Syntax Conventions for the SAS Language

Overview of Syntax Conventions for the SAS Language

SAS uses standard conventions in the documentation of syntax for SAS language elements. These conventions enable you to easily identify the components of SAS syntax. The conventions can be divided into these parts:

- syntax components
- style conventions
- special characters
- references to SAS libraries and external files

Syntax Components

The components of the syntax for most language elements include a keyword and arguments. For some language elements, only a keyword is necessary. For other language elements, the keyword is followed by an equal sign (=). The syntax for arguments has multiple forms in order to demonstrate the syntax of multiple arguments, with and without punctuation.

keyword
specifies the name of the SAS language element that you use when you write your program. Keyword is a literal that is usually the first word in the syntax. In a CALL routine, the first two words are keywords.

In these examples of SAS syntax, the keywords are bold:

CHAR (*string, position*)

CALL RANBIN (*seed, n, p, x*);

ALTER (*alter-password*)

BEST *w*.

REMOVE <*data-set-name*>

In this example, the first two words of the CALL routine are the keywords:

CALL RANBIN(*seed*, *n*, *p*, *x*)

The syntax of some SAS statements consists of a single keyword without arguments:

DO;
... *SAS code* ...
END;

Some system options require that one of two keyword values be specified:

DUPLEX | **NODUPLEX**

Some procedure statements have multiple keywords throughout the statement syntax:

CREATE <UNIQUE> **INDEX** *index-name* **ON** *table-name* (*column-1* <, *column-2*, ...>)

argument
specifies a numeric or character constant, variable, or expression. Arguments follow the keyword or an equal sign after the keyword. The arguments are used by SAS to process the language element. Arguments can be required or optional. In the syntax, optional arguments are enclosed in angle brackets (< >).

In this example, *string* and *position* follow the keyword CHAR. These arguments are required arguments for the CHAR function:

CHAR (*string, position*)

Each argument has a value. In this example of SAS code, the argument *string* has a value of 'summer', and the argument *position* has a value of 4:

```
x=char('summer', 4);
```

In this example, *string* and *substring* are required arguments, whereas *modifiers* and *startpos* are optional.

FIND(*string, substring* <, *modifiers*> <, *startpos*>

argument(s)
specifies that one argument is required and that multiple arguments are allowed. Separate arguments with a space. Punctuation, such as a comma (,) is not required between arguments.

The MISSING statement is an example of this form of multiple arguments:

MISSING *character(s)*;

<LITERAL_ARGUMENT> *argument-1* <<LITERAL_ARGUMENT> *argument-2* ... >
specifies that one argument is required and that a literal argument can be associated with the argument. You can specify multiple literals and argument

pairs. No punctuation is required between the literal and argument pairs. The ellipsis (...) indicates that additional literals and arguments are allowed.

The BY statement is an example of this argument:

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...>;

argument-1 <*options*> <*argument-2* <*options*> ...>
specifies that one argument is required and that one or more options can be associated with the argument. You can specify multiple arguments and associated options. No punctuation is required between the argument and the option. The ellipsis (...) indicates that additional arguments with an associated option are allowed.

The FORMAT procedure PICTURE statement is an example of this form of multiple arguments:

PICTURE name <(*format-options*)>
<*value-range-set-1* <(*picture-1-options*)>
<*value-range-set-2* <(*picture-2-options*)> ...>>;

argument-1=*value-1* <*argument-2*=*value-2* ...>
specifies that the argument must be assigned a value and that you can specify multiple arguments. The ellipsis (...) indicates that additional arguments are allowed. No punctuation is required between arguments.

The LABEL statement is an example of this form of multiple arguments:

LABEL *variable-1*=*label-1* <*variable-2*=*label-2* ...>;

argument-1 <, *argument-2*, ...>
specifies that one argument is required and that you can specify multiple arguments that are separated by a comma or other punctuation. The ellipsis (...) indicates a continuation of the arguments, separated by a comma. Both forms are used in the SAS documentation.

Here are examples of this form of multiple arguments:

AUTHPROVIDERDOMAIN (*provider-1:domain-1* <, *provider-2:domain-2*, ...>

INTO :*macro-variable-specification-1* <, :*macro-variable-specification-2*, ...>

Note: In most cases, example code in SAS documentation is written in lowercase with a monospace font. You can use uppercase, lowercase, or mixed case in the code that you write.

Style Conventions

The style conventions that are used in documenting SAS syntax include uppercase bold, uppercase, and italic:

UPPERCASE BOLD
identifies SAS keywords such as the names of functions or statements. In this example, the keyword ERROR is written in uppercase bold:

ERROR <*message*>;

UPPERCASE
identifies arguments that are literals.

In this example of the CMPMODEL= system option, the literals include BOTH, CATALOG, and XML:

CMPMODEL=BOTH | CATALOG | XML |

italic
identifies arguments or values that you supply. Items in italic represent user-supplied values that are either one of the following:

- nonliteral arguments. In this example of the LINK statement, the argument *label* is a user-supplied value and therefore appears in italic:

  LINK *label*;

- nonliteral values that are assigned to an argument.

  In this example of the FORMAT statement, the argument DEFAULT is assigned the variable *default-format*:

  FORMAT *variable(s)* <*format* > <DEFAULT = *default-format*>;

Special Characters

The syntax of SAS language elements can contain the following special characters:

=
an equal sign identifies a value for a literal in some language elements such as system options.

In this example of the MAPS system option, the equal sign sets the value of MAPS:

MAPS=*location-of-maps*

< >
angle brackets identify optional arguments. A required argument is not enclosed in angle brackets.

In this example of the CAT function, at least one item is required:

CAT (*item-1* <, *item-2*, ...>)

|
a vertical bar indicates that you can choose one value from a group of values. Values that are separated by the vertical bar are mutually exclusive.

In this example of the CMPMODEL= system option, you can choose only one of the arguments:

CMPMODEL=BOTH | CATALOG | XML

...
an ellipsis indicates that the argument can be repeated. If an argument and the ellipsis are enclosed in angle brackets, then the argument is optional. The repeated argument must contain punctuation if it appears before or after the argument.

In this example of the CAT function, multiple *item* arguments are allowed, and they must be separated by a comma:

CAT (*item-1* <, *item-2*, ...>)

'*value*' or "*value*"
indicates that an argument that is enclosed in single or double quotation marks must have a value that is also enclosed in single or double quotation marks.

In this example of the FOOTNOTE statement, the argument *text* is enclosed in quotation marks:

FOOTNOTE <*n*> <*ods-format-options* '*text*' | "*text*">;

;
a semicolon indicates the end of a statement or CALL routine.

In this example, each statement ends with a semicolon:

```
data namegame;
   length color name $8;
   color = 'black';
   name = 'jack';
   game = trim(color) || name;
run;
```

References to SAS Libraries and External Files

Many SAS statements and other language elements refer to SAS libraries and external files. You can choose whether to make the reference through a logical name (a libref or fileref) or use the physical filename enclosed in quotation marks.

If you use a logical name, you typically have a choice of using a SAS statement (LIBNAME or FILENAME) or the operating environment's control language to make the reference. Several methods of referring to SAS libraries and external files are available, and some of these methods depend on your operating environment.

In the examples that use external files, SAS documentation uses the italicized phrase *file-specification*. In the examples that use SAS libraries, SAS documentation uses the italicized phrase *SAS-library* enclosed in quotation marks:

```
infile file-specification obs = 100;
libname libref 'SAS-library';
```

What's New in Base SAS 9.4 Procedures

Overview

The following procedures are new:

- PROC AUTHLIB
- PROC DELETE
- PROC DS2
- PROC DSTODS2
- PROC FEDSQL
- PROC FMTC2ITM
- PROC HDMD
- PROC JSON
- PROC LUA
- PROC PRESENV
- PROC PRODUCT_STATUS
- PROC S3
- PROC SCOREACCEL
- PROC SQOOP
- PROC STREAM

The following Base SAS procedures have been enhanced:

PROC APPEND	PROC IMPORT
PROC CIMPORT	PROC MIGRATE
PROC CONTENTS	PROC OPTIONS
PROC COPY	PROC PRINT
PROC CPORT	PROC PRINTTO
PROC DATASETS	PROC PROTO

PROC EXPORT	PROC PWENCODE
PROC FCMP	PROC QDEVICE
PROC FONTREG	PROC REPORT
PROC FORMAT	PROC SOAP
PROC HADOOP	PROC SORT
PROC HDMD	PROC SQOOP
PROC HTTP	PROC XSL

New Base SAS Procedures

The AUTHLIB Procedure

The AUTHLIB procedure is a utility procedure that enables you to manage metadata-bound libraries. For more information, see Chapter 8, "AUTHLIB Procedure," on page 125.

SAS 9.4M1 has a new option for the AUTHLIB procedure. By using the REQUIRE_ENCRYPTION=YES option in the CREATE or MODIFY statements, an administrator can require that all data sets in a metadata-bound library be automatically encrypted when created. For more information, see "Requiring Encryption for Metadata-Bound Data Sets" on page 134.

SAS 9.4M3 has the following changes and enhancements for the MODIFY statement of the AUTHLIB procedure:

- The PURGE statement removes any retained metadata-bound library credentials older than a given date of replacement. For more information, see "PURGE Statement" on page 148 and "Retaining and Purging Metadata-Bound Library Credentials" on page 133.
- The MODIFY statement has a PURGE= option that automatically removes all retained metadata-bound library credentials if all tables in the library are successfully modified to the newer credentials. For more information, see "PURGE=YES | NO" on page 146 and "Retaining and Purging Metadata-Bound Library Credentials" on page 133.

SAS 9.4M5 adds a stronger encryption AES2 algorithm.

The DELETE Procedure

The DELETE procedure enables you to delete SAS files from the disk or tape on which they are stored. For more information, see Chapter 19, "DELETE Procedure," on page 785.

The DS2 Procedure

The DS2 procedure enables you to submit DS2 language statements from a Base SAS session. DS2 is a SAS programming language that is appropriate for advanced data manipulation and data modeling applications. For more information, see *SAS DS2 Language Reference*. DS2 supports many data types besides SAS character and numeric. When appropriate SAS/ACCESS software is installed, DS2 can manipulate data in some, but not all, SAS/ACCESS data sources. In SAS 9.0, the language supports access to SAS data sets, SAS Scalable Performance Data (SPD) Engine data sets, and tables from Aster, DB2 for UNIX and Windows operating environments, Greenplum, Netezza, SAP, Sybase IQ, and Teradata databases. For more information, see Chapter 21, "DS2 Procedure," on page 801.

SAS 9.4M1 has a new name for the INDB= procedure option. The name changed to DS2ACCEL=. The default value for the option also changed from YES to NO, which prevents DS2 code from executing in the database unless requested. INDB= is still supported as an alias. SAS 9.4M1 adds support for SAP HANA as a data source, when appropriate SAS/ACCESS software is installed.

SAS 9.4M2 has a new XCODE= procedure option that controls the behavior of the SAS session when an NLS transcoding failure occurs. In addition, the SYSCC macro variable now contains the current SAS condition code that is returned to your operating environment. SAS 9.4M2 adds support for Hive and PostgreSQL as data sources, when appropriate SAS/ACCESS software is installed.

SAS 9.4M3 adds a new LIBS= procedure option that enables you to override the default data source connection string that is sent the DS2 program, which includes all active librefs. LIBS= restricts the data source connection to the specified libref(s) and the Work library or User library (if a User library is defined). LIBS= can facilitate connections when many librefs are active in the SAS session. SAS 9.4M3 adds support for HAWQ and Impala as data sources, when appropriate SAS/ACCESS software is installed.

SAS 9.4M4 adds SAS Scalable Performance Data (SPD) Server tables as a data source. PROC DS2 can access SPD Server 5.3 and later.

SAS 9.4M5 adds the following new features:

- Support for Amazon Redshift, Microsoft SQL Server, and Vertica as data sources, when appropriate SAS/ACCESS software is installed.

- Support for SAS Cloud Analytic Services (CAS) tables as a data source. You must have SAS Viya 3.3 software in addition to SAS 9.4M5 software. You must start a CAS session. You connect to the CAS session by specifying a new SESSREF= or new SESSUUID= procedure option. The SESSREF= procedure option identifies the CAS session by its session name. The SESSUUID= procedure option identifies the session by its universally unique identifier (UUID). You work with data in memory. PROC DS2 provides no way to promote or persist data in CAS.

SAS 9.4M6 adds support for JDBC-compliant databases as data sources, when appropriate SAS/ACCESS software is installed.

PROC DS2 is included in SAS Viya beginning with SAS Viya 3.1. In SAS Viya 3.1, PROC DS2 supports SAS data sets and SAS Cloud Analytic Services (CAS) tables as data sources. The DS2 functionality of SAS 9.4 is available for SAS data sets. Most DS2 functionality is available in CAS, but not all of it. For information about the differences, see *SAS DS2 Programmer's Guide*. You must start a CAS session. You connect to the CAS session by specifying the SESSREF= or SESSUUID= procedure option. You must create tables or explicitly load tables in your CAS session before you can manipulate them with PROC DS2. All work is in the default caslib, unless you assign a caslib. For more information, see *SAS Cloud Analytic Services: User's Guide*. You work with CAS tables in memory. PROC DS2 cannot be used to persist tables to the CAS server or to promote them to other CAS sessions.

In SAS Viya 3.2, PROC DS2 can automatically load tables into the CAS session when you reference a caslib that specifies a SAS data connector.

SAS Viya 3.3 adds support for SPD Engine data sets and for all SAS 9.4 external data sources, except SPD Server, as data sources in SAS Viya. The procedure operates on the data sources on the SAS Compute Server by default. You can process external data sources that have a data connector in CAS by assigning a caslib and specifying the SESSREF= or SESSUUID= procedure option on the PROC DS2 statement. Not all data sources have data connectors. See information about available data connectors in *SAS Cloud Analytic Services: User's Guide*.

SAS Viya 3.4 adds the following features:

- Support for JDBC-compliant databases as data sources in SAS Viya. When appropriate SAS/ACCESS software is installed and a SAS library is assigned, you can process JDBC databases with all of the DS2 functionality that is available for a SAS library. When you start a CAS session and assign a caslib, you can process data from JDBC databases on the CAS server.
- Support for accessing SPD Server tables from SAS Viya. SPD Server tables are accessed by assigning a libref for the server using the SAS Viya client for SPD Server, SASSPDS. A SAS data connector is not available for SPD Server.

Beginning in April 2019, the MongoDB and Salesforce non-relational databases are supported as data sources for SAS 9.4M6. Access to both databases is Read-only and through a SAS library. Appropriate SAS/ACCESS software must be installed.

Beginning in August 2019, the Google BigQuery and Snowflake databases are supported as data sources for SAS 9.4M6 and for SAS Viya 3.4. Read and write access is supported from a SAS library and on the CAS server. Appropriate SAS/ACCESS software must be installed.

Beginning in November 2019 on SAS 9.4M6 and with SAS Viya 3.5, write access is available for MongoDB and Salesforce data sources. The write support is available through a SAS library and on the CAS server. Appropriate SAS/ACCESS software must be installed.

In addition in SAS Viya 3.5, the VARBINARY data type is supported for DS2 programming in CAS.

Beginning with SAS 9.4M7, Spark and Yellowbrick are supported as data sources, when appropriate SAS/ACCESS software is installed. Access is read and write through a SAS library only.

The DSTODS2 Procedure

SAS Viya 3.4 adds support for the new OUTDIR= argument that enables you to specify the output directory name for the file.

SAS 9.4M5 adds support for the DSTODS2 procedure. This procedure enables you to translate a subset of your SAS DATA step code into DS2 code. Then, if necessary, you can revise your program to take advantage of DS2 features and submit your program using PROC DS2. For more information, see Chapter 22, "DSTODS2 Procedure," on page 837.

The FEDSQL Procedure

The FEDSQL procedure enables you to submit FedSQL language statements from a Base SAS session. The FedSQL language is the SAS implementation of ANSI SQL:1999 core standard. FedSQL supports many more data types than SAS character and numeric and supports federated access to data.For more information about the FedSQL language, see *SAS FedSQL Language Reference*. When appropriate SAS/ACCESS software is installed, FedSQL can create, query, and update data in some, but not all, SAS/ACCESS data sources. In SAS 9.0, the language supports access to SAS data sets, SAS Scalable Performance Data (SPD) Engine data sets, and tables from Aster, DB2 for UNIX and Windows operating environments, Greenplum, Netezza, SAP, Sybase IQ, and Teradata databases. For more information, see Chapter 27, "FEDSQL Procedure," on page 1001.

SAS 9.4M1 adds support for SAP HANA as a data source, when appropriate SAS/ACCESS software is installed.

SAS 9.4M2 adds the new XCODE= option that controls the behavior of the SAS session when an NLS transcoding failure occurs. SAS 9.4M2 adds support for Hive and PostgreSQL as data sources, when appropriate SAS/ACCESS software is installed.

SAS 9.4M3 adds the following features:

- The new LIBS= procedure option enables you to override the default data source connection string that is sent the FedSQL program, which includes all

active librefs. LIBS= restricts the data source connection to the specified libref(s) and the Work library or User library (if a User library is assigned). LIBS= can facilitate connections when many librefs are active in the SAS session.

- Support for HAWQ and Impala as data sources, when appropriate SAS/ACCESS software is installed.
- The behavior of the QUIT statement is documented.

SAS 9.4M4 adds SAS Scalable Performance Data (SPD) Server tables as a data source. PROC FEDSQL can access SPD Server 5.3 and later. The documentation has been enhanced to include an example that shows how to use a DS2 package method as an expression.

SAS 9.4M5 adds the following new features:

- Support for Amazon Redshift, Microsoft SQL Server, and Vertica as data sources, when appropriate SAS/ACCESS software is installed.
- Support for SAS Cloud Analytic Services (CAS) tables as a data source. You must have SAS Viya 3.3 software in addition to SAS 9.4M5 software. You must start a CAS session. You connect to the CAS session by specifying a new SESSREF= or SESSUUID= procedure option. The SESSREF= option identifies the CAS session by its session name. The SESSUUID= option identifies the session by its universally unique identifier (UUID). You must load tables into CAS before you can operate on them using the CAS server. FedSQL functionality in CAS is limited. For more information, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*. You operate on tables in memory. PROC FEDSQL cannot be used to persist a table to the CAS server or to promote a table to another CAS session.

SAS 9.4M6 adds support for JDBC-compliant databases as data sources, when appropriate SAS/ACCESS software is installed.

PROC FEDSQL is included in SAS Viya applications beginning with SAS Viya 3.1. In SAS Viya 3.1, PROC FEDSQL supports SAS data sets and SAS Cloud Analytic Services (CAS) tables as data sources. The FedSQL functionality of SAS 9.4 is available for SAS data sets. A subset of the functionality that FedSQL has in SAS 9.4 is available for CAS tables. For information about CAS functionality, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*. You connect to a CAS session by specifying the SESSREF= or SESSUUID= procedure option. The SESSREF= option identifies the CAS session by its session name. The SESSUUID= option identifies the session by its universally unique identifier (UUID). You must explicitly load tables in your CAS session before you can submit FedSQL statements. You work with the CAS tables in memory. PROC FEDSQL cannot be used to persist tables to the CAS server or promote them to other CAS sessions.

SAS Viya 3.1 adds two procedure options. The new _METHOD procedure option prints a text description of the FedSQL query plan for executing the specified FedSQL statements. The new _POSTOPTPLAN procedure option prints an XML tree illustrating the FedSQL query plan.

In SAS Viya 3.2, PROC FEDSQL can automatically load tables into CAS when you reference a caslib that specifies a SAS data connector.

SAS Viya 3.3 adds support for SPD Engine data sets and for all SAS 9.4 external data sources, except SPD Server, as data sources in SAS Viya. The procedure

operates on the data sources on the SAS Compute Server by default. You can process external data sources that have a data connector in CAS by assigning a caslib and specifying the SESSREF= or SESSUUID= procedure option on the PROC DS2 statement. Not all data sources have data connectors. See information about available data connectors in *SAS Cloud Analytic Services: User's Guide*.

In addition, SAS Viya 3.3 adds the following new features in CAS:

- FedSQL implicit pass-through is available for SQL-based caslibs. In the previous SAS Viya release, with SAS data connector software, FedSQL automatically loaded data into CAS for processing. In SAS Viya 3.3, the FedSQL language supports single-source, full query implicit pass-through in CAS. When a request is accessing a single data source, an attempt is made to implicitly pass the full query down to the data source for processing. If pass-through is not possible, the request is loaded for processing in CAS. FEDSQL output is always an in-memory CAS table.
- PROC FEDSQL supports a new procedure option, CNTL=. CNTL= specifies optional control parameters for the FedSQL query planner in CAS.

SAS Viya 3.4 adds the following functionality:

- Support for JDBC-compliant databases as data sources in SAS Viya, when appropriate SAS/ACCESS software is installed. You can process JDBC databases with all of the FedSQL functionality that is available for a SAS library. When a caslib is assigned, you can process JDBC databases with the FedSQL functionality that is available in CAS.
- Support for explicit pass-through in CAS libraries. For more information, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.
- Support for accessing SPD Server tables from SAS Viya. SPD Server tables are accessed by assigning a libref for the server using the SAS Viya client for SPD Server (SASSPDS). A SAS data connector is not available for SPD Server.

Beginning in April 2019, the MongoDB and Salesforce non-relational databases are supported as data sources for SAS 9.4M6. Access to both databases is Read-only and through a SAS library. Appropriate SAS/ACCESS software must be installed.

Beginning in August 2019, the Google BigQuery and Snowflake databases are supported as data sources for SAS 9.4M6 and for SAS Viya 3.4. Read and Write access is supported from a SAS library and on the CAS server. Appropriate SAS/ACCESS software must be installed.

Beginning in November 2019 on SAS 9.4M6 and with SAS Viya 3.5, write access is available for MongoDB and Salesforce data sources. The write support is available from a SAS library and on the CAS server. Appropriate SAS/ACCESS software must be installed.

Also in SAS Viya 3.5:

- use of the UNION set operator is supported for FedSQL programming in CAS
- the VARBINARY data type is supported for FedSQL programming in CAS
- there are several CNTL= options for optimizing FedSQL performance on the CAS server: DYNAMICCARDINALITY, OPTIMIZEVARBINARYPRECISION, and

OPTIMIZEVARCHARPRECISION. For more information, see "CNTL=(*parameter*)" on page 1011.

- the output of the _METHOD procedure option has changed. This procedure option no longer returns the stage query and number of threads used by a FedSQL query plan in its textual description of the plan.
- there is a new CNTL= option, showStages, which returns the information previously printed by the _METHOD procedure option. In addition, showStages returns query execution details such as whether the tables in a query were partitioned, the number of rows and columns processed by each stage of the query, and the elapsed time for each processing stage.

Beginning with SAS 9.4M7, Spark and Yellowbrick are supported as data sources, when appropriate SAS/ACCESS software is installed. Access is read and write through a SAS library only.

The FMTC2ITM Procedure

The December 2017 release of SAS 9.4M5 adds support for the FMTC2ITM procedure. This procedure converts one or more format catalogs into a single CAS item store.

The HDMD Procedure

The HDMD procedure generates metadata that is defined in SAS for tables or files. It does not rely on Hive or HiveServer2.

The JSON Procedure

May 2022: The documentation has been updated to clarify the behavior of the KEYS | NOKEYS and SASTAGS | NOSASTAGS options. In addition, there are new examples: "Example 3: Suppressing SAS Variable Names in Observation Data When Using the EXPORT Statement" and "Example 5: Writing Values and Exporting Data in the Same Program".

The JSON procedure reads data from a SAS data set and writes it to an external file in JSON representation. For more information, see Chapter 38, "JSON Procedure," on page 1357.

The LUA Procedure

SAS 9.4M3 adds support for the LUA procedure. This procedure enables you to run Lua code within a SAS session and to call SAS functions within Lua commands. For more information, see Chapter 39, "LUA Procedure," on page 1403.

In SAS 9.4M5, the following enhancements were made for PROC LUA:

- For customers running SAS Viya, PROC LUA enables you to call CAS actions.
- The LUA_PATH environment variable was added. Use this environment variable to identify multiple locations for Lua scripts when one or more locations contains a special character, such as a single quotation mark.
- The SAS.OPEN function accepts data set options, such as KEEP=, DROP=, or WHERE=.
- The SAS.PUT_VALUE function replaces the SAS.PUT function from previous releases. The SAS.PUT_VALUE function requires you to identify a variable by its name only (and does not accept its position in the data set).
- Support for several functions from the TABLE library has been added. These functions are TABLE.CONCAT, TABLE.INSERT, TABLE.REMOVE, and TABLE.SORT.

In SAS Viya 3.3, support was added for the VARCHAR data type.

In SAS Viya 3.4, the following changes and enhancements were made:

- The Lua constant Math.Huge is now represented in SAS as the value 1.7976931348623E308. In previous releases, SAS represented this value as nil.
- Support has been added for the following string-manipulation functions. These functions are SAS extensions to the Lua language and can be used only within PROC LUA:

  STRING.ENDS_WITH STRING.STARTS_WITH
  STRING.RESOLVE STRING.TRIM
  STRING.SPLIT

In SAS 9.4M6, information about the scope of variables and other objects that are defined for PROC LUA was added to the documentation. For more information, see "Scope for PROC LUA" on page 1410.

The PRESENV Procedure

The PRESENV procedure preserves all global statements and macro variables in your SAS code from one SAS session to another. For more information, see Chapter 47, "PRESENV Procedure," on page 1739.

The PRODUCT_STATUS Procedure

The PRODUCT_STATUS procedure returns a list of the SAS Foundation products that are installed on your system, along with the version numbers of those products. For more information, see Chapter 50, "PRODUCT_STATUS Procedure," on page 1881.

Note: PROC PRODUCT_STATUS is deprecated for SAS Viya 3.5 and will not be available in future SAS Viya releases. PROC PRODUCT_STATUS is available to SAS 9.4 users.

The S3 Procedure

SAS 9.4M4 adds support for the S3 procedure. The S3 procedure enables you to perform object management for objects in Amazon S3. These objects include buckets, files, and directories. For more information, see Chapter 60, "S3 Procedure," on page 2259.

SAS 9.4M5 adds the following enhancements:

- PROC S3 can read AWS CLI configuration files. The AWSCONFIG= and PROFILE= options were added to the PROC S3 statement to support this feature. For more information, see "PROC S3 Configuration" on page 2261.
- Transfer acceleration is available when data is uploaded or downloaded. The BUCKET and GETACCEL statements were added to support this feature. For more information, see "Transfer Acceleration" on page 2265.

The S3 procedure is now available in SAS Viya 3.3.

The following enhancements were made in SAS Viya 3.4:

- Additional regions are supported in the configuration file and the REGION= argument. These additional regions are apindia, apseoul, cacentral, cnbeijing, cnningxa, eulondon, euparis, and useastoh.
- The AWSCREDENTIALS= option was added. This option enables you to specify alternative locations for the credentials file.
- The CREDENTIALSPROFILE= option was added. This option enables you to specify the profile to use in the credentials file.

In SAS 9.4M6, support was added for encryption when working with the Amazon S3 or Amazon Redshift environment. This support includes the new ENCKEY statement that enables you to register encryption keys. There are also new options available with the COPY, GET, GETDIR, INFO, PUT, and PUTDIR statements that

enable encryption. For more information, see "Using Server-Side Encryption with AWS Data" on page 2264.

In SAS 9.4M7 and SAS Viya 3.5, support was added for the OUT= option in the LIST statement. This option enables you to save LIST output to an external file.

Also in SAS 9.4M7, support was added for the ROLENAME= and ROLEARN= options in the PROC S3 statement.

In the May 2021 update for SAS 9.4M7 and SAS Viya 3.5, support was added for the SESSION= option in the PROC S3 statement. This option enables you to specify an AWS session token.

In the July 2021 update for SAS Viya 3.5, support was added for the REGION statement for PROC S3. This statement enables you to define a custom region.

In the August 2021 update for SAS Viya 3.5, support was added for the HOST= option in the REGION statement.

In the May 2022 update for SAS 9.4M7 and SAS Viya 3.5, the CREDENTIALSPROFILE= option is no longer supported.

In SAS 9.4M8, support has been added for EC2 Instance Metadata Service version 2 (IMDSv2) and the REGION statement.

The SCOREACCEL Procedure

SAS Viya 3.3 adds support for the SCOREACCEL procedure. You can use this procedure to publish and execute DATA step and DS2 models in CAS, or in an external database.

In SAS Viya 3.4, the following enhancements have been made to the SCOREACCEL procedure:

- The DELETEMODEL statement enables you to delete models previously published to CAS, Teradata, and Hadoop.
- The AUTHDOMAIN option is added to the PUBLISHMODEL, RUNMODEL, and DELETEMODEL statements. This option enables you to specify the name of the authentication domain that contains the credentials that are used to access Teradata.
- The PUBLISHMODEL statement now supports the FORMATITEMSTOREFILE and STORETABLES options. The FORMATITEMSTOREFILE option enables you to specify the file containing the format item store to be published. The STORETABLES option enables you to specify one or more CAS blob table names that contain the analytic stores to be published.
- The KEEPLIST option in the PUBLISHMODEL statement enables you to specify whether to include a KEEP statement in the DS2 model program that was automatically generated from an analytic store model.
- The PLATFORM option in the RUNMODEL statement enables you to specify MAPRED or SPARK as the platform where the Hadoop Embedded Process is to be executed.

- The CONFIGPATH option in the RUNMODEL statement enables you to specify a folder where the Hadoop and Spark configuration files reside.

SAS Viya 3.5 adds support for publishing a model to a global model table. The PUBLISHGLOBAL= option in the PUBLISHMODEL statement enables you to publish a model to a global model table, and the DELETEGLOBAL= option in the DELETEMODEL statement enables you to delete a model from a global model table.

SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix) adds the following options:

- The WEBHDFSURL= option specifies a URL to delete, publish, or run a model in a platform that is configured to access the distributed file system through the REST API.
- The JOBMANAGEMENTURL= option specifies a URL to submit execution requests over a REST interface to services such as Apache Livy.
- The INDATASET= and OUTDATASET= options provide additional support for Spark.

For more information, see Chapter 62, "SCOREACCEL Procedure," on page 2305.

The SQOOP Procedure

SAS 9.4M3 adds support for the SQOOP procedure. You can use this procedure to access Apache Sqoop within a SAS session so that you can transfer data between a database and HDFS. A separate license to SAS/ACCESS Interface to Hadoop is required to use this procedure. For more information, see Chapter 66, "SQOOP Procedure," on page 2413.

The STREAM Procedure

The STREAM procedure enables you to process an input stream that consists of arbitrary text that can contain SAS macro specifications. It can expand macro code and store it in a file. For more information, see Chapter 68, "STREAM Procedure," on page 2441.

Enhanced Base SAS Procedures

The APPEND Procedure

The following enhancements have been made to the APPEND procedure:

- ENCRYPTKEY= option specifies the key value for an AES-encrypted data set. For more information, see ENCRYPTKEY= on page 616.
- Extended attributes are customized metadata for your SAS files. They are user-defined characteristics that you associate with a SAS data set or variable. For more information, see “Extended Attributes” on page 567.

The CIMPORT Procedure

The following enhancements have been made to the CIMPORT procedure:

- PROC CIMPORT does not import data miner database catalog entries that were generated from SAS 9.3 or earlier versions of SAS. A warning message is logged.
- Extended attributes in data sets are supported in SAS 9.4. Transporting a file using PROC CIMPORT where the data sets contain extended attributes requires that you use SAS 9.4 or later. Refer to information about Extended Attributes in Chapter 17, “DATASETS Procedure,” on page 561 and to “Error and Warning Messages for Transport Files ” in *Moving and Accessing SAS Files* for details.
- In SAS 9.4, when you use PROC CPORT to create a transport file that is encoded with US-ASCII on an ASCII platform, regardless of the session encoding, the encoding value is set to US-ASCII encoding. If you then use PROC CIMPORT to transport the data set to an ASCII platform, the US-ASCII encoding is preserved and not transcoded.
- In SAS 9.4, the COMPRESS= option is added to allow compressing the CIMPORT data set. You can specify the type of compression used.
- SAS 9.4M1 has the following changes and enhancements:
  - The ENCODINGINFO=option provides the ability to determine the encoding of the data sets in the transport file. The encoding information is written to the SAS log. For more information, see ENCODINGINFO= on page 394.

  - Data sets with time zone offsets can now be transported using PROC CPORT (with the DATECOPY option specified) and PROC CIMPORT. For more information, see "DATECOPY" on page 542.

- SAS 9.4M2 adds the SORT option to PROC CIMPORT. This option causes the data set that is being imported to be re-sorted according to the destination operating system's collating sequence. For more information, see "SORT" on page 398.
- SAS 9.4M3 adds support to PROC CIMPORT for importing data sets created in non-UTF-8 SAS sessions into UTF-8 SAS sessions. Prior to this release, transport files were encoded in a Windows encoding that corresponded to the SAS session encoding.
- In SAS Viya 3.5, PROC CIMPORT can be used to import a file that was created in UTF-8 encoding into non-UTF-8 SAS sessions and output corresponding data sets.
- SAS Viya 3.5 adds options EXTENDVAR= and the EXTENDFORMAT = options to PROC CIMPORT. When a transport file is imported, the original string variable length might not be large enough for the transcoded strings.To ensure that your destination buffer size is sufficient for the transcoded data, specify the EXTENDVAR= and the EXTENDFORMAT = options.

  Note: The EXTENDAVAR= and EXTENDFORMAT= options are not supported in SAS 9.

For more information, see CIMPORT Procedure on page 389.

The CONTENTS Procedure

The following enhancements have been made to the CONTENTS procedure:

- ENCRYPTKEY= option specifies the key value for an AES-encrypted data set. For more information, see ENCRYPTKEY= on page 616.
- Extended attributes are customized metadata for your SAS files. They are user-defined characteristics that you associate with a SAS data set or variable. For more information, see "Extended Attributes" on page 567.
- The TRANSCODE option indicates whether the variable is transcoded. For more information, see "The OUT= Data Set" on page 683.

SAS 9.4M5 adds support for the VARCHAR data type. PROC CONTENTS output shows the number of bytes and characters for variables.

The COPY Procedure

The following enhancements have been made to the COPY procedure:

- ENCRYPTKEY= option specifies the key value for an AES-encrypted data set. For more information, see ENCRYPTKEY= on page 616.
- Extended attributes are customized metadata for your SAS files. They are user-defined characteristics that you associate with a SAS data set or variable. For more information, see "Extended Attributes" on page 567.

SAS 9.4M5 adds support for the VARCHAR data type.

In SAS 9.4M5, you can copy a CAS table to another CAS table on the CAS server.

The CPORT Procedure

The following enhancements have been made to the CPORT procedure:

- PROC CPORT does not export data miner database catalog entries that were generated from SAS 9.3 or earlier versions of SAS. A warning message is logged.
- Extended attributes in data sets are supported in SAS 9.4. Transporting a file using PROC CPORT where the data sets contain extended attributes requires that you run SAS 9.4 or later. Refer to information about Extended Attributes in Chapter 17, "DATASETS Procedure," on page 561 and to "Error and Warning Messages for Transport Files " in *Moving and Accessing SAS Files* for details.
- In SAS 9.4, when you use PROC CPORT to create a transport file that is encoded with US-ASCII on an ASCII platform, regardless of the session encoding, the encoding value is set to US-ASCII encoding. If you then use PROC CIMPORT to transport the data set to an ASCII platform, the US-ASCII encoding is preserved and not transcoded.
- SAS 9.4M1 adds support for transporting data sets that have time zone offsets using PROC CPORT (with the DATECOPY option specified) and PROC CIMPORT. For more information, see "DATECOPY" on page 542.

For more information, see CPORT Procedure on page 537.

The DATASETS Procedure

The following enhancements have been made to the DATASETS procedure:

- The DATASETS procedure supports extended attributes. For more information, see "Extended Attributes" on page 567. The following statements were added to the DATASETS procedure to enable you to manage extended attributes.
  - XATTR ADD on page 660 statement adds extended attributes to variables or data sets.
  - XATTR DELETE on page 661 statement deletes extended attributes from variables or data sets.
  - XATTR OPTIONS on page 662 statement specifies options for extended attributes.

  - XATTR REMOVE on page 662 statement removes extended attributes to variables or data sets.
  - XATTR SET on page 663 statement updates or adds extended attributes to variables or data sets.
  - XATTR UPDATE on page 664 statement updates extended attributes in variables or data sets.
- The APPEND, COPY, and CONTENTS statements support AES encryption. For more information, see "Appending AES-Encrypted Data Sets" on page 592, "Copying AES-Encrypted Data Files" on page 623, and "Library Contents and AES Encryption" on page 498.
- The CONTENTS statement prints the International Components for Unicode (ICU) revision number. For more information, see "Displaying the ICU Revision Number" on page 498.

SAS 9.4M5 adds support for the VARCHAR data type for the COPY and CONTENTS statements.

