What's New in the SAS 9.4 Logging Facility

Overview

The logging facility has the following changes and enhancements:

- support for writing messages to z/OS operating system consoles in ConsoleAppender
- enhanced logger security
- enhanced support for auditing logging configurations and SAS data set deletion and renaming changes
- enhanced support for auditing SAS data sets
- support for auditing metadata-bound libraries
- modifications to the DEFAULT and TRACE pattern layouts

Support for Writing Messages to z/OS Operating System Consoles

Support for writing messages to z/OS operating system consoles has been added to ConsoleAppender. For more information, see "ConsoleAppender" on page 49.

New Parameters for ConsoleAppender, FileAppender, and RollingFileAppender

Effective with the second maintenance release for SAS 9.4, ConsoleAppender has the following new parameters:

- The ImmediateFlush parameter enables you to force messages to be written to the console immediately as they are received.
The Target parameter enables you to write messages to the console’s standard error stream instead of the standard output stream. This parameter is valid only for Windows and UNIX environments.

Effective with the second maintenance release for SAS 9.4, the FilePermissions parameter of FileAppender and RollingFileAppender enables you to set permissions on log files.

---

**Enhanced Logger Security**

Appenders cannot be referenced by a logger using the SAS language if logger immutability is set. For more information, see “Logger” on page 41.

---

**Enhanced Support for Auditing Logging Configurations**

The following three loggers record changes to the logging configuration:

- Audit.Logging.Configuration.Logger
- Audit.Logging.Configuration.Appender
- Audit.Logging.Configuration.Config

For more information, see “SAS Server Logger Names” on page 10.

---

**Enhanced Support for Auditing SAS Data Sets**

Two new loggers, Audit.Data.Dataset.Delete and Audit.Data.Dataset.Rename, write messages to an audit log when a data set is deleted and when a data set is renamed. New conversion patterns enhance audit messages with information about the type of action that was taken on a SAS data set and the status of the action. For more information, see Appendix 1, “Audit Messages for SAS Library Access,” on page 205 and “E Conversion Character” on page 122.

---

**Support for Auditing Metadata-Bound Libraries**

Two new loggers, Audit.Data.MetaBoundLib.PermDenied and Audit.Data.MetaBoundLib.AuthAudit, audit access to metadata-based libraries. New conversion patterns enhance audit messages with information about the action that was taken on a metadata-bound library. For more information, see “About Audit
Modification to the Root Logger

In the second maintenance release for SAS 9.4, the default level for the root logger is INFO. For more information, see “XML Elements for Configuring SAS Logging” on page 34.

Modification to the DEFAULT and TRACE Pattern Layouts

The DEFAULT and TRACE patterns include the client ID. For more information, see "Conversion Patterns Supplied by SAS" on page 108.

- Best Practices for SAS Server Logging 22
Overview of the SAS Logging Facility

What Is the Logging Facility?

The SAS logging facility is a flexible, configurable framework that you can use to collect, categorize, and filter events and write them to a variety of output devices. The logging facility supports problem diagnosis and resolution, performance and capacity management, and auditing and regulatory compliance. The logging facility has the following features:

- Log events are categorized using a hierarchical naming system that enables you to configure logging at a broad or a fine-grained level.
- Log events can be directed to multiple output destinations, including fixed files, rolling files, operating system facilities, client applications, database tables, message queues, and custom Java classes. For each output destination, you can specify the following logging facility components:
  - the categories and levels of log events to report
  - the message layout, including the types of data to be included, the order of the data, and the format of the data
  - filters based on criteria such as diagnostic levels and message content
- Logging levels can be adjusted dynamically without starting and stopping processes.
- Performance-related log events can be generated for processing by the Application Response Measurement (ARM) 4.0 agent.

The logging facility is used by most SAS server processes. You can also use the logging facility within SAS programs.

Who Uses the Logging Facility?

This guide is for both administrators, who configure the SAS logging facility, and for programmers, who can use the logging facility in their SAS programs.

Auditors use this guide to understand the logging process and the information that the logging facility generates.

Comparing the SAS Logging Facility and the SAS Log

The SAS logging facility and the SAS log are two different logging systems within SAS.
Traditionally, the SAS log displays information, warning, and error messages as a result of executing SAS programs or SAS global statements. Regardless of their origin, all messages are destined for a single log.

By contrast, the SAS logging facility is a framework that categorizes and filters log messages in SAS server and SAS programming environments, and writes log messages to various output devices. In the server environment, the logging facility logs messages based on predefined message categories, such as Admin for administrative messages, App for application messages, and Perf for performance messages. Messages for a category can be written to files, consoles, and other system destinations simultaneously. The logging facility also enables messages to be filtered based on the following thresholds: TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

In the programming environment, if the logging facility is initialized for SAS server logging, messages are written to logging facility destinations only. If the logging facility is not initialized for SAS server logging, messages are written to the SAS log and to logging facility destinations that are created in a SAS program.

Logging Facility Terminology

Here are the common terms that this document uses:

**appender**
- a named entity that represents a specific output destination for messages. Destinations include fixed files, rolling files, operating system facilities, client applications, database tables, message queues, and custom Java classes. You can configure appenders by specifying thresholds, filters, log directories and filenames, pattern layouts, and other parameters that control how messages are written to the destination.

**filter**
- a set of character strings or thresholds, or a combination of strings and thresholds that you specify. Log events are compared to the filter to determine whether they should be processed.

**level**
- the diagnostic level that is associated with a log event. The levels, from lowest to highest, are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

**log event**
- an occurrence that is reported by a program for possible inclusion in a log.

**logger**
- a named entity that identifies a message category. Loggers are named using a hierarchical system that enables you to configure logging at a broad or a fine-grained level.

The logging facility includes a set of high-level loggers for SAS servers, including Audit, Admin, App, IOM, and Perf. Some loggers are subdivided into lower-level (child) loggers. For example, the Audit logger has descendant loggers called Audit.Meta and Audit.Authentication, and Audit.Meta has descendant loggers called Audit.Meta.Security and Audit.Meta.Updates. The Root logger is the highest-level logger and does not represent a specific message category.

Loggers inherit settings from their higher-level (ancestor) loggers.
logging configuration
   an XML file or a set of SAS program statements that determines how log events are processed. You use the logging configuration to assign thresholds to loggers, to configure appenders, and to specify which categories and levels of log events are to be written to each appender.

   If you perform a planned deployment, then the SAS Deployment Wizard provides default logging configuration files for your SAS servers.

message category
   a classification for messages that are produced by a SAS sub-system. Message categories for the logging facility are administrative messages, application-specific messages, audit messages, IOM messages, and performance messages.

pattern layout
   a template that you create to format messages. The pattern layout identifies the types of data, the order of the data, and the format of the data that is generated in a log event. It is delivered as output.

threshold
   the lowest event level that is processed. Log events whose levels are below the threshold are ignored.

How the Logging Facility Works

Setting Up the Logging Process

To use the SAS logging facility, you must set up your logging environment:

- Define a logging configuration, which configures appenders and loggers. You can define the configuration by setting up an XML file or by using SAS language elements. If you perform a planned deployment, then logging configuration files are provided for your SAS servers.

- Specify the LOGCONFIGLOC= system option to enable logging, if you are using configuration files. If you perform a planned deployment, then this system option is included in the SAS configuration files for your SAS servers.

- Issue log events in a format that can be processed by the logging facility, if you are developing your own SAS programs.

Note: You can experiment with the logging facility without creating logging configuration files. SAS provides three basic logging configurations that write messages to either a file, the current console, or to the traditional SAS log using the root logger. For more information, see “LOGCONFIGLOC= System Option” on page 28.
The Logging Process

After your logging environment is in place, the SAS logging facility begins processing as follows:

1 A SAS process (for example, a SAS server process) issues a log event. Each event includes the following attributes: a name that indicates the message category, a diagnostic level, and a message that describes the context for the event.

2 The logging facility receives the log event and determines which logger to assign it to, based on the event's name attribute.

3 The log event's level is compared to the threshold that is specified for the logger in the logging configuration. If the event's level is at or above the specified threshold, then processing continues. If the level is below the threshold, then the event is ignored.

   If no threshold is specified for the event's logger, then the event inherits the threshold setting of the nearest ancestor logger. For example, if an Audit.Meta.Security event is being processed, then inheritance occurs as follows:

   a The event's level is compared to the threshold for the Audit.Meta.Security logger.

   b If no threshold is specified for Audit.Meta.Security, then the threshold for Audit.Meta is applied.

   c If no threshold is specified for Audit.Meta, then the threshold for Audit is applied.

   d If no threshold is specified for Audit, then the threshold for Root is applied.

   If no thresholds are assigned to the logger or its ancestors, then the event is ignored.

4 The log event is processed by the appenders that are assigned to the logger and any of its ancestors in the logging configuration. For example, an Audit.Meta.Security event is processed by the appenders that are assigned to the following loggers: Audit.Meta.Security, Audit.Meta, Audit, and Root.

   Each of these appenders processes the event according to the appender's configuration as specified in the logging configuration. Appender processing is performed as follows:

   a If the appender configuration includes a threshold, then the event's level is compared to the threshold. If the event's level is at or above the threshold, then processing continues. If the level is below the threshold, then processing stops.

   b If the appender configuration includes a filter, then the event is compared to the filtering criteria. Processing either continues or stops depending on the results of the comparison.

   c The event is written to the output destination using the specifications that are defined in the appender configuration. Appender specifications include
parameters such as pattern layouts, log directories, log filenames, rolling policies, locales, and encoding.

Loggers

What Is a Logger?

A logger is a named entity that identifies a message category. A logger's attributes consist of a level and one or more appenders that process the log events for the message category. The level indicates the threshold, or lowest event level, that is processed for this message category.

Loggers are specified in log events to associate the log event with a message category. By categorizing log events, the logger can write messages of the same category to the same destinations. When a log event occurs, the log event message is processed by the appender that is associated with the logger that is named in the event log. However, the log event level must be the same or higher than the level that is specified for the logger.

Loggers are organized hierarchically and inherit the attributes of their ancestor logger. Hierarchical logger names are separated by a period (.) (for example, Admin.Meta.Security). The root logger is the highest level logger. All loggers inherit the root logger's attributes. The logging configuration file defines several message categories that are immediate descendants of the root logger. These high-level categories, Admin, App, Audit, IOM, and Perf, are used for SAS server logging and can be referenced by log events in SAS programs.

You configure loggers in a logging configuration file for SAS server logging or by using SAS language elements in a DATA step or macro program. If you perform a planned deployment, then the SAS Deployment Wizard provides logging configuration files for your SAS servers. You can dynamically adjust thresholds by using the server management features of SAS Management Console. For more information, see “Administering Logging for SAS Servers” in the SAS Intelligence Platform: System Administration Guide.

For more information, see “Logging Thresholds” on page 18 and “Appenders” on page 12.

XML Elements for Configuring Loggers

In a logging configuration file, a logger has the following structure:

```xml
<logger name="logger-name" additivity="TRUE  | FALSE"
   immutability="TRUE  | FALSE">
   <level value="threshold"/>
   <appender-ref ref="appender-name"/>
</logger>
```

Syntax Description:
name="logger-name"
    specifies the name of a message category name. The logger name is specified in a log event to associate a message with a message category.

additivity= |
    specifies whether to pass the log event to loggers in the hierarchy.

immutability= |
    specifies whether the logger’s additivity and level settings are permanent or whether they can be changed by using the SAS language. In addition, specifies whether an appender can be attached to a logger by using the SAS language. If the value of IMMUTABILITY is TRUE, no changes can be made to the logger’s additivity and level settings and an appender cannot be attached to a logger by using the SAS language. If the value of IMMUTABILITY is FALSE, the logger level and the additivity setting can be changed using the SAS language and appenders can be attached to loggers by using the SAS language.
    IMMUTABILITY is ignored for configuration changes that were made by administrators using SAS Management Console or the IOMOPERATE procedure.

level value="threshold"
    specifies one of the following levels, from lowest to highest: TRACE, DEBUG, INFO, WARN, ERROR, FATAL. You use the threshold to filter log events. If the log event diagnostic level is the same or higher than the threshold that is specified for the log event's logger, the logging facility continues to process the log event. If the log event diagnostic level is lower than the logger's threshold, the log event is ignored.

appender-ref ref="appender-name"
    specifies the name of an appender to record messages for this logger's message category.

Hierarchical Logger Names

The logger architecture enables logger names to be multiple levels so that descendant loggers can inherit thresholds and appender references from their parent loggers, therefore omitting the appender reference and threshold in the descendant logger definition. You separate hierarchical logger names with a period (.).

For example, suppose that your logging facility configuration file defines the Admin logger with an appender reference value of MyRollingFile and a threshold of Info. A second logger definition, Admin.MyPgm, specifies the logger name and a threshold of Debug. Because no appender reference is specified in Admin.MyPgm, the appender reference is inherited from its parent, the Admin logger. The appender reference MyRollingFile logs messages for Admin log events whose level is INFO or higher, as well as Admin.MyPgm log events whose level is DEBUG or higher.

These loggers might be defined using the following logger elements in the logging configuration file:

```xml
<logger name="Admin">
    <level value="Info"/>
    <appender-ref ref="MyRollingFile"/>
</logger>

<logger name="Admin.MyPgm">
```

```xml
```
If a log event specifies a hierarchical logger name that does not exist, the logging facility checks for a parent logger definition. If the parent logger exists, the log event is processed by the parent logger. If a logger definition does not exist for the parent, the root logger processes the log event.

Consider the example logger definitions in this section. If a log event specifies the logger Admin.Special, the logging facility determines that the logger Admin.Special does not exist. The logging facility then checks for the Admin logger. In this case, the Admin logger exists and the log event is processed by the Admin logger. If the Admin logger was not defined, the root logger would process the log event.

SAS Server Logger Names

Log events for SAS servers use a hierarchical logger name where each name in the hierarchy identifies a category such as an operation, a server, and a server operation. For example, log events that specify the Admin.OLAP.Security logger indicate that the message is an OLAP server security message that is intended for a system administrator or computer operator.

SAS server logger names begin with one of the following logger categories:

Admin 
processes log events that are relevant to system administrators or computer operators.

App 
processes log events that are related to specific applications. For example, metadata servers, OLAP servers, stored process servers, and workspace servers use loggers that are named App.class.interface.method to record method calls that are issued to the server.

Audit 
processes log events to be used for auditing. These events include updates to public metadata objects, user access to SAS libraries, accepted and rejected user authentication requests, and administration of users, groups, and access controls.

IOM 
processes log events for servers that use the Integrated Object Model (IOM). The IOM interface provides access to Foundation SAS features such as the SAS language, SAS libraries, the server file system, results content, and formatting services. IOM servers include metadata servers, OLAP servers, stored process servers, and workspace servers.

Perf 
processes log events that are related to system performance.

The second category in a hierarchical logger name can indicate a type of server or some type of event, such as authentication. In most cases, however, the categories
are self-explanatory. The following list gives some examples of server categories for
the logging facility.

<table>
<thead>
<tr>
<th>Logging Facility Server Category</th>
<th>SAS Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect</td>
<td>SAS/CONNECT Server</td>
</tr>
<tr>
<td>Meta</td>
<td>SAS Metadata Server</td>
</tr>
<tr>
<td>ObjectSpawner</td>
<td>SAS Object Spawner</td>
</tr>
<tr>
<td>OLAP</td>
<td>SAS OLAP Server</td>
</tr>
</tbody>
</table>

Here is a list of some of the loggers that the logging facility uses for SAS servers:

**Admin.Operations**
- processes log events that are related to server operations, such as starting,
  pausing, and stopping an instance of a workspace server.

**Admin.Session**
- processes log events that are related to starting and stopping batch, windowing,
  and SAS/CONNECT server sessions.

**Audit.Authentication**
- processes log events for server authentication requests.

**Audit.Data.Dataset.Open**
- processes log events that are related to users’ access to SAS libraries.

**Audit.Logging.Configuration.Logger**
- processes log events that are related to configuring a logger.

**Audit.Logging.Configuration.Appender**
- processes log events that are related to configuring an appender.

**Audit.Logging.Configuration.Config**
- processes log events for all logging configuration changes.

**App.Program**
- processes log events that are related to running a program using the SAS
  language.

**IOM**
- processes log events that are related to client interactions.

**IOM.PE**
- processes log events that are related to packets that are processed by the
  BRIDGE and COM protocol engines.

**Perf.ARM**
- processes log events that are related to ARM 4.0 transactions.

SAS issues an error message if a logger cannot be configured or accessed.

---

**Loggers in the SAS Language**

You create loggers in SAS programs by using the following SAS language elements:
%log4sas_logger( ) autocall macro for macro programming
log4sas_logger function in a DATA step
Declare Logger object constructor statement in a DATA step

See the following reference documents for information about defining loggers in the SAS language:

"%LOG4SAS_LOGGER Autocall Macro" on page 168
"LOG4SAS_LOGGER Function" on page 179
"DECLARE Statement: Logger Object" on page 193

If you are writing SAS programs, you can write log events for loggers that are defined in one of the logging configuration files, or you can write log events for loggers that you create by using the SAS language.

Loggers that are created by using the SAS language exist for the duration of the SAS session.

---

### Appenders

#### Appender Overview

An appender is a named entity that is referenced by a logger. An appender specifies the destination for the message, specifies how the message is formatted, specifies attributes for the appender class, and provides additional filtering capabilities.

When a log event occurs, the logging facility processes the message by using the appender that is named. The appender can be named either in the logger's <appender-ref> element in a logging facility configuration file, or in the APPENDER-REF argument of a logger language element in a SAS program.

SAS has several appender classes for processing messages:

- appenders to log messages to an operating system console
- an IOM server appender to log messages from any IOM server
- file appenders for writing log messages to a file on disk
- appenders to write to Windows, UNIX, and z/OS operating system logs
- an appender to write messages to a message queue

For a complete list and description of the SAS server appenders, see "SAS Appenders for Server Logging" on page 16.

You define appenders in the logging configuration file or in a SAS program by using a SAS function, autocall macro, or DATA step component object. An appender definition requires an appender class and name and the required parameters for the appender class. To customize the message, you specify the message layout within the appender definition. In a logging facility configuration file, you can include additional filtering arguments in the appender definition.

Logger definitions in SAS programs can reference appenders that are defined in a SAS program or any of the SAS server appenders. Appenders that you create by
using the SAS language can be attached to a logger only if the logger immutability is not set.

For more information, see “Creating and Using Appenders in a SAS Program ” on page 151.

XML Elements for Configuring Appenders

General Appender Syntax

In a logging configuration file, the appender has the following general structure:

```xml
<appender class="appender-class" name="appender-name">
  [ <param name="parameter-name" value="parameter-value"/>-1
  _ <param name="parameter-name" value="parameter-value"/>-n ]
  [ <layout>
    <layout-parameters/>
  </layout> ]  [ <filter>
    <filter-definitions>
  </filter> ]
</appender>
```

The brackets ([ ]) indicate that the element is optional.

Syntax Description:

- **class="appender-class"**
  
The appender class is a type of appender. The following appender classes can be used in the logging facility:
  
  - ARMAppender
  - ConsoleAppender
  - DBAppender
  - FileAppender
  - FilteringAppender
  - IOMServerAppender
  - JavaAppender
  - JMSAppender
  - RollingFileAppender
  - sLogAppender
  - UNIXFacilityAppender
  - WindowsEventAppender
  - ZOSFacilityAppender
  - ZOSWtoAppender

See “Appendver Reference” on page 45
name="appender-name"
The appender name is a user-specified name for the appender. An appender is associated with a logger when the appender name is specified as the value of the logger's appender-ref attribute.

<param name="parameter-name" value="parameter-value"/>
Most appenders have required parameters for specifying information that is relevant to the appender. Many parameter names are unique for individual appenders. The name= attribute specifies the name of the parameter, and the value= attribute specifies the value for the parameter.

For example, appenders that write messages to a user-specified file use the File parameter, where the value of the File parameter specifies the location and name of the log file.

See “Appender Reference” on page 45 for each appender's required parameters

Note: The following layout syntax is valid only for SAS 9.4 environments.

<layout>
<param name="ConversionPattern" value="conversion-pattern"/>
<param name="Header" value="literal-string"/>
<param name="HeaderPattern" value="conversion-pattern"/>
<param name="Footer" value="literal-string"/>
<param name="FooterPattern" value="conversion-pattern"/>
<param name="XMLEscape"/>
</layout>
You use the <layout> elements to specify how messages should be formatted in the log. The conversion pattern is a series of conversion characters that represent the types of data to include in the log. For example, use the conversion characters %d, %t, and %m to include the date and time, the thread identifier, and the message, respectively, in the log.

You can use the Header, HeaderPattern, Footer, and FooterPattern parameters to specify the conversion characters that appear at the top and the bottom of the log. You can use the XMLEscape parameter to specify whether certain characters (for example, "<") are converted to their entity representation, which in this case would be "&lt;".

See “Formatting Messages” on page 19

Note: The following layout syntax is valid only if you have SAS 9.4 and SAS Viya in your environment.

<layout type=|<param name=|\<layout-parameters>\</layout>
You use the <layout> elements to specify how messages should be formatted in the log. If the layout type is "standard", then the conversion pattern is used to configure the output as it is configured in an environment that is running SAS 9.4 only. If the layout type is "json", then JSON options that are included in the ensuing layout parameters are used to configure the output into a JSON object. All of the ensuing layout parameters except for the Individual parameter are considered to be JSON options.
Individual parameter

The Individual parameter indicates whether to write multiple JSON records out as a comma-separated list that can be processed with a JSON processor or to write them out individually with no separating commas or with no beginning or ending square braces. Use the parameter as follows:

1 Individual parameter is “false”.

This is the default value for the Individual parameter. Use this when you want to write out multiple JSON log records to be processed in one file as follows:

```json
[
    {"key": "value"...},
    {"key": "value"...},
    {"key": "value"...},
    {"key": "value"...}
]
```

2 Individual parameter is “true”.

Use this when you want to write out individual JSON log records as follows:

```json

{"key": "value"...}
{"key": "value"...}
{"key": "value"...}
{"key": "value"...}
```

JSON type

The type of the parameter value can be specified by adding one of the following strings to the end of the parameter name. If one of these set strings is present, then the logging facility tries to format the value into that type. The supported types and their associated strings are as follows:

<table>
<thead>
<tr>
<th>JSON Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>String:</td>
<td>This is the default value. No string is specified.</td>
</tr>
<tr>
<td>Numeric</td>
<td>#</td>
</tr>
<tr>
<td>List</td>
<td>[]</td>
</tr>
<tr>
<td>Boolean</td>
<td>^</td>
</tr>
<tr>
<td>Object</td>
<td>{}</td>
</tr>
</tbody>
</table>

Here is an example of a parameter for which the numeric type is specified.

This parameter, `<param name="version#" value="5">`, outputs this value: `{"version":5}`.

Here is an example of the same parameter with no specified type. The type defaults to the string type.

This parameter, `<param name="version" value="5">`, outputs the following value: `{"version":"5"}`.
The JSON layout type is used by the RabbitmqAppender for internal log processing.

```xml
<filter>
<filter-definitions/>
</filter>
```

You can use filters to accept or deny messages based on the following:

- a character string in the message
- a range of message thresholds
- a single message threshold
- a combination of character string, single message threshold, or a range of message thresholds

See “Filters” on page 135

---

**SAS Appenders for Server Logging**

The following appenders can be configured as the value of the `<appender>` "class" attribute in the XML configuration files for SAS servers:

**ARMAppender**
processes all Application Response Measurement (ARM) messages that are submitted by an external ARM agent or by the SAS ARM agent.

**ConsoleAppender**
writes messages to the UNIX and Windows operating system consoles.

**DBAppender**
writes log events to a SAS table or to a table in a third-party DBMS.

**FileAppender**
writes messages to the specified file in the specified path.

**FilteringAppender**
applies specified filters to determine whether events should be passed to a referenced appender. You can specify a layout to be applied to the events before they are passed.

**IOMServerAppender**
commits messages from any IOM server to a volatile run-time cache.

**JavaAppender**
sends messages to a custom Java class.

**JMSAppender**
sends messages to a message queue by using the Java Message Server (JMS) interface.

**RollingFileAppender**
writes messages to the specified file in the specified path, and begins writing messages to a new file that has a different name when specified criteria are met.

**sLogAppender**
is a reserved appender. You should not define new instances of this appender.

**UNXFacilityAppender**
writes messages to the syslogd logging facility in UNIX operating systems.
WindowsEventAppender
writes messages to the Windows Event log.

ZOSFacilityAppender
enables multiple instances of SAS in the z/OS operating system to write
messages to a common location.

ZOSWtoAppender
directs SAS application messages to the z/OS operating system console.

Appenders in the SAS Language

When you specify an appender reference in a logger language element, you can
use any of the appenders that are defined for SAS server logging and the appender
FileRefAppender.

FileRefAppender is an appender that you create only in the SAS language, and only
by using a SAS function, DATA step object, or autocall macro. As the name
indicates, FileRefAppender names a fileref that defines a location to store
messages. FileRefAppender is the only appender that can be created by using the
SAS language. FileRefAppender can be attached to a logger only if logger
immutability is not set.

When you create an appender in a DATA step, the appender is available only for the
duration of the DATA step. After the DATA step has run, the appender is no longer
available.

For more information, see “Creating and Using Appenders in a SAS Program” on
page 151.

Referencing Appenders in a Logger

After an appender is defined, it can be referenced by a logger. To reference an
appender in a logging configuration file, you include the appender name in the
logger's <appender-ref> element. In the following logger and appender definitions,
the appender WinEvntVwr is referenced by the logger WEVLogger:

```xml
<appender class="WindowsEventAppender" name="WinEvntVwr">
  <param name="Appname" value="myApp"/>
</appender>

<logger name="WEVLogger">
  <level="error"/>
  <appender-ref ref="WinEvntVwr"/>
</logger>
```

To reference an appender in a logger language element, you specify the appender
name as the value of the APPENDER-REF argument:

```sas
%log4sas_logger(myLogger, "appender-ref=(myAppender) level=error");
rc= log4sas_logger("myLogger", "appender-ref=(myAppender) level=error");
```

declare logger logobj("myLogger");
logobj.appenderref="myAppender";
To write the same message in multiple logs, you can specify multiple appender references in a configuration file logger definition:

```xml
<logger name="MyLoggers">
  <level="error"/>
  <appender-ref ref="WinEvntVwr"/>
  <appender-ref ref="RollingFileAppender"/>
</logger>
```

In a SAS program, you can add multiple appender names separated by a space in the APPENDER-REF argument:

```sas
%log4sas_logger(myLogger, "appender-ref=(myAppender myRollingFile) level=error");
```

---

### Logging Thresholds

The SAS logging facility provides six thresholds: TRACE, DEBUG, INFO, WARN, ERROR, and FATAL. Thresholds are used to ignore log events that are lower than a particular level, or to filter messages so that only a single message level is logged.

When a log event occurs, up to three levels of filtering can take place:

1. filtering log events by comparing the log event level to the log event's logger level
2. filtering log events by comparing the log event level to the appender's threshold
3. filtering log events by comparing the log event level to the threshold that is specified in the filter definition, which is a part of the appender configuration

In the first two cases, if the log event level is lower than the logger or appender threshold, the logging facility ignores the log event. Otherwise, processing of the log event continues.

In the third case, the log event level is compared to the filter threshold. If there is a match, the log event can be either accepted or denied. If there is no match, the filtering process continues to the next filter in the filtering policy. For more information, see “Filters” on page 135.

The logging levels, from the lowest to the highest, are as follows:

- **TRACE** produces the most detailed information about your application. This level is primarily used by SAS Technical Support or development.
- **DEBUG** produces detailed information that you use to debug your application. This level is primarily used by SAS Technical Support or development.
- **INFO** provides information that highlights the progress of an application.
- **WARN** provides messages that identify potentially harmful situations.
- **ERROR** provides messages that indicate that errors have occurred. The application might continue to run.
FATAL provides messages that indicate that severe errors have occurred. These errors will probably cause the application to end.

Requirement: In a logging configuration file, the level must be enclosed in quotation marks.

An appender can be configured to have a threshold. By default, however, appenders do not have a threshold. When set, all log events that have a level lower than the threshold are ignored by the appender.

Formatting Messages

The format of a message can be customized by specifying a unique pattern layout for each appender class in the SAS logging facility. To create a pattern layout for an appender class, you use conversion characters that represent the types of data to include in the message. You can also control the sequence of the data and the alignment of the data in columns in the message.

Note: Conversion patterns that are used in the SAS logging facility are similar to the conversion patterns that are used in the C language PRINTF statement.

Note: The ARMAppender classes use a set of pattern layouts that are only for the ARM subsystem. For more information, see "ARM Appender Pattern Layouts for ARM Messages" in SAS Interface to Application Response Measurement (ARM): Reference.

Here is an excerpt of an XML file that contains a pattern layout:

```
<layout>
  <param name="ConversionPattern" value="%d; %-5p; %t; %c; %m"/>
</layout>
```

Each data item to be included in the message is represented by a conversion character. Also, literal text and alignment commands can be specified to enhance the message format. In this example, the data items are the date, the logging level, the thread, the logger, and the message.

Here is an example of a message:

```
2008–06–25–10:24:22,234; WARN; 3; Appender.IOMCallContext; (yn14.sas.c:149);
  Numeric maximum was larger than 8, am setting to 8.
```

For more information, see "Pattern Layouts" on page 107.
Message Filtering

In addition to filtering log events based on thresholds that are assigned to loggers or appender definitions, the logging facility enables you to use filter classes to filter log events based on the following:

- a character string in the message
- a single threshold
- a range of thresholds
- a combination of strings and thresholds

Here is a list of the filter classes:

RepeatMatchFilter
  filters repeated log messages.

StringMatchFilter
  filters messages based on a character string in the message.

LevelRangeFilter
  filters messages based on a range of thresholds.

LevelMatchFilter
  filters messages based on a single threshold.

AndFilter
  filters messages based on the results of a list of other filters.

DenyAllFilter
  denies log events that did not meet the criteria of previous filters in a filter policy.

You can define one or more filters within the <appender> definition in the logging configuration file. Filters are not available in the logging facility language elements for SAS programs.

Filters are processed in the order in which they appear in the <appender> definition, creating a filtering policy for the appender. The filters either accept the filtering criteria and process the log event, deny the filtering criteria and deny the log event, or accept the filtering criteria, and the filtering process checks the next filter in the filtering policy. If the log event has not been denied, and if there are no other filters in the filtering policy, the appender accepts and processes the log event.

For more information, see “Filters” on page 135.
About the Initial Logging Configuration for SAS Servers

When you install the SAS Intelligence Platform, the installation process performs the following configuration steps:

- It enables logging for each server by specifying the LOGCONFIGLOC= option in the server's configuration file.
- For each server, it provides a logging configuration file called `logconfig.xml` that is located in the server's configuration directory.
- For each server, it provides the following alternative logging configuration files:
  - `logconfig_trace.xml`, which can be used for troubleshooting.
  - `logconfig.apm.xml`, which can be used with the SAS Enterprise Business Intelligence Audit and Performance Measurement package. This package is available for download from [http://support.sas.com/rnd/emi](http://support.sas.com/rnd/emi).

For more information, see the following topics in the *SAS Intelligence Platform: System Administration Guide*:

- "Initial Logging Configuration for SAS Servers"
- "Default Locations for Server Logs"

Viewing SAS Logging Messages and Adjusting Logging Levels in Client Applications

The initial logging configurations for some SAS servers include appender definitions that make logging messages available in the following client applications:

- SAS Management Console. From this application, you can view logging messages for metadata servers, object spawners, OLAP servers, pooled workspace servers, and stored process servers. In this example, the metadata server log is displayed:
You can also use the Loggers tab in SAS Management Console to dynamically adjust server logging levels, without the need to restart the server. The following example shows the Loggers tab for the metadata server:

For more information, see "Using SAS Management Console to Monitor SAS Servers" in the SAS Intelligence Platform: System Administration Guide.

- SAS Data Integration Studio. From this application, you can view performance-related events that are associated with a SAS Data Integration Studio job. For more information, see the product Help.

You can also use enterprise systems management products to view server logging messages and dynamically adjust server logging levels. For more information, see the Enterprise Management Integration web page at [http://support.sas.com/rnd/emi](http://support.sas.com/rnd/emi).

### Best Practices for SAS Server Logging

When using the logging facility for SAS servers, follow these best practices:

- Use the initial logging configuration files that are created during installation. These files provide a good starting point for server logging.

- If you need to change a server's logging configuration, back up the initial configuration file before making changes. Make configuration changes incrementally, and evaluate the effect of each change before making additional changes.

- In the initial configuration files for several of the SAS servers, certain loggers are defined as immutable. To protect the integrity of server logging, you should not change these settings. The immutability setting prevents the use of SAS code to change the loggers' additivity settings or logging levels, or to attach appenders to loggers.
Do not use the TRACE and DEBUG levels unless you are directed to do so by SAS Technical Support, since these logging levels can affect performance. You can use either of these methods to adjust logging levels for SAS Technical Support:

- Enable the `logconfig_trace.xml` file that is provided for the server.
- Use the server manager features of SAS Management Console to adjust levels temporarily and avoid having to restart the servers.

For more information, see the following documents:

- *SAS Interface to Application Response Measurement (ARM): Reference* describes SAS features that are compliant with the ARM 2.0 and ARM 4.0 standards and that enable you to monitor the performance of SAS applications.
Enabling the SAS Logging Facility

Enabling the Logging Facility for SAS Server Logging

You enable the SAS logging facility for SAS servers, by specifying the LOGCONFIGLOC= system option when SAS starts. The LOGCONFIGLOC= system option names the location of the logging configuration file.

