS 9.4M3.

The Hive complex data types can be read, beginning with SAS 9.4M3.

For data source-specific information about Hive data types, see the Hive database documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to Hadoop in SAS Cloud Analytic Services: User’s Guide.

</tbody>
</table>
### Data Type Definition

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Hive Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>TINYINT</td>
<td>A signed one-byte integer, from -127 to 127.</td>
<td>TINYINT</td>
</tr>
<tr>
<td>1, 6</td>
<td>UNION&lt;\text{data-type}, \text{data-type-n}&gt;</td>
<td>A type that can hold one of several specified data types.</td>
<td>STRING\textsuperscript{10}</td>
</tr>
<tr>
<td>VARCHAR(n)\textsuperscript{7}</td>
<td>VARCHAR(n)</td>
<td>A varying-length character string.</td>
<td>STRING</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>BINARY\textsuperscript{2}</td>
<td>A varying length binary string up to 32K.</td>
<td>BINARY</td>
</tr>
</tbody>
</table>

\textsuperscript{1} The Hive data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

\textsuperscript{2} Full support for this data type is available in Hive 0.13 and later. In Hadoop environments that use earlier Hive versions (which do not support the CHAR and DECIMAL types), columns defined as CHAR are mapped to VARCHAR. Columns that are defined as DECIMAL are not supported. In Hadoop environments that use Hive versions earlier than Hive 0.13, BINARY columns can be created but not retrieved.

\textsuperscript{3} Full support for this data type is available in Hive 0.12 and later. In Hadoop environments that use earlier Hive versions (which do not support the DATE type), when the DATE data type is used for data definition, the DATE type is mapped to a STRING column with SASFMT TableProperties. Any SASFMT TableProperties that are defined on STRING columns are applied when reading Hive, allowing the STRING columns to be treated as DATE columns. For more information about SASFMT TableProperties, see “SAS Table Properties for Hive and HADOOP” in SAS/ACCESS for Relational Databases: Reference.

\textsuperscript{4} The supported date values are between October 15, 1582 and December 31, 9999. Date values containing years earlier than 1582 return an error. Date values later than 9999 are read back as null values.

\textsuperscript{5} In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

\textsuperscript{6} String and Hive complex types are loaded as VARCHAR(n), whose length is determined by the DBMAX_TEXT= data source connection option.

\textsuperscript{7} VARCHAR columns with values greater than 65,535 characters are created as STRING.

\textsuperscript{8} SASFMT TableProperties are applied when reading STRING columns.

\textsuperscript{9} Hive does not support the TIME(p) data type. When data is read from Hive, STRING columns that have SASFMT TableProperties defined that specify the SAS TIME8. format are converted to the TIME(p) data type. When the TIME type is used for data definition, it is mapped to a STRING column with SASFMT TableProperties. Fractional seconds are not preserved. For more information about SASFMT TableProperties, see “SAS Table Properties for Hive and HADOOP” in SAS/ACCESS for Relational Databases: Reference.

\textsuperscript{10} The complex types ARRAY, MAP, STRUCT, and UNION are read as their STRING representation of the underlying complex type. ARRAY values are read back within brackets, for example: [1, 2, 4]. STRUCT and MAP values are read back within braces, for example: {"firstname":"robert","nickname":"bob"}.

---

### Data Types for Impala

The following table lists the data type support for Impala. Impala version 2.0 and later are supported, running on CDH 5.1 and later.

The BINARY, DECIMAL(p,s)/NUMERIC, NCHAR, NVARCHAR, and VARBINARY data types are not available for data definition.
For data source-specific information about Impala data types, see the vendor documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to Impala in *SAS Cloud Analytic Services: User’s Guide*.

### Table A7.12  Mapping of FedSQL Data Types to Data Types Used by Impala

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>Impala Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(n)</td>
<td>CHAR1</td>
<td>A fixed-length character string up to 255 characters.</td>
<td>CHAR</td>
</tr>
<tr>
<td>DATE</td>
<td></td>
<td>An ANSI SQL date type.</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>DOUBLE</td>
<td>An eight-byte, double-precision floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>FLOAT(p)</td>
<td>FLOAT</td>
<td>A four-byte, single-precision floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INT</td>
<td>A signed four-byte integer, from -2,147,483,647 to 2,147,483,647.</td>
<td>INTEGER</td>
</tr>
<tr>
<td>REAL</td>
<td>DOUBLE</td>
<td>An eight-byte, double-precision floating-point number.</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>SMALLINT</td>
<td>A signed two-byte integer, from -32,767 to 32,767.</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>TIME</td>
<td></td>
<td>A time value.</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>A UNIX timestamp with optional nanosecond precision.</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>TINYINT</td>
<td>TINYINT</td>
<td>A signed one-byte integer, from -127 to 127.</td>
<td>TINYINT</td>
</tr>
<tr>
<td>Data Type Definition Keyword</td>
<td>Impala Data Type</td>
<td>Description</td>
<td>Data Type Returned</td>
</tr>
<tr>
<td>------------------------------</td>
<td>------------------</td>
<td>-------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>VARCHAR(n)</td>
<td>VARCHAR</td>
<td>A varying-length character string.</td>
<td>VARCHAR</td>
</tr>
</tbody>
</table>

1. Support for this data type is available in CDH 5.2 and later. In environments that use earlier CDH versions, which do not support the CHAR and VARCHAR types, columns defined as CHAR or VARCHAR are mapped to STRING.

2. Impala does not support this data type. When a DATE or TIME column is defined, it is created as a column of type TIMESTAMP.

---

### Data Types for JDBC

The following table lists the data type support for JDBC. JDBC 4.1 and later is supported.

For data source-specific information about JDBC data types, see the database documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to JDBC in *SAS Cloud Analytic Services: User’s Guide*.

#### Table A7.13  Mapping of FedSQL Data Types to Data Types Supported by JDBC

<td>SQL_VARCHAR</td>
<td>Varying-length character string.</td>
<td>VARCHAR(n)</td>
</tr>
</tbody>
</table>
### Data Types for MDS

The following table lists the data type support for the in-memory database.

**Note:** This data source is not supported on the CAS server.

<table>
<thead>
<tr>
<th>Data Type Definition Keyword 2</th>
<th>MDS Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>BIGINT</td>
<td>64-bit, signed integer.</td>
<td>BIGINT</td>
</tr>
<tr>
<td>BINARY(n)</td>
<td>BINARY(n)</td>
<td>Fixed-length binary data.</td>
<td>BINARY(n)</td>
</tr>
<tr>
<td>CHAR(n)</td>
<td>CHAR(n)</td>
<td>Fixed-length character string data.</td>
<td>CHAR(n)</td>
</tr>
<tr>
<td>DATE</td>
<td>DATE</td>
<td>Date value.</td>
<td>DATE</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NUMERIC(p,s)</td>
<td>NUMERIC(p,s)</td>
<td>Precision scale numeric.</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>DOUBLE</td>
<td>8-byte IEEE floating-point value.</td>
<td>DOUBLE</td>
</tr>
</tbody>
</table>

1. The JDBC SQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.
2. When you use the CHAR(n) or VARCHAR(n) data type to store multibyte data, you must specify the encoding in the CLIENT_ENCODING= connection option. Or, to avoid having to set the encoding, use the NCHAR or NVARCHAR data types for multibyte data instead.
3. In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.
<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>

</tbody>
</table>

1 The MDS SQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.
2 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.
3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.
Data Types for Microsoft SQL Server

The following table lists the data type support for a Microsoft SQL Server database. SAS supports SQL Server 2008 and later.

For data source-specific information about the Microsoft SQL Server data types, see the Microsoft SQL Server database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to Microsoft SQL Server in SAS Cloud Analytic Services: User’s Guide.

The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

The Microsoft SQL Server data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

---

### Data Types for MongoDB

The following table lists the data type support for a MongoDB non-relational database. MongoDB 3.6 and later is supported.

The MongoDB types Timestamp, Min key, and Max key are internal to MongoDB. Therefore, they are not read by SAS.

The FedSQL BINARY, DATE, DECIMAL, FLOAT, NCHAR, NVARCHAR, REAL, SMALLINT, TINYINT, and VARBINARY data types are not supported for data definition.

For data source-specific information about MongoDB data types, see the MongoDB documentation.

Note: Beginning in SAS Viya 3.5, access to this data source is supported on the CAS server.

---

1 The MongoDB data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.
2 Arrays can be created as child tables. For more information, see information about MongoDB in SAS/ACCESS for Nonrelational Databases: Reference.
3 You can customize the default MongoDB schema to use CHAR(n). For more information, see the documentation for MongoDB in SAS/ACCESS for Nonrelational Databases: Reference.
4 The array and object types are modeled as separate child tables. For more information, see the documentation for MongoDB in SAS/ACCESS for Nonrelational Databases: Reference. The Javascript type is mapped to VARCHAR.
5 Contains a hexadecimal string representation of binary data.
Data Types for MySQL

The following table lists the data type support for a MySQL database. Support for MySQL begins with MySQL 5.1 and, beginning in SAS Viya 3.5, includes MySQL 8 server.