The EXPORT Procedure

The following enhancements have been made to the EXPORT procedure:

- SAS Viya 3.5 adds support for all access types that are available in the FILENAME statement.
- SAS 9.4M5 adds support for the VARCHAR data type.
- SAS 9.4M1 adds support for exporting CSV files with a SAS data set name that contains a single quotation mark when the VALIDMEMNAME=EXTEND system option is specified. Using VALIDMEMNAME= expands the rules for SAS data set names. For more information, see "Using the External File Interface (EFI) " in *SAS/ACCESS Interface to PC Files: Reference*.
- The following is true for JMP files:
  - SAS 9.4 imports data from JMP files that are saved in JMP 7 or later formats, and it exports to files in JMP 7 or later formats. File formats in JMP 3 through 6 are no longer supported. Support for these newer formats enables you to access JMP files for viewing in a variety of ways, such as with the JMP Graph Builder iPad app.
  - The META data type for JMP files is no longer supported. Instead, extended attributes are automatically used. META can remain in programs but doing so generates a NOTE in the log and the statement is ignored.
  - The META statement for PROC EXPORT is no longer supported for JMP files and is ignored. Instead, extended attributes are automatically used.
  - JMP variable names can be up to 255 characters in length.
  - The ROWSTATE data type is generated by JMP and is used to store several row-level characteristics. When PROC EXPORT sees a column named **_rowstate_**, it converts it back into row state information in the output JMP

file. (If the JMP file contains row state information, then PROC IMPORT stores this information as a new variable with the name **_rowstate_**.)

- For more information, see Chapter 23, "EXPORT Procedure," on page 849.

For more information, see Chapter 23, "EXPORT Procedure," on page 849.

The FCMP Procedure

The following enhancements have been made to the FCMP procedure:

- The FCMP procedure now contains an example that compares the RUN_MACRO function and the DOSUBL function. In the RUN_MACRO invocation, all variables are passed as arguments so that they can be set. In the DOSUBL invocation, all macro variables are imported to the code to be executed and then exported on completion. For more information, see "RUN_MACRO Function" on page 971.
- PROC OPTMODEL has been added to the table that lists the procedures which you can use for functions and subroutines that you create in PROC FCMP. For more information, see Overview: FCMP Procedure on page 874.

SAS 9.4M3 adds the STATIC statement. For more information see "STRUCT Statement" on page 896 .

SAS 9.4M5 adds dictionary and ASTORE support to PROC FCMP. For more information see "Dictionaries" on page 918 and "PROC FCMP and ASTORE" on page 918.

SAS 9.4M6 adds these options:

OUTFILE=*filename*
: writes referenced functions and the main program to a text file. Programs that have been parsed by PROC FCMP, including macro variables, can be exported.

OUTITEMSTORE=*path name*
: exports symbols, referenced functions, and the main program to the specified item store. OUTITEMSTORE does not support a fileref. You must use a quoted path.

In SAS Viya 3.5, the quoted string size limit and label size limit for PROC FCMP were updated to match the DATA step size limits. PROC FCMP now supports quoted strings up to 32,767 bytes and labels up to 256 bytes.

The FMTC2ITM Procedure

SAS 9.4M5 adds support for the ENCODING= option. The new option enables you to specify an encoding for a format catalog or for all format catalogs in a list. For more information, see "ENCODING=*encoding-name*" on page 1051.

The FONTREG Procedure

SAS 9.4M2 has the following changes and enhancements to the FONTREG procedure:

- The OPENTYPE statement was added. This statement specifies one or more directories to be searched for valid OpenType font files.
- The ability to use a fileref was added. This ability enables you to use the FILENAME statement and its features.

For more information, see Chapter 29, "FONTREG Procedure," on page 1057.

The FORMAT Procedure

The following enhancements have been made to the FORMAT procedure:

- A month can be formatted using a shortened version by specifying the number of characters to use in the %*n*B directive.
- The range to specify a default length of an informat, picture, or format 1-32767.
- You can create a format based on a Perl regular expression by using the INVALUE statement options REGEXP and REGEXPE.

For more information, see FORMAT Procedure on page 1075.

The HADOOP Procedure

The following enhancements have been made to the HADOOP procedure:

- The HADOOP procedure now provides the PROPERTIES statement to submit configuration properties to the Hadoop server.
- You can now specify the NOWARN option in the HDFS statement to suppress the Warning message when there is an attempt to delete a file that does not exist.
- SAS 9.4M3 has the following changes and enhancements:
  - The HDFS statement supports the CAT= option to display the contents of files, the CHMOD= option to change file access permissions, and the LS= option to list HDFS files.
  - Several HDFS statement options support wildcard characters when you specify HDFS files and request recursive action to execute the operation on the specified directory as well as subdirectories.

- You can connect to the Hadoop cluster by copying the Hadoop cluster configuration files to a physical location that is accessible to the SAS client machine, and then set a SAS environment variable to the location of the configuration files.
- You can submit a MapReduce program and Pig language code to a Hadoop cluster through the Apache Oozie RESTful API.

The HADOOP procedure is available in both SAS 9.4 and in SAS Viya. However, the HADOOP procedure is not supported in a CAS session

For more information, see Chapter 33, "HADOOP Procedure," on page 1233.

The HDMD Procedure

The HDMD procedure is available in SAS Viya 3.4, but it is not supported in a CAS session.

SAS 9.4M5 supports the NAME= option, where you can specify Hadoop or the new Spark data source.

In SAS 9.4M6, Hive 3.0 supports managed, external, and transactional tables. By default, a new table is created as managed and transactional.

The HTTP Procedure

The following enhancements were made to the HTTP procedure:

- SAS 9.4 adds the SSLCALISTLOC system option to configure the trust source for connections that use the HTTPS protocol. The Java system options that were used to configure this trust source in previous versions of SAS software are no longer supported.
- SAS 9.4M1 has the following changes and enhancements:
  - The HTTP_TOKENAUTH option is added to enable you to generate a one-time password from the metadata server that can be used to access the SAS Content Server.
  - PROC HTTP supports user identity authentication. If the server that you are connecting to support the NTLM (for Windows only) or the Kerberos authentication protocols, then you do not need to specify a user name and password. As long as your current user identity has permissions, authentication is established.
- SAS 9.4M3 expands method support for PROC HTTP to include all methods that support the HTTP/1.1 standard and are supported by the target server. It also adds a HEADER statement, authentication type specification, and HTTP/1.1 features such as persistent connections, cookie caching, and EXPECT_100_CONTINUE support. Input data can be specified in a quoted string or submitted from a fileref. Custom request headers can be specified as

name=value pairs in a HEADERS statement or by submitting a fully formatted input file from a fileref. For web servers that support it, the procedure uses connection caching and cookie caching by default. You can toggle the behavior of both types of caching and clear the caches within the procedure by specifying procedure arguments. Or you turn cookie caching off by using a macro variable. A HEADEROUT_OVERWRITE argument is also provided to manage response headers for requests that involve redirects.

- The SSLCALISTLOC= system option is configured globally for the SAS system. It should not be changed for a specific PROC HTTP request.
- SAS 9.4M5 adds a DEBUG statement, TIMEOUT= procedure option, and PROC HTTP response status macro variables. The DEBUG statement and macro variables expand the messaging available for the procedure. TIMEOUT= specifies the number of seconds of inactivity to wait before canceling an HTTP request. SAS 9.4M5 also adds the OAUTH_BEARER= procedure option. OAUTH_BEARER= sends an OAuth token along with the HTTP call.

  SAS 9.4M6 adds a new statement, SSLPARMS, new options for the DEBUG statement, and changes the default DEBUG output format for body components to binary. The settings in the SSLPARMS statement enable you to override the global secure communication settings for the SAS system with local settings for the PROC HTTP request. The local settings last for the duration of the HTTP request. The new DEBUG options enable you to request debugging information about individual components of the PROC HTTP request instead of or in addition to messages for a debug level. The request header body and response header body are now written as binary by default. An OUTPUT_TEXT option is provided to request them as text.

The HTTP procedure is available in both SAS 9.4 and in SAS Viya. The initial versions of SAS Viya have the same functionality as SAS 9.4M3.

- SAS Viya 3.3 adds the DEBUG statement, the TIMEOUT= procedure option, and the PROC HTTP response status macro variables to SAS Viya. It also adds a new OAUTH_BEARER= procedure option and a new value for OAUTH_BEARER=, the constant SAS_SERVICES. The SAS_SERVICES constant is supported in SAS Viya only.
- In May 2019, the documentation was updated to include the following:
  - three new procedure options: AUTH_NONE, FOLLOWLOC, and NOFOLLOWLOC. AUTH_NONE specifies not to use basic authentication, NTLM authentication, or to negotiate authentication, even when authentication using one of these methods is possible. The OAUTH_BEARER= procedure option can be used with AUTH_NONE. FOLLOWLOC enables methods that write data to be automatically redirected to an alternate URL. NOFOLLOWLOC prevents the GET method from following URL redirections.
  - Aliases for the WEBUSERNAME= and WEBPASSWORD= procedure options. WEBUSERNAME= supports the alias USERNAME=. WEBPASSWORD= supports the alias PASSWORD=.

  In addition:

  - The CLEAR_COOKIE_CACHE procedure option has been renamed to CLEAR_COOKIES.

- The NO_COOKIE_CACHE option has been renamed to NO_COOKIES.
- Support for the OAUTH_BEARER= procedure option has been clarified.

- SAS Viya 3.5 adds the SSLPARMS statement to SAS Viya.

  In addition, SAS Viya 3.5 and the November 2019 release of SAS 9.4M6 add two new procedure options, two new parameters for the IN= procedure option, change quoting requirements for the METHOD= procedure option, and include a documentation enhancement.

  - The MAXWAITS= procedure option enables you to specify the maximum number of redirects that are allowed.
  - The QUERY= procedure option enables you to submit URL-encoded query parameters for the URL= argument.
  - The FORM parameter to the IN= procedure option enables you to send input data as a standard HTML form.
  - The MULTI parameter to the IN= procedure option enables you to upload generic multipart data or generic form data, when it is used with the FORM option. When the FORM option is used, the upload is performed using the specialized multipart type known as multipart/form-data.
  - The METHOD= procedure option no longer requires the *http-method* argument to be quoted.
  - The documentation now describes how to send chunked data in the HEADERS statement.

- In May 2022, the documentation was updated to include a new example: "Specify Local Options for Two-Way Encryption in UNIX".

For more information, see Chapter 35, "HTTP Procedure," on page 1279.

The IMPORT Procedure

The following enhancements have been made to the IMPORT procedure:

- SAS Viya 3.5 adds support for all access types that are available in the FILENAME statement.
- SAS 9.4M5 adds support for the VARCHAR data type.
- SAS 9.4M1 adds support for exporting CSV files with a SAS data set name that contains a single quotation mark when the VALIDMEMNAME=EXTEND system option is specified. Using VALIDMEMNAME= expands the rules for SAS data set names. For more information, see "Using the External File Interface (EFI) " in *SAS/ACCESS Interface to PC Files: Reference*.
- The following is true for JMP files:
  - SAS 9.4 imports data from JMP files that are saved in JMP 7 or later formats, and it exports to files in JMP 7 or later formats. File formats in JMP 3 through 6 are no longer supported. Support for these newer formats enables

you to access JMP files for viewing in a variety of ways, such as with the JMP Graph Builder iPad app.

- The META data type for JMP files is no longer supported. Instead, extended attributes are automatically used. META can remain in programs but doing so generates a NOTE in the log and the statement is ignored.
- The META statement for PROC IMPORT is no longer supported for JMP files and is ignored. Instead, extended attributes are automatically used. When importing a JMP file with extended attributes, the attributes are automatically attached to the new SAS data set.
- JMP variable names can be up to 255 characters in length.
- The ROWSTATE data type is generated by JMP and is used to store several row-level characteristics. When the JMP file contains row state information, PROC IMPORT stores this information as a new variable with the name **_rowstate_**. (If PROC EXPORT sees a column named **_rowstate_**, then it converts it back into row state information in the JMP output file.)

For more information, see "JMP Files" in *SAS/ACCESS Interface to PC Files: Reference* and Chapter 36, "IMPORT Procedure," on page 1323.

The MEANS Procedure

- Beginning with SAS 9.4M5, PROC MEANS summarization can be executed on the CAS server.
- SAS supports In-Database processing for PROC MEANS.
  - SAS 9.4M3 supports In-Database processing for PROC MEANS with the Impala, HAWK, and SAP HANA database management systems.

The MIGRATE Procedure

The following enhancements have been made to the MIGRATE procedure:

- Extended attributes are supported for data sets. For more information, see MIGRATE Procedure on page 1559.
- SAS 9.4M3 has a new default value for BUFSIZE. The new default is the buffer page size of the current session. To continue using the previous behavior, which is to clone the page size of the members from the source library, specify BUFSIZE=KEEPSIZE.

The OPTIONS Procedure

The following enhancements have been made to the OPTIONS procedure:

- The LISTOPTSAVE option lists the system options that can be saved by using the OPTSAVE procedure or the DMOPTSAVE command. For more information, see "PROC OPTIONS Statement" on page 1582.
- SAS 9.4M2 enhances the OPTIONS procedure to display passwords in the SAS log as eight Xs, regardless of the actual password length.

The PRINT Procedure

The following enhancements have been made to the PRINT procedure:

- The PROC PRINT SUMLABEL= option and the GRANDTOTAL_LABEL= option enable you to specify labels for the BY group total and grand total values.
- The PROC PRINT statement STYLE= option style attributes for the HEADER location no longer affect the Obs column heading. You specify style attributes for the Obs column heading using the OBSHEADER location.
- In SAS 9.4M6, the PROC PRINT CONTENTS= option on page 1759 accepts #BY directives.
- SAS 9.4M5 adds support for the VARCHAR data type.

For more information, see PRINT Procedure on page 1857.

The PRINTTO Procedure

The PROC PRINTTO PRINT= statement opens the LISTING destination. You no longer need to specify the ODS LISTING statement before you use the PRINTTO procedure. For more information, see Chapter 49, "PRINTTO Procedure," on page 1857.

SAS 9.4M3 has an enhancement to restore the previous location of the SAS log and LISTING output files. SAS saves the path of the SAS log and LISTING output files in automatic macro variables. For more information, see Chapter 49, "PRINTTO Procedure," on page 1857.

The PROTO Procedure

SAS 9.4M6 has a new system option, PROTOLIBS, that SAS administrators can use to control the function of the LINK statement. Controlling the function of the LINK statement can prevent security issues that might occur by calling third-party software to a valid path for a load module that contains your functions. For more information, see "The PROTOLIBS System Option" on page 1897.

The PWENCODE Procedure

The following enhancements have been made to the PWENCODE procedure:

- Encoding method SAS004 is added. SAS004 uses AES encryption with a 256-bit fixed key and a 64-bit random salt value. The salt size was increased to 64 bits to comply with the minimum recommended salt size for PKCS #5: Password Based Cryptography Specification Version 2.0.
- SAS 9.4M5 adds encoding method SAS005. SAS005 uses AES encryption with a 256-bit fixed key and a 64-bit random salt value. SAS005 increases security for stored passwords by using the SHA-256 hashing algorithm and is hashed for additional iterations.

The QDEVICE Procedure

The following enhancements have been made to the QDEVICE procedure:

- The PROC QDEVICE DEVLOC= option enables you to specify a device library other than the SAS/GRAPH Gdevice*n* libraries and the Sashelp library. You can report on the first occurrence of a device, or you can report on all occurrences of a device in the Gdevice*n* and Sashelp libraries.
- The PROC QDEVICE CATALOG= option enables you to specify a catalog, other than the DEVICES catalog, to search.
- The DEVICE statement and the PRINTER statement allow the wildcards * and ? in device names and printer names.
- The value for a Windows printer device type, as reported by the TYPE variable, is Printer Interface Device. Printer Interface Device replaces the value System Printer.
- For all reports, the NAMETYPE variable has been renamed to TYPE.
- The General report includes new this information:
  - The ALIAS variable reports font aliases.

  - The ANIMATION variable reports on the status of printer animation.
  - The FVERSION variable reports the font version.
  - The COMPRESSION variable now indicates a condition under which compression is used.
  - The COMPMETHOD variable indicates the compression method.
  - The MODULE variable reports the name of the device driver module.
  - The character variable lengths in a report output data set are now a fixed length.
- The Font reports now include information for font aliases and font versions. The new variables are ALIAS and FVERSION, respectively.
- For all reports, except the General report, information about prototypes has been removed. The PROTOTYPE variable information is now reported in only the General report.
- Character variable lengths in report output data sets have a fixed length of 128 characters. The LENGTH statement is no longer required when reports are merged or concatenated.

For more information, see QDEVICE Procedure on page 1951.

The REPORT Procedure

The following enhancements have been made to the REPORT procedure:

- In SAS 9.4M6, the following options are supported.
  - the CONTENTS= option in the PROC REPORT statement accepts #BY directives when the ACCESSIBLETABLE system option is specified.
  - the CAPTION= option can be specified in the PROC REPORT statement and creates visual and accessible table captions when the ACCESSSIBLETABLE system option is specified.
- In-Database processing for PROC REPORT is supported as follows:
  - In-Database processing for PROC REPORT supports the Aster, Greenplum, and Hadoop database management systems.
  - SAS 9.4M6 supports In-Database processing for PROC REPORT with the Google BigQuery database management system.
  - SAS 9.4M7 supports In-Database processing for PROC REPORT with the Yellowbrick database management system.
- NOWINDOWS (NOWD) is now the default windowing environment for PROC REPORT.
- SAS 9.4M2 has the following changes and enhancements:
  - A new section was added to describe the use of ODS Styles with PROC REPORT. For more information, see "Using ODS Styles with PROC REPORT" on page 2142.

  - PROC REPORT now supports statistical keywords P20, P30, P40, P60, P70, and P80. For information, see "Statistics That Are Available in PROC REPORT" on page 2140.

- In SAS 9.4M6, the PROC PRINT CONTENTS= option on page 1759 accepts #BY directives.

Beginning with SAS 9.4M5, PROC REPORT summarization can be executed on the CAS server.

For more information, see Chapter 58, "REPORT Procedure," on page 2047.

Starting with SAS 9.4M6, you can specify the CAPTION= option in the PROC REPORT statement and specify the ACCESSIBLETABLE system option to add visible captions to the tables. Starting with SAS 9.4M6, when BY directives are specified in the CAPTION= and CONTENTS= options, labels for the BY group tables are displayed in the table of contents in PDF output and in the contents file in HTML output. The labels are based on the values of the BY variable.

The SOAP Procedure

SAS 9.4M2 removed support for the SOAP procedure when SAS is in a locked-down state. For more information, see Chapter 63, "SOAP Procedure," on page 2341.

The SORT Procedure

The following enhancements have been made to the SORT procedure:

- PROC SORT supports extended attributes. PROC SORT copies the attributes that are defined for the data set to the output data set. For more information, see "Extended Attributes" on page 567.
- The page size of the utility file that is used by PROC SORT is influenced by the new STRIPESIZE= system option. For more information, see "STRIPESIZE= System Option" in *SAS System Options: Reference*.
- In SAS 9.4, the International Components for Unicode (ICU) library used by PROC SORT is 4.8.1. This ICU version uses locale data from version 2.0 of the Unicode Common Locale Data Repository (CLDR), improves language support, and provides software fixes. For more information, see Download the ICU 4.8 Release and CLDR 2.0 Release Note.

  A change in the ICU version used by SAS can affect the interpretation of some data sets sorted by previous versions of SAS. For information about these effects, see Chapter 64, "SORT Procedure," on page 2355, Chapter 15, "COPY Procedure," on page 521, and Chapter 41, "MIGRATE Procedure," on page 1559.
- The CONTENTS procedure or CONTENTS statement output shows the ICU version number of a data set that is linguistically sorted. See "Example 5: Linguistic Sorting Using ALTERNATE_HANDLING=" on page 2401.

- SAS supports In-Database processing for PROC SORT.
  - SAS 9.4M3 supports In-Database processing for PROC SORT with the Impala, HAWK, and SAP HANA database management systems.
  - SAS 9.4M6 supports In-Database processing for PROC SORT with the Google BigQuery database management system.
  - SAS 9.4M7 supports In-Database processing for PROC SORT with the Yellowbrick database management system.
- SAS Viya 3.4 supports ICU version 56. This ICU version uses locale data from version 28 of the Unicode Common Locale Data Repository (CLDR). For in-depth information, see Download ICU 56 and CLDR 28 Release Note.
- In SAS Viya 3.5, PROC SORT supports the ability to run the duplicate detection and manipulation options (NODUPKEY, NOUNIKEY, DUPOUT=, UNIOUT=) in CAS. This functionality is provided to facilitate migration of code for users of SAS Viya. This task is performed by using the deduplicate Action.

For more information, see Chapter 64, "SORT Procedure," on page 2355.

The SQOOP Procedure

For SAS 9.4M5, PROC SQOOP supports workflows and Kerberos on Linux, and the WFHDFSPATH= option is now optional.

In SAS Viya 3.5, support was added for the HIVE_SERVER= and HIVE_URI= options.

The SUMMARY Procedure

- Beginning with SAS 9.4M5, PROC SUMMARY summarization can be executed on the CAS server.
- SAS supports In-Database processing for PROC SUMMARY.
  - SAS 9.4M3 supports In-Database processing for PROC SUMMARY with the Impala, HAWK, and SAP HANA database management systems.
  - SAS 9.4M7 supports In-Database processing for PROC SUMMARY with the Yellowbrick database management system.

The TABULATE Procedure

The following enhancements have been made to the TABULATE procedure:

- In SAS 9.4M6, the CONTENTS= option in the TABLE statement and the PROC TABULATE statement now accepts #BY directives.

- In SAS 9.4M6, the CAPTION= option is new for the TABLE statement.
- In SAS 9.4M6, PROC TABULATE provides the ability to create accessible output tables when used with the ACCESSIBLETABLE system option.
- Beginning with SAS 9.4M5, PROC TABULATE summarization can be executed on the CAS server.
- SAS supports In-Database processing for PROC TABULATE.
  - SAS 9.4M6 supports In-Database processing for PROC TABULATE with the Google BigQuery database management system.
  - SAS 9.4M7 supports In-Database processing for PROC TABULATE with the Yellowbrick database management system.

The TRANSPOSE Procedure

Beginning with SAS 9.4M5, PROC TRANSPOSE summarization can be executed on the CAS server.

-
-
- SAS supports In-Database processing for PROC TRANSPOSE.
  - SAS 9.4 supports In-Database processing for PROC TRANSPOSE with the HADOOP and Terradata database management system.

The XSL Procedure

The XSL procedure now provides the PARAMETER statement to pass a parameter value to an XSL style sheet. For more information, see Chapter 73, "XSL Procedure," on page 2685.

Software Enhancements

SAS supports access to files that are created with the Advanced Encryption Standard (AES). For more information, see "AES Encryption" on page 25.

The International Components for Unicode (ICU) libraries have been upgraded from version 4.2 to version 4.8. The ICU is used by SAS for linguistic collation of character data. For more information about ICU version 4.8, see the ICU website at https://icu.unicode.org/download/48.

Data sets that are sorted linguistically by one release of SAS might not be recognized as sorted by another release. For more information about the effect of a change in the ICU version, see:

- " Linguistic Sorting of Data Sets and ICU" on page 2362
- Chapter 14, "CONTENTS Procedure," on page 489
- Chapter 15, "COPY Procedure," on page 521
- Chapter 41, "MIGRATE Procedure," on page 1559

Documentation Enhancements

The following changes have been made to the *Base SAS Procedures Guide*:

- "Threaded Processing for Base SAS Procedures" on page 26 contains information about SAS procedures that support threaded processing.
- "Using PROC FCMP Component Objects" on page 918 contains more information about hashing.
- SAS 9.4M1 adds a link and supporting text for Microsoft Excel functions that are available to PROC FCMP.
- Information about the Chapter 34, "HDMD Procedure" was moved to this document from *SAS/ACCESS for Relational Databases: Reference*.
- Chapter 41, "MIGRATE Procedure," on page 1559 contains more information about using the BUFSIZE= option to improve the performance of migrated data sets.

PART 1

Concepts

1

Choosing the Right Procedure

Functional Categories of Base SAS Procedures

Report Writing

These procedures display useful information, such as data listings (detail reports), summary reports, calendars, letters, labels, multipanel reports, and graphical reports.

CALENDAR	PLOT	SQL[1]
CHART[1]	PRINT	SUMMARY[1]
FREQ[1]	QDEVICE[1]	TABULATE [1]

MEANS[1]	REPORT[1]	TIMEPLOT

1 These procedures produce reports and compute statistics.

Statistics

These procedures compute elementary statistical measures that include descriptive statistics based on moments, quantiles, confidence intervals, frequency counts, crosstabulations, correlations, and distribution tests. They also rank and standardize data.

CHART	RANK	SUMMARY
CORR	REPORT	TABULATE
FREQ	SQL	UNIVARIATE
MEANS	STANDARD	

Utilities

These procedures perform the following basic utility operations:

- create, edit, sort, and transpose data sets
- create and restore transport data sets
- create user-defined formats
- provide basic file maintenance such as copy, append, and compare data sets
- deletes permanent or temporary data files from disk or tape

APPEND	FEDSQL	PRESENV
AUTHLIB	FONTREG	PRINTTO
CATALOG	FSLIST	PRTDEF
CIMPORT	GROOVY	PRTEXP
COMPARE	HADOOP	PWENCODE
CONTENTS	IMPORT[4]	REGISTRY

CONVERT[1]	INFOMAPS [5]	RELEASE[1]
COPY	JAVAINFO	SCAPROC
CPORT	JSON	SORT
CV2VIEW[3]	METADATA[6]	SOURCE
DATASETS	METALIB[6]	SQL[1]
DELETE	MIGRATE	TAPECOPY
DISPLAY	OPTIONS	TAPELABEL [1]
DOCUMENT [2]	OPTLOAD	TEMPLATE
DS2	OPTSAVE	TRANSPOSE[1]
EXPORT[4]	PDS	TRANSTAB [2]
FCMP	PDSCOPY[1]	XSL
	PMENU[1]	

1 See the SAS documentation for your operating environment for a description of this procedure.
2 For a description of this procedure, see the *SAS Output Delivery System: User's Guide*.
3 For a description of this procedure, see the *SAS/ACCESS for Relational Databases: Reference*.
4 For a description of this procedure, see the *SAS/ACCESS Interface to PC Files: Reference*.
5 For a description of this procedure, see the *Base SAS Guide to Information Maps*.
6 For a description of this procedure, see the *SAS Language Interfaces to Metadata*.

Report-Writing Procedures

The following table lists report-writing procedures according to the type of report.

Table 1.1 *Report-Writing Procedures by Task*

Report Type	Procedure	Description
Detail reports	PRINT	Produces data listings quickly; can supply titles, footnotes, and column sums.

Report Type	Procedure	Description
	REPORT	Offers more control and customization than PROC PRINT; can produce both column and row sums; has DATA step computation abilities.
	SQL	Combines Structured Query Language and SAS features such as formats; can manipulate data and create a SAS data set in the same step that creates the report; can produce column and row statistics; does not offer as much control over output as PROC PRINT and PROC REPORT.
Summary reports	MEANS or SUMMARY	Computes descriptive statistics for numeric variables; can produce a printed report and create an output data set.
	PRINT	Produces only one summary report; can sum the BY variables.
	QDEVICE	Produces reports about graphics devices and universal printers.
	REPORT	Combines features of the PRINT, MEANS, and TABULATE procedures with features of the DATA step in a single report-writing tool that can produce a variety of reports; can also create an output data set.
	SQL	Computes descriptive statistics for one or more SAS data sets or DBMS tables; can produce a printed report or create a SAS data set.
	TABULATE	Produces descriptive statistics in a tabular format; can produce stub-and-banner reports (multidimensional tables with descriptive statistics); can also create an output data set.
Miscellaneous highly formatted reports		
Calendars	CALENDAR	Produces schedule and summary calendars; can schedule tasks around nonwork periods and holidays, weekly work schedules, and daily work shifts.
Multipanel reports (telephone book listings)	REPORT	Produces multipanel reports.
Low-resolution graphical reports [1]		

Report Type	Procedure	Description
	CHART	Produces bar charts, histograms, block charts, pie charts, and star charts that display frequencies and other statistics.
	PLOT	Produces scatter diagrams that plot one variable against another.
	TIMEPLOT	Produces plots of one or more variables over time intervals.

1 These reports quickly produce a simple graphical picture of the data. To produce high-resolution graphical reports, use SAS/GRAPH software.

Statistical Procedures

Available Statistical Procedures

The following table lists statistical procedures according to task. Table A1.1 on page 2701 lists the most common statistics and the procedures that compute them.

Table 1.2 *Elementary Statistical Procedures by Task*

Report type	Procedure	Description
Descriptive statistics	CORR	Computes simple descriptive statistics.
	MEANS or SUMMARY	Computes descriptive statistics; can produce printed output and output data sets. By default, PROC MEANS produces printed output, and PROC SUMMARY creates an output data set.
	REPORT	Computes most of the same statistics as PROC TABULATE; allows customization of format.
	SQL	Computes descriptive statistics for data in one or more DBMS tables; can produce a printed report or create a SAS data set.
	TABULATE	Produces tabular reports for descriptive statistics; can create an output data set.

Report type	Procedure	Description
	UNIVARIATE	Computes the broadest set of descriptive statistics; can create an output data set.
Frequency and crosstabulation tables	FREQ	Produces one-way to *n*-way tables; reports frequency counts; computes chi-square tests; computes test and measures of association and agreement for two-way to *n*-way crosstabulation tables; can compute exact tests and asymptotic tests; can create output data sets.
	TABULATE	Produces one-way and two-way crosstabulation tables; can create an output data set.
	UNIVARIATE	Produces one-way frequency tables.
Correlation analysis	CORR	Computes Pearson's, Spearman's, and Kendall's correlations and partial correlations. Also, computes Hoeffding's measures of dependence (D) and Cronbach's coefficient alpha.
Distribution analysis	UNIVARIATE	Computes tests for location and tests for normality.
	FREQ	Computes a test for the binomial proportion for one-way tables; computes a goodness-of-fit test for one-way tables; computes a chi-square test of equal distribution for two-way tables.
Robust estimation	UNIVARIATE	Computes robust estimates of scale, trimmed means, and Winsorized means.
Data transformation		
Computing ranks	RANK	Computes ranks for one or more numeric variables across the observations of a SAS data set and creates an output data set; can produce normal scores or other rank scores.
Standardizing data	STANDARD	Creates an output data set that contains variables that are standardized to a given mean and standard deviation.
Low-resolution graphics[1]		
	CHART	Produces a graphical report that can show one of the following statistics for the chart variable: frequency counts, percentages, cumulative frequencies, cumulative percentages, totals, or averages.

Report type	Procedure	Description
	UNIVARIATE	Produces descriptive plots such as stem-and-leaf plot, box plots, and normal probability plots.

1 To produce high-resolution graphical reports, use SAS/GRAPH software.

Efficiency Issues

Quantiles

For a large sample size *n*, the calculation of quantiles, including the median, requires computing time proportional to *n*log(*n*). Therefore, a procedure, such as UNIVARIATE, that automatically calculates quantiles might require more time than other data summarization procedures. Furthermore, because data is held in memory, the procedure also requires more storage space to perform the computations. By default, the report procedures PROC MEANS, PROC SUMMARY, and PROC TABULATE require less memory because they do not automatically compute quantiles. These procedures also provide an option to use a new fixed-memory, quantiles estimation method that is usually less memory-intense. For more information, see "Quantiles" on page 1512 in the PROC MEANS documentation.

Computing Statistics for Groups of Observations

To compute statistics for several groups of observations, you can use any of the previous procedures with a BY statement to specify BY-group variables. However, BY-group processing requires that you previously sort or index the data set, which for very large data sets might require substantial computer resources. A more efficient way to compute statistics within groups without sorting is to use a CLASS statement with one of the following procedures: MEANS, SUMMARY, or TABULATE.

Additional Information about the Statistical Procedures

Appendix 1, "SAS Elementary Statistics Procedures," on page 2699 lists standard keywords, statistical notation, and formulas for the statistics that Base SAS procedures compute frequently. The sections on the individual statistical

procedures discuss the statistical concepts that are useful to interpret a procedure output.

Utility Procedures

The following table groups utility procedures according to task.

Table 1.3 *Utility Procedures by Task*

Tasks	Procedure	Description
Supply information	COMPARE	Compares the contents of two SAS data sets.
	CONTENTS	Describes the contents of a SAS library or specific library members.
	JAVAINFO	Conveys diagnostic information about the Java environment that SAS is using.
	OPTIONS	Lists the current values of all SAS system options.
	SCAPROC	Implements the SAS Code Analyzer, which captures information about input, output, and the use of macro symbols from a SAS job while it is running.
	SQL	Supplies information through dictionary tables on an individual SAS data set as well as all SAS files active in the current SAS session. Dictionary tables can also provide information about macros, titles, indexes, external files, or SAS system options.
Manage SAS system options	OPTIONS	Lists the current values of all SAS system options.
	OPTLOAD	Reads SAS system option settings that are stored in the SAS registry or a SAS data set.
	OPTSAVE	Saves SAS system option settings to the SAS registry or a SAS data set.
Affect printing and Output Delivery System output	DOCUMENT[2]	Manipulates procedure output that is stored in ODS documents.

Tasks	Procedure	Description
	FONTREG	Adds system fonts to the SAS registry.
	FORMAT	Creates user-defined formats to display and print data.
	PRINTTO	Routes procedure output to a file, a SAS catalog entry, or a printer; can also redirect the SAS log to a file.
	PRTDEF	Creates printer definitions.
	PRTEXP	Exports printer definition attributes to a SAS data set.
	TEMPLATE[2]	Customizes ODS output.
Create, browse, and edit data	FCMP	Enables creation, testing, and storage of SAS functions and subroutines before they are used in other SAS procedures.
	FSLIST	Browses external files such as files that contain SAS source lines or SAS procedure output.
	INFOMAPS[6]	Creates or updates a SAS Information Map.
	PRESENV	Preserves all global statements and macro variables in your SAS code from one SAS session to another. When this procedure is invoked at the end of a SAS session, all of the global statements and macro variables are written to a file.
	SQL	Creates SAS data sets using Structured Query Language and SAS features.
	FORMAT	Creates user-defined informats to read data and user-defined formats to display data.
	SORT	Sorts SAS data sets by one or more variables.
	SQL	Sorts SAS data sets by one or more variables.
	STREAM	Enables you to process an input stream that consists of arbitrary text that can contain SAS macro specifications. It can expand macro code and store it in a file.

Tasks	Procedure	Description
	TRANSPOSE	Transforms SAS data sets so that observations become variables and variables become observations.
	TRANTAB[4]	Creates, edits, and displays customized translation tables.
	XSL	Transforms an XML document into another format, such as HTML, text, or another XML document type.
Manage SAS files	APPEND	Appends one SAS data set to the end of another.
	AUTHLIB	Manages metadata-bound libraries.
	CATALOG	Manages SAS catalog entries.
	CIMPORT	Restores a transport sequential file that PROC CPORT creates (usually in another operating environment) to its original form as a SAS catalog, a SAS data set, or a SAS library.
	CONVERT[1]	Converts BMDP system files, OSIRIS system files, and SPSS portable files to SAS data sets.
	COPY	Copies a SAS library or specific members of the library.
	CPORT	Converts a SAS catalog, a SAS data set, or a SAS library to a transport sequential file that PROC CIMPORT can restore (usually in another operating environment) to its original form.
	CV2VIEW[3]	Converts SAS/ACCESS view descriptors to PROC SQL views.
	DATASETS	Manages SAS files.
	DELETE	Deletes permanent or temporary SAS files.
	EXPORT[5]	Reads data from a SAS data set and writes them to an external data source.
	IMPORT[5]	Reads data from an external data source and writes them to a SAS data set.

Tasks	Procedure	Description
	JSON	Reads data from a SAS data set and writes it to an external file in JSON representation.
	MIGRATE	Migrates members in a SAS library forward to the most current release of SAS.
	PDS[1]	Lists, deletes, and renames the members of a partitioned data set.
	PDSCOPY[1]	Copies partitioned data sets from disk to tape, disk to disk, tape to tape, or tape to disk.
	PROTO	Enables registration, in batch mode, of external functions that are written in the C or C++ programming languages.
	REGISTRY	Imports registry information to the USER portion of the SAS registry.
	RELEASE[1]	Releases unused space at the end of a disk data set under the z/OS environment.
	SOURCE[1]	Provides an easy way to back up and process source library data sets.
	SQL	Concatenates SAS data sets.
	TAPECOPY[1]	Copies an entire tape volume or files from one or more tape volumes to one output tape volume.
	TAPELABEL[1]	Lists the label information of an IBM standard-labeled tape volume in the z/OS environment.
Control windows	PMENU	Creates customized menus for SAS applications.
Miscellaneous	DISPLAY	Executes SAS/AF applications.
	DS2	Submits DS2 language statements from a Base SAS session.
	FEDSQL	Submits FedSQL language statements from a Base SAS session.
	GROOVY	Enables SAS code to execute Groovy code on the Java Virtual Machine (JVM).

Tasks	Procedure	Description
	HADOOP	Enables SAS to run Apache Hadoop code against Hadoop data.
	PWENCODE	Encodes passwords for use in SAS programs.
Manage metadata in a SAS Metadata Repository	METADATA[7]	Sends a method call, in the form of an XML string, to a SAS Metadata Server.
	METALIB[7]	Updates metadata to match the tables in a library.
	METAOPERATE[7]	Performs administrative tasks on a metadata server.