You can add the LOGCONFIGLOC= system option to either the SAS configuration file or to the SAS command that you use to start SAS. If you perform a planned deployment, then the SAS Deployment Wizard includes this system option in the configuration for your SAS servers.

This system option can be set only when SAS starts and not during a SAS session. For more information, see “LOGCONFIGLOC= System Option” on page 28.

Enabling the Logging Facility in SAS Programs

The logging facility is enabled for SAS programs at all times. That is, it is not necessary to specify the LOGCONFIGLOC= system option in order for SAS programs to use the logging facility.

If you use the logging facility autocall macros, the MAUTOSOURCE system option must be set and the %LOG4SAS autocall macro must be invoked before any other logging facility autocall macros are invoked. The MAUTOSOURCE system option is set by default. No further action is required unless this option is turned off.

The logging facility functions and DATA step objects have no initialization requirements.
Naming a SAS Session

Logging facility messages can be set to include the name of the SAS session, which might help you to read the log and to diagnose problems.

To identify a SAS session by name, you specify a session name as the value of the LOGAPPLNAME= system option.

To display the value of the LOGAPPLNAME= system option in a message, you must include the S conversion character in the conversion pattern layout, using the key App.Name.

For more information, see “LOGAPPLNAME= System Option” on page 27 and the “S Conversion Character” on page 128.
System Options for Enabling the SAS Logging Facility

Dictionary

LOGAPPLNAME= System Option

Specifies a SAS session name for SAS logging.

Valid in: configuration file, SAS invocation

Category: Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP=

LOGCONTROL

Syntax

LOGAPPLNAME=name

Syntax Description

name specifies a name for the SAS session. If the name contains a space, enclose the name in either single or double quotation marks.

Details

The name that is specified by the LOGAPPLNAME= system option is used to identify the name of a SAS session in logging facility logs if the S conversion character is specified in the pattern layout.

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.
You can use the &SYSLOGAPPLNAME automatic macro variable to obtain the name of the SAS session in a SAS program.

See Also
- “S Conversion Character” on page 128

Automatic Macro Variables:
- “SYSLOGAPPLNAME Automatic Macro Variable” in SAS Macro Language: Reference

LOGCONFIGLOC= System Option

Specifies the name of the XML configuration file or a basic logging configuration that is used to initialize the SAS logging facility.

Valid in: configuration file, SAS invocation, spawner invocation
Category: Environment Control: Initialization and Operation
PROC OPTIONS GROUP=
Alias: LOGCFGLOC=
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

Production Syntax
LOGCONFIGLOC=file-specification

Basic Logging Configuration Syntax
LOGCONFIGLOC=basic:level, FileAppender, path-and-filename-pattern
LOGCONFIGLOC=basic:level, ConsoleAppender
LOGCONFIGLOC=basic:level

Syntax Description

file-specification
specifies the physical name of the XML configuration file that is used to initialize the SAS logging facility. The physical name is the name that is recognized by your operating system. Enclose the physical name in single or double quotation marks if the name contains spaces.

basic:level,FileAppender, path-and-filename-pattern
specifies to write messages to the specified file. basic: indicates to use the root logger. FileAppender indicates to use the FileAppender class.

Provide values for these arguments:
**level**
specifies the logging threshold. Valid values are TRACE, DEBUG, INFO, WARN, ERROR, or FATAL.

See “Logging Thresholds” on page 18

**path-and-filename-pattern**
specifies the path to which the log file is written and the conversion pattern that is used to create the log filename. The conversion pattern can include the %d and %S(key) conversion characters.

See “d Conversion Character” on page 121

“S Conversion Character” on page 128

**Note**
The appender that SAS creates uses DEFAULTHEADER as the HeaderPattern parameter and DEFAULT for the ConversionPattern parameter. For more information, see “Conversion Patterns Supplied by SAS” on page 108.

See “FileAppender” on page 57

“About Basic Logging Configurations” on page 30

**basic:level,ConsoleAppender**
specifies to write messages to the current console. basic: indicates the root logger. ConsoleAppender indicates to use the ConsoleAppender class.

Provide a value for this argument:

**level**
specifies the logging threshold. Valid values are TRACE, DEBUG, INFO, WARN, ERROR, or FATAL.

See “Logging Thresholds” on page 18

**Note**
This configuration uses the conversion pattern DEFAULTHEADER for the HeaderPattern parameter and the conversion pattern DEFAULT for the ConversionPattern parameter.

See “ConsoleAppender” on page 49

“About Basic Logging Configurations” on page 30

**basic:level**
specifies to use the root logger. When the root logger is specified without an appender, messages are written to the traditional SAS log.

Provide a value for this argument:

**level**
specifies the logging threshold. Valid values are TRACE, DEBUG, INFO, WARN, ERROR, or FATAL.

See “Logging Thresholds” on page 18

See “Logger” on page 41
Details

The Basics

If the LOGCONFIGLOC= system option is specified when SAS starts, and if the SYSIN= option or the OBJECTSERVER option is also specified, logging is performed only by the logging facility; the SAS log is not started and the LOGPARM= system option is ignored. The LOG= system option is applied only when the %S{App.Log} conversion character is specified in the logging configuration file.

About Basic Logging Configurations

SAS provides three basic logging configurations for you to experiment with the logging facility:

- basic:level,FileAppender,path-and-filename-pattern
- basic:level,ConsoleAppender
- basic:level

By using one of the basic logging configurations, you can experiment with the logging facility without creating a configuration file. SAS creates a configuration file for you based on the basic logging configuration that you specify in the LOGCONFIGLOC= system option. The basic logging configurations enable messages to be written to a file, the current console, and the traditional SAS log.

Example

The following example shows the use of the LOGCONFIGLOC= system option for a user-specified logging configuration:

```
sas -logconfigloc metaserverlog.xml
```

The following example shows the use of the LOGCONFIGLOC= system option for a basic logging configuration:

```
sas -logconfigloc basic:INFO,FileAppender,c:\mylog\logFacility.%S{hostname}.log
```

Overview of the Logging Configuration File

Typographical Conventions

Type styles have special meaning for some components of XML syntax in the logging configuration file. The following list explains the style conventions for the syntax:

*italics* identifies arguments or values that you supply. Items in italics can represent user-supplied values that are either one of the following:

- nonliteral values that are assigned to an argument (for example, value="column-parameter")
- nonliteral arguments (for example, <filter-definitions>)

*case sensitivity*

All text is case sensitive in the logging configuration file. Enter element and attribute names, as well as literal values, as they are shown in the syntax.
Syntax Conventions

In traditional SAS syntax, angle brackets (<>) are used to denote optional syntax. In the logging configuration file syntax, square brackets ([ ]) are used to denote optional syntax. The logging configuration file syntax uses the following symbols:

< >
The left angle bracket begins an XML element. The right angle bracket ends an XML element.

/ A slash before an element name ends the element definition.

/> A slash followed by a right angle bracket ends the definition for the <param>, <level>, and <appender-ref> subelements.

[ ] Square brackets identify optional elements or arguments. Any XML element or attribute that is not enclosed in square brackets is required.

| A vertical bar indicates that you can choose one value from a group of values. Values separated by bars are mutually exclusive.

-1-n... For repeated elements, the -1 after an element indicates the first element. The ellipsis before an element and the -n after the same element indicate that the element can be repeated any number of times.

" " Double quotation marks identify an attribute value.

XML Elements for Configuring SAS Logging

You use <?xml?> and <logging:configuration> elements as the first XML elements in the configuration file to specify XML attributes and the SAS logging message category.

The <appender>, <logger>, and <root> elements define the loggers and appenders. The <param>, <layout>, <level>, <filter>, and <appender-ref> elements are child elements that customize appender and logger definitions.

The following table summarizes the XML DTD for SAS logging:
<table>
<thead>
<tr>
<th>Element Name and Description</th>
<th>Element Characteristics</th>
</tr>
</thead>
</table>
| `<?xml ?>` | - Number of instances: one  
- Required attributes:  
  - version="1.0"  
- Optional attributes:  
  - encoding= "encoding-specification " specifies a language encoding. For more information, see the SAS National Language Support (NLS): Reference Guide. |
| `<logging:configuration>` | - Number of instances: one  
- Required attributes:  
  - xmlns:logging="http://support.sas.com/xml/logging/1.0/"  
- Optional attributes:  
  - threshold="level" specifies the default message threshold for filtering log messages; the default is null, two double quotation marks with no space between them (""). For a list of levels, see "Logging Thresholds" on page 18.  
  - debug="TRUE|FALSE" specifies whether to run in debug mode; the default is "FALSE". Setting a value of "TRUE" is the same as setting the level to a value of "DEBUG" for the logger that is specified in the log event.  
  - modify="TRUE|FALSE" specifies whether to modify the configuration file; the default is "FALSE". Set modify="TRUE" to add a new appender, connect a logger to a new or existing appender, remove an appender, or change a logger level. Set modify="FALSE" if you are not modifying the logging configuration file or if you are replacing the configuration file. You can use the IOMOPERATE procedure to modify the configuration file. For more information, see “IOMOPERATE Procedure” in SAS Intelligence Platform: Application Server Administration Guide at http://support.sas.com.  
- Optional child elements: number of instances  
  - `<appender>`: zero or more  
  - `<logger>`: zero or more  
  - `<root>`: zero or one |
<table>
<thead>
<tr>
<th>Element Name and Description</th>
<th>Element Characteristics</th>
</tr>
</thead>
</table>

- `<appender>`
  - Defines a destination for log messages, filters to limit log messages, and the format of the log message
  - Number of instances: zero or multiple
  - Required attributes:
    - `name="appender-name"` is a user-defined name for the appender.
    - `class="class-name"` specifies the type of appender. For more information, see “SAS Appenders for Server Logging” on page 16.
    - `remove="TRUE|FALSE"` specifies whether to remove the appender from the logging configuration file; the default is "FALSE". A value of "TRUE" removes the appender from the logging configuration file. A value of "FALSE" does not remove the appender from the logging configuration file.
  - You can use the IOMOPERATE procedure to modify the configuration file. For more information, see “IOMOPERATE Procedure” in SAS Intelligence Platform: Application Server Administration Guide at http://support.sas.com.
  - Optional child elements: number of instances
    - `<param>`: zero or multiple
    - `<layout>`: zero or one
    - `<filter>`: zero or multiple
    - `<appender-ref>`: zero or multiple
    - `<rollingPolicy>`: zero or one; required when the appender class is RollingFileAppender. Otherwise, do not include this element.

- `<logger>`
  - Names a message category, references an appender, and defines a message threshold
  - Number of instances: zero or multiple
  - Required attribute:
    - `name="logger-name"` is the name of the message category.
  - Optional attribute:
    - `additivity="TRUE | FALSE"` specifies whether to pass the log event to loggers in a hierarchy.
    - `immutability="TRUE | FALSE"` specifies whether settings for additivity and level can be changed by using the SAS language, and whether an appender can be attached to a logger using the SAS language.
  - Optional child elements: number of instances
    - `<level>`: zero or one
    - `<appender-ref>`: zero or multiple

- `<root>`
  - A fixed SAS logger and the highest logger in any logging hierarchy
  - Number of instances: one
  - Note: A root logger is not required for a logging configuration file that is used to modify a logging configuration.
  - Attributes: none
  - Optional child elements: number of instances
    - `<level>`: zero or one, the default is "INFO"
    - `<appender-ref>`: zero or multiple
<table>
<thead>
<tr>
<th>Element Name and Description</th>
<th>Element Characteristics</th>
</tr>
</thead>
</table>
| `<param />`                 | - Number of instances: zero or multiple  
| defines a logger, appender, or a filter parameter and a parameter value | - Required attributes:  
|                             |   - `name="attribute-name"` specifies the literal name of an attribute.  
|                             |   - `value="attribute-value"` specifies either a literal or user-supplied value. |
| `<layout>`                  | - Number of instances: zero or one  
| specifies conversion-pattern layouts | - Optional child element: number of instances  
| `/layout>`                  | - `<param>`: zero or multiple |
| `<level>`                   | - Number of instances: zero or one  
| defines the message threshold that a logger accepts | - Required attribute:  
|                             |   - `value="level"` specifies a message threshold for filtering log events; by default, a level is inherited from the parent logger. For more information, see "Logging Thresholds" on page 18. |
| `<filter>`                  | - Number of instances: zero or one  
| specifies message-filtering values | - Required attribute:  
| `/filter>`                  |   - `class="filter-class"` specifies the name of the filter. For more information, see “Message Filtering” on page 20.  
|                             |   - Optional child element: instances  
|                             |     - `<param>`: zero or multiple |
| `<appender-ref>`            | - Number of instances: zero or multiple  
| names an appender for processing a log event | - Required attribute:  
| `/appender-ref>`            |   - `ref="appender-name"` specifies a user-defined appender name |

Structure of the Logging Configuration File

The layout of a logging facility XML configuration file must contain, at minimum, the `<xml?>` element, the `<logging>` element, and a `<root>` logger. The first two elements, in order, are these elements:

1. `<xml>`
2. `<logging:configuration>`

After the `<logging: configuration>` element, these elements can appear in any order:

- `<appender>`
Here is an example configuration file that shows the structure of the configuration file:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<logging:configuration xmlns:logging="http://support.sas.com/xml/logging/1.0/">
  <appender class="RollingFileAppender" name="TimeBasedRollingFile">
    <param name="Append" value="true"/>
    <param name="ImmediateFlush" value="true"/>
    <param name="Unique" value="true"/>
    <filter class="StringMatchFilter">
      <param name="LevelToMatch" value="error"/>
      <param name="AcceptOnMatch" value="true"/>
    </filter>
    <rollingPolicy class="TimeBasedRollingPolicy">
      <param name="FileNamePattern" value="c:\sas\logs\server\workspace_%d.log"/>
    </rollingPolicy>
    <layout>
      <param name="ConversionPattern" value="%d %-5p [%t] %u - %m"/>
    </layout>
  </appender>
  <appender class="FileAppender" name="rootAppender">
    <param name="Append" value="true"/>
    <param name="ImmediateFlush" value="true"/>
    <param name="File" value="c:\logs\root\root1.log"/>
  </appender>
  <logger name="log4WServer">
    <level value="info"/>
    <appender-ref ref="TimeBasedRollingFile"/>
  </logger>
  <root>
    <level value="error"/>
    <appender-ref ref="rootAppender"/>
  </root>
</logging:configuration>
```

Sample Configuration Files

SAS supplies sample logging facility configuration files in the SASHOME directory. Under Windows, from the SASHOME directory, expand SASFoundation 9.4 core and select sample. Scroll to find these sample configuration files:

1. logconfig.xml.win.admin.event.viewer
2. logconfig.xml.win.audit.event.viewer
3. logconfig.xml.win.audit.file
Modifying or Replacing the Logging Configuration File

You can use the SET LOG CFG command of the IOMOPERATE procedure to replace or modify the logging configuration.

You can modify the logging configuration to do the following:

- configure a logger with a new or existing appender
- change a logger level
- add a new appender
- remove an appender

Note: SAS ignores the IMMUTABILITY settings of a logger when an administrator modifies a configuration file using the IOMOPERATE procedure or SAS Management Console.

To modify the logging configuration, you create a logging configuration file only with the changes that you would like to make. A complete configuration file is not required. The configuration file must contain the `<xml>`, `<logging:configuration>`, and `<logging:configuration>` elements. Any time you modify the logging configuration, the `<logging:configuration>` element must have the modify attribute set to "TRUE". If you are removing an appender, the remove attribute on the appender element must be set to "TRUE". Here is an example of a logging configuration file that is used to associate an existing appender with a logger:

```xml
<?xml version="1.0"?>
<logging:configuration
   xmlns:logging="http://www.sas.com/xml/logging/1.0/" modify="true">
  <logger name="App.Program">
    <appender-ref ref="newcons"/>
  </logger>
</logging:configuration>
```
To replace the logging configuration, you create a new logging configuration file. The `<logging:configuration>` element must have the modify attribute set to "FALSE" or the modify attribute must not be present in the `<logging:configuration>` element.

When you modify or replace the logging configuration, the IOMOPERATE procedure might look similar to this:

```sas
proc iomoperate uri="iom://localhost:15976;Bridge;TRUSTEDSAS" type=METADATA;
  set log cfg="newcfg.xml";
quit;
```

---

Error Messages for Logging Configuration Files

If an error occurs in a logging configuration file, SAS issues one of the following error messages:

- Failed to create Appender.
- Failed to configure Appender.
- Failed to add Appender
- Failed to configure Logger.
- Failed to get Logger.
- Failed to allocate a buffer for the configuration path.
Logger Reference

Dictionary

Logger

A logger names a specific message category and associates the message category with a message level and one or more appenders that process the log message.

See: “Loggers” on page 8

Syntax

XML Configuration

<logger name="logger-name" additivity="TRUE | FALSE"
   immutability="TRUE | FALSE">
   <level value="TRACE | DEBUG | INFO | WARN | ERROR | FATAL"/>
   <appender-ref ref="appender-name"/>
</logger>

Syntax Description

name="logger-name"

specifies the name of a message category. The value of logger-name is case sensitive and can be a single name or a hierarchical name. Use a period to separate hierarchical names. Quotation marks are required.

Default None

Requirement Yes

additivity=" | "

specifies whether to pass the log event to loggers in the hierarchy:
TRUE
specifies to pass the log event to loggers in the hierarchy.

FALSE
specifies not to pass the log event to loggers in the hierarchy.

Default TRUE
Requirement No

**immutability=**

specifies whether the logger’s additivity and level settings are permanent or whether they can be changed by using the SAS language. In addition, specifies whether an appender can be attached to a logger using the SAS language. These are the only changes that can be made using the SAS language.

TRUE
specifies that no changes can be made to the logger’s additivity and level settings and that an appender cannot be attached to a logger using the SAS language.

FALSE
logger level and additivity setting can be changed using the SAS language and an appender can be attached to a logger using the SAS language.

Default FALSE
Requirement No

Interaction
IMMUTABILITY is ignored for configuration changes made by administrators using SAS Management Console or the IOMOPERATE procedure.

See
“%LOG4SAS_LOGGER Autocall Macro” on page 168

“LOG4SAS_LOGGER Function” on page 179

“DECLARE Statement: Logger Object” on page 193

**level value=**

specifies the lowest event level that is processed by this logger. Log events that have messages that are below the specified level are ignored. The valid level values are listed here from lowest to highest. If a level is not specified, SAS uses the level of the next highest parent logger that defines a level. Quotation marks are required.

Default None
Requirement No

See
“Logging Thresholds” on page 18

**appender-ref ref="appender-name"**

specifies the name of an appender whose destination receives messages for log events that are specified for this logger. The value of appender-name must be defined in the XML configuration file. You can define multiple appenders for a logger.

Default None
Restriction  
An appender can be attached to a logger using the SAS language only if the logger option IMMUTABILITY="FALSE" is set for the logger. Logger immutability can be set only in an XML configuration file.

Requirement  
No

Details
The definition of an appender can appear anywhere in a logging configuration file. In a SAS program, an appender that is specified as an appender reference in a logger must be defined before the logger is defined.

Examples:

Example 1: Define a Logger to Log Error Messages for an Application in Production
This example creates a logger to record error log events for an application that is in production. The appender ApplProduction_Appender must also be defined in the XML configuration file.

```xml
<logger name="ApplProduction_Logger">
  <level value="error"/>
  <appender-ref ref="ApplProduction_Appender"/>
</logger>
```

Example 2: Define Loggers That Inherit the Level
In this configuration example, IOMSrv is the parent logger for IOMSrv.Workspace and IOMSrv.Metadata. The IOMSrv.Workspace logger and the IOMSrv.Metadata logger do not define a level. Therefore, they inherit the level of the closest parent, which is IOMSrv. IOMSrv defines a level of error. Log events for the IOMSrv.Workspace and the IOMSrv.Metadata message categories use the level of error and write error and fatal messages to their respective appender destinations.

```xml
<logger name="IOMSrv">
  <level value="error"/>
</logger>

<logger name="IOMSrv.Workspace">
  <appender-ref ref="WorkspaceLog"/>
</logger>

<logger name="IOMSrv.Metadata">
  <appender-ref ref="MetadataLog"/>
</logger>
```
Dictionary

ARMAAppender
Logs performance data based on ARM 2.0 and ARM 4.0 standards. It supports default transaction correlation and converts ARM transaction events that were created prior to SAS 9.2 into SAS log events.

Valid in: XML Configuration

Note: ARMAAppender syntax is case sensitive.

See: This document covers only the syntax of ARMAAppender. For information about using ARM in SAS, including details about using ARMAAppender, see SAS Interface to Application Response Measurement (ARM): Reference

Syntax

```xml
<Appender class="FileAppender" name="ARM-log-name">
  <param name="File" value="file-name"/>
  <layout>
```

<param name="ConversionPattern" value="%d,
%{App.Name},
%{ARM.Id},
%{ARM.GroupName},
%{ARM.TranName},
%{ARM.TranState},
%{ARM.TranId},
%{ARM.TranHandle},
%{ARM.ParentCorrelator},
%{ARM.CurrentCorrelator},
%{ARM.TranStatus},
%{ARM.TranStart.Time},
%{ARM.TranStop.Time},
%{ARM.TranBlocked.Time},
%{ARM.TranResp.Time}
"/>
</layout>
</appender>
<appender class="ARMAppender" name="ARM-appender-name">
<param name="Agent" value="ARM-agent-library"/>
<param name="Encoding" value="encoding-value"/>
<param name="GetTimes" value="TRUE | FALSE"/>
<param name="ManageCorrelators" value="TRUE | FALSE"/>
<param name="AppName" value="application-name"/>
<param name="GroupName" value="group-name"/>
<appender-ref ref="ARM-log-names"/>
</appender>

Syntax Description

**appender class="ARMAppender" name="ARM-appender-name"**

specifies an appender name for the ARM appender.

<table>
<thead>
<tr>
<th>Default</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restriction</td>
<td>Only one instance of an ARMAppender can exist per process.</td>
</tr>
</tbody>
</table>

**name="Agent" value="ARM-agent-library"**

specifies the name of the library that contains the external ARM 4.0 agent library that receives the events, in addition to the referenced appenders. See your vendor documentation for the correct library name. Two values can be used:

- **value=""**
  - if no agent is specified, output is sent to any referenced appenders. In the syntax example, the output is sent to the file appender, "ARM-log-name".

  **Note** If you intend to have a null value for the Agent parameter, you do not need to specify the parameter.

- **value="library-name"**
  - specifies the name of the library that contains the external ARM 4.0 agent library that receives the events.
### Notes

Output is always sent to all referenced appenders as well as to the external agent, if specified, and to the ARM log.

This parameter is not required.

---

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AppName</td>
<td>application-name</td>
</tr>
</tbody>
</table>

specifies the name of the application. The maximum length of the value is 128 characters, which includes the termination character ( / ). This value is sent to the ARM_REGISTER_APPLICATION() function call. To override this value, specify the SAS start-up option LOGAPPLNAME=application-name.

**Default** SAS

**Note** This parameter is not required.

---

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConversionPattern</td>
<td>conversion-pattern</td>
</tr>
</tbody>
</table>

specifies how the log event is written to the ARM log.

**Default** None. If a conversion pattern is not specified, then the log event produces an empty string.

**Note** This parameter is not required.

---

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encoding</td>
<td>encoding-value</td>
</tr>
</tbody>
</table>

specifies the type of character set encoding that is used for strings that are sent to and calls that are received by the ARM 4.0 agent library.

**Default** Native Unicode character is set for the host, or UTF-8 as required by the ARM 4.0 standards.

**Note** This parameter is not required.

---

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>File</td>
<td>path-and-filename</td>
</tr>
</tbody>
</table>

specifies the path and filename of the file to which ARM messages are written.

**Default** None

**Note** This parameter is required.

---

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetTimes</td>
<td></td>
</tr>
</tbody>
</table>

enables the ARM appender to compute transaction response time metrics.

**TRUE** Enables the appender to compute transaction response times.

**FALSE** Disables the appender to compute transaction response times.

**Default** FALSE

**Note** This parameter is not required.

---

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ManageCorrelators</td>
<td></td>
</tr>
</tbody>
</table>

specifies whether ARMAppler manages transaction correlation.

**TRUE** Enables automatic transaction correlation. The true value might affect existing benchmarks for ARM 2.0 records.
FALSE enables the application to manage transaction correlation.

**Default** TRUE

**Note** This parameter is not required.

**name**="GroupName" value="group-name"

specifies the name of a group of application instances, if any. Application instances that are started with a common run-time purpose are candidates for using the same group name. The maximum length of the value is 256 characters. This value is passed to the ARM_START_APPLICATION() function call.

**Default** The current user ID if available, otherwise NULL

**Note** This parameter is not required.

**Details**

ARMApender is configured and customized for accessing performance data. The primary role of ARMApender is to record ARM transaction events, process the events, and route the events to an appropriate output destination. These events, when processed by ARMApender, are formatted in the appropriate ARM 4.0 format, using the fixed portion of the message and the values that were recorded in the diagnostic context.

The existing ARM 2.0 implementations are changed to logger requests that contain the appropriate performance event attribute settings.

For more information about ARM and ARMApender, see *SAS Interface to Application Response Measurement (ARM): Reference*.

**Example**

The following example is a SAS logging facility configuration file that includes ARMApender. In the appender FileAppender class definition, the conversion pattern is separated by the vertical bar (|). The log message contains any character that you enter between conversion patterns.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<logging:configuration xmlns:logging="http://www.sas.com/xml/logging/1.0/">

<appender class="FileAppender" name="ARM2LOG">
  <param name="File" value="arm2.log"/>
  <param name="ImmediateFlush" value="true"/>
  <layout>
    <param name="ConversionPattern" value="%X{ARM2.Record}"/>
  </layout>
</appender>

<appender class="FileAppender" name="ARM4LOG">
  <param name="File" value="arm4.log"/>
  <param name="ImmediateFlush" value="true"/>
  <layout>
    <param name="ConversionPattern" value="%d|%12X{App.Name}|%14X{ARM.GroupName}|%12X{ARM.TranName}"/>
  </layout>
</appender>
```

48 Chapter 6 / Appender Reference
ConsoleAppender

Writes messages to the UNIX, Windows, and z/OS operating system consoles.

Valid in: XML configuration

Syntax

```xml
<appender class="ConsoleAppender" name="appender-name">
    <param name="ImmediateFlush" value="TRUE | FALSE"/>
    <param name="Target" value="STDOUT | STDERR"/>
    <layout>
        <param name="ConversionPattern" value="conversion-pattern"/>
    </layout>
</appender>
```
Syntax Description

```xml
<class="ConsoleAppender" name="appender-name">
  specifies the user-assigned name for this instance of ConsoleAppender.
</class>
```

Default None

Requirement The appender class and name are required in order to specify a console appender.

**name="ImmediateFlush"**

determines whether messages are written to the console immediately as they are received. Specify one of the following values:

TRUE
  writes messages to the console immediately as they are received.

FALSE
  does not force messages to be written to the console immediately as they are received.

Default FALSE

Requirement This parameter is not required.

**name="Target"**

specifies the console output stream to which messages are to be written. Specify one of the following values:

STDOUT
  writes messages to the console’s standard output stream.

STDERR
  writes messages to the console’s standard error stream.

Valid in Windows and UNIX environments only.

Default STDOUT

Requirement This parameter is not required.

```xml
<param name="ConversionPattern" value="conversion-pattern"/>
```

specifies a series of conversion characters that represent the types of data to include in the log. For example, use the conversion characters %d %t %m to include the date, the thread, and the message, respectively, in the log.

See “Pattern Layouts” on page 107

Details

ConsoleAppender is a logging facility appender that supports event logging on UNIX, Windows, and z/OS operating systems. ConsoleAppender writes messages to the current console.

Example

The following example is a typical XML configuration file that specifies ConsoleAppender.
<?xml version="1.0" encoding="UTF-8"?>
<logging:configuration xmlns:logging="http://www.sas.com/xml/logging/1.0/"
  <appender class="ConsoleAppender" name="console">
    <layout>
      <param name="ConversionPattern" value="%d %-5p [%t] %u - %m"/>
    </layout>
  </appender>
  <!-- Root logger -->
  <root>
    <level value="Error"/>
    <appender-ref ref="console"/>
  </root>
</logging:configuration>

DBAppender

Writes log events to a SAS table or to a table in a third-party DBMS.

Valid in: XML Configuration

Syntax

<appender class="DBAppender" name="appender-name">
  <param name="ConnectionString" value="connection-string"/>
  <param name="Locale" value="locale"/>
  <param name="MaxBufferedEvents" value="integer"/>
  <param name="SelectStatement" value="SQL-statement"/>
  <param name="TableName" value="table-name"/>
  <param name="Column" value="column-parameter-1"/>
  [...]<!-- Additional parameters -->
</appender>

Syntax Description

class="DBAppender" name="appender-name"
  specifies the user-assigned name for this instance of DBAppender.

  Default: None
  Requirement: This parameter is required.

name="ConnectionString" value="connection-string"
  specifies options for connecting to the data store to which events are to be written. Within the connection string, place a semicolon between each option. The options vary depending on the type of data store you are using. For details, see:

  - "DBAppender Connection Options for DB2" on page 99
  - "DBAppender Connection Options for ODBC" on page 100
name="Locale" value="locale"
specifies the locale that is used to write messages to the file.

Defaults
The locale setting that is in effect for the SAS session. For example, the LOCALE system option might be specified in the configuration file for a SAS server or in the configuration file for Base SAS.

For logging processes that run outside a SAS session (for example, logging for the SAS Object Spawner), the default is the locale that is specified in the operating system settings.

Requirement
This parameter is not required.

See

name="MaxBufferedEvents" value="integer"
specifies the maximum number of log events to buffer before sending them to the data store. When MaxBufferedEvents is set to 0, messages are processed synchronously, one row at a time.

Default
1

Requirement
This parameter is not required.

name="SelectStatement" value="SQL-statement"
specifies an SQL statement that identifies the name of the table, and the names of specific columns within the table, where event information is to be written. The table must already exist. If you want to write information to all of the columns in the table, use TableName instead of SelectStatement.

Requirement
SelectStatement is required if TableName is not specified.

Interaction
The TableName and SelectStatement parameters are mutually exclusive. If both of these parameters are specified, the SelectStatement parameter takes precedence.

Example
<param name="SelectStatement"
value="select date,level,message from dblog;"/>

name="TableName" value="table-name"
specifies the name of the table to which event information is to be written. The table must already exist. If you want to write to just a subset of the columns in the table, use SelectStatement instead of TableName.

Requirement
TableName is required if SelectStatement is not specified.

Interaction
The TableName and SelectStatement parameters are mutually exclusive. If both of these parameters are specified, the SelectStatement parameter takes precedence.
name="Column" value="column parameter"
specifies a conversion character indicating the type of information that is to be written to a particular column in the table. The following conversion characters are valid: c, d, F, L, m, p, r, S, sn, t, u, x, and X.

To write literal text to a column, specify @ (the at sign) followed by the literal text.

Specify the Column parameters in exactly the same order that the columns occur in the table.

Restrictions
Limit each column parameter to a single conversion character. Combining multiple conversion characters in a single column could cause alignment problems in the output.

DBAppender does not support the following:
- the n (newline) conversion character
- format modifiers, which control text justification and field widths for data items in a log event

DBAppender has limited support for the d (date/time) conversion character. To insert a date, specify the underlying column to be either a DATE or any character type of length 10. To insert a timestamp, specify the underlying column to be either a TIMESTAMP or any character type of length 24.

If you use the m (message) conversion character, position it in the final column of the table. Because DBAppender does not use format modifiers to control column widths, a lengthy message in an interior column position could cause text overflow problems.

Requirement
At least one Column parameter is required.

See
Conversion character details in the "Pattern Layouts" chapter: c on page 120, d on page 121, F on page 124, L on page 124, m on page 125, p on page 126, r on page 126, S on page 128, sn on page 130, t on page 130, u on page 130, x on page 131, X on page 131

Example
<param name="column" value="d"/>
<param name="Column" value="p"/>
<param name="Column" value="u"/>
<param name="Column" value="@A literal string value to insert"/>
<param name="Column" value="m"/>

Details
Before using DBAppender, you must first create the table to which the log events are to be written. The Column parameters must be specified in exactly the same order that the corresponding columns occur in the table.

DBAppender processes only a subset of loggers and ignores events for all other loggers. For each ignored event, a new event is created that contains the original event and a message stating that the event was ignored. These new events, which are written to the Logging.Appender.DB logger at the DEBUG level, can be routed to another appender for capture.

DBAppender processes the following subset of loggers:
Admin and all of its child loggers
App.Initialize and all of its child loggers
App.Program and all of its child loggers
Audit.Data and all of its child loggers
Audit.Meta and all of its child loggers
Perf.ARM.application-name.APPL
Perf.ARM.application-name.DSIO
Perf.ARM.application-name.PROC
All child loggers of Perf.ARM.IOM (but not Perf.ARM.IOM itself)
Perf.ARM.OLAP_SERVER
Perf.ARM.User and all of its child loggers
For the Perf.ARM loggers, you can use any of the following methods to specify application-name:
- specify the LOGAPPLNAME= system option on the command line. See "LOGAPPLNAME= System Option" on page 27.
- specify the AppName parameter in the configuration for the ARMAppender. See "ARMAppender" on page 45.
- specify the value when coding one of the Application Response Measurement (ARM) macros. See the SAS Interface to Application Response Measurement (ARM): Reference.