The NCHAR, NVARCHAR, REAL, and VARBINARY data types are not supported for data type definition.

For data source-specific information about MySQL data types, see the MySQL database documentation.

Note: This data source is not supported on the CAS server.

</tr>
</tbody>
</table>

\(^1\) The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined.
The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the
specified precision or scale is not within the data source range.

2 The MySQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL
columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect
precision. For more information, see "Data Types" on page 14.

Data Types for Netezza

The following table lists the data type support for a Netezza database.
The BINARY and VARBINARY data types are not supported for data type definition.
For data source-specific information about Netezza data types, see the Netezza
database documentation.

Note: This data source is not supported on the CAS server.

<table>
<thead>
<tr>

</table>
Data Types for ODBC

The following table lists the data type support for a data source that is compliant with ODBC.

For data source-specific information about ODBC SQL data types, see the specific ODBC data source documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to ODBC in SAS Cloud Analytic Services: User’s Guide.

Table A7.19 Mapping of FedSQL Data Types to Data Types Supported by ODBC

<table>
<thead>
<tr>
<th>Data Type Definition Keyword(^1)</th>
<th>ODBC SQL Identifier</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>SQL_BIGINT</td>
<td>Large signed, exact whole number.</td>
<td>BIGINT</td>
</tr>
<tr>
<td>BINARY((n))</td>
<td>SQL_BINARY</td>
<td>Fixed-length binary string.</td>
<td>BINARY((n))</td>
</tr>
<tr>
<td></td>
<td>SQL_BIT</td>
<td>Single bit binary data.</td>
<td></td>
</tr>
</tbody>
</table>

\(^1\) The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

\(^2\) Due to the ODBC-style interface that is used to communicate with the Netezza server, fractional seconds are lost in the data transfer from server to client.

\(^3\) In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

<td>Varying-length character string.</td>
<td>VARCHAR(n)</td>
</tr>
</tbody>
</table>

2. SQL_WLONGVARCHAR

Varying-length Unicode character string.

---

1. The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2. The ODBC SQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3. When you use the CHAR(n) or VARCHAR(n) data type to store multibyte data in a DB2, Greenplum, or Oracle database, you must specify the encoding in the CLIENT_ENCODING= connection option. Or, for Oracle only, to avoid having to set the encoding, use the NCHAR or NVARCHAR data types for multibyte data instead.

4. In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

---

### Data Types for Oracle

The following table lists the data type support for an Oracle database.

For data source-specific information about Oracle data types, see the Oracle database documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to Oracle in SAS Cloud Analytic Services: User’s Guide.

#### Table A7.20 Mapping of FedSQL Data Types to Data Types Used by Oracle

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>Oracle Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>NUMBER</td>
<td>Large signed, exact whole number.</td>
<td>BIGINT</td>
</tr>
<tr>
<td>BINARY(n)</td>
<td>RAW(n)</td>
<td>Fixed or varying length binary string.</td>
<td>BINARY(n)</td>
</tr>
</tbody>
</table>
The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined.
The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Oracle data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 The timestamp returned by the DATE and TIME data types can be changed to date and time values by using the DATEPART function with the PUT function.

4 The ORNUMERIC= connection argument and table option determine how numbers read from or inserted into the Oracle NUMBER column are treated. ORNUMERIC=YES, which is the default, indicates that non-integer values with explicit precision are treated as NUMERIC values.

5 The TIMESTAMP(p) data type is not available on z/OS.

6 The VARCHAR2(n) type is supported for up to 32,767 bytes if the Oracle version is 12c and the Oracle MAX_STRING_SIZE= parameter is set to EXTENDED.

## Data Types for PostgreSQL

The following table lists the data type support for a PostgreSQL database.

The BINARY, NCHAR, NVARCHAR, TINYINT, and VARBINARY data types are not supported for data type definition.

For data source-specific information about PostgreSQL data types, see the PostgreSQL database documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to PostgreSQL in *SAS Cloud Analytic Services: User’s Guide*.

</table>

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The PostgreSQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.
Data Types for Reading from Salesforce

The following table lists the data type support for reading from Salesforce. SAS/ACCESS software uses the Salesforce SOAP API to read from Salesforce. The Salesforce SOAP API returns primitive types.

SAS supports the Winter '19 release of Salesforce and later.

The calculated type and compound types are not supported. Examples of compound types are address and location.

For more information, see documentation for the Salesforce SOAP API.

<table>

</table>
Salesforce Field or Primitive Type | Description | Data Type Returned by FedSQL
--- | --- | ---
url | A Uniform Resource Locator (URL) value. | VARCHAR(n)

1 base64 fields remain in base64 format as a VARCHAR type.
2 The earliest valid date is 1700-01-01T00:00:00Z GMT, or just after midnight on January 1, 1700. The latest valid date is 4000-12-31T00:00:00Z GMT, or just after midnight on December 31, 4000. These values are offset by time zone. For example, in the Pacific time zone, the earliest valid date is 1699-12-31T16:00:00, or 4:00 PM on December 31, 1699.
3 double columns that match the precision and scale described for the numeric types in “Data Types for Writing to Salesforce” on page 1059 are mapped as shown in that table. For example, a double column that has a precision of 10 and scale of 0 is mapped to INTEGER.

Data Types for Writing to Salesforce

The following table lists the data type support for writing to Salesforce. SAS/ACCESS software uses the Salesforce Metadata API to write to Salesforce. The Salesforce Metadata API uses Custom Field types.

SAS supports the Winter ‘19 release of Salesforce and later.

The BINARY, FLOAT, and VARBINARY data types are not supported for data definition.

For more information, see documentation for the Salesforce Metadata API.

Table A7.23 Data Type Mapping When Writing to Salesforce

### Data Types for SAP

The following table lists the data type support for an SAP system.

For an SAP system, no data types are supported for column definition. Native ABAP SAP data types are mapped to similar data types for data retrieval only.

For data source-specific information about the ABAP SAP data types, see the SAP system database documentation.

Note: This data source is not supported on the CAS server.

---

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>Salesforce Custom Field Type</th>
<th>Description</th>
<th>Data Type Returned by CREATE TABLE with AS Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCHAR($n)</td>
<td>Text</td>
<td>A Unicode character string of fixed length.</td>
<td>CHAR($n)</td>
</tr>
<tr>
<td>NVARCHAR($n)</td>
<td>Text</td>
<td>A Unicode character string of varying length.</td>
<td>VARCHAR($n)</td>
</tr>
<tr>
<td>REAL</td>
<td>Number</td>
<td>A number with precision 18, scale 4.</td>
<td>DOUBLE</td>

<tr>
<td>VARCHAR($n)³</td>
<td>LongTextArea</td>
<td>A character string that is greater than 255 characters and less than 32K characters.</td>
<td>VARCHAR($n)</td>
</tr>
</tbody>
</table>

¹ CHAR($n) values where $n is greater than 255 characters are created as VARCHAR($n).
² The earliest valid date is 1700-01-01T00:00:00Z GMT, or just after midnight on January 1, 1700. The latest valid date is 4000-12-31T00:00:00Z GMT, or just after midnight on December 31, 4000. These values are offset by time zone. For example, in the Pacific time zone, the earliest valid date is 1699-12-31T16:00:00, or 4:00 PM on December 31, 1699.
³ VARCHAR($n) values where $n is less than or equal to 255 characters are created as CHAR($n).

### Data Types for SAP HANA

The following table lists the data type support for an SAP HANA database.

For data source-specific information about the SAP HANA data types, see the SAP HANA database documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to SAP HANA in *SAS Cloud Analytic Services: User’s Guide*.

</tbody>
</table>

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The SAP HANA data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

Data Types for SAP IQ

The following table lists the data type support for an SAP IQ database.

For data source-specific information about the SAP IQ database data types, see the SAP IQ database documentation.

Note: This data source is not supported on the CAS server.

### Data Types for Snowflake

The following table lists the data type support for Snowflake. SAS support for Snowflake is based on version 2.19.2 or later of the Snowflake ODBC driver.

The FedSQL NCHAR, NVARCHAR, and TINYINT data types are not supported for data definition.

For data source-specific information about the Snowflake data types, see the Snowflake documentation.

#### Note:
This data source is supported on the CAS server. See SAS Data Connector for Snowflake documentation for information about data type support in the CAS server.

#### Table A7.27  Mapping of FedSQL Data Types to Data Types Used by Snowflake

<table>
<thead>
<tr>
<th>Data Type Definition Keyword</th>
<th>Snowflake Data Type</th>
<th>Description</th>
<th>Data Type Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARBINARY(n)</td>

</tbody>
</table>

1 The Snowflake data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

2 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

Data Types for Spark

The following table lists the data type support for Apache Spark. Apache Spark 2.2.0 and later is supported.

The NCHAR and NVARCHAR data types are not available for data definition.

For data source-specific information about Spark SQL data types, see the Spark SQL documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Apache Spark in SAS Cloud Analytic Services: User’s Guide.