1 See the SAS documentation for your operating environment for a description of these procedures.
2 For a description of this procedure, see the *SAS Output Delivery System: User's Guide*.
3 For a description of this procedure, see the *SAS/ACCESS for Relational Databases: Reference*.
4 For a description of this procedure, see the *SAS National Language Support (NLS): Reference Guide*
5 For a description of this procedure, see the *SAS/ACCESS Interface to PC Files: Reference*.
6 For a description of this procedure, see the *Base SAS Guide to Information Maps*.
7 For a description of this procedure, see the *SAS Language Interfaces to Metadata*.

Brief Descriptions of Base SAS Procedures

APPEND procedure
: adds observations from one SAS data set to the end of another SAS data set.

AUTHLIB procedure
: manages metadata-bound libraries, which are physical libraries that are tied to corresponding metadata secured table objects. Each physical table within a metadata-bound library has information in its header that points to a specific metadata object.

CALENDAR procedure
: displays data from a SAS data set in a monthly calendar format. PROC CALENDAR can display holidays in the month, schedule tasks, and process data for multiple calendars with work schedules that vary.

CATALOG procedure
: manages entries in SAS catalogs. PROC CATALOG is an interactive, non-windowing procedure that enables you to display the contents of a catalog; copy an entire catalog or specific entries in a catalog; and rename, exchange, or delete entries in a catalog.

CHART procedure
: produces vertical and horizontal bar charts, block charts, pie charts, and star charts. These charts provide a quick visual representation of the values of a single variable or several variables. PROC CHART can also display a statistic associated with the values.

CIMPORT procedure
: restores a transport file created by the CPORT procedure to its original form (a SAS library, catalog, or data set) in the format appropriate to the operating environment. Coupled with the CPORT procedure, PROC CIMPORT enables you to move SAS libraries, catalogs, and data sets from one operating environment to another.

COMPARE procedure
: compares the contents of two SAS data sets. You can also use PROC COMPARE to compare the values of different variables within a single data set. PROC COMPARE produces a variety of reports on the comparisons that it performs.

CONTENTS procedure
: prints descriptions of the contents of one or more files in a SAS library.

CONVERT procedure
: converts BMDP system files, OSIRIS system files, and SPSS portable files to SAS data sets. For more information, see the SAS documentation for your operating environment.

COPY procedure
: copies an entire SAS library or specific members of the library. You can limit processing to specific types of library members.

CORR procedure
: computes Pearson product-moment and weighted product-moment correlation coefficients between variables and descriptive statistics for these variables. In addition, PROC CORR can compute three nonparametric measures of association (Spearman's rank-order correlation, Kendall's tau-b, and Hoeffding's measure of dependence, D), partial correlations (Pearson's partial correlation, Spearman's partial rank-order correlation, and Kendall's partial tau-b), and Cronbach's coefficient alpha. For more information, see *Base SAS Procedures Guide: Statistical Procedures*.

CPORT procedure
: writes SAS libraries, data sets, and catalogs in a special format called a transport file. Coupled with the CIMPORT procedure, PROC CPORT enables you to move SAS libraries, data sets, and catalogs from one operating environment to another.

CV2VIEW procedure
: converts SAS/ACCESS view descriptors to PROC SQL views. Starting in SAS 9, conversion of SAS/ACCESS view descriptors to PROC SQL views is recommended because PROC SQL views are platform-independent and enable you to use the LIBNAME statement. For more information, see the *SAS/ACCESS for Relational Databases: Reference*.

DATASETS procedure
: lists, copies, renames, and deletes SAS files and SAS generation groups; manages indexes; and appends SAS data sets in a SAS library. The procedure provides all the capabilities of the APPEND, CONTENTS, and COPY procedures.

You can also modify variables within data sets; manage data set attributes, such as labels and passwords; or Create and Delete integrity constraints.

DELETE procedure
deletes SAS files from the disk or tape on which it is stored.

DISPLAY procedure
executes SAS/AF applications. For information about building SAS/AF applications, see the *Guide to SAS/AF Applications Development*.

DOCUMENT procedure
manipulates procedure output that is stored in ODS documents. PROC DOCUMENT enables a user to browse and edit output objects and hierarchies, and to replay them to any supported ODS output format. For more information, see *SAS Output Delivery System: User's Guide*.

DS2 procedure
enables you to submit DS2 language statements from a Base SAS session.

EXPORT procedure
reads data from a SAS data set and writes it to an external data source.

FCMP procedure
enables you to create, test, and store SAS functions and subroutines before you use them in other SAS procedures. PROC FCMP accepts slight variations of DATA step statements. Most features of the SAS programming language can be used in functions and subroutines that are processed by PROC FCMP.

FEDSQL procedure
enables you to submit FedSQL language statements from a Base SAS session.

FONTREG procedure
adds system fonts to the SAS registry.

FORMAT procedure
creates user-defined informats and formats for character or numeric variables. PROC FORMAT also prints the contents of a format library, creates a control data set to write other informats or formats, and reads a control data set to create informats or formats.

FREQ procedure
produces one-way to *n*-way frequency tables and reports frequency counts. PROC FREQ can compute chi-square tests for one-way to *n*-way tables; for tests and measures of association and of agreement for two-way to *n*-way crosstabulation tables; risks and risk difference for 2×2 tables; trends tests;and Cochran-Mantel-Haenszel statistics. You can also create output data sets. For more information, see *Base SAS Procedures Guide: Statistical Procedures*.

FSLIST procedure
displays the contents of an external file or copies text from an external file to the SAS Text Editor.

GROOVY procedure
enables SAS code to execute Groovy code on the Java Virtual Machine (JVM).

HADOOP procedure
enables SAS to run Apache Hadoop code against Hadoop data.

HDMD procedure
: generate XML-based metadata that describes the contents of files that are stored in HDFS.

HTTP procedure
: issues Hypertext Transfer Protocol (HTTP) requests.

IMPORT procedure
: reads data from an external data source and writes them to a SAS data set.

INFOMAPS procedure
: creates or updates a SAS Information Map. For more information, see the *Base SAS Guide to Information Maps*.

JAVAINFO procedure
: conveys diagnostic information to the user about the Java environment that SAS is using. The diagnostic information can be used to confirm that the SAS Java environment has been configured correctly and can be helpful when reporting problems to SAS technical support.

JSON procedure
: reads data from a SAS data set and writes it to an external file in JSON representation.

MEANS procedure
: computes descriptive statistics for numeric variables across all observations and within groups of observations. You can also create an output data set that contains specific statistics and identifies minimum and maximum values for groups of observations.

METADATA procedure
: sends a method call, in the form of an XML string, to a SAS Metadata Server. For more information, see *SAS Language Interfaces to Metadata*.

METALIB procedure
: updates metadata in a SAS Metadata Repository to match the tables in a library. For more information, see *SAS Language Interfaces to Metadata*.

METAOPERATE procedure
: performs administrative tasks on a metadata server. For more information, see *SAS Language Interfaces to Metadata*.

MIGRATE procedure
: migrates members in a SAS library forward to the most current release of SAS. The migration must occur within the same engine family; for example, V6, V7, or V8 can migrate to V9, but V6TAPE must migrate to V9TAPE.

OPTIONS procedure
: lists the current values of all SAS system options.

OPTLOAD procedure
: reads SAS system option settings from the SAS registry or a SAS data set, and puts them into effect.

OPTSAVE procedure
: saves SAS system option settings to the SAS registry or a SAS data set.

PDS procedure
: lists, deletes, and renames the members of a partitioned data set. For more information, see the *SAS Companion for z/OS*.

PDSCOPY procedure
: copies partitioned data sets from disk to tape, disk to disk, tape to tape, or tape to disk. For more information, see the *SAS Companion for z/OS*.

PLOT procedure
: produces scatter plots that graph one variable against another. The coordinates of each point on the plot correspond to the two variables' values in one or more observations of the input data set.

PMENU procedure
: defines menus that you can use in DATA step windows, macro windows, and SAS/AF windows, or in any SAS application that enables you to specify customized menus.

PRESENV procedure
: preserves all global statements and macro variables in your SAS code from one SAS session to another. When this procedure is invoked at the end of a SAS session, all of the global statements and macro variables are written to a file.

PRINT procedure
: prints the observations in a SAS data set, using all or some of the variables. PROC PRINT can also print totals and subtotals for numeric variables.

PRINTTO procedure
: defines destinations for SAS procedure output and the SAS log.

PROTO procedure
: enables you to register, in batch mode, external functions that are written in the C or C++ programming languages. You can use these functions in SAS as well as in C-language structures and types. After these functions are registered in PROC PROTO, they can be called from any SAS function or subroutine that is declared in the FCMP procedure. After registration, they can also be called from any SAS function, subroutine, or method block that is declared in the COMPILE procedure.

PRTDEF procedure
: creates printer definitions for individual SAS users or all SAS users.

PRTEXP procedure
: exports printer definition attributes to a SAS data set so that they can be easily replicated and modified.

PWENCODE procedure
: encodes passwords for use in SAS programs.

QDEVICE procedure
: produces reports about graphics devices and universal printers.

RANK procedure
: computes ranks for one or more numeric variables across the observations of a SAS data set. The ranks are written to a new SAS data set. Alternatively, PROC RANK produces normal scores or other rank scores.

REGISTRY procedure
: imports registry information into the USER portion of the SAS registry.

RELEASE procedure
: releases unused space at the end of a disk data set in the z/OS environment. For more information, see the *SAS Companion for z/OS*.

REPORT procedure
: combines features of the PRINT, MEANS, and TABULATE procedures with features of the DATA step in a single report-writing tool that can produce both detail and summary reports.

SCAPROC procedure
: implements the SAS Code Analyzer, which captures information about input, output, and the use of macro symbols from a SAS job while it is running.

SCOREACCEL procedure
: provides an interface to the CAS server for DATA step and DS2 model publishing and scoring.

SOAP procedure
: reads XML input from a file that has a fileref and writes XML output to another file that has a fileref.

SORT procedure
: sorts observations in a SAS data set by one or more variables. PROC SORT stores the resulting sorted observations in a new SAS data set or replaces the original data set.

SOURCE procedure
: provides an easy way to back up and process source library data sets. For more information, see the SAS documentation for your operating environment.

SQL procedure
: implements a subset of the Structured Query Language (SQL) for use in SAS. SQL is a standardized, widely used language that retrieves and updates data in SAS data sets, SQL views, and DBMS tables, as well as views based on those tables. PROC SQL can also create tables and views, summaries, statistics, and reports and perform utility functions such as sorting and concatenating. For more information, see *SAS SQL Procedure User's Guide*.

SQOOP procedure
: allows access to Apache Sqoop using options to allow data transfer between a database and HDFS.

STANDARD procedure
: standardizes some or all of the variables in a SAS data set to a given mean and standard deviation and produces a new SAS data set that contains the standardized values.

STREAM procedure
: enables you to process an input stream that consists of arbitrary text that can contain SAS macro specifications. It can expand macro code and store it in a file.

SUMMARY procedure
: computes descriptive statistics for the variables in a SAS data set across all observations and within groups of observations, and writes the results to a new SAS data set.

TABULATE procedure
: displays descriptive statistics in tabular form. The value in each table cell is calculated from the variables and statistics that define the pages, rows, and columns of the table. The statistic associated with each cell is calculated on values from all observations in that category. You can write the results to a SAS data set.

TAPECOPY procedure
: copies an entire tape volume or files from one or more tape volumes to one output tape volume. For more information, see the *SAS Companion for z/OS*.

TAPELABEL procedure
: lists the label information of an IBM standard-labeled tape volume under the z/OS environment. For more information, see the *SAS Companion for z/OS*.

TEMPLATE procedure
: customizes ODS output for an entire SAS job or a single ODS output object. For more information, see *SAS Output Delivery System: User's Guide*.

TIMEPLOT procedure
: produces plots of one or more variables over time intervals.

TRANSPOSE procedure
: transposes a data set that changes observations into variables and vice versa.

TRANTAB procedure
: creates, edits, and displays customized translation tables. For more information, see *SAS National Language Support (NLS): Reference Guide*.

UNIVARIATE procedure
: computes descriptive statistics (including quantiles), confidence intervals, and robust estimates for numeric variables. Provides detail on the distribution of numeric variables, which include tests for normality, plots to illustrate the distribution, frequency tables, and tests of location. For more information, see *Base SAS Procedures Guide: Statistical Procedures*.

XSL procedure
: transforms an XML document into another format, such as HTML, text, or another XML document type.

2

Fundamental Concepts for Using Base SAS Procedures

Language Concepts

Temporary and Permanent SAS Data Sets

Naming SAS Data Sets

SAS data sets can have a one-level name or a two-level name. Typically, names of temporary SAS data sets have only one level and are stored in the WORK library. The WORK library is defined automatically at the beginning of the SAS session and is deleted automatically at the end of the SAS session. Procedures assume that SAS data sets that are specified with a one-level name are to be read from or written to the WORK library. To indicate otherwise, you specify a USER library. For more information, see "USER Library" on page 22. For example, the following PROC PRINT steps are equivalent. The second PROC PRINT step assumes that the DEBATE data set is in the WORK library.

```
proc print data=work.debate;
run;

proc print data=debate;
run;
```

The SAS system options WORK=, WORKINIT, and WORKTERM affect how you work with temporary and permanent libraries. For more information, see *SAS System Options: Reference*.

Typically, two-level names represent permanent SAS data sets. A two-level name takes the form *libref.SAS-data-set*. The *libref* is a name that is temporarily associated with a SAS library. A SAS library is an external storage location that stores SAS data sets in your operating environment. A LIBNAME statement associates the libref with the SAS library. In the following PROC PRINT step, PROCLIB is the libref and EMP is the SAS data set within the library:

```
libname proclib 'SAS-library';
proc print data=proclib.emp;
run;
```

USER Library

You can use one-level names for permanent SAS data sets by specifying a USER library. You can assign a USER library with a LIBNAME statement or with the SAS system option USER=. After you specify a USER library, the procedure assumes

that data sets with one-level names are in the USER library instead of the WORK library. For example, the following PROC PRINT step assumes that DEBATE is in the USER library:

```
options user='SAS-library';
proc print data=debate;
run;
```

Note: If you have a USER library defined, then you can still use the WORK library by specifying WORK.*SAS-data-set*.

SAS System Options

Some SAS system option settings affect procedure output. The SAS system options listed below are the options that you are most likely to use with SAS procedures:

- BYLINE | NOBYLINE
- DATE | NODATE
- DETAILS | NODETAILS
- FMTERR | NOFMTERR
- FORMCHAR=
- FORMDLIM=
- LABEL | NOLABEL
- LINESIZE=
- NUMBER | NONUMBER
- PAGENO=
- PAGESIZE=
- REPLACE | NOREPLACE
- SOURCE | NOSOURCE

For a complete description of SAS system options, see the *SAS System Options: Reference*.

Data Set Options

Most of the procedures that read data sets or create output data sets accept data set options. SAS data set options appear in parentheses after the data set specification. Here is an example:

```
proc print data=stocks(obs=25 pw=green);
```

The individual procedure chapters contain reminders that you can use data set options where it is appropriate.

SAS data set options are as follows:

ALTER=	OBS=
BUFNO=	OBSBUF=
BUFSIZE=	OUTREP=
CNTLLEV=	POINTOBS=
COMPRESS=	PW=
DLDMGACTION=	PWREQ=
DROP=	READ=
ENCODING=	RENAME=
ENCRYPT=	REPEMPTY=
FILECLOSE=	REPLACE=
FIRSTOBS=	REUSE=
GENMAX=	SORTEDBY=
GENNUM=	SPILL=
IDXNAME=	TOBSNO=
IDXWHERE=	TYPE=
IN=	WHERE=
INDEX=	WHEREUP=
KEEP=	WRITE=
LABEL=	

For a complete description of SAS data set options, see the *SAS Data Set Options: Reference*.

Global Statements

You can use these global statements anywhere in SAS programs except after a DATALINES, CARDS, or PARMCARDS statement:

comment	ODS
DM	OPTIONS
ENDSAS	PAGE
FILENAME	RUN
FOOTNOTE	%RUN
%INCLUDE	SASFILE
LIBNAME	SKIP
%LIST	TITLE
LOCK	X

For information about all the above statements except for the ODS statement, see the *SAS DATA Step Statements: Reference*. For information about the ODS statement, see "Output Delivery System" on page 72 and *SAS Output Delivery System: User's Guide*.

AES Encryption

Prior to the SAS 9.4M5 release, SAS supported only one Advanced Encryption Standard (AES) encryption algorithm that was specified with the ENCRYPT=AES data set option. Beginning with the SAS 9.4M5 release, SAS supports a stronger AES key generation algorithm specified with the ENCRYPT=AES2 data set option. This stronger algorithm meets newer standards requested by some SAS customers. The same key value passphrase specified by the ENCRYPTKEY= data set option can be used with either algorithm. A data set that is encrypted with the AES2 algorithm cannot be accessed by any SAS release prior to SAS 9.4M5.

To access a data set that is created with AES encryption, you have to supply the encryption key value with the ENCRYPTKEY= option. If you omit the ENCRYPTKEY= key value when accessing an AES secured data set, a dialog box appears and prompts you to add the ENCRYPTKEY= key value. For more

information, see "AES Encryption" in *SAS Programmer's Guide: Essentials* and "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*.

Procedure Concepts

Input Data Sets

Many Base SAS procedures require an input SAS data set. You specify the input SAS data set by using the DATA= option in the procedure statement, as in this example:

```
proc print data=emp;
```

If you omit the DATA= option, the procedure uses the value of the SAS system option _LAST_=. The default of _LAST_= is the most recently created SAS data set in the current SAS job or session. _LAST_= is described in detail in the *SAS Data Set Options: Reference*.

Threaded Processing for Base SAS Procedures

Threaded processing enables multiple pieces of executable code to run simultaneously. Many SAS procedures, including several SAS/STAT and High-Performance Analytics (HPA) procedures, support threaded processing. However, not all SAS procedures support threaded processing. See the documentation for the procedures that you are using to determine whether they support threaded processing.

Calculated statistics can vary slightly, depending on the order in which observations are processed. Such variations are due to numerical errors that are introduced by floating–point arithmetic, the results of which should be considered approximate and not exact. The order of observation processing can be affected by nondeterministic effects of multithreaded or parallel processing. The order of processing can also be affected by inconsistent or nondeterministic ordering of observations that are produced by a data source, such as a DBMS that delivers query results through an ACCESS engine. For more information, see "Numerical Accuracy in SAS Software" in *SAS Language Reference: Concepts* and "Threading in Base SAS" in *SAS Language Reference: Concepts*.

The following Base SAS procedures support threaded processing:

- Chapter 40, "MEANS Procedure," on page 1463
- Chapter 58, "REPORT Procedure," on page 2047
- Chapter 64, "SORT Procedure," on page 2355

- Chapter 69, "SUMMARY Procedure," on page 2455
- Chapter 70, "TABULATE Procedure," on page 2459
- "SQL Procedure" in *SAS SQL Procedure User's Guide*

Controlling the Order of Data Values

Ordering of Data Values

Procedures apply an ordering scheme for data values and certain conditions affect how procedures order data:

- operating-environment-specific collating sequences
- the BY statement
- a single classification variable
- multiple classification variables
- formats
- the ORDER= option
- supplemental ordering options

Examples for ordering data use the Sasuser.Houses data set.

```
data sasuser.houses;
input style $ 1-9 sqfeet 10-13 bedrooms 15 baths 17-19 street $ 21-36 price 38-44;
datalines;
RANCH     1250 2 1.0 Sheppart Avenue    64000
SPLIT     1190 1 1.0 Rand Street        65850
CONDO     1400 2 1.5 Market Street      80050
TWOSTORY  1810 4 3.0 Garris Street     107250
RANCH     1500 3 3.0 Kemble Avenue      86650
SPLIT     1615 4 3.0 West Drive         94450
SPLIT     1305 3 1.5 Graham Avenue      73650
```

```
CONDO     1390 3 2.5 Hampshire Avenue   79650
TWOSTORY  1040 2 1.0 Sanders Road       55850
CONDO     2105 4 2.5 Jeans Avenue      127150
RANCH     1535 3 3.0 State Highway      89100
TWOSTORY  1240 2 1.0 Fairbanks Circle   69250
RANCH      720 1 1.0 Nicholson Drive    34550
TWOSTORY  1745 4 2.5 Highland Road     102950
CONDO     1860 2 2.0 Arcata Avenue     110700
run;

proc datasets lib=sasuser memtype=data;
   modify houses;
   attrib price format=dollar8.;
run;

proc print data=sasuser.houses;
run;
```

Figure 2.1 *The Sasuser.Houses Data Set*

The SAS System

Obs	style	sqfeet	bedrooms	baths	street	price
1	RANCH	1250	2	1.0	Sheppard Avenue	$64,000
2	SPLIT	1190	1	1.0	Rand Street	$65,850
3	CONDO	1400	2	1.5	Market Street	$80,050
4	TWOSTORY	1810	4	3.0	Garris Street	$107,250
5	RANCH	1500	3	3.0	Kemble Avenue	$86,650
6	SPLIT	1615	4	3.0	West Drive	$94,450
7	SPLIT	1305	3	1.5	Graham Avenue	$73,650
8	CONDO	1390	3	2.5	Hampshire Avenue	$79,350
9	TWOSTORY	1040	2	1.0	Sanders Road	$55,850
10	CONDO	2105	4	2.5	Jeans Avenue	$127,150
11	RANCH	1535	3	3.0	State Highway	$89,100
12	TWOSTORY	1240	2	1.0	Fairbanks Circle	$69,250
13	RANCH	720	1	1.0	Nicholson Drive	$34,550
14	TWOSTORY	1745	4	2.5	Highland Road	$102,950
15	CONDO	1860	2	2.0	Arcata Avenue	$110,700

Data Ordered by the Operating Environment

Operating environments use either the ASCII or EBCIDIC collating sequences to order data:

- Windows and UNIX use the ASCII collating sequence.
- z/OS uses the EBCIDIC collating sequence.

This example code was run on Windows and z/OS, changing the title for each system:

```
data order;
   input x $1.;
   datalines;
1
a
A
z
Z
\
;

proc print;
run;
```

The following table shows the difference in the PRINT procedure output between ASCII and EBCIDIC:

ASCII Collating Sequence	EBCDIC Collating Sequence
1	a
A	z
Z	A
\	\
a	Z
z	1

For more information, see "Collating Sequence" in *SAS National Language Support (NLS): Reference Guide*.

Order Data Using the BY Statement

To order data by one or more variables, you must first use the SORT procedure. After the data is sorted, you use the same variables in a procedure BY statement to indicate how the data is sorted. The procedure subsets the data into BY groups based on the BY variables.

```
proc sort data=sasuser.houses out=houses;
   by style;
run;
proc freq data=houses;
  by style;
  tables bedrooms /nopercent;
run;
```

Here are the first two BY groups ordered by the Style variable for the house styles:

Figure 2.2 *The First of Two BY Groups in Ascending Order*

The FREQ Procedure

style=CONDO

bedrooms	Frequency	Cumulative Frequency
2	2	2
3	1	3
4	1	4

Figure 2.3 *The Second of Two BY Groups in Ascending Order*

The FREQ Procedure

style=RANCH

bedrooms	Frequency	Cumulative Frequency
1	1	1
2	1	2
3	2	4

By default, the SORT procedure orders BY groups in ascending order. To reverse the order, you use the DESCENDING option in the BY statement in PROC SORT and in subsequent procedures that process the data set.

```
proc sort data=sasuser.houses out=houses;
   by descending style;
run;
proc freq data=houses;
  by descending style;
  tables bedrooms /nopercent;
  run;
```

Figure 2.4 *First of Two BY Groups in Descending Order*

The FREQ Procedure

style=TWOSTORY

bedrooms	Frequency	Cumulative Frequency
2	2	2
4	2	4

Figure 2.5 *Second of Two BY Groups in Descending Order*

The FREQ Procedure

style=SPLIT

bedrooms	Frequency	Cumulative Frequency
1	1	1
3	1	2
4	1	3

The BY statement has another option, NOTSORTED. The NOTSORTED option is useful when you want to list a variable in a BY statement whose values are grouped together, but are not sorted in either ascending or descending order.

Order Data Using a Single Classification Variable

Classification variables organize data into groups that are meaningful for analysis. The values are grouped and ordered after all of the data values in a data set or BY group have been read by the procedure.

The following table lists some of the procedures and their statements that define classification variables:

Procedure	Statement
FREQ	TABLES
MEANS	CLASS
REPORT	DEFINE use options GROUP, ORDER, or ACROSS
SUMMARY	CLASS
TABULATE	CLASS

For most procedures, the default ordering scheme is ascending for single classification variables with no formats or ordering options:

```
proc means data=sasuser.houses nway mean;
   class style;
   var sqfeet;
run;
```

Figure 2.6 *The Default Ascending Order for a Single Classification Variable*

The MEANS Procedure

Analysis Variable : sqfeet Square footage		
Style of homes	N Obs	Mean
CONDO	4	1688.75
RANCH	4	1251.25
SPLIT	3	1370.00
TWOSTORY	4	1458.75

For information about the default data ordering behavior for PROC REPORT, see "Order Data Using the ORDER= Option" on page 44.

Order Data Using Multiple Classification Variables

Only one variable can be considered the higher-order grouping variable when you use multiple classification variables to create subgroups of data. All other variables are used to create subgroups of the immediate preceding higher-order variable.

Here is a list of statements, by procedure, that specifies the higher-order variable. The first variable in the procedure statement is the higher-order variable. In all examples in the table, A is the higher-order variable.

Procedure	Statement That Specifies the Higher-Order Variable	Example

FREQ	TABLES	`proc freq;`
		`  tables A * B * C * D;`
		`run;`

MEANS	CLASS	`proc means;`
		`  class A B C D;`
		`run;`

REPORT	COLUMN	`proc report;`
		`  column A B C D;`
		`  define C / group;`
		`  define A / group;`
		`  define B / group;`
		`  define D / group;`
		
		`run;`

SUMMARY	CLASS	`proc summary;`
		`  class A B C D;`
		`run;`

TABULATE	TABLE	`proc tabulate;`
		`  class D C B A;`
		`  table A, B, C * D;`
		`run;`

The ordering scheme is determined first by developing a master order for each class variable, for the entire data set or BY group. The master order is then applied to each subgroup of the hierarchy. The order does not change from one class subgroup to the next.

Consider this example:

```
proc tabulate data=sasuser.houses format=3. noseps;
   class style bedrooms;
   table style*bedrooms, n / rts=23;
run;
```

The master order for Style and Bedrooms is determined separately. Style is the higher-order class variable. Bedrooms forms subgroups of each value of Style. The order for Bedrooms is not determined again for each value of Style. Instead, the order is taken from the master order that is determined before generating subgroups.

When no ORDER= option is specified in the CLASS statement, the data is ordered by using unformatted values, which results in the same order as the SORT procedure. The master order for Style is ascending alphabetically, and the master order for Bedrooms is ascending numerically:

Figure 2.7 Master Order Using No ORDER= Option

The SAS System

		N
style	bedrooms	
CONDO	2	2
	3	1
	4	1
RANCH	1	1
	2	1
	3	2
SPLIT	1	1
	3	1
	4	1
TWOSTORY	2	2
	4	2

Consider this example where the order also considers frequency counts:

```
proc tabulate data=sasuser.houses format=3. noseps order=freq;
   class style bedrooms;
   table style*bedrooms, n / rts=23;
run;
```

For PROC TABULATE, if the frequency count is the same for multiple variables, then the master order uses the order in which the data was read by the procedure. When PROC TABULATE reads the data set, the frequency count for Ranch is 4, Split is 3, Condo is 4, and TwoStory is 4. Therefore, the master order of the higher-order variable, Style, is Ranch, Condo, TwoStory, and Split.

The master order for bedrooms is then determined. Two bedrooms has a count of 5, four bedrooms has a count of 4, three bedrooms has a count of 4, and one bedroom has a count of 2. The master order for bedrooms is 2, 4, 3, 1. Here is the output:

Figure 2.8 *The Order of Values Using the Master Order*

The SAS System

		N
Style of homes	Number of bedrooms	
RANCH	2	1
	3	2
	1	1
CONDO	2	2
	4	1
	3	1
TWOSTORY	2	2
	4	2
SPLIT	4	1
	3	1
	1	1

The order becomes obvious when you add the PRINTMISS option to the TABLE statement to show the frequency count:

Figure 2.9 *The Master Order with Frequency Counts*

The SAS System

		N
Style of homes	Number of bedrooms	
RANCH	2	1
	4	.
	3	2
	1	1
CONDO	2	2

	1	.
TWOSTORY	2	2
	4	2
	3	.
	1	.
SPLIT	2	.
	4	1
	3	1
	1	1

Order Data Using Formats: Procedure Default Behavior

The FREQ, MEANS, SUMMARY, and TABULATE procedures default to order class variable values in ascending order by the actual value in the SAS data set and not their formatted values.

The REPORT procedure default order is ascending order based on the formatted values of the order, group, or across variable.

The following table summarizes the default ordering schemes for procedures when formats are applied to classification variables:

Procedure	Variable Type	Format Specified	Ordered By
FREQ	Numeric or Character	Yes or No	Actual value
MEANS	Numeric or Character	Yes or No	Actual value
REPORT	Numeric	Yes or No	Formatted value [1]
	Character	Yes No	Formatted value Actual value
SUMMARY	Numeric or Character	Yes or No	Actual value
TABULATE	Numeric or Character	Yes or No	Actual value

1 BEST*w.d* is the default format if no format is assigned.

Order Data Using Formats: Using the Lowest Actual Value

When you format multiple values of a class variable and use ORDER=INTERNAL, the ordering of data uses the actual values from the data set and not formatted values. The value that applies to a particular class level is the lowest actual value that was encountered in the data set for the format range. This occurs whether you are producing printed output or an output data set.

In this example, GROUP B appears before GROUP A because the lowest actual value encountered for GROUP B is 1. For GROUP A, the lowest actual value is 3. The lowest possible actual value that could be in GROUP A is 0, but 0 does not exist in the data.

```
proc format;
   value numf 0,3,4='GROUP A'
              1,2='GROUP B';

proc report data=sasuser.houses;
   column bedrooms;
   define bedrooms / group format=numf. order=internal;
run;
```

Figure 2.10 Ordering by the Lowest Value in a Format Range

The SAS System

bedrooms
GROUP B
GROUP A

Another situation that uses the lowest actual value occurs when a format contains groups or ranges that are independent from one another.

In this example, for DEPT=PET, the value OTHER appears last in the sequence. It appears first for DEPT=PLANT. This is because the master ordering sequence for ID is determined before subgroups are created. ID=199 and ID=299 have the same format, OTHER. Because only the formatted value OTHER was established in the master ordering for ID, OTHER is ordered first for DEPT=PLANT.

```
data sample;

   length dept $ 5;
   input dept id;
   datalines;
PET   100
PET   110
PET   120
PET   199
PLANT 200
PLANT 210
PLANT 220
PLANT 299
;

proc format;
   value idfmt
         100='CAT'
         110='DOG'
         120='FISH'
         199='OTHER'
         200='CACTUS'
         210='IVY'
         220='FERN'
         299='OTHER';

proc tabulate data=sample noseps;
   class dept id;
   table dept*id, n;
   format id idfmt.;
run;
```

Figure 2.11 *Ordering by the Lowest Actual Value*

The SAS System

		N
dept	id	
PET	CAT	1
	DOG	1
	FISH	1
	OTHER	1
PLANT	OTHER	1
	CACTUS	1
	IVY	1
	FERN	1

Order Data Using Formats: Missing Values

If missing values exist in the data and in a format range, they can have one of two possible effects on the output, depending on the procedure and options that you specify:

1. The entire format group is treated as invalid.
2. The entire format range has the lowest internal value, possibly resulting in the format range appearing first in an ordering scheme.

Most procedures that use class variables provide the MISSING option, which enables you to specify whether missing values are to be considered valid class levels. PROC FREQ has the option MISSPRINT, which displays missing class levels but does not use them in calculating statistics.

The MEANS, REPORT, SUMMARY, and TABULATE procedures classify missing values as valid or invalid before formats are applied. If you do not specify the MISSING option, and you use a format range that groups nonmissing class levels with missing class levels, then the nonmissing class levels are treated as valid, whereas the missing class levels are not valid.

PROC FREQ applies formats before classifying missing values as valid or invalid. If MISSING or MISSPRINT is not used and a format range groups nonmissing class levels with missing class levels, then both the nonmissing and missing class levels are considered invalid. The following example demonstrates the difference in effect between PROC FREQ and PROC REPORT:

```
proc format;
   value bedfmt 1='ONE' 2='TWO' other='OTHER';
```

```
data houses;
   set sasuser.houses end=last;
   output;
   if last then do;
      bedrooms=.;
      output;
   end;
   format bedrooms bedfmt.;
run;

proc print data=houses;
   title "PROC PRINT";
   title2 "WORK.HOUSES";
   var bedrooms;
   format bedrooms;
run;

proc freq data=houses;
   title1 "PROC FREQ";
   title2 "Without MISSING Specified";
   tables bedrooms / nocum nopercent;
run;

proc report data=houses;
   title1 "PROC REPORT";
   title2 "Without MISSING Specified";
   column beddrooms n;
   define bedrooms /group width=8;
run;
```

Output 2.1 *Order of Data Compared in PROC FREQ and PROC REPORT*

PROC PRINT
WORK.HOUSES

Obs	bedrooms
1	2
2	1
3	2
4	4
5	3
6	4
7	3
8	3
9	2
10	4
11	3
12	2
13	1
14	4
15	2
16	.

PROC FREQ
Without MISSING Specified

The FREQ Procedure

Number of bedrooms	
bedrooms	Frequency
ONE	2
TWO	5
Frequency Missing = 9	

PROC REPORT
Without MISSING Specified

Number of bedrooms	n
ONE	2
OTHER	8
TWO	5

PROC FREQ does not include the formatted class level OTHER, where PROC REPORT does. This is because PROC FREQ applied the BEDFMT. format to the Bedrooms variable before classifying missing values as invalid. PROC REPORT classifies missing values as invalid before applying the format. This allows the nonmissing class levels that would normally be grouped with the missing class levels to be treated as valid.

You can verify this by observing the frequency counts. A total of 16 observations reside in the Work.Houses data set. PROC FREQ reports nine invalid class levels. PROC REPORT treats only one class level as invalid. If the lowest internal value in a format group is a missing value, then the entire group is treated as missing. Because missing values are considered the lowest possible internal value for either numeric or character variables, missing values cause an entire format group to have the lowest internal value. Missing values rank first when ordering by internal values. The following code demonstrates this by adding the MISSING option to the previous example:

```
proc freq data=houses;
   title1 "PROC FREQ";
   title2 "With MISSING Specified";
   tables bedrooms / nocum nopercent missing ;
run;

proc report data=houses missing;
   title1 "PROC REPORT";
   title2 "With MISSING Specified";
   column bedrooms n;
   define bedrooms / group width=8;
run;
```

Output 2.2 *PROC FREQ and PROC REPORT with MISSING Specified*

PROC FREQ
With MISSING Specified

The FREQ Procedure

bedrooms	Frequency
OTHER	9
ONE	2
TWO	5

PROC REPORT
With MISSING Specified

bedrooms	n
ONE	2
OTHER	9
TWO	5

In the results for PROC FREQ, the group OTHER is ordered first in the sequence. In the results for PROC REPORT, OTHER is ordered second. By default, PROC FREQ orders by internal values and PROC REPORT orders by formatted values. Note that the frequency count is the same for both procedures. In PROC FREQ, OTHER corresponds to the missing frequency in the Work.Houses data set. For PROC REPORT, the frequency increases by one to account for the single missing value that was not included in Work.Houses.

Order Data Using Formats: BY Variables

If a format is applied to a variable in a BY statement, then the values of the BY variable are grouped unless the internal values are not sequenced in the format range:

```
proc sort data=sasuser.houses out=houses;
   by bedrooms;
run;

proc format;
   value numf 3='GROUP A' 1,2,4='GROUP B';
run;

proc report data=houses;
   by bedrooms;
```

```
   format bedrooms numf.;
   column price;
run;
```

Output 2.3 *Ordering with a Formatted BY Variable*

Order Data Using the ORDER= Option

The ORDER= option enables you to choose the ordering scheme that the procedure uses. The ORDER= option can have the values INTERNAL or UNFORMATTED, FORMATTED, DATA, and FREQ.

Note: The MEANS, REPORT, SUMMARY, and TABULATE procedures accept both the INTERNAL and UNFORMATTED as a value for the ORDER= option to order unformatted data.

You can use the option with these procedures:

Procedure	SAS Product	Default Value
CATMOD	SAS/STAT	INTERNAL
FREQ	Base SAS	INTERNAL

Procedure	SAS Product	Default Value
GLM	SAS/STAT	FORMATTED
LIFEREG	SAS/STAT	FORMATTED
LOGISTIC	SAS/STAT	FORMATTED
MEANS	Base SAS	UNFORMATTED
PROBIT	SAS/STAT	FORMATTED
REPORT	Base SAS	FORMATTED
SUMMARY	Base SAS	UNFORMATTED
TABULATE	Base SAS	UNFORMATTED

The following topics explain each value of ORDER=.