If you do not specify a value for application-name, the default value SAS is used.

Examples:

Example 1: Writing Events to a DB2 Table
In this example, log events are written to a DB2 table called LOG. The table includes the following columns: sequence number, date, logger name, and message.

Step 1: Use the following SQL statement to create the table:
```sql
create table LOG ( seqno VARCHAR(10), date VARCHAR(24), logger VARCHAR(100),
msg VARCHAR(500) );
```

Step 2: Use the DB2 command-line processor to create a DSN called LOGDSN.

Step 3: In the logging configuration file, use the following instance of DBAppender to connect to the database and write log events to the table:
```xml
<append name="dblog" class="DBAppender">
  <param name="ConnectionString" value="DRIVER=DB2;UID=User1;PWD=*******;CONOPTS=(DSN=LOGDSN);CATALOG=X;" />
  <param name="MaxBufferedEvents" value="300" />
  <param name="TableName" value="LOG" />
</append>
```

The column parameters must be specified in exactly the same order that the columns occur in the table.
Example 2: Writing Events to an ODBC-Compliant Database

In this example, log events are written to a table called LOG on a Microsoft SQL Server. The table includes the following columns: sequence number, date, logger name, and message.

Step 1: Use the following SQL statement to create the table:

```sql
create table LOG ( seqno VARCHAR(10), date VARCHAR(24), logger VARCHAR(100), msg VARCHAR(500) );
```

Step 2: Use Windows Data Source Administrator to create an ODBC data source for Microsoft SQL Server. Specify a DSN called SQLSERVERDSN.

Step 3: In the logging configuration file, use the following instance of DBAppender to connect to the server and write log events to the table:

```xml
<appender name="dblog" class="DBAppender">
  <param name="ConnectionString" value="DRIVER=ODBC;UID=User1;PWD=********;CONOPTS=(DSN=SQLSERVERDSN);" />
  <param name="MaxBufferedEvents" value="300" />
  <param name="TableName" value="LOG" />
  <param name="Column" value="sn" />
  <param name="Column" value="d" />
  <param name="Column" value="c" />
  <param name="Column" value="m" />
</appender>
```

Example 3: Writing Events to an Oracle Table

In this example, log events are written to an Oracle table called LOG. The table includes the following columns: sequence number, date, logger name, and message.

Step 1: To create the table, the SAS/ACCESS Engine for Oracle can be used as follows:

```sas
libname x oracle user=User1 password=******** path='mypath';
data x.LOG;
length segno $10;
length date $24;
length logger $100;
length msg $500;
run;
```

Step 2: In the logging configuration file, use the following instance of DBAppender to connect to the Oracle database and write log events to the table:

```xml
<appender name="dblog" class="DBAppender">
  <param name="ConnectionString" value="DRIVER=oracle;UID=User1;PWD=********;PATH=mypath;CATALOG=oracle_log" />
  <param name="MaxBufferedEvents" value="300" />
</appender>
```
Example 4: Writing Events to a SAS Table

In this example, log events are written to a SAS table called LOG. The table includes the following columns: sequence number, date, logger name, and message.

Step 1: Use the following SAS statements to create the table:

```sas
libname x 'c:\temp';
data x.LOG;
  length seqno $10;
  length date $24;
  length logger $100;
  length msg $500;
run;
```

Step 2: In the logging configuration file, use the following instance of DBAppender to connect to the database and write log events:

```xml
<appender name="dblog" class="DBAppender">
  <param name="ConnectionString" value="DRIVER=base;CATALOG=base;
schema=(name=mywork;primarypath='C:\temp');" />
  <param name="MaxBufferedEvents" value="300" />
  <param name="TableName" value="LOG" />
</appender>
```

Example 5: Writing Events to a Teradata Table

In this example, log events are written to a Teradata table called LOG. The table includes the following columns: sequence number, date, logger name, and message.

Step 1: Use the following SQL statement to create the table:

```sql
create table LOG ( seqno VARCHAR(10), date VARCHAR(24), logger VARCHAR(100),
  msg VARCHAR(500) );
```

Step 2: In the logging configuration file, use the following instance of DBAppender to connect to the database and write log events to the table:

```xml
<appender name="dblog" class="DBAppender">
```

Chapter 6 / Appender Reference
<appender class="FileAppender" name="appender-name">
   <param name="Append" value="TRUE | FALSE"/>
   <param name="Encoding" value="encoding-value"/>
   <param name="File" value="path-and-filename"/>
   <param name="FileNamePattern" value="path-and-filename-pattern"/>
   <param name="FilePermissions" value="permission-value-1,permission-value-2..."/>
   <param name="ImmediateFlush" value="TRUE | FALSE"/>
   <param name="Locale" value="locale"/>
   <param name="Threshold" value="TRACE | DEBUG | INFO | WARN | ERROR | FATAL"/>
   <param name="Unique" value="TRUE | FALSE"/>
   <filter>
      <filter-definitions>
      </filter>
   </filter>
   <layout>
      <param name="ConversionPattern" value="conversion-pattern"/>
   </layout>
</appender>

Syntax Description

class="FileAppender" name="appender-name"
specifies the user-assigned name for this instance of FileAppender.

Default None
This element is required.

**name**="Append" |
controls how messages are written to the log file if the file already exists when logging begins. Specify one of the following values:

TRUE
  appends new messages to the end of the existing file.

FALSE
  erases the contents of the existing file and overwrites them with new messages.

Default  TRUE

This parameter is not required.

If both the Unique parameter and the Append parameter are specified, then the Unique parameter takes precedence. For details, see name="Unique" on page 60.

**name**="Encoding" value="encoding-value"
specifies the encoding that is used to write messages to the file.

The encoding setting that is in effect for the SAS session. For example, the ENCODING system option might be specified in the configuration file for a SAS server or for Base SAS. If the ENCODING system option is not specified for the SAS session, then the defaults that are described in the SAS National Language Support (NLS): Reference Guide

For logging processes that run outside a SAS session (for example, logging for the SAS Object Spawner), the default is the encoding that is specified in the operating system settings.

This parameter is not required.

**name**="File" value="path-and-filename"
specifies the path and filename of the file to which messages are written.

None

This parameter is required if the FileNamePattern parameter is not specified.

If both the File parameter and the FileNamePattern parameter are specified, then the File parameter takes precedence.

**name**="FileNamePattern" value="path-and-filename-pattern"
specifies the path to which the log file is written and the conversion pattern that is used to create the log filename. The conversion pattern can include the following characters:

%d
  indicates where the current date appears. You can specify a date format or a date and time pattern in braces after %d if you want the date to appear in a
format other than *yyyy-mm-dd*, or if you want to include additional information such as the hour.

See “d Conversion Character” on page 121

%S{key}
indicates where system information (such as the host name, operating system, system description, or process ID) appears. You must specify a *key* to indicate the type of system information that appears.

See “S Conversion Character” on page 128

For example, suppose you want the log files to be written to the path `c:\logs\`, and you want the filename to include the current date and the name of the metadata server host machine. Specify `c:\logs\MetadataServer_%d_%S{host_name}.log`.

Default None

Requirement This parameter is required if the File parameter is not specified.

Interaction If both the File parameter and the FileNamePattern parameter are specified, then the File parameter takes precedence.

**name**="FilePermissions" value="permission-value-1,permission-value-2..."
specifies one or more sets of permissions to set for the log file. To specify more than one set, separate them with a comma within the quotation marks. Use the following syntax for each permission value:

A::<trustee_type>::<permissions>

A indicates that these are access permissions. No other values are supported.

**trustee_type**
indicates which users the permissions apply to. The following values are supported:

u the user whose credentials are being used to generate the log file.

g all groups that the user belongs to.

o all other users. On UNIX systems, this value includes all users except those specified by *u* and *g*. On Windows systems, this value includes all users including those specified by *u* and *g*.

**permissions**
the permission string that applies to the trustee type. The permission string takes the values *r* (Read), *w* (Write), and *x* (Execute), in that order. If you do not want to grant one of these permissions, enter a hyphen (−) in its place. For example, specify *r-x* or *rw-*.

Note: The specified file permissions take effect only when a new file is being created or when the current user is the owner of the existing file.

Default If this parameter is not specified, the logging facility does not apply any permissions other than those that are applied by the operating system.
**name**="ImmediateFlush" |

determines whether messages are written to the file immediately or held in a buffer. Specify one of the following values:

**TRUE**

writes messages to the file immediately as they are received.

**FALSE**

holds messages in a buffer and writes them to the file when the buffer is full.

The buffer size is 16 KB.

**Default**

FALSE

**Requirement**

This parameter is not required.

**name**="Locale" value="locale"

specifies the locale that is used to write messages to the file.

**Defaults**

The locale setting that is in effect for the SAS session. For example, the LOCALE system option might be specified in the configuration file for a SAS server or in the configuration file for Base SAS.

For logging processes that run outside a SAS session (for example, logging for the SAS Object Spawner), the default is the locale that is specified in the operating system settings.

**Requirement**

This parameter is not required.

**See**

**name**="Threshold" |

specifies the lowest event level that this appender processes. Events that are below the specified level are ignored. The valid values are listed here from lowest to highest.

**Default**

None

**Requirement**

No

**See**

"Logging Thresholds" on page 18

**name**="Unique" |

creates a new file, with an underscore and a unique number appended to the filename, if the log file already exists when logging begins. Numbers are assigned sequentially from 0 to 32766.
For example, suppose `Events.log` is specified in path-and-filename. If the files `Events.log` and `Events.log_0` already exist, then the next log file that is created is named `Events.log_1`.

Default: FALSE

Requirement: This parameter is not required.

Interactions: If both the Unique parameter and the Append parameter are specified, then the Unique parameter takes precedence. If the log file already exists when logging begins, messages are logged as follows:

- If Unique is set to TRUE and Append is set to either TRUE or FALSE, then messages are written to a new file with a unique number appended to the filename.
- If Unique is set to FALSE and Append is set to TRUE, then messages are appended to the end of the existing file.
- If Unique is set to FALSE and Append is set to FALSE, then the contents of the existing file are erased and overwritten with new messages.

filter-definitions

specifies the names and associated parameters of filters that limit the messages that are logged by this appender.

Default: None

Requirement: No

See: “Filters” on page 135

name="ConversionPattern" value="conversion-pattern"

specifies how the log message is written to the log.

Default: None. If a conversion pattern is not specified, then the log event produces an empty string.

Requirement: No

See: “Pattern Layouts” on page 107

Details

FileAppender writes messages to the specified file in the specified path. When you create an instance of FileAppender, you can specify the following:

- how messages are written if the file already exists when logging begins. Messages can be appended to the end of the existing file, they can overwrite the existing file contents, or they can be written to a new file that has a unique name.
- whether to write messages immediately upon receipt or to hold them in a buffer.
- the minimum (threshold) event level to be logged.
- the locale and encoding to be used when writing to the file.
- a conversion pattern to be used for creating the filename.
The following best practices apply to FileAppender:

- Use of the Unique parameter is recommended to avoid overwriting log files. However, if numerous files are created that have the same root filename and different numerical suffixes, then the system must perform multiple comparisons to determine a unique number. To conserve system resources, consider specifying a *path-and-filename-pattern* that includes a unique identifier such as process ID (`%s{pid}`).

Example: Appending Messages to a File

The following instance of FileAppender writes messages to a file called *Events.log*. If the file already exists when logging begins, messages are appended to the end of the file.

```xml
<appender class="FileAppender" name="File">
  <param name="File" value="c:\logs\Events.log"/>
  <param name="Append" value="true"/>
  <param name="ImmediateFlush" value="true"/>
  <layout>
    <param name="ConversionPattern" value="%d %-5p [%t] %u - %m"/>
  </layout>
</appender>
```

FilteringAppender

Filters events based on thresholds and string values to determine whether the events should be passed to a referenced appender. You can specify a layout to be applied to the events before they are passed.

**Valid in:** XML configuration

**Syntax**

```xml
<appender class="FilteringAppender" name="appender-name">
  <appender-ref ref="referenced-appender-name"/>
  <filter>
    <filter-definitions>
    </filter>
  <layout>
    <param name="ConversionPattern" value="conversion-pattern"/>
  </layout>
  <param name="Locale" value="locale"/>
  <param name="PropagateLayout" value="TRUE | FALSE"/>
  <param name="Threshold" value="TRACE | DEBUG | INFO | WARN | ERROR | FATAL"/>
</appender>
```

**Syntax Description**

*class="FilteringAppender" name="appender-name"*

specifies the user-assigned name for this instance of FilteringAppender.
ref="referenced-appender-name"
specifies the appender that events are to be passed to.

Requirement
This element attribute is required.

filter-definitions
specifies the names and associated parameters of filters that limit the messages that are passed to the referenced appender.

Default None
Requirement Filters are not required.
See "Filters" on page 135

name="ConversionPattern" value="conversion-pattern"
specifies formatting that is to be applied to the event before it is passed to the referenced appender. The resulting string becomes the %m portion of the event in the layout of the referenced appender.

Default None. If a conversion pattern is not specified, then the log message is formatted only by the layout that is specified in the referenced appender.
Requirement This parameter is not required.
See "Pattern Layouts" on page 107

name="Locale" value="locale"
specifies the locale that is used when the specified layout is applied to the event.

Defaults The locale setting that is in effect for the SAS session. For example, the LOCALE system option might be specified in the configuration file for a SAS server or in the configuration file for Base SAS.

For logging processes that run outside a SAS session (for example, logging for the SAS Object Spawner), the default is the locale that is specified in the operating system settings.

Requirement This parameter is not required.

name="PropagateLayout" |
specifies whether the layout that is specified in the conversion pattern is to be applied to events before they are passed to the referenced appender. Specify one of the following values:

**TRUE**
applies the specified layout to events before they are passed to the referenced appender. The resulting string becomes the %m portion of the event in the layout of the referenced appender.
FALSE
passes events to the referenced appender without applying the specified
layout. Messages are formatted only by the layout that is specified in the
referenced appender.

Default TRUE
Requirement This parameter is not required.

name="Threshold" 

Default None
Requirement This parameter is not required.
See “Logging Thresholds” on page 18

Details
FilteringAppender enables you to do one or both of the following:

- filter events based on thresholds and string values to determine whether the
events should be passed to a referenced appender.
- apply a layout to events before they are passed to the referenced appender. The
resulting string becomes the %m portion of the event in the layout of the
referenced appender.

Since FilteringAppender is an intermediate appender rather than a logging
destination, it must be configured with an appender reference.

The primary use of FilteringAppender is to specify different layouts for different
categories of events that are to appear together in the same log. Specify a separate
instance of FilteringAppender for each event category that requires a different
layout. After the layout is applied, the resulting string becomes the %m portion of the
event in the layout of the referenced appender. You can specify filters to limit the
events that are passed.

If you do not specify a layout, or if you set the PropagateLayout parameter to
FALSE, then events are formatted only by the layout of the referenced appender.

Example
The following logging configuration file writes two different categories of events to
the same log file:

- Events from the App.Program logger. These events are written directly to the log
file.
- Events from loggers other than App.Program, if they contain the word “state.”
  For these events, a layout is applied that includes the event's level and logger
  followed by the message. The resulting string becomes the %m portion of the
event in the log file’s layout.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<logging:configuration xmlns:logging="http://support.sas.com/xml/logging/1.0">
  <!-- Write just the message portion of the event to the log file. -->
```
<appender name="file" class="FileAppender">
    <param name="Append" value="false" />
    <param name="FileNamePattern" value="logfile.%S{pid}.log" />
    <layout>
        <param name="ConversionPattern" value="%m" />
    </layout>
</appender>

<!-- Include only the events that contain the word "state," and prepend the level and the logger name of the event to the message. -->

<appender name="filter" class="FilteringAppender">
    <appender-ref ref="file" />
    <filter class="StringMatchFilter">
        <param name="StringToMatch" value="state" />
        <param name="AcceptOnMatch" value="true" />
    </filter>
    <filter class="DenyAllFilter" />
    <layout>
        <param name="ConversionPattern" value="%c - %p - %m" />
    </layout>
</appender>

<!-- Send App.Program messages directly to the log file -->
<logger name="App.Program" additivity="false">
    <appender-ref ref="file" />
    <level value="INFO" />
</logger>

<!-- Send all other events to the filter so that a different layout can be applied. -->

<root>
    <appender-ref ref="filter" />
    <level value="INFO" />
</root>
</logging:configuration>

IOMServerAppender

Writes log messages from any IOM server to a volatile run time cache.

Valid in: XML configuration

Syntax

<appender class="IOMServer" name="appender-name">
    <param name="MaxEntries" value="maximum-number-of-entries"/>
    <param name="Threshold" value="TRACE | DEBUG | INFO | WARN | ERROR | FATAL"/>
    <layout>

IOMServerAppender

Writes log messages from any IOM server to a volatile run time cache.

Valid in: XML configuration

Syntax

<appender class="IOMServer" name="appender-name">
    <param name="MaxEntries" value="maximum-number-of-entries"/>
    <param name="Threshold" value="TRACE | DEBUG | INFO | WARN | ERROR | FATAL"/>
    <layout>
Syntax Description

**name**="MaxEntries" value="maximum-number-of-entries"

An integer that specifies the maximum number of messages that are stored in the cache. When the maximum number is reached, the oldest messages are deleted as new messages are added.

- **Default**: 10000
- **Range**: 0 to 1000000
- ** Requirement**: This parameter is not required.

**name**="Threshold" ||||

Specifies the lowest event level that this appender processes. Events that are below the specified level are ignored. The valid values are listed here from lowest to highest.

- **Default**: None
- **Requirement**: This parameter is not required.
- **See**: “Logging Thresholds” on page 18

**name**="ConversionPattern" value="conversion-pattern"

Specifies how the log message is written to the log.

- **Default**: None. If a conversion pattern is not specified, then the log event produces an empty string.
- **Requirement**: This parameter is not required.
- **See**: “Pattern Layouts” on page 107

Details

IOM Server Appender writes log messages from any IOM server (for example, a SAS Metadata Server, a SAS OLAP Server, or a SAS Stored Process Server) to a volatile run time cache. The contents of the cache are available for display on the Log tab of SAS Management Console. For more information, see “Use the Log Tab in Server Manager” in the SAS Intelligence Platform: System Administration Guide.

If you perform a planned deployment, then IOMServerAppender definitions are included in the logging configurations for most of your SAS servers. Follow these best practices when modifying these definitions:

- You can adjust the MaxEntries value to capture a larger or smaller number of messages for display.
- Do not change the message layout. Changing the message layout could cause messages to be captured incorrectly.

**Note**: A location for temporary files must be defined on the host operating system. If a location has not been defined, then the process that is being logged fails with
the following message: Error creating IOMServerAppender index cache. The location required for storing temporary utility files does not exist. If a location for temporary files is not already defined, use one of the following procedures to define it:

- On Windows systems, define the TEMP environment variable.
- On UNIX systems, create the directory /tmp.
- On z/OS systems, create the directory /tmp if you are using a UNIX file system (UFS); or submit the following TSO command:

  ALLOC UNIT(SYSDA) BLOCK(8192) SPACE(1280,1280)

Example

The following instance of IOMServerAppender writes a maximum of 10,000 messages to a run time cache. When the cache contains 10,000 messages, the oldest messages are deleted as new messages are added.

```xml
<appender class="IOMServerAppender" name="IOMServer">
  <param name="MaxEntries" value="10000"/>
  <layout>
    <param name="ConversionPattern" value="%d %-5p [%t] %X{Client.ID}:%u - %m"/>
  </layout>
</appender>
```

JavaAppender

Sends messages to a custom Java class.

Valid in: XML configuration

Syntax

```xml
<appender class="JavaAppender" name="appender-name">
  <param name="Class" value="class"/>
  <param name="ClassPath" value="class-path"/>
  <param name="MaxBufferedEvents" value="maximum-buffered-events"/>
  <param name="SASEncodedPassword" value="SAS-encoded-password"/>
  <layout>
    <param name="ConversionPattern" value="conversion-pattern"/>
  </layout>
</appender>
```

Syntax Description

- `class="JavaAppender" name="appender-name"` specifies the user-assigned name for this instance of JavaAppender.

  Default: None
These element attributes are required.

**name**="Class" value="class"

specifies the custom Java class to which events are to be sent. The class that you specify must support the following methods:

- A no-argument constructor for creating the object.
- An append method for handling each event:
  
  ```java
  void append( int level, String logger, String msg )
  ```

  The class can also support the following methods:

  ```java
  void setOption( String name, Object value )
  ```
  
  specifies the handling for any parameters in the configuration file that are not recognized by JavaAppender

  ```java
  void activate()
  ```
  
  is called after all of the options have been set and before any calls to the append method

  ```java
  void destroy
  ```
  
  is called when the appender is destroyed

  **Default**
  com.sas.jms.logging.JMSAppender. If you use the default class, then JavaAppender has the same functionality and uses the same parameters as JMSAppender. For details, see "JMSAppender" on page 75.

  **Requirement**
  This parameter is required if you want to use a class other than com.sas.jms.logging.JMSAppender.

**name**="ClassPath" value="class-path"

specifies the path for classes that are included in this appender configuration.

**Default**
None

**Requirement**
This parameter is not required.

**Interaction**
When JavaAppender searches for classes to load, the CLASSPATH environment variable takes precedence over the ClassPath parameter, and the ClassPath parameter takes precedence over the JAR files that are provided by SAS.

**name**="MaxBufferedEvents" value="maximum-buffered-events"

specifies the maximum number of events that can be waiting to be sent to the Java class. JavaAppender stores events in an internal list that is bounded by the number that is specified in this parameter. A worker thread removes events from the list and sends them to the Java class. In the meantime, SAS can continue processing without waiting for the Java class. When the list contains the specified number of events, the appender blocks further events until the list can accommodate them.

**TIP**
A high number favors performance over reliability. A catastrophic error could cause events in the list to be lost. A high number also increases the memory usage of the appender.
A low number favors reliability and memory usage over performance.

Default: Infinite

Requirement: This parameter is not required.

**name**="SASEncodedPassword" value="SAS-encoded-password"

specifies a plain-text password or a password that has been encoded by using sas001, sas002, or sas003 encoding. If the password is encoded, JavaAppender converts it to plain text before sending it to the Java class.

For information about how to obtain the encoded password, see "PWENCODE Procedure" in Base SAS Procedures Guide.

Default: None.

Requirement: This parameter is not required.

**name**="ConversionPattern" value="conversion-pattern"

specifies how the log message is written to the Java class.

Default: None. If a conversion pattern is not specified, then the log event produces an empty string.

Requirement: This parameter is not required.

**See**  "Pattern Layouts" on page 107

Details

If additional parameters are needed by your custom Java class, you can include them in the appender configuration. Any parameters that JavaAppender does not recognize are passed to the custom Java class.

Examples:

**Example 1: Displaying a Supplementary Log Window for Trace Events**

This example uses a custom Java class to display trace events in a separate log window in the SAS windowing environment, while preserving the contents of the main Log window.

**Step 1: Create a custom Java class called TraceWindow.**

Note that the main class cannot inherit directly from JFrame. To prevent a HeadlessException, you must set the java.awt.headless system property before the JFrame constructor runs.

```java
import javax.swing.JFrame;
import javax.swing.JScrollPane;
```
import javax.swing JTextArea;
import java.awt Font;

public class TraceWindow
{
    JFrame window;
    JTextArea console;
    String separator;

    public TraceWindow(){
        System.setProperty( "java.awt.headless", "false" );
        separator = System.getProperty("line.separator");
    }

    public void activate() {
        window = new JFrame( "Trace window" );
        console = new JTextArea();
        console.setFont( new Font("Courier New", Font.PLAIN, 12) );
        console.setEditable( false );
        JScrollPane scroll = new JScrollPane( console );
        window.getContentPane().add(scroll);
        window.setSize( 600, 600 );
        window.setLocation( 200, 200 );
        window.setVisible( true );
    }

    public void terminate() {
        window.dispose();
    }

    public void append( int level, String logger, String msg ){
        window.setVisible( true );
        console.append( msg );
        console.append( separator );
        console.setCaretPosition( console.getText().length() );
    }
}

Step 2: Create the following logging configuration file. The file specifies JavaAppender with the custom Java class TraceWindow, which is displayed in the preceding code. Because of the specified threshold, only trace events are sent to the custom class.

<?xml version="1.0"?>
<logging:configuration xmlns:logging="http://www.sas.com/xml/logging/1.0/"
    threshold="trace">
    <appender name="java" class="JavaAppender">
        <param name="Class" value="TraceWindow"/>
        <layout>
            <param name="ConversionPattern" value="[%F:%L] %c %6p - %m"/>
        </layout>
    </appender>
    <root>
        <level value="info"/>
        <appender-ref ref="java"/>
    </root>
</logging:configuration>
Example 2: Sending Events to a Database Using a JDBC Driver

This example uses a custom Java class to connect to a MySQL server via JDBC and write events to a table.

Step 1: Use the following MySQL code to create the database and the table:

```sql
CREATE DATABASE log;
CREATE TABLE log ( level varchar(10), logger varchar(50), msg varchar(500) );
```

Step 2: Create the following Java class, called LogToJDBC. This class uses JDBC to connect to the MySQL server and writes events to the table.

```java
import java.sql.DriverManager;
import java.sql.Connection;
import java.sql.PreparedStatement;

class LogToJDBC {
    String              driver;
    String              url;
    String              tablename;
    String              username;
    String              password;
    long                rowsetsize;
    long                eventCount;
    Connection          connection;
    PreparedStatement   stmt;

    public LogToJDBC() {
        /*------------------------------
         | Nothing to do in the constructor.
         |------------------------------*/
    }

    public void setOption( String name, Object value ) {
        if( name.equalsIgnoreCase( "driver" ) ) {
            driver = value.toString();
        } else if( name.equalsIgnoreCase( "url" ) ) {
            url = value.toString();
        } else if( name.equalsIgnoreCase( "tablename" ) ) {
            tablename= value.toString();
        } else if( name.equalsIgnoreCase( "username" ) ) {
            username = value.toString();
        } else if( name.equalsIgnoreCase( "password" ) ) {
            password = value.toString();
        } else if( name.equalsIgnoreCase( "rowsetsize" ) ) {
            rowsetsize = Long.valueOf(value.toString());
        }
    }

    public void activate() throws Exception {
        /*------------------------------
         | Set up all of our JDBC objects and set any properties we
         |------------------------------*/
    }
}
```
Class.forName( driver );
connection = DriverManager.getConnection( url, username, password );
connection.setAutoCommit( false );
stmt = connection.prepareStatement( "insert into " + tablename + " (level, logger, msg ) values (?, ?, ?)" );

public void append( int level, String logger, String msg ) throws Exception {
    stmt.setString( 1, new Integer(level).toString() );
    stmt.setString( 2, logger );
    stmt.setString( 3, msg );
    stmt.addBatch();
    eventCount++;
    if( eventCount >= rowsetsize )
    {
        stmt.executeBatch();
        connection.commit();
        eventCount = 0L;
    }
}

public void destroy() throws Exception {
    if( eventCount > 0 )
    {
        stmt.executeBatch();
        connection.commit();
        eventCount = 0L;
    }
    if( stmt != null )
        stmt.close();
    if( connection != null )
        connection.close();
}

Step 3: Create the following logging configuration file. This file specifies JavaAppender with the custom Java class LogToJDBC, which is displayed in the preceding code. The Driver, URL, TableName, UserName, Password, and RowSetSize parameters are passed to LogToJDBC, which uses them to connect to the server and to write to the table.

<?xml version="1.0" encoding="UTF-8" ?>
<logging:configuration xmlns:logging="http://www.sas.com/xml/logging/1.0/>
<appender name="java" class="JavaAppender">
  <param name="classpath" value="mysql-connector-java-commercial-5.0.8-bin.jar"/>
  <param name="class" value="LogToJDBC"/>
  <param name="Driver" value="com.mysql.jdbc.Driver"/>
  <param name="URL" value="jdbc:mysql://mysql.example.com:3306/log"/>
  <param name="TableName" value="log"/>
  <param name="UserName" value="myusername"/>
  <param name="Password" value="mypassword"/>
  <param name="RowSetSize" value="1000" />
  <param name="MaxBufferedEvents" value="2000" />
  <layout>
    <param name="conversionpattern" value="%sn %d %c %p %m"/>
  </layout>
</appender>

<root>
  <level value="info" />
  <appender-ref ref="java" />
</root>
</logging:configuration>

Example 3: Sending Events to log4j Appenders

This example uses a custom Java class to invoke a log4j configuration. The example uses org.apache.log4j.net.SocketServer to listen for events, which are then sent to the log4j ConsoleAppender. By following these steps, you can send events to any log4j appender.

Step 1: Create a custom Java class called SendToLog4j that sends events from SAS to log4j:

```java
import org.apache.log4j.*;

public class SendToLog4j {
    public SendToLog4j() {
        PropertyConfigurator.configure(System.getProperty("log4j.configuration"));
    }

    public void append(int level, String logger, String msg) {
        Logger l = Logger.getLogger(logger);
        switch (level) {
            case 0:
                case 1:
                case 2:
                    l.log(Level.TRACE, msg);
                    break;
            case 3:
            case 4:
                l.log(Level.INFO, msg);
                break;
            case 5:
                l.log(Level.WARN, msg);
                break;
            case 6:
                l.log(Level.ERROR, msg);
                break;
            default:
                l.log(Level.SEVERE, msg);
                break;
        }
    }
}
```

Example 3: Sending Events to log4j Appenders
case 6:
    log(Level.ERROR, msg);
    break;

case 7:
    log(Level.FATAL, msg);
    break;
}
}
}
}

Step 2: Create a SAS logging configuration file called socket.xml. In the file, specify JavaAppender with the custom Java class SendToLog4j.

```xml
<?xml version="1.0"?>
<logging:configuration xmlns:logging="http://www.sas.com/xml/logging/1.0/"
    threshold="trace">
    <appender name="java" class="JavaAppender">
        <param name="class" value="SendToLog4j"/>
        <layout>
            <param name="ConversionPattern" value="%d - %S{hostname} - %S{pid} - %c - %m"/>
        </layout>
    </appender>
    <root>
        <level value="info"/>
        <appender-ref ref="java"/>
    </root>
</logging:configuration>
```

Step 3: Create a client-side log4j configuration file called client.properties. In the file, specify the use of SocketAppender to listen for events.

```
log4j.rootLogger=DEBUG,A2
log4j.appender.A2=org.apache.log4j.net.SocketAppender
log4j.appender.A2.Port=55555
log4j.appender.A2.RemoteHost=localhost
log4j.appender.A2.layout=org.apache.log4j.PatternLayout
log4j.appender.A2.layout.ConversionPattern=%-4r [%t] %-5p %c %x - %m%n
```

Step 4: Create a server-side log4j configuration file called server.properties. In the file, specify the use of ConsoleAppender. (Any log4j appender could be specified.)

```
log4j.rootLogger=DEBUG,A2
log4j.appender.A2=org.apache.log4j.net.SocketAppender
log4j.appender.A2.Port=55555
log4j.appender.A2.RemoteHost=localhost
log4j.appender.A2.layout=org.apache.log4j.PatternLayout
log4j.appender.A2.layout.ConversionPattern=%-4r [%t] %-5p %c %x - %m%n
```

Step 5: Use the following command to start the socket server. The command specifies the server.properties log4j configuration file.

```
java -classpath log4j.jar org.apache.log4j.net.SocketServer 55555 server.properties
```

Step 6: Specify the following options when you start SAS. The first option specifies the socket.xml logging configuration file, and the second option passes the client.properties log4j configuration file to the SAS Java environment.