<tr>
<td>TINYINT</td>
<td>TINYINT</td>
<td>A signed one-byte integer, from -128 to 127.</td>
<td>TINYINT</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>BINARY</td>
<td>A varying length binary string up to 32K.</td>
<td>BINARY</td>
</tr>
<tr>
<td>VARCHAR(n)</td>
<td>VARCHAR(n)°</td>
<td>A varying-length character string.</td>
<td>VARCHAR(n)°</td>
</tr>
</tbody>
</table>

1. The Spark data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.
2. The supported date values are between January 1, 0001 and December 31, 9999. Date values later than 9999 are read back as null values.
3. If you specify CHAR with a value greater than 255 characters, the column is created as VARCHAR(n) instead.
4. In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" on page 14.
5. The maximum length of VARCHAR(n) and the Hive complex types is determined by the DBMAX_TEXT= data source connection option.
6. SASFMT TableProperties are applied when reading STRING columns.
7. The complex types ARRAY, MAP, STRUCT are read as their STRING representation of the underlying complex type. ARRAY values are read back within brackets, for example: [1, 2, 4]. STRUCT and MAP values are read back within braces, for example: {"firstname":"robert","nickname":"bob"}.
8. Spark does not support the TIME(p) data type. When data is read from Spark, STRING columns that have SASFMT TableProperties defined that specify the SAS TIME8. format are converted to the TIME(p) data type. When the TIME type is used for data definition, it is mapped to a STRING column with SASFMT TableProperties. Fractional seconds are not preserved. For more information about SASFMT TableProperties, see "SAS Table Properties for Spark and Hadoop" in SAS/ACCESS for Relational Databases: Reference.
9. In Apache Spark 2.0.0, the maximum number of columns allowed in a Spark table might be limited by https://issues.apache.org/jira/browse/SPARK-18016.

---

### Data Types for Teradata

The following table lists the data type support for a Teradata database.

The NCHAR, NVARCHAR, and REAL data types are not supported for data type definition.

For data source-specific information about the Teradata data types, see the Teradata database documentation.

**Note:** The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector to Teradata in SAS Cloud Analytic Services: User’s Guide.

The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

1 The Teradata data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

2 In FedSQL, the DECIMAL and NUMERIC data types are supported in requests that can be fully passed down to the data source. DECIMAL and NUMERIC columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.

Data Types for Vertica

The following table lists the data type support for a Vertica database.

The NCHAR and NVARCHAR data types are not supported for data definition.

For data source-specific information about Vertica data types, see the Vertica database documentation.

Note: This data source is not supported on the CAS server.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Vertica data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see “Data Types” on page 14.
Dynamically Executing FedSQL Statements from DS2

Note: With the exception of the SET statement in a DS2 action or PROC DS2, using a FedSQL query within your DS2 program is not currently supported on the CAS server.

You can embed and execute FedSQL statements from within your DS2 programs. You can use FedSQL with DS2 in the following instances:

- You can invoke a DS2 package method expression as a function in a FedSQL SELECT statement.
  
  For more information, see “Using DS2 Packages in Expressions” on page 204.

- You can use the SQLSTMT package to generate, prepare, and execute FedSQL statements to create, select, modify, insert, or delete rows from a table at run time.
  
  The SQLSTMT package is intended for use with FedSQL statements that are executed multiple times, statements with parameters, or statements that generate a result set. For more information, see “Using the SQLSTMT Package” in SAS DS2 Programmer’s Guide.

- You can also use the SQLEXEC function to generate, prepare, and execute FedSQL statements to create, select, modify, insert, or delete rows from a table at run time.
  
  The SQLEXEC function is intended for use with FedSQL statements that are executed only one time, do not have parameters, and do not produce a result set.
  
  For more information, see the “SQLEXEC Function” in SAS DS2 Language Reference.

- You can load data into a hash instance at run time by using a FedSQL SELECT statement in the DECLARE PACKAGE statement or the DATASET method.
  
  For more information, see “Using a FedSQL Query with a Hash Instance to Get Rows Dynamically at Run Time” in SAS DS2 Programmer’s Guide.

- You can use the SET statement to read in data by using a FedSQL SELECT statement.

Introduction

This section provides the code to create the tables used in the examples provided in this book. It also provides output listings that show the content of the tables.

AfewWords

Code

```sql
create table afewwords(Word1 char(10), Word2 char(10));
insert into afewwords values ('*some/', 'WHERE');
insert into afewwords values ('*every*', 'THING');
insert into afewwords values ('*no*', 'BODY');
select * from afewwords;
```

Content

*Output A9.1  Content of Table AfewWords*
create table customers
    ( custid double primary key,
      name char(16),
      address char(64),
      city char(16),
      state char(2),
      country char(16),
      phone char(16),
      initorder date
    );
insert into customers values (1,'Peter Frank', '300 Rock Lane', 'Boulder', 'CO',
'United States', '3039564321', date '2012-01-14');
insert into customers values (2,'Jim Stewart', '1500 Lapis Lane', 'Little Rock',
'AR', 'United States', '8705553978', date '2012-03-20');
insert into customers values (3,'Janet Chien', '75 Jujitsu', 'Nagasaki', '',
'Japan', '01181956879932', date '2012-06-07');
insert into customers values (4,'Qing Ziao', '10111 Karaje', 'Tokyo', '',
'Japan', '0118136774351', date '2012-10-12');
insert into customers values (5,'Humberto Sertu', '876 Avenida Blanca', 'Buenos Aires'
'', 'Argentina','01154118435029', date '2012-12-15');
select * from customers;

Output A9.2  Content of Table Customers

<table>

<td>Description of catalog</td>
</tr>
</tbody>
</table>

### DICTIONARY.COLUMNS

The following table lists the columns that appear in the result table for the DICTIONARY.COLUMNS table.

Note: Null indicates either a null or a missing value.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Number</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CAT</td>
<td>1</td>
<td>NVARCHAR</td>
<td>Catalog name</td>
</tr>
<tr>
<td>TABLE_SCHEM</td>
<td>2</td>
<td>NVARCHAR</td>
<td>Schema name</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Null is returned if the schema is not applicable to the data source. If a driver supports schemas for some tables but not for others, such as when the driver retrieves data from different DBMSs, it returns an empty string (&quot;&quot;) for those tables that do not have schemas.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>3</td>
<td>NVARCHAR</td>
<td>Table name</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>4</td>
<td>NVARCHAR</td>
<td>Column name</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The driver returns an empty string for a column that does not have a name.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>5</td>
<td>signed INT</td>
<td>TKTS data type.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>INTEGER</td>
<td>This can be a SAS FedSQL data type or a remote table driver-specific data type. For datetime and interval data types, this column returns the concise data type such as DATE or INTERVAL_YEAR_TO_MONTH, rather than the nonconcise data type such as DATETIME or INTERVAL.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For information about driver-specific TKTS data types, see the remote table driver's documentation.</td>
</tr>
<tr>
<td>TYPE_NAME</td>
<td>6</td>
<td>NVARCHAR</td>
<td>Data source-dependent common data type name (for example, CHAR, NVARCHAR, or BIGINT).</td>
</tr>
<tr>
<td>COLUMN_SIZE</td>
<td>7</td>
<td>signed</td>
<td>If DATA_TYPE is CHAR or VARCHAR, this column contains the maximum length of the column in characters. For datetime data types, this is the total number of characters required to display the value when it is converted to characters. For numeric data types, this is either the total number of digits or the total number of bits allowed in the column, according to the NUM_PREC_RADIX column. For interval data types, this is the number of characters in the character representation of the interval literal.</td>
</tr>
<tr>
<td>BUFFER_LENGTH</td>
<td>8</td>
<td>signed</td>
<td>The length in bytes of data transferred. For numeric data, this size might be different from the size of the data stored on the data source. This value might be different from COLUMN_SIZE column for character data.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Number</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DECIMAL_DIGITS</td>
<td>9</td>
<td>signed INTEGER</td>
<td>The total number of significant digits to the right of the decimal point. If DATA_TYPE is TIME and TIMESTAMP, this column contains the number of digits in the fractional seconds component. For the other data types, this is the decimal digits of the column on the data source. For interval data types that contain a time component, this column contains the number of digits to the right of the decimal point (fractional seconds). For interval data types that do not contain a time component, this column is 0. Null is returned for data types where DECIMAL_DIGITS is not applicable.</td>
</tr>
<tr>
<td>NUM_PREC_RADIX</td>
<td>10</td>
<td>signed INTEGER</td>
<td>For numeric data types, either 10 or 2 is returned. If the value returned is 10, the values in COLUMN_SIZE and DECIMAL_DIGITS contain the number of decimal digits allowed for the column. For example, a DECIMAL(12,5) column would return 10 for NUM_PREC_RADIX, 12 for COLUMN_SIZE, and 5 for DECIMAL_DIGITS; a FLOAT column could return 10 for NUM_PREC_RADIX, 15 for COLUMN_SIZE, and null for DECIMAL_DIGITS. If the value returned is 2, the values in COLUMN_SIZE and DECIMAL_DIGITS give the number of bits allowed in the column. For example, a FLOAT column could return 2 for RADIX, 53 for COLUMN_SIZE, and null for DECIMAL_DIGITS. Null is returned for data types where NUM_PREC_RADIX is not applicable.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Number</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>NULLABLE</td>
<td>11</td>
<td>signed</td>
<td>TKTS_NO_NULLS if the column will not accept null values. TKTS_NULLABLE if the column accepts null values. TKTS_NULLABLE_UNKNOWN if it is not known whether the column accepts null values. The value returned for this column is different from the value returned for the IS_NULLABLE column. The NULLABLE column indicates with certainty that a column can accept null values, but cannot indicate with certainty that a column does not accept null values. The IS_NULLABLE column indicates with certainty that a column cannot accept null values, but cannot indicate with certainty that a column accepts null values.</td>
</tr>
<tr>
<td>REMARKS</td>
<td>12</td>
<td>NVARCHAR</td>
<td>A description of the column. For a FedSQL view, the value in the REMARKS column is FedSQL.VIEW.</td>
</tr>
<tr>
<td>COLUMN_DEF</td>
<td>13</td>
<td>NVARCHAR</td>
<td>The default value of the column. The value in this column should be interpreted as a string if it is enclosed in quotation marks. If null was specified as the default value, then this column is the word NULL, not enclosed in quotation marks. If the default value cannot be represented without truncation, then this column contains TRUNCATED, not enclosed in quotation marks. If no default value is specified, then this column is null. The value of COLUMN_DEF can be used in generating a new column definition, except when it contains the value TRUNCATED.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Number</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TKTS_DATA_TYPE</td>
<td>14</td>
<td>signed</td>
<td>Data type, as it appears in the TKTS_DESC_TYPE record field. This can be a SAS FedSQL data type or a remote table driver-specific data type. This column is the same as the DATA_TYPE column, with the exception of datetime and interval data types. This column returns the nonconcise data type (such as DATETIME or INTERVAL), rather than the concise data type (such as DATE or YEAR_TO_MONTH) for datetime and interval data types. If this column returns DATETIME or INTERVAL, the specific data type can be determined from the TKTS_DATETIME_SUB column. For information about driver-specific TKTS data types, see the remote table driver's documentation.</td>
</tr>
<tr>
<td>TKTS_DATETIME_SUB</td>
<td>15</td>
<td>signed</td>
<td>The subtype code for datetime and interval data types. For other data types, this column returns a null.</td>
</tr>
<tr>
<td>CHAR_OCTET_LENGTH</td>
<td>16</td>
<td>signed</td>
<td>The maximum length in bytes of a character or binary data type column. For all other data types, this column returns a null.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>17</td>
<td>signed</td>
<td>The ordinal position of the column in the table. The first column in the table is number 1.</td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>18</td>
<td>NVARCHAR</td>
<td>NO if the column does not include nulls. YES if the column could include nulls. This column returns a zero-length string if nullability is unknown. ISO rules are followed to determine nullability. An ISO SQL-compliant DBMS cannot return an empty string. The value returned for this column is different from the value returned for the NULLABLE column.</td>
</tr>
</tbody>
</table>