Order Data Using the ORDER= INTERNAL Option

When you specify ORDER=INTERNAL with no other ordering options specified, it causes class variable values to be listed in ascending order by their actual, unformatted values:

```
proc format;
   value numf 1='ONE' 2='TWO' 3='THREE' 4='FOUR';
run;
proc report data=sasuser.houses;
   column bedrooms;
   define bedrooms /group format=numf8. order=internal;
run;
```

Output 2.4 *Output When ORDER=INTERNAL*

The SAS System

Number of bedrooms
ONE
TWO
THREE
FOUR

The values for bedroom are ONE, TWO, THREE, and FOUR, which correspond to the numbers 1, 2, 3, 4. If you do not specify ORDER=INTERNAL, the values are listed in alphabetical order by the formatted value: FOUR, ONE, THREE, TWO.

Order Data Using the ORDER= FORMATTED Option

When you specify ORDER=FORMATTED with no other ordering options specified causes class variable values to be listed in alphabetical order by their formatted values:

```
proc format;
   value numf 1='ONE' 2='TWO' 3='THREE' 4='FOUR';
run;
proc freq data=sasuser.houses order=formatted;
   tables bedrooms / nopercent;
   format bedrooms numf8. ;
run;
```

Output 2.5 *Output When ORDER=FORMATTED*

The SAS System

The FREQ Procedure

Number of bedrooms		
bedrooms	Frequency	Cumulative Frequency
FOUR	4	4
ONE	2	6
THREE	4	10
TWO	5	15

If ORDER=FORMATTED is specified and a class variable does not have a format associated with it, then the output is listed by its internal, or unformatted values.

In a special case, as the default behavior for PROC REPORT is ORDER=FORMATTED, this setting might cause problems because PROC REPORT uses BEST*w*. as the default format for numeric values. Here is an example:

```
proc report data=sasuser.houses;
   title1 "ORDER=FORMATTED";
   title2 "(default)";
   title4 "FORMAT=BEST9.";
   title5 "(default)";
   column baths;
   define baths / group;
run;
```

Here, BEST9. is the default format because a format is not specified. Since the default setting for PROC REPORT is ORDER=FORMATTED, the values are sorted using the formatted values. This can be complicated by character comparisons that sometimes give misleading results. The values that are being compared are " 1", " 2", " 3", "1.5", and "2.5". The single-digit values have leading blanks. Since a blank character sorts before a number or a period (.), the values "1", "2", and "3" sort before the values 1.5 or 2.5.

Output 2.6 *PROC REPORT Default Formatting When Values Have Leading Blanks*

ORDER=FORMATTED
(default)

FORMAT=BEST9.
(default)

Number of bathrooms
1
2
3
1.5
2.5

This problem is corrected in the next output by using the 3.1 format, causing no leading blanks to appear in the comparison:

```
proc report data=sasuser.houses;
   title1 "ORDER=FORMATTED";
   title2 "(default)";
   title4 "FORMAT=3.1";
   title5 "(specified)";
   column baths;
   define baths / group format=3.1;
run;
```

Output 2.7 *PROC REPORT Formatted When Values Have No Leading Blanks*

ORDER=FORMATTED (default)

FORMAT=3.1 (specified)

Number of bathrooms
1.0
1.5
2.0
2.5
3.0

The problem is also corrected in the following output because the internal values and not the formatted values are used to determine the order:

```
proc report data=sasuser.houses nowd;
   title1 "ORDER =INTERNAL";
   title2 "(specified)";
   title4 "FORMAT=BEST9.";
   title5 "(default)";
   column baths;
   define baths / group order=internal;
run;
```

Output 2.8 *PROC FORMAT Output Based on Internal Values*

ORDER =INTERNAL (specified)

FORMAT=BEST9. (default)

Number of bathrooms
1
1.5
2
2.5
3

Order Data Using the ORDER= DATA Option

ORDER=DATA specifies that the order is set according to how the data is initially read by the procedure. ORDER=DATA can be complicated depending on the use of BY statements or multiple classification variables. Here is a simple case:

```
proc tabulate data=sasuser.houses order=data format=3. noseps;
   class style;
   table style, n;
run;
```

Output 2.9 *PROC TABULATE with ORDER=DATA*

	N
Style of homes	
RANCH	4
SPLIT	3
CONDO	4
TWOSTORY	4

The output order for Style is neither ascending nor descending. RANCH appears first because it is the first value that is encountered in the input data set. SPLIT appears second because it is encountered second, and so on. If you use a BY statement, then the order is reset at the beginning of each new BY group, as if a new data set were being processed.

When you use multiple classification variables, the order is determined independently for each classification variable across the entire data set or BY group. The ordering scheme is developed first using the master order of the highest order variable and then the next highest, and so on. Here is an example:

```
proc tabulate data=sasuser.houses order=data format=3. noseps;
   class style bedrooms;
   table style*bedrooms, n;
run;
```

Output 2.10 *PROC TABULATE Using Two Classification Variables*

		N
Style of homes	Number of bedrooms	
RANCH	2	1
	1	1
	3	2
SPLIT	1	1
	4	1
	3	1
CONDO	2	2
	4	1
	3	1
TWOSTORY	2	2
	4	2

To compare, the order for Style is RANCH, SPLIT, CONDO, TWOSTORY. The order for Bedrooms is 2, 1, 4, 3. This is not clearly apparent in the output because no value of STYLE has all four values of Bedrooms. The order of values is established independently for each variable and not according to the subgroups. You can verify this by adding the PRINTMISS option to the TABLE statement or by comparing the order of Style and Bedrooms in the Sasuser.Houses data set. See "Order Data Using Multiple Classification Variables" on page 32.

Order Data Using the ORDER= FREQ Option

ORDER=FREQ specifies that classification variables are to be ordered by the frequencies of each of their values. With the exception of PROC FREQ, missing class levels are ordered by their frequency counts just as nonmissing class levels are. PROC FREQ always lists missing class levels first, regardless of their frequency counts. All Base SAS procedures, except for PROC REPORT, list the frequencies in descending order. PROC REPORT, by default, lists the frequencies in ascending order. If you use the PROC REPORT option DESCENDING in conjunction with ORDER=FREQ, then the class levels are ordered by their descending frequency counts.

If two class levels have the same frequency, a secondary ordering algorithm is used. All Base SAS procedures, except for PROC FREQ, use ORDER=DATA as a secondary ordering method.

If duplicate frequency counts occur with PROC FREQ and ORDER=FREQ has been specified, then PROC FREQ uses ORDER=FORMATTED as a secondary ordering method. If in PROC FREQ a format has not been applied, then the tie is broken

using the ORDER=INTERNAL method. If you use PROC REPORT with ORDER=FREQ and the DESCENDING option, and a tie occurs, then the ORDER=DATA method is used, but the levels are listed in reverse order of occurrence in the data.

The following table summarizes the behavior across the Base SAS procedures that use the ORDER= option:

Procedure	Order Direction	Format	Order Value In a Tie
FREQ	Descending	No	ORDER=INTERNAL
		Yes	ORDER=FORMATTED
MEANS	Descending	Yes or No	ORDER=DATA
REPORT	Ascending	Yes or No	ORDER=DATA
	Descending	Yes or No	ORDER=DATA [1]
SUMMARY	Descending	Yes or No	ORDER=DATA
TABULATE	Descending	Yes or No	ORDER=DATA

1 If you specify the DESCENDING option, then both the primary method, ORDER=FREQ, and the secondary method, ORDER=DATA, list levels in descending order.

Here are some examples when ORDER=FREQ is specified with the TABULATE, FREQ, and REPORT procedures. First we have PROC TABULATE and PROC FREQ output without a format specified:

```
proc format;
   value bedfmt 1='ONE' 2='TWO' 3='THREE' 4='FOUR';

proc tabulate data=sasuser.houses order=freq noseps format=3.;
   title1 "PROC TABULATE";
   title2 "Without Format";
   class bedrooms;
   table bedrooms, n;
run;

proc freq data=sasuser.houses order=freq;
   title1 "PROC FREQ";
   title2 "Without Format";
   tables bedrooms / nocum nopercent;
run;
```

Both outputs list data values in descending order of the frequency counts.

Output 2.11 *ORDER=FREQ Examples*

PROC TABULATE
Without Format

	N
Number of bedrooms	
2	5
4	4
3	4
1	2

PROC FREQ
Without Format

The FREQ Procedure

Number of bedrooms	
bedrooms	Frequency
2	5
3	4
4	4
1	2

PROC REPORT, when no format is specified, lists the output in ascending order:

```
proc report data=sasuser.houses;
   title1 "PROC REPORT";
   title2 "Without Format";
   title3 "Without DESCENDING";
   column bedrooms n;
   define bedrooms / group order=freq;
run;
```

Output 2.12 *PROC REPORT with No Format Specified*

PROC REPORT
Without Format
Without DESCENDING

Number of bedrooms	n
1	2
4	4
3	4
2	5

For PROC REPORT to list output in descending order, you must specify DESCENDING in the DEFINE statement:

```
proc report data=sasuser.houses;
   title1 "PROC REPORT";
   title2 "Without Format";
   title3 "With DESCENDING";
   column bedrooms n;
   define bedrooms / group order=freq descending;
run;
```

PROC REPORT
Without Format
With DESCENDING

Number of bedrooms	n
2	5
4	4
3	4
1	2

PROC TABULATE and PROC REPORT use the ORDER=DATA method to handle values that are the same.

```
proc tabulate data=sasuser.houses order=freq noseps format=3.;
   title1 "PROC TABULATE";
   title2 "With Format";
   class bedrooms;
   table bedrooms, n;
   format bedrooms bedfmt.;
run;
proc report data=sasuser.houses;
   title1 "PROC REPORT";
   title2 "With Format";
   title3 "Without DESCENDING";
```

```
   column bedrooms n;
   define bedrooms / group order=freq format=bedfmt8.;
run;
```

Output 2.13 *Descending Output Examples*

PROC TABULATE With Format

	N
Number of bedrooms	
TWO	5
FOUR	4
THREE	4
ONE	2

PROC REPORT With Format Without DESCENDING

Number of bedrooms	n
ONE	2
FOUR	4
THREE	4
TWO	5

PROC FREQ uses ORDER=FORMATTED when a format is specified and values are the same.

```
proc freq data=sasuser.houses order=freq;
   title1 "PROC FREQ";
   title2 "With Format";
   tables bedrooms / nocum nopercent;
   format bedrooms bedfmt.;
run;
```

Output 2.14 *Descending Output Using PROC FREQ with a Format*

PROC FREQ
With Format

The FREQ Procedure

Number of bedrooms	
bedrooms	Frequency
TWO	5
FOUR	4
THREE	4
ONE	2

If you do not specify a format, PROC FREQ uses ORDER=INTERNAL.

In PROC REPORT when DESCENDING is applied, data values are listed in descending order of frequency counts and the data values that had the same frequency are listed in reverse order of occurrence. In other words, ORDER=DATA is used to handle values that are the same, and the data values are listed in reverse order.

Output 2.15 *Output Using PROC REPORT with a Format and the DESCENDING Option*

PROC REPORT
With Format
With DESCENDING

Number of bedrooms	n
TWO	5
FOUR	4
THREE	4
ONE	2

As with ORDER=DATA, when you add a BY statement, the order for classification variables is established as if each BY group were a separate data set. When you use multiple classification variables with ORDER=FREQ, the order is determined independently for each classification variable. The overall ordering scheme is then applied first by using the order of the highest order variable and then the next-highest order variable, and so on.

In this example, consider the frequencies for Baths:

```
proc tabulate data=sasuser.houses order=freq format=3. noseps;
```

```
   class baths;
   table baths, n;
run;
```

Output 2.16 *The Frequency of Baths Using PROC TABULATE*

	N
Number of bathrooms	
1	5
3	4
2.5	3
1.5	2
2	1

If you make Bedrooms the highest order variable and Baths the next-highest order variable, you expect the rows to be ordered by the descending frequency of values first in Bedrooms, then in Baths.

```
proc tabulate data=sasuser.houses order=freq format=3. noseps;
   class baths bedrooms;
   table bedrooms*baths, n;
run;
```

The N statistic does not list the frequencies of the combinations in descending order. Instead, the order is set first by the descending frequencies of BEDROOMS and then by BATHS. You can verify this by comparing the order of each variable against the orders used in Output 2.11 on page 52. The master ordering sequence for BEDROOMS is 2, 4, 3, 1. The master ordering sequence for BATHS is 1, 3, 2.5, 1.5, 2.

Output 2.17 *PROC TABULATE with Bedrooms as the High Order Variable*

		N
Number of bedrooms	Number of bathrooms	
2	1	3
	1.5	1
	2	1
4	3	2
	2.5	2
3	3	2
	2.5	1
	1.5	1
1	1	2

RUN-Group Processing

RUN-group processing enables you to submit a PROC step with a RUN statement without ending the procedure. You can continue to use the procedure without issuing another PROC statement. To end the procedure, use a RUN CANCEL or a QUIT statement. Several Base SAS procedures support RUN-group processing:

CATALOG	DS2	PLOT	TRANTAB
DATASETS	FEDSQL	PMENU	

See the section on the individual procedure for more information.

Note: PROC SQL executes each query automatically. Neither the RUN nor RUN CANCEL statement has any effect.

Creating Titles That Contain BY-Group Information

BY-Group Processing

BY-group processing uses a BY statement to process observations that are ordered, grouped, or indexed according to the values of one or more variables. By default, when you use BY-group processing in a procedure step, a BY line identifies each group. This section explains how to create titles that serve as customized BY lines.

Suppressing the Default BY Line

When you insert BY-group processing information into a title, you usually want to suppress the default BY line. To suppress it, use the SAS system option NOBYLINE.

Note: You must use the NOBYLINE option if you insert BY-group information into titles for the following procedures:

- MEANS
- PRINT
- STANDARD
- SUMMARY

If you use the BY statement with the NOBYLINE option, then these procedures always start a new page for each BY group. This behavior prevents multiple BY

groups from appearing on a single page and ensures that the information in the titles matches the report on the pages.

Inserting BY-Group Information into a Title

The general form for inserting BY-group information into a title is as follows:

#BY-specification<.suffix>

BY-specification is one of the following specifications:

BYVAL*n* | BYVAL(*BY-variable*)
places the value of the specified BY variable in the title. You specify the BY variable with one of the following options:

n
is the *n*th BY variable in the BY statement.

BY-variable
is the name of the BY variable whose value you want to insert in the title.

BYVAR*n* | BYVAR(*BY-variable*)
places the label or the name (if no label exists) of the specified BY variable in the title. You designate the BY variable with one of the following options:

n
is the *n*th BY variable in the BY statement.

BY-variable
is the name of the BY variable whose value you want to insert in the title.

BYLINE
inserts the complete default BY line into the title.

suffix supplies text to place immediately after the BY-group information that you insert in the title. No space appears between the BY-group information and the suffix.

Example: Inserting a Value from Each BY Variable into the Title

This example demonstrates these actions:

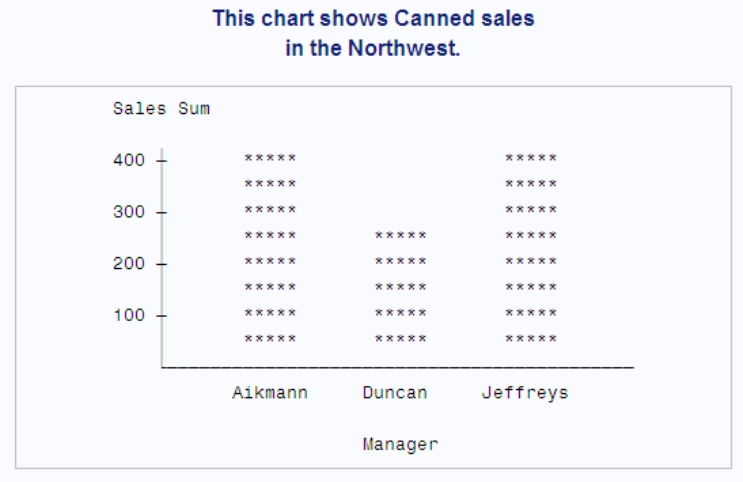
1. creates a data set, GROC, that contains data for stores from four regions. Each store has four departments. See "GROC" on page 2792 for the DATA step that creates the data set.
2. sorts the data by Region and Department.
3. uses the SAS system option NOBYLINE to suppress the BY line that normally appears in output that is produced with BY-group processing.

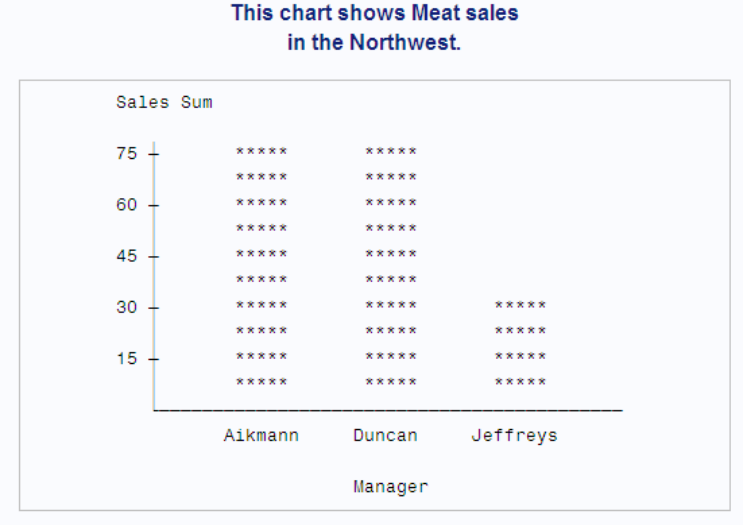
4 uses PROC CHART to chart sales by Region and Department. In the first TITLE statement, #BYVAL2 inserts the value of the second BY variable, Department, into the title. In the second TITLE statement, #BYVAL(Region) inserts the value of Region into the title. The first period after Region indicates that a suffix follows. The second period is the suffix.

5 uses the SAS system option BYLINE to return to the creation of the default BY line with BY-group processing.

```
data groc;                                                    1
   input Region $9. Manager $ Department $ Sales;
   datalines;
Southeast    Hayes       Paper       250
Southeast    Hayes       Produce     100
Southeast    Hayes       Canned      120
Southeast    Hayes       Meat         80
...more lines of data...
Northeast    Fuller      Paper       200
Northeast    Fuller      Produce     300
Northeast    Fuller      Canned      420
Northeast    Fuller      Meat        125
;
proc sort data=groc;                                          2
   by region department;
run;
options nobyline nodate pageno=1
        linesize=64 pagesize=20;                              3
proc chart data=groc;                                         4
   by region department;
   vbar manager / type=sum sumvar=sales;
   title1 'This chart shows #byval2 sales';
   title2 'in the #byval(region)..';
run;
options byline;                                               5
```

This partial output shows two BY groups with customized BY lines:





Example: Inserting the Name of a BY Variable into a Title

This example inserts the name of a BY variable and the value of a BY variable into the title. The program does these actions.

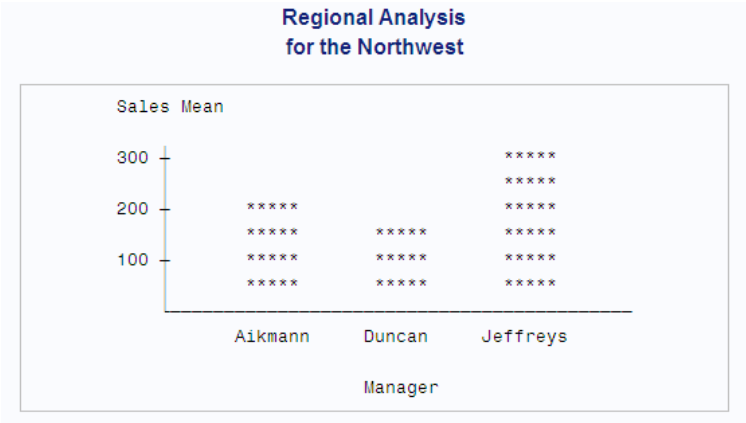
1 uses the SAS system option NOBYLINE to suppress the BY line that normally appears in output that is produced with BY-group processing.

2 uses PROC CHART to chart sales by Region. In the first TITLE statement, #BYVAR(Region) inserts the name of the variable Region into the title. (If Region had a label, #BYVAR would use the label instead of the name.) The suffix `al` is appended to the label. In the second TITLE statement, #BYVAL1 inserts the value of the first BY variable, Region, into the title.

3 uses the SAS system option BYLINE to return to the creation of the default BY line with BY-group processing.

```
options nobyline nodate pageno=1
        linesize=64 pagesize=20;          1
proc chart data=groc;                     2
   by region;
   vbar manager / type=mean sumvar=sales;
   title1 '#byvar(region).al Analysis';
   title2 'for the #byval1';
run;
options byline;                           3
```

This partial output shows one BY group with a customized BY line:



Example: Inserting the Complete BY Line into a Title

This example inserts the complete BY line into the title. The program does these actions:

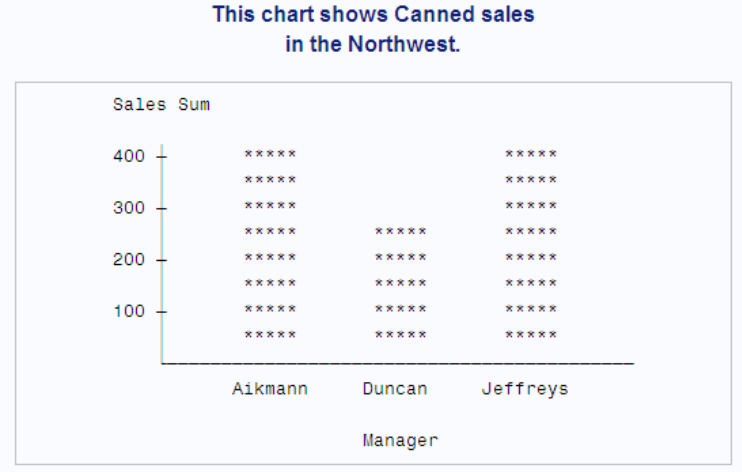
1 uses the SAS system option NOBYLINE to suppress the BY line that normally appears in output that is produced with BY-group processing.

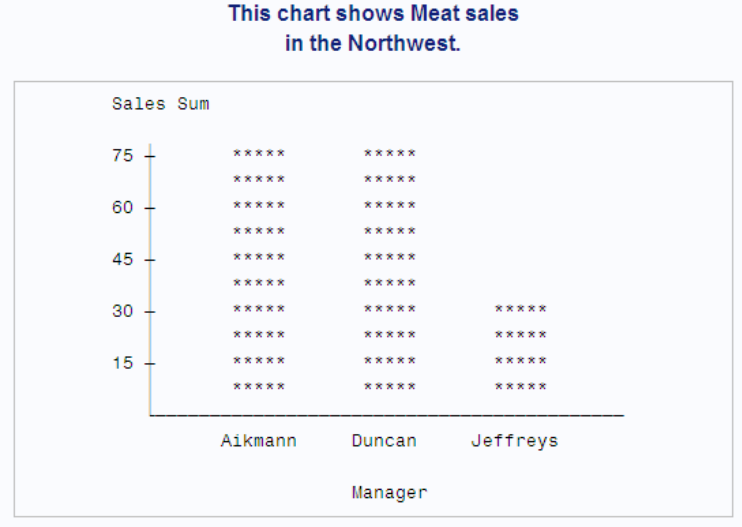
2 uses PROC CHART to chart sales by Region and Department. In the TITLE statement, #BYLINE inserts the complete BY line into the title.

3 uses the SAS system option BYLINE to return to the creation of the default BY line with BY-group processing.

```
options nobyline nodate pageno=1
        linesize=64 pagesize=20;          1
proc chart data=groc;                     2
   by region department;
   vbar manager / type=sum sumvar=sales;
   title 'Information for #byline';
run;
options byline;                           3
```

This partial output shows two BY groups with customized BY lines:





Error Processing of BY-Group Specifications

SAS does not issue error or warning messages for incorrect #BYVAL, #BYVAR, or #BYLINE specifications. Instead, the text of the item becomes part of the title.

Shortcuts for Specifying Lists of Variable Names

Several statements in procedures allow multiple variable names. You can use these shortcut notations instead of specifying each variable name:

Notation	Meaning
`x1-xn`	Specifies variables X1 through X*n*. The numbers must be consecutive.

Notation	Meaning
`x:`	Specifies all variables that begin with the letter X.
`x--a`	Specifies all variables between X and A, inclusive. This notation uses the position of the variables in the data set.
`x-numeric-a`	Specifies all numeric variables between X and A, inclusive. This notation uses the position of the variables in the data set.
`x-character-a`	Specifies all character variables between X and A, inclusive. This notation uses the position of the variables in the data set.
`_numeric_`	Specifies all numeric variables.
`_character_`	Specifies all character variables.
`_all_`	Specifies all variables.

Note: You cannot use shortcuts to list variable names in the INDEX CREATE statement in PROC DATASETS.

For more information, see the *SAS Language Reference: Concepts*.

Formatted Values

Using Formatted Values

Typically, when you print or group variable values, Base SAS procedures use the formatted values. This section contains examples of how Base SAS procedures use formatted values.

Example: Printing the Formatted Values for a Data Set

The following example prints the formatted values of the data set PROCLIB.PAYROLL. (For details about the DATA step that creates this data set, see "PROCLIB.PAYROLL" on page 2801.) In PROCLIB.PAYROLL, the variable

Jobcode indicates the job and level of the employee. For example, **TA1** indicates that the employee is at the beginning level for a ticket agent.

```
options nodate pageno=1
        linesize=64 pagesize=40;
proc print data=proclib.payroll(obs=10)
           noobs;
   title  'PROCLIB.PAYROLL';
   title2 'First 10 Observations Only';
run;
```

The following example is a partial printing of PROCLIB.PAYROLL:

PROCLIB.PAYROLL
First 10 Observations Only

IdNumber	Gender	Jobcode	Salary	Birth	Hired
1919	M	TA2	34376	12SEP60	04JUN87
1653	F	ME2	35108	15OCT64	09AUG90
1400	M	ME1	29769	05NOV67	16OCT90
1350	F	FA3	32886	31AUG65	29JUL90
1401	M	TA3	38822	13DEC50	17NOV85
1499	M	ME3	43025	26APR54	07JUN80
1101	M	SCP	18723	06JUN62	01OCT90
1333	M	PT2	88606	30MAR61	10FEB81
1402	M	TA2	32615	17JAN63	02DEC90
1479	F	TA3	38785	22DEC68	05OCT89

The following PROC FORMAT step creates the format $JOBFMT., which assigns descriptive names for each job:

```
proc format;
    value $jobfmt
          'FA1'='Flight Attendant Trainee'
          'FA2'='Junior Flight Attendant'
          'FA3'='Senior Flight Attendant'
          'ME1'='Mechanic Trainee'
          'ME2'='Junior Mechanic'
          'ME3'='Senior Mechanic'
          'PT1'='Pilot Trainee'
          'PT2'='Junior Pilot'
          'PT3'='Senior Pilot'
          'TA1'='Ticket Agent Trainee'
          'TA2'='Junior Ticket Agent'
          'TA3'='Senior Ticket Agent'
          'NA1'='Junior Navigator'
          'NA2'='Senior Navigator'
          'BCK'='Baggage Checker'
          'SCP'='Skycap';
run;
```

The FORMAT statement in this PROC MEANS step temporarily associates the $JOBFMT. format with the variable Jobcode:

```
options nodate pageno=1
        linesize=64 pagesize=60;
proc means data=proclib.payroll mean max;
   class jobcode;
   var salary;
   format jobcode $jobfmt.;
   title 'Summary Statistics for';
   title2 'Each Job Code';
run;
```

PROC MEANS produces this output, which uses the $JOBFMT. format:

Summary Statistics for Each Job Code

The MEANS Procedure

Analysis Variable : Salary			
Jobcode	**N Obs**	**Mean**	**Maximum**
Baggage Checker	9	25794.22	26896.00
Flight Attendant Trainee	11	23039.36	23979.00
Junior Flight Attendant	16	27986.88	28978.00
Senior Flight Attendant	7	32933.86	33419.00
Mechanic Trainee	8	28500.25	29769.00
Junior Mechanic	14	35576.86	36925.00
Senior Mechanic	7	42410.71	43900.00
Junior Navigator	5	42032.20	43433.00
Senior Navigator	3	52383.00	53798.00
Pilot Trainee	8	67908.00	71349.00
Junior Pilot	10	87925.20	91908.00
Senior Pilot	2	10504.50	11379.00
Skycap	7	18308.86	18833.00
Ticket Agent Trainee	9	27721.33	28880.00
Junior Ticket Agent	20	33574.95	34803.00
Senior Ticket Agent	12	39679.58	40899.00

Note: Because formats are character strings, formats for numeric variables are ignored when the values of the numeric variables are needed for mathematical calculations.

Example: Grouping or Classifying Formatted Data

If you use a formatted variable to group or classify data, then the procedure uses the formatted values. The following example creates and assigns a format, $CODEFMT., that groups the levels of each job code into one category. PROC MEANS calculates statistics based on the groupings of the $CODEFMT. format.

```
proc format;
    value $codefmt
          'FA1','FA2','FA3'='Flight Attendant'
          'ME1','ME2','ME3'='Mechanic'
          'PT1','PT2','PT3'='Pilot'
          'TA1','TA2','TA3'='Ticket Agent'
                'NA1','NA2'='Navigator'
                      'BCK'='Baggage Checker'
                      'SCP'='Skycap';
run;

options nodate pageno=1
        linesize=64 pagesize=40;
proc means data=proclib.payroll mean max;
   class jobcode;
   var salary;
   format jobcode $codefmt.;
   title 'Summary Statistics for Job Codes';
   title2 '(Using a Format that Groups the Job Codes)';
run;
```

PROC MEANS produces this output:

Summary Statistics for Job Codes
(Using a Format that Groups the Job Codes)

The MEANS Procedure

Analysis Variable : Salary			
Jobcode	N Obs	Mean	Maximum
Baggage Checker	9	25794.22	26896.00
Flight Attendant	34	27404.71	33419.00
Mechanic	29	35274.24	43900.00
Navigator	8	45913.75	53798.00
Pilot	20	72176.25	91908.00
Skycap	7	18308.86	18833.00
Ticket Agent	41	34076.73	40899.00

Example: Temporarily Associating a Format with a Variable

If you want to associate a format with a variable temporarily, then you can use the FORMAT statement. For example, the following PROC PRINT step associates the DOLLAR8. format with the variable Salary for the duration of this PROC PRINT step only:

```
options nodate pageno=1
        linesize=64 pagesize=40;
proc print data=proclib.payroll(obs=10)
           noobs;
   format salary dollar8.;
   title 'Temporarily Associating a Format';
   title2 'with the Variable Salary';
run;
```

PROC PRINT produces this output:

Temporarily Associating a Format with the Variable Salary

IdNumber	Gender	Jobcode	Salary	Birth	Hired
1919	M	TA2	$34,376	12SEP60	04JUN87
1653	F	ME2	$35,108	15OCT64	09AUG90
1400	M	ME1	$29,769	05NOV67	16OCT90
1350	F	FA3	$32,886	31AUG65	29JUL90
1401	M	TA3	$38,822	13DEC50	17NOV85
1499	M	ME3	$43,025	26APR54	07JUN80
1101	M	SCP	$18,723	06JUN62	01OCT90
1333	M	PT2	$88,606	30MAR61	10FEB81
1402	M	TA2	$32,615	17JAN63	02DEC90
1479	F	TA3	$38,785	22DEC68	05OCT89

Example: Temporarily Dissociating a Format from a Variable

If a variable has a permanent format that you do not want a procedure to use, then temporarily dissociate the format from the variable by using a FORMAT statement.

In this example, the FORMAT statement in the DATA step permanently associates the $YRFMT. variable with the variable Year. Thus, when you use the variable in a PROC step, the procedure uses the formatted values. The PROC MEANS step,

however, contains a FORMAT statement that dissociates the $YRFMT. format from Year for this PROC MEANS step only. PROC MEANS uses the stored value for Year in the output.

```
proc format;
   value $yrfmt  '1'='Freshman'
                 '2'='Sophomore'
                 '3'='Junior'
                 '4'='Senior';
run;
data debate;
    input Name $ Gender $  Year $  GPA  @@;
    format year $yrfmt.;
    datalines;
Capiccio m 1 3.598 Tucker   m 1 3.901
Bagwell  f 2 3.722 Berry    m 2 3.198
Metcalf  m 2 3.342 Gold     f 3 3.609
Gray     f 3 3.177 Syme     f 3 3.883
Baglione f 4 4.000 Carr     m 4 3.750
Hall     m 4 3.574 Lewis    m 4 3.421
;

options nodate pageno=1
        linesize=64 pagesize=40;
proc means data=debate mean maxdec=2;
   class year;
   format year;
   title 'Average GPA';
run;
```

PROC MEANS produces this output, which does not use the YRFMT. format:

Average GPA

The MEANS Procedure

Analysis Variable : GPA		
Year	N Obs	Mean
1	2	3.75
2	3	3.42
3	3	3.56
4	4	3.69

Formats and BY-Group Processing

When a procedure processes a data set, it checks to determine whether a format is assigned to the BY variable. If it is, then the procedure adds observations to the current BY groups until the formatted value changes. If *nonconsecutive* internal values of the BY variables have the same formatted value, then the values are grouped into different BY groups. Therefore, two BY groups are created with the same formatted value. Also, if different and *consecutive* internal values of the BY variables have the same formatted value, then they are included in the same BY group.

Formats and Error Checking

If SAS cannot find a format, then it stops processing and prints an error message in the SAS log. You can suppress this behavior with the SAS system option NOFMTERR. If you use NOFMTERR, and SAS cannot find the format, then SAS uses a default format and continues processing. Typically, for the default, SAS uses the BEST *w*. format for numeric variables and the $*w*. format for character variables.

Note: To ensure that SAS can find user-written formats, use the SAS system option FMTSEARCH=. How to store formats is described in "Storing Informats and Formats " on page 1080.

Processing All the Data Sets in a Library

You can use the SAS Macro Facility to run the same procedure on every data set in a library. The macro facility is part of the Base SAS software.

"Example 10: Printing All the Data Sets in a SAS Library" on page 1851 shows how to print all the data sets in a library. You can use the same macro definition to perform any procedure on all the data sets in a library. Simply replace the PROC PRINT piece of the program with the appropriate procedure code.

Operating Environment-Specific Procedures

Several Base SAS procedures are specific to one operating environment or one release. Appendix 2, "Operating Environment-Specific Procedures," on page 2743 contains a table with additional information. These procedures are described in more detail in the SAS documentation for operating environments.

Statistic Descriptions

The following table identifies common descriptive statistics that are available in several Base SAS procedures. For more detailed information about available statistics and theoretical information, see "Keywords and Formulas" on page 2700.

Table 2.1 *Common Descriptive Statistics That Base SAS Procedures Calculate*

Statistic	Description	Procedures
Confidence intervals		FREQ, MEANS or SUMMARY, TABULATE, UNIVARIATE
CSS	Corrected sum of squares	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
CV	Coefficient of variation	MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
Goodness-of-fit tests		FREQ, UNIVARIATE
KURTOSIS	Kurtosis	MEANS or SUMMARY, TABULATE, UNIVARIATE
MAX	Largest (maximum) value	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
MEAN	Mean	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
MEDIAN	Median (50^{th} percentile)	CORR (for nonparametric correlation measures), MEANS or SUMMARY, TABULATE, UNIVARIATE
MIN	Smallest (minimum) value	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
MODE	Most frequent value (if not unique, the smallest mode is used)	UNIVARIATE
N	Number of observations on which calculations are based	CORR, FREQ, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE

Statistic	Description	Procedures
NMISS	Number of missing values	FREQ, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
NOBS	Number of observations	MEANS or SUMMARY, UNIVARIATE
PCTN	Percentage of a cell or row frequency to a total frequency	REPORT, TABULATE
PCTSUM	Percentage of a cell or row sum to a total sum	REPORT, TABULATE
Pearson correlation		CORR
Percentiles		FREQ, MEANS or SUMMARY, REPORT, TABULATE, UNIVARIATE
RANGE	Range	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
Robust statistics	Trimmed means, Winsorized means	UNIVARIATE
SKEWNESS	Skewness	MEANS or SUMMARY, TABULATE, UNIVARIATE
Spearman correlation		CORR
STD	Standard deviation	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
STDERR	Standard error of the mean	MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
SUM	sum	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
SUMWGT	Sum of weights	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE
Tests of location		UNIVARIATE
USS	Uncorrected sum of squares	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE

Statistic	Description	Procedures
VAR	Variance	CORR, MEANS or SUMMARY, REPORT, SQL, TABULATE, UNIVARIATE

Computational Requirements for Statistics

The following computational requirements are for the statistics that are listed in Table 2.1 on page 70. They do not describe recommended sample sizes.

- N and NMISS do not require any nonmissing observations.
- SUM, MEAN, MAX, MIN, RANGE, USS, and CSS require at least one nonmissing observation.
- VAR, STD, STDERR, and CV require at least two observations.
- CV requires that MEAN is not equal to zero.

Statistics are reported as missing if they cannot be computed.