```
-logconfigloc socket.xml
-jreoptions '(-Dlog4j.configuration=client.properties)'
```
JMSAppender

Sends messages to a message queue by using the Java Message Service (JMS) interfaces.

Valid in: XML configuration

Syntax

```xml
<appender class="JMSAppender" name="appender-name">
  <param name="ClassPath" value="class-path"/>
  <param name="MaxBufferedEvents" value="maximum-buffered-events"/>
  <param name="Persistent" value="TRUE | FALSE"/>
  <param name="Factory" value="factory"/>
  <param name="Queue | Destination" value="queue-name"/>
  <param name="UserName" value="user-name"/>
  <param name="SASEncodedPassword" value="SAS-encoded-password"/>
  <param name="Priority" value="priority"/>
  <param name="TimeToLive" value="time-to-live"/>
  <layout>
    <param name="ConversionPattern" value="conversion-pattern"/>
  </layout>
</appender>
```

Syntax Description

class="JMSAppender" name="appender-name"

specifies the user-assigned name for this instance of JMSAppender.

Default: None

Requirement: These element attributes are required.

name="ClassPath" value="class-path"

specifies the path for classes that are included in this appender configuration.

Default: None

Requirement: This parameter is not required.

Interaction: When JMSAppender searches for classes to load, the CLASSPATH environment variable takes precedence over the ClassPath parameter, and the ClassPath parameter takes precedence over the JAR files that are provided by SAS.

name="MaxBufferedEvents" value="maximum-buffered-events"

specifies the maximum number of events that can be waiting to be sent to the message queue. JMSAppender stores events in an internal list that is bounded by the number that is specified in this parameter. A worker thread removes events from the list and sends them to the message queue. In the meantime,
SAS can continue processing without waiting for the JMS provider. When the list contains the specified number of events, the appender blocks further events until the list can accommodate them.

**TIP**  A high number favors performance over reliability. A catastrophic error could cause events in the list to be lost. A high number also increases the memory usage of the appender.

TIP  A low number favors reliability and memory usage over performance.

Default  Infinite

Requirement  This parameter is not required.

**name**="Persistent" | specifies whether the persistent delivery mode is to be used to send messages to the queue.

**TRUE** specifies the use of the persistent delivery mode to send messages to the queue. This mode instructs the JMS provider to store messages after they are sent to ensure that they are not lost in transit if a provider failure occurs.

**FALSE** specifies the use of the nonpersistent delivery mode to send messages to the queue. If you specify this mode, the JMS provider is not required to store messages or otherwise guarantee that they will be preserved if the provider fails.

**TIP**  The nonpersistent delivery mode can improve performance and reduce storage overhead on the message queue server. However, you should use this mode only if it is acceptable for messages to be missed.

Default  TRUE

Requirement  This parameter is not required.

**name**="Factory" value="factory"
specifies the name of a connection factory that is administered through the Java Naming and Directory Interface (JNDI) and that is to be used to connect to the message queue.

Default  None

Requirement  This parameter is required.

**name**="Queue" value="queue-name"
specifies the name of the JNDI-administered queue to which messages are to be sent.

Alias  name="Destination"
name="Username" value="user-name"
  specifies the user name that is to be used to connect to the message queue.

  Default: If a user name is not specified, then the user name of the process owner is used to connect to the message queue.

  Requirement: This parameter is not required.

name="SASEncodedPassword" value="SAS-encoded-password"
  specifies the password that is to be used with user-name to connect to the message queue. You can specify a plain-text password or a password that has been encoded by using sas001, sas002, or sas003 encoding. If the password is encoded, JMSAppender converts it to plain text before connecting to the queue.

  TIP For information about how to obtain the encoded password, see “PWENCODE Procedure” in Base SAS Procedures Guide.

  Default: None.

  Requirement: This parameter is not required.

name="Prioritize" |
  specifies whether messages are to be prioritized based on the level of the event.

  TRUE
    sets the message priority based on the level of the event, as follows:

<table>
<thead>
<tr>
<th>Level</th>
<th>Assigned Message Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trace</td>
<td>2</td>
</tr>
<tr>
<td>Debug</td>
<td>3</td>
</tr>
<tr>
<td>Info</td>
<td>4</td>
</tr>
<tr>
<td>Warn</td>
<td>5</td>
</tr>
<tr>
<td>Error</td>
<td>6</td>
</tr>
<tr>
<td>Fatal</td>
<td>7</td>
</tr>
</tbody>
</table>

  Some message queueing systems, such as IBM WebSphere MQ, might return events with a higher priority to a caller before events with a lower priority. This might occur regardless of when the events were added to the queue.

  FALSE
    sets the message priority to 4 for all events.
<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority</td>
<td>priority</td>
<td>Specifies an integer that is to be assigned as the message priority for each message that is written to the queue.</td>
</tr>
<tr>
<td>TimeToLive</td>
<td>time-to-live</td>
<td>Specifies the message time-to-live in milliseconds. When a message is sent, JMS computes the message’s expiration time by adding the time-to-live value to the current Greenwich Mean Time. If time-to-live is specified as zero, the message does not expire.</td>
</tr>
<tr>
<td>ConversionPattern</td>
<td>conversion-pattern</td>
<td>Specifies how the log message is written to the queue.</td>
</tr>
</tbody>
</table>

**Default**
- `Priority`: FALSE
- `TimeToLive`: 0
- `ConversionPattern`: None

**Requirement**
- `Priority`: Optional
- `TimeToLive`: Optional
- `ConversionPattern`: Optional

**Interaction**
- If both the Prioritize parameter and the Priority parameter are specified, then the Priority parameter takes precedence.

**Details**

If additional JNDI parameters (for example, `java.naming.factory.initial` or `java.naming.provider.url`) are needed by your messaging provider, you can include them in the appender configuration. Any parameters that JMSAppender does not recognize are passed to the `javax.naming.InitialContext` constructor in the JNDI initial context as part of the HashMap parameter.

**Note:** You can also use the JREOPTIONS system option to pass JNDI parameters directly to SAS. See the following topics:

- “JREOPTIONS System Option: Windows” in SAS Companion for Windows
- “JREOPTIONS System Option: UNIX” in SAS Companion for UNIX Environments
- “JREOPTIONS= System Option: z/OS” in SAS Companion for z/OS
Depending on the provider, you might be able to use other methods to specify these parameters.

**TIP**  By default, JMSAppender uses the Java class com.sas.logging.appenders.JMSAppender. If you want events to be handled by a custom Java class, use JavaAppender.

**TIP**  When the Java Runtime Environment attempts to append messages to a message queue, additional events might be generated. These events are captured by the App.tkjni logger and are ignored by JMSAppender. If you want to log these events, specify a different appender (for example, FileAppender) for the App.tkjni logger in your logging configuration.

See also:

- Application Messaging with SAS for details about SAS language interfaces to JMS.

**Examples:**

**Example 1: Sending Events to IBM WebSphere MQ**

The following instance of JMSAppender writes messages to a queue called TEST.Q that is managed by IBM WebSphere MQ. The JNDI objects are located in the folder C:\JNDI on the local machine.

```xml
<appender name="java" class="JMSAppender">
  <!-- Common properties for all Java Appender configurations -->

  <!-- Properties specific to the Default JMSAppender implementation -->
  <param name="persistent" value="true"/>

  <!-- This is an example configuration for WebSphere MQ. -->
  <!-- This example assumes that the Websphere MQ classes -->
  <!-- are in your classpath environment variable. -->
  <param name="java.naming.factory.initial" value="com.sun.jndi.fscontext.RefFSContextFactory"/>
  <param name="java.naming.provider.url" value="file:/c:/JNDI"/>
  <param name="factory" value="TEST.FACTORY"/>
  <param name="destination" value="TEST.Q"/>

  <layout>
    <param name="ConversionPattern" value="%d - %c - %m"/>
  </layout>
</appender>
```
Example 2: Sending Events to Apache ActiveMQ

The following instance of JMSAppender writes messages to a queue called TEST.Q that is managed by Apache ActiveMQ:

```xml
<appender class="JMSAppender" name="java">
  <!-- Common properties for all Java Appender configurations -->
  <param name="classpath" value="C:\ProgramFiles\apache-activemq-5.2.0\activemq-all-5.2.0.jar"/>

  <!-- Properties specific to the Default JMSAppender implementation -->
  <param name="persistent" value="true"/>

  <!-- Active MQ example configuration -->
  <param name="java.naming.factory.initial" value="org.apache.activemq.jndi.ActiveMQInitialContextFactory"/>
  <param name="java.naming.provider.url" value="tcp://localhost:61616"/>
  <param name="factory" value="ConnectionFactory"/>
  <param name="destination" value="TEST.Q"/>

  <!-- An additional property is required only for Active MQ to map the queue name into the JNDI namespace. Use the form -->
  <param name="queue.[jndiName]" value="[physicalName]"/>
  See http://activemq.apache.org/jndi-support.html. -->
  <param name="queue.TEST.Q" value="TEST.Q"/>

  <layout>
    <param name="ConversionPattern" value="%d - %c - %m"/>
  </layout>
</appender>
```

RabbitmqAppender

Writes log messages to a Rabbitmq broker.

Note: The RabbitmqAppender writes log messages as JSON objects to a Rabbitmq broker. The layout described in the appender definition defines how the JSON records should be created. It is pre-determined, and should not be modified without the guidance of technical support.

CAUTION: Do not modify the RabbitmqAppender without the assistance of technical support.

RollingFileAppender

Writes messages to the specified file in the specified path, and begins writing messages to a new file that has a different name when specified criteria are met.

Valid in: XML configuration
Syntax

<appender class="RollingFileAppender" name="appender-name">
  <param name="Append" value="TRUE | FALSE"/>
  <param name="Encoding" value="encoding-value"/>
  <param name="File" value="path-and-filename"/>
  <param name="FilePermissions" value="permission-value-1,permission-value-2..."/>
  <param name="ImmediateFlush" value="TRUE | FALSE"/>
  <param name="Locale" value="locale"/>
  <param name="Threshold" value="TRACE | DEBUG | INFO | WARN | ERROR | FATAL"/>
  <param name="Unique" value="TRUE | FALSE"/>
  <filter>
    <filter-definitions>
  </filter>
  <layout>
    <param name="ConversionPattern" value="conversion-pattern"/>
  </layout>
  <rollingPolicy class="FixedWindowRollingPolicy | TimeBasedRollingPolicy">
    <rollingPolicy-parameters>
  </rollingPolicy>
  <triggeringPolicy class="SizeBasedTriggeringPolicy | FilterBasedTriggeringPolicy">
    <triggeringPolicy-parameters>
  </triggeringPolicy>
</appender>

Syntax Description

class="RollingFileAppender" name="appender-name"
  specifies the user-assigned name for this instance of RollingFileAppender.

<table>
<thead>
<tr>
<th>Default</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirement</td>
<td>These attributes are required.</td>
</tr>
</tbody>
</table>

name="Append" |
  controls how messages are committed to the log file if the file already exists when logging begins. Specify one of the following values:

TRUE
  appends new messages to the end of the existing file.

FALSE
  erases the contents of the existing file and overwrites them with new messages.

<table>
<thead>
<tr>
<th>Default</th>
<th>TRUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirement</td>
<td>This parameter is not required.</td>
</tr>
</tbody>
</table>
If both the Unique parameter and the Append parameter are specified, then the Unique parameter takes precedence. For details, see the Unique parameter on page 84.

**name=**"Encoding" **value=**"encoding-value"

specifies the encoding that is used to write messages to the file.

**Defaults**

The encoding setting that is in effect for the SAS session. For example, the ENCODING system option might be specified in the configuration file for a SAS server or for Base SAS. If the ENCODING system option is not specified for the SAS session, then the defaults that are described in the *SAS National Language Support (NLS): Reference Guide* are used.

For logging processes that run outside a SAS session (for example, logging for the SAS Object Spawner), the default is the encoding that is specified in the operating system settings.

**Requirement**

This parameter is not required.

**See**

**name=**"File" **value=**"path-and-filename"

specifies the path and filename of the file to which messages are written.

**Default**

None

**Requirement**

This parameter is not required.

**Interaction**

This filename overwrites any value that you specify for path-and-filename-pattern in a RollingPolicy or TriggeringPolicy configuration.

**name=**"FilePermissions" **value=**"permission-value-1,permission-value-2..."

specifies one or more sets of permissions to set for the log file. To specify more than one set, separate them with a comma within the quotation marks. Use the following syntax for each permission value:

\[
A:<\text{trustee\_type}>::<\text{permissions}>
\]

- **A** indicates that these are access permissions. No other values are supported.

- **trustee\_type** indicates which users the permissions apply to. The following values are supported:
  - **u** the user whose credentials are being used to generate the log file.
  - **g** all groups that the user belongs to.
  - **o** all other users. On UNIX systems, this value includes all users except those specified by u and g. On Windows systems, this value includes all users including those specified by u and g.

- **permissions** the permission string that applies to the trustee type. The permission string takes the values r (Read), w (Write), and x (Execute), in that order. If you do...
not want to grant one of these permissions, enter a hyphen (-) in its place. For example, specify r-x or rw-.

**Note:** The specified file permissions take effect only when a new file is being created or when the current user is the owner of the existing file.

<table>
<thead>
<tr>
<th>Default</th>
<th>Requirement</th>
<th>See</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>If this parameter is not specified, the logging facility does not apply any permissions other than those that are applied by the operating system.</td>
<td>This parameter is not required.</td>
<td>For additional details and examples, see the PERMISSION argument in the following documentation topics: &quot;FILE Statement: Windows&quot; in SAS Companion for Windows and &quot;FILE Statement: UNIX&quot; in SAS Companion for UNIX Environments.</td>
<td>The following parameter sets permissions that enable only the owning user to write to the log file. All other users can only read the file. &lt;param name=&quot;FilePermissions&quot; value=&quot;A::u::rw-,A::g::r--,A::o::r--&quot;/&gt;</td>
</tr>
</tbody>
</table>

**name="ImmediateFlush"**

determines whether messages are written to the file immediately or held in a buffer. Specify one of the following values:

**TRUE**
writes messages to the file immediately as they are received.

**FALSE**
holds messages in a buffer and writes them to the file when the buffer is full. The default buffer size is 16 KB.

**Default**
FALSE

**Requirement**
This parameter is not required.

**name="Locale" value="locale"**
specifies the locale that is used to write messages to the file.

** Defaults**
The locale setting that is in effect for the SAS session. For example, the LOCALE system option might be specified in the configuration file for a SAS server or for Base SAS.

For logging processes that run outside a SAS session (for example, logging for the SAS Object Spawner), the default is the locale that is specified in the operating system settings.

**Requirement**
This parameter is not required.

**See**

**name="Threshold"**
specifies the lowest event level that this appender processes. Events that are below the specified level are ignored. The valid values are listed here from lowest to highest.

**Default**
None
**Requirement**
This parameter is not required.

**See**
“Logging Thresholds” on page 18

**name="Unique"**
creates a new file, with an underscore and a unique number appended to the filename, if the log file already exists when logging begins. Numbers are assigned sequentially from 0 to 32766.

For example, suppose `Events_%d.log` is specified in `path-and-filename-pattern` for TimeBasedRollingPolicy. If the current date is August 3, 2008, and a file already exists that has the name `Events_20080803.log`, then the next log file that is created is named `Events_20080803_0.log`. If a file already exists that has the name `Events_20080803_0.log`, then the next log file that is created is named `Events_20080803_1.log`.

**Default**
FALSE

**Requirement**
This parameter is not required.

**Interactions**
If both the Unique parameter and the Append parameter are specified, then the Unique parameter takes precedence. If the log file already exists when logging begins, and if Unique is set to TRUE, then messages are written to a new file with a unique number appended to the filename. This occurs whether Append is set to TRUE or FALSE.

If Unique is set to TRUE and FixedWindowRollingPolicy is specified, then a complete set of unique files is created when logging begins. For details, see the Interaction for “FixedWindowRollingPolicy” on page 85

**filter-definitions**
specifies the names and associated parameters of filters that limit the messages that are logged by this appender.

**Default**
None

**Requirement**
filter-definitions are not required.

**See**
“Filters” on page 135

**name="ConversionPattern" value="conversion-pattern"**
specifies how the log message is written to the log.

**Default**
None. If a conversion pattern is not specified, then the log event produces an empty string.

**Requirement**
This parameter is not required.

**See**
“Pattern Layouts” on page 107

**rollingPolicy**
specifies the policy that controls the creation of new log files and filenames when messages roll over to a new file. SAS provides the following instances of rollingPolicy:

- FixedWindowRollingPolicy on page 85
FixedWindowRollingPolicy
specifies a fixed set of filenames that include sequentially assigned index numbers. To specify when log files roll over, specify either SizeBasedTriggeringPolicy or FilterBasedTriggeringPolicy in the TriggeringPolicy parameter. When the specified criteria are met, the log files are rolled over as follows:

The appender renames each existing log file by incrementing the index number in the filename by 1. For example, Events03.log is renamed to Events04.log, Events02.log is renamed to Events03.log, and Events01.log is renamed to Events02.log.

If a file already exists that has a filename that includes maximum-index, then the messages in that file are overwritten. For example, if Events04.log already exists when rollover occurs, and if 4 is specified in maximum-index, then the contents of Events04.log are replaced with the contents of Events03.log.

The appender creates a new file with minimum-index in the filename (for example, Events01.log), and subsequent messages are written to that file.

Use the following syntax to specify FixedWindowRollingPolicy:

```xml
<rollingPolicy class="FixedWindowRollingPolicy">
  <param name="FileNamePattern" value="path-and-filename-pattern"/>
  <param name="maxIndex" value="maximum-index"/>
  <param name="minIndex" value="minimum-index"/>
</rollingPolicy>
```

name="FileNamePattern" value="path-and-filename-pattern"
specifies the path to which the log file is written and the conversion pattern that is used to create the log filename when messages roll over to a new file. The conversion pattern can include the following characters:

%i
indicates where the index number is to appear. The index number is incremented by 1 each time a new file is created.

%S{key}
indicates where system information (such as the host name, operating system, or system description) appears. You must specify a key to indicate the type of system information that appears.

See “S Conversion Character” on page 128

Default None

Requirement This parameter is not required.

Interaction If both the File parameter and the FileNamePattern parameter are specified, then the File parameter takes precedence.

Example Specify c:\logs\MetadataServer_S{host_name}_%i.log if you want the log files to be written to the path c:\logs\ and if you want the files to be named MetadataServer_host-name_01.log, MetadataServer_host-name_02.log, and so on.
name="maxIndex" value="maximum-index"
specifies an integer that is the highest number to be used as an index in the log filename. For example, if you set minimum-index to 1 and maximum-index to 10, the appender creates a maximum of ten log files. When the maximum has been reached, the appender overwrites the most recently created file.

Default 7
Range 1–14
Requirement This parameter is not required.
Interaction If maximum-index is equal to minimum-index, then only one file is created.

name="minIndex" value="minimum-index"
specifies an integer that is the beginning number to be used as an index in the log filename. For example, if you set minimum-index to 3, the name of the first log file that is created will contain the characters 03 in the position that is specified by %i in the filename pattern.

Default 1
Range 1–14
Requirement This parameter is not required.

Interactions If Unique is set to TRUE and FixedWindowRollingPolicy is specified, then a complete set of fixed window files is created when logging begins. If one or more sets of fixed window files already exist when logging begins, then a new set of fixed window files is created. The new set of files has an underscore character and a unique number appended to each filename.

For example, suppose Unique is set to TRUE and FixedWindowRollingPolicy is specified with a filename pattern of Events%i.log, a minimum-index of 1, and a maximum-index of 4. The log files are created as follows:

When logging first begins, the following empty files are created: Events01.log, Events02.log, Events03.log, and Events04.log. Messages are written to Events01.log and are rolled over to the other files in the group as specified by the triggering policy.

The next time logging begins, the following set of files is created and written to Events01_0.log, Events02_0.log, Events03_0.log, and Events04_0.log.

Each subsequent time that logging begins, a new set of files is created with a new unique suffix (for example, _1, _2, _3).

TimeBasedRollingPolicy specifies the use of a log filename that contains the current date. You do not need to specify a value for triggeringPolicy when you use this policy. To specify when a new log file is created, you can specify either of the following options:
- Creation of (rollover to) a new log file whenever the generated filename differs from the current filename. This is the default behavior.
  
  For example, if the filename includes the current year, month, and day, then a new file is created when the system date changes to a new day.

- Creation of a new log file only when a new session begins.
  
  When rollover occurs, the message Log continues in path-and-filename is written to the end of the current file. The message Log continued from path-and-filename is written to the beginning of the newly created file.

Use the following syntax to specify TimeBasedRollingPolicy:

```
<rollingPolicy class="TimeBasedRollingPolicy">
  <param name="FileNamePattern" value="filename-pattern"/>
  <param name="rollOver" value="TRUE | FALSE"/>
</rollingPolicy>
```

name="FileNamePattern" value="path-and-filename-pattern"

specifies the path to which the log file is written and the conversion pattern that is used to create the log filename. The conversion pattern can include the following characters:

%$d

indicates where the current date appears. You can specify a date format or a date and time pattern in braces after %d if you want the date to appear in a format other than yyyy-mm-dd, or if you want to include additional information such as the hour.

See

%$S{key}

indicates where system information (such as the host name, operating system, or system description) appears. You must specify a key to indicate the type of system information that appears.

See "Pattern Layouts" on page 107 "S Conversion Character" on page 128

Default

None

Requirement

This parameter is required.

Interaction

If both the File parameter and the FileNamePattern parameter are specified, then the File parameter takes precedence.

Example

For example, specify c:\logs\MetadataServer_%d_%$S{host_name}\log if you want the log files to be written to the path c:\logs\ and the filename to include the current date and the name of the metadata server host machine.

name="rollOver" |

indicates whether a new log file is created whenever the generated filename differs from the current filename. Specify one of the following values:

TRUE

creates (rolls over to) a new file whenever the generated filename differs from the current filename.
false
creates a new log file only when a new session begins.

Default TRUE

Requirement This argument is not required.

triggeringPolicy class=

specifies the policy that determines when a new log file is created. SAS provides the following instances of triggeringPolicy:

- SizeBasedTriggeringPolicy on page 88
- FilterBasedTriggeringPolicy on page 88

SizeBasedTriggeringPolicy

specifies the creation of a new log file when the number of bytes in the current log file is greater than or equal to the specified maximum-file-size. Along with this policy, specify FixedWindowRollingPolicy in the RollingPolicy parameter to control how new log filenames are assigned and the number of files that are created.

Use the following syntax to specify SizeBasedTriggeringPolicy:

```xml
<triggeringPolicy class="SizeBasedTriggeringPolicy">
   <param name="MaxFileSize" value ="maximum-file-size">
</triggeringPolicy>
```

name="MaxFileSize" value="maximum-file-size"

specifies the maximum size, in bytes, of the log file. When the log file reaches this size, messages roll over to a new file. You can use the suffix KB (for kilobytes), MB (for megabytes), or GB (for gigabytes) when you are specifying the size. For example, 10KB is interpreted as 10240 bytes.

FilterBasedTriggeringPolicy

specifies the creation of a new log file when a log event is received that meets the specified filtering criteria. Along with this policy, specify FixedWindowRollingPolicy in the RollingPolicy parameter to control how new log filenames are assigned and the number of files that are created.

Use the following syntax to specify FilterBasedTriggeringPolicy:

```xml
<triggeringPolicy class="FilterBasedTriggeringPolicy">
   <filter-definitions>
</triggeringPolicy>
```

filter-definitions

specifies the filters that are used to trigger rollover to a new log file.

See “Filters” on page 135

Details

You can configure an instance of RollingFileAppender to do the following:

- roll over to a new log file when the system date or time changes (for example, every day or every hour)
- roll over to a new log file when a new session begins
- roll over to a new log file when the file reaches a specified size
- roll over to a new log file when log events match the specified filtering criteria

In addition, RollingFileAppender provides all of the functionality of FileAppender on page 57.

The following best practices apply to RollingFileAppender:

- Use of the Unique parameter is recommended to avoid overwriting log files. However, if numerous files are created that have the same root filename and different numerical suffixes, then the system must perform multiple comparisons to determine a unique number. To conserve system resources when using this parameter, consider specifying a *path-and-filename-pattern* that includes a unique identifier such as process ID (`%S{pid}`).

**Examples:**

**Example 1: Roll Over to a New Log File Every Day**

This RollingFileAppender configuration writes messages to a log file whose name contains the current date (for example, `MetadataServer_2012-03-01.log`). When the system date changes, messages roll over to a new log file whose name contains the new date (for example, `MetadataServer_2012-03-02.log`).

```xml
<appender class="RollingFileAppender" name="TimeBasedRollingFile">
  <param name="Append" value="true"/>
  <param name="ImmediateFlush" value="true"/>
  <rollingPolicy class="TimeBasedRollingPolicy">
    <param name="FileNamePattern" value="c:\logs\MetadataServer_%d.log"/>
  </rollingPolicy>
  <layout>
    <param name="ConversionPattern" value="%d %-5p [%t] %u - %m"/>
  </layout>
</appender>
```

**Example 2: Roll Over to a New Log When a New Session Begins**

This RollingFileAppender configuration writes messages to a log file whose name contains the current date (for example, `MetadataServer_2012-03-01.log`). When a new session begins, messages roll over to a new log file whose name contains the current date (for example, `MetadataServer_2012-03-02.log`).

```xml
<appender class="RollingFileAppender" name="TimeBasedRollingFile">
  <param name="Append" value="true"/>
  <param name="ImmediateFlush" value="true"/>
  <rollingPolicy class="TimeBasedRollingPolicy">
    <param name="FileNamePattern" value="c:\logs\MetadataServer_%d.log"/>
    <param name="rollOver" value="false"/>
  </rollingPolicy>
  <layout>
    <param name="ConversionPattern" value="%d %-5p [%t] %u - %m"/>
  </layout>
</appender>
```
Example 3: Roll Over to a New Log File When the File Reaches a Specified Size

In this example, RollingFileAppender writes messages to a log file whose name contains an index number. The first file that is created is called MetadataServer_01.log. When the size of MetadataServer_01.log is greater than or equal to 100 KB, the file is renamed to MetadataServer_02.log, and subsequent messages are written to a newly created instance of MetadataServer_01.log.

The next time MetadataServer_01.log reaches or exceeds 100 KB, MetadataServer_02.log is renamed to MetadataServer_03.log, MetadataServer_01.log is renamed to MetadataServer_02.log, and subsequent messages are written to a newly created instance of MetadataServer_01.log.

Rollover continues until nine files have been created, at which point the contents of MetadataServer_09.log are overwritten when rollover occurs.

<!-- Rolling log file based on log file size -->
<appender class="RollingFileAppender" name="FixedWindowRollingFile">
  <param name="Append" value="true"/>
  <param name="ImmediateFlush" value="true"/>
  <rollingPolicy class="FixedWindowRollingPolicy">
    <param name="FileNamePattern" value="c:\logs\MetadataServ_%i.log"/>
    <param name="minIndex" value="1"/>
    <param name="maxIndex" value="9"/>
  </rollingPolicy>
  <triggeringPolicy class="SizeBasedTriggeringPolicy">
    <param name="MaxFileSize" value="100KB"/>
  </triggeringPolicy>
  <layout>
    <param name="ConversionPattern" value="%d %-5p [%t] %u - %m"/>
  </layout>
</appender>

sLogAppender

Is a reserved class. You should not define new instances of this appender.

Note: Various appender definitions that rely on sLogAppender are enabled by default for several SAS servers. These appender definitions enable SAS client and SAS middle tier applications to access SAS server internal logging facilities.

CAUTION: Do not modify sLogAppender definitions that are provided in default logging configuration files. Modifying these definitions results in unpredictable behavior.

UNXFacilityAppender

Writes messages to the syslogd logging facility in UNIX operating systems.

Valid in: XML configuration
Syntax

```xml
<appender class="UNXFacilityAppender" name="LOG">
    <param name="facilitycode" value="log_value"/>
    <layout>
        <param name="ConversionPattern" value="conversion-pattern"/>
    </layout>
</appender>
```

Syntax Description

**name="facilitycode" value="/log_value"**

The `facilitycode` configuration option specifies the system facility value that generated the message. It can have any of the following log values:

- **LOG_USER**
  
  specifies that messages that are generated by user processes are logged. 
  LOG_USER is the default value for `facilitycode`.

- **LOG_LOCAL0 through LOG_LOCAL7**

  specifies values that are reserved for use by your site.

See For information about the generic elements of the appender syntax, see “General Appender Syntax” on page 13

Details

**UNXFacilityAppender Usage**

UNXFacilityAppender is supported on the Solaris, HP, Linux, and AIX operating systems. The logging facility that these operating systems provide is named `syslogd`. The `syslogd` daemon must be running before you can see the output that is sent to it by UNXFacilityAppender. To enable UNXFacilityAppender to communicate with `syslogd`, make sure that the `/etc/syslog.conf` file contains one or more of the following entries:

- an entry for the `user` facility
- an entry for the `local0` through `local7` facilities
- an asterisk (`*`), which specifies all facilities

**Note:** Use caution when specifying `*`. It can cause facilities other than `user` and `local0` through `local7` to log to the destination.

These entries should have a format of `'<facility>.<priority> <destination>'`. The following examples show the formats for entries in the configuration file:

```plaintext
user.info       /tmp/userinfo.log
or
*.info          /tmp/allinfo.log
```

For more information about `syslogd` on the UNIX platform that you are using, see the documentation written by that provider.
UNXFacilityAppender Diagnostic Levels

The following SAS logging facility’s diagnostic levels are sent to the UNIX syslogd logging facility with the specified syslogd priorities:

<table>
<thead>
<tr>
<th>SAS Logging Level</th>
<th>syslogd Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRACE, DEBUG</td>
<td>debug</td>
</tr>
<tr>
<td>INFO</td>
<td>info</td>
</tr>
<tr>
<td>WARN</td>
<td>warning</td>
</tr>
<tr>
<td>ERROR</td>
<td>err</td>
</tr>
<tr>
<td>FATAL</td>
<td>crit</td>
</tr>
<tr>
<td>no level</td>
<td>notice</td>
</tr>
</tbody>
</table>

syslogd priority is sometimes referred to as level in UNIX documentation for syslogd. When you use syslogd priority as a value for the SAS logging level, it specifies the severity of the message. It can also be used to specify the part of the system that generated the message. The following list contains definitions for the SAS logging levels that are listed in the table above:

- **TRACE, DEBUG**: specifies messages that are helpful in debugging a program.
- **INFO**: specifies messages that contain general information.
- **WARN**: specifies messages that contain warnings.
- **ERROR**: specifies messages that identify error conditions.
- **FATAL**: specifies messages that identify critical conditions.
- **no level**: specifies messages that identify conditions that require special attention. These conditions are not error conditions. If you do not specify a SAS logging level, then the syslogd value of notice is the default.

Example

The following example is a typical XML configuration file that specifies UNXFacilityAppender.

```xml
<appender class="UNXFacilityAppender" name="LOG">
  <layout>
    <param name="ConversionPattern" value="%d %-5p [%t] %c - %m"/>
  </layout>
</appender>
```
**WindowsEventAppender**

*WindowsEventAppender* writes messages to the Windows Event log.

**Valid in:** XML configuration

**Syntax**

```xml
<appender class="WindowsEventAppender" name="eventAppender">
</appender>
```

**Syntax Description**

For information about the generic elements of the appender syntax, see “General Appender Syntax” on page 13.

**Details**

*WindowsEventAppender* is a logging facility appender that supports event logging on Windows operating systems.

*WindowsEventAppender* sends events to the Windows event log. The event log might be easily overloaded. You should configure *WindowsEventAppender* so that the event log does not receive more events than it can handle.

**Example**

The following example is a typical XML configuration file that specifies the *WindowsEventAppender*. The parameter identifies the role of SAS as the SAS Foundation.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<logging:configuration xmlns:logging="http://www.sas.com/xml/logging/1.0/">
  <appender name="eventLog" class="WindowsEventAppender">
    <layout>
      <param name="ConversionPattern" value="%d %5p [%t] %c (%F:%L) - %m"/>
    </layout>
  </appender>
  <root>
    <level value="trace"/>
    <appender-ref ref="eventLog"/>
  </root>
</logging:configuration>
```
ZOSFacilityAppender

Enables multiple instances of SAS in the z/OS operating system to write messages to a common location.

Valid in: XML configuration

Syntax

```xml
<appender class="ZOSFacilityAppender" name="appender-name">
  <param name="stream" value="stream-name"/>
  <layout>
    <param name="ConversionPattern" value="conversion-pattern"/>
  </layout>
</appender>
```

Syntax Description

- **name="stream" value="stream-name"**
  - Specifies the log stream for ZOSFacilityAppender.

  **Restriction**
  - The log stream must be defined, using the IBM IXCMIA?APU utility.

  **See**
  - For information about the generic elements of the appender syntax, see “General Appender Syntax” on page 13.

Details

ZOSFacilityAppender is a logging facility appender that supports event logging on z/OS operating systems. ZOSFacilityAppender enables multiple instances of SAS in the z/OS environment to write log information to a common location. If the z/OS environment uses the coupling facility, all of the SAS jobs that run on all of the z/OS systems that are on the sysplex can write their logs to the same location.

To use z/OS Facility Appender, specify a class of ZOSFacilityAppender that has a stream parameter that names the z/OS log stream that is used. You can define coupling facility (CF) log streams or DASD-only log streams for use with ZOSFacilityAppender. RACF access must be granted to any SAS user or batch SAS job that writes to the system logger.

Examples:

Example 1: Configuring ZOSFacility Appender

The following example is a typical XML configuration file that specifies ZOSFacilityAppender.

```xml
<appender class="ZOSFacilityAppender" name="LOG">
  <param name="stream" value="SAS.LOG"/>
  <layout>
    <param name="ConversionPattern" value="conversion-pattern"/>
  </layout>
</appender>
```
Example 2: Defining the Log Stream

The following example is for use with direct access storage devices (DASD) only. The values that are included are not necessarily the values that you might want to use. The values that you specify can depend on the amount of data that is being processed, or on other variables.

```plaintext
//STEP1  EXEC PGM=IXCMIAPU
//SYSIN   DD *
DATA TYPE(LOGR)
DEFINE LOGSTREAM NAME(SAS.LOG)
   LS_DATACLAS(STD)
   LS_MGMTCLAS(STD)
   LS_STORCLAS(STD)
   HLQ(IXGLOGR)
   MODEL(NO)
   LS_SIZE(0)
   STG_MGMTCLAS(STD)
   STG_STORCLAS(STD)
   STG_DATACLAS(STD)
   STG_SIZE(3000)
   LOWOFFLOAD(60)
   HIGHOFFLOAD(95)
   STG_DUPLEX(YES)
   DUPLEXMODE(UNCOND)
   RETPD(3)
   AUTODELETE(YES)
   OFFLOADRECALL(YES)
   DASDONLY(YES)
   DIAG(NO)
   LOGGERDUPLEX()
   EHLQ(NO_EHLQ)
   MAXBUFSIZE(64000)
```

Example 3: Using the SUBSYS DD Statement

To see the contents of the log stream, you can activate the LOGR subsystem by placing SUBSYS SUBNAME(LOGR) in SYS1.PARMLIB(IEFSSNxx). The following example shows how, after the LOGR subsystem has started, you can treat the log stream as a data set by using the SUBSYS DD statement.

```plaintext
//REPRO  EXEC PGM=IDCAMS,REGION=20M
//SYSUT1 DD DISP=SHR,DSN=SAS.LOG,
   //   SUBSYS=(LOGR),
   //   DCB=(DSORG=PS,RECFM=VB,LRBCL=32756,RLKSIZE=32760)
//SYSUT2 DD SYSOUT=*,
   //   DCB=(DSORG=PS,RECFM=VB,LRBCL=32756,RLKSIZE=32760)
//SYSIN   DD *
```
Example 4: Limiting the Output

The FROM and TO options in the following example are options of the LOGR subsystem that limit the output.

```
//IN   DD DSN=SAS.LOG,DISP=SHR,
//        DCB=(DSORG=PS,RECFM=VB,LRECL=32756,BLKSIZ=32760)
//        SUBSYS=(LOGR,IXGSEXIT,
//        'FROM=(1997/152,05:00),TO=(1997/153,23:59),GMT'
```

Example 5: Deleting the Contents of the Log Stream

To delete the entire contents of the logstream, copy the IBM sample PROC IXGDELAB into SYS1.PROCLIB and start it with the log stream name as the parameter. Although this code does not delete the log stream, it resets the stream to an empty condition.

```
S IXGDELAB,LOGSTRM=SAS.LOG
```

---

**ZOSWtoAppender**

Directs SAS application messages to the z/OS operating system console.