1 Value cannot be a null
The following table lists the columns that appear in the result table for the DICTIONARY.COLUMN_STATISTICS table.

Note: Null indicates either a null or a missing value.

Note: The first four columns do not appear in the result table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Number</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CAT</td>
<td>1</td>
<td>NVARCHAR</td>
<td>Catalog name</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>2</td>
<td>NVARCHAR</td>
<td>Schema name</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Null is returned if the schema is not applicable to the data source. If a driver supports schemas for some tables but not for others, such as when the driver retrieves data from different DBMSs, it returns an empty string (&quot;&quot;) for those tables that do not have schemas.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>3</td>
<td>NVARCHAR</td>
<td>Table name</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>4</td>
<td>NVARCHAR</td>
<td>Column name</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The driver returns an empty string for a column that does not have a name.</td>
</tr>
<tr>
<td>TYPE</td>
<td>5</td>
<td>unsigned INTEGER</td>
<td>Type of information being returned: TKTS_COL_STAT indicates a statistic for the columns specified in the CARDINALITY and HISTOGRAM columns.</td>
</tr>
<tr>
<td>CARDINALITY</td>
<td>6</td>
<td>unsigned INTEGER</td>
<td>Cardinality of column or column set in table. This is the number of distinct, non-null values in the column or column set. Null is returned if the value is not available from the data source.</td>
</tr>
<tr>
<td>NULL_FRAC</td>
<td>7</td>
<td>DOUBLE</td>
<td>Fraction (expressed as a decimal) of the column's entries that are null. If any of the columns in a set of columns is null, then that entry is considered null.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Number</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MOST_COMMON_VALS</td>
<td>8</td>
<td>NVARCHAR</td>
<td>Contains a value that is common for this column. Null if there are no common values. Null if the number of columns is greater than one.</td>
</tr>
<tr>
<td>MOST_COMMON_FREQS</td>
<td>9</td>
<td>DOUBLE</td>
<td>A frequency of the common value returned in MOST_COMMON_VALS. This would likely be the number of occurrences of that particular column value divided by the total number of rows in the table. Null if the number of columns is greater than one.</td>
</tr>
<tr>
<td>HISTOGRAM_ENTRY</td>
<td>10</td>
<td>unsigned INTEGER</td>
<td>The entry for the HISTOGRAM_BOUNDS value. Null if the number of columns is greater than one.</td>
</tr>
<tr>
<td>HISTOGRAM_BOUNDS</td>
<td>11</td>
<td>NVARCHAR</td>
<td>One entry in a list of values that divide the column's values into groups of approximately equal population. The most common values (returned by MOST_COMMON_VALS) are omitted from the histogram calculation. No HISTOGRAM_BOUNDS are returned if the column's data type does not have a less than (&lt;) operator, or if the values returned by MOST_COMMON_VALS account for the entire population of the column. Null if the number of columns is greater than one.</td>
</tr>
<tr>
<td>CORRELATION</td>
<td>12</td>
<td>DOUBLE</td>
<td>Statistical correlation between the physical row ordering and the logical ordering of the column values. The values range from -1 to +1. This value is not returned if the column's data type does not have a less than (&lt;) operator. Null if the number of columns is greater than one.</td>
</tr>
</tbody>
</table>

1 Value cannot be a null or missing value
The following table lists the columns that appear in the result table for the DICTIONARY.STATISTICS table.

Note: Null indicates either a null or a missing value.

<table>

**DICTIONARY.TABLES**

The following table lists the columns that appear in the result table for the DICTIONARY.TABLES table.

**Note:** Null indicates either a null or a missing value.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Column number</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CAT</td>
<td>1</td>
<td>NVARCHAR</td>
<td>Catalog name</td>
</tr>
<tr>
<td>TABLE_SCHEM</td>
<td>2</td>
<td>NVARCHAR</td>
<td>Schema name; null if not applicable to the data source. For a driver supports schemas for some tables but not for others, such as when the driver retrieves data from different DBMSs, it returns an empty string (&quot;&quot;) for those tables that do not have schemas.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>3</td>
<td>NVARCHAR</td>
<td>Table name</td>
</tr>
<tr>
<td>TABLE_TYPE</td>
<td>4</td>
<td>NVARCHAR</td>
<td>Table type name; one of the following: TABLE, VIEW, SYSTEM TABLE, GLOBAL TEMPORARY, LOCAL TEMPORARY, ALIAS, SYNONYM, or a data source-specific type name. The meanings of ALIAS and SYNONYM are driver-specific.</td>
</tr>
<tr>
<td>Column name</td>
<td>Column number</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>REMARKS</td>
<td>5</td>
<td>NVARCHAR</td>
<td>A description of the table</td>
</tr>
<tr>
<td>NATIVE_CAT</td>
<td>6</td>
<td>NVARCHAR</td>
<td>The native data store's Catalog; null if not applicable to the data source. If a driver supports catalogs for some tables but not for others, such as when the driver retrieves data from different DBMSs, it returns an empty string (&quot;&quot;) for those tables that do not have catalogs.</td>
</tr>
<tr>
<td>SECURITY</td>
<td>7</td>
<td>NVARCHAR</td>
<td>The security environment the view executes under. Valid values are &quot;DEFINER&quot;, &quot;INVOKER&quot;, or null. A value of &quot;DEFINER&quot; indicates the view executes under the rights of the owner of the schema containing the view. A value of &quot;INVOKER&quot; indicates the view executes under the rights of the invoker. Null is returned if the security environment is unknown or the view is a native view.</td>
</tr>
<tr>
<td>SERVICE</td>
<td>8</td>
<td>NVARCHAR</td>
<td>The service responsible for managing the view. Valid values are &quot;FEDSQL&quot;, &quot;DRIVER&quot;, or null. A value of &quot;FEDSQL&quot; indicates the view is managed via a FEDSQL connection to the appropriate driver. A value of &quot;DRIVER&quot; (or a null value) indicates a native view managed by a DBMS driver.</td>
</tr>
</tbody>
</table>
About Performing PROC SQL Tasks with FedSQL

This appendix describes how popular PROC SQL tasks that rely on non-ANSI functionality can be performed with FedSQL. It also describes quoting differences between the two languages. To create the tables used in the examples, see “Code to Create the Sample Tables” on page 1127. The examples assume that the source tables are stored in a location that has been assigned by using the libref SQL.
Overwrite an Existing Table with FedSQL

When creating tables with FedSQL, you cannot overwrite an existing table by default. You must destroy the table with the DROP TABLE statement first. To drop an existing table in the same procedure request as the CREATE TABLE statement, specify the FORCE option in the DROP TABLE statement as follows:

```sql
proc fedsql;
    drop table test force;
    create table test (col1 char(5), col2 int);
    insert into test values ('high', 5);
quit;
```

The FORCE option suppresses completion messages that, when FORCE is omitted, cause the CREATE TABLE statement to fail.