Output Delivery System

The Output Delivery System (ODS) gives you greater flexibility in generating, storing, and reproducing SAS procedure and DATA step output, with a wide range of formatting options. ODS provides formatting functionality that is not available from individual procedures or from the DATA step alone. ODS overcomes these limitations and enables you to format your output more easily.

Prior to Version 7, most SAS procedures generated output that was designed for a traditional line-printer. This type of output has limitations that prevent you from getting the most value from your results:

- Traditional SAS output is limited to monospace fonts. With today's desktop document editors and publishing systems, you need more versatility in printed output.
- Some commonly used procedures do not produce output data sets. Before ODS, if you wanted to use output from one of these procedures as input to another procedure, then you relied on PROC PRINTTO and the DATA step to retrieve results.

For more information about the Output Delivery System, see the *SAS Output Delivery System: User's Guide*.

3

Statements with the Same Function in Multiple Procedures

Statements with the Same Function in Multiple Procedures

Overview

Several Base SAS statements have the same function in a number of Base SAS procedures. Some of the statements are fully documented in the *SAS DATA Step Statements: Reference*, and others are documented in this section.

Note: For procedure steps that create output, these statements apply only to the INPUT data set.

The following list shows you where to find more information about each statement:

ATTRIB
: affects the procedure output and the output data set. The ATTRIB statement does not permanently alter the variables in the input data set. The LENGTH=

option has no effect. For the complete documentation, see the *SAS DATA Step Statements: Reference*.

BY
orders the output according to the BY groups. See "BY" on page 74.

FORMAT
affects the procedure output and the output data set. The FORMAT statement does not permanently alter the variables in the input data set. The DEFAULT= option is not valid. For the complete documentation, see the *SAS DATA Step Statements: Reference*.

FREQ
treats observations as if they appear multiple times in the input data set. See "FREQ" on page 79.

INFORMAT
applies a pattern to or executes instructions for a data value to be read as input. The DEFAULT= option is not valid. For the complete documentation, see the *SAS DATA Step Statements: Reference*.

LABEL
affects the procedure output and the output data set. The LABEL statement does not permanently alter the variables in the input data set except when it is used with the MODIFY statement in PROC DATASETS. For complete documentation, see the *SAS DATA Step Statements: Reference*.

QUIT
executes any statements that have not executed and ends the procedure. See "QUIT" on page 81.

WEIGHT
specifies weights for analysis variables in the statistical calculations. See "WEIGHT" on page 82.

WHERE
subsets the input data set by specifying certain conditions that each observation must meet before it is available for processing. See "WHERE" on page 88.

Statements

BY

Overview of the BY Statement

Orders the output according to the BY groups.

For more information, see "Creating Titles That Contain BY-Group Information " on page 57.

BY <DESCENDING> *variable-1*

<... <DESCENDING> *variable-n*>

<NOTSORTED>;

Required Arguments

variable

specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then either the observations in the data set must be sorted by all the variables that you specify, or they must be indexed appropriately. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING

specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED

specifies that observations are not necessarily sorted in alphabetic or numeric order. The observations are grouped in another way (for example, chronological order).

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

You cannot use the NOTSORTED option in a PROC SORT step.

Note: You cannot use the GROUPFORMAT option, which is available in the BY statement in a DATA step, in a BY statement in any PROC step.

BY-Group Processing

Procedures create output for each BY group. For example, the elementary statistics procedures and the scoring procedures perform separate analyses for each BY group. The reporting procedures produce a report for each BY group.

Note: All Base SAS procedures except PROC PRINT process BY groups independently. PROC PRINT can report the number of observations in each BY group as well as the number of observations in all BY groups. Similarly, PROC PRINT can sum numeric variables in each BY group and across all BY groups.

You can use only one BY statement in each PROC step. When you use a BY statement, the procedure expects an input data set that is sorted by the order of the BY variables or one that has an appropriate index. If your input data set does not meet these criteria, then an error occurs. Either sort it with the SORT procedure or create an appropriate index on the BY variables.

Depending on the order of your data, you might need to use the NOTSORTED or DESCENDING option in the BY statement in the PROC step.

- For more information about the BY statement, see *SAS DATA Step Statements: Reference*.
- For more information about PROC SORT, see Chapter 64, "SORT Procedure," on page 2355.
- For more information about creating indexes, see "INDEX CREATE Statement" on page 638.

Formatting BY-Variable Values

When a procedure is submitted with a BY statement, the following actions are taken with respect to processing of BY groups:

1. The procedure determines whether the data is sorted by the internal (unformatted) values of the BY variable(s).
2. The procedure determines whether a format has been applied to the BY variable(s). If the BY variable is numeric and has no user-applied format, then the BEST12. format is applied for the purpose of BY-group processing.
3. The procedure continues adding observations to the current BY group until both the internal and formatted values of the BY variable or variables change.

This process can have unexpected results if, for example, nonconsecutive internal BY values share the same formatted value. In this case, the formatted value is represented in different BY groups. Alternatively, if different consecutive internal BY values share the same formatted value, then these observations are grouped into the same BY group.

BY Variables That Have Different Lengths in Two Data Sets

When a procedure has a BY statement and two input data sets, one of the input data sets is called the primary data set and the other is called the secondary data

set. The primary data set is usually, but not always, the DATA= data set. A BY statement always applies to the primary data set. The variables in the BY statement must appear in the primary data set.

Each procedure determines whether a BY statement applies to a secondary data set, and performs one of the following actions:

- The procedure might always apply the BY statement to the secondary data set. In this case, one or more variables in the BY statement must appear in the secondary data set.
- The procedure might never apply the BY statement to the secondary data set. In this case, the variables in the BY statement are not required in the secondary data set.
- The procedure might check whether the BY variables are in the secondary data set. If none of the BY variables are in the secondary data set, then BY processing does not occur for the secondary data set. If one or more of the BY variables are in the secondary data set, and they match the BY variables in the primary data set, then BY processing is done for the secondary data set. If some but not all BY variables are in the secondary data set, then the procedure might issue an error message and quit. Or, it might take some other action described in the documentation for that particular procedure.

If the BY statement is applied to the secondary data set, then each BY variable that exists on both the data sets must have the same type, character or numeric, in both data sets. The BY variables are required to have either the same formatted value or the same unformatted value. Formatted values match only if both the formatted lengths and the formatted values are the same. Unformatted values are not required to have the same length in order to match. The unformatted character values match if the unformatted values are the same after stripping the trailing blanks. The unformatted doubles match if they have the same value.

A secondary data set does not need to have all of the BY variables that are in the primary data set. A procedure can define a subset of the BY variables for the secondary data set. For example, if the primary data set has the BY variables A,B,C,D, then the procedure can define the following BY variables on the secondary data set:

- A
- A,B
- A,B,C
- A,B,C,D

If both the primary and secondary data sets have the same number of BY variables, and all the BY variables have the same byte lengths and format lengths, then either the unformatted values or the formatted values in the BY buffer (for all of the BY variables) have to match. If they do not match, then each variable is compared. The formatted values of each variable are compared first. The formatted lengths have to match, and the formatted values have to match. If the formatted lengths and values do not match, then the unformatted values are compared even if the byte lengths are different.

If corresponding character variable lengths differ, then the longer character variable can contain only trailing blanks for the extra characters. If the lengths of the

character variables are different, then the values match as long as they are the same after stripping the trailing blanks. For example, 'ABCD' in the primary data set matches 'ABCD ' in the secondary data set. If the secondary data set contained 'ABCDEF', then they would not match.

Base SAS Procedures That Support the BY Statement

CALENDAR	REPORT (nonwindowing environment only)
CHART	SORT (required)
COMPARE	STANDARD
CORR	SUMMARY
FREQ	TABULATE
MEANS	TIMEPLOT
PLOT	TRANSPOSE
PRINT	UNIVARIATE
RANK	

Note: In the SORT procedure, the BY statement specifies how to sort the data. In the other procedures, the BY statement specifies how the data is currently sorted.

Example

This example uses a BY statement in a PROC PRINT step. There is output for each value of the BY variable Year. The DEBATE data set is created in "Example: Temporarily Dissociating a Format from a Variable" on page 67.

```
options nodate pageno=1 linesize=64
        pagesize=40;
proc print data=debate noobs;
   by year;
   title 'Printing of Team Members';
   title2 'by Year';
run;
```

Printing of Team Members by Year

Year=Freshman

Name	Gender	GPA
Capiccio	m	3.598
Tucker	m	3.901

Year=Sophomore

Name	Gender	GPA
Bagwell	f	3.722
Berry	m	3.198
Metcalf	m	3.342

Year=Junior

Name	Gender	GPA
Gold	f	3.609
Gray	f	3.177
Syme	f	3.883

Year=Senior

Name	Gender	GPA
Baglione	f	4.000
Carr	m	3.750
Hall	m	3.574
Lewis	m	3.421

FREQ

Overview of the FREQ Statement

Treats observations as if they appear multiple times in the input data set.

You can use a WEIGHT statement and a FREQ statement in the same step of any procedure that supports both statements.

FREQ *variable*;

Required Arguments

variable
specifies a numeric variable whose value represents the frequency of the observation. If you use the FREQ statement, then the procedure assumes that each observation represents *n* observations, where *n* is the value of *variable*. If *variable* is not an integer, then SAS truncates it. If *variable* is less than 1 or is missing, then the procedure does not use that observation to calculate statistics. If a FREQ statement does not appear, then each observation has a default frequency of 1.

The sum of the frequency variable represents the total number of observations.

Procedures That Support the FREQ Statement

- CORR
- MEANS or SUMMARY
- REPORT
- STANDARD
- TABULATE
- UNIVARIATE

Example

The data in this example represents a ship's course and speed (in nautical miles per hour), recorded every hour. The frequency variable Hours represents the number of hours that the ship maintained the same course and speed. Each of the following PROC MEANS steps calculates average course and speed. The different results demonstrate the effect of using Hours as a frequency variable.

The following PROC MEANS step does not use a frequency variable:

```
options nodate pageno=1 linesize=64 pagesize=40;

data track;
   input Course Speed Hours @@;
   datalines;
30  4  8 50 7 20
75 10 30 30 8 10
80  9 22 20 8 25
```

```
83 11  6 20 6 20
;

proc means data=track maxdec=2 n mean;
   var course speed;
   title 'Average Course and Speed';
run;
```

Without a frequency variable, each observation has a frequency of 1, and the total number of observations is 8.

Average Course and Speed

The MEANS Procedure

Variable	N	Mean
Course	8	48.50
Speed	8	7.88

The second PROC MEANS step uses Hours as a frequency variable:

```
proc means data=track maxdec=2 n mean;
   var course speed;
   freq hours;
   title 'Average Course and Speed';
run;
```

When you use Hours as a frequency variable, the frequency of each observation is the value of Hours. The total number of observations is 141 (the sum of the values of the frequency variable).

Average Course and Speed

The MEANS Procedure

Variable	N	Mean
Course	141	49.28
Speed	141	8.06

QUIT

Overview of the QUIT Statement

Executes any statements that have not executed and ends the procedure.

QUIT;

Procedures That Support the QUIT Statement

- CATALOG
- DATASETS
- PLOT
- PMENU
- SQL

WEIGHT

Overview of the WEIGHT Statement

Specifies weights for analysis variables in the statistical calculations.

You can use a WEIGHT statement and a FREQ statement in the same step of any procedure that supports both statements.

WEIGHT *variable*;

Required Arguments

variable
specifies a numeric variable whose values weight the values of the analysis variables. The values of the variable do not have to be integers.

Different behavior for nonpositive values is discussed in the WEIGHT statement syntax under the individual procedure.

Prior to Version 7 of SAS, no Base SAS procedure excluded the observations with missing weights from the analysis. Most SAS/STAT procedures, such as PROC GLM, have always excluded not only missing weights but also negative and zero weights from the analysis. You can achieve this same behavior in a Base SAS procedure that supports the WEIGHT statement by using the EXCLNPWGT option in the PROC statement.

Weight value	Procedure
0	Counts the observation in the total number of observations

Less than 0	Converts the weight value to zero and counts the observation in the total number of observations
Missing	Excludes the observation from the analysis

The procedure substitutes the value of the WEIGHT variable for w_i, which appears in "Keywords and Formulas" on page 2700.

Procedures That Support the WEIGHT Statement

- CORR
- FREQ
- MEANS or SUMMARY
- REPORT
- STANDARD
- TABULATE
- UNIVARIATE

Note: In PROC FREQ, the value of the variable in the WEIGHT statement represents the frequency of occurrence for each observation. For more information, see the information about PROC FREQ in the *Base SAS(R) 9.3 Procedures Guide: Statistical Procedures*.

Calculating Weighted Statistics

The procedures that support the WEIGHT statement also support the VARDEF= option, which lets you specify a divisor to use in the calculation of the variance and standard deviation.

By using a WEIGHT statement to compute moments, you assume that the *i*th observation has a variance that is equal to σ^2/w_i. When you specify VARDEF=DF (the default), the computed variance is a weighted least squares estimate of σ^2. Similarly, the computed standard deviation is an estimate of σ. Note that the computed variance is not an estimate of the variance of the *i*th observation, because this variance involves the observation's weight, which varies from observation to observation.

If the values of your variable are counts that represent the number of occurrences of each observation, then use this variable in the FREQ statement rather than in the WEIGHT statement. In this case, because the values are counts, they should be integers. (The FREQ statement truncates any noninteger values.) The variance that

is computed with a FREQ variable is an estimate of the common variance σ^2 of the observations.

Note: If your data comes from a stratified sample where the weights w_i represent the strata weights, then neither the WEIGHT statement nor the FREQ statement provides appropriate stratified estimates of the mean, variance, or variance of the mean. To perform the appropriate analysis, consider using PROC SURVEYMEANS, which is a SAS/STAT procedure that is documented in the *Base SAS(R) 9.3 Procedures Guide: Statistical Procedures*.

Weighted Statistics Example

As an example of the WEIGHT statement, suppose 20 people are asked to estimate the size of an object 30 cm wide. Each person is placed at a different distance from the object. As the distance from the object increases, the estimates should become less precise.

The SAS data set SIZE contains the estimate (ObjectSize) in centimeters at each distance (Distance) in meters and the precision (Precision) for each estimate. Notice that the largest deviation (an overestimate by 20 cm) came at the greatest distance (7.5 meters from the object). As a measure of precision, 1/Distance, gives more weight to estimates that were made closer to the object and less weight to estimates that were made at greater distances.

The following statements create the data set SIZE:

```
options nodate pageno=1 linesize=64 pagesize=60;

data size;
   input Distance ObjectSize @@;
   Precision=1/distance;
   datalines;
1.5 30 1.5 20 1.5 30 1.5 25
3   43 3   33 3   25 3   30
4.5 25 4.5 36 4.5 48 4.5 33
6   43 6   36 6   23 6   48
7.5 30 7.5 25 7.5 50 7.5 38
;
```

The following PROC MEANS step computes the average estimate of the object size while ignoring the weights. Without a WEIGHT variable, PROC MEANS uses the default weight of 1 for every observation. Thus, the estimates of object size at all distances are given equal weight. The average estimate of the object size exceeds the actual size by 3.55 cm.

```
proc means data=size maxdec=3 n mean var stddev;
   var objectsize;
   title1 'Unweighted Analysis of the SIZE Data Set';
run;
```

Unweighted Analysis of the SIZE Data Set

The MEANS Procedure

Analysis Variable : ObjectSize			
N	Mean	Variance	Std Dev
20	33.550	80.892	8.994

The next two PROC MEANS steps use the precision measure (Precision) in the WEIGHT statement and show the effect of using different values of the VARDEF= option. The first PROC step creates an output data set that contains the variance and standard deviation. If you reduce the weighting of the estimates that are made at greater distances, the weighted average estimate of the object size is closer to the actual size.

```
proc means data=size maxdec=3 n mean var stddev;
   weight precision;
   var objectsize;
   output out=wtstats var=Est_SigmaSq std=Est_Sigma;
   title1 'Weighted Analysis Using Default VARDEF=DF';
run;

proc means data=size maxdec=3 n mean var std
                     vardef=weight;
   weight precision;
   var objectsize;
   title1 'Weighted Analysis Using VARDEF=WEIGHT';
run;
```

The variance of the *i*th observation is assumed to be $var(x_i) = \sigma^2/w_i$ and w_i is the weight for the *i*th observation. In the first PROC MEANS step, the computed variance is an estimate of σ^2. In the second PROC MEANS step, the computed variance is an estimate of $(n - 1/n)\,\sigma^2/\overline{w}$, where $\overline{w}$ is the average weight. For large n, this value is an approximate estimate of the variance of an observation with average weight.

Weighted Analysis Using Default VARDEF=DF

The MEANS Procedure

Analysis Variable : ObjectSize			
N	Mean	Variance	Std Dev
20	31.088	20.678	4.547

Weighted Analysis Using VARDEF=WEIGHT

The MEANS Procedure

Analysis Variable : ObjectSize			
N	Mean	Variance	Std Dev
20	31.088	64.525	8.033

The following statements create and print a data set with the weighted variance and weighted standard deviation of each observation. The DATA step combines the output data set that contains the variance and the standard deviation from the weighted analysis with the original data set. The variance of each observation is computed by dividing Est_SigmaSq (the estimate of σ^2 from the weighted analysis when VARDEF=DF) by each observation's weight (Precision). The standard deviation of each observation is computed by dividing Est_Sigma (the estimate of σ from the weighted analysis when VARDEF=DF) by the square root of each observation's weight (Precision).

```
data wtsize(drop=_freq_ _type_);
   set size;
   if _n_=1 then set wtstats;
   Est_VarObs=est_sigmasq/precision;
   Est_StdObs=est_sigma/sqrt(precision);

proc print data=wtsize noobs;
   title 'Weighted Statistics';
   by distance;
   format est_varobs est_stdobs
          est_sigmasq est_sigma precision 6.3;
run;
```

Weighted Statistics

Distance=1.5

ObjectSize	Precision	Est_SigmaSq	Est_Sigma	Est_VarObs	Est_StdObs
30	0.667	20.678	4.547	31.017	5.569
20	0.667	20.678	4.547	31.017	5.569
30	0.667	20.678	4.547	31.017	5.569
25	0.667	20.678	4.547	31.017	5.569

WHERE

Overview of the WHERE Statement

Subsets the input data set by specifying certain conditions that each observation must meet before it is available for processing.

WHERE *where-expression*;

Required Arguments

where-expression
is a valid arithmetic or logical expression that generally consists of a sequence of operands and operators. For more information about where processing, see *SAS DATA Step Statements: Reference*.

Procedures That Support the WHERE Statement

You can use the WHERE statement with any of the following Base SAS procedures that read a SAS data set:

CALENDAR	RANK
CHART	REPORT
COMPARE	SORT
CORR	SQL
DATASETS (APPEND statement)	STANDARD
FREQ	TABULATE
MEANS or SUMMARY	TIMEPLOT
PLOT	TRANSPOSE
PRINT	UNIVARIATE

Details

- The CALENDAR and COMPARE procedures and the APPEND statement in PROC DATASETS accept more than one input data set. For more information, see the documentation for the specific procedure.
- To subset the output data set, use the WHERE= data set option:

```
proc report data=debate nowd
            out=onlyfr(where=(year='1'));
run;
```

  For more information about WHERE=, see *SAS DATA Step Statements: Reference*.

Example

In this example, PROC PRINT prints only those observations that meet the condition of the WHERE expression. The DEBATE data set is created in "Example: Temporarily Dissociating a Format from a Variable" on page 67.

```
options nodate pageno=1 linesize=64
        pagesize=40;

proc print data=debate noobs;
   where gpa>3.5;
   title 'Team Members with a GPA';
   title2 'Greater than 3.5';
run;
```

Team Members with a GPA Greater than 3.5

Name	Gender	Year	GPA
Capiccio	m	Freshman	3.598
Tucker	m	Freshman	3.901
Bagwell	f	Sophomore	3.722
Gold	f	Junior	3.609
Syme	f	Junior	3.883
Baglione	f	Senior	4.000
Carr	m	Senior	3.750
Hall	m	Senior	3.574

In-Database Processing of Base Procedures

Base Procedures That Are Enhanced for In-Database Processing

In-database processing has several advantages over processing within SAS. These advantages include increased security, reduced network traffic, and the potential for faster processing. Increased security is possible because sensitive data does not have to be extracted from the data source. Faster processing is possible for the following reasons:

- Data is manipulated locally, on the data source, using high-speed secondary storage devices instead of being transported across a relatively slow network connection.
- The data source might have more processing resources at its disposal.
- The data source might be capable of optimizing a query for execution in a highly parallel and scalable fashion.

Beginning with SAS 9.2M3, Base SAS procedures were enhanced to process data inside the Teradata, DB2, and Oracle data sources. In SAS 9.3, procedures were enhanced to process data inside the Netezza data source. In SAS 9.4, procedures have been enhanced to process data inside the Amazon Redshift, Aster, Google BigQuery, Greenplum, Hadoop, HAWQ, Impala, Microsoft SQL Server, PostgreSQL, SAP HANA, Snowflake, Vertica, and Yellowbrick data sources. The in-database procedures are used to generate more sophisticated queries that allow the aggregations and analytics to be run inside the data source.

All of these in-database procedures generate SQL queries. You use SAS/ACCESS or SQL as the interface to the data source.

The following Base SAS procedures support in-database processing.

Table 4.1 *In-Database Base Procedures*

Procedure	Description
PROC FREQ in *Base SAS Procedures Guide: Statistical Procedures*	Produces one-way to *n*-way tables; reports frequency counts; computes test and measures of association and agreement for two-way to *n*-way crosstabulation tables; can compute exact tests and asymptotic tests; can create output data sets.
PROC MEANS on page 1471	Computes descriptive statistics; can produce printed output and output data sets. By default, PROC MEANS produces printed output.
PROC RANK on page 2006[1]	Computes ranks for one or more numeric variables across the observations of a SAS data set; can produce some rank scores.
PROC REPORT on page 2154	Combines features of the PRINT, MEANS, and TABULATE procedures with features of the DATA step in a single report-writing tool that can produce a variety of reports.
PROC SORT on page 2387[1]	Orders SAS data set observations by the values of one or more character or numeric variables.
PROC SUMMARY on page 2455	Computes descriptive statistics; can produce a printed report and create an output data set. By default, PROC SUMMARY creates an output data set.
PROC TABULATE on page 2537	Displays descriptive statistics in tabular format, using some or all of the variables in a data set.
PROC TRANSPOSE on page 2655 [2]	Creates an output data set by restructuring the values in a SAS data set, transposing selected variables into observations.

1 Supported by Hadoop with Hive .14 and later.

2 Supported only by Hadoop. Additional licensed products and configuration are required.

For more information, see “In-Database Procedures” in *SAS In-Database Products: User’s Guide*.

5

CAS Processing of Base Procedures

About CAS Processing

Beginning with SAS 9.4M5, some Base SAS procedures are enhanced to process data inside SAS Cloud Analytic Services (CAS) with CAS actions. Processing with CAS actions can result in faster processing times. Faster processing is possible for the following reasons:

- The CAS server processes the in-memory tables instead of transferring the data across a relatively slow network connection between the server and the SAS client machine.
- The hardware for a CAS server typically has greater processing resources at its disposal.
- The majority of CAS actions are scalable for multithreaded processing. For large data volumes, distributed servers use multiple hosts to perform massively parallel processing.

Note: SAS 9.4 CAS-enabled procedures are designed to work with CAS in SAS Viya 3.5. In the SAS Viya 4 platform, some CAS-enabled procedures have been further optimized to take advantage of multithreading and the cloud-native platform.

When processing data in the SAS Viya 4 CAS server, SAS recommends that you submit the code from a SAS client on the SAS Viya 4 platform for best results.

The principle is to summarize and analyze large data volumes in the in-memory tables in the CAS server. The smaller, summarized results, are transferred from the server to the SAS client. The procedure then post-processes the summarized results to produce additional statistics, Output Delivery System (ODS) objects, and so on.

The core product of SAS Viya is SAS Visual Analytics. If you install SAS Visual Analytics only, then you have access to a subset of the Base SAS procedures. If you have SAS Viya with any other offering (in addition to SAS Visual Analytics) that is licensed and installed, you also have access to all SAS 9.4 Base procedures. The *Base SAS Procedures Guide* contains complete documentation for all Base procedures.

Some Base SAS procedures execute code on the CAS server. See Chapter 5, "CAS Processing of Base Procedures," on page 93.

Procedures That Use CAS Actions

The following Base SAS procedures can run CAS actions:

Procedure	Description
PROC APPEND on page 109	Adds rows from a CAS table to the end of a SAS data set, and adds rows from a SAS data set to the end of a CAS table.
PROC CONTENTS on page 489	Shows the contents of a CAS table and prints the directory of the caslib.
PROC COPY on page 521	Copies entire SAS libraries or specific members of the library.
PROC DATASETS on page 561	Manages CAS tables.
PROC DELETE on page 785	Deletes SAS data sets and CAS tables.
PROC DS2 [1]	Manipulates data with DS2 language statements.
PROC FCMP on page 873	Enables you to create, test, and store SAS functions, CALL routines, and subroutines before you use them in other SAS procedures or in DATA steps.

Procedure	Description
PROC FEDSQL [2]	Manipulates data and performs reporting with FedSQL language statements.
PROC FORMAT on page 1075	Creates user-defined informats to read data and user-defined formats to display data.
PROC LUA on page 1403	Enables you to run statements from the Lua programming language within SAS code.
PROC MEANS on page 1473	Computes descriptive statistics; can produce printed output and output data sets. By default, PROC MEANS produces printed output.
PROC REPORT on page 2155	Combines features of the PRINT, MEANS, and TABULATE procedures with features of the DATA step in a single report-writing tool that can produce a variety of reports.
PROC SCOREACCEL on page 2305	Provides an interface to the CAS server for DATA step and DS2 model publishing and scoring.
PROC SORT on page 2389	Provides the ability to manage duplicate observations in data sets. The SORT procedure uses the CAS deduplicate action to perform the equivalent functionality of the NODUPKEY or NOUNIKEY options of PROC SORT.
PROC SUMMARY on page 2455	Computes descriptive statistics; can produce a printed report and create an output data set. By default, PROC SUMMARY creates an output data set.
PROC TABULATE on page 2536	Displays descriptive statistics in tabular format, using some or all of the variables in a data set.

Procedure	Description
PROC TRANSPOSE on page 2656	Transforms SAS data sets so that observations become variables and variables become observations.

1 The DS2 procedure does not use the CAS LIBNAME engine to access in-memory tables. Instead, the procedure accesses tables by caslib and name. For information and limitations, see "DS2 in CAS: Concepts" in *SAS DS2 Programmer's Guide*.

2 The FEDSQL procedure does not use the CAS LIBNAME engine to access in-memory tables. Instead, the procedure accesses tables by caslib and name. For information and limitations, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*

When CAS Processing Cannot Be Used

The documentation for each procedure identifies the supported aggregations and supported statements and options. When your program includes a statement or option that cannot be processed with a CAS action, the observation-level data for the in-memory table is transferred to the SAS client. The procedure then runs on the transferred data.

By default, the CAS LIBNAME engine limits data transfer to 100 MB. If you reach the limit:

1. You might be able to achieve the result that you want with a SAS Visual Statistics procedure or SAS Visual Data Mining and Machine Learning procedure.
2. You might be able to program with CAS actions so that the summarization is performed by the server.
3. You can increase the limit with the CASDATALIMIT= system option or the DATALIMIT= LIBNAME option or data set option.

BY-Group Processing

For procedures that support a BY statement, the information is passed to the CAS server. This enables two optimizations:

1. The data does not need to be pre-sorted by the specified variables.
2. When the results are transferred by the server to the SAS client, the groups are already formed. These results can be summarized results as with PROC MEANS or they can be observation-level as is the case with PROC PRINT.

If you know in advance that you will perform BY-group processing, especially if you have large in-memory tables, you can partition the in-memory table as a further efficiency. When you partition an in-memory table with the same variables that you use for BY-group processing, you avoid the performance penalty for forming the groups each time you access the table.

Filtering Observations

Procedures that support a WHERE statement, the expression is sent to the server. The server resolves the expression and subsets the data for the analysis. This can greatly reduce processing time and data transfer from the server to the SAS client.

The same is true of the WHERE= data set option when it is used with the CAS LIBNAME engine—the expression is sent to the server to subset the data.

```
cas casauto host="cloud.example.com" port=5570;
libname mycas cas sessref=casauto;

proc casutil;
  load data=sashelp.prdsale;
quit;

/* View informational messages in the SAS log.       */
options msglevel=i;

/* The WHERE statement is processed by the server.   */
proc means data=mycas.prdsale;
  where region eq 'EAST';
run;

/* These results are identical to the preceding use  */
/* of PROC MEANS, but uses a WHERE= data set option. */
proc means data=mycas.prdsale(where=(region eq 'EAST'));
run;
```

Base SAS Procedures Documented in Other Publications

Base SAS Procedures Documented in Other Publications

Some Base SAS procedures are documented in other SAS publications. The following table lists these procedures and the publications that contain them.

Procedure	Description	Publication
CALLRFC	Executes Remote Function Calls (RFC) or RFC-compatible functions on an SAP System.	*SAS/ACCESS Interface to R/3: User's Guide*
CORR	Computes Pearson correlation coefficients, three nonparametric measures of association, and the probabilities associated with these statistics.	Base SAS Procedures Guide: Statistical Procedures
DOCUMENT	Enables you to rearrange, duplicate, or remove output from the results of a procedure or a database query that are in ODS documents.	*SAS Output Delivery System: User's Guide*

Procedure	Description	Publication
EXPLODE	Produces printed output with oversized text by expanding each letter into a matrix of characters.	The EXPLODE Procedure
FedSQL	Specifies that the subsequent input is FedSQL statements.	*SAS FedSQL Language Reference*
FORMS	Produces labels for envelopes, mailing labels, external tape labels, file cards, and any other printer forms that have a regular pattern.	The FORMS Procedure
FREQ	Produces one-way to n-way frequency and contingency (crosstabulation) tables.	Base SAS Procedures Guide: Statistical Procedures
GCHART	Produces six types of charts: block charts, horizontal and vertical bar charts, pie and donut charts, and star charts.	*SAS/GRAPH: Reference*
GEOCODE	Adds geographic coordinates (latitude and longitude values) and attribute values such as census blocks to an address.	*SAS/GRAPH and Base SAS: Mapping Reference*
GINSIDE	Compares a data set of X and Y coordinates to a map data set containing map polygons. It determines whether the X and Y coordinates for each point fall inside or outside of the map polygons. The resulting output map data set contains the points inside the map polygons. It can be used as input by the GMAP procedure in SAS/GRAPH, or the ODS Graphics SGMAP procedure in Base SAS.	*SAS/GRAPH and Base SAS: Mapping Reference*
GPLOT	Plots the values of two or more variables on a set of coordinate axes (X and Y).	*SAS/GRAPH: Reference*
GPROJECT	Processes map data sets by converting spherical coordinates (longitude and latitude) into Cartesian coordinates for use by the GMAP and SGMAP procedures.	*SAS/GRAPH and Base SAS: Mapping Reference*
GREDUCE	Processes map data sets so that they can draw simpler maps with fewer boundary points. The resulting output map data set with an added DENSITY variable can be used as an input map data set by the GMAP	*SAS/GRAPH and Base SAS: Mapping Reference*

Procedure	Description	Publication
	procedure in SAS/GRAPH, or the ODS Graphics SGMAP procedure in Base SAS.	
GREMOVE	Combines unit areas defined in a map data set into larger unit areas by removing internal borders between the original unit areas. The resulting output map data set can be used as input by the GMAP procedure in SAS/GRAPH, or the ODS Graphics SGMAP procedure in Base SAS.	*SAS/GRAPH and Base SAS: Mapping Reference*
INFOMAPS	Enables you to create information maps programmatically.	*Base SAS Guide to Information Maps*
MAPIMPORT	Enables you to import Esri shapefiles (spatial data formats) and process the SHP files into map data sets that are made available with SAS/GRAPH or through third-party sources.	*SAS/GRAPH and Base SAS: Mapping Reference*
METADATA	Sends an XML string to the SAS Metadata Server.	*SAS Language Interfaces to Metadata*
METALIB	Updates the metadata in the metadata server to match the tables in a library.	*SAS Language Interfaces to Metadata*
METAOPERATE	Enables you to perform administrative tasks in batch mode that are associated with the SAS Metadata Server.	*SAS Language Interfaces to Metadata*
ODSLIST	Stores a report's individual components and then enables you to modify and replay the report.	*SAS Output Delivery System: User's Guide*
ODSTABLE	Creates your tabular output templates.	*SAS Output Delivery System: User's Guide*
ODSTEXT	Creates paragraphs and lists that can be customized and nested an infinite number of times.	*SAS Output Delivery System: User's Guide*
SGDESIGN	Produces a graph from one or more input SAS data sets and a user-defined ODS Graphics Designer (SGD) file.	*SAS ODS Graphics: Procedures Guide*

Procedure	Description	Publication
SGMAP	Identifies the data sets needed for map areas, map response values, and overlay plots.	*SAS ODS Graphics: Procedures Guide*
SGPANEL	Creates a panel of graph cells for the values of one or more classification variables.	*SAS ODS Graphics: Procedures Guide*
SGPIE	Identifies the data set that contains the plot variables. The statement also gives you the option to specify a description, control automatic legends, and specify whether the chart background is opaque or transparent.	*SAS ODS Graphics: Procedures Guide*
SGPLOT	Creates one or more plots and overlays them on a single set of axes.	*SAS ODS Graphics: Procedures Guide*
SGRENDER	Produces graphical output from templates that are created with the Graph Template Language (GTL).	*SAS ODS Graphics: Procedures Guide*
SGSCATTER	Creates a paneled graph of scatter plots for multiple combinations of variables, depending on the plot statement that you use.	*SAS ODS Graphics: Procedures Guide*
SQL	Implements Structured Query Language (SQL) for SAS.	*SAS SQL Procedure User's Guide*
TEMPLATE	Enables you to customize the appearance of your SAS output.	*SAS Output Delivery System: User's Guide*
TRANTAB	Creates, edits, and displays customized translation tables, and enables you to view and modify translation tables that are supplied by SAS.	*SAS National Language Support (NLS): Reference Guide*
UNIVARIATE	Provides a variety of descriptive measures, graphical displays, and statistical methods, which you can use to summarize, visualize, analyze, and model the statistical distributions of numeric variables.	Base SAS Procedures Guide: Statistical Procedures

For information about all SAS procedures, see *SAS Procedures by Name and Product*. The information in *SAS Procedures by Name and Product* is arranged alphabetically by the procedures' names and by their products' names.

PART 2

Procedures

7

APPEND Procedure

Overview: APPEND Procedure

What Does the APPEND Procedure Do?

The APPEND procedure adds the observations from one SAS data set to the end of another SAS data set.

For more information, see Chapter 5, “CAS Processing of Base Procedures,” on page 93.

Generally, the APPEND procedure functions the same as the APPEND statement in the DATASETS procedure. The only difference between the APPEND procedure and the APPEND statement in PROC DATASETS is the default for *libref* in the BASE= and DATA= options. For PROC APPEND, the default is either Work or User. For the APPEND statement, the default is the libref of the procedure input library.

Syntax: APPEND Procedure

Requirement: The BASE= data set must be a member of a SAS library that supports update processing. Because the CAS libname engine does not support update processing, an existing CAS table cannot be specified with the BASE= option.

Notes: NOTE: _LAST_ is the name of the last data set created in your session. When the BASE= data set does not exist and PROC APPEND creates it, PROC APPEND sets _LAST_ to the name of the BASE= data set.

If you use the DROP=, KEEP=, or RENAME= options on the BASE= data set, the options affect ONLY the APPEND processing and does not change the variables in the appended BASE= data set. Variables that are dropped or not kept using the DROP= and KEEP= options still exist in the appended BASE= data set. Variables that are renamed using the RENAME= option remain with their original name in the appended BASE= data set.

Tips: Complete documentation for the APPEND procedure is located within the DATASETS procedure in APPEND Statement on page 586.

You can use the ATTRIB, FORMAT, LABEL, and WHERE statements. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

You can use data set options with the BASE= and DATA= options when using the APPEND procedure.

PROC APPEND BASE=*<libref.>SAS-data-set*

<APPENDVER=V6>
<DATA=*<libref.>SAS-data-set*>
<ENCRYPTKEY=*key-value*>
<FORCE>
<GETSORT>
<NOWARN>;

Statement	Task	Example
APPEND	Add observations from one SAS data set to the end of another SAS data set	Ex. , Ex. 3

Usage: APPEND Procedure

Using the APPEND Procedure

To copy only the table metadata and structure of a data set but not the data, use the following example where Dataset1 is nonexistent:

```
proc append base=dataset1 data=dataset2(obs=0);
run;

proc contents data=dataset1;
run;
quit;
```

Examples: APPEND Procedure

Example 1: Concatenating Two SAS Data Sets

Features:
- PROC APPEND statement options
  - BASE=
  - DATA=
  - FORCE
- OPTIONS statement
- PRINT procedure

Data set: EXP Library

Details

This example demonstrates the following tasks:

- suppresses the printing of a library
- appends two data sets
- prints the new data set after appending

To create the Exp.Results and Exp.Sur data sets and print them out before using this example to concatenate them, see "EXP Library" on page 2789.