**Valid in:** XML configuration

**See:** For more information about the z/OS write-to-operator (WTO) service macro and the parameters that are listed here, see the IBM reference document, *MVS Assembler Services Reference*.

For information about the generic elements of the appender syntax, see "General Appender Syntax" on page 13.

**Syntax**

```
<appender class="ZOSWtoAppender" name="appender-name">
  <layout>
    <param name="ConversionPattern" value="conversion-pattern"/>
  </layout>
  <param name="routecode" value="value"/>
  <param name="descocode" value="value"/>
  <param name="mcsflag" value="HRDCPY | BRDCST | NOTIME"/>
</appender>
```

**Syntax Description**

- **name="routecode" value="value"**
  specifies the routing code that is used for ZOSWtoAppender messages.

- **name="descocode" value="value"**
  specifies the descriptor code that is used for ZOSWtoAppender messages.
name="mcsflag" value="value"

specifies the mcs flag that is used for ZOSWtoAppender messages. Valid values for the mcs flag parameter are HRDCPY, BRDCST, NOTIME, and BUSYEXIT.

Details

ZOSWtoAppender is a logging facility appender that supports event logging on z/OS operating systems. ZOSWtoAppender enables you to direct SAS application messages, such as automation messages in the Admin message category, to the operating system consoles. ZOSWtoAppender uses the z/OS write-to-operator (WTO) service macro to direct the messages to the consoles. The appender also enables SAS servers to send messages about the status of applications to z/OS for automation purposes.

The "routeocode", "descocode", and "mcsflag" parameters can be included multiple times in your XML file. For example, you can have multiple "routeocode" parameters if you want to specify more than one routing code.

Example

The following example initiates ZOSWtoAppender; specifies a conversion pattern; specifies the name of the logger; and specifies values for the "routeocode", "descocode", and "mcsflag" parameters.

```xml
<appender name="WTO" class="ZOSWtoAppender">
  <layout>
    <param name="ConversionPattern" value="%d %-5p [%t] %c (%F:%L) — %m"/>
  </layout>
  <param name="routeocode" value="11"/>
  <param name="descocode" value="7"/>
  <param name="mcsflag" value="HRDCPY"/>
</appender>
<logger name ="ADMIN.OPERATIONS">
  <level value="trace"/>
  <appender-ref ref="WTO"/>
</logger>
```
Database Connection Options
Reference for DBAppender

Dictionary

DBAppender Connection Options for DB2

The following is an example of the basic syntax for specifying options in the ConnectionString parameter of a DBAppender configuration for a DB2 database. If you need additional details, contact SAS Technical Support.

Valid in: ConnectionString parameter of DBAppender configuration
See: “DBAppender” on page 51

Syntax

CATALOG=.catalog-identifier;
DATABASE=database-specification;
DRIVER=DB2;
PWD=password;
UID=user-id;
CONOPTS=(valid-DB2-compliant-database-connection-string);

Syntax Description

The data source connection options for a DB2 database include the following:

**CATALOG=** *catalog-identifier*

specifies an arbitrary identifier for an SQL catalog, which groups logically related schemas. Any identifier is valid (for example, catalog=db2).
You must specify a catalog. For the DB2 database, this is a logical catalog name to use as an SQL catalog identifier.

**DATABASE=database-specification**
Specifies the name of the DB2 database.

**DRIVER=DB2;**
identifies the data source to which you want to connect, which is a DB2 database.

You must specify the driver.

**PWD=password;**
specifies the DB2 password.

**UID=user-id;**
specifies the DB2 login user ID.

**CONOPTS=(valid-DB2-compliant-database-connection-string);**
specifies, within parentheses, a DB2 connection string. This parameter enables you to specify connection options that cannot be specified with the other ConnectionString parameters.

For example, you can use this parameter as follows to specify a DSN called logdata:

```conLOPTS=(DSN=logdata);```

---

**Example: Connection String for DB2**

```
DRIVER=DB2;DB=SAMPLE;UID=User1;PWD=Password1;CATALOG=db2;
```

---

**DBAppender Connection Options for ODBC**

The following is an example of the basic syntax for specifying options in the ConnectionString parameter of a DBAppender configuration for an ODBC-compliant database. If you need additional details, contact SAS Technical Support.

**Valid in:** ConnectionString parameter of DBAppender configuration

**See:** "DBAppender" on page 51

**Syntax**

```conLOPTS=(valid-ODBC-compliant-database-connection-string);```

```
CATALOG=catalog-identifier;
ODBC_DSN=ODBC-DSN-name
DRIVER=ODBC;
PWD=password;
UID=user-id;
```
Syntax Description

The data source connection options for an ODBC-compliant database include the following:

**CATALOG=catalog-identifier**
specifies an arbitrary identifier for an SQL catalog, which groups logically related schemas.

For the Microsoft SQL Server, you can specify a logical name for the catalog, and map it to the native catalog name that is defined in the SQL Server. For example, to specify the logical catalog logcat and map it to a native catalog called sqlcat, you would specify the following:

catalog=(logcat=sqlcat);

For databases that do not support native catalogs, any identifier is valid (for example, catalog=myodbc).

**Default**
If this parameter is omitted for the Microsoft SQL Server, the default setting CATALOG=* is used.

**Requirements**
For the Microsoft SQL Server, which is a multiple-catalog database, CATALOG= is optional.

For databases that do not support native catalogs, you must specify a catalog.

**ODBC_DSN=ODBC-DSN-name**
specifies a valid ODBC-compliant database DSN that contains information for connecting to the ODBC-compliant database.

**Interaction**
To specify database-connection options that cannot be specified with the other ConnectionString parameters, you can use the CONOPTS= option along with the ODBC_DSN option. However, do not specify the ODBC DSN in both CONOPTS= and ODBC_DSN=.

**DRIVER=ODBC;**
identifies the type of data source to which you want to connect, which is ODBC.

**Requirement**
You must specify the driver.

**PASSWORD=**
specifies the password that is associated with the user ID.

**Alias**
**PWD=**

**USER=user-id;**
specifies the user ID for logging on to the ODBC-compliant database.

**Alias**
**UID=**

**Default**
If no user ID is specified, the default user ID for the database is used to log on.

**CONOPTS=(valid-ODBC-compliant-database-connection-string);**
specifies, within parentheses, an ODBC-compliant database connection string. This optional parameter enables you to specify connection options that cannot be specified with the other ConnectionString parameters. Here is an example:

- If the database uses a DSN, you can use this parameter to specify a value for DSN= or FILESDSN=. Here is an example:
CONOPTS=(DSN=LogSql);

For databases that do not use a DSN, use this parameter to specify the DRIVER= keyword. Here is an example:

CONOPTS=(DRIVER=SQL Server);

Interaction Do not specify the ODBC DSN in both CONOPTS= and ODBC_DSN=.

Example: Connection String for ODBC
The following example uses ODBC to connect to a Microsoft SQL Server:

```
DRIVER=ODBC;ODBC_DSN=LogSql;UID=User1;PWD=Password1;
```

DBAppender Connection Options for Oracle
The following is an example of the basic syntax for specifying options in the ConnectionString parameter of a DBAppender configuration for an Oracle database. If you need additional details, contact SAS Technical Support.

Valid in: ConnectionString parameter of DBAppender configuration

See: “DBAppender” on page 51

Syntax

```
CATALOG=catalog-identifier;
DRIVER=ORACLE;
PATH=database-specification;
PWD=password;
UID=user-id;
```

Syntax Description

The data source connection options for an Oracle database include the following:

- **CATALOG=** *catalog-identifier*:
  specifies an arbitrary identifier for an SQL catalog, which groups logically related schemas. Any identifier is valid (for example, `catalog=oracle_log`).

  **Requirement** You must specify a catalog. For the Oracle database, this is a logical catalog name to use as an SQL catalog identifier.

- **DRIVER=** *ORACLE*:
  identifies the data source to which you want to connect, which is an Oracle database.

  **Requirement** You must specify the driver.

- **PATH=** *database-specification*:
  specifies the Oracle connect identifier. A connect identifier can be a net service name, a database service name, or a net service alias.
**PWD=** *password*;
specifies the Oracle database password that is associated with user ID that is specified in **UID=**.

**Default**
If this parameter is not specified, then the password for the default Oracle user ID (OPS$sysid) is used, if it is enabled.

**Requirement**
This parameter is required if **UID=** is specified.

**UID=** *user-id*;
specifies an Oracle user ID. If the user ID contains blanks or national characters, enclose it in quotation marks.

**Default**
If this parameter is not specified, then the default Oracle user ID (OPS$sysid) is used, if it is enabled.

**Requirement**
This parameter is required if **PWD=** is specified.

**Example: Connection String for Oracle**

```
DRIVER=oracle;UID=User1;PWD=Password1;PATH=MyDatabaseService;CATALOG=x;
```

---

**DBAppender Connection Options for SAS Tables**

The following is an example of the basic syntax for specifying options in the ConnectionString parameter of a DBAppender configuration if the data store is a SAS table. If you need additional details, contact SAS Technical Support.

Valid in:  
ConnectionString parameter of DBAppender configuration

See:  
“DBAppender” on page 51

**Syntax**

```
CATALOG=**catalog-identifier**;
DRIVER=BASE;
SCHEMA=(NAME=**schema-name**;PRIMARYPATH=**schema-path**);
```

**Syntax Description**

The data source connection options for a SAS table include the following:

**CATALOG=** *catalog-identifier*;
specifies an arbitrary identifier for the SAS catalog. Any identifier is valid (for example, catalog=base).

**Requirement**
You must specify a catalog.

**DRIVER=** BASE;
identifies the data source to which you want to connect, which is a Base SAS table.

**Requirement**
You must specify the driver.
SCHEMA=(NAME=schema-name;PRIMARYPATH=schema-path);
    specifies the name and path for the schema. Any name is valid (for example, name=MySchema). For PRIMARYPATH=, specify the path where the SAS table is located, relative to the local machine.

Requirement    You must specify the SCHEMA= option.

Example: Connection String for SAS Tables

    DRIVER=base;CATALOG=base;schema=(name=MySchema;primarypath='C:\LogsData');

DBAppender Connection Options for Teradata

The following is an example of the basic syntax for specifying options in the ConnectionString parameter of a DBAppender configuration for a Teradata database. If you need additional details, contact SAS Technical Support.

Valid in:     ConnectionString parameter of DBAppender configuration
Note:         To set up the connection, you must run the Teradata TTU.exe client.
See:          “DBAppender” on page 51

Syntax

CATALOG=catalog-identifier;
DATABASE=database-name;
DRIVER=TERADATA;
PASSWORD=password;
SERVER=Teradata-server-identifier;
USER=user-id;

Syntax Description

The data source connection options for a Teradata database include the following:

CATALOG=catalog-identifier;
    specifies an arbitrary identifier for an SQL catalog, which groups logically related schemas. Any identifier is valid (for example, catalog=tera).

Requirement    You must specify a catalog.

DATABASE=database-name;
    specifies the Teradata database. If this option is not specified, a connection is made to the default Teradata database for the user ID that is associated with the process. If the database name contains spaces or non-alphanumeric characters, you must enclose it in quotation marks.

DRIVER=TERADATA;
    identifies the data source to which you want to connect, which is a Teradata database.

Requirement    You must specify the driver.
**PASSWORD=password;**
specifies a Teradata password. The password that you specify must be correct for your USER= value.

<table>
<thead>
<tr>
<th>Alias</th>
<th>PWD=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirement</td>
<td>You must specify the PASSWORD= option.</td>
</tr>
</tbody>
</table>

**SERVER=Teradata-server-identifier;**
specifies the Teradata server identifier.

**USER=user-id;**
specifies a Teradata user ID. If the user ID contains blanks or national characters, enclose it in quotation marks.

<table>
<thead>
<tr>
<th>Alias</th>
<th>UID=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirement</td>
<td>You must specify the USER= option.</td>
</tr>
</tbody>
</table>

Example: Connection String for Teradata

```
DRIVER=TERADATA;UID=User1;PWD=Password1;server=dbc;database=mydatabase;CATALOG=X;
```

About Pattern Layouts

Overview of Pattern Layouts

A pattern layout is a template that you create in order to format log messages for the appender classes in the SAS logging facility. The pattern layout that you define identifies the type of data, the order of the data, and the format of the data that is generated in a log event and that is delivered as output. A unique pattern layout is created for each instance of an appender class. You configure a pattern layout by
using the <layout> appender subelement in a logging configuration file or the PATTERN attribute of an appender language element.

The pattern layout is created by using a conversion pattern, which consists of literal text and format-control directives. Format-control directives are also called conversion specifiers.

The conversion patterns that you use to format log messages are similar to, but not identical to, the conversion patterns that are used in the C language PRINTF statement.

Note: The conversion patterns that you use to format log messages are also similar to, but not identical to, these formatting methods that are used in these contexts:

- the directives that are used in the SAS LOGPARM= system option to format log names.
- the set of conversion patterns that are used by the ARMApplier. For details, see “ARM Appender Pattern Layouts for ARM Messages” in SAS Interface to Application Response Measurement (ARM): Reference.

The meaning of a specific character that is used in a pattern can vary according to the context. Do not interchange characters.

SAS issues an error message if the message layout fails.

Here is an example of a formatted log event that is delivered to the appropriate output device:

<table>
<thead>
<tr>
<th>Date</th>
<th>Level</th>
<th>Thread ID</th>
<th>Logger</th>
<th>Filename or Line Number</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2008-06-25</td>
<td>WARN;</td>
<td>3;</td>
<td>Appender.IO</td>
<td>(ynl4.sas.c:149);</td>
<td>Numeric maximum was larger than 8, am setting to 8.</td>
</tr>
<tr>
<td>10:24:22, 234;</td>
<td></td>
<td></td>
<td>MCallContext;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Here is another view of the formatted log event as output:

2008-06-25-10:24:22,234; WARN; 3; Appender.IOMCallContext; (ynl4.sas.c:149); Numeric maximum was larger than 8, am setting to 8.

Conversion Patterns Supplied by SAS

SAS supplies several conversion patterns that you can specify as the value for HeaderPattern, ConversionPattern, and FooterPattern parameters in appender configurations. You specify a conversion pattern name in place of the conversion pattern.

In this example, DEFAULTHEADER and DEFAULT are conversion pattern names:

```xml
<appender name="myDefault" class="FileAppender">
  <param name="File" value="default.log"/>
  <param name="ImmediateFlush" value="true"/>
  <param name="Append" value="false"/>
</appender>
```
Here are some rules for using conversion pattern names:

- Conversion pattern names are case sensitive and must be specified in uppercase letters.
- Conversion pattern names cannot be specified with other conversion specifiers. For example, the following ConversionPattern value is not valid:

```xml
<param name="ConversionPattern" value="%d:DEFAULT"/>
```

SAS supplies DEFAULT and DEFAULTHEADER conversion patterns for each version of SAS as well as a version-specific DEFAULTversion-number and DEFAULTHEADERversion-number conversion patterns. If the default layouts change in a new version of SAS, you can use the version-specific conversion patterns to use the previous version's layout. If you have a program to parse logs, you might want to use the version-specific default. If the default conversion pattern changes in a new version of SAS, you do not need to change your program.

The following table lists the conversion patterns that SAS supplies.

<table>
<thead>
<tr>
<th>Conversion Pattern Name and Description</th>
<th>Conversion Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULTHEADER</td>
<td>A default conversion pattern for the HeaderPattern value.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>A default conversion pattern for the ConversionPattern parameter.</td>
</tr>
<tr>
<td>DEFAULTHEADER9.3</td>
<td>A default conversion pattern for the HeaderPattern parameter in SAS 9.3.</td>
</tr>
<tr>
<td>DEFAULT9.3</td>
<td>A default conversion pattern for the ConversionPattern parameter in SAS 9.3.</td>
</tr>
<tr>
<td>TRACE</td>
<td>A conversion pattern for tracing messages.</td>
</tr>
<tr>
<td>TRACE9.3</td>
<td>A conversion pattern for tracing messages in SAS 9.3.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Conversion Pattern Name and Description</th>
<th>Conversion Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULTHEADER</td>
<td>Host: '%S{hostname}', OS: '%S{os_family}', Release: '%S{os_release}', SAS Version: '%S{sup_ver_long2}', Command: '%S{startup_cmd}'</td>
</tr>
<tr>
<td>DEFAULT</td>

Operating Environment Information for z/OS: When you specify %uuid or WEF in a logging facility configuration file, the identifiers that SAS creates are unique only for the current computer node. %uuid or WEF does not create a UUID. You can obtain a computer node name by using the %S{ hostname} conversion character.

1
A pattern layout is configured by using the `<layout>` and `</layout>` elements. Any `<appender>` element attributes and subelements in the syntax are present to show the context for the pattern layout elements.

**Syntax**

**XML Configuration**

```xml
<appender class="AppenderName" name="appender-reference-name">
  <layout>
    <param name="Header" value="header-text"/>
    <param name="HeaderPattern" value="conversion-pattern"/>
    <param name="ConversionPattern" value="conversion-pattern"/>
    <param name="Footer" value="footer-text"/>
    <param name="FooterPattern" value="conversion-pattern"/>
    <param name="XmlEscape" value="TRUE | FALSE"/>
  </layout>
</appender>
```

**Syntax Description**

- **class= "AppenderName "name="appender-reference-name"**  
  *specifies the name of the appender reference that is to be used as an appender-ref for a logger.*
  
  *See*  
  *For appender class names, see “Appender Reference” on page 45.*

- **name="Header" value="header-text"**  
  *specifies the header text that the appender uses when it starts a new log.*
  
  *Valid in*  
  *XML configuration files for the File, RollingFile, and Console appender classes.*

- **name="HeaderPattern" value="conversion-pattern"**  
  *specifies the pattern layout that is used to identify, order, and format information in a header. A conversion pattern consists of optional literal text and optional format-control directives, which are called conversion specifiers. Each conversion specifier begins with a percent sign (%) and is followed by optional format modifiers and one or more instances of the S conversion character or the d conversion character. The format modifiers control field width, padding, and left and right justification.*
  
  *Here is the syntax for a header pattern:*
Syntax for a Pattern Layout

\[ [\text{literal-text}] \%[\text{format-modifier-1}] \text{conversion-character-1} \]
\[ [... [\text{literal-text}] \%[\text{format-modifier-n}] \text{conversion-character-n}] /> \]

Valid in  XML configuration files for the File, RollingFile, and Console appender classes.

Restriction  The header pattern is limited to the S conversion character and the d conversion character in a logging configuration file.

Interaction  The Header parameter header-text takes precedence over the HeaderPattern conversion-pattern parameter.

Tips  The specification of format modifiers is optional.

There is no explicit separator between literal text and the conversion specifier. The pattern parser recognizes the end of a conversion specifier when it detects the S conversion character or the d conversion character.

See  “d Conversion Character” on page 121

“S Conversion Character” on page 128

“Format Modifiers” on page 133

Example  
\<param name="HeaderPattern" value="%%d%%s\{os_name\}%%s\{jobid\}%%s\{host_name\}%%s\{user_name\}" /> 

\text{name="ConversionPattern" value="conversion-pattern"} 

specifies the pattern layout that is used to identify, order, and format information in the log event. A conversion pattern consists of literal text and format-control directives called conversion specifiers. Each conversion specifier begins with a percent sign (%) and is followed by optional format modifiers and a conversion character. The conversion character specifies the type of data (for example, category, priority, date, and thread name). The format modifiers control field width, padding, and left and right justification.

Here is the syntax for a conversion pattern:

\[ [\text{literal-text}] \%[\text{format-modifier-1}] \text{conversion-character-1} \]
\[ [... [\text{literal-text}] \%[\text{format-modifier-n}] \text{conversion-character-n}] /> \]

Valid in  XML configuration files for any appender class.

Default  None. The log event produces an empty string if a conversion pattern is not specified.

Restrictions  Conversion specifiers are case sensitive.

Do not use these problematic characters, known as variants, in pattern layouts in EBCDIC encoding environments: ! # $ @ \ [ ] ^ \{ \} ~ \n \n represents the use of the New Line (or Enter) key.

These characters are problematic because they might occupy different code positions in various encodings that are supported by SAS. For example, the EBCDIC code point location 5A (hexadecimal) represents the exclamation point (!) in U.S. English and the right bracket ( ] ) in Spanish.
**Tips**

The specification of format modifiers is optional.

There is no explicit separator between literal text and a conversion specifier. The pattern parser recognizes the end of a conversion specifier when it detects a conversion character.

**See**

“S Conversion Character” on page 128

“Format Modifiers” on page 133

For more information about variant characters, see the SAS National Language Support (NLS): Reference Guide.

**Example**

```xml
<param name="ConversionPattern" value="%d; %-5p; %t; %c; (%F:%L); %m"/>
```

**name="Footer" value="footer-text"**

specifies the footer text that the appender uses when it ends a log.

**Valid in**

XML configuration files for the File, RollingFile, and Console appender classes.

**name="FooterPattern" value="conversion-pattern"**

specifies the pattern layout that is used to identify, order, and format information in a footer. A conversion pattern consists of optional literal text and optional format-control directives, which are called conversion specifiers. Each conversion specifier begins with a percent sign (%) and is followed by optional format modifiers and one or more instances of the S conversion character or the d conversion character. The format modifiers control field width, padding, and left and right justification.

Here is the syntax for a footer pattern:

```
[literal-text] %[format-modifier-1] conversion-character-1
   [… [literal-text] %[format-modifier-n] conversion-character-n] />
```

**Valid in**

XML configuration files for the File, RollingFile, and Console appender classes.

**Restriction**

The footer pattern is limited to the S and d conversion characters in a logging configuration file.

**Interaction**

The Footer parameter footer-text takes precedence over the FooterPattern conversion-pattern parameter.

**Tip**

There is no explicit separator between literal text and a conversion specifier. The pattern parser recognizes the end of a conversion specifier when it detects a conversion character.

**See**

“d Conversion Character” on page 121

“S Conversion Character” on page 128

“Format Modifiers” on page 133

**Example**

```xml
<param name="FooterPattern" value="%d %S{host_name}"/>
```
name="XmlEscape" |
specifies whether certain characters that can be specified in the m, x, X, and S conversion specifiers are converted to their entity representations.

TRUE
specifies that the following characters are converted when they are used in the m, x, X, and S conversion specifiers:
- "<" is converted to "&lt;"
- ">" is converted to "&gt;"
- "" (double quotation marks) is converted to "&quot;"
- "" (single quotation mark) is converted to "&apos;"
- "&" is converted to "&amp;"

FALSE
specifies that no character conversion to entity representations is performed.

Example: Example of a Pattern Layout
Here is an excerpt of an XML file that contains a pattern layout:
```xml
<layout>
  <param name="ConversionPattern" value="%d %-5p %t %c{2} (%F:%L) %m"/>
</layout>
```

Here is an explanation:

<table>
<thead>
<tr>
<th>Pattern Layout</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>%d</td>
<td>reports the date of the log event and formats the date using the default format, ISO8601.</td>
<td>2011-06-25 10:24:22,234</td>
</tr>
<tr>
<td>%-5p</td>
<td>reports the level of the log event and left-justifies the level in output. If the level occupies fewer than five characters, the level is padded on the right.</td>
<td>WARN</td>
</tr>
<tr>
<td>%t</td>
<td>reports the identifier of the thread that generated the log event.</td>
<td>0000000</td>
</tr>
<tr>
<td>%c{2}</td>
<td>reports the name of the logger that generated the log event. The precision specifier limits the logger name to two subfields, causing left-truncation.</td>
<td>The full logger name is Log4SAS.Appender.IOMCall Context. The formatted output is Appender.IOMCallContext;</td>
</tr>
<tr>
<td>Pattern Layout</td>
<td>Explanation</td>
<td>Example</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>(%F:%L)</td>
<td>reports the filename and the line number in the application that generated the log event. The parentheses and colon are literal text that was specified in the conversion pattern.</td>
<td>(ynl4sas.c:149) The parentheses ( ) and colon (:) are literal text.</td>
</tr>
<tr>
<td>%m</td>
<td>reports the message that is supplied by the application and that is associated with the log event.</td>
<td>Numeric maximum was larger than 8; I am setting to 8.</td>
</tr>
</tbody>
</table>

### c Conversion Character

Reports the name of the logger that generates the log event.

**Alias:** logger  
**Default:** Complete logger name; for example, "Logging.Appender.IOMCallContext".

#### Syntax

\[
c \ [ \{ precision-specifier \} ]
\]

#### Optional Argument

**precision-specifier**

specifies a decimal constant to indicate the number of logger levels to display in the message. If you specify `precision-specifier`, only the corresponding number of right-most components of the logger name are included in the output.

<table>
<thead>
<tr>
<th>Requirement</th>
<th>If the precision specifier is used, it must be enclosed in a pair of braces.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interaction</td>
<td>If the precision specifier is used, only the corresponding number of right-most components of the logger name are included in the output.</td>
</tr>
</tbody>
</table>

#### Example

For the logger name "Logging.Appender.IOMCallContext", the pattern `%c{2}` generates this output:

"Appender.IOMCallContext"
**d Conversion Character**

Reports the date of the log event.

**Alias:**  
date

**Defaults:**  
For the ConversionPattern parameter, the ISO8601 format, which is represented as `yyyy-MM-dd HH:mm:ss,SSS`.  
For the FileNamePattern parameter, `yyyy-MM-dd`.

**Requirement:**  
If the date conversion specifier is used, it must be enclosed in a pair of braces.

**Tip:**  
The `d` conversion character formats three digits for the precision of milliseconds, regardless of the number of `S` simple date format characters that are specified, and regardless of the machine precision of the timing that is available.

---

**Syntax**

```
d [ {date-conversion-specifier} ]
```

**Optional Argument**

**date-conversion-specifier**

specifies the format of the date. Here are the supported date conversion specifiers:

**ABSOLUTE**

specifies the time in the format `HH:mm:ss,SSS`.

**Example**  
15:49:37,459

**DATE**

specifies the date and time in the format `dd MMM yyyy HH:mm:ss,SSS`.

**Example**  
06 Nov 2010 15:49:37,459

**ISO8601**

specifies the date and time in the format `yyyy-MM-dd HH:mm:ss,SSS`.

**Example**  
2011-11-27 15:49:37,459

**Simple Date Format**

specifies a date in the form of a string that can contain any of these sets of characters:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aa:</td>
<td>a.m. or p.m. marker (string)</td>
</tr>
<tr>
<td>dd:</td>
<td>Day in month (numeric)</td>
</tr>
<tr>
<td>hh:</td>
<td>Hour in a.m. or p.m. (numeric 1-12)</td>
</tr>
<tr>
<td>mm:</td>
<td>Minute in hour (numeric)</td>
</tr>
<tr>
<td>FF:</td>
<td>Day of week in month (numeric)</td>
</tr>
<tr>
<td>GG:</td>
<td>Era designator (string &quot;AD&quot;)</td>
</tr>
<tr>
<td>HH:</td>
<td>Hour in day (numeric 0-23)</td>
</tr>
<tr>
<td>KK:</td>
<td>Hour in a.m. or p.m. (numeric 0-11)</td>
</tr>
</tbody>
</table>
Example

Here are examples of the d conversion character:

d{ABSOLUTE}

d{EEEE MMMM yyyy HH:mm:ss,SSS 'Ship date'}

E Conversion Character

Reports library access audit information.

Syntax

E{key}

Optional Arguments

$key$ can be one of the following:

Audit.Dataset.Action
reports the action that is being logged (OPEN, DELETE, or RENAME).

Audit.Dataset.Libref
reports the libref that was used to access the library.

Audit.Dataset.Engine
reports the engine that is associated with the library.

Audit.Dataset.Member
reports the name of the data set member.

Audit.Dataset.Memtype
reports the type of data set member.

Audit.Dataset.NewMember
reports the new name of the renamed data set member.
Audit.Dataset.Openmode
reports whether the data set is open in READ, WRITE, or UPDATE mode.

Audit.Dataset.Path
reports the path to the library.

Audit.Dataset.Status
reports the status of opening a data set. Valid values are SUCCESS or FAILED.

Audit.Dataset.Sysmsg
reports the message (if any) that is associated with the return code.

Audit.Dataset.Sysrc
reports the numeric return code from the action.

Audit.MetaBoundLib.Action
reports the action that the user is attempting to perform on data that is bound to
the metadata-bound library.

Audit.MetaBoundLib.DataSetInfo.SecuredLibrary
reports the secured library object’s metadata path as it is recorded in the location
information in the SAS data set.

Audit.MetaBoundLib.DataSetInfo.SecuredLibraryGuid
reports the secured library object’s global unique identifier (GUID) as it is
recorded in the location information in the SAS data set.

Audit.MetaBoundLib.DataSetInfo.SecuredTableGuid
reports the GUID for the secured table object.

Audit.MetaBoundLib.DataSetInfo.SecuredTableName
reports the name of the secured table object.

Audit.MetaBoundLib.DataSet.MemberName
reports the member name.

Audit.MetaBoundLib.DataSet.MemberType
reports the member type.

Audit.MetaBoundLib.LibraryInfo.SecuredLibrary
reports the secured library object’s metadata path as it is recorded in the location
information in the physical library.

Audit.MetaBoundLib.LibraryInfo.SecuredLibraryGuid
reports the metadata-bound library’s GUID as it is recorded in the location
information in the physical library.

Audit.MetaBoundLib.Library.Path
reports the physical path for the metadata-bound library.

Audit.MetaBoundLib.Library.Reference
reports the libref for the metadata-bound library.

Audit.MetaBoundLib.RequiredPermission
reports the required permission for the action that the user is attempting to
perform.

Audit.MetaBoundLib.StepName
reports the step name that attempted to access the metadata-bound data.

Audit.MetaBoundLib.User.EffectivePermissions
reports the user’s effective permissions for the metadata-bound data.

Audit.MetaBoundLib.User.IdentityName
reports the user’s metadata identity name.
Audit.MetaBoundLib.User.LoginId reports the user’s login ID.

Example
Here is an example of the E conversion character:

libref=%E{Audit.Dataset.Libref}

See Also
- Appendix 1, “Audit Messages for SAS Library Access,” on page 205
- Appendix 2, “Audit Messages for Metadata-Bound Libraries,” on page 211

F Conversion Character
Reports the name of the file in the application that generated the log event.
Alias: file

Syntax
F

K Conversion Character
Retrieves a message key for any appender / layout combination that is generated in the log event.
Alias: messageKey
Default: None
Note: A message key is a language-neutral, unique, search message identifier as defined in the logging event model specification.
Tip: If no key is associated with a specific log event, this specifier returns an empty string.

Syntax
K

L Conversion Character
Reports the line number in the application that generated the log event.
Alias: line
m Conversion Character

Write the messages that are associated with the log event.

Alias: message
Default: None
Requirement: If the prefix identifier is used, it must be enclosed in a pair of braces.

Syntax

m [ {prefix-identifier} ]

Required Argument

prefix-identifier

specifies an optional identifier to precede all lines after the first line. The following are valid values for prefix-identifier:

- HYPHEN: inserts a hyphen (-) before each message.
- PLUS: inserts a plus sign (+) before each message.

Details

When the message is more than one line long, all lines are written. When a prefix identifier is specified, all lines after the first line are preceded by the prefix identifier.

n Conversion Character

Enables you to supply discretionary newline characters among the data items that compose the log event.

Default: None
Requirement: If the prefix identifier is used, it must be enclosed in a pair of braces.