In CAS, you can overwrite an existing session table by specifying the REPLACE=table option in the CREATE TABLE statement. Here is an example:

```sql
cas mysess;
proc fedsql sessref=mysess;
    create table test2 {options replace=true} as
        select * from test1;
quit;
```

Defining SAS Formats, Informats, and Labels When Creating a Table

**Note:** The information in this topic applies to FedSQL in SAS 9.4. By contrast, FedSQL in CAS supports creation of FedSQL output tables from existing input tables only.

FedSQL supports SAS FORMAT, INFORMAT, and LABEL modifiers for data definitions in the CREATE TABLE statement. Here is an example of how the modifiers are specified in FedSQL.

**Note:** When executing the code in this example and the first example in “Inserting Values into a Table” on page 1111, be sure to use the Work library. Otherwise, you can mistakenly overwrite the Countries table that you downloaded.

```sql
proc fedsql;
    create table countries
    (    Name char(35) having format $35. informat $35. label 'Name',
        Capital char(35) having format $35. informat $35. label 'Capital',
        Population double having format comma15. informat comma15. label 'Population',
```
Area double having format comma10. informat comma10. label 'Area',
Continental char(30) having format $30. informat $30. label 'Continent',
UNDate double having format year4. label 'UNDate'
);
quit;

For comparison, here is an example of how the modifiers are specified in PROC SQL:

```
proc sql;
create table countriesA
{
    Name char(35) format=$35. informat=$35. label="Name",
    Capital char(35) format=$35. informat=$35. label="Capital",
    Population num format=comma15. informat=comma15. label="Population",
    Area num format=comma10. informat=comma10. label="Area",
    Continent char(30) format=$30. informat=$30. label="Continent",
    UNDate num format=year4. label="UNDate"
};
quit;
```

Note the following points about the modifiers in FedSQL:

- The FORMAT, INFORMAT, and LABEL modifiers are specified in a HAVING clause.
- Values are separated from their modifiers with a blank value instead of an equal sign.
- The label value must be enclosed in single quotation marks.

When you specify a format or informat, if the data type is not either CHAR nor DOUBLE, it is converted to either CHAR or DOUBLE.

FedSQL applies formats when data is selected for display for data sources where format catalogs are available. The informat is not applied to the data; it is for information only. The client application applies the informat to the data.

---

**Inserting Values into a Table**

Both SAS SQL and FedSQL support a VALUES clause and query expressions in the INSERT statement. However, a FedSQL INSERT statement can contain a single VALUES clause. FedSQL does not support stacked VALUES clauses. A request similar to the following returns a syntax error in FedSQL:

```
proc sql;
insert into countries
values ('Afghanistan', 'Kabul', 17070323, 251825, 'Asia', 1946)
values ('Albania', 'Tirane', 3407400, 11100, 'Europe', 1955)
values ('Algeria', 'Algiers', 28171132, 919595, 'Africa', 1962)
values ('Andorra', 'Andorra la Vella', 64634, 200, 'Europe', 1993);
quit;
```

To accomplish the same result in FedSQL, you must submit multiple INSERT statements:

```
proc fedsql;
insert into countries values ('Afghanistan', 'Kabul', 17070323, 251825,
The example defines a new table named Newcountries and submits a query expression in the INSERT statement to populate the table.

Table Newcountries could also have been created by using the FedSQL CREATE TABLE statement with the AS expression. Here is an example:

```sql
proc fedsql;
create table newcountries2 as
    select * from sql.countries
    where population >= 130000000;
slect * from newcountries;
quit;
```

However, FedSQL does not support the use of FORMAT and LABEL modifiers in a query expression. If it is important to define formats and labels for a table, define the
table with the modifiers first and insert the data with a query expression as a separate step. FedSQL preserves formats and labels from an existing table when reading the table.

There is an important difference from PROC SQL to note about FedSQL query expressions: PROC SQL supports symbols and mnemonics for comparison operators. FedSQL supports operators only. For a listing of supported operators, see “<sql-expression> Expression” on page 820.

Specifying SAS Formats and Labels in a Query Expression

Note: The information in this topic applies to FedSQL use in SAS 9.4 and in CAS.

To format a column in the SELECT statement, apply a temporary format by using the PUT function. Formats that are applied with the PUT function are supported for all FedSQL data sources. For a listing of the formats supported in the PUT function, see “Formats Supported with the PUT Function, by Category” on page 87.

To label a column in the SELECT statement, specify a column alias in the place of a label.

The following example illustrates how formats and aliases can be specified in a query expression:

```
proc fedsql;
  title 'Bonus Information';
  select IdNumber as "IdNumber",
     put(Salary,dollar8.) as "Salary",
     put(Salary*.025, dollar8.) as "Bonus"
  from sql.payroll limit 10;
quit;
```

When you apply a function on a column and an alias is not specified for the column, the stored column name is the literal “column” (for the PUT function) or the name of the function. A column alias enables you to specify a more meaningful name.

**TIP**  If you use a quoted alias for a computed column, consider defining quoted aliases for other columns as well. FedSQL stores regular identifiers as uppercase. It stores delimited identifiers as they are specified. A column alias is displayed as uppercase unless you quote the alias. Use of column aliases ensures that the letter casing of column names in output is consistent.

Note the following:

- In FedSQL, a column alias must be preceded by the AS keyword.
- When quotation marks are used with a column alias, they must be double quotation marks.
Rewriting a GROUP BY Remerge Query in FedSQL

Note: The information in this topic applies to FedSQL use in SAS 9.4 and in CAS.

FedSQL does not support PROC SQL remerge functionality. Remerge is not an ANSI concept. Remerge occurs whenever any of the following conditions exist in a PROC SQL request:

- The SELECT clause references a column name that is not in an aggregate function or other column names that are not specified in the GROUP BY clause.
- The ORDER BY clause references a column name that is not referenced by the SELECT clause.

Another way to recognize a remerge query is that PROC SQL writes the following message to the log:NOTE: The query requires remerging summary statistics back with the original data.

Remerge queries perform a statistical analysis and integrate the results of the analysis with other columns from the data.

In a GROUP BY query, remerge is a useful feature when you want to return only the extreme rows from data based on a set of groupings. For example, you might have rows describing only the closest (or farthest) item in one or more areas, the oldest (or youngest) person in one or more groupings, or the most popular (or least popular) items in one or more groupings.

Here is an example of a PROC SQL query that uses remerge. The query identifies the oldest employee of each gender in a payroll table. The extreme condition in the query is earliest birthdate. The grouping criterion is gender.

```sql
proc sql;
  title 'Oldest Employee of Each Gender';
  select *
    from sql.payroll
  group by gender
    having birth=min(birth);
quit;
```

Note that this query references column names (by means of the SELECT * statement) that are neither in an aggregate function nor included in the GROUP BY statement.
The output table includes values for all columns in table Payroll for the oldest female and oldest male in the Payroll table. The oldest female was born on March 28, 1954. The oldest male was born on January 16, 1944.

To write a GROUP BY remerge request using FedSQL:

1. Identify the extreme value and the groupings for your query.
2. Select the rest of the row based on the results of the subquery, reversing the requirements that remerge was meant to address for the GROUP BY clause.

To rewrite the example above in FedSQL:

1. Identify the earliest birthdates in table Payroll by gender:

   ```
   proc fedsql;
   title 'Earliest Birthdate by Gender';
   select Gender, min(Birth) from sql.payroll
   group by Gender;
   quit;
   ```

   This is your subquery.

2. Specify the subquery and retrieve other column values from the original data for the rows returned by the subquery.

   ```
   proc fedsql;
   title 'Oldest Employee of Each Gender';
   select
   from
     (select Gender, min(Birth) as min_birth
      from sql.payroll
      group by Gender
     ) as t
   ```
inner join sql.payroll as p on p.Gender=t.gender and p.Birth=t.min_birth;
quit;

a The subquery is executed first. It performs the statistical analysis and creates the groupings. Column Birth is the analysis column. Column Gender is the grouping column.

b The outer query explicitly specifies the names of the columns to include in the output.

c The grouping column, Gender, is included in the inner query, the outer query, and again as a join condition in addition to being specified as the grouping column. The analysis column, Birth, is specified in the outer query and also as a join condition.

Here are the results of the query. The FedSQL query returns the same results as the PROC SQL remerge query.

Figure A11.3 Result of FedSQL Subquery and Self-join

Here is an example of a remerge query that involves two tables. The Stores table contains information about the stores in a given area. The Houses table contains information about the houses in the same area. The PROC SQL query uses a calculated column from the SELECT statement as a grouping condition in the HAVING clause to identify the store that is closest to each house.

proc sql;
   title 'Each House and the Closest Store';
   select house, store, sqrt((abs(s.x-h.x)**2)+(abs(h.y-s.y)**2)) as dist
   from sql.stores s, sql.houses h
   group by house
      having dist=min(dist);
quit;
To write the query in FedSQL:

1. Create the subquery. In this query, the extreme condition is nearest store distance. The groupings are by house. The following code calculates the distance between the houses and the stores, defines the Min_Dist column to store the results, and groups the results by house.

   ```fedsql
   proc fedsql;
   title 'House and Minimum Distance';
   select house, min(sqrt((abs(s.x-h.x)**2)+(abs(h.y-s.y)**2))) as min_dist
       from sql.stores s, sql.houses h
       group by house;
   quit;
   ```

2. Execute the subquery and retrieve other column values from the two tables for the rows returned by the subquery.

   ```fedsql
   proc fedsql;
   title 'Each House and the Closest Store';
   select 2
       h.house, s.store, t.min_dist as Dist
   from
       sql.houses h
       cross join
       sql.stores s
       inner join
       /* minimum distance from each house to any store */

Rewriting a Query That Specifies the CALCULATED Keyword

Note: The information in this topic applies to FedSQL use in SAS 9.4 and in CAS.