Program

```
options pagesize=40 linesize=64 nodate pageno=1;

LIBNAME exp 'SAS-library';

proc append base=exp.results data=exp.sur force;
run;

proc print data=exp.results noobs;
   title 'The Concatenated RESULTS Data Set';
run;
quit;
```

Program Description

This example appends one data set to the end of another data set.

The data set Exp.Sur contains the variable Wt6Mos, but the Exp.Results data set does not.

Set the system options. The NODATE option suppresses the display of the date and time in the output. The PAGENO= option specifies the starting page number. The LINESIZE= option specifies the output line length, and the PAGESIZE= option specifies the number of lines on an output page.

```
options pagesize=40 linesize=64 nodate pageno=1;
```

The LIBNAME statement assigns the library.

```
LIBNAME exp 'SAS-library';
```

Append the data set Exp.Sur to the Exp.Results data set. PROC APPEND appends the data set Exp.Sur to the data set Exp.Results. FORCE causes PROC APPEND to carry out the Append operation even though Exp.Sur has a variable that Exp.Results does not. PROC APPEND does not add the Wt6Mos variable to Exp.Results.

```
proc append base=exp.results data=exp.sur force;
run;
```

Print the data set. See Output 7.20 on page 114.

```
proc print data=exp.results noobs;
   title 'The Concatenated RESULTS Data Set';
run;
quit;
```

Output: Concatenating Two Data Sets

Output 7.1 *The Results Data Set*

Example 2: Concatenating a CAS Table to a SAS Data Set

Features:

PROC APPEND statement options
- BASE=
- DATA=
- FORCE

OPTIONS statement

CONTENTS procedure

Details

This example demonstrates the following tasks:

- appending a CAS table to a SAS data set
- contents of the table, the data set, and the new data set after appending

Program

```
options pagesize=40 linesize=64 nodate pageno=1;

libname sascas1 cas;

libname saleslib 'directory-name';

proc contents data=saleslib.monthly;
run;

proc contents data=sascas1.lastmonth;
run;

proc append base=saleslib.monthly data=sascas1.lastmonth force;
run;

proc sql outobs=5;
   select store_id, address, city, state, zipcode, totalsales
   format dollar12.
   from saleslib.monthly(obs=4)
   where totalsales gt 2000000;
quit;
```

Program Description

This example appends a CAS table to the end of a SAS data set.

Set the system options. The NODATE option suppresses the display of the date and time in the output. The PAGENO= option specifies the starting page number. The LINESIZE= option specifies the output line length, and the PAGESIZE= option specifies the number of lines on an output page.

```
options pagesize=40 linesize=64 nodate pageno=1;
```

The LIBNAME statements assign the CAS engine and BASE engine libraries.

```
libname sascas1 cas;

libname saleslib 'directory-name';
```

Check the contents of the table and data set. Use PROC CONTENTS to view the data set and table.

```
proc contents data=saleslib.monthly;
run;

proc contents data=sascas1.lastmonth;
run;
```

Append the SasCas1.LastMonth table to the SalesLib.Monthly data set. The data for last month's sales in a CAS table is appended to the accumulated sales data stored in a SAS data set. The CAS table uses VARCHAR to store the city and address values. The SAS data set stores the values in character variables. Since the attribute for the two values differ, the FORCE option is used in PROC APPEND.

```
proc append base=saleslib.monthly data=sascas1.lastmonth force;
run;
```

Retrieve total sales. Use PROC SQL to retrieve five variables and sales that are greater than $2,000,000.

```
proc sql outobs=5;
   select store_id, address, city, state, zipcode, totalsales
   format dollar12.
   from saleslib.monthly(obs=4)
   where totalsales gt 2000000;
quit;
```

Warnings in the Log

Note the warnings that were sent to the log.

```
117        proc append base=saleslib.monthly data=sascas1.lastmonth force;
 118        run;

 NOTE: Appending SASCAS1.LASTMONTH to SALESLIB.MONTHLY.
 WARNING: Variable city has different lengths on BASE and DATA files
         (BASE 100 DATA 21).
 WARNING: Variable address has different lengths on BASE and DATA files
         (BASE 160 DATA 19).
 NOTE: There were 12 observations read from the data set SASCAS1.LASTMONTH.
 NOTE: 12 observations added.
 NOTE: The data set SALESLIB.MONTHLY has 24 observations and 7 variables.
```

Output: Concatenating a CAS Table to a SAS Data Set

Output 7.4 *The CAS Table Contents*

LastMonth Table

Example 3: Getting Sort Indicator Information

Features:

PROC APPEND statement options
    GETSORT

BY statement

CONTENTS procedure

ODS statement

SORT procedure

Details

This example demonstrates the following tasks:

- creates two data sets: one with no observations and one with observations
- sorts a data set in descending order
- creates a sort indicator using the SORTEDBY data set option
- creates a sort indicator using the SORT procedure

Program

```
data mtea;
    length var1 8.;
    stop;
run;

data phull;
    length var1 8.;
    do var1=1 to 100000;
    output;
end;
run;

proc sort data=phull;
    by DESCENDING var1;
run;

proc append base=mtea data=phull getsort;
run;

ods select sortedby;

proc contents data=mtea;
run;

data mysort(sortedby=var1);
    length var1 8.;
    do var1=1 to 10;
    output;
end;
run;

ods select sortedby;

proc contents data=mysort;
run;
quit;

data mysort;
    length var1 8.;
```

```
    do var1=1 to 10;
    output;
end;
run;

proc sort data=mysort;
    by var1;
run;

ods select sortedby;

proc contents data=mysort;
run;
quit;
```

Program Description

The following example shows that a sort indicator can be inherited using the GETSORT option with the APPEND procedure.

Create a "shell" data set that contains no observations.

```
data mtea;
    length var1 8.;
    stop;
run;
```

Create another data set with the same structure, but with many observations. Sort the data set.

```
data phull;
    length var1 8.;
    do var1=1 to 100000;
    output;
end;
run;

proc sort data=phull;
    by DESCENDING var1;
run;

proc append base=mtea data=phull getsort;
run;

ods select sortedby;

proc contents data=mtea;
run;
```

A sort indicator is being created using the SORTEDBY data set option.

```
data mysort(sortedby=var1);
    length var1 8.;
    do var1=1 to 10;
    output;
end;
```

```
run;

ods select sortedby;

proc contents data=mysort;
run;
quit;
```

A sort indicator is being created by PROC SORT.

```
data mysort;
    length var1 8.;
    do var1=1 to 10;
    output;
end;
run;

proc sort data=mysort;
    by var1;
run;

ods select sortedby;

proc contents data=mysort;
run;
quit;
```

AUTHLIB Procedure

Overview: AUTHLIB Procedure

What Does the AUTHLIB Procedure Do?

The AUTHLIB procedure is a utility procedure that manages metadata-bound libraries. With PROC AUTHLIB, you can do the following:

- create a metadata-bound library by binding a physical library to metadata within a SAS Metadata Repository
- modify password and encryption key values for a metadata-bound library
- purge replaced password and encryption key values that are also known as metadata-bound library credentials
- repair metadata-bound libraries by recovering security information, secured library objects, and secured table objects
- remove the physical security information and metadata objects that protect a metadata-bound library
- report inconsistencies between physical library contents and corresponding metadata objects within a specified metadata-bound library

Users cannot access metadata-bound data sets from any release of SAS prior to 9.3M2.

Note: For a z/OS direct-access bound library that has been bound to metadata, the constraint is slightly broader. Neither the library nor any of its members can be accessed by earlier releases of SAS.

Concepts: AUTHLIB Procedure

Metadata-Bound Library

A metadata-bound library is a physical library that is tied to a corresponding metadata secured table object. Each physical table within a metadata-bound library has information in its header that points to a specific metadata object. The pointer creates a security binding between the physical table and the metadata object. The binding ensures that SAS universally enforces metadata-layer access requirements for the physical table—regardless of how a user requests access from SAS. For more information, see *SAS Guide to Metadata-Bound Libraries*.

Using Metadata-Bound Library Passwords

A metadata-bound library contains a single set of passwords that are stored in the secured library object. This set of passwords is added to all data sets that are created in the metadata-bound library. These passwords are not used to authorize user access to the data. They are used to authorize administrator access to repair the binding of physical data to the secured library or table metadata objects. The passwords are also validated in the process of authorizing a user's access to a data set. They do not determine the permissions that any user is authorized to have.

The metadata-bound library passwords are intended to be known only by the administrators of the metadata-bound library. Knowledge of these passwords is required to restore or re-create secured library and secured table objects in a SAS Metadata Server for data sets in a data library that have lost their previously recorded metadata objects and permissions.

The metadata-bound library passwords also prevent a user from exporting the secured library and secured table objects from a SAS Metadata Server and then importing them to a SAS Metadata Server that an unauthorized user created and controls. This prevents the unauthorized user from using such objects where the user has modified the permissions.

The metadata-bound library passwords are always stored and transmitted in encrypted formats. The encrypted password is not usable to access the data if it is

captured from a transmission and presented to SAS as a password value in the SAS language. Administrators might choose to use the PWENCODE procedure to encode the passwords for use in a PROC AUTHLIB statement. Using an encoded password prevents a casual observer from seeing the clear-text password in the PROC AUTHLIB statements that the administrator types.

There are three passwords in the metadata-bound library set that correspond to the READ=, WRITE=, and ALTER= passwords of SAS data sets. For greater simplicity in administration of metadata-bound libraries, it is recommended that you use the PW= option in PROC AUTHLIB statements to specify a single password value. In the context of metadata-bound libraries, the READ=, WRITE=, and ALTER= options do not Create access distinctions. If you are concerned that a single eight character password does not meet your security requirements, then you can choose to set three different password values (using READ=, WRITE=, and ALTER=). Setting different values for these three options can create a 24-character password. However, you must keep track of all password values that you have assigned to a metadata-bound library. You must specify the passwords to do the following:

- unbind the library
- modify the passwords
- repair any inconsistencies in the binding information between what is recorded in the physical files and the actual metadata objects

For more information, see "Setting and Modifying Metadata-Bound Library Passwords" on page 128.

TIP All password values must be valid SAS names with a maximum length of 8 characters.

CAUTION
If you lose the password (or passwords) for a metadata-bound library, then you cannot unbind the library or change its passwords. Be sure to keep track of passwords that you assign in the CREATE and MODIFY statements.

Setting and Modifying Metadata-Bound Library Passwords

The metadata-bound library passwords are set in the CREATE statement and can be changed with the MODIFY statement. The passwords stored in data sets in the operating system library can be changed by those statements and subordinate TABLES statements. The passwords stored in the data sets can also be changed if the library is unbound from the metadata with a REMOVE statement.

All of the password options in the CREATE, MODIFY, TABLES, and REMOVE statements accept a syntax where two values can be specified separated by a slash (/) (for example, `PW=password-value/new-password-value`). For CREATE and MODIFY statements, a password value to set in the metadata or data sets is obtained from the password value before the slash (/) if no new password value is specified after the slash (/). The same is true for the REMOVE statement with the additional possibility of specifying the slash (/) and no new password value to indicate that the password should be removed from the data sets during the unbind process. However, note that if the CREATE, MODIFY, or REMOVE statement also specifies TABLESONLY=YES, then any new password values on those statements are ignored.

In general, you do not specify a new password value in a TABLES statement following a CREATE or MODIFY statement. The new value is obtained from the metadata to which the data set is bound or being bound. You can specify a new password value in TABLES statements following a REMOVE statement if you want different data sets to have unique passwords. In that case, you follow these steps:

1. Change the password for the data sets using a REMOVE statement with TABLESONLY=YES and an individual TABLES statement for each unique password.
2. Remove the metadata-bound library with a REMOVE statement without TABLESONLY=YES.

Encrypted Data Set Considerations

Some data sets in metadata-bound libraries might be encrypted either with the SAS Proprietary Encryption or Advanced Encryption Standard (AES) encryptions. SAS Proprietary Encryption is specified as ENCRYPT=YES when the data set is created. AES encryption is specified as ENCRYPT=AES or ENCRYPT=AES2 and as ENCRYPTKEY= key value (passphrase) when the data set is created. Special

considerations apply for these encrypted data sets when processed by the AUTHLIB procedure. The same encrypt passphrase is used for both AES and AES2, but different keys are generated for the actual encryption. AES2 keys meet stricter NIST (National Institute of Standards and Technology) guidelines..

CAUTION

AES encryption is supported only in SAS 9.4 and later releases. Do not use AES encryption if the data sets need to be accessible by SAS 9.3M2. The AES2 key generation algorithm is supported only in SAS 9.4M5 and later. Do not use it if data sets need to be accessible by earlier releases.

SAS Proprietary Encrypted Data Sets

SAS Proprietary Encryption uses the READ password of the data set as part of the encryption key. Since all metadata-bound data sets in the library share the same set of passwords, it is not necessary to specify the READ password when accessing the file. However, when the READ password is modified on the data set in a CREATE, MODIFY, or REMOVE statement, the data must be re-encrypted with the new password value. This process is done automatically for you in the 9.4 release with a copy-in-place operation. For more information about the copy-in-place operation, see "Copy-In-Place Operation" on page 166.

AES-Encrypted Data Sets

There are two ways to access an AES-encrypted data set:

- the user must provide the ENCRYPTKEY= passphrase value to open the data set
- the administrator must have recorded an optional or required encryption key for the metadata-bound library with the ENCRYPTKEY= option in the CREATE or MODIFY statement

Note: The ENCRYPTKEY= value is a passphrase that can be up to 64 characters long from which the actual AES encryption key is later derived, but it is referred to as the encryption key in most SAS documentation.

By recording an optional or required ENCRYPTKEY= key value for the metadata-bound library, the metadata becomes a key store for the encryption key value. Like password values, the key value is always stored and transmitted in encrypted formats. The encrypted key value is not usable to access the data if it is captured from a transmission and presented to SAS as an encryption key value in the SAS language. For more information, see "Setting and Modifying Metadata-Bound Library Encryption Options" on page 132. If there is no recorded encryption key for the library or the data set is encrypted with a different key, then you can specify the encryption key value by specifying the ENCRYPTKEY= option in a TABLES statement. For more information, see "TABLES Statement" on page 161.

Note: If an encryption key is recorded in the metadata with the AUTHLIB procedure, then it is honored by the SAS 9.4 release when creating and replacing SAS data sets, whether SAS 9.4M1 has been applied or not. The SAS 9.4 release of the AUTHLIB procedure cannot be used to administer the metadata-bound library if the REQUIRE_ENCRYPTION=YES attribute has been set.

CAUTION

Even if you record the encryption key in metadata for the library, you should also record the key elsewhere when using ENCRYPT=AES or ENCRYPT=AES2. If you lose the metadata and forget the ENCRYPTKEY= key value, then you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value. The following note is written to the log:

```
NOTE: If you lose or forget the ENCRYPTKEY= value,
there will be no way  to open the file or
recover the data.
```

For more information, see "Setting and Modifying Metadata-Bound Library Encryption Options" on page 132.

CAUTION

If data sets using AES encryption have referential integrity constraints, then the encryption key for all data sets must be available when they are opened for Update access. Normally, SAS requires that all data sets share the same encryption key. With a recorded optional or required encryption key in metadata, related data sets can have different keys. However, issues can arise if you change the encryption key on one library that has data sets related to data sets in a different library.

TIP If a metadata-bound library contains AES-encrypted data sets, then SAS recommends that you record an encryption key and use it for all metadata-bound data sets in the library that are encrypted with AES. The best way to ensure that the encryption key is used for all data sets is to require encryption. For more information, see "Requiring Encryption for Metadata-Bound Data Sets" on page 134.

- "Example 14: Changing the Encryption Key on a Metadata-Bound Library That Requires AES Encryption" on page 196

Setting and Modifying Metadata-Bound Library Encryption Options

There are three options that affect metadata-bound library encryption:

- REQUIRE_ENCRYPTION=
- ENCRYPT=
- ENCRYPTKEY=

The metadata-bound library encryption options are set in the CREATE statement and can be changed with the MODIFY statement. The encryption of data sets in the operating system library can be changed by the CREATE and MODIFY statements and subordinate TABLES statements. The encryption of data sets can also be changed if the library is unbound from the metadata by using a REMOVE statement. However, note that if the CREATE, MODIFY, or REMOVE statement also specifies TABLESONLY=YES, then any new encryption options on those statements are ignored. Also note that when encryption options are changed for a data set, the copy-in-place operation is automatically executed to re-encrypt the data with the new options. For more information about the copy-in-place operation, see “Copy-In-Place Operation” on page 166.

The default for the REQUIRE_ENCRYPTION= option is NO when it is used in the CREATE statement. The REQUIRE_ENCRYPTION= option can be changed in the MODIFY statement to YES or NO.

The ENCRYPT= option specifies the encryption type to use: AES, AES2, YES, or NO. ENCRYPT=NO is not valid if encryption is required. To record or change a metadata-bound library encryption key, ENCRYPT=AES or ENCRYPT=AES2 must be specified. If you want to switch from a required encryption with a recorded AES or AES2 encryption key to a required encryption with the SAS Proprietary algorithm, then specify ENCRYPT=YES in the MODIFY statement. This process also removes the recorded encryption key. To remove the recorded encryption key when encryption is not required, specify ENCRYPT=NO in the MODIFY statement. To change the encryption of data sets when unbinding with the REMOVE statement, perform one of the following tasks:

- specify different encryption options for data sets that are unbound by using TABLESONLY=YES and the encryption options on different TABLES statements
- change to a common encryption for all data sets that are unbound with the ENCRYPT= option if TABLESONLY is not YES

Similar to password options, the ENCRYPTKEY= option on statements accepts a syntax where two values that are separated by a slash (/) can be specified. Here is an example:

```
ENCRYPTKEY=key-value/new-key-value
```

For CREATE and MODIFY statements, the encryption key value to record in the metadata or data sets is obtained from the encryption key value before the slash (/) if

- ENCRYPT=AES or ENCRYPT=AES2
- there is no new key value specified after the slash (/)

If you do not specify ENCRYPT=AES or ENCRYPT=AES2, then the encryption key value is used to open data sets but it is not recorded in metadata. Unlike password options, you do not remove an encryption key value by specifying a slash (/) after it and leaving it blank. Instead, you use ENCRYPT=YES or ENCRYPT=NO, as discussed in the previous paragraph.

If encryption is required, then you do not specify a new key value in a TABLES statement following a CREATE or MODIFY statement. The new value is obtained from the metadata to which the data set is bound or being bound. If encryption is not required or if you are following a REMOVE statement with TABLESONLY=YES, then you can specify ENCRYPT=AES or ENCRYPT=AES2 and a new key value in TABLES statements to have the data set re-encrypted with the new key value.

- "Example 15: Binding a Library with Existing Data Sets That Are AES-Encrypted with Different Encryption Keys" on page 199
- "Example 16: Changing a Metadata-Bound Library to Require AES Encryption When Existing Data Sets Are Encrypted with Different Encryption Keys" on page 202

Retaining and Purging Metadata-Bound Library Credentials

Passwords and encryption keys for a metadata-bound library are collectively referred to as *metadata-bound library credentials*. Prior to SAS 9.4M3, when any of these credentials were modified, the replaced values were immediately removed from the metadata. Sometimes tables were not processed because another user was accessing the table.

Beginning with SAS 9.4M3, the credentials are retained in metadata and can be used by the system to open data sets that were not modified. This retention enables the user to continue processing tables and the administrator to complete the modification of credentials. The retained credentials are purged if a MODIFY statement that is processing all of the tables in the library determines that all the tables have been successfully changed with the credentials.

An administrator might want to retain the credentials even after all the existing tables have been processed successfully. The following are reasons for retaining the credentials:

- It enables processing of view files that implemented row and column level security on underlying tables by using the old passwords in the view definition.

SAS does not know which view files might contain the passwords and does not have the ability to modify them in the view file. The administrator must redefine the views with the new passwords.

- It enables processing of data sets restored from backups prior to the modification.

An administrator who wants to retain older credentials and not purge them can specify the PURGE=NO option in the MODIFY statement.

Note: The administrator must specify the PURGE=NO option in each MODIFY statement that processes all tables until the administrator is ready for the replaced credentials to be purged.

If a library contains tables that do not follow our best practices, automatic deletion of old credentials might not occur when issuing a MODIFY statement for all tables. For example, a MODIFY statement that changes the stored encryption key for a library with optional encryption would not modify the keys of data sets whose keys do not match the stored key. Because some data sets were not modified, the old encryption key is not removed. In this case, the PURGE statement must be used to remove the old credentials.

Note: Notes are written to the SAS log whenever a metadata-bound table is accessed and the replaced credentials are used to successfully open the data set. The Note identifies the date and time that these credentials were replaced.

For more information, see "PURGE Statement" on page 148.

Requiring Encryption for Metadata-Bound Data Sets

Beginning in SAS 9.4M1, an administrator can require that all data sets in a metadata-bound library be automatically encrypted when created. This is specified by using the REQUIRE_ENCRYPTION=YES option in the CREATE or MODIFY statements. The type of encryption required depends on whether there is a recorded encryption key or not. If there is a recorded encryption key, then all data sets that are bound to the secured library object are automatically encrypted with an encryption key that is generated from the recorded passphrase with the recorded key generation algorithm. If there is no recorded encryption key, then all data sets are automatically encrypted with the SAS Proprietary algorithm.

In order to automatically encrypt the data sets, a copy-in-place operation is used. For an explanation of the copy-in-place operation, see "Copy-In-Place Operation" on page 166. If the data set is currently encrypted with a different key value, then that key value must be either the current recorded encryption key value or specified with the ENCRYPTKEY= option in the TABLES statement.

Note: If the REQUIRE_ENCRYPTION=YES attribute of a metadata-bound library is set in the metadata with the AUTHLIB procedure, then it is honored by SAS 9.4 when creating and replacing SAS data sets whether SAS 9.4M1 has been applied or not. The pre-maintenance version of the AUTHLIB procedure cannot be used to administer the metadata-bound library if the REQUIRE_ENCRYPTION=YES attribute has been set. SAS 9.3M2 does not honor the REQUIRE_ENCRYPTION=YES attribute, and its AUTHLIB procedure should not be used to administer the library if the REQUIRE_ENCRYPTION=YES attribute is set.

- "Example 15: Binding a Library with Existing Data Sets That Are AES-Encrypted with Different Encryption Keys" on page 199
- "Example 16: Changing a Metadata-Bound Library to Require AES Encryption When Existing Data Sets Are Encrypted with Different Encryption Keys" on page 202

Data Sets in a Metadata-Bound Library That Are Not Bound to Secured Table Objects

It is possible that some data sets in a metadata-bound library do not have the metadata-bound library passwords. These data sets are not considered to be part of the bound library for authorization purposes. This can occur with either of the following scenarios:

- the data sets existed in the library before it was bound and their passwords differed from the metadata library passwords
- the data set is AES-encrypted and the encryption key was not available to open the data set in a CREATE or MODIFY statement

See the following examples:

- "Example 2: Binding a Physical Library That Contains Password-Protected Data Sets" on page 169
- "Example 12: Binding a Library with an Optional Recorded Encryption Key When Existing AES-Encrypted Data Sets Have Different Encryption Keys " on page 189

This can also occur if data sets were to be copied into the library by an operating system copy utility.

If a data set was bound before being copied, then the data set is still protected by the permissions that the users have in the secured table object to which it is bound in the original secured library.

If a data set was not bound before being copied, then it is also not bound in the new library or protected by the metadata permissions. If the data set has passwords, then you must supply the appropriate passwords to access the data.

You can use the MODIFY statement to modify the passwords if necessary and to bind the data set to a secured table object in the secured library object to which the library is bound. For more information, see "Example 5: Changing Passwords on Data Sets" on page 176.

Syntax: AUTHLIB Procedure

Restrictions: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Users cannot access metadata-bound data sets from any release of SAS prior to SAS 9.3M2.

The AUTHLIB procedure is intended for use by SAS administrators. Users who lack sufficient privileges in either the metadata layer or the host layer cannot use this statement.

The AUTHLIB procedure cannot operate on libraries that are assigned for access through a SAS/SHARE server.

The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and must be processed by an engine that supports metadata-bound libraries.

This procedure is not supported on the CAS server.

Requirement: The AUTHLIB procedure requires a connection to the target metadata server.

Tip: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

See: *SAS Guide to Metadata-Bound Libraries*

Statement	Task	Example
PROC AUTHLIB	Create and manage metadata-bound libraries	
CREATE	Create the secured library object in the SAS Metadata Server and record the physical	Ex. 1, Ex. 2, Ex. 3, Ex. 4,

Statement	Task	Example
	security information in the directory or bound files	Ex. 11, Ex. 10, Ex. 12, Ex. 13, Ex. 15
MODIFY	Modify password values and encryption key values for a metadata-bound library	Ex. 5, Ex. 6, Ex. 16
PURGE	Removes any retained metadata-bound library credentials older than a given date of replacement.	
REMOVE	Remove the physical security information and metadata objects that protect a metadata-bound library	Ex. 7
REPAIR	Recover security information (in physical data) or secured library and table objects (in metadata)	
REPORT	For a specified metadata-bound library, compare physical library contents with corresponding metadata objects (in order to identify any inconsistencies)	Ex. 8
TABLES	Specify which tables within a specified metadata-bound library are affected by certain AUTHLIB statements	Ex. 4, Ex. 9, Ex. 11, Ex. 10, Ex. 12, Ex. 15, Ex. 16

PROC AUTHLIB Statement

Manages metadata-bound libraries.

Note: Data set names and variable names that end with large numeric values that are larger than a long integer cannot be used in numbered-range lists. For more information, see "Restriction for Numbered Range Lists" in *SAS Language Reference: Concepts*.

Syntax

PROC AUTHLIB <*options*>;

Summary of Optional Arguments

LIBRARY=*libref*
: is the name of the physical library for which the secured library object is created and the security information is stored.

NOWARN
: suppresses error processing.

PWREQ=YES | NO
: controls the pop up of a dialog box.

Optional Arguments

LIBRARY=*libref*
is the name of the physical library for which the secured library object is created and the security information is stored.

If the LIBRARY= option is not specified, then the LIBRARY=*libref* (physical library) from the CREATE, MODIFY, REMOVE, REPORT, or REPAIR statement is used.

Aliases
: LIB=

  DDNAME=

  DD=

Restriction
: The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and must be processed by an engine that supports metadata-bound libraries.

NOWARN
suppresses the **`file not found`** error message when a data set in a TABLES statement does not exist.

PWREQ=YES | NO
controls the pop up of a dialog box for a data set password in interactive mode.

YES
: specifies that a dialog box appear if a missing or invalid password is entered when required.

NO
: prevents a dialog box from appearing. If a missing or invalid password is entered, then the data set is not opened, and an error message is written to the SAS log.

Default
: NO

CREATE Statement

Binds a physical library and data sets in the library to metadata by generating corresponding metadata objects in the SAS Metadata Repository and creating a record of the metadata objects in the physical directory and data sets.

Requirement: The AUTHLIB CREATE statement requires a connection to the target metadata server. For more requirements, see "Requirements for Using the AUTHLIB Statements" on page 165.

Tip: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Syntax

CREATE

SECUREDLIBRARY='*secured-library-name*'
<SECUREDFOLDER='*secured-folder-path*'>
<LIBRARY=*libref*>
PW=*all-password-value* </ *new-all-password-value*> |
ALTER=*alter-password-value* </ *new-alter-password-value*>
READ=*read-password-value* </ *new-read-password-value*>
WRITE=*write-password-value* </ *new-write-password-value*>
<REQUIRE_ENCRYPTION=YES | NO>
<ENCRYPT=YES | NO | AES | AES2>
<ENCRYPTKEY=*key-value* </ *new-key-value*>>;

Required Arguments

SECUREDLIBRARY='*secured-library-name*'
names the secured library object in the SAS Metadata Server.

Alias SECLIB=

Restriction The total length of the secured library object pathname including the fully qualified secured folder path cannot exceed 256 characters.

PW=*all-password-value* <*/ new-all-password-value*>
sets a single password for a metadata-bound library.

ALTER=*alter-password-value* <*/ new-alter-password-value*>
sets one of a maximum of three password values for a metadata-bound library.

READ=*read-password-value* <*/ new-read-password-value*>
sets one of a maximum of three password values for a metadata-bound library.

WRITE=*write-password-value* <*/ new-write-password-value* >
sets one of a maximum of three password values for a metadata-bound library.

> **TIP** All password values must be valid SAS names with a maximum length of 8 characters.

Optional Arguments

SECUREDFOLDER='*secured-folder-path*'
is the name of the metadata folder within the **`/System/Secured Libraries`** folder tree where the secured library object is created.

If the SECUREDFOLDER= option is not specified, then the metadata-bound library is created directly in the **`/System/Secured Libraries`** folder of the Foundation repository. If the SECUREDFOLDER= option does not begin with a slash (/), then it is a relative path and the value is appended to **`/System/Secured Libraries/`** to find the folder. If the SECUREDFOLDER= option begins with a slash (/), then it is an absolute path and the value must begin with **`/System/Secured Libraries`** or **`/<repository_name>/System/Secured Libraries`**.

Alias SECFLDR=

Restriction The total length of the secured library object pathname including the fully qualified secured folder path cannot exceed 256 characters.

ENCRYPT=YES | NO | AES | AES2
specifies the encryption type.

YES	specifies the SAS Proprietary algorithm.
NO	specifies no encryption.
AES | AES2	specifies Advanced Encryption Standard (AES) encryption and to record the key in metadata.

Restriction ENCRYPTKEY= option is required if the library has AES encryption.

See "Encrypted Data Set Considerations" on page 129

ENCRYPTKEY=*key-value* </ *key-value*>
specifies a key value for AES encryption.

Requirement ENCRYPTKEY= option is required if the library or a data file has AES or AES2 encryption.

Note The encryption key value for all the data sets in a library can be stored in a metadata-bound library so that an authorized user does not have to supply the encryption key value every time a data set is opened. For more information, see "Considerations for Data File Encryption" in the *SAS Guide to Metadata-Bound Libraries*.

Tip The ENCRYPTKEY= value is a passphrase that can be up to 64 characters long from which the actual AES or AES2 encryption key is later derived, but it is referred to as the encryption key in most SAS documentation.

See "Encrypted Data Set Considerations" on page 129

"ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*

LIBRARY=*libref*

name of the physical library for which the secured library object is created and the security information is stored.

If the LIBRARY= option is not specified, then the physical library from the AUTHLIB procedure is used.

Aliases LIB=

DDNAME=

DD=

Restriction The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and must be processed by an engine that supports metadata-bound libraries.

REQUIRE_ENCRYPTION=YES | NO

YES specifies that all data sets in a metadata-bound library are automatically encrypted.

NO specifies that data sets in a metadata-bound library are not automatically encrypted.

See "Requiring Encryption for Metadata-Bound Data Sets" on page 134

Details

Specifying Passwords

If your physical library does not contain password-protected data sets, then you need to specify the new metadata-bound library password(s) with either the PW= option or READ=,WRITE=, and ALTER= options in the CREATE statement. This is the most common case. For an example, see "Example 1: Binding a Physical Library That Contains Unprotected Data Sets" on page 167.

If your physical library contains some password-protected data sets that all share the same current set of passwords, then you can specify the most restrictive password on the data sets before a slash (/) in the CREATE statement password option(s) and the new password(s) after the slash (/). For an example, see "Example 3: Binding a Library When Existing Data Sets Are Protected with the Same Passwords" on page 171.

If your physical library contains password-protected data sets with different sets of passwords, then you can specify the data sets with each set of passwords on separate TABLES statements (see "Example 4: Binding a Library When Existing

Data Sets Are Protected with Different Passwords" on page 173) or you can subsequently use MODIFY and TABLES statements to change the passwords after the library has been bound with the CREATE statement (see "Example 5: Changing Passwords on Data Sets" on page 176).

Specifying Encryption Keys

To create or access a metadata-bound library that is protected using AES or AES2 encryption requires an encryption key value. You must use ENCRYPT=AES or ENCRYPT=AES2 and ENCRYPTKEY=*key-value* data set options.

If your physical library contains some AES-encrypted data sets that all share the same AES or AES2 encryption key, then you can specify the key value following ENCRYPTKEY= in the CREATE statement. If you want to record the key in metadata, then specify ENCRYPT=AES or ENCRYPT=AES2. For an example, see "Example 13: Binding a Library with Required AES Encryption When Existing Data Sets Are Encrypted with the Same Encryption Key" on page 192.

If your physical library contains AES or AES2-encrypted data sets with different encryption keys, then you can specify the data sets with each encryption key on separate TABLES statements. For an example, see "Example 15: Binding a Library with Existing Data Sets That Are AES-Encrypted with Different Encryption Keys" on page 199.

> **TIP** For more information, see "Considerations for Data File Encryption" in the *SAS Guide to Metadata-Bound Libraries*.

For more information, see "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference* and "ENCRYPT= Data Set Option" in *SAS Data Set Options: Reference*.

CAUTION
If data sets using AES encryption have referential integrity constraints, then the encryption key for all data sets must be available when they are opened for Update access. Normally, SAS requires that all data sets share the same encryption key. With a recorded optional or required encryption key in metadata, related data sets can have different keys. However, issues can arise if you change the encryption key on one library that has data sets related to data sets in a different library.

CAUTION
For AES-encrypted data sets that are referentially related to one another, follow these best practices to ensure that the data does not become inaccessible: Store the encryption key in the library's metadata. You can modify the stored key, but do not remove the key from metadata and do not unbind the library.

CAUTION
Even if you record the encryption key in metadata for the library, then you should also record the key elsewhere when using ENCRYPT=AES or ENCRYPT=AES2. If you lose the metadata and forget the ENCRYPTKEY= key value,

then you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value. The following note is written to the log:

```
NOTE: If you lose or forget the ENCRYPTKEY= value,
there will be no way  to open the file or
recover the data.
```

MODIFY Statement

Modifies password and encryption key values for a metadata-bound library.

Requirement: The AUTHLIB MODIFY statement requires a connection to the target metadata server. For more requirements, see "Requirements for Using the AUTHLIB Statements" on page 165.

Tip: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Syntax

MODIFY

<LIBRARY=*libref*>
PW=*all-password </ new-all-password>* |
ALTER=*alter-password </ new-alter-password>*
READ=*read-password </ new-read-password>*
WRITE=*write-password </ new-write-password>*
<TABLESONLY=YES | NO>
<REQUIRE_ENCRYPTION=YES | NO>
<ENCRYPT=YES | NO | AES | AES2>
<ENCRYPTKEY=*key-value </ new-key-value*>>
<PURGE=YES | NO>;

Required Arguments

PW=*all-password </ new-all-password >*
modifies a single password for a metadata-bound library.

ALTER=*alter-password </ new-alter-password>*
modifies one of a maximum of three password values for a metadata-bound library.

READ=*read-password </ new-read-password>*
modifies one of a maximum of three password values for a metadata-bound library.

WRITE=*write-password </ new-write-password>*
modifies one of a maximum of three password values for a metadata-bound library.

> **TIP** All password values must be valid SAS names with a maximum length of 8 characters.

Optional Arguments

ENCRYPT=YES | NO | AES | AES2
specifies the encryption type.

YES
specifies the SAS Proprietary algorithm.

NO
specifies no encryption.

AES
AES2
specifies Advanced Encryption Standard (AES) encryption and to record the key in metadata.

Requirement ENCRYPTKEY= option is required if the library has AES encryption.

See "Encrypted Data Set Considerations" on page 129

ENCRYPTKEY=*key-value </ key-value>*
specifies a key value for AES encryption.

Requirement ENCRYPTKEY= option is required if the library or a data file has AES encryption.

Note The encryption key value for all the data sets in a library can be stored in a metadata-bound library so that an authorized user does not have to supply the encryption key value every time a data set is opened. For more information, see "Considerations for Data File Encryption" in the *SAS Guide to Metadata-Bound Libraries*.

Tip The ENCRYPTKEY= value is a passphrase that can be up to 64 characters long from which the actual AES or AES2 encryption key is later derived, but it is referred to as the encryption key in most SAS documentation.

See "Encrypted Data Set Considerations" on page 129

"ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*

LIBRARY=*libref*
name of the physical library that is metadata-bound.

If the LIBRARY= option is not specified, then the physical library from the AUTHLIB procedure is used.

Alias LIB=, DDNAME=, DD=

Restriction The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and must be processed by an engine that supports metadata-bound libraries.

PURGE=YES | NO

YES
removes all retained metadata-bound library credentials if all tables in the library are successfully modified to the newer credentials.

Default YES

NO
does not remove replaced metadata-bound library credentials even if all tables in the library were successfully modified.

See "Retaining and Purging Metadata-Bound Library Credentials" on page 133

REQUIRE_ENCRYPTION=YES | NO

YES
specifies that all data sets in a metadata-bound library are automatically encrypted.

NO
specifies that data sets in a metadata-bound library are not automatically encrypted.

See "Requiring Encryption for Metadata-Bound Data Sets" on page 134

TABLESONLY=YES | NO
specifies whether the MODIFY statement action is applied at the library level or just to the tables. If TABLESONLY=NO, then the action is applied to the library and data sets. If TABLESONLY=YES, then the action is applied only to the data sets.