Syntax

n [ {newline-prefix-identifier} ]

Optional Argument

newline-prefix-identifier

specifies an optional newline identifier. The following are valid values for newline-prefix-identifier:
HYPHEN  inserts a hyphen (-) before each message.
PLUS    inserts a plus sign (+) before each message.

p Conversion Character
Reports the level of the log event.
Alias: level

Syntax
p

Details
Here are the supported levels:
- TRACE
- DEBUG
- INFO
- WARN
- ERROR
- FATAL

r Conversion Character
Reports the number of milliseconds that elapsed between the start of the application and the creation of the log event.
Alias: relative

Syntax
r

severity Conversion Character
 Translates error levels to Common Base Event (CBE) and Web Services Distributed Management Event Format (WEF) severity codes.
Syntax

`severity(key)`

Required Arguments

`key` can be one of the following:

**CBE**

reports a CBE severity code. The following table correlates levels with CBE severity codes:

<table>
<thead>
<tr>
<th>Logging Facility Level</th>
<th>CBE Severity Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>FATAL</td>
<td>60</td>
</tr>
<tr>
<td>ERROR</td>
<td>50</td>
</tr>
<tr>
<td>WARN</td>
<td>30</td>
</tr>
<tr>
<td>INFO</td>
<td>10</td>
</tr>
<tr>
<td>DEBUG</td>
<td>5</td>
</tr>
<tr>
<td>TRACE</td>
<td>0</td>
</tr>
</tbody>
</table>

**WEF**

reports a WEF severity code. The following table correlates levels with WEF severity codes:

<table>
<thead>
<tr>
<th>Logging Facility Level</th>
<th>WEF Severity Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>FATAL</td>
<td>6</td>
</tr>
<tr>
<td>ERROR</td>
<td>4</td>
</tr>
<tr>
<td>WARN</td>
<td>2</td>
</tr>
<tr>
<td>INFO</td>
<td>1</td>
</tr>
<tr>
<td>DEBUG</td>
<td>0</td>
</tr>
<tr>
<td>TRACE</td>
<td>0</td>
</tr>
</tbody>
</table>

WEF has two additional codes that do not correlate to the logging facility levels:

- 5 is a critical condition.
- 3 is a minor problem of relatively low severity.
S Conversion Character

Delivers various system information to the log event.

Alias: systemInfo

Requirements: The S conversion character must be followed by the specified value, which is also referred to as a key, and must be enclosed in a pair of braces. If you specify a default value, you must specify key and default, separated by " | " (the vertical bar), enclosed in a pair of braces.

Syntax

S {key}
S {key | default}

Required Arguments

default
specifies the value that is used when the information that is specified by key cannot be found. The value of default is a character string that appears between | (the vertical bar) and } (the closing bracket).

Note
If the character string contains quotation marks, the quotation marks become part of the value of default. Quotation marks in an XML attribute must be specified using the character entity &quot;.

Example
%S{App.Log|Spawner.log}

key
key can be one of the following types of information:

App.Log
reports the filename that is specified by the LOG= system option when SAS starts. Otherwise, these actions occur:

- If the LOG= system option does not specify a filename, but a filename is specified by the SYSIN= system option, the filename that is specified by the SYSIN= option is used. The file extension is changed to .log.
- If the filename that is specified by the SYSIN= system option lacks a full pathname, the path of the current working directory is prepended to the filename.

App.Name
reports the value of the LOGAPPLNAME= system option.

App.Sysin
reports the filename that is specified by the SYSIN= system option.

model_name
reports the name of the manufacturer of the computer hardware. Examples are HP, SUN, and IBM.
model_num
    reports the model number of the computer hardware. Examples are Itanium,
    X86, RS/6000, SPARC, and 9000/800.

host_name
hostname
    reports the node name that is assigned to the computer hardware. An
    example is apex.com.

serial
    reports the serial number of the operating system.

os_name
    reports the name of the operating system. Examples are LINUX, HP-UX,
    SUNOS, and XP_HOME.

os_version
    reports the version of the operating system.

os_release
    reports the release number of the operating system. Examples are Linux2.6,
    Linux 5, Linux 9, and Linux 11.22.

os_family
    reports the family of operating system. Examples are LINUX ITANIUM,
    LINUX, SUN 64, HP IPF, and WIN.

jobid
pid
    reports the job ID or the process ID, as appropriate.

user_name
username
    reports the user name in the appropriate form.

Note  The user_name is the identity that owns the process rather than the
       client identity that is associated with the current thread.

See  “u Conversion Character” on page 130

startup_cmd
    reports the arguments that are specified when the application was started.

version
    reports either of these versions: TK_BASE_MAJOR or TK_BASE_MINOR.

system_desc
    reports a description of the hardware and software environment. Examples
    are X86_64 Linux, HP Itanium Processor Family, and Sun Sparc 64-bit.

build_date
    reports the date on which the kernel for threaded processing was built.

build_time
    reports the time at which the kernel for threaded processing was built.

sup_ver
    reports the version number of the SAS supervisor.

sup_ver_long2
    reports the version number of the SAS supervisor that is Y2K compliant.
Example
Here is an example of the S conversion character:
%S{os_family}

### sn Conversion Character
Reports the sequence number of the log event.

Alias: sequenceNumber

#### Syntax
```
sn
```

### t Conversion Character
Reports the identifier of the thread that generated the log event.

Alias: thread

#### Syntax
```
t
```

### u Conversion Character
Reports the client identity that is associated with the current thread or task.

Alias: username

See: “user_name|username” on page 129 in the S conversion character.

#### Syntax
```
u
```

#### Details
If the current thread or task does not have an associated identity, the identity that owns the current process is reported to the log event.
uuid Conversion Character
Reports the universal unique identifier (UUID) for the log event.

z/OS specifics: Identifiers that were created by the uuid conversion character on z/OS are unique only to the current computer node. If this conversion pattern is encountered on z/OS, a warning is written to the log.

Syntax

\texttt{uuid}

x Conversion Character
Reports the NDC (nested diagnostic context) that is associated with the thread that generated the log event.

Alias: \texttt{ndc}

Syntax

\texttt{x}

X Conversion Character
Reports the MDC (mapped diagnostic context) that is associated with the thread that generated the log event.

Alias: \texttt{properties}

Requirements: The key must be enclosed in a pair of braces.
If you specify a default value, you must specify \texttt{key} and \texttt{default}, separated by \texttt{\mid} (the vertical bar), enclosed in a pair of braces.

Syntax

\texttt{X \{key\}}

\texttt{X \{key \mid default\}}

Required Arguments

\texttt{default}

specifies the value that is used when the information that is specified by \texttt{key} cannot be found. The value of default is a character string that appears between \texttt{\mid} (the vertical bar) and \texttt{\}} (the closing bracket).
### Note
If the character string contains quotation marks, the quotation marks become part of the value of `default`. Quotation marks in an XML attribute must be specified using the character entity `&quot;`.

### Example
%X{clientNumber}|clientNumberNotFound}

### key
specifies a parameter that is used to identify the portion of the log to retrieve using MDC. The values for `key` are specific for an application or subsystem. Refer to the application or subsystem documentation for values for `key`.

Here are some common values for `key`:

- **Client.ID** is the connection ID that is associated with the connecting client.
- **Client.IPAddress** is the IP address and the port of the connecting client.
- **Client.AppName** is the name of the application that is used by the connecting client. If the application does not supply the name, this information is not returned in the message.

**See** System MDC values on page 128

### ARM MDC values

### Details
MDC is used to distinguish interleaved log output from different sources. Log output is typically interleaved when a server manages multiple clients in parallel. The MDC is managed on a per-thread basis.

The X conversion character must be followed by the key for the map. The value in the MDC that corresponds to the key is reported.

### Example
Here is an example of the X conversion character:

%X(clientNumber), where clientNumber is the key.

---

### %% Conversion Character

Enables you to specify a literal percent sign symbol in a text string of a conversion pattern.

#### Syntax

```
%%
```

#### Details

A single percent sign is interpreted as a conversion specifier. Two percent signs are interpreted as literal text, which is delivered as a single percent sign in the log event.
Example

Here is an example of the %% conversion character:

```xml
<param name="ConversionPattern" value="%d;text%%text;%m"/>
```

Here is sample output:

```
2011–06–25–10:24:22,234; text%text; Numeric maximum was larger than 8, am setting to 8
```

Format Modifiers

Controls the field width, padding, and justification of the specified data item in log output.

Syntax

- (hyphen)

```
minimum-field-width-modifier
maximum-field-width-modifier
```

Format Modifier Descriptions

- **(hyphen)**
  specifies left-justification of the data item that is defined by the conversion character.

  **Examples**  
  `%-p`

  The `p` conversion character reports the level that is specified by the log event. For example, the text of the level, "WARN" is left-justified within its field in the log event.

**minimum-field-width-modifier**

specifies a decimal constant to indicate the minimum width of the field for the data item that is specified by the conversion character. If the data item is smaller than the minimum field width, the field is padded on either the left or the right until the minimum width is reached. The padding character is a space. If the data item exceeds the minimum field width, the field is expanded to accommodate the data item.

**Default**  
Pad on the right (left-justify)

**Examples**  
`%10p`

The constant value, 10, provides a minimum width for the data item that is specified by the `p` conversion character. For example, the text of the level, "WARN", is left-justified and is padded to the right with six spaces.

**maximum-field-width-modifier**

specifies a period (.) and a decimal constant to indicate the maximum width of the field for the data item that is specified by the conversion character.
If the data item exceeds the maximum field width, characters are left-truncated rather than right-truncated.

The behaviors of `maximum-field-width-modifier` in the SAS logging facility and in the C language `PRINTF` statement are different. The `PRINTF` statement uses right-truncation rather than left-truncation.

%.3p is the pattern layout. "DEBUG" is the data item. "BUG" is the generated output.

The constant value, 3, provides a maximum width for the data item that is specified by the p conversion character. For example, the text of the level, "DEBUG" is left-truncated to form "BUG".

**Example**

Here are examples of format modifiers that are used with the c conversion character. The c conversion character reports the name of the logger.

<table>
<thead>
<tr>
<th>Format Modifier</th>
<th>Left Justification</th>
<th>Minimum Width</th>
<th>Maximum Width</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>%20c</td>
<td>no</td>
<td>20</td>
<td>none</td>
<td>If the data item occupies fewer than 20 characters, pad to the left, using spaces.</td>
</tr>
<tr>
<td>%-20c</td>
<td>yes</td>
<td>20</td>
<td>none</td>
<td>If the data item occupies fewer than 20 characters, pad to the right, using spaces.</td>
</tr>
<tr>
<td>%.30c</td>
<td>not applicable</td>
<td>none</td>
<td>30</td>
<td>If the data item exceeds 30 characters, left-truncate the data item.</td>
</tr>
<tr>
<td>%20.30c</td>
<td>no</td>
<td>20</td>
<td>30</td>
<td>If the data item occupies fewer than 20 characters, pad to the left, using spaces. If the data item exceeds 30 characters, left-truncate the data item.</td>
</tr>
<tr>
<td>%-20.30c</td>
<td>yes</td>
<td>20</td>
<td>30</td>
<td>If the data item occupies fewer than 20 characters, pad to the right, using spaces. If the data item exceeds 30 characters, left-truncate the data item.</td>
</tr>
</tbody>
</table>
Overview of Filters

When the logging facility filters log events by thresholds, it uses logger and appender configurations. You can also use filter classes to filter log events, based on character strings and thresholds:

<table>
<thead>
<tr>
<th>Filter Class Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RepeatMatchFilter</td>
<td>filters repeated log messages.</td>
</tr>
<tr>
<td>StringMatchFilter</td>
<td>filters log messages based on a character string in the log message.</td>
</tr>
<tr>
<td>LevelRangeFilter</td>
<td>filters log messages based on a range of message thresholds.</td>
</tr>
<tr>
<td>LevelMatchFilter</td>
<td>filters log messages based on a single message threshold.</td>
</tr>
<tr>
<td>AndFilter</td>
<td>filters log messages based on the results of a list of other filters.</td>
</tr>
<tr>
<td>Filter Class Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>DenyAllFilter</td>
<td>denies log events that did not meet the criteria of previous filters in a filter policy.</td>
</tr>
</tbody>
</table>

By using filter classes to filter messages, you can choose whether to accept or deny a log event if a match occurs between a filter parameter and the string or threshold in the log event.

You configure filter classes by using the `<filter>` subelements within an appender configuration.

Filters are processed in the order in which they appear in the appender definition, creating a filtering policy for the appender.

The results of filtering depend on filter arguments. The `AcceptOnMatch` argument in the RepeatMatchFilter, StringMatchFilter, LevelMatchFilter, and LevelRangeFilter filters indicate whether to accept the log event if there is a match. The following lists describe the process of deciding whether a log event is accepted or denied:

- **RepeatMatchFilter**
  - If the immediate previous message (%m) is the same as the message (%m) specified in the log event and if `AcceptOnMatch` is TRUE, then the appender processes the log event.
  - If the previous message (%m) is the same as the message (%m) specified in the log event and if `AcceptOnMatch` is FALSE, then the appender denies the log event.

- **StringMatchFilter and LevelMatchFilter**
  - If there is a match between the filter string or the filter threshold (level) and the log event, and if `AcceptOnMatch` is TRUE, then the appender processes the log event.
  - If there is a match between the filter string or the filter threshold (level) and the log event, and if `AcceptOnMatch` is FALSE, then the appender denies the log event.
  - If there is no match between the filter and the log event, then the appender processes the next filter in the filtering policy. If the log event has not been denied and if there are no other filters in the filtering policy, then the appender accepts and processes the log event.

- **LevelRangeFilter**
  - If there is a match between the minimum and maximum thresholds (inclusive) in the filter and the log event, and if `AcceptOnMatch` is TRUE, the appender processes the log event.
  - If there is no match, the appender denies the log event.
  - If there is a match between the minimum and maximum thresholds (inclusive) in the filter and the log event, and if `AcceptOnMatch` is FALSE, then the appender processes the next filter in the filtering policy. If the log event has not been denied and if there are no other filters in the filtering policy, the appender accepts and processes the log event.

- **AndFilter** uses StringMatchFilter, LevelMatchFilter, and LevelRangeFilter as arguments. The results of these filters as arguments to the AndFilter class is the same as it is in the individual filters.
You can include DenyAllFilter as the last filter in the filtering policy to deny any log events that do not meet the filtering policy for the appender.

The following example is a simple filtering policy to log only performance messages for the ARM subsystem:

```xml
<filter class="StringMatchFilter">
   <param name="StringToMatch" value="Perf.ARM"/>
   <param name="AcceptOnMatch" value="true"/>
</filter>
<filter class="DenyAllFilter">
</filter>
```

**Note:** Filter definitions are not available in the logging facility language elements for SAS programs.

---

**Filter Examples**

**Example 1: Filter for a Specific User's Error Messages**

In this example, the filtering policy first checks to determine whether the message has already been logged. The filtering policy then writes to the Windows Event Log the messages whose log event threshold is ERROR and which are issued by user sasuser1:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<logging:configuration xmlns:logging="http://www.sas.com/xml/logging/1.0/">
   <appender name="eventLog" class="WindowsEventAppender">
      <param name="AppName" value="SAS Foundation"/>
      <layout>
         <param name="ConversionPattern" value="%d %t %c (%F:%L) %u - %m"/>
      </layout>
      <filter class="RepeatMatchFilter">
         <param name="AcceptOnMatch" value="false"/>
      </filter>
      <filter class="AndFilter">
         <filter class="LevelMatchFilter">
            <param name="LevelToMatch" value="error"/>
            <param name="AcceptOnMatch" value="true"/>
         </filter>
         <filter class="StringMatchFilter">
            <param name="StringToMatch" value="sasuser1"/>
            <param name="AcceptOnMatch" value="true"/>
         </filter>
      </filter>
      <filter class="DenyAllFilter">
      </filter>
   </appender>
</logging:configuration>
```
Example 2: Filter for a Specific Date

The following filtering policy denies log events that were sent on 2011–09–22:

```xml
<filter class="StringMatchFilter">
  <param name="StringToMatch" value="2011-09-22"/>
  <param name="AcceptOnMatch" value="false"/>
</filter>
```

Dictionary

Syntax for Filters

Note: Filters are configured, using the `<filter>` and `</filter>` elements and their respective filter parameters. Any `<appender>` element attributes and subelements in the syntax are present to show the context for the pattern layout elements. See the syntax for each filter for the parameters that are used by that filter.

Syntax

**XML Configuration**

```xml
<appender class="AppenderName" name="log-name">
  <filter class="filter-class">
    <param name="filter-parameter-1" value="parameter-value-1"/>
    <param name="filter-parameter-n" value="parameter-value"/>
  </filter>
</appender>
```

**AndFilter**

Use AndFilter when you want to log messages that meet multiple criteria.
Syntax

```xml
<filter class="AndFilter">
  <param name="AcceptOnMatch" value="TRUE | FALSE">
  <filter class="filter-name">
    <param name="filter-parameter" value="filter-parameter-value"/>
    <param name="AcceptOnMatch" value="TRUE | FALSE"/>
  </filter>/-1
  [... <filter class="filter-name">
    <param name="filter-parameter-name" value="filter-parameter-value"/>
    <param name="AcceptOnMatch" value="TRUE | FALSE"/>
    <filter/>-n }
  </filter/>
</filter>
```

Syntax Description

**class="AndFilter"**
Specifies to apply the AND logical operation on the subfilter results to determine whether the log event is accepted by the appender.

**name="AcceptOnMatch"**
For AndFilter, specifies whether to accept or deny the log event if the result of the logical AND is TRUE. For subfilter definitions, specifies whether to accept or deny the log event if the threshold or string matches. Valid values are TRUE or FALSE.

- **TRUE**
  Specifies to accept the log event.

- **FALSE**
  For AndFilter, StringMatchFilter, and LevelMatchFilter, specifies to deny the log event.

**class="filter-name"**
Specifies the name of a filter to use as an argument to the AND logical operation. Here is a list of valid filters:

- AndFilter
- LevelMatchFilter
- LevelRangeFilter
- StringMatchFilter

**name="filter-parameter-name" value="filter-parameter-value"**
Specifies the name of a filter parameter and the parameter value that is used to compare with either the log event threshold or the message. The following table shows the filter parameters:

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Filter Parameter Name</th>
<th>Filter Parameter Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LevelMatchFilter</td>
<td>LevelToMatch</td>
<td>DEBUG</td>
</tr>
<tr>
<td>LevelRangeFilter</td>
<td>LevelMax</td>
<td>DEBUG</td>
</tr>
<tr>
<td></td>
<td>LevelMin</td>
<td>DEBUG</td>
</tr>
<tr>
<td>Filter Name</td>
<td>Filter Parameter Name</td>
<td>Filter Parameter Value</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------</td>
<td>-------------------------------------------------------------</td>
</tr>
<tr>
<td>StringMatchFilter</td>
<td>StringToMatch</td>
<td>a character string enclosed in quotation marks</td>
</tr>
<tr>
<td>AndFilter</td>
<td>AcceptOnMatch</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

In addition to the AcceptOnMatch parameter, specify two or more filters as arguments to a nested AndFilter.

Details

AndFilter syntax allows for two or more subfilter definitions within the AndFilter definition. The subfilters are evaluated to decide whether to accept or deny the log event. AndFilters performs a logical AND operation, using the results of each subfilter evaluation to determine the results of AndFilter.

An example of using AndFilter might be that you want to filter log messages that have a threshold of INFO and that contain the string "New client connection". You can filter by a single threshold, a range of thresholds, or by string matching.

Example

The following filter accepts log events that have a threshold of INFO and the string RETURN in the following log message:

```xml
<filter class="AndFilter">
  <param name="AcceptOnMatch" value="true"/>
  <filter class="LevelMatchFilter">
    <param name="LevelToMatch" value="info"/>
    <param name="AcceptOnMatch" value="true"/>
  </filter>
  <filter class="StringMatchFilter">
    <param name="StringToMatch" value="RETURN"/>
    <param name="AcceptOnMatch" value="true"/>
  </filter>
</filter>
<filter class="DenyAllFilter">
</filter>
```

DenyAllFilter

DenyAllFilter can be configured as the last filter in a chain of filters to deny all messages that do not meet the filter specifications in the filter chain.

Syntax

```xml
<filter class="DenyAllFilter">
```
Syntax Description

`class="DenyAllFilter"`
specifies to deny all messages that do not meet the filter chain criteria.

**TIP** Use DenyAllFilter as the last filter if you use `AcceptOnMatch="TRUE"` and you want only the messages that match to be processed.

---

**LevelMatchFilter**

Use LevelMatchFilter when you want to filter log events for a single message threshold. For example, you might want to log only error messages, or you might want all messages that do not have a threshold of FATAL.

**Syntax**

```xml
<filter class="LevelMatchFilter">
  <param name="LevelToMatch" value="DEBUG | TRACE | INFO | WARN | ERROR | FATAL"/>
  <param name="AcceptOnMatch" value="TRUE | FALSE"/>
</filter>
```

**Syntax Description**

`class="LevelMatchFilter"`
specifies to filter messages based on a log event threshold.

`name="AcceptOnMatch"` |
specifies whether to accept or deny the log event if the log event threshold matches the value in this filter. Valid values are TRUE or FALSE:

- **TRUE** specifies to accept the log event.
- **FALSE** specifies to deny the log event.

`name="LevelToMatch"` |
specifies the threshold to filter log events for this appender. Valid values are DEBUG, TRACE, INFO, WARN, ERROR, or FATAL.

See "Logging Thresholds" on page 18

---

**Details**

To use this filter, you specify a threshold, and you specify whether to accept or deny the log event if the filter threshold matches the log event threshold. If there is no match, the filtering process continues with the next filter in the filtering policy. If there are no other filters in the filtering policy and if the log event has not been denied, the appender accepts and processes the log event.
Example

The following filter denies log events whose threshold is INFO:

```xml
<filter class="LevelMatchFilter">
  <param name="LevelToMatch" value="info"/>
  <param name="AcceptOnMatch" value="false"/>
</filter>
```

LevelRangeFilter

Use LevelRangeFilter when you want to filter log event messages whose message threshold falls within a range of message thresholds.

Syntax

```xml
<filter class="LevelRangeFilter">
  <param name="LevelMax" value="threshold"/>
  <param name="LevelMin" value="threshold"/>
  <param name="AcceptOnMatch" value="TRUE | FALSE"/>
</filter>
```

Syntax Description

class="LevelRangeFilter"
  specifies to use the LevelRangeFilter

name="LevelMax" value="threshold"
  specifies the highest threshold that can be written to the appender.

name="LevelMin" value="threshold"
  specifies the lowest threshold that can be written to the appender.

name="AcceptOnMatch" |
  specifies whether to accept the log event when the log event message threshold falls within the threshold range that is specified by the filter. Valid values are TRUE or FALSE:

  TRUE
    specifies to accept the log event.

  FALSE
    specifies to pass the filtering process to the next filter in the filtering policy. If the log event has not been denied and there are no other filters in the filtering policy, the appender accepts and processes the log event.

Details

The thresholds are, from lowest to highest: TRACE, DEBUG, INFO, WARN, ERROR, and FATAL. For example, if the minimum threshold is DEBUG and the maximum threshold is ERROR, and if AcceptOnMatch is FALSE, messages that have the thresholds TRACE and FATAL are denied.
To use this filter, you specify a minimum and a maximum threshold range to compare with the log event threshold. If there is no match, the log event is denied. If there is a match and if AcceptOnMatch is TRUE, the appender accepts and processes the log event. If there is a match and AcceptOnMatch is FALSE, the next filter in the filtering policy is processed. If there are no other filters in the filtering policy and if the log event has not been denied, the appender accepts and processes the log event.

Example

The following filter accepts log events only if the log event threshold is between WARN and ERROR:

```xml
<filter class="LevelRangeFilter">
  <param name="LevelMax" value="error"/>
  <param name="LevelMin" value="warn"/>
  <param name="AcceptOnMatch" value="true"/>
</filter>
```

**RepeatMatchFilter**

Use RepeatMatchFilter to discard a message if the message has already been logged by the appender.

**Syntax**

```xml
<filter class="RepeatMatchFilter">
  <param name="AcceptOnMatch" value="TRUE | FALSE"/>
</filter>
```

**Syntax Description**

- `name="AcceptOnMatch"`:
  - Specifies whether to accept or deny the log event when the log event message is identical to the last message processed by the appender. Valid values are TRUE or FALSE:
    - **TRUE**
      - Specifies to accept the log event.
    - **FALSE**
      - Specifies to deny the log event.

**Details**

This filter compares only the last message that was processed by this appender with the current log event message.

As a best practice, you can use this filter as the first filter in appender filtering policies to discard repeated messages.
Example

The following filter definition does not accept log events if a log event message has already been logged by this appender:

```xml
<filter class="RepeatMatchFilter">
  <param name="AcceptOnMatch" value="FALSE"/>
</filter>
```

StringMatchFilter

Use StringMatchFilter when you want to filter messages based on a string in the log event message.

Syntax

```xml
<filter class="StringMatchFilter">
  <param name="StringToMatch" value="character-string"/>
  <param name="AcceptOnMatch" value="TRUE | FALSE"/>
</filter>
```

Syntax Description

- **name="StringToMatch" value="character-string"**
  specifies the string to search for in the log event message.

- **name="AcceptOnMatch"**
  specifies whether to accept or deny the log event when the log event message contains `character-string`. Valid values are TRUE or FALSE:

  - **TRUE**
    specifies to accept the log event.

  - **FALSE**
    specifies to deny the log event.

Details

To use this filter, you specify a character string, and you specify whether to accept or deny the log event if the filter character string matches a character string in the log event message. If there is no match, the filtering process continues with the next filter in the filtering policy. If there are no other filters in the filtering policy and if the log event has not been denied, the appender accepts and processes the log event.

Performing string matches on every message requires significant resources. To avoid performance issues, consider limiting the number of messages that are processed by this filter. For example, filter only those messages that are associated with a particular logger or a particular logging level.

Example

The following filter definition does not accept log events that contain the string "RETURN":

```xml
<filter class="StringMatchFilter">
  <param name="StringToMatch" value="RETURN"/>
  <param name="AcceptOnMatch" value="FALSE"/>
</filter>
```
<filter class="StringMatchFilter">
  <param name="StringToMatch" value="RETURN"/>
  <param name="AcceptOnMatch" value="false"/>
</filter>

Chapter 12
Function Reference ................................................................................................ 173

Chapter 13
Component Object Reference ............................................................................... 185
Overview of the SAS Logging Facility in the SAS Language

The SAS language enables you to use the SAS logging facility in a DATA step and in macro programs. By using the SAS logging facility language elements, you can create appenders, loggers, and log events within your SAS programs. Loggers that you create in your SAS program can reference appenders that are created in your SAS program or appenders that are defined in a logging configuration file. When you write a log event in your SAS program, the logger that you specify in the log event can be one that has been created within your SAS program or one that is configured in the logging configuration file.

SAS logging facility language elements are both functions and DATA step component objects for DATA step programming. For more information, see “Function Reference” on page 173 and “Component Object Reference” on page 185. The elements are also autocall macros for macro programming. For more information, see “Autocall Macro Reference” on page 157.
Appenders and loggers must be defined before SAS can process a log event in your SAS program. You include log events at any point in your SAS programs where you want to log a message of any diagnostic level. The levels, from lowest to highest, are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL. Log events specify the logger, the diagnostic level, and the message.

The logging facility is enabled for SAS programs at all times. If the LOGCONFIGLOC= system option is not specified when SAS starts, all SAS logging facility messages are written to the SAS log. They are also written to the appender destinations that are associated with the logger that is named in a log event. When the LOGCONFIGLOC= system option is specified when SAS starts, messages are written to destinations, based on the logger hierarchy. For more information, see “Hierarchical Logger Names” on page 9 and “LOGCONFIGLOC= System Option” on page 28.

Initializing the SAS Logging Facility for SAS Programs

Which Language Elements Need Initializing?

Initializing the logging facility for SAS programs is necessary only if you use the logging facility autocall macros. SAS has no initialization process for the logging facility functions and DATA step objects.

Initializing the Logging Facility Autocall Macros

In order to use autocall macros in SAS, you must set the MAUTOSOURCE system option. When SAS starts, the MAUTOSOURCE option is set, and no further action is required unless this option is turned off.

The logging facility autocall macro %LOG4SAS must be invoked before SAS processes any other logging facility autocall macros. The %LOG4SAS autocall macro defines all other logging facility autocall macros to the SAS session. You can invoke the %LOG4SAS autocall macro in an autoexec file, in an INITSTMT= system option, or at the beginning of your SAS program.

After the MAUTOSOURCE system option is set and the %LOG4SAS autocall macro has been invoked, you can invoke any of the logging facility autocall macros in your SAS program.

The LOGCONFIGLOC= System Option

If your SAS program does not write log events for SAS server loggers, the LOGCONFIGLOC= system option does not need to be set. If the program does write log events using SAS server loggers, you can check that the
LOGCONFIGLOC= system option names a logging configuration file. You can check either by issuing the OPTIONS procedure or by viewing the LOGCONFIGLOC= system option in the SAS System Options window.

For more information, see “LOGCONFIGLOC= System Option” on page 28 and “SAS Server Logger Names” on page 10.

Creating and Using Appenders in a SAS Program

Creating Appenders

You create appenders in your SAS program or in the logging configuration file before you define loggers or before you invoke a log event. The only appender class that you can create is FileRefAppender, which specifies to write messages to a file that is referenced by a fileref.

Although appenders can be created at any time in a SAS program, appender names must be unique within a DATA step. Creating the same appender in each iteration of the implicit loop can result in a DATA step error. To avoid the error, use an IF-THEN statement to create an appender in only the first iteration of the implicit loop:

```sas
if _n_ = 1 then
  do;
    rc=log4sas_appender("myAppenderName", "FileRefAppender", "fileref=myfile");
    if rc ne 0 then do
      msg = sysmsg();
      put msg;
      ABORT;
    end;
  end;
end;
```

When you create an appender, you specify the appender name, the keyword FileRefAppender, and appender options. You use appender options to specify a fileref that references a log file, a conversion pattern to format the message, and the appender message threshold. The appender THRESHOLD argument enables appender-level log event message filtering at the appender level. The filtering occurs after the logging facility processes logger-level message filtering.

The appender name is case sensitive. Be sure to specify the appender name exactly as it is specified in the respective appender syntax.

An appender that is created by using an autocall macro is defined to SAS for the duration of the SAS program. An appender that is created in a DATA step exists only for the duration of the DATA step. After the DATA step or SAS program is complete, appenders that are created in a DATA step are no longer defined to SAS.

For details, see the following language elements that create appenders in the SAS language:

- “%LOG4SAS_APPENDER Autocall Macro” on page 162
- “LOG4SAS_APPENDER Function” on page 177
Associating Appenders with Loggers

After an appender is defined to SAS, you can associate one or more appenders with a logger. All logger language elements have an APPENDER-REF argument. The argument's value must be one or more appender names that are defined to SAS either in the logging configuration file or in a SAS program. Appenders can be referenced by a logger only if the option IMMUTIBILITY="FALSE" is set for a logger. When a log event is invoked, the message is written to all destinations that are associated with the logger.

For details about the logger APPENDER-REF argument, see the following logger language elements:

- "%LOG4SAS_LOGGER Autocall Macro" on page 168
- "LOG4SAS_LOGGER Function" on page 179
- "DECLARE Statement: Logger Object" on page 193

Creating Loggers in a SAS Program

Using SAS Language Elements to Create Loggers

You create loggers in your SAS program by using either the %LOG4SAS_LOGGER autocall macro, the LOG4SAS_LOGGER function, or the logger object DECLARE statement. Loggers must be created after you define appenders and before you invoke log events.

A named logger can be created only once. In order to prevent the DATA step from processing the creation of the same logger in each iteration of the implicit loop, use an IF-THEN statement to create a logger in only the first iteration of the implicit loop:

```sas
if _n_ = 1 then do;
  rc=log4sas_logger("myLoggerName", "appender-ref=(myAppenderName) level=info");
  if rc ne 0 then do
    msg = sysmsg();
    put msg;
    ABORT;
  end;
end;
```

When you create a logger, you specify the logger name and optional arguments for the message threshold and for one or more appender references. The logger name is case sensitive and can be a one-level or multiple-level name. The LEVEL argument specifies the message threshold that the logger processes. The logger-level threshold is the first level of message filtering. If a log event threshold is the same or greater than the logger threshold, the logger accepts the log event and the
logging facility uses the appender arguments to process the log event. The thresholds, from lowest to highest, are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL. Loggers can be associated with one or more appenders by specifying appender names in the APPENDER-REF argument. You separate appender names with a space and enclose the appender names in parentheses.

A logger is defined for the duration of the SAS session. For information about loggers, see the following topics:

- "Loggers" on page 8
- "Creating Log Events in a SAS Program" on page 154
- "%LOG4SAS_LOGGER Autocall Macro" on page 168
- "LOG4SAS_LOGGER Function" on page 179
- "DECLARE Statement: Logger Object" on page 193

### Updating Logger Attributes

You can update a logger's attributes by using one of the language elements that create loggers. To update logger attributes, you specify the logger creation language element by using the name of a logger that already exists and the new attributes. SAS updates the attributes of the logger with the new attributes.

**Note:** If the logger IMMUTABILITY attribute is set to TRUE, you cannot change the additivity setting or the level setting using the SAS language, and you cannot reference an appender in a logger using the SAS language.

### Message Categories in the SAS Language

When you create a logger in the SAS language, you create a category for messages that are logging messages. The message category is user-specified and is meaningful in your environment for the types of messages that you want to log. For example, if you are testing an existing SAS program where you have added new functionality, you might want messages in preexisting code to be logged as regression messages. Log messages for new code could be logged as new feature messages. Other logger categories might include department names, SAS program names, or analytical model names. For an example of logger category definitions, see “Example of Creating Logger and Appender Categories” on page 155.

Message categories that you create in the SAS language differ from the types of message categories for SAS servers. The SAS language message categories are user-defined and the SAS server message categories are defined by SAS.

You can create message categories in a hierarchy where the hierarchy levels are separated by a . (period). Here are examples: IT, IT.Pgm1, and IT.Pgm2. The attributes that are defined in the higher-level logger can be used by lower-level loggers when the lower-level logger does not define an attribute. For example, you could create a high-level logger IT for your IT department. The logger IT specifies the level as INFO. Loggers IT.Pgm1 and IT.Pgm2 do not specify a level attribute. Therefore, they inherit the level of the next highest logger, which in this case is IT.
Because the logger IT specifies the level as INFO, when a log event specifies the IT.Pgm1 or IT.Pgm2 logger, the logger level INFO is compared to the log event message level. The logger definitions in this scenario might look like the following functions:

```sas
/* Create the context for logging regression messages. */
/* Regression log events of level info or higher are written */
/* to the destination, specified by the appender to be defined as ITPgmRegression. */
if _n_=1 then
  do;
  rc=log4sas_logger("IT", "appender-ref=(ITPgmRegression) level=info");
  if rc ne 0 then do
    msg = sysmsg();
    put msg;
    ABORT;
  end;
  end;

/* Create the context for Pgm1 in the IT department. */
/* Do not specify a level; use the IT logger level. */
if _n_=1 then
  do;
  rc=log4sas_logger("IT.Pgm1", "appender-ref=(ITPgm1Regression)");
  if rc ne 0 then do
    msg = sysmsg();
    put msg;
    ABORT;
  end;
  end;

/* Create the context for Pgm2 in the IT department. */
/* Do not specify a level; use the IT logger level. */
if _n_=1 then
  do;
  rc=log4sas_logger("IT.Pgm2", "appender-ref=(ITPgm2Regression)");
  if rc ne 0 then do
    msg = sysmsg();
    put msg;
    ABORT;
  end;
  end;
```

Creating Log Events in a SAS Program

After loggers and appenders are defined either in a logging configuration file or a SAS program, you can add log events to your program. You insert log events at any
point in your program or DATA step that you want to log a message. A log event takes three arguments: a logger name, a level, and the log message.

The logger that you specify in the log event names the message category for the message. It can be a category that you created in your SAS program or a category that is defined for SAS servers. The diagnostic level indicates one of the following diagnostic types for the message: TRACE, DEBUG, INFO, WARN, ERROR, and FATAL. The log message is the message that you want to appear in the log. Enclose the message in single or double quotation marks.

For more information, see the following topics:

- “Loggers” on page 8
- “Logging Thresholds” on page 18
- “%LOG4SAS_TRACE Autocall Macro” on page 170
- “%LOG4SAS_DEBUG Autocall Macro” on page 164
- “%LOG4SAS_INFO Autocall Macro” on page 167
- “%LOG4SAS_WARN Autocall Macro” on page 171
- “%LOG4SAS_ERROR Autocall Macro” on page 165
- “%LOG4SAS_FATAL Autocall Macro” on page 166
- "LOG4SAS_LOGEVENT Function” on page 182
- “TRACE Method” on page 199
- “DEBUG Method” on page 189
- “INFO Method” on page 197
- “WARN Method” on page 200
- “ERROR Method” on page 195
- “FATAL Method” on page 196

---

Example of Creating Logger and Appender Categories

The following appender and logger functions create regression and new function categories for testing a SAS program. This example assumes that filerefs that are named myPgmReg and myPgmNew have been created in the SAS program.