FedSQL does not support the CALCULATED keyword in query expressions. The CALCULATED keyword is not an ANSI concept. The CALCULATED keyword is similar to an in-line view. However, instead of defining a temporary alias for a
column, the keyword defines a shortcut to a previous SQL expression. You can use it to reference column aliases that are associated with calculated expressions. Consider the following example that specifies the CALCULATED keyword.

```sql
proc sql;
  title 'Total First Quarter Sales';
  select sum(January) as JanTotal,
         sum(February) as FebTotal,
         sum(March) as MarTotal,
         sum(calculated JanTotal, calculated FebTotal, 
             calculated MarTotal) as GrandTotal format=dollar10.
  from sql.Sales;
quit;
```

In the preceding query, the CALCULATED keyword is used to reference the previous statements as follows:

- the first instance of the CALCULATED keyword references the expression `select sum(January)`
- the second instance references the expression `select sum(February)`
- the third instance references the expression `select sum(March)`
- to enable the computation `sum(January) + sum(February) + sum(March) = GrandTotal`.

Figure A11.7  Result of SQL Query with the CALCULATED Keyword

<table>
<thead>
<tr>
<th>JanTotal</th>
<th>FebTotal</th>
<th>MarTotal</th>
<th>GrandTotal</th>
</tr>
</thead>
<tbody>
<tr>
<td>6800</td>
<td>7500</td>
<td>8100</td>
<td>$22,400</td>
</tr>
</tbody>
</table>

To write the preceding query using FedSQL, repeat the calculated expression:

```fedsql
proc fedsql;
  title 'Total First Quarter Sales';
  select sum(January) as JanTotal,
         sum(February) as FebTotal,
         sum(March) as MarTotal,
         put(sum(January) + sum(February) + sum(March), dollar10.) as GrandTotal
  from sql.Sales;
quit;
```

A better way to write the FedSQL request, however, is as a subquery:

```fedsql
proc fedsql;
  select t.JanTotal, 
         t.FebTotal, 
         t.MarTotal, 
         put(sum(January) + sum(February) + sum(March), dollar10.) as GrandTotal
  from sql.Sales;
quit;
```
When you write the request as a subquery, you can reference each expression by using its column alias instead of repeating the expression. Use of a subquery is more efficient, and it is also safer to use when the SQL expressions are complex.

### Specifying Multiple Arguments in an SQL Expression

**Note:** The information in this topic applies to the use of FedSQL in a SAS library and in CAS.

When more than one condition is specified in the WHEN argument of a CASE expression in PROC SQL, the conditions are linked with an implicit AND operator. Consider the following PROC SQL example, which queries the table `WorldCityCoords` to label the climate zones of world cities with a descriptor.

```sql
proc sql outobs=12;
   title 'Climate Zones of World Cities';
   select City, Country, Latitude,
       case
         when Latitude gt 67 then 'North Frigid'
         when 67 ge Latitude ge 23 then 'North Temperate'
         when 23 gt Latitude gt -23 then 'Torrid'
         when -23 ge Latitude ge -67 then 'South Temperate'
         else 'South Frigid'
       end as ClimateZone
   from sql.worldcitycoords
   order by City;
quit;
```
PROC SQL processes the highlighted sections of the code as shown below:

- When 67 is greater than or equal to Latitude (and) Latitude is greater than or equal to 23, specify 'North Temperate'.
- When 23 is greater than Latitude (and) Latitude is greater than -23, specify 'Torrid'.
- When -23 is greater than or equal to Latitude (and) Latitude is greater than or equal to -67, specify 'South Temperate'.
- Otherwise, specify "South Frigid".

By contrast, when more than one condition is specified in the WHEN argument of a CASE expression in FedSQL, the highlighted sections of code are processed as shown below:

- The conditions must be equal.
- An operator must specify the comparison that is to be made between the conditions.

Here is an example:

```sql
proc fedsql;
  title 'Climate Zones of World Cities';
  select City, Country, Latitude,
  case
    when Latitude > 67 then 'North Frigid'
    when (67 >= Latitude) and (Latitude >= 23) then 'North Temperate'
    when (23 > Latitude) and (Latitude > -23) then 'Torrid'
    when (-23 >= Latitude) and (Latitude >= -67) then 'South Temperate'
    else 'South Frigid'
  end as "ClimateZone"
  from sql.worldcitycoords
  order by City limit 12;
quit;
```
Note that PROC SQL’s mnemonics also must be converted to operators to run in FedSQL. FedSQL requires the use of operators.

Using Explicit Pass-Through

Both FedSQL and SAS SQL enable you to submit DBMS-specific SQL statements to the DBMS by using explicit SQL pass-through. Non-query DBMS SQL statements are submitted to the DBMS by using the EXECUTE statement. Queries can be submitted in the CONNECTION TO component of the SELECT statement FROM clause.

In SAS SQL, statements requesting explicit pass-through are used in conjunction with the CONNECT and DISCONNECT statements. Here is an example:

```sas
proc sql;
connect to oracle as ora2 (user=user-id password=password);
execute (create table new (a NUMBER, b TIMESTAMP, c VARCHAR2(15))) by ora2;
execute(insert into new values(12345, date’2003-11-22’, ’John Doe’)) by ora2;
select * from connection to ora2 (select a, b, c from new);
disconnect from ora2;
quit;
```

In FedSQL, there is no need to specify CONNECT and DISCONNECT statements. The data source connection is established with a libref (or a caslib in CAS). Here is an example:

```sas
libname ora2 oracle ...;
proc fedsql;
execute (create table new2 (a NUMBER, b TIMESTAMP, c VARCHAR2(15))) by ora2;
execute(insert into new2 values(12345, date’2003-11-22’, ’John Doe’)) by ora2;
select * from connection to ora2 (select a, b, c from new2);
quit;
```

Note: Currently, only the SELECT from CONNECTION TO explicit pass-through syntax is supported for FedSQL in CAS.

However, in FedSQL, you can more easily create, populate, and query tables in a DBMS by using FedSQL statements than by submitting native statements using explicit pass-through. FedSQL is a vendor-neutral SQL dialect that accesses data from various data sources without having to submit queries in the SQL dialect that is specific to the data source. It provides ANSI compliant data types for writing DBMS data and, when reading DBMS data, it maps non-ANSI data types to ANSI types internally. For more information about SAS and third-party data type mappings, see Appendix 2, “Data Type Reference,” on page 1017.

For example, the following FedSQL statements can create a table in any DBMS that is supported by FedSQL.

```sas
proc fedsql;
create table ora2.new3(a decimal(10,2), b timestamp, c varchar(15));
insert into ora2.new3 values (12345, timestamp(2003-11-22 02:25:00), ’John Doe’);
select * from ora2.new3;
quit;
```
Data type conversions are processed internally by FedSQL. In addition, FedSQL supports full and partial implicit pass-through for third-party data sources by default.

**Note:** Partial FedSQL pass-through is not yet available for FedSQL in CAS.

---

### Comparing Implicit SQL Pass-Through

Both PROC FEDSQL and SAS SQL are capable of passing requests to the DBMS for processing via implicit SQL pass-through.

SAS SQL supports implicit pass-through when the IPASSTHRU statement option is set. IPASSTHRU is set by default. PROC SQL statement options, SAS system options, and SAS/ACCESS LIBNAME statement options are available to control aspects of the pass-through process such as the following:

- How many times SAS SQL retries a query when an implicit SQL pass-through fails (SQLIPONEATTEMPT statement option and system option)
- How formats and observations are handled (SQLREDUCEPUTVALUES= and SQLREDUCEPUTOBS= SQL statement options and system options)
- Which functions are passed down to the DBMS for processing (SQL_FUNCTIONS=)
- Whether the SAS/ACCESS engine generates database-specific queries for CREATE TABLE, INSERT, and DELETE FROM TABLE statement requests, or whether SAS SQL statements are used (DBIDIRECTEXEC= system option)

FedSQL queries are automatically evaluated for implicit pass-through based on the following rules:

- FedSQL passes single source queries to the underlying data source unless the query includes one of the following:
  - Functions that are specific to SAS such as PUT
  - Certain aggregate statistics such as SKEWNESS, STUDENTS_T, NMISS, KURTOSIS, CSS, USS, and PROBT
  - Mathematical functions such as SIN, COS, ATAN, and TAN
  - ANSI-compliant FedSQL syntax that might prevent IP if the data source is not ANSI compliant in that area

  When full-query single source pass-through is not possible, the predicates (for example, the WHERE clauses) are passed down to subset the rows that must be transported into FedSQL for local processing.