Default NO

Tip If you specify TABLESONLY=YES and a new password or encryption key value in the CREATE, MODIFY, or REMOVE statement, then the new password value or encryption key value is ignored. The current password or encryption key value is still required if the library is metadata-bound.

Details

Using the MODIFY Statement

The MODIFY statement can modify the value of the required metadata-bound library passwords and encryption options. This statement can also modify passwords on data sets (tables) that do not have the required metadata-bound library password values. The TABLES statement follows the MODIFY statement to specify current passwords and encryption keys in the data sets.

If your physical library is currently bound to a metadata library with one set of passwords and you want to change the metadata-bound library passwords to another set, then specify the current and new values for the metadata-bound library passwords separated by a / in the MODIFY statement. For an example, see "Example 6: Changing Metadata-Bound Library Passwords" on page 178.

If your physical library contains password-protected data sets with different sets of passwords from the metadata-bound library passwords, then you can modify the data set passwords to match the metadata-bound library required passwords using the MODIFY and TABLES statements. Specify the metadata-bound library passwords in the MODIFY statement. Specify the data sets with each set of passwords in separate TABLES statements. For more information, see "Example 5: Changing Passwords on Data Sets" on page 176.

If you want to change encryption options for the library, then specify the new options in the MODIFY statement. If your physical library contains AES-encrypted data sets, then you must specify the ENCRYPTKEY= key value in the MODIFY or TABLES statements or have a recorded encryption key for the library to make any modifications to the encrypted data sets. For and example, see "Example 16: Changing a Metadata-Bound Library to Require AES Encryption When Existing Data Sets Are Encrypted with Different Encryption Keys" on page 202.

For more information, see "TABLES Statement" on page 161.

CAUTION

For AES-encrypted data sets that are referentially related to one another, follow these best practices to ensure that the data does not become inaccessible: Store the encryption key in the library's metadata. You can modify the stored key, but do not remove the key from metadata and do not unbind the library.

CAUTION

Even if you record the encryption key in metadata for the library, you should also record the key elsewhere when using ENCRYPT=AES or ENCRYPT=AES2. If you lose the metadata and forget the ENCRYPTKEY= key value, then you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value.

You might have a need to import a SecuredLibrary object from a backup package for one of the following reasons:

- the SecuredLibrary object was inadvertently deleted
- you are promoting the metadata-bound library to a new metadata server

Password values and encryption key values are not exported with the SecuredLibrary object. This prevents them from being imported to a rogue Metadata Server. In this case, the passwords and any recorded encryption key values need to be reset in the imported SecuredLibrary object. Until you do this, libname assignments that refers to the imported SecuredLibrary object will fail with the following messages:

```
ERROR: The secured library object information for library library-name
could not be obtained from the metadata server or has invalid data.
ERROR: Association not found.
ERROR: Error in the LIBNAME statement.
```

For an example, see "Example 18: Resetting Credentials on Imported SecuredLibrary Objects" on page 208.

Using the LIBRARY= Option

If you want to override the default library from the AUTHLIB procedure, then use LIBRARY=.

```
MODIFY <LIBRARY=library-name>
```

If you want to modify the passwords or encryption options for a secured library object that is no longer bound to a physical library, then specify LIBRARY=_NONE_ with the SECUREDLIBRARY= and SECUREDFOLDER= options to locate the secured library object.

```
MODIFY <LIBRARY=_NONE_ SECUREDLIBRARY=secured-library-name>
                <SECUREDFOLDER=secured-folder-name>
```

CAUTION

Do not use LIB=_none_ when the secured library object is bound to a physical library. LIB=_none_ causes the action to operate only on the secured library object and has no effect on the physical data.

Using the PURGE Option

Passwords and encryption keys for a metadata-bound library are collectively referred to as *metadata-bound library credentials*. For information about retaining and purging credentials, see "Retaining and Purging Metadata-Bound Library Credentials" on page 133.

PURGE Statement

Removes any retained metadata-bound library credentials older than a given date of replacement.

Requirement: The AUTHLIB PURGE statement requires a connection to the target metadata server. For more requirements, see "Requirements for Using the AUTHLIB Statements" on page 165.

Tip: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Syntax

PURGE CREDENTIALS | CREDS <LIBRARY=*libref*>

PW=*all-password* |
ALTER=*alter-password*
READ=*read-password*
WRITE=*write-password*
BEFORE=*datetime*;

Required Arguments

PW=*all-password*
specifies a single password for a metadata-bound library.

ALTER=*alter-password*
specifies one of a maximum of three password values for a metadata-bound library.

READ=*read-password*
specifies one of a maximum of three password values for a metadata-bound library.

WRITE=*write-password*
specifies one of a maximum of three password values for a metadata-bound library.

> **TIP** All password values must be valid SAS names with a maximum length of 8 characters.

BEFORE=*datetime*
specifies a datetime constant before any replaced, but retained, credentials are removed.

Optional Argument

LIBRARY=*libref*
name of the physical library for which the metadata-bound library is created and the security information is stored.

If the LIBRARY= option is not specified, then the physical library from the AUTHLIB procedure is used.

Alias LIB=, DDNAME=, DD=

Restriction The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and

must be processed by an engine that supports metadata-bound libraries.

Details

Using the PURGE Statement

Passwords and encryption keys for a metadata-bound library are collectively referred to as *metadata-bound library credentials*. For more information about purging metadata-bound library credentials, see "Retaining and Purging Metadata-Bound Library Credentials" on page 133.

Using the LIBRARY= Option

If you want to override the default library from the AUTHLIB procedure, then use LIBRARY= option.

```
PURGE CREDENTIALS <LIBRARY=library-name>
```

If you want to purge the credentials for a secured library object that is no longer bound to a physical library, then specify LIBRARY=_NONE_ with the SECUREDLIBRARY= and SECUREDFOLDER= options to locate the secured library object.

```
PURGE CREDENTIALS <LIBRARY=_NONE_ SECUREDLIBRARY=secured-library-name>
<SECUREDFOLDER=secured-folder-name>
```

REMOVE Statement

Removes the physical security information and metadata objects that protect a metadata-bound library so that it is no longer a metadata-bound library.

Requirement: The AUTHLIB REMOVE statement requires a connection to the target metadata server. For more requirements, see "Requirements for Using the AUTHLIB Statements" on page 165.

Note: If any data set uses SAS Proprietary Encryption, then you cannot remove passwords unless you also specify ENCRYPT=NO to remove encryption.

Tips: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

If you do not want the non-secured data sets altered, then move all non-secured data sets from the physical library before performing a REMOVE statement.

Before you use the REMOVE statement, consider running the REPORT statement. The output from the REPORT statement identifies any physical tables that do not have corresponding secured table objects in metadata. In the unusual circumstance that such physical tables exist, their security location information is unaffected by the REMOVE statement unless you specify AUTHADMIN=YES in the LIBNAME

statement. You should use the AUTHADMIN=YES option in the LIBNAME statement in this circumstance.

Examples: "Example 7: Using the REMOVE Statement" on page 180

"Example 17: Using the REMOVE Statement on a Metadata-Bound Library with Required AES Encryption" on page 205

Syntax

REMOVE<LIBRARY=*libref*>

PW=*all-password* </ <*new-all-password*>> |
ALTER=*alter-password* </ <*new-alter-password*>>
READ=*read-password* </ <*new-read-password*>>
WRITE=*write-password* </ <*new-write-password*>>
<TABLESONLY=YES | NO>
<ENCRYPT=YES | NO | AES | AES2>
<ENCRYPTKEY=*key-value* </ *new-key-value*>>;

Required Arguments

PW=*all-password* </ <*new-all-password*>>
specifies a single password for a metadata-bound library.

ALTER=*alter-password* </ <*new-alter-password*>>
specifies one of a maximum of three password values for a metadata-bound library.

READ=*read-password* </ <*new-read-password*>>
specifies one of a maximum of three password values for a metadata-bound library.

WRITE=*write-password* </ <*new-write-password*>>
specifies one of a maximum of three password values for a metadata-bound library.

Optional Arguments

ENCRYPT=YES | NO | AES | AES2
specifies the encryption type.

YES	specifies the SAS Proprietary algorithm.
NO	specifies no encryption.
AES | AES2	specifies Advanced Encryption Standard (AES) encryption and is required if specifying that data sets be encrypted with a new key value.

See "Encrypted Data Set Considerations" on page 129

ENCRYPTKEY=*key-value* </ *key-value*>
specifies a key value for AES encryption.

Tip The ENCRYPTKEY= value is a passphrase that can be up to 64 characters long from which the actual AES or AES2 encryption key is later derived, but it is referred to as the encryption key in most SAS documentation.

See "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*

LIBRARY=*libref*
name of the physical library that is metadata-bound.

If the LIBRARY= option is not specified, then the physical library from the PROC AUTHLIB statement is used.

Alias LIB=, DDNAME=, DD=

Restriction The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and must be processed by an engine that supports metadata-bound libraries.

TABLESONLY=YES | NO
specifies whether the REMOVE statement action is applied at the library level or just to the tables. If TABLESONLY=NO, then the action is applied to the library and data sets. If TABLESONLY=YES, then the action is applied only to the individual data sets listed.

Default NO

Tip If you specify TABLESONLY=YES and a new password or encryption options, then the new password or encryption options are ignored. The current password is still required if the library is metadata-bound.

Details

The REMOVE statement is used to unbind the metadata-bound library feature from a SAS library and the data sets within it. This statement also removes the secured library and secured table objects from the SAS Metadata Server. The data sets remain in the physical library protected by the metadata-bound library passwords unless the administrator specifies password modifications in the REMOVE statement. Since the metadata-bound library feature is being removed and there is no longer a requirement that the data set passwords match the metadata-bound library passwords, the data set passwords can be removed by using a slash (/) after the current password but not specifying a new password. If you choose to do this, then you are warned in the SAS log that the data sets no longer have any SAS protection. You can also modify the encryption key of data sets by specifying the new key following a slash (/) in ENCRYPTKEY= and specifying ENCRYPT=AES or ENCRYPT=AES2. You can change to SAS Proprietary Encryption by specifying ENCRYPT=YES. You can remove all encryption by specifying ENCRYPT=NO.

The REMOVE statement removes the location information from any data set if the passwords specified match the metadata-bound library passwords stored in the data set. Note also that if the data set is AES or AES2-encrypted, the encryption

key must either be recorded in metadata or specified in the REMOVE or TABLES statements. However, it does not delete the referenced secured table object unless that secured table object is under the secured library object to which the operating system library is bound. If a data set has been copied into the bound library by a utility not written in SAS from another metadata-bound library, then this process prevents a REMOVE from deleting the secured table object that belongs to the other metadata-bound library.

Note: Ensure that all physical tables that are protected by a particular metadata-bound library remain within that library (directory). This best practice maximizes clarity and is essential in order for REMOVE statements to be fully effective. Special circumstances (for example, a table that is host copied to another directory) can prevent a REMOVE statement from unbinding the relocated data set.

CAUTION

If you have to unbind a library that contains AES-encrypted data sets that are referentially related to other data sets, then either make sure that all related data sets are no longer AES-encrypted or make sure that all related data sets share the same encryption key. If you preserve AES encryption, the data will be available only to those users who supply the key and have host-layer access.

REPAIR Statement

Recovers security information (in physical data) or secured library and table objects (in metadata).

Requirement: The AUTHLIB REPAIR statement requires a connection to the target metadata server. For more requirements, see "Requirements for Using the AUTHLIB Statements" on page 165.

Tip: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Syntax

REPAIR ADD | UPDATE | DELETE

LOCATION | METADATA
SECUREDLIBRARY='*secured-library-name*'
SECUREDFOLDER='*secured-folder-path*'
<LIBRARY=*libref*>
PW=*all-password* |
ALTER=*alter-password*
READ=*read-password*
WRITE=*write-password*
<TABLESONLY=YES | NO>
<ENCRYPT=YES | NO | AES | AES2>

<ENCRYPTKEY=*key-value*>;

Required Arguments

ADD | UPDATE | DELETE
one of these actions must be specified.

LOCATION | METADATA
clarifies whether the action is to apply to the physical security information in the file system, to the metadata objects in the SAS Metadata Server, or to both.

PW=*all-password*
specifies a single password for a metadata-bound library.

ALTER=*alter-password*
assigns, changes, or removes an Alter password from the secured library object and from the data sets in the physical library.

READ=*read-password*
assigns, changes, or removes a Read password from the secured library object and from the data sets in the physical library.

WRITE=*write-password*
assigns, changes, or removes a Write password from the secured library object and from the data sets in the physical library.

TABLESONLY= YES | NO
specifies whether the REPAIR statement action is applied at the library level or just to the tables. If TABLESONLY=NO, then the action is applied to the library and the tables. If TABLESONLY=YES, then the action is applied only to the tables. This is especially important for REPAIR because it gives the administrator a way to delete specific secured table objects without deleting the secured library and all secured tables.

Optional Arguments

/
is required if any options are included, such as passwords or MEMTYPE=. Here is an example:

```
tables table-name / pw=password;
```

ENCRYPT=YES | NO | AES | AES2
specifies the encryption type.

YES	specifies the SAS Proprietary algorithm.
NO	specifies no encryption.
/	is required if any options are included, such as passwords or MEMTYPE.
AES | AES2	specifies Advanced Encryption Standard (AES) encryption and is required if changing and encrypting with a new key value and TABLESONLY=YES in the action statement.

Requirement A / is reuired when using TABLES.

```
tables table-name / pw=password;
```

See "Encrypted Data Set Considerations" on page 129

ENCRYPTKEY=*key-value*
specifies a key value for AES encryption.

Requirement ENCRYPTKEY= data set option is required if the library or a data file has AES encryption and if the key is not recorded in the library metadata.

Note The encryption key value for all the data sets in a library can be stored in a metadata-bound library so that an authorized user does not have to supply the encryption key value every time a data set is opened. For more information, see "Considerations for Data File Encryption" in the *SAS Guide to Metadata-Bound Libraries*.

Tip The ENCRYPTKEY= value is a passphrase that can be up to 64 characters long from which the actual AES encryption key is later derived, but it is referred to as the encryption key in most SAS documentation.

See "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*

LIBRARY=*libref*
name of the physical library where the security information is stored.

If the LIBRARY= option is not specified, then the physical library from the PROC AUTHLIB statement is used.

Alias LIB=, DDNAME=, DD=

Restriction The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and must be processed by an engine that supports metadata-bound libraries.

SECUREDLIBRARY='*secured-library-name*'
names the secured library object in the SAS Metadata Server.

Alias SECLIB=

Restriction The total length of the secured library object pathname including the fully qualified secured folder path cannot exceed 256 characters.

SECUREDFOLDER='*secured-folder-path*'
name of the metadata folder within a **`/System/Secured Libraries`** folder tree where the secured library is repaired or re-created.

Alias SECFLDR=

Restriction The total length of the secured library object pathname including the fully qualified secured folder path cannot exceed 256 characters.

TABLESONLY=YES | NO

specifies whether the REPAIR statement action is applied at the library level or just to the tables. If TABLESONLY=NO, then the action is applied to the library and the tables. If TABLESONLY=YES, then the action is applied only to the tables. This is especially important for REPAIR because it gives the administrator a way to delete specific secured table objects without deleting the secured library and all secured tables.

Default NO

Details

The REPAIR statement feature that has been fully tested is REPAIR DELETE LOCATION. Use this combination of options when you need to delete the security information in a metadata-bound library and or data sets within the library without deleting the metadata objects.

It is possible for a system administrator to get in situations where a data set still has location information pointing to a secured table object that no longer exists. REPAIR DELETE LOCATION is required to remove that location information before the data set can be accessed in any other way.

When using the REPAIR statement, one of the ADD, UPDATE, or DELETE actions must be specified. LOCATION, METADATA, or both are used to clarify if the action is to apply to the metadata security information in the file system, to the metadata objects in the SAS Metadata Server, or to both. Other than DELETE LOCATION, these other actions have not been fully tested and are considered pre-production implementations. They are documented here but should be used only under advise and direction from Technical Support.

One or more TABLES statements can follow the REPAIR statement to perform the same action on the specified data sets. An implicit TABLES _ALL_ is used if no TABLES statement follows the REPAIR statement.

Inconsistencies between the metadata security information stored in the operating system files and the secured library object in the SAS Metadata Server that need repair can prevent the assignment of a LIBNAME statement to the physical library. The administrator that owns the physical library and knows the metadata-bound library passwords can perform a library assignment and repair the data by adding the AUTHADMIN=YES option to the LIBNAME statement. Best practice is to use the AUTHADMIN=YES option when performing any REPAIR actions.

CAUTION

Repairing a metadata-bound library is an advanced task. Make sure you have a current backup (of both metadata and physical data) before you use this statement.

Use the REPAIR statement to restore metadata-bound library security information or metadata objects that are inadvertently deleted. The administrator can carefully use the REPAIR statement to make some repairs to inconsistencies reported by the REPORT statement. If there are a significant number of groupings in the REPORT listing, then it might be more advisable to do the following:

1. Create a new operating system directory and metadata-bound library, and then use SAS Management Console to set appropriate default library permissions for the new secured library object.
2. Access the current library with the AUTHADMIN=YES, AUTHPW= or AUTHALTER=, AUTHWRITE=, and AUTHREAD= options in the LIBNAME statement.
3. Use the SAS COPY procedure to copy the SAS data sets to the new library. Use CONSTRAINT=YES if any data sets have referential integrity constraints. Use SAS Management Console to set any permissions on the secured table objects that differ from those inherited from the secured library object. The following is an example of using the COPY procedure.

Metadata-bound library ABCDE also has data sets Employees, EmpInfo, and Product. The REPORT statement has shown some inconsistencies between the physical library contents and the corresponding metadata objects. This is an example of a way to resolve these differences.

```
libname klmno "SAS-library-2";

proc authlib lib=klmno;
 create securedfolder="Department XYZZY"
        securedlibrary="KLMNOEmps"
        pw=password;
run;
quit;

libname abcde "SAS-library"
   AUTHADMIN=yes
   AUTHPW=password;

proc copy in=abcde out=klmno ;run;
```

Example Code 8.1 *Using PROC COPY to Resolve Differences*

```
88   proc copy in=abcde out=klmno ;run;

NOTE: Copying ABCDE.EMPINFO to KLMNO.EMPINFO (memtype=DATA).
NOTE: Data set ABCDE.EMPINFO.DATA has secured table object location information, but the
      secured library object location information that it contains:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 38C24AF4-9CF5-458B-8389-52092307007E
      is different from the registered location for the library ABCDE:
           SecuredFolder:
           SecuredLibrary:
           SecuredLibraryGUID:
      The data set might have been copied to this directory with a host copy utility.
NOTE: Permissions are obtained from the secured table and the secured library objects that are
      referenced in the header of the metadata-bound table.
NOTE: Metadata-bound library permissions are used for KLMNO.EMPINFO.DATA.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object
      at path "/System/Secured Libraries/Department XYZZY/KLMNOEmps" for data set
      KLMNO.EMPINFO.DATA.
NOTE: There were 5 observations read from the data set ABCDE.EMPINFO.
NOTE: The data set KLMNO.EMPINFO has 5 observations and 6 variables.
NOTE: Copying ABCDE.EMPLOYEES to KLMNO.EMPLOYEES (memtype=DATA).
NOTE: Data set ABCDE.EMPLOYEES.DATA has secured table object location information, but the
      secured library object location information that it contains:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 38C24AF4-9CF5-458B-8389-52092307007E
      is different from the registered location for the library ABCDE:
           SecuredFolder:
           SecuredLibrary:
           SecuredLibraryGUID:
      The data set might have been copied to this directory with a host copy utility.
NOTE: Permissions are obtained from the secured table and the secured library objects that are
      referenced in the header of the metadata-bound table.
NOTE: Metadata-bound library permissions are used for KLMNO.EMPLOYEES.DATA.
NOTE: Successfully added new secured table object "EMPLOYEES.DATA" to the secured library
      object at path "/System/Secured Libraries/Department XYZZY/KLMNOEmps" for data set
      KLMNO.EMPLOYEES.DATA.
```

```
NOTE: There were 5 observations read from the data set ABCDE.EMPLOYEES.
NOTE: The data set KLMNO.EMPLOYEES has 5 observations and 6 variables.
NOTE: Copying ABCDE.PRODUCT to KLMNO.PRODUCT (memtype=DATA).
NOTE: Data set ABCDE.PRODUCT.DATA has secured table object location information, but the
      secured library object location information that it contains:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 38C24AF4-9CF5-458B-8389-52092307007E
      is different from the registered location for the library ABCDE:
           SecuredFolder:
           SecuredLibrary:
           SecuredLibraryGUID:
      The data set might have been copied to this directory with a host copy utility.
NOTE: Permissions are obtained from the secured table and the secured library objects that are

NOTE: Metadata-bound library permissions are used for KLMNO.PRODUCT.DATA.
NOTE: Successfully added new secured table object "PRODUCT.DATA" to the secured library object
      at path "/System/Secured Libraries/Department XYZZY/KLMNOEmps" for data set
      KLMNO.PRODUCT.DATA.
NOTE: There were 5 observations read from the data set ABCDE.PRODUCT.
NOTE: The data set KLMNO.PRODUCT has 5 observations and 2 variables.
NOTE: PROCEDURE COPY used (Total process time):
      real time           0.14 seconds
      cpu time            0.04 seconds
```

The following REPAIR statement combination of options are *preproduction* and have not been fully tested. Preproduction means that this feature is a preliminary release of software that has not completed full development and testing. Because it has not been fully tested, preproduction software should be used with care. After final testing is completed, preproduction software is likely to be offered in a future release as a production-quality component or product.

REPAIR ADD LOCATION
: Use this combination of options when metadata-bound library and secured table security information is missing in the metadata-bound library or data sets within the metadata-bound library. The secured library and secured tables objects must exist in the SAS Metadata Server.

REPAIR UPDATE LOCATION
: Use this combination of options when metadata-bound library and secured table security information exists in the metadata-bound library or data sets within the metadata-bound library but points to incorrect or non-existent metadata objects. The secured library and secured tables objects to which you update the location information must exist in the SAS Metadata Server.

REPAIR ADD METADATA LOCATION
: Use this combination of options when secured library and secured table objects have been deleted from the SAS Metadata Server and their security information is no longer registered in the metadata-bound library and data sets within the metadata-bound library. The metadata objects are created in the SAS Metadata Server, and the security information for these objects are registered in the metadata-bound library and data sets.

REPAIR DELETE METADATA
: Use this combination of options when you need to delete the secured library, the secured table metadata objects, or both without deleting the security information in a metadata-bound library or in the data sets within that library.

REPAIR DELETE METADATA LOCATION
: Use this combination of options when you need to delete the secured library, the secured table metadata objects, or both and the security information in a metadata-bound library or in the data sets within that library.

REPAIR UPDATE LOCATION
: Use this combination of options when you need to update the security information in a metadata-bound library, in the data sets, or both to point to different existing secured library and secured table metadata objects.

Note: The METADATA option is not supported with a REPAIR UPDATE action.

REPORT Statement

For a specified metadata-bound library, compares physical library contents with corresponding metadata objects (in order to identify any inconsistencies).

Requirement: The AUTHLIB REPORT statement requires a connection to the target metadata server. For more requirements, see "Requirements for Using the REPORT Statement" on page 160.

Tip: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Example: "Example 8: Using the REPORT Statement" on page 181

Syntax

REPORT

<LIBRARY=*libref*>
<ENCRYPTKEY=*key-value*>;

Optional Arguments

LIBRARY=*libref*
name of the physical library on which to report binding information.

If the LIBRARY= option is not specified, then the physical library from the PROC AUTHLIB statement is used.

Alias: LIB=, DDNAME=, DD=

Restriction: The physical library specified cannot be a concatenated library, temporary library, or accessed through a SAS/SHARE server and must be processed by an engine that supports metadata-bound libraries.

ENCRYPTKEY=*key-value*
specifies a key value for an AES encryption.

Tip: The ENCRYPTKEY= value is a passphrase that can be up to 64 characters long from which the actual AES encryption key is later derived, but it is referred to as the encryption key in most SAS documentation.

See: "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*

Details

Requirements for Using the REPORT Statement

An administrator uses the REPORT statement to identify any inconsistencies between a physical metadata-bound library and its corresponding metadata objects.

In order to use the REPORT statement, you must meet the following criteria:

- The SAS session runs under an account that has host-layer Read access to the target physical library. This is necessary in order to assign the libref.
- The SAS session connects to the metadata server as an identity that has the ReadMetadata permission for the target secured library object and secured table objects.
- If the library has secured library object location information and the secured library object cannot be obtained, then you will need to use the AUTHADMIN=YES option in the LIBNAME= statement in order to assign the library.

Reporting Inconsistencies

The REPORT statement is used to report any inconsistencies between the physical library contents and the corresponding metadata objects.

Inconsistencies between the metadata security information in the physical directory, data sets, the secured library, and secured table objects might occur if the metadata or the operating system files are manipulated using nonstandard SAS processing. For example, an operating system data set copied from one directory into a metadata-bound library directory using an operating system copy utility will not have the appropriate security information for that metadata-bound library. Another example is that an administrator might mistakenly delete a secured library or secured table object using SAS Management Console.

The REPORT statement reports the secured table and metadata-bound library security information for each data set in the operating system directory of the library. This data set information is grouped by the metadata-bound library attributes that all the data sets share. If any data sets in the physical library are correctly registered to the secured library object for the library and have the required passwords, then those data sets and attributes will be listed as the first grouping in the report. Subsequent groupings are for data sets with either passwords that differ from the metadata-bound library passwords or whose metadata-bound library security information does not match the metadata-bound library location registered for the operating system directory.

TABLES Statement

Used after a CREATE, MODIFY, REMOVE, REPAIR, and REPORT statement to specify the tables to process a statement action. Also, you can specify the current passwords or encryption key value of the data sets in the TABLES statement, if different from the metadata-bound library passwords or recorded encryption key.

Default: When no TABLES statement is specified, the TABLES _ALL_ statement is the default behavior.

Requirement: The TABLES statement must be preceded by a CREATE, MODIFY, REMOVE, REPAIR, REPORT, or another TABLES statement.

Tip: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Example: "Example 9: Using the TABLES Statement" on page 183

Syntax

TABLES *SAS-dataset(s)* | _ALL_ | _NONE_

</>
<PW=*all-password* > </ *<new-all-password>*> |
<ALTER=*alter-password*> </ *<new-alter-password>*>
<READ=*read-password*> </ *<new-read-password>*>
<WRITE=*write-password*> </ *<new-write-password>*>;
<MEMTYPE= DATA | VIEW>
<ENCRYPT=YES | NO | AES | AES2>
<ENCRYPTKEY=*key-value*< / *new-key-value*>>;

Required Argument

***SAS-dataset(s)* | _ALL_ | _NONE_**

SAS-dataset(s)	name of one or more SAS data sets.
ALL	specifies password options to apply to all data sets.
NONE	limits the action of the previous CREATE, MODIFY, or REPAIR statements to the library level and does not apply the action to any table.

Optional Arguments

/

is required if any options are included, such as passwords or MEMTYPE=. Here is an example:

```
tables table-name / pw=password;
```

ENCRYPT=YES | NO | AES | AES2

specifies the encryption type.

YES	specifies the SAS Proprietary algorithm.
NO	specifies no encryption.
AES | AES2	specifies Advanced Encryption Standard (AES) encryption and is required if changing and encrypting with a new key value and TABLESONLY=YES in the action statement.

See "Encrypted Data Set Considerations" on page 129

ENCRYPTKEY=*key-value* </ *key-value*>

specifies a key value for AES encryption.

Requirement ENCRYPTKEY= data set option is required if the data file has AES encryption and the key is not recorded for the library.

Tip The ENCRYPTKEY= value is a passphrase that can be up to 64 characters long from which the actual AES or AES2 encryption key is later derived, but it is referred to as the encryption key in most SAS documentation.

See "Encrypted Data Set Considerations" on page 129

"ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*

MEMTYPE= DATA | VIEW
restricts processing to a single member type of DATA or VIEW. If not specified, then the default is both types.

DATA specifies SAS data file member type.

VIEW specifies SAS view member type.

Aliases MTYPE=

MT=

Default ALL

PW=*all-password* </ *<new-all-password>*>
specifies the current password of the data set.

ALTER=*alter-password* </ *<new-alter-password>*>
specifies the current ALTER= password of the data set.

READ=*read-password* </ *<new-read-password>*>
specifies the current READ= password of the data set.

WRITE=*write-password* </ *<new-write-password>*>
specifies the current WRITE= password of the data set.

> **TIP** All password values must be valid SAS names with a maximum length of 8 characters.

Details

Using the TABLES Statement

The TABLES statement is primarily used to specify the current password(s) and encryption key(s) on data sets when different from the current metadata-bound library required password(s) or encryption key(s). A TABLES statement usually follows a CREATE or MODIFY statement to make the data set passwords and encryption keys change to the metadata-bound library passwords and encryption keys. For an example, see "Example 4: Binding a Library When Existing Data Sets Are Protected with Different Passwords" on page 173.

TABLES _NONE_ can be used to limit the action of the previous CREATE, MODIFY, or REPAIR statements to the library level and not apply the action to any table. TABLES _ALL_ is the default behavior if no TABLES statement is specified. You might wish to write an explicit TABLES _ALL_ if you want to specify passwords or encryption key values to use when opening all data sets.

Using the TABLES Statement with the CREATE Statement

The CREATE statement can be followed by one or more TABLES statements to specify current passwords or encryption key values for data sets when different from the metadata-bound library passwords and encryption keys. If the TABLES statement is not used, then only two groups of data sets are bound:

- data sets without passwords or encryption keys
- data sets with passwords or encryption key values matching the metadata-bound library

In effect, omitting TABLES statements is equivalent to specifying one TABLES _ALL_ statement. For more information, see "CREATE Statement" on page 140.

Using the TABLES Statement with the MODIFY Statement

The MODIFY statement can be followed by one or more TABLES statements to specify modifications to passwords or an encryption key value in the data sets. If no TABLES statement follows the MODIFY statement, then there is an implicit TABLES _ALL_ statement. A separate TABLES statement is required for sets of data sets (tables) that might have different current passwords or encryption keys. For more information, see "MODIFY Statement" on page 144.

Using the TABLES Statement with the REPAIR Statement

When using the REPAIR statement, one of the ADD, UPDATE, or DELETE actions must be specified. LOCATION, METADATA, or both are used to clarify if the action is to apply to the physical security information in file system, to the metadata objects in the SAS Metadata Server, or to both. The REPAIR statement can be followed by one or more TABLES statements to perform the same action on the specified data sets. However, you cannot specify a new password or encryption key value in a TABLES statement that follows a REPAIR statement. For more information, see "REPAIR Statement" on page 153.

Using the TABLES Statement with the REMOVE Statement

You can use a TABLES statement with TABLESONLY=YES in the REMOVE statement to only remove the location information and secured table objects for specific tables in the metadata-bound library. If you do not use TABLESONLY=YES with a TABLES statement, then the secured library object and all secured table objects are deleted by the REMOVE statement.

When you use the TABLES statement after the REMOVE statement, an ENCRYPT=NO option removes the encryption on the data set as the table is being removed. For more information, see "Encrypted Data Set Considerations" on page 129. This process is necessary only if the administrator is trying to remove the passwords or encryption of a data set.

If you are removing the binding of the physical library to metadata or the physical library is not bound to a secured library, then you might want to modify the data set passwords or encryption to some other value. You are not restricted to changing to a common metadata-bound library password or encryption. You might choose to specify both a current and new password or current and new encryption key separated by a slash (/) in the REMOVE statement. If you want the different data sets to have unique passwords or encryption, then use the following two steps:

1 Change the PW= option for the data sets using a REMOVE statement with TABLESONLY=YES and an individual TABLES statement for each unique password and encryption.

2 Remove the metadata-bound library using a REMOVE statement **without** TABLESONLY=YES.

Using the TABLES Statement with the REPORT Statement

The TABLES statement is syntactically accepted with the REPORT statement but has little use. Specifying TABLES limits the report to the tables listed if used. For more information, see "REPORT Statement" on page 159.

Usage: AUTHLIB Procedure

Requirements for Using the AUTHLIB Statements

Except for the REPORT statement, all statements within the AUTHLIB procedure require that you must meet the following criteria:

- The SAS session runs under an account that has host-layer control of the target physical library. To ensure that only users who have host control can bind a physical library to metadata, the SAS session must run under a privileged host account as follows:
  - On UNIX, the account must be the owner of the directory.
  - On Windows, the account must have full control of the directory.
  - On z/OS, for UNIX file system libraries, the account must be the owner of the directory.
  - On z/OS, for direct-access bound libraries, the account must have RACF ALTER access authority to the library data set.
- The SAS session connects to the SAS Metadata Server as an identity that has ReadMetadata and WriteMemberMetadata permissions to the target secured data folder.

- You must supply the password(s) in CREATE, MODIFY, REPAIR, and REMOVE statements.

The REPORT statement requirements are less restrictive and are documented with that statement.

Copy-In-Place Operation

In the SAS 9.4 release, the copy-in-place operation is used to re-encrypt data sets.

Prior to SAS 9.4M2, metadata-bound data sets in different representations other than the host environment executing the AUTHLIB code fails in CREATE, MODIFY, REPAIR, and REMOVE actions. In SAS 9.4M2, the copy-in-place operation is used to bind or alter bindings of most metadata-bound data files and view files that are accessed through CEDA (Cross-Environment Data Access). However, metadata-bound data sets accessed through CEDA that contain indexes, extended attributes, and integrity constraints are detected and the copy-in-place operation is not attempted as it would still fail.

The following steps are performed in the copy-in-place operation:

1. The data set is renamed to _TEMP_ENCRYPT_FILE_NAME_.
2. The data set is copied back to the original data set name, which re-encrypts the data in the process.
3. The _TEMP_ENCRYPT_FILE_NAME_ file is deleted.

See the following SAS log examples of the copy-in-place operation:

- “Example 12: Binding a Library with an Optional Recorded Encryption Key When Existing AES-Encrypted Data Sets Have Different Encryption Keys ” on page 189
- “Example 16: Changing a Metadata-Bound Library to Require AES Encryption When Existing Data Sets Are Encrypted with Different Encryption Keys” on page 202

Results: AUTHLIB Procedure

Results: AUTHLIB Procedure

The REPORT statement produces the following output.

Output 8.1 *Using the REPORT Statement*

The OS library is properly registered to this SecuredLibrary. These data sets are properly registered to SecuredTables in it.
SecuredLibrary Path: /System/Secured Libraries/Department XYZZY/ABCDEEmps
SecuredLibrary Guid: F25E6004-EF15-4792-B0BD-9A8499435A07
Registered in OS Path: C:\lib1
Password Set: 0

MemberName	MemberType	SecuredTableName	SecuredTableGUID
PRODUCT	DATA	PRODUCT.DATA	5057208E-7EB0-4090-BD6D-57EA856DEA8B

The OS library is properly registered to this SecuredLibrary. These data sets have no registered SecuredTable location information.
SecuredLibrary Path: /System/Secured Libraries/Department XYZZY/ABCDEEmps
SecuredLibrary Guid: F25E6004-EF15-4792-B0BD-9A8499435A07
Registered in OS Path: C:\lib1
Password Set: 1

MemberName	MemberType	SecuredTableName	SecuredTableGUID
EMPINFO	DATA		
EMPLOYEES	DATA		

Examples: AUTHLIB Procedure

Example 1: Binding a Physical Library That Contains Unprotected Data Sets

Features: PROC AUTHLIB statement options
CREATE statement options:
PW=
SECUREDLIBRARY=
SECUREDFOLDER=

Details

This example demonstrates binding a physical library that contains data sets that do not have passwords or AES encryption.

Program

```
proc authlib lib=zyxwvut;

    create securedfolder="Department XYZZY"
        securedlibrary="ZYXWVUTEmps"
        pw=secretpw;
run;
quit;
```

Program Description

Library ZYXWVUT contains three data sets that do not have passwords: Employees, EmpInfo, Product.

```
proc authlib lib=zyxwvut;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. Specify metadata-bound library passwords with the PW= option.