```sas
/* Define the destination where regression messages are written. */
if _n_ = 1 then
  do;
    rc=log4sas_appender("myPgmRegression", "FileRefAppender", "fileref=myPgmReg");
    if rc ne 0 then do
      msg = sysmsg();
      put msg;
      ABORT;
    end;
  end;
```

---
/* Define the destination where new function messages are to be written. */

if _n_ = 1 then
  do;
    rc=log4sas_appender("myPgmNewFunction", "FileRefAppender", "fileref=myPgmNew");
    if rc ne 0 then do
      msg = sysmsg();
      put msg;
      ABORT;
    end;
  end;

/* Create the context for logging regression messages. */
/* Regression log events of level info or higher are written */
/* to the destination specified by the appender defined as myPgmRegression. */

if _n_=1 then
  do;
    rc=log4sas_logger("regression", "appender-ref=(myPgmRegression) level=info");
    if rc ne 0 then do
      msg = sysmsg();
      put msg;
      ABORT;
    end;
  end;

/* Create the context for logging new function messages. */
/* New functionality log events of level debug or higher are written */
/* to the destination that is specified by the appender defined as myPgmNewFunction. */

if _n_=1 then
  do;
    rc=log4sas_logger("newFunction", "appender-ref=(myPgmNewFunction) level=debug");
    if rc ne 0 then do
      msg = sysmsg();
      put msg;
      ABORT;
    end;
  end;
Using Autocall Macros to Log Messages

SAS supplies a set of autocall macros that you can use in your SAS programs to log messages by using the SAS logging facility. SAS writes the SAS language logging facility messages to a file using the appender, FileRefAppender. FileRefAppender is the only logging facility appender that is available in the SAS language.

You use the following autocall macros to log messages by using the logging facility:

- **%LOG4SAS**: initializes the autocall macro logging environment.
- **%LOG4SAS_APPENDER**: defines an appender, which names the destination of the log message, a message layout, and a message threshold.
- **%LOG4SAS_LOGGER**: defines a logger, which defines a message category for log messages and the appenders that are associated with the message category.
- **%LOG4SAS_DEBUG**: is the log event that you use to write debug messages.
- **%LOG4SAS_TRACE**: is the log event that you use to write trace messages.
- **%LOG4SAS_WARN**: is the log event that you use to write warning messages.
%LOG4SAS_INFO
is the log event that you use to write informational messages.

%LOG4SAS_ERROR
is the log event that you use to write error messages.

%LOG4SAS_FATAL
is the log event that you use to write fatal messages.

In order to use the logging facility autocall macros, you must set the MAUTOSOURCE system option in order to activate the autocall facility. The MAUTOSOURCE system option is set by default.

For more information about autocall macros and the MAUTOSOURCE system option, see *SAS Macro Language: Reference*.

---

**Example of Using Autocall Macros to Log Messages**

The macro program first retrieves the number of variables in a SAS data set and then appends each variable name to a macro variable. Logging facility debug log events send progress messages to a file that is referenced by the REV1 fileref. You can see from the SAS log output that the messages are written in the SAS log as well. By writing debug messages to a separate file, the logging facility acts as a filter where only the messages that you want to see are written to the file. The shaded code lines that follow are the statements that create logging messages.

```sas
filename rev1 ('c:\mySAS\Logs\rev1.log');
%log4sas();
%log4sas_appender(dsvar2mvar, "FileRefAppender", 'fileref=rev1');
%log4sas_logger(macroVar, 'level=debug appender-ref=(dsvar2mvar)');

/* Create sample data */
data one;
  input x y z;
datalines;
  1 2 3;
;
%macro lst(dsn);
  %global x;
  %let x=;
  /* Open the data set */
  %let dsid=%sysfunc(open(&dsn));
  %let cnt=%sysfunc(attrn(&dsid,nvars));
  %put cnt=&cnt;
  %log4sas_debug(macroVar, 'The number of variables is set in CNT');
  /* Create a macro variable that contains all data set variables */
  %do i = 1 %to &cnt;
    %let x=&x%sysfunc(varname(&dsid,&i));
  %end;
%endoftest;
```

---
%log4sas_debug(macroVar, 'data set variable appended to macro variable');
%end;

/* Close the data set */
%let rc=%sysfunc(close(&dsid));
%mend lst;
%log4sas_debug(macroVar, 'lst Macro complete');

/* Call the macro and pass the name of the data set to be processed */
%log4sas_debug(macroVar, 'calling lst(one)');
%lst(one)
%put macro variable x = &x

%log4sas_debug(macroVar, 'macro lst(one) complete');

The file that is referenced by fileref REV1 contains these lines of text:

Output 11.1  Contents of the File Referenced by the REV1 Fileref

lst Macro complete
calling lst(one)
The number of variables is set in CNT
data set variable appended to macro variable
data set variable appended to macro variable
data set variable appended to macro variable
macro lst(one) complete

The following messages were written to the SAS log:
%log4sas();
%log4sas_appender(dsvar2mvar, "FileRefAppender", 'fileref=rev1');
%log4sas_logger(macroVar, 'level=debug appender-ref=dsvar2mvar');

/* Create sample data */
data one;
  input x y;
datalines;
NOTE: The data set WORK.ONE has 1 observations and 3 variables.
NOTE: DATA statement used (Total process time):
  real time           0.03 seconds
cpu time            0.03 seconds
;
%macro lst(dsn);
  %global x;
  %let x=;
  /* Open the data set */
  %let dsid=%sysfunc(open(&dsn));
  /* Assign the number of variables into the macro variable CNT */
  %let cnt=%sysfunc(attrn(&dsid,nvars));
  %put cnt=&cnt;
  %log4sas_debug(macroVar, 'The number of variables is set in CNT');
  /* Create a macro variable that contains all data set variables */
  %do i = 1 %to &cnt;
    %let x=&x%sysfunc(varname(&dsid,&i));
    %log4sas_debug(macroVar, 'data set variable appended to macro variable');
  %end;
  /* Close the data set */
  %let rc=%sysfunc(close(&dsid));
%mend lst;

%log4sas_debug(macroVar, 'lst Macro complete');
lst Macro complete

/* Call the macro and pass the name of the data set to be processed */
%log4sas_debug(macroVar, 'calling lst(one)');
calling lst(one)
%lst(one)
cnt= 3
The number of variables is set in CNT
data set variable appended to macro variable
data set variable appended to macro variable
data set variable appended to macro variable
%put macro variable x = &x
macro variable x = xyz
%log4sas_debug(macroVar, 'macro lst(one) complete');
macro lst(one) complete
%LOG4SAS Autocall Macro

Initializes the logging environment to use autocall macros.

**Category:** Logging

**Requirements:**
- The MAUTOSOURCE system option must be set.
- This macro must be invoked before any other logging autocall macro can be invoked.

**Syntax**

%LOG4SAS()

**Details**

You invoke the %LOG4SAS autocall macro in order to initialize the logging environment for SAS programming. To ensure that the logging environment is initialized when SAS starts, you can invoke the %LOG4SAS autocall macro as follows:

- in your autoexec file
- as a statement that is specified in the INITSTMT system option, which can be placed in the SAS configuration file or on the SAS command line

You can also invoke the %LOG4SAS autocall macro by placing it at the beginning of your SAS program.

**See Also**

- “Example of Using Autocall Macros to Log Messages” on page 158

**Auto Call Macros:**

- “%LOG4SAS_APPENDER Autocall Macro” on page 162
- “%LOG4SAS_DEBUG Autocall Macro” on page 164
- “%LOG4SAS_ERROR Autocall Macro” on page 165
- “%LOG4SAS_FATAL Autocall Macro” on page 166
- “%LOG4SAS_INFO Autocall Macro” on page 167
- “%LOG4SAS_LOGGER Autocall Macro” on page 168
- “%LOG4SAS_TRACE Autocall Macro” on page 170
- “%LOG4SAS_WARN Autocall Macro” on page 171
%LOG4SAS_APPENDER Autocall Macro

Defines an appender.

Category: Logging

Restriction: An appender can be attached to a logger using the SAS language only if the logger option IMMUTABILITY="FALSE" is set for the logger. Logger immutability can be set only in an XML configuration file.

Requirements: The MAUTOSOURCE system option must be set.

The %LOG4SAS autocall macro must be invoked before this macro is invoked to initialize the logging facility autocall macros.

Arguments that follow the FileRefAppender argument must be enclosed as a group in single quotation marks.

Syntax

%LOG4SAS_APPENDER(name, "FileRefAppender"
<, '<FILEREF=fileref> <PATTERN="pattern"> <THRESHOLD=threshold> ' )

Syntax Description

name
specifies the name of the appender.

Requirement Appender names that you create using the SAS language must be unique for a SAS session.

Tip Appender names are case sensitive.

"FileRefAppender"
specifies the FileRefAppender class to which the defined appender belongs.

Note: This is the only supported appender class. More appender classes might be supported in the future.

Requirements Appender classes are case sensitive. In this instance, the class name must be FileRefAppender.

FILEREF=fileref
specifies the destination for log events that the FileRefAppender class processes.

PATTERN="pattern"
specifies the conversion pattern that is used to format the log message.

Requirement The pattern must be enclosed in double quotation marks.

Tip If PATTERN is not specified, the default is the message.
**Thresholds**

An appender can be configured to have a threshold level. By default, appenders do not have a threshold set. When a threshold is set, all log events that have a level that is lower than the threshold level are ignored by the appender.

For more information, see "Logging Thresholds" on page 18.

**Example**

The following appender definition names the appender `debugMyProgram`, names a log message destination using the fileref `debugOut`, and specifies a pattern that reports the filename and the line number of the application that generated the log event:

```sas
filename debugOut="c:\myDebugOutput.txt";
%log4sas();
%log4sas_appender(debugMyProgram, "FileRefAppender", "fileref=debugOut pattern="(%F:%L)%m" threshold=trace");
```

- "%LOG4SAS_TRACE Autocall Macro" on page 170
- "%LOG4SAS_WARN Autocall Macro" on page 171

%LOG4SAS_DEBUG Autocall Macro
Logs a DEBUG message if the specified logger accepts DEBUG messages.

Category: Logging
Requirements: The MAUTOSOURCE system option must be set.
The %LOG4SAS autocall macro must be invoked to initialize SAS logging before this macro is invoked.

Syntax
%LOG4SAS_DEBUG(logger-name, message)

Syntax Description
- **logger-name** specifies the name of the logger to process this log event.
- **message** specifies the log event message.

Requirement
The message must be enclosed in single or double quotation marks.

Details
The %LOG4SAS_DEBUG autocall macro is a log event for debugging messages. In order to log messages using this macro, you must previously define loggers and appenders either in a SAS program or in a logging configuration file.

See Also
- "Example of Using Autocall Macros to Log Messages" on page 158

Auto Call Macros:
- "%LOG4SAS Autocall Macro" on page 161
%LOG4SAS_ERROR Autocall Macro

Logs an ERROR message if the specified logger accepts ERROR messages.

Category: Logging

Requirements: The MAUTOSOURCE system option must be set. The %LOG4SAS autocall macro must be invoked to initialize SAS logging before this macro is invoked.

Syntax

%LOG4SAS_ERROR(logger-name, message)

Syntax Description

**logger-name**
- specifies the name of the logger to process this log event.

**message**
- specifies the log event message.

Requirement: The message must be enclosed in single or double quotation marks.

Details

The %LOG4SAS_ERROR autocall macro is a log event for error messages. In order to log messages using this macro, you must previously define loggers and appenders either in a SAS program or in a logging configuration file.

See Also

- “%LOG4SAS Autocall Macro” on page 161
- “%LOG4SAS_APPENDER Autocall Macro” on page 162
- “%LOG4SAS_LOGGER Autocall Macro” on page 168
- “%LOG4SAS_TRACE Autocall Macro” on page 170
%LOG4SAS_FATAL Autocall Macro

Logs a FATAL message if the specified logger accepts FATAL messages.

Category: Logging

Requirements:
The MAUTOSOURCE system option must be set.
The %LOG4SAS autocall macro must be invoked to initialize SAS logging before this macro is invoked.

Syntax

%LOG4SAS_FATAL(logger-name, message)

Syntax Description

**logger-name**
specifies the name of the logger to process this log event.

**message**
specifies the log event message.

Requirement
The message must be enclosed in single or double quotation marks.

Details

The %LOG4SAS_FATAL autocall macro is a log event for fatal messages. In order to log messages using this macro, you must previously define loggers and appenders either in a SAS program or in a logging configuration file.

%LOG4SAS_INFO Autocall Macro

Logs an INFO message if the specified logger accepts INFO messages.

Category: Logging
Requirements: The MAUTOSOURCE system option must be set.
The %LOG4SAS autocall macro must be invoked to initialize SAS logging before this macro is invoked.

Syntax

%LOG4SAS_INFO(logger-name, message)

Syntax Description

logger-name
specifies the name of the logger to process this log event.

message
specifies the log event message.

Requirement
The message must be enclosed in single or double quotation marks.

Details

The %LOG4SAS_INFO autocall macro is a log event for informational messages. In order to log messages using this macro, you must previously define loggers and appenders either in a SAS program or in a logging configuration file.

%LOG4SAS_LOGGER Autocall Macro

Defines a logger.

Category: Logging

Requirements: The MAUTOSOURCE system option must be set.
The %LOG4SAS autocall macro must be invoked before this macro is invoked to initialize SAS logging.

Syntax

%LOG4SAS_LOGGER(name <, "<ADDITIVITY=TRUE | FALSE> <APPENDER-REF=(appender-list)> <LEVEL=level>"))

Syntax Description

name

specifies the name of the logger.

Tip You can specify the root logger by setting name equal to either two double quotation marks with no space between them (""), or to "root".

ADDITIVITY= | 

specifies whether to pass log events to only the appender that is associated with the logger or to all of the appenders in the logger’s hierarchy.

Restriction ADDITIVITY can be modified for a logger only if the logger’s IMMUTABILITY option in the logging configuration file is set to FALSE. If you cannot modify a logger’s ADDITIVITY option, contact your system administrator.

APPENDER-REF=(appender-list)

specifies one or more appender names to which log events are passed.

Requirements The appender names must already exist. Appenders are created by the %LOG4SAS_APPENDER autocall macro or defined in a logging configuration file.

When you specify more than one appender, the list must be enclosed in parentheses.

Interaction If ADDITIVITY=TRUE, log events are also passed to all of the appenders that are associated with the logger’s hierarchy.

LEVEL=level

specifies the level at which log events of the specified level and higher are processed by the logger. The following are the valid level values, from lowest to highest: TRACE, DEBUG, INFO, WARN, ERROR, FATAL.

Restriction LEVEL can be modified for a logger only if the logger is defined in a logging configuration file and if the IMMUTABILITY attribute in the
logger configuration file is set to FALSE. If you cannot modify a logger’s LEVEL option, contact your system administrator.

Details

Logger Names

A logger is an ancestor of another logger if the logger name, followed by a dot, is the prefix of the other logger.

In the following example, MYPROGRAM is the parent logger. MYPROGRAM is the ancestor of the UNITTEST logger, and both MYPROGRAM and UNITTEST are ancestors of the REV1 logger.

MYPROGRAM
MYPROGRAM.UNITTEST
MYPROGRAM.UNITTEST.REV1

The hierarchical organization of loggers enables them to inherit log event levels and appenders from their ancestors.

Additivity

By default, each log event is passed to the appenders that are referenced by the logger and to the appenders that are referenced by loggers in the logger's hierarchy. This is the meaning of the term *appender additivity*.

For example, by default, when a log event is processed by the logger MyProgram.UnitTest.Rev1, the log message is also directed to the appenders that are referenced in the MyProgram.UnitTest and MyProgram loggers. If ADDITIVITY=FALSE, the log message is directed only to the appenders that are referenced by MyProgram.UnitTest.Rev1.

Levels

A logging request is applied if its level is greater than or equal to the level of the logger. Otherwise, the logging request is ignored. Loggers without an explicitly assigned level inherit their level from the hierarchy. For more information about logging levels, see “Logging Thresholds” on page 18.

- “%LOG4SAS_WARN Autocall Macro” on page 171
%LOG4SAS_TRACE Autocall Macro

Logs a TRACE message if the specified logger accepts TRACE messages.

Category: Logging

Requirements:
- The MAUTOSOURCE system option must be set.
- The %LOG4SAS autocall macro must be invoked to initialize SAS logging before this macro is invoked.

Syntax

```
%LOG4SAS_TRACE(logger-name, message)
```

Syntax Description

- `logger-name` specifies the name of the logger to process this log event.
- `message` specifies the log event message.
  
  Requirement: The message must be enclosed in single or double quotation marks.

Details

The %LOG4SAS_TRACE autocall macro is a log event for trace messages. In order to log messages using this macro, you must previously define loggers and appenders either in a SAS program or in a logging configuration file.

%LOG4SAS_WARN Autocall Macro

Logs a WARN message if the specified logger accepts WARN messages.

Category: Logging
Requirements: The MAUTOSOURCE system option must be set.
The %LOG4SAS autocall macro must be invoked to initialize SAS logging before this macro is invoked.

Syntax

%LOG4SAS_WARN(logger-name, message)

Syntax Description

*logger-name*

specifies the name of the logger to process this log event.

*message*

specifies the log event message.

Requirement The message must be enclosed in single or double quotation marks.

Details

The %LOG4SAS_WARN autocall macro is a log event for warning messages. In order to log messages using this macro, you must previously define loggers and appenders either in a SAS program or in a logging configuration file.

Using the Logging Facility Functions in the DATA Step

SAS supplies three logging facility functions that you can use in the DATA step:

LOG4SAS_APPENDER
   creates an appender. FileRefAppender is the only type of appender that can be created by using the SAS language.

LOG4SAS_LOGGER
   logs a message by using a specific logger.

LOG4SAS_LOGEVENT
   logs a message by using a specific logger.

You use logging facility functions in the same way as you use other functions in SAS: by assigning the function to a variable.

```sas
rc=log4sas_appender("myAppenderName", "FileRefAppender", "fileref=myfile");
```

When you create appenders and loggers, remember to create them only once in a DATA step, as in this example:

```sas
if _n_ = 1 then do;
   rc=log4sas_appender("myAppenderName", "FileRefAppender", "fileref=myfile");
   if rc ne 0 then do;
      msg = sysmsg();
      put msg;
      ABORT;
   end;
rc=log4sas_logger("myLoggerName", "appender-ref=(myAppenderName) level=info");
```

if rc ne 0 then do;
    msg = sysmsg();
    put msg;
    ABORT;
end;
end;

Logging Example Using Functions

The example program determines the number of years, months, and days between two SAS date values. It uses logging facility functions to write progress messages to an external file. To ensure efficiency of the program, the program is structured so that the appender and the logger are created, and variables are initialized during the first iteration of the DATA step.

filename myfile 'c:\em\log4sasfunction.log';
data a;
    input @1 dob mmddyy10.;
    format dob tod mmddyy10.;
    /* In the first iteration of the DATA step, create an appender */
    /* and a logger, and initialize variables tod and bdays. Then, determine */
    /* the number of days in the month prior to the current month. */
    if _n_ = 1 then
        do;
            rc=log4sas_appender("functionAppender", "FileRefAppender",
                "fileref=myfile");
            if rc ne 0 then do;
                msg = sysmsg();
                put msg;
                ABORT;
            end;
            rc=log4sas_logger("functionLogger", "appender-ref=(functionAppender)
                level=info");
            if rc ne 0 then do;
                msg = sysmsg();
                put msg;
                ABORT;
            end;
        /* Get the current date from the operating system */
        tod=today();
        retain tod;
        rc=log4sas_logevent("functionLogger", "info", "Obtained today's date.");
        if rc ne 0 then do;
            msg = sysmsg();
            put msg;
            ABORT;
        end;
    /* In the first iteration of the DATA step, create an appender */
    /* and a logger, and initialize variables tod and bdays. Then, determine */
    /* the number of days in the month prior to the current month. */
    if _n_ = 1 then
        do;
            rc=log4sas_appender("functionAppender", "FileRefAppender",
                "fileref=myfile");
            if rc ne 0 then do;
                msg = sysmsg();
                put msg;
                ABORT;
            end;
            rc=log4sas_logger("functionLogger", "appender-ref=(functionAppender)
                level=info");
            if rc ne 0 then do;
                msg = sysmsg();
                put msg;
                ABORT;
            end;
        /* Get the current date from the operating system */
        tod=today();
        retain tod;
        rc=log4sas_logevent("functionLogger", "info", "Obtained today's date.");
        if rc ne 0 then do;
            msg = sysmsg();
            put msg;
            ABORT;
        end;
    end;
/* Determine the number of days in the month prior to current month */
bdays=day(intnx('month',tod,0)-1);
retain bdays;

rc=log4sas_logevent("functionLogger", "info",
"Determined the number of business
days.");
if rc ne 0 then do;
    msg = sysmsg();
    put msg;
    ABORT;
end;
end; /* end the processing for first iteration */

/* Find the difference in days, months, and years between */
/* start and end dates                                */
dd=day(tod)-day(dob);
mm=month(tod)-month(dob);
yy=year(tod)-year(dob);

rc=log4sas_logevent("functionLogger", "info", "Found date differences.");

run;

The file that is represented by the MYFILE fileref contains the following logging facility messages:

Here is the program output:
LOG4SAS_APPENDER Function

Creates a fileref appender that can be referenced by a logger.

Category: Logging

Restriction: An appender can be attached to a logger using the SAS language only if the logger option IMmutability="FALSE" is set for the logger. Logger immutability can be set only in an XML configuration file.

Example: "Logging Example Using Functions" on page 174

Syntax

LOG4SAS_APPENDER("name", "FileRefAppender", <'options'>)

Required Arguments

"name"

specifies a name for the appender.

Requirement Appender names that you create using the SAS language must be unique for a SAS session.

Tip The appender name is case sensitive.
"FileRefAppender"
specifies that a fileref is used as the destination for the appender.

'options'
specify one or more of the following values:

FILEREF=fileref
specifies a fileref that is used as the log message destination for this appender.

Requirement  Yes

PATTERN="pattern"
specifies one or more message layout patterns that are used to format the log message.

See  "Pattern Layouts" on page 107

THRESHOLD=threshold
specifies a level at which log events that are lower than threshold are filtered out for the appender. Valid values for threshold, from lowest to highest, are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

Requirement  Options must be enclosed in single quotation marks.

Details

Appender Names
Appender names follow SAS naming conventions. An appender is associated with a logger by using the appender name as one of the values of the APPENDER-REF option in the LOG4SAS_LOGGER function.

FileRefAppender
A FileRefAppender is the only type of appender that can be used in the SAS language.

Patterns
Patterns are a feature of SAS logging that enable you to associate a layout with a particular logging output destination. The layout specifies how the output is formatted before it is sent to the output destination. The layout is specified as a pattern string that is similar to the pattern strings that are used in the C language PRINTF statement. The pattern layout contains literal text and format directives that are called conversion specifiers.

Each conversion specifier has the following syntax:

%\[format_modifiers\]conversion_character

If a pattern is not specified, the default is the message.

For more information, see "Pattern Layouts" on page 107.
Thresholds
An appender can be defined to have a threshold level. By default, appenders do not have a threshold. When a threshold is set, all log events that have a level that is lower than the threshold level are ignored by the appender.

For more information, see “Logging Thresholds” on page 18.

Processing Appenders in the DATA Step
An appender needs to be created only one time for each DATA step. The DATA step uses the implicit loop to process observations in a data set. Therefore, you can use the automatic variable _N_ in an IF statement to process the LOG4SAS_APPENDER function during the first DATA step iteration:

```sas
if _n_ = 1 then do;
    rc=log4sas_appender("myAppenderName", "FileRefAppender", "fileref=myfile");
    if rc ne 0 then do;
        msg = sysmsg();
        put msg;
        ABORT;
    end;
end;
```

See Also

Functions:
- “LOG4SAS_LOGEVENT Function” on page 182
- “LOG4SAS_LOGGER Function” on page 179

LOG4SAS_LOGGER Function
Creates a logger.

Category: Logging

Example: “Logging Example Using Functions” on page 174

Syntax

```
LOG4SAS_LOGGER("name", <"options">)
```

Required Arguments

"name"

specifies a name for the logger.

Requirements

The name must be enclosed in double quotation marks.

Tips

Requests to create a logger are ignored if they use the name of an existing logger.
You can specify the root logger by setting `name` equal to either two double quotation marks with no space between them (""), or to "root". If you specify the root logger, these settings are in effect only during the lifespan of the DATA step. Root settings before and after the DATA step are based on the logging configuration file.

**Example**

App.Security

**"options"**

specify one or more of the following options for this logger:

### ADDITIVITY=( | )

specifies whether to pass a log event to only the appender that is associated with the logger or to all of the appenders in the logger's hierarchy. TRUE specifies to send a log event to all of the appenders in the logger's hierarchy. FALSE specifies to send a log event to only the appenders that are referenced by the APPENDER-REF= option.

**Default**

TRUE

**Restriction**

ADDITIVITY can be modified for a logger only if the logger's IMMUTABILITY option in the logging configuration file is set to FALSE. If you cannot modify a logger’s ADDITIVITY option, contact your system administrator.

### APPENDER-REF=(appender_name_list)

specifies one or more appender names to which log events for the logger are passed. Separate the appender names with a space or a comma.

**Requirement**

An appender must be defined in a SAS program before it can be used in `appender_name_list`.

**Tip**

If the value of ADDITIVITY is TRUE, then the log events are processed by appenders that are found in the logger’s hierarchy.

### LEVEL=level

specifies the ranking, or level, of a log event message that the logger processes. The logger processes log events whose level is the same as or greater than `level`. The levels, from the lowest level to the highest level are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

**Restriction**

LEVEL can be modified for a logger only if the logger’s IMMUTABILITY option in the logger configuration file is set to FALSE. If you cannot modify a logger’s LEVEL option, contact your system administrator.

**Details**

**Logger Names**

The logger name associates a logger with a log message. You can send log messages to be processed by a logger by specifying the logger name as the `name` argument in the LOG4SAS_LOGEVENT function.

A logger is an ancestor of another logger if the logger name, followed by a dot, is the prefix of the other logger. The following names are logger names:
Testing
Testing.MyProg
Testing.MyProg.TraceMsgs

Testing is the parent logger and the ancestor of the loggers MyProg and TraceMsgs. MyProg is the ancestor of TraceMsgs. The logger Testing.MyProg.TraceMsgs provides a message category that can be used to log trace messages when you are testing the program MyProg.

The hierarchical organization of loggers enables loggers to inherit levels and appenders from their ancestors. For information about configuring loggers in a hierarchy, see “Hierarchical Logger Names” on page 9.

Appender Reference and Additivity

The appenders that are in append_name_list must be defined by using the LOG4SAS_APPENDER function or in a logging configuration file before the LOG4SAS_LOGGER function executes.

By default, each log event is passed to the appenders that are referenced by the logger and to the appenders that are referenced by loggers in the logger's hierarchy. This is the meaning of the term appender additivity.

For example, by default, when a log event is processed by the logger Testing.MyProg.TraceMsgs, the log message is also directed to the appenders that are referenced in the Testing.MyProg and Testing loggers. If ADDITIVITY=FALSE, the log message is directed to only the appenders that are referenced by Testing.MyProg.TraceMsgs.

Levels

A log event is applied if the level of the log event is the same or greater than the level of the logger. If the level of the log event is lower than the level of the logger, then the log event is discarded. For more information about levels, see “Logging Thresholds” on page 18.

If a logger does not define a level, the logger inherits the level from the next highest ancestor that has an assigned level.

Processing Loggers in the DATA Step

A logger needs to be created only one time for each DATA step. The DATA step uses the implicit loop to process observations in a data set. Therefore, you can use the automatic variable _N_ in an IF statement to process the LOG4SAS_LOGGER function during the first DATA step iteration:

```plaintext
if _n_ = 1 then
do;
   rc=log4sas_logger("myLoggerName", "appender-ref=(functionAppender) level=info");
   if rc ne 0 then do;
      msg = sysmsg();
      put msg;
      ABORT;
   end;
end;
```
LOG4SAS_LOGEVENT Function

Logs a message by using a specific logger.

Category: Logging

Example: “Logging Example Using Functions” on page 174

Syntax

LOG4SAS_LOGEVENT("name", "level", "message")

Required Arguments

"name"
specifies a name for the logger that processes the log event.

Requirement The name must be enclosed in quotation marks.

"level"
specifies one of the following message levels:

TRACE produces the most detailed information about your application. This level is primarily used by SAS Technical Support or development.

DEBUG produces detailed information that you use to debug your application. This level is primarily used by SAS Technical Support or development.

INFO provides information that highlights the progress of an application.

WARN provides messages that identify potentially harmful situations.

ERROR provides messages that indicate that errors have occurred. The application might be able to continue.

FATAL provides messages that indicate that severe errors have occurred. These errors will probably cause the application to end.

Requirement The level must be enclosed in quotation marks.

"message"
specifies the message that is logged.

Requirement The message must be enclosed in quotation marks.
Interaction

The only variables that the message can resolve are macro variables. DATA step variables do not resolve in the message.

Details

Name

The log message name argument names a logger to process the log message.

A logger is an ancestor of another logger if the logger name, followed by a dot, is the prefix of the other logger. The following names are logger names:

Testing
Testing.MyProg
Testing.MyProg.TraceMsgs

Testing is the parent logger and the ancestor of the loggers MyProg and TraceMsgs. MyProg is the ancestor of the logger TraceMsgs. The logger Testing.MyProg.TraceMsgs provides a message category that can be used to log trace messages when you are testing the program MyProg.

The hierarchical organization of loggers enables loggers to inherit levels and appenders from their ancestors. For information about configuring loggers in a hierarchy, see “Hierarchical Logger Names” on page 9.

The Logger and Appender Component Object Interface

SAS provides two predefined component objects that you can use in a DATA step to access SAS logging: the appender object and the logger object. These objects enable you to record log events and write these events to the appropriate destinations.

The DATA step Component Interface enables you to create and manipulate the logger and appender objects by using statements, attributes, and methods. You use the DECLARE statement to declare and create a component object. You use DATA step object dot notation to access the component object's attributes and methods. Attributes are the properties that specify the information that is associated with an object. Methods define the operations that an object can perform.

An appender and logger object need to be created only one time for each DATA step. Because the DATA step uses the implicit loop to process observations in a data set, you can use the automatic variable _N_ in an IF statement to process the appender and logger object code during the first DATA step iteration.
Note: The DATA step component object statements, attributes, and methods are limited to those defined for these objects. You cannot use SAS Component Language functionality with these predefined DATA step objects.

Dot Notation and DATA Step Component Objects

Definition

Dot notation provides a shortcut for invoking methods and for setting and querying attribute values. Using dot notation makes your SAS programs easier to read.

To use dot notation with a DATA step component object, you must declare and instantiate the component object by using the DECLARE statement.

Syntax

object.attribute

or

object.method(<argument_tag-1: value-1>, ...argument_tag-n: value-n>);

Arguments

object

specifies the variable name for the DATA step component object.

attribute

specifies an object attribute to assign or query.

When you set an attribute for an object, the code takes this form:

object.attribute = value;

When you query an object attribute, the code takes this form:

value = object.attribute;

method

specifies the name of the method to invoke.

argument_tag

identifies the arguments that are passed to the method. Enclose the argument tag in parentheses. The parentheses are required whether or not the method contains argument tags.

All DATA step component object methods take this form:

return_code = object.method(<argument_tag-1: value-1
                           <,...argument_tag-n: value-n>>);
The return code indicates whether the method is successful or failed. A return code of zero indicates success; a nonzero value indicates failure. If you do not supply a return code variable for the method call and if the method fails, an error message is printed to the log.

**value**

specifies the argument value.

---

### Dictionary

**ADDITIVITY Attribute**

Specifies whether to pass a log event only to the appender that is associated with the logger or to the appenders in the logger's hierarchy.

**Applies to:** logger object

#### Syntax

```
object.ADDITIVITY=" | ";
```

#### Required Arguments

**object**

specifies the name of the logger object.

**"TRUE | FALSE"**

determines whether a log event is processed by the appenders that exist in the specified logger's hierarchy.

**Default** TRUE

#### Details

By default, each log event is passed to the appenders that are associated with the logger and to the appenders that are associated with the logger's hierarchy. This is the meaning of the term *appender additivity.*

For example, by default, when a log event is processed by the logger Testing.MyProg.TraceMsgs, the log message is also directed to the appenders that are referenced in the Testing.MyProg and Testing loggers. If ADDITIVITY=FALSE, the log message is directed to only the appenders that are referenced by Testing.MyProg.TraceMsgs.

---

**Note:** You can also specify the logger additivity in the logger's constructor by using the DECLARE statement. For more information, see “DECLARE Statement: Logger Object” on page 193.
Example

The following code sets the additivity attribute to FALSE.