- When FedSQL processes queries that include multiple data sources, it accomplishes implicit pass-through by breaking the query into multiple queries and passing these individual queries to their respective drivers. The queries must meet the requirements for single-source implicit pass-through. In addition, multiple source IP has the following additional limitations:
  - A maximum of ten tables can be in one comma join.
The tables in each side of a set operation (for example, UNION, INTERSECT, and EXCEPT) must share the same data source for multiple source IP to perform correctly. Here is an example:

/* join of two Teradata tables */
select t.col1, t.col2, t1.col1, t1.col4
from tera.employees t, tera.employees t1
where t.col1=t1.col1
Union
/* join of two Oracle tables */
select b.col1, b.col2, b1.col1, b1.col4
from ora.test1 b, ora.test2 b1
where b.col1=b1.col1;

If the tables from either side of the set operation are from multiple data sources, then partial implicit pass-through might not occur.

If the query contains a correlated subquery, no multiple source IP is attempted.

Database tables must be in the same catalog in order to be merged and joined using implicit pass-through. Merges and joins of database tables that exist in different catalogs are processed on the client. A query that contains references to multiple schemas (but only one catalog) can be passed to the data source.

Note: Neither partial FedSQL implicit pass-through nor multi-source FedSQL implicit pass-through are currently supported in CAS.
FedSQL writes messages to the log that indicate when implicit SQL pass-through is used.

Using SAS Macros with FedSQL

Note: The information in this topic applies to FedSQL use in SAS 9.4.

Macros that are used by PROC SQL can be executed from PROC FEDSQL by modifying the macro definition to meet FedSQL semantics. Consider the following example from the PROC SQL documentation that has been modified for use in PROC FEDSQL. In the example, table Survey contains data from a questionnaire about diet and exercise habits. SAS enables you to use a special notation for missing values. In the EDUC column of table Survey, note the following:

- The .x notation indicates that the respondent gave an answer that is not valid.
- An .n indicates that the respondent did not answer the question.
- A period (.) that is used as a missing value indicates a data entry error.

The macro counts the number of rows that have each value and returns the information in a table.

Here is the PROC SQL code:

```sas
%macro countm(col);
```
count(&col) "Valid Responses for &col",
nmiss(&col) "Missing or NOT VALID Responses for &col",
count(case
  when &col=.n then "count me"
end) "Coded as NO ANSWER for &col",
count(case
  when &col=.x then "count me"
end) "Coded as NOT VALID answers for &col",
count(case
  when &col=.  then "count me"
end) "Data Entry Errors for &col"
%mend;

proc sql;
title 'Counts for Each Type of Missing Response';
select count(*)  "Total No. of Rows",
%countm(educ)
from sql.survey;
quit;

Here are the macro definition and the query, modified for FEDSQL:

$macro countm_fedsql(col);
count(&col) as "Valid Responses for &col",
nmiss(&col) as "Missing or NOT VALID Responses for &col",
count(case
  when &col=.n then 'count me'
end) as "Coded as NO ANSWER for &col",
count(case
  when &col=.x then 'count me'
end) as "Coded as NOT VALID answers for &col",
count(case
  when &col=.  then 'count me'
end) as "Data Entry Errors for &col"
%mend;

proc fedsql;
title 'Counts for Each Type of Missing Response';
select count(*) as "Total No. of Rows",
%countm_fedsql(educ)
from sql.survey;
quit;

1 FedSQL requires the keyword AS between a column expression and its alias. To preserve case, an alias must be double-quoted.
2 FedSQL requires the character constant 'count me' to be single-quoted, not double-quoted.
3 FedSQL specifies a replacement column name as a column alias instead of applying a label.
## Comparison of FedSQL and PROC SQL Quoting Requirements

### Table A11.1 FedSQL and PROC SQL Quoting Differences

<table>
<thead>
<tr>
<th>Task</th>
<th>FedSQL</th>
<th>PROC SQL</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Preserve the case, spacing, or use of special characters in an identifier (delimited identifier)</strong></td>
<td>Identifiers are stored as uppercase by default; use double quotation marks to preserve casing or to include spaces or special characters. <strong>Note:</strong> When a delimited identifier is used, FedSQL preserves casing; it does not enforce case sensitivity. The target data source determines whether values that differ only in case are seen as the same or different.</td>
<td>The casing of identifiers is preserved by default. Use of quotation marks returns an error. The identifiers must follow rules for SAS names, unless PROC SQL is communicating with a SAS/ACCESS engine that supports the PRESERVE_COL_NAME S= and PRESERVE_MEM_NAME S= options. When these options are set to YES, the data source enforces its own case sensitivity rules.</td>
</tr>
<tr>
<td><strong>Preserve the case of a column alias (delimited alias)</strong></td>
<td>Column aliases are displayed as uppercase by default. To preserve casing or use spaces or special characters, enclose the alias in double quotation marks. <strong>Examples:</strong> as &quot;ListPrice&quot; as &quot;Data Entry Errors for &amp;col&quot;</td>
<td>Column aliases are displayed as specified. If the alias includes a space or a special character other than an underscore (_), use double quotation marks. <strong>Examples:</strong> as ListPrice as &quot;Data Entry Errors for &amp;col&quot;</td>
</tr>
<tr>
<td><strong>Specify a value for the LABEL modifier</strong></td>
<td>Label values must be specified within single quotation marks. <strong>Example:</strong> label 'Continent'</td>
<td>Label values can be specified within single or double quotation marks. <strong>Examples:</strong> label=&quot;Continent&quot; label='Continent'</td>
</tr>
</tbody>
</table>
Refer to a character constant

Character constants must be specified within single quotation marks.
Example:
where col1='count me'

Character constants can be specified within single or double quotation marks.
Example:
where col1='count me'
where col1="count me"

Escape a reserved word

Reserved words can be escaped by enclosing them within double quotation marks.
Example: "CASE"
See “FedSQL Reserved Words” on page 71.

If you have a column named CASE in a table and you want to specify it in a PROC SQL step, you can use the SAS data set option RENAME= to rename that column for the duration of the query. You can enclose CASE in double quotation marks ("CASE") and set the PROC SQL procedure option DQUOTE=ANSI.

The following example illustrates use of a delimiter with the reserved word CASE:

```
proc fedsql;
create table test ("Case" char(4));
insert into test values ('test');
title 'Reading a Reserved Word with FedSQL';
select "Case" from test;
quit;
```

Reading a Reserved Word with FedSQL

<table>
<thead>
<tr>
<th>Case</th>
<th>test</th>
</tr>
</thead>
</table>

Code to Create the Sample Tables

Countries and WorldCityCoords Tables

Because of the tables’ size, the code to create the Countries table that is used in “Inserting Values into a Table” on page 1111 and the WorldCityCoords table used in “Specifying Multiple Arguments in an SQL Expression” on page 1120 is not provided here. These tables are available as a download from http://support.sas.com/documentation/onlinedoc/base/index.html. Under the “Related Documentation” topic
on this page, see “Example Tables for SAS SQL Procedure User’s Guide”. Download the ZIP file and extract the data files to a location that is accessible by SAS.

Houses

The Houses table is used in "Rewriting a GROUP BY Remerge Query in FedSQL" on page 1114.

data houses;
  input House $ x y;
  datalines;
  house1 1 1
  house2 3 3
  house3 2 3
  house4 7 7
;

Payroll

The Payroll table is used in "Rewriting a GROUP BY Remerge Query in FedSQL" on page 1114.

data payroll;
  input IdNumber $4. +3 Gender $1. +4 Jobcode $3. +9 Salary 5.
  +2 Birth date7. +2 Hired date7.;
  informat birth date7. hired date7.;
  format birth date7. hired date7.;
  datalines;

Sales

The Sales table is used in "Rewriting a Query That Specifies the CALCULATED Keyword" on page 1118.

data Sales;
    input Salesperson $ January February March;
datalines;
Smith 1000 650 800
Johnson 0 900 900
Reed 1200 700 850
Davis 1050 900 1000
Thompson 750 850 1000
Peterson 900 600 500
Jones 800 900 1200
Murphy 700 800 700
Garcia 400 1200 1150
;

Stores

The Stores table is used in "Rewriting a GROUP BY Remerge Query in FedSQL" on page 1114.

data stores;
    input Store $ x y;
datalines;
store1 5 1
store2 5 3
store3 3 5
store4 7 5
;
Survey

The Survey table is used in "Using SAS Macros with FedSQL" on page 1124.

```sas
data survey;
    input id $ diet $ exer $ hours xwk educ;
    datalines;
    1001 yes yes 1 3 1
    1002 no yes 1 4 2
    1003 no no . . .n
    1004 yes yes 2 3 .x
    1005 no yes 2 3 .x
    1006 yes yes 2 4 .x
    1007 no yes .5 3 .
    1008 no no . . .
;
```
Appendix 7

FedSQL and the ANSI Standard

Compliance

FedSQL is core compliant with the 1999 ANSI Standard for SQL.¹

FedSQL Enhancements

Reserved Words

For a complete list of reserved words in FedSQL, see "FedSQL Reserved Words" on page 71.