```
    create securedfolder="Department XYZZY"
        securedlibrary="ZYXWVUTEmps"
        pw=secretpw;
run;
quit;
```

Results: The library and data sets are bound with the password *secretpw*. The binding is straightforward, as PROC AUTHLIB has unhindered access to the data.

Log Examples

Example Code 8.2 *Unprotected Data Sets*

```
79   proc authlib lib=zyxwvut;
80
81    create securedfolder="Department XYZZY"
82           securedlibrary="ZYXWVUTEmps"
83           pw=XXXXXXXX;
84
85   run;

NOTE: Successfully created a secured library object for the physical library ZYXWVUT and recorded its
      location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ZYXWVUTEmps
           SecuredLibraryGUID: 1A323C03-A3D8-4A83-9615-2BC2CB9FAAE2
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at
      path "/System/Secured Libraries/Department XYZZY/ZYXWVUTEmps" for data set ZYXWVUT.EMPINFO.DATA.
NOTE: The passwords on ZYXWVUT.EMPINFO.DATA were successfully modified.
NOTE: Successfully added new secured table object "EMPLOYEES.DATA" to the secured library object at
      path "/System/Secured Libraries/Department XYZZY/ZYXWVUTEmps" for data set
      ZYXWVUT.EMPLOYEES.DATA.
NOTE: The passwords on ZYXWVUT.EMPLOYEES.DATA were successfully modified.
NOTE: Successfully added new secured table object "PRODUCT.DATA" to the secured library object at
      path "/System/Secured Libraries/Department XYZZY/ZYXWVUTEmps" for data set ZYXWVUT.PRODUCT.DATA.
NOTE: The passwords on ZYXWVUT.PRODUCT.DATA were successfully modified.
86   quit;
```

Example 2: Binding a Physical Library That Contains Password-Protected Data Sets

Features: PROC AUTHLIB statement options
CREATE statement options:
PW=
SECUREDLIBRARY=
SECUREDFOLDER=

Details

This example demonstrates what happens if you use a similar CREATE statement as Example 1 when the physical library contains two data sets that have the same READ=, WRITE=, and ALTER= passwords and one data set that does not have any passwords. None of the data sets are AES-encrypted.

Program

```
proc authlib lib=abcde;

    create securedfolder="Department XYZZY"
        securedlibrary="ABCDEEmps"
        pw=secretpw;
run;
quit;
```

Program Description

Library ABCDE has Employees, EmpInfo, and Product data sets. However, in library ABCDE, the Employees and EmpInfo data sets are protected with a READ= password `abcd`, WRITE= password `efgh`, and an ALTER= password `ijkl` before the library is secured by the statements. The third data set, Product, is not protected with passwords.

```
proc authlib lib=abcde;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. Specify metadata-bound library passwords with the PW= option.

```
    create securedfolder="Department XYZZY"
        securedlibrary="ABCDEEmps"
        pw=secretpw;
run;
quit;
```

Results: The ABCDE library is bound and the unprotected Product data set is bound and the password was set. The protected data sets are not bound and their passwords did not change because their current passwords were not specified.

Log Examples

Example Code 8.3 *Password-Protected Data Sets*

```
179  proc authlib lib=abcde;
180
181   create securedfolder="Department XYZZY"
182          securedlibrary="ABCDEEmps"
183          pw=XXXXXXXX;
184
185  run;

NOTE: Successfully created a secured library object for the physical library ABCDE and recorded its
      location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 4881263D-C346-41F7-AC49-BF9181AF13D2
ERROR: The ALTER password is the most restrictive on ABCDE.EMPINFO.DATA. You must supply its value in
       order to alter or add any passwords.
ERROR: The ALTER password is the most restrictive on ABCDE.EMPLOYEES.DATA. You must supply its value
       in order to alter or add any passwords.
NOTE: Successfully added new secured table object "PRODUCT.DATA" to the secured library object at
      path "/System/Secured Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.PRODUCT.DATA.

NOTE: Some statement actions not processed because of errors noted above.
186  quit;

NOTE: The SAS System stopped processing this step because of errors.
```

Example 3: Binding a Library When Existing Data Sets Are Protected with the Same Passwords

Features:

PROC AUTHLIB statement options
- CREATE statement options:
- PW=
- SECUREDLIBRARY=
- SECUREDFOLDER=

Details

This example demonstrates how to specify the passwords for the Employees and EmpInfo data sets from the preceding example in the PROC AUTHLIB CREATE statement. None of the data sets are AES-encrypted.

Program

```
proc authlib lib=abcde;

    create securedlibrary="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=ijkl/secretpw;
run;
quit;
```

Program Description

Library ABCDE also has Employees, EmpInfo, and Product data sets. However, in library ABCDE, the Employees and EmpInfo data sets are protected with a READ= password `abcd`, WRITE= password `efgh`, and ALTER= password `ijkl` before the library is secured by the statements. The third data set, Product, is not protected with any passwords.

```
proc authlib lib=abcde;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. Specify the ALTER= password `ijkl` for the data sets in the PW= argument before the new password *secretpw*, separated by a slash (/).

```
    create securedlibrary="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=ijkl/secretpw;
run;
quit;
```

Results: The library ABCDE is bound. All three data sets are bound with the same password *secretpw*.

Log Examples

Example Code 8.4 *Securing a Library with Data Sets That Are Protected with the Same Passwords*

```
39   proc authlib lib=abcde;
40   create securedlibrary="ABCDEEmps"
41   securedfolder="Department XYZZY"
42   pw=XXXX/XXXXXXXX;
43   run;

NOTE: Successfully created a secured library object for the physical library ABCDE and recorded its
location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 9F746F86-2336-4E2F-A67E-BFB77DEC27F0
NOTE: Successfully added new secured table object "DEPTNAME.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.DEPTNAME.DATA.
NOTE: The passwords on ABCDE.DEPTNAME.DATA were successfully modified.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPINFO.DATA.
NOTE: The passwords on ABCDE.EMPINFO.DATA were successfully modified.
NOTE: Successfully added new secured table object "EMPLOYEE.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPLOYEE.DATA.
NOTE: The passwords on ABCDE.EMPLOYEE.DATA were successfully modified.
44   quit;
```

Example 4: Binding a Library When Existing Data Sets Are Protected with Different Passwords

Features:

PROC AUTHLIB statement options
- CREATE statement options:
- ALTER=
- READ=
- SECUREDLIBRARY=
- SECUREDFOLDER=
- WRITE=
- TABLE statement options:
- ALTER=
- PW=
- READ=
- WRITE=

Details

This example demonstrates how to bind the library KLMNO, which contains three data sets with different passwords. None of the data sets are AES-encrypted. It also demonstrates creating a longer metadata-bound library password by specifying the READ=, WRITE=, and ALTER= password options.

Program

```
proc authlib lib=klmno;

    create securedlibrary="KLMNOEmps"
        securedfolder="Department XYZZY"
        read=abcdefgh
        write=ijklmno
        alter=pqrstuvw;

    tables employees /
        pw=lmno;
    tables empinfo /
        read=abcd
        write=efgh
        alter=ijkl;
    tables product;
run;
quit;
```

Program Description

Library KLMNO has Employees, EmpInfo, and Product data sets. The Employees data set is protected with the PW= password `lmno`. The EmpInfo data set is protected with a READ= password `abcd`, a WRITE= password `efgh`, and an ALTER= password `ijkl`. The Product data set is not protected.

```
proc authlib lib=klmno;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. Specify the values for READ= password `abcdefgh`, WRITE= password `ijklmno`, and ALTER= password `pqrstuvw` to create a longer metadata-bound library password.

```
    create securedlibrary="KLMNOEmps"
        securedfolder="Department XYZZY"
        read=abcdefgh
        write=ijklmno
        alter=pqrstuvw;
```

Use the TABLES statement to specify the current password for each data set. When using TABLES statements, a TABLES statement must be specified for all data sets.

```
      tables employees /
          pw=lmno;
      tables empinfo /
          read=abcd
          write=efgh
          alter=ijkl;
      tables product;
run;
quit;
```

Results: The library KLMNO is bound, and all three data sets are bound with the same passwords. The passwords are READ= password `abcdefgh`, WRITE= password `ijklmno`, and ALTER= password `pqrstuvw`.

Log Examples

Example Code 8.5 *Securing a Library with Existing Data Sets That Are Protected with Different Passwords*

```
177  libname klmno "c:\lib2";
NOTE: Libref KLMNO was successfully assigned as follows:
      Engine:        V9
      Physical Name: c:\lib2
178
179  proc authlib lib=klmno;
180  create securedlibrary="KLMNOEmps"
181  securedfolder="Department XYZZY"
182  read=XXXXXXXX
183  write=XXXXXXX
184  alter=XXXXXXXX;
185  tables employees /
186  pw=XXXX;
187  tables empinfo /
188  read=XXXX
189  write=XXXX
190  alter=XXXX;
191  tables product;
192  run;

NOTE: Successfully created a secured library object for the physical library KLMNO and recorded its
location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     KLMNOEmps
           SecuredLibraryGUID: BC74E81F-E86B-402E-8C16-F9A94A078F81
NOTE: Successfully added new secured table object "EMPLOYEES.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.EMPLOYEES.DATA.
NOTE: The passwords on KLMNO.EMPLOYEES.DATA were successfully modified.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.EMPINFO.DATA.
NOTE: The passwords on KLMNO.EMPINFO.DATA were successfully modified.
NOTE: Successfully added new secured table object "PRODUCT.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.PRODUCT.DATA.
NOTE: The passwords on KLMNO.PRODUCT.DATA were successfully modified.
193  quit;
```

Example 5: Changing Passwords on Data Sets

Features:

PROC AUTHLIB statement options
- MODIFY statement options:
- PW=
- TABLESONLY=
- TABLES statement options:
- PW=

Details

This example shows a different approach for modifying the passwords of existing data sets to match the metadata-bound library passwords. It uses the MODIFY statement. Here, the MODIFY statement is used to modify the data set passwords of the Employees and EmpInfo data sets from Example 2 on page 169 to match the metadata-bound library password. Neither of these data sets are AES-encrypted.

The MODIFY statement can also be used to modify the data set passwords of data sets that are copied into a metadata-bound library by operating system commands after the library has been bound.

Program

```
proc authlib lib=abcde;

    modify tablesonly=yes
        pw=secretpw;

    tables _all_ /
        pw=ijkl/secretpw;
run;
quit;
```

Program Description

Library ABCDE has Employees, EmpInfo, and Product data sets. The library is bound with metadata-bound library password *secretpw*. However, in library ABCDE, the Employees and EmpInfo data sets are not bound to the library and are protected with an ALTER= password `ijkl`. The third data set, Product, is already bound.

```
proc authlib lib=abcde;
```

The MODIFY statement is used to modify the data set passwords of the Employees and EmpInfo data sets to match the metadata-bound library password. The TABLESONLY= statement specifies to modify table passwords only.

```
    modify tablesonly=yes
        pw=secretpw;
```

A TABLES statement must be specified. The existing data sets' ALTER password is specified in the PW= argument before the metadata-bound password, separated by a slash (/) in the TABLES statement.

```
    tables _all_ /
        pw=ijkl/secretpw;
run;
```

```
quit;
```

Results: All three data sets are now bound with the *secretpw* password.

Log Examples

Example Code 8.6 *Changing Data Set Passwords*

```
76   proc authlib lib=abcde;
77   modify tablesonly=yes
78   pw=XXXXXXXX;
79   tables _all_ /
80   pw=XXXX/XXXXXXXX;
81   run;

NOTE: The passwords on ABCDE.DEPTNAME.DATA do not require modification.
NOTE: The passwords on ABCDE.EMPINFO.DATA do not require modification.
NOTE: The passwords on ABCDE.EMPLOYEE.DATA do not require modification.
82   quit;
```

Example 6: Changing Metadata-Bound Library Passwords

Features:

PROC AUTHLIB statement options
MODIFY statement options:
PW=
SECUREDLIBRARY=
SECUREDFOLDER=

Details

This example demonstrates how to use the MODIFY statement to change the library passwords if you believe that the metadata-bound library passwords have been compromised. The following code changes the library passwords and the data set passwords of all data sets in the library that use the specified passwords or do not have a password. In this example, no data sets are AES-encrypted. See later examples if your library has AES-encrypted data.

Program

```
proc authlib lib=abcde;
```

```
    modify securedlibrary="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secretpw/new-password;
run;
quit;
```

Program Description

Library ABCDE requires a password change.

```
proc authlib lib=abcde;
```

Use the MODIFY statement to change the library passwords and the data set passwords. Note that the name of the secured library object and the name of the metadata folder are optional, but can be specified to ensure that the library is bound to that secured library object before making the change. This is used when the SAS Management Console submits the code from the Modify action to ensure that the correct operation system library path was specified.

```
    modify securedlibrary="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secretpw/new-password;
run;
quit;
```

Results: The library ABCDE remains bound and the library password is modified to the *new-password*. All three data sets remain bound, and their passwords are modified with *new-password*. An error message would be displayed in the SAS log for any data set that had a password other than *secretpw*.

Log Examples

Example Code 8.7 *Changing Metadata-bound Library Passwords*

```
217  proc authlib lib=abcde;
218    modify securedlibrary="ABCDEEmps"
219        securedfolder="Department XYZZY"
220        pw=XXXXXXXX/XXXXXXXX;
221
222  run;

NOTE: The passwords for the secured library object with path "/System/Secured Libraries/Department
      XYZZY/ABCDEEmps" were successfully modified."
NOTE: The passwords on ABCDE.EMPINFO.DATA were successfully modified.
NOTE: The passwords on ABCDE.EMPLOYEES.DATA were successfully modified.
NOTE: The passwords on ABCDE.PRODUCT.DATA were successfully modified.
223  quit;
```

Example 7: Using the REMOVE Statement

Features: PROC AUTHLIB statement options
REMOVE statement options:
PW=

Details

This example demonstrates how to unbind a metadata-bound library. The code does the following:

- deletes metadata that describes the library and its tables from the SAS Metadata Repository
- removes security bindings from the physical library and data sets
- removes the assigned password from the data sets, leaving them unprotected

The slash (/) after the password is optional and is used to remove or replace the password from the data sets. If a library is bound with READ=, WRITE=, and ALTER= passwords, as in Example 4 on page 173, then you must specify all of the passwords, and they must each have a slash (/). None of the data sets are AES-encrypted.

Program

```
proc authlib lib=abcde;

    remove
        pw=currntpw/;
run;
quit;
```

Program Description

Unbinding the metadata-bound library ABCDE.

```
proc authlib lib=abcde;
```

Use the REMOVE statement to unbind the metadata-bound library. The slash (/) after the password is used to remove the password from the data sets.

```
    remove
        pw=currntpw/;
```

```
run;
quit;
```

Results: The library ABCDE and all the data sets that are bound to it are no longer bound. All passwords are removed from the unbound data sets making them unprotected.

Log Examples

Example Code 8.8 *Unbinding a Metadata-Bound Library*

```
195  proc authlib lib=abcde;
196  remove
197  pw=XXXXXXXX/;
198  run;

WARNING: Some or all the passwords on ABCDE.DEPTNAME.DATA were removed along with the secured library
object location,
         leaving the data set unprotected.
NOTE: The secured table object location for ABCDE.DEPTNAME.DATA was successfully removed.
WARNING: Some or all the passwords on ABCDE.EMPINFO.DATA were removed along with the secured library
object location, leaving
         the data set unprotected.
NOTE: The secured table object location for ABCDE.EMPINFO.DATA was successfully removed.
WARNING: Some or all the passwords on ABCDE.EMPLOYEE.DATA were removed along with the secured library
object location,
         leaving the data set unprotected.
NOTE: The secured table object location for ABCDE.EMPLOYEE.DATA was successfully removed.
NOTE: Successfully deleted the secured library object that was located at:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 9F746F86-2336-4E2F-A67E-BFB77DEC27F0
NOTE: Successfully deleted the recorded location of the secured library object for the physical
library ABCDE.
199  quit;
```

Example 8: Using the REPORT Statement

Features: PROC AUTHLIB statement options
Report statement

Details

This example demonstrates how to check a library's bindings.

Program

```
proc authlib lib=abcde;

    report;
run;
quit;
```

Program Description

Check the bindings of the metadata-bound library ABCDE.

```
proc authlib lib=abcde;
```

Use the REPORT statement.

```
    report;
run;
quit;
```

Results: For the REPORT statement results, see"Output Example" on page 183.

Log Examples

Example Code 8.9 *Creating a Report*

```
49   proc authlib lib=abcde;
50    report;
51   run;

52   quit;
```

Output Example

Output 8.2 *REPORT Statement Results for the ABCDE Library*

The OS library is properly registered to this SecuredLibrary. These data sets are properly registered to SecuredTables in it.
SecuredLibrary Path: /System/Secured Libraries/Department XYZZY/ABCDEEmps
SecuredLibrary Guid: F25E6004-EF15-4792-B0BD-9A8499435A07
Registered in OS Path: C:\lib1
Password Set: 0

MemberName	MemberType	SecuredTableName	SecuredTableGUID
EMPINFO	DATA	EMPINFO.DATA	C8EA8780-83E8-4F32-9912-14F109FA1D50
EMPLOYEES	DATA	EMPLOYEES.DATA	A0F173F6-9D0B-40A0-B38F-C56433CE22E1
PRODUCT	DATA	PRODUCT.DATA	5057208E-7EB0-4090-BD6D-57EA856DEA8B

Example 9: Using the TABLES Statement

Features:

PROC AUTHLIB statement options
CREATE statement options:
ALTER=
READ=
SECUREDLIBRARY=
SECUREDFOLDER=
WRITE=
TABLE statements options:
ALTER=
PW=
READ=
WRITE=

Details

Example 4 on page 173 demonstrates how to use the TABLES statement.

Example 10: Binding a Library When Existing Data Sets Are SAS Proprietary Encrypted

Features: PROC AUTHLIB statement options
CREATE statement options:
PW=
SECUREDLIBRARY=
SECUREDFOLDER=
TABLES statement options:
PW=
READ=

Details

The following example demonstrates how to bind and change passwords on SAS Proprietary encrypted data sets.

Program

```
proc authlib lib=klmno;

    create securedlibrary="KLMNOEmps"
        securedfolder="Department XYZZY"
        pw=pqrstuvw;

    tables employees /
        pw=lmno;
    tables empinfo /
        read=abcd;
    tables product;
run;
quit;
```

Program Description

Library KLMNO has three data sets: Employees, EmpInfo, and Product. In this library, the Employees data set is protected with the PW= password `lmno`. The EmpInfo data set is protected with a READ= password `abcd`. Both Employees and EmpInfo data sets are SAS Proprietary encrypted. The Product data set is not protected.

```
proc authlib lib=klmno;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. Set the library password to `pqrstuvw`.

```
      create securedlibrary="KLMNOEmps"
          securedfolder="Department XYZZY"
          pw=pqrstuvw;
```

Because these data sets have different passwords, a TABLES statement must be specified for all data sets in order to change their passwords.

```
      tables employees /
          pw=lmno;
      tables empinfo /
          read=abcd;
      tables product;
run;
quit;
```

Results: The library KLMNO is bound. All three data sets are bound and use the same PW= password `pqrstuvw`. Data sets Employees and EmpInfo are copied-in-place to encrypt with the password `pqrstuvw`. Data set Product is bound, but not encrypted.

Log Examples

Example Code 8.10 *TABLES Statement for the KLMNO Library Containing a SAS Proprietary Data Set*

```
265  proc authlib lib=klmno;
266  create securedlibrary="KLMNOEmps"
267  securedfolder="Department XYZZY"
268  pw=XXXXXXXX;
269  tables employees /
270  pw=XXXX;
271  tables empinfo /
272  read=XXXX;
273  tables product;
274  run;

NOTE: Successfully created a secured library object for the physical library KLMNO and recorded its
location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     KLMNOEmps
           SecuredLibraryGUID: E71881CD-8C54-4E21-A8B5-FD7D4FBDAA7D
NOTE: Copying data set KLMNO.EMPLOYEES in place to encrypt with the new secured library passwords or
encryption options.

NOTE: Copying the data set KLMNO.__TEMP_ENCRYPT_FILE_NAME__ to KLMNO.EMPLOYEES.
NOTE: Metadata-bound library permissions are used for KLMNO.EMPLOYEES.DATA.
NOTE: Successfully added new secured table object "EMPLOYEES.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.EMPLOYEES.DATA.
NOTE: There were 5 observations read from the data set KLMNO.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set KLMNO.EMPLOYEES has 5 observations and 6 variables.
NOTE: Deleting the data set KLMNO.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on KLMNO.EMPLOYEES.DATA were successfully modified.
NOTE: Copying data set KLMNO.EMPINFO in place to encrypt with the new secured library passwords or
encryption options.
NOTE: Renaming the data set KLMNO.EMPINFO to KLMNO.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set KLMNO.__TEMP_ENCRYPT_FILE_NAME__ to KLMNO.EMPINFO.
NOTE: Metadata-bound library permissions are used for KLMNO.EMPINFO.DATA.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.EMPINFO.DATA.
NOTE: There were 5 observations read from the data set KLMNO.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set KLMNO.EMPINFO has 5 observations and 6 variables.
NOTE: Deleting the data set KLMNO.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on KLMNO.EMPINFO.DATA were successfully modified.
NOTE: The passwords on KLMNO.PRODUCT.DATA do not require modification.
NOTE: Successfully added new secured table object "PRODUCT.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.PRODUCT.DATA.
275  quit;
```

Example 11: Binding a Library When Existing Data Sets Are AES-Encrypted

Features: PROC AUTHLIB statement options
CREATE statement options:
PW=

SECUREDLIBRARY=
SECUREDFOLDER=
TABLES statement option:
ENCRYPTKEY=

Details

This example demonstrates how to bind data sets that are AES-encrypted. None of the data sets have passwords.

CAUTION
SAS strongly recommends that you not have AES-encrypted data sets with different encryption keys in metadata-bound libraries, like this example creates. Instead, SAS recommends that you record a default encryption key in metadata and convert all AES-encrypted data sets to use that key. Doing this, your users, and programs do not have to specify the key when opening the data sets. The examples following this example show you how to do this process.

Program

```
proc authlib lib=klmno;

    create securedlibrary="KLMNOEmps"
        securedfolder="Department XYZZY"
        pw=pqrstuvw;

    tables employees /
        encryptkey=lmno;
    tables empinfo /
        encryptkey=abcd;
    tables product;
run;
quit;
```

Program Description

Library KLMNO has three data sets: Employees, EmpInfo, and Product. In this library, the Employees data set is AES-encrypted and has the ENCRYPTKEY= value `lmno`. The EmpInfo data set is AES-encrypted and has the ENCRYPTKEY= value `abcd`. The Product data set is not protected.

```
proc authlib lib=klmno;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. Set the library password to pqrstuvw.

```
      create securedlibrary="KLMNOEmps"
          securedfolder="Department XYZZY"
          pw=pqrstuvw;
```

Using the TABLES statements, specify the encrypt key for each data set. A TABLES statement must be specified for all data sets.

```
      tables employees /
          encryptkey=lmno;
      tables empinfo /
          encryptkey=abcd;
      tables product;
  run;
  quit;
```

Results: The library KLMNO is bound. All three data sets are bound. The Employees and EmpInfo data sets remain AES-encrypted. The Product data set is not encrypted. The encrypt key values for the Employees and Empinfo data sets are different. SAS strongly recommends that you not have AES-encrypted data sets with different encryption keys in metadata-bound libraries, like this example created.

Log Examples

Example Code 8.11 *TABLES Statement for the KLMNO Library Containing AES-Encrypted Data Sets*

```
351  proc authlib lib=klmno;
352  create securedlibrary="KLMNOEmps"
353  securedfolder="Department XYZZY"
354  pw=XXXXXXXX;
355  tables employees /
356  encryptkey=XXXX;
357  tables empinfo /
358  encryptkey=XXXX;
359  tables product;
360  run;

NOTE: Successfully created a secured library object for the physical library KLMNO and recorded its
location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     KLMNOEmps
           SecuredLibraryGUID: 48E2C4C7-ADE1-49D2-BBFE-14E5EAAB8961
NOTE: Successfully added new secured table object "EMPLOYEES.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.EMPLOYEES.DATA.
NOTE: The passwords on KLMNO.EMPLOYEES.DATA were successfully modified.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.EMPINFO.DATA.
NOTE: The passwords on KLMNO.EMPINFO.DATA were successfully modified.
NOTE: Successfully added new secured table object "PRODUCT.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/KLMNOEmps" for data set KLMNO.PRODUCT.DATA.
NOTE: The passwords on KLMNO.PRODUCT.DATA were successfully modified.
361  quit;
```

Example 12: Binding a Library with an Optional Recorded Encryption Key When Existing AES-Encrypted Data Sets Have Different Encryption Keys

Features:

PROC AUTHLIB statement options
- CREATE statement options:
- ENCRYPT=
- ENCRYPTKEY=
- PW=
- SECUREDLIBRARY=
- SECUREDFOLDER=
- TABLES statement options:
- ENCRYPT=
- ENCRYPTKEY=

Details

This example demonstrates how to bind a library with an optional recorded encryption key. None of the data sets have passwords.

Since some SAS code existed that created and references the EmpInfo data set with ENCRYPTKEY=DEF and since the recorded library key is not required, the specification of the ENCRYPTKEY=DEF should be removed from the code. Any code that re-creates the data must keep the ENCRYPT=AES or ENCRYPT=AES2 option so that the optional recorded key is used when the data set is re-created.

Program

```
proc authlib lib=abcde;

    create securedlibrary="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secret
        encrypt=aes
        encryptkey=optionalkey;

    tables employee;
    tables empinfo /
        encryptkey=def/optionalkey
        encrypt=aes;
    tables deptname;
run;
quit;
```

Program Description

Library ABCDE has Employees, EmpInfo, and DeptName data sets. In this library, the EmpInfo data set is AES-encrypted and has the ENCRYPTKEY= value `def`.

```
proc authlib lib=abcde;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. The optional encrypt key is specified for the metadata-bound library.

```
    create securedlibrary="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secret
        encrypt=aes
        encryptkey=optionalkey;
```

A TABLES statement is required for each data set.

```
      tables employee;
      tables empinfo /
          encryptkey=def/optionalkey
          encrypt=aes;
      tables deptname;
run;
quit;
```

Results: The ABCDE library is bound and the optional encrypt key is stored. When the statements are executed, the following happens to the three data sets. The Employee data set is updated with the new metadata-bound library password but is not encrypted. The DeptName data set is updated with the metadata-bound library password but is not encrypted. The EmpInfo data set is copied to re-encrypt with the optional recorded key and gets the new metadata-bound library password. Note that it is necessary to supply both the current and new optional key in the TABLES statement for EmpInfo in the following program. Without the new key specification, the data set would remain encrypted with the `def` key.

Log Examples

Example Code 8.12 *Changing an Encryption Key Value to the Recorded Encryption Key*

```
467  libname abcde "c:\lib1";
NOTE: Libref ABCDE was successfully assigned as follows:
      Engine:        V9
      Physical Name: c:\lib1
468
469  proc authlib lib=abcde;
470  create securedlibrary="ABCDEEmps"
471  securedfolder="Department XYZZY"
472  pw=XXXXXX
473  encrypt=aes
474  encryptkey=XXXXXXXXXXX;
475  tables employee;
476  tables empinfo /
477  encryptkey=XXX/XXXXXXXXXX
478  encrypt=aes;
479  tables deptname;
480  run;

NOTE: Successfully created a secured library object for the physical library ABCDE and recorded its
location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 8E683650-B306-4871-A92D-16D481EC6456
NOTE: Successfully added new secured table object "EMPLOYEE.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPLOYEE.DATA.
NOTE: The passwords on ABCDE.EMPLOYEE.DATA were successfully modified.
NOTE: Copying data set ABCDE.EMPINFO in place to encrypt with the new secured library passwords or
encryption options.
NOTE: Renaming the data set ABCDE.EMPINFO to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPINFO.
NOTE: Metadata-bound library permissions are used for ABCDE.EMPINFO.DATA.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPINFO.DATA.
NOTE: There were 5 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPINFO has 5 observations and 6 variables.

NOTE: The passwords on ABCDE.EMPINFO.DATA were successfully modified.
NOTE: Successfully added new secured table object "DEPTNAME.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.DEPTNAME.DATA.
NOTE: The passwords on ABCDE.DEPTNAME.DATA were successfully modified.
480  quit;
```

Example 13: Binding a Library with Required AES Encryption When Existing Data Sets Are Encrypted with the Same Encryption Key

Features: PROC AUTHLIB statement options
CREATE statement options:

ENCRYPT=
ENCRYPTKEY=
PW=
REQUIRE_ENCRYPTION
SECUREDLIBRARY=
SECUREDFOLDER=

Details

This example demonstrates how to bind a library with requiring that all of the data sets in this metadata-bound library have AES encryption and have the same encryption key.

Program

```
proc authlib lib=abcde;

    create  seclib="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secret
        require_encryption=yes
        encrypt=aes
        encryptkey=abc ;
run;
quit;
```

Program Description

Library ABCDE has three data sets: Employees, EmpInfo, and DeptName. Data set EmpInfo has encryption key value of `abc`. The other two data sets are not AES-encrypted. None of the data sets have passwords.

```
proc authlib lib=abcde;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server.
REQUIRE_ENCRYPTION=YES specifies that all data sets in the metadata-bound library are automatically AES-encrypted and use the AES key generation algorithm. Note that with required encryption and an encryption key, the specific key generation algorithm specified with ENCRYPT= is always used. With optional encryption, whichever key generation algorithm is specified in code with ENCRYPT= is used with the recorded key.

```
    create  seclib="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secret
```

```
        require_encryption=yes
        encrypt=aes
        encryptkey=abc ;
run;
quit;
```

Results: The library ABCDE is bound, and all of the data sets are bound and AES-encrypted with the same encryption key.

Log Examples

Example Code 8.13 *Library ABCDE Requiring AES Encryption When the Data Sets Are Already Encrypted with the Same Encryption Key*

```
40   proc authlib lib=abcde;
41   create  seclib="ABCDEEmps"
42         securedfolder="Department XYZZY"
43         pw=XXXXXX
44         require_encryption=yes
45         encrypt=aes
46         encryptkey=XXX ;
47   run;

NOTE: Setting library to require encryption.
NOTE: Required encryption will use AES encryption with the recorded key.

NOTE: Successfully created a secured library object for the physical library ABCDE and recorded its
location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 9FD6C5D9-EF00-4CDC-8D0A-348D08BB329E
NOTE: Copying data set ABCDE.DEPTNAME in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.DEPTNAME to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.DEPTNAME.
NOTE: Metadata-bound library permissions are used for ABCDE.DEPTNAME.DATA.
NOTE: Successfully added new secured table object "DEPTNAME.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.DEPTNAME.DATA.
NOTE: There were 10 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.DEPTNAME has 10 observations and 2 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.DEPTNAME.DATA were successfully modified.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPINFO.DATA.
NOTE: The passwords on ABCDE.EMPINFO.DATA were successfully modified.
NOTE: Copying data set ABCDE.EMPLOYEE in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.EMPLOYEE to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPLOYEE.
NOTE: Metadata-bound library permissions are used for ABCDE.EMPLOYEE.DATA.
NOTE: Successfully added new secured table object "EMPLOYEE.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPLOYEE.DATA.
NOTE: There were 22 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPLOYEE has 22 observations and 11 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.EMPLOYEE.DATA were successfully modified.
48   quit;
```

Example 14: Changing the Encryption Key on a Metadata-Bound Library That Requires AES Encryption

Features: PROC AUTHLIB statement options
MODIFY statement options:
ENCRYPT=
ENCRYPTKEY=
PW=

Details

This example demonstrates how to use the MODIFY statement to change the stored library encryption key if you believe that the metadata-bound library encryption keys might have been compromised.

Program

```
proc authlib lib=abcde;

    modify
       pw=secret
       encrypt=aes
       encryptkey=/new;

run;
quit;
```

Program Description

Library ABCDE has three data sets: Employees, EmpInfo, and DeptName. In this library, all data sets are AES-encrypted with encryption key value `abc` since AES encryption is required for the metadata bound library.

```
proc authlib lib=abcde;
```

Use the MODIFY statement to change the library encryption key and the data set encryption key. You must specify ENCRYPT=AES or ENCRYPT=AES2. Note that

the key generation algorithm can also be changed here between AES and AES2 simply by changing the value in the ENCRYPT= option.

```
      modify
         pw=secret
         encrypt=aes
         encryptkey=/new;

run;
quit;
```

Results: The library ABCDE remains bound with the same password and a new encryption key. All three data sets remain bound with the same password and a new encryption key. Note that the data sets were copied-in-place to be encrypted with the new key value and the specified encryption key algorithm, AES in this case.

Example Code 8.14 *Changing the Encryption Key ABCDE Library*

```
502  proc authlib lib=abcde;
503  modify
504  pw=XXXXXX
505  encrypt=aes
506  encryptkey=/XXX;
507  run;

NOTE: Changing the required encryption key.

NOTE: The passwords on ABCDE.DEPTNAME.DATA do not require modification.
NOTE: Copying data set ABCDE.DEPTNAME in place to do required encryption with the
library's required encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.DEPTNAME to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.DEPTNAME.
NOTE: There were 4 observations read from the data set
ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.DEPTNAME has 4 observations and 2 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.EMPINFO.DATA do not require modification.
NOTE: Copying data set ABCDE.EMPINFO in place to do required encryption with the
library's required encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.EMPINFO to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPINFO.
NOTE: There were 5 observations read from the data set
ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPINFO has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.EMPLOYEE.DATA do not require modification.
NOTE: Copying data set ABCDE.EMPLOYEE in place to do required encryption with the
library's required encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.EMPLOYEE to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPLOYEE.
NOTE: There were 5 observations read from the data set
ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPLOYEE has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords and/or encryption options for the secured library object with
path "/System/Secured Libraries/Department
      XYZZY/ABCDEEmps" were successfully modified."
NOTE: All data sets in library ABCDE are properly protected with the metadata-bound
library passwords and encryption options.
      Replaced Passwords and encryption keys were purged.
NOTE: Purged 1 versions of the replaced passwords and encryption keys older than
2015-05-04T15:40:57-05:00.
508  quit;
NOTE: Renaming the data set ABCDE.EMPLOYEE to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPLOYEE.
NOTE: There were 22 observations read from the data set
ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPLOYEE has 22 observations and 11 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords and/or encryption options for the secured library object with
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" were successfully modified.
```

Example 15: Binding a Library with Existing Data Sets That Are AES-Encrypted with Different Encryption Keys

Features:

PROC AUTHLIB statement options
CREATE statement options:
ENCRYPT=
ENCRYPTKEY=
PW=
REQUIRE_ENCRYPTION
SECUREDLIBRARY=
SECUREDFOLDER=
TABLES statement option:
ENCRYPTKEY=

Details

This example demonstrates how to change all data sets in the metadata-bound library that contain different encryption keys to have the required AES encryption and have the same encryption key. None of the data sets have passwords.

Program

```
proc authlib lib=abcde;

    create  seclib="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secret
        require_encryption=yes
        encrypt=aes
        encryptkey=new ;
    tables employee /
        encryptkey=abc;
    tables empinfo /
        encryptkey=def;
    tables deptname ;
run;
quit;
```

Program Description

Library ABCDE has three data sets: Employee, EmpInfo, and DeptName. The Employee and EmpInfo data sets are already AES-encrypted with different keys. The DeptName data set is not encrypted.

```
proc authlib lib=abcde;
```

Using the CREATE statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. REQUIRE_ENCRYPTION=YES specifies that all data sets in the metadata-bound library are automatically AES-encrypted.

```
      create  seclib="ABCDEEmps"
          securedfolder="Department XYZZY"
          pw=secret
          require_encryption=yes
          encrypt=aes
          encryptkey=new ;
```

Using the TABLES statement, specify the encrypt key for each data set. TABLES statements are required for each data set.

```
      tables employee /
          encryptkey=abc;
      tables empinfo /
          encryptkey=def;
      tables deptname ;
run;
quit;
```

Results: The library ABCDE is bound. All data sets in the metadata-bound library ABCDE have been copied-in-place to be encrypted with the required key and the specified encryption key algorithm, AES in this case.

Log Examples

Example Code 8.15 *Library ABCDE Requiring AES Encryption When Each Data Set Has Different Encryption Key Values*

```
554  proc authlib lib=abcde;
555  create seclib="ABCDEEmps"
556  securedfolder="Department XYZZY"
557  pw=XXXXXX
558  require_encryption=yes
559  encrypt=aes
560  encryptkey=XXX ;
561  tables employee /
562  encryptkey=XXX;
563  tables empinfo /
564  encryptkey=XXX;
565  tables deptname ;
566  run;

NOTE: Setting library to require encryption.
NOTE: Required encryption will use AES encryption with the recorded key.

NOTE: Successfully created a secured library object for the physical library ABCDE and recorded its
location as:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 097E9A84-D6E8-488E-B779-1E2AB0670036
NOTE: Copying data set ABCDE.EMPLOYEE in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.EMPLOYEE to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPLOYEE.
NOTE: Metadata-bound library permissions are used for ABCDE.EMPLOYEE.DATA.
NOTE: Successfully added new secured table object "EMPLOYEE.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPLOYEE.DATA.
NOTE: There were 5 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPLOYEE has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.EMPLOYEE.DATA were successfully modified.
NOTE: Copying data set ABCDE.EMPINFO in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.EMPINFO to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPINFO.
NOTE: Metadata-bound library permissions are used for ABCDE.EMPINFO.DATA.
NOTE: Successfully added new secured table object "EMPINFO.DATA" to the secured library object at path
"/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.EMPINFO.DATA.
NOTE: There were 5 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPINFO has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.EMPINFO.DATA were successfully modified.
NOTE: Copying data set ABCDE.DEPTNAME in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.DEPTNAME to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.DEPTNAME.
NOTE: Metadata-bound library permissions are used for ABCDE.DEPTNAME.DATA.
NOTE: Successfully added new secured table object "DEPTNAME.DATA" to the secured library object at
path "/System/Secured
      Libraries/Department XYZZY/ABCDEEmps" for data set ABCDE.DEPTNAME.DATA.
NOTE: There were 4 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.DEPTNAME has 4 observations and 2 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.DEPTNAME.DATA were successfully modified.
567  quit;
```

Example 16: Changing a Metadata-Bound Library to Require AES Encryption When Existing Data