```sas
data _null_;  
  if _n_ = 1 then do;  
    declare logger logobj("mylog");  
    end;  
  logobj.additivity="false";  
run;
```

Alternatively, you can set the additivity attribute in the DECLARE statement.

```sas
data _null_;  
  if _n_ = 1 then do;  
    declare logger logobj("mylog", additivity:"false");  
    end;  
run;
```

See Also

**Statements:**
- "DECLARE Statement: Logger Object" on page 193

---

**APPENDERREF Attribute**

Specifies the name of the appender to which log events are passed.

- **Applies to:** logger object
- **Restriction:** An appender can be attached to a logger using the SAS language only if the logger option IMmutABILITY="FALSE" is set for the logger. Logger immutability can be set only in an XML configuration file.

**Syntax**

```sas
object.APPENDERREF="appender-name";
```

**Required Arguments**

- **object** specifies the name of the logger object.
- **appender-name** specifies the name of the appender to which the log events for the specified logger are passed.

**Requirement**

Appender names that you create using the SAS language must be unique for a SAS session.

**Interactions**

If the ADDITIVITY attribute is set to TRUE, the log events are also passed to all the appenders that are associated with the logger's hierarchy.
The appender name must already exist. Appender names are created by using the DECLARE statement or in a logging configuration file.

See "DECLARE Statement: Appender Object" on page 190

Details

You can specify more than one appender for each logger.

Example

The logger object in the following example references the myappd appender.

```plaintext
filename myfref "my.log";

data _null_;  
  if _n_ = 1 then do;
    declare appender appobj("myappd", "FileRefAppender", "FileRef=myfref");
    declare logger logobj("mylog", level: "info");
    logobj.appenderref="myappd";
    end;
    logobj.additivity="false"
    logobj.info("my info message");
  run;
```

---

**DEBUG Method**

Logs a DEBUG message if the specified logger accepts DEBUG messages.

**Applies to:** logger object

**Syntax**

```plaintext
object.DEBUG("message");
```

**Required Arguments**

`object`

specifies the name of the logger object.
**message**

specifies the message to write at the debug level.

**Requirement** The message must be enclosed in quotation marks.

**Details**

The debug level designates fine-grained informational events that are most useful to debug an application. For more information about logging levels, see “Logging Thresholds” on page 18.

**Example**

The following example creates a debugging message for the logger.

```sas
data _null_;  
  if _n_=1 then do;  
    declare appender appobj("myappender","FileRefAppender","fileref=myfile");  
    declare logger logobj("testlog",AppenderRef:"myappender");  
  end;  
  ...more-sas-code...  
  logobj.debug("Test debug message");  
  ...more-sas-code...  
  run;
```

---

**DECLARE Statement: Appender Object**

Declares an appender object; creates an instance of an appender object and initializes data for an appender object.

<table>
<thead>
<tr>
<th>Valid in</th>
<th>DATA step</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category</td>
<td>Action</td>
</tr>
<tr>
<td>Type</td>
<td>Executable</td>
</tr>
<tr>
<td>Alias</td>
<td>DCL</td>
</tr>
</tbody>
</table>
Syntax

DECLARE APPENDER appender-object ("appender-name", "FileRefAppender", "FILEREF =fileref" <<, PATTERN: "pattern">> <<, THRESHOLD: "threshold">>);

Required Arguments

**appender-object**
specifies the name of the appender object.

**appender-name**
specifies the name of the appender to which the log events are passed.

- **Requirement**
The name must be enclosed in double quotation marks.

- **Interaction**
This name is valid for use wherever an AppenderRef is accepted (for example, in the DECLARE statement for the logger object).

- **Tip**
Appender names are case sensitive.

**FileRefAppender**
specifies the FileRefAppender class to which the defined appender instance belongs.

- **Requirements**
Appender class names are case sensitive. In this instance, the name must be "FileRefAppender".

- **Note**
FileRefAppender must be enclosed in double quotation marks.

**FILEREF="fileref"**
specifies the destination for log events that the FileRefAppender class processes.

- **Requirement**
If the FileRefAppender argument is specified, this argument also must be specified.

**PATTERN: "pattern"**
specifies the conversion pattern that is used to format the log message.

- **Requirement**
The pattern must be enclosed in double quotation marks.

- **Tip**
If a conversion pattern is not specified, the default pattern is %m, the message.

**THRESHOLD: "threshold"**
specifies the level at which log events are filtered out for the specified appender object. Valid values are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

- **Requirement**
The level must be enclosed in double quotation marks.
Details

Appender Names

Appender names follow the rules for SAS naming conventions. For appender objects, the name can be referenced by the logger object in the APPENDERREF attribute. For more information, see “APPENDERREF Attribute” on page 188. Here is an example:

```
filename myfile "my.log";
declare appender appobj("workappd", "FileRefAppender", "FileRef=myfile");
declare logger logobj("testlog");
logobj.appenderref="workappd";
```

FileRefAppender

A FileRefAppender is the only type of appender that can be used in the SAS language.

Patterns

Patterns are a feature of SAS logging that enables you to associate a layout with a particular logging output destination. The layout specifies how the output is formatted before it is sent to the output destination. The layout is specified as a pattern string that is similar to the pattern strings that are used in the C language PRINTF statement. The pattern layout contains literal text and format directives that are called conversion specifiers.

Each conversion specifier has the following syntax:

```
% [format_modifiers] conversion_character
```

If a pattern is not specified, the default pattern is %m, the message.

For more information, see “Pattern Layouts” on page 107.

Thresholds

An appender can be configured to have a threshold level. By default, appenders do not have a threshold set. When a threshold is set, all log events that have a level that is lower than the threshold level are ignored by the appender.

For more information, see “Logging Thresholds” on page 18.

Example

This example creates an appender object.

```
data _null_;   
  if _n_ = 1 then do;
    declare appender appobj("testappd", "FileRefAppender", "fileref=testfref", 
                           pattern:="%nrstr(%d{yyyMMdd:HH:mm:ss.SS}: %t:%8p %m)",
                           threshold:"fatal");
  end;
run;
```

See Also

Attributes:
DECLARE Statement: Logger Object

Declares a logger object; creates an instance of a logger object and initializes data for a logger object.

Valid in: DATA step
Category: Action
Type: Executable
Alias: DCL

Syntax

DECLARE LOGGER logger-object("logger-name" <, ADDITIVITY: | >
<, LEVEL:"level">
<, APPENDERREF:"appender-name-1" <, APPENDERREF:"appender-name-2"> … >);

Required Arguments

logger-object specifies the name of the logger object.

logger-name specifies the name of the logger to which the specified options are applied.

Requirement The name must be enclosed in double quotation marks.

Tip You can specify the root logger by setting name equal to either double quotation marks with no space between them (""), or to "root". If you specify the root logger, these settings are in effect only during the lifespan of the DATA step. Root settings before and after the DATA step are based on the logging configuration file.

ADDITIVITY: | specifies whether to pass a log event only to the appender that is associated with the logger or to all the appenders in the logger's hierarchy.

Restriction ADDITIVITY can be modified for a logger only if the logger's IMMUTABILITY option in the logging configuration file is set to FALSE. If you cannot modify a logger's ADDITIVITY option, contact your system administrator.

Tip You can also specify this optional argument by using the ADDITIVITY attribute after the logger instance has been created. For more information, see “ADDITIVITY Attribute” on page 187.
**LEVEL: "level"**
specifies the level at which a logging request is applied for the specified logger object. Valid values are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

<table>
<thead>
<tr>
<th>Requirement</th>
<th>LEVEL can be modified for a logger only if the logger’s IMMUTABILITY option in the logger configuration file is set to FALSE. If you cannot modify a logger’s LEVEL option, contact your system administrator.</th>
</tr>

</tr>
</tbody>
</table>

See “DECLARE Statement: Appender Object” on page 190

**Details**

**Logger Names**

A logger instance is said to be an ancestor of another logger instance if the logger instance name, followed by a dot, is the prefix of the other logger.

In the following example, IOM is the parent logger, IOM is an ancestor of the APP logger, and both IOM and IOM.APP are ancestors of the WORKSPACE logger.

```java
logobj.name="IOM";
logobj.name="IOM.APP";
logobj.name="IOM.APP.WORKSPACE";
```

The hierarchical organization of loggers enables them to inherit log event levels and appenders from their ancestors.

**Additivity**

By default, each log event is passed to the appenders that are associated with the logger and to the appenders that are associated with the logger’s hierarchy. This is the meaning of the term *appender additivity.*
For example, by default, when a log event is processed by the logger Iom.App.Workspace, the log message is also directed to the appenders that are referenced in the Iom.App and Iom loggers. If ADDITIVITY=FALSE, the log message is directed only to the appenders that are referenced by Iom.App.Workspace.

Levels

A logging request is applied if its level is greater than the level of the logger. Otherwise, the logging request is ignored. Loggers that do not have an explicitly assigned level inherit their level from the hierarchy. For more information about the logging levels, see “Logging Thresholds” on page 18.

Example

The following example creates a logger object, logobj.

```
data _null_;  
  if _n_ = 1 then do;  
    declare appender appobj("myappd", "FileRefAppender", *fileref=myfref*);  
    appobj.threshold="trace";  
    declare logger logobj("mylog");  
    logobj.appenderref="myappd";  
  end;  
  logobj.level="trace";  
  logobj.debug("Test debug message");  
  logobj.level="info";  
  logobj.info("Test info message");  
run;  
```

---

**ERROR Method**

Logs an ERROR message if the specified logger accepts ERROR messages.

**Applies to:** logger object

**Syntax**

```
object.ERROR("message");
```
Required Arguments

**object**
specifies the name of the logger object.

**message**
specifies the message to write at the error level.

**Requirement**
The message must be enclosed in double quotation marks.

Details
The error level designates error events. The application might be able to continue running. For more information about the logging levels, see “Logging Thresholds” on page 18.

Example
The following example creates an error message for the logger.
```sas
data _null_;  
  if _n_ = 1 then do;  
    declare logger logobj("testlog");  
    end;  
  logobj.error("Test error message");  
run;
```

**Methods:**
- “DEBUG Method” on page 189
- “FATAL Method” on page 196
- “INFO Method” on page 197
- “TRACE Method” on page 199
- “WARN Method” on page 200

**FATAL Method**
Logs a FATAL message if the specified logger accepts FATAL messages.

**Applies to:** logger object

**Syntax**
```sas
object.FATAL("message");
```
Required Arguments

**object**
specifies the name of the logger object.

**message**
specifies the message to write at the fatal level.

__Requirement__
The message must be enclosed in double quotation marks.

Details
The fatal level designates very severe error events that might cause the application to end abruptly. For more information about logging levels, see "Logging Thresholds" on page 18.

Example
The following example creates a fatal message for the logger.

```plaintext
data _null_; if _n_ = 1 then do; declare logger logobj("testlog"); end; logobj.fatal("Test fatal message"); run;
```

**Methods:**
- “DEBUG Method” on page 189
- “ERROR Method” on page 195
- “INFO Method” on page 197
- “TRACE Method” on page 199
- “WARN Method” on page 200

INFO Method
Logs an INFO message if the specified logger accepts INFO messages.

**Applies to:** logger object

**Syntax**

```
object.INFO("message");
```
Required Arguments

- **object**
  - specifies the name of the logger object.

- **message**
  - specifies the message to write at the info level.

**Requirement**

The message must be enclosed in double quotation marks.

Details

The info level designates informational events that highlight the progress of an application at a coarse-grained level. For more information about logging levels, see "Logging Thresholds" on page 18.

Example

The following example creates an info message for the logger.

```plaintext
data _null_;  
  if _n_ = 1 then do;  
    declare logger logobj("testlog");  
    end;  
  logobj.info("Test info message");  
run;
```

**Methods:**

- "DEBUG Method" on page 189
- "ERROR Method" on page 195
- "FATAL Method" on page 196
- "TRACE Method" on page 199
- "WARN Method" on page 200

LEVEL Attribute

Defines the level of message that is accepted by the specified logger.

**Applies to:**

logger object

**Syntax**

```
object.LEVEL="level";
```
Required Arguments

**object**
specifies the name of the logger object.

**level**
specifies the level at which a logging request is applied for the specified logger object. Valid values are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

**Requirement** The level must be enclosed in double quotation marks.

Details

A logging request is applied if its level is greater than the level of the logger. Otherwise, the logging request is ignored. Loggers without an explicitly assigned level inherit their level from the hierarchy. For more information about the logging levels, see "Logging Thresholds" on page 18.

**Note:** You can specify the logger level in the logger's constructor by using the DECLARE statement. For more information, see "DECLARE Statement: Logger Object" on page 193.

Example

The following code sets the attribute level to trace.

data _null_;  
if _n_ = 1 then do;  
   declare logger logobj("mylog");  
end;  
logobj.additivity="false";  
logobj.level="trace";  
run;

Alternatively, you can set the level attribute in the DECLARE statement constructor.

data _null_;  
if _n_ = 1 then do;  
   declare logger logobj("mylog", additivity:"false", level:"trace");  
end;  
run;

See Also

**Statements:**

- "DECLARE Statement: Logger Object" on page 193

TRACE Method

Logs a TRACE message if the specified logger accepts TRACE messages.

Applies to: logger object
Syntax

\texttt{object.TRACE("message");}

Required Arguments

\texttt{object} specifies the name of the logger object.

\texttt{message} specifies the message to write at the trace level.

\textbf{Requirement} The message must be enclosed in double quotation marks.

Details

The trace level designates finer-grained informational events then DEBUG. For more information about logging levels, see "Logging Thresholds" on page 18.

Example

The following example creates a trace message for a logger.

\begin{verbatim}
data _null_;  
  if _n_ = 1 then do;  
    declare logger logobj("testlog");  
  end;  
  logobj.trace("Test trace message");  
run;
\end{verbatim}

- "FATAL Method" on page 196
- "INFO Method" on page 197
- "WARN Method" on page 200

\begin{description}
\item[WARN Method] Logs a WARN message if the specified logger accepts WARN messages.
\end{description}

Applies to: logger object
Syntax

\texttt{object.WARN("message");}

Required Arguments

\texttt{object}

specifies the name of the logger object.

\texttt{message}

specifies the message to write at the warn level.

\underline{Requirement} \quad The message must be enclosed in double quotation marks.

Details

The warn level designates potentially harmful situations. For more information about logging levels, see "Logging Thresholds" on page 18.

Example

The following example creates a warn message for a logger.

\begin{verbatim}
data _null_;  
  if _n_ = 1 then do;  
    declare logger logobj("testlog");  
  end;  
  logobj.warn("Test warn message");  
run;
\end{verbatim}

Appendix

Appendix 1
Audit Messages for SAS Library Access ........................................... 205

Appendix 2
Audit Messages for Metadata-Bound Libraries ............................... 211
About Audit Messages for SAS Library Access

The logging facility provides three loggers to audit access to SAS libraries, including database tables that have been assigned by a LIBNAME statement. Here are the loggers:

- **Audit.Data.Dataset.Delete**: writes a message to an audit log when a SAS data set is deleted.
- **Audit.Data.Dataset.Open**: writes a message to an audit log when a SAS data set is opened.
- **Audit.Data.Dataset.Rename**: writes a message to an audit log when a SAS data set is renamed.

You can obtain the following information about a SAS library:

- the action taken on the SAS data set: OPEN, DELETE, or RENAME.
- the status of the action taken on the SAS data set: SUCCESS or FAILED.
- the return code from the action and the associated message (if any). Warning and note messages have a status of SUCCESS and negative return codes. Error messages have a status of FAILED and positive return codes.
- the libref.
- the engine associated with the library.
- the library member name.
- if a SAS data set was renamed, the new member name.
- the library member type, such as catalog or data set.
the mode that the library was opened for: INPUT, OUTPUT, or UPDATE.

the path to the library or to a database table.

Note: Audit messages are not available for in-database tables, filerefs, or SAS cubes.

Based on the XML configuration files that SAS provides, auditing messages appear when the logging threshold is TRACE.

To configure the XML configuration file for auditing SAS libraries, you specify a path and filename for the audit log in the appender fileNamePattern parameter. Then, specify a conversion pattern in the conversionPattern parameter.

Here is an example audit path and filename:

"SAS-configuration-directory/Lev1/
 SAS-application/server-name/Logs/
 Audit.Library_server_%d_%S{hostname}_%S{pid}.log"

In the appender’s conversionPattern parameter, use the %E conversion character to specify the type of information that you want the audit messages to contain. The syntax for this conversion character is %E(key). The key can be one of the following:

- **Audit.Dataset.Action** reports the action that is being logged (OPEN, DELETE, or RENAME).
- **Audit.Dataset.Libref** reports the libref that was used to access the library.
- **Audit.Dataset.Engine** reports the engine that is associated with the library.
- **Audit.Dataset.Member** reports the name of the data set member.
- **Audit.Dataset.Memtype** reports the type of data set member.
- **Audit.Dataset.NewMember** reports the new name of the renamed data set member.
- **Audit.Dataset.Openmode** reports whether the data set is open in INPUT, OUTPUT, or UPDATE mode.
- **Audit.Dataset.Path** reports the path to the library.
- **Audit.Dataset.Status** reports the status of opening a data set. Valid values are SUCCESS or FAILED.
- **Audit.Dataset.Sysmsg** reports the message (if any) that is associated with the return code.
- **Audit.Dataset.Sysrc** reports the numeric return code from the action.

Here is a sample conversion pattern:

```plaintext
DateTime=%d Userid=%u Action=%E{Audit.Dataset.Action} Status=%E{Audit.Dataset.Status} Libref=%E{Audit.Dataset.Libref} Engine=%E{Audit.Dataset.Engine} Member=%E{Audit.Dataset.Member} NewMember=%E{Audit.Dataset.NewMember} Memtype=%E{Audit.Dataset.Memtype} Openmode=%E{Audit.Dataset.Openmode} Path=%E{Audit.Dataset.Path} Sysrc=%E{Audit.Dataset.Sysrc}
```
Here is a message from the audit log reporting a failed action:

DateTime=2013-08-15T11:08:46,851 Userid=user1@DEPTPROG Action=OPEN Status=FAILED
Libref=MULTI Engine=V9 Member=MYTESTDATA NewMember= MemberType=DATA Openmode=INPUT
Path=c:\temp Sysrc=70045 Sysmsg=  ERROR: Invalid or missing READ password on member
MULTI.MYTESTDATA.DATA.

Here is a message from the audit log reporting a successful action:

DateTime=2013-08-15T11:08:46,881 Userid= user1@DEPTPROG Action=OPEN Status=SUCCESS
Libref=MULTI Engine=V9 Member=MYTESTDATA NewMember= MemberType=DATA Openmode=INPUT
Path=c:\temp Sysrc=0 Sysmsg=

For a sample logger and appender, see “Sample: XML Logger and Appender” on page 207.

See Also

"E Conversion Character" on page 122

Sample: XML Logger and Appender

Here are sample loggers for auditing access to SAS libraries:

<!-- Audit.Data.Dataset.Open logger definition -->
<logger name="Audit.Data.Dataset.Open" additivity="false">
  <appender-ref ref="AuditLibraryFile"/>
  <level value="Trace"/>
</logger>

<!-- Audit.Data.Dataset.Delete logger definition -->
<logger name="Audit.Data.Dataset.Delete" additivity="false">
  <appender-ref ref="AuditLibraryFile"/>
  <level value="Trace"/>
</logger>

<!-- Audit.Data.Dataset.Rename logger definition -->
<logger name="Audit.Data.Dataset.Rename" additivity="false">
  <appender-ref ref="AuditLibraryFile"/>
  <level value="Trace"/>
</logger>
Sample Appender for Auditing SAS Library Access

Here is a sample appender for auditing access to SAS libraries:

```xml
<!-- Audit.Data.Dataset File Appender Definition -->

<appender name="AuditLibraryFile" class="FileAppender">
    <param name="Append" value="true"/>
    <param name="ImmediateFlush" value="true"/>
    <param name="fileNamePattern" value="
        *SAS-configuration-directory/Lv1/
        SAS-application/server-name/Logs/
        Audit.Library_server_%d_%S{hostname}_%S{pid}.log"
    />
    <layout>
        <param name="ConversionPattern" value="
            DateTime=%d Userid=%u Action=%E{Audit.Dataset.Action} Status=%E{Audit.Dataset.Status} Libref=%E{Audit.Dataset.Libref} Engine=%E{Audit.Dataset.Engine} Member=%E{Audit.Dataset.Member} NewMember=%E{Audit.Dataset.NewMember} MemberType=%E{Audit.Dataset.Memtype} Openmode=%E{Audit.Dataset.Openmode} Path=%E{Audit.Dataset.Path} Sysrc=%E{Audit.Dataset.Sysrc} Sysmsg=%E{Audit.Dataset.Sysmsg} Sysmsg=
        ">
    </layout>
</appender>
```

Sample Code to Look for Log Files and Build an Audit Report Data Set

**Note:** If you use this sample program, take these precautions when specifying the conversion pattern:

- Do not place commas or other special characters between the conversion specifiers. For example, specify `DateTime=%d Userid=%u` instead of `DateTime= %d, Userid=%u`.
- Include two blank spaces after `Sysmsg=`. This enables the program to correctly read messages that contain an equal sign (=).

Here is a sample SAS program that creates an audit report data set from your audit log data:

```sas
/* Specify the directory where your log files are saved. */
%let logdir=your-log-directory;

/* Specify a directory to save the audit data. */
libname audit "your-audit-data-directory";
```
/* Expand a passed in directory name and find all the filenames. */

%macro findfiles(logdir);
  data filelist (keep=directory logfile hostname pid);
    format directory logfile $512. hostname $80. pid $8.;
    directory="&logdir.";
    rc=filename("ONE","&logdir.");
    if rc ne 0 then do;
      msgLine="NOTE: Unable to assign a filename to directory &logdir.";
      put msgLine;
    end;
    else do;
      did=dopen("ONE");
      if did > 0 then do;
        numfiles=dnum(did);
        put numfiles=;
        do i=1 to numfiles;
          logfile=dread(did,i);
          hostname=scan(logfile,-3,'_.');
          pid=scan(logfile,-2,'_.');
          output;
        end;
      end;
    /* close the open filename and data set pointer */
    rc=filename("ONE");
    did=dclose(did);
  run;
%mend;

/* Read through a data set of directory name and filenames and read the audit logs. */

%macro readfiles(list);
  %let dsid = %sysfunc(open(&list));

About Audit Messages for Metadata-Bound Libraries

The logging facility provides two loggers to audit access to metadata-bound tables:

The Audit.Data.MetaBoundLib.PermDenied logger logs events when a user attempts to access metadata-bound tables to which the user has insufficient effective permissions in the metadata layer.

The Audit.Data.MetaBoundLib.AuthAudit logger logs these events:

- A user accesses a metadata-bound table that is located within a traditional (unbound) library.
- A user accesses a traditional (unbound) table that is located within a metadata-bound library.
- A user accesses a metadata-bound table whose security location reference does not match the security location reference of its parent library.
- A user accesses a metadata-bound table whose security name reference does not match the corresponding secured table object. There is a mismatch of names.
- A user attempts to access a metadata-bound table whose passwords do not match the passwords of the corresponding secured library object. Even if the user's metadata layer permissions are sufficient, access is not allowed.
Auditing messages appear when the logging threshold for these loggers is set to TRACE.

Generating Audit Messages for Metadata-Bound Libraries

To generate audit messages for metadata-bound libraries and tables, add the following items to the XML logging configuration file for the SAS server or for another SAS process that is accessing the libraries and tables:

- a logger definition for each audit logger. In each logger definition, specify a level of TRACE, and use the appender-ref parameter to specify the name of the appender that is to collect the messages.

- appender definitions for log files to collect the messages. In each appender definition, use the fileNamePattern parameter to specify a path and filename for the audit log.

  In the appender’s conversionPattern parameter, use the %E conversion character to specify the type of information that you want the audit messages to contain. The syntax for this conversion character is %E{key}. The key can be one of the following:

  - Audit.MetaBoundLib.Action
    - reports the action that the user is attempting to perform on data that is bound to the metadata-bound library

  - Audit.MetaBoundLib.DataSetInfo.SecuredLibrary
    - reports the secured library object’s metadata path as it is recorded in the location information in the SAS data set

  - Audit.MetaBoundLib.DataSetInfo.SecuredLibraryGuid
    - reports the secured library object’s global unique identifier (GUID) as it is recorded in the location information in the SAS data set

  - Audit.MetaBoundLib.DataSetInfo.SecuredTableGuid
    - reports the GUID for the secured table object

  - Audit.MetaBoundLib.DataSetInfo.SecuredTableName
    - reports the name of the secured table object

  - Audit.MetaBoundLib.DataSet.MemberName
    - reports the member name

  - Audit.MetaBoundLib.DataSet.MemberType
    - reports the member type

  - Audit.MetaBoundLib.LibraryInfo.SecuredLibrary
    - reports the secured library object’s metadata path as it is recorded in the location information in the physical library

  - Audit.MetaBoundLib.LibraryInfo.SecuredLibraryGuid
    - reports the metadata-bound library’s GUID as it is recorded in the location information in the physical library

  - Audit.MetaBoundLib.Library.Path
    - reports the physical path for the metadata-bound library
Audit.MetaBoundLib.Library.Reference
  reports the libref for the metadata-bound library

Audit.MetaBoundLib.RequiredPermission
  reports the required permission for the action that the user is attempting to perform

Audit.MetaBoundLib.StepName
  reports the step name that attempted to access the metadata-bound data

Audit.MetaBoundLib.User.EffectivePermissions
  reports the user's effective permissions for the metadata-bound data

Audit.MetaBoundLib.User.IdentityName
  reports the user's metadata identity name

Audit.MetaBoundLib.User.LoginId
  reports the user's login ID

For sample appender definitions and logger definitions, see “Sample: XML Loggers and Appenders” on page 213. For a sample log message, see “Sample: Audit Message for a Metadata-Bound Library” on page 215.

Sample: XML Loggers and Appenders

Sample Loggers for Auditing Access to Metadata-Bound Libraries

Here are sample loggers for auditing access to metadata-bound libraries:

<!-- Logger definition for authorization failures -->

<logger name="Audit.Data.MetaBoundLib.PermDenied" additivity="false">
  <appender-ref ref="Perm"/>
  <level value="Trace"/></logger>

<!-- Logger definition for misalignment issues -->

<logger name="Audit.Data.MetaBoundLib.AuthAudit" additivity="false">
  <appender-ref ref="Audit"/>
Sample Appenders for Auditing Access to SAS Metadata-Bound Libraries

Here are sample appenders for auditing access to SAS metadata-bound libraries:

<!-- Appender definition for authorization failures -->

```xml
<appender name="Perm" class="FileAppender">
  <param name="Append" value="true"/>
  <param name="ImmediateFlush" value="true"/>
  <param name="fileNamePattern" value="SAS-configuration-directory/Lev1/
  SAS-application/server-name/Logs/
  Audit.Data.MetaBoundLib.PermDenied_server%d%S{hostname}%S{pid}.log"/>
  <layout>
    <param name="ConversionPattern" value="DateTime=%d Userid=%u
    StepName=%E{Audit.MetaBoundLib.StepName}
    Action=%E{Audit.MetaBoundLib.Action}
    LoginId=%E{Audit.MetaBoundLib.User.LoginId}
    IdentityName=%E{Audit.MetaBoundLib.User.IdentityName}
    Libref=%E{Audit.MetaBoundLib.Library.Reference}
    OSLibraryPath=%E{Audit.MetaBoundLib.Library.Path}
    MemberName=%E{Audit.MetaBoundLib.DataSet.MemberName}
    MemberType=%E{Audit.MetaBoundLib.DataSet.MemberType}
    DataSetInfoSecLib=%E{Audit.MetaBoundLib.DataSetInfo.SecuredLibrary}
    DataSetInfoSecLibGuid=%E{Audit.MetaBoundLib.DataSetInfo.SecuredLibraryGuid}
    DataSetInfoSecTableName=%E{Audit.MetaBoundLib.DataSetInfo.SecuredTableName}
    DataSetInfoSecTableGuid=%E{Audit.MetaBoundLib.DataSetInfo.SecuredTableGuid}
    LibraryInfoSecLib=%E{Audit.MetaBoundLib.LibraryInfo.SecuredLibrary}
    LibraryInfoSecLibGuid=%E{Audit.MetaBoundLib.LibraryInfo.SecuredLibraryGuid}
    RequiredPermission=%E{Audit.MetaBoundLib.RequiredPermission}
    UserEffectivePermissions=%E{Audit.MetaBoundLib.User.EffectivePermissions}
    Message=%m"/>
  </layout>
</appender>

<!-- Appender definition for misalignment issues -->

```xml
<appender name="Audit" class="FileAppender">
  <param name="Append" value="true"/>
  <param name="ImmediateFlush" value="true"/>
  <param name="fileNamePattern" value="SAS-configuration-directory/Lev1/
  SAS-application/server-name/Logs/
  MetaboundLibAuditSetup_server%d%S{hostname}%S{pid}.log"/>
  <layout>
    <param name="ConversionPattern" value="DateTime=%d Userid=%u
    StepName=%E{Audit.MetaBoundLib.StepName}
    Action=%E{Audit.MetaBoundLib.Action}
    LoginId=%E{Audit.MetaBoundLib.User.LoginId}
    IdentityName=%E{Audit.MetaBoundLib.User.IdentityName}
    Libref=%E{Audit.MetaBoundLib.Library.Reference}
    OSLibraryPath=%E{Audit.MetaBoundLib.Library.Path}
    MemberName=%E{Audit.MetaBoundLib.DataSet.MemberName}
    MemberType=%E{Audit.MetaBoundLib.DataSet.MemberType}
    DataSetInfoSecLib=%E{Audit.MetaBoundLib.DataSetInfo.SecuredLibrary}
    DataSetInfoSecLibGuid=%E{Audit.MetaBoundLib.DataSetInfo.SecuredLibraryGuid}
    DataSetInfoSecTableName=%E{Audit.MetaBoundLib.DataSetInfo.SecuredTableName}
    DataSetInfoSecTableGuid=%E{Audit.MetaBoundLib.DataSetInfo.SecuredTableGuid}
    LibraryInfoSecLib=%E{Audit.MetaBoundLib.LibraryInfo.SecuredLibrary}
    LibraryInfoSecLibGuid=%E{Audit.MetaBoundLib.LibraryInfo.SecuredLibraryGuid}
    RequiredPermission=%E{Audit.MetaBoundLib.RequiredPermission}
    UserEffectivePermissions=%E{Audit.MetaBoundLib.User.EffectivePermissions}
    Message=%m"/>
  </layout>
</appender>
```
Sample: Audit Message for a Metadata-Bound Library

Here is a sample message from the audit log:

DateTime=2012-02-15T17:48:28.671, Userid=JOE@COMPANY, StepName=DATASTEP, Action=Read, LoginId=JOE@COMPANY, IdentityName=Joe, Libref=REVENUE, OSLibraryPath=\machine.company.com\Data\Revenue, MemberName=CSV, MemberType=VIEW, DataSetInfoSecLib=/System/Secured Libraries/Data/, DataSetInfoSecLibGuid=5200B831-50A1-4E66-92CD-AD86ACDB43B7, DataSetInfoSecTabName=CSV.VIEW, DataSetInfoSecTabGuid=5BE37390-986F-45B4-8227-F3653C79768A, LibraryInfoSecLib=/System/Secured Libraries/Data, LibraryInfoSecLibGuid=5200B831-50A1-4B66-92CD-AD86ACDB43B7, RequiredPermission=Select,UserEffectivePermissions=None, Message=ERROR: JOE@COMPANY as Joe is not authorized to read data set REVENUE.CSV.VIEW. Select permission is required.