Reserved Words

FedSQL Limitations

Granting User Privileges

Base SAS, SPD Engine, and SPD Server Identifiers and Naming Conventions

Column Modifiers

FedSQL supports the FORMAT=, INFORMAT=, and LABEL= modifiers in the HAVING clause of the CREATE TABLE statement. These modifiers control the format in which output data is displayed and labeled. For more information, see “How to Store, Change, Delete, and Use Stored Formats” on page 80, “How to Specify Informat in FedSQL” on page 828, and the “HAVING Clause” on page 890.

The FedSQL SELECT statement preserves formats and labels in existing tables, and enables you to specify temporary formats with the PUT function. For more information, see “How to Format Output with the PUT Function” on page 81.

Functions

Aggregate Functions

FedSQL supports many more aggregate functions than are required by the ANSI Standard for SQL. For a complete list of aggregate functions that FedSQL supports, see “Aggregate Functions” on page 206.

Base SAS DATA Step Functions

FedSQL supports many of the functions that are available to the Base SAS DATA step. Functions that are not supported include the variable information functions and functions that work with arrays of data. Other FedSQL data sources support their own sets of functions.

For a complete list of functions that FedSQL supports, see “Overview of FedSQL Functions” on page 202.

Table Options

A table option specifies actions that enable you to perform operations on a table such as assigning or specifying passwords. A table option in the FedSQL performs much of the same functionality as a Base SAS data set option. For more information, see “Overview of Statement Table Options” on page 909.

SAS Missing Values and Null Values

FedSQL supports both SAS missing values and null values. Nonexistent data is represented by a SAS missing value in SAS data sets, SPD Engine data sets, and SPD Server tables. For all other data sources, nonexistent data is represented by an ANSI SQL null value. For more information, see “How FedSQL Processes Nulls and SAS Missing Values” on page 22.
DS2 Package Methods as Functions

You can invoke a DS2 package method as a function in a FedSQL SELECT statement. For more information, see “Using DS2 Packages in Expressions” on page 204.

Integrity Constraints

Integrity constraints are a set of data validation rules that you can specify to preserve the validity and consistency of your data. Integrity constraints that are specified in the CREATE TABLE statement are passed through to the data source. When a transaction modifies the table, the data source enforces integrity constraints. For more information, see the “CREATE TABLE Statement” on page 840.

FedSQL DICTIONARY Tables

FedSQL supports DICTIONARY tables that are similar to the DICTIONARY tables that are available in Base SAS. A FedSQL DICTIONARY table is a Read-only table that contains information about columns, tables, and catalogs, and statistics about a single table and its associated indexes. For more information, see “DICTIONARY Tables” on page 67.

FedSQL Limitations

Granting User Privileges

The GRANT statement, PRIVILEGES keyword, and authorization-identifier features of SQL are not supported. You might want to use operating environment-specific means of security instead.

Base SAS, SPD Engine, and SPD Server Identifiers and Naming Conventions

Table, column, and index names for SAS data sets, SPD Engine data sets, and SPD Server tables are limited to 32 characters. For more information, see “Identifiers” on page 19.
Teradata: Enhancing Performance of FedSQL on Teradata

FedSQL queries that access system catalog tables (for example, the UPDATE statement, DROP TABLE statement, etc.) depend on joins of the system tables to obtain a result set from the Teradata database. In environments that create and drop a large number of database objects, performance suffers if the statistics about these system tables are not current. The following commands can be added to regular database maintenance processes to keep system table statistics up-to-date.

```sql
drop stats on dbc.tvm;
drop stats on dbc.owners;
drop stats on dbc.dbase;
drop stats on dbc.accessrights;
drop stats on dbc.tvfields;

collect stats on dbc.tvm column (tvmId);
collect stats on dbc.tvm INDEX (DatabaseId,TVMNameI);
collect stats on dbc.tvm column (DatabaseId);
collect stats on dbc.owners INDEX (ownerId);
collect stats on dbc.dbase INDEX (DatabaseId);
collect stats on dbc.dbase column (JournalId);
collect stats on dbc.accessrights INDEX (UserId,DatabaseId);
collect stats on dbc.accessrights INDEX (TVMId);
collect stats on dbc.accessrights column (UserId,TVMId);
collect stats on dbc.accessrights column (DatabaseId);
collect stats on dbc.tvfields column (DatabaseId);
collect stats on dbc.tvfields column (FieldId);
collect stats on dbc.tvfields column (tableId);

/* help stats displays what's there, this is optional */
help stats dbc.tvm;
```
help stats dbc.owners;
help stats dbc.dbase;
help stats dbc.accessrights;
help stats dbc.tvfields;

/* routine recollect, if stats have not been dropped */

collect stats on dbc.tvm;

collect stats on dbc.owners;
collect stats on dbc.dbase;
collect stats on dbc.accessrights;

collect stats on dbc.tvfields;

and Technology. All Rights Reserved.

Use, reproduction, and distribution of this software is permitted.
Any copy of this software, whether in its original form or modified,
must include both the above copyright notice and the following
paragraphs.

Nara Institute of Science and Technology (NAIST),
the copyright holders, disclaims all warranties with regard to this
software, including all implied warranties of merchantability and
fitness, in no event shall NAIST be liable for
any special, indirect or consequential damages or any damages
whatsoever resulting from loss of use, data or profits, whether in an
action of contract, negligence or other tortuous action, arising out
of or in connection with the use or performance of this software.

A large portion of the dictionary entries
originate from ICOT Free Software. The following conditions for ICOT
Free Software applies to the current dictionary as well.

Each User may also freely distribute the Program, whether in its
original form or modified, to any third party or parties, PROVIDED
that the provisions of Section 3 ("NO WARRANTY") will ALWAYS appear
on, or be attached to, the Program, which is distributed substantially
in the same form as set out herein and that such intended
distribution, if actually made, will neither violate or otherwise
contravene any of the laws and regulations of the countries having
jurisdiction over the User or the intended distribution itself.

NO WARRANTY
The program was produced on an experimental basis in the course of the research and development conducted during the project and is provided to users as so produced on an experimental basis. Accordingly, the program is provided without any warranty whatsoever, whether express, implied, statutory or otherwise. The term "warranty" used herein includes, but is not limited to, any warranty of the quality, performance, merchantability and fitness for a particular purpose of the program and the nonexistence of any infringement or violation of any right of any third party.

Each user of the program will agree and understand, and be deemed to have agreed and understood, that there is no warranty whatsoever for the program and, accordingly, the entire risk arising from or otherwise connected with the program is assumed by the user.

Therefore, neither ICOT, the copyright holder, or any other organization that participated in or was otherwise related to the development of the program and their respective officials, directors, officers and other employees shall be held liable for any and all damages, including, without limitation, general, special, incidental and consequential damages, arising out of or otherwise in connection with the use or inability to use the program or any product, material or result produced or otherwise obtained by using the program, regardless of whether they have been advised of, or otherwise had knowledge of, the possibility of such damages at any time during the project or thereafter. Each user will be deemed to have agreed to the foregoing by his or her commencement of use of the program. The term "use" as used herein includes, but is not limited to, the use, modification, copying and distribution of the program and the production of secondary products from the program.

In the case where the program, whether in its original form or modified, was distributed or delivered to or received by a user from any person, organization or entity other than ICOT, unless it makes or grants independently of ICOT any specific warranty to the user in writing, such person, organization or entity, will also be exempted from and not be held liable to the user for any such damages as noted above as far as the program is concerned.

3. Time Zone Database

ICU uses the public domain data and code derived from Time Zone Database for its time zone support. The ownership of the TZ database is explained in BCP 175: Procedure for Maintaining the Time Zone Database section 7.

7. Database Ownership

The TZ database itself is not an IETF Contribution or an IETF document. Rather it is a pre-existing and regularly updated work that is in the public domain, and is intended to remain in the public domain. Therefore, BCPs 78 [RFC5378] and 79 [RFC3979] do not apply to the TZ Database or contributions that individuals make to it. Should any claims be made and substantiated against the TZ Database, the organization that is providing the IANA Considerations defined in this RFC, under the memorandum of understanding with the IETF, currently ICANN, may act in accordance with all competent court orders. No ownership claims will be made by ICANN or the IETF Trust on the database or the code. Any person making a contribution to the database or code waives all rights to future claims in that contribution or in the TZ Database.

Unicode, Inc. License Agreement - Data Files and Software: ICU 58 and Later

See Terms of Use for definitions of Unicode Inc.’s Data Files and Software.
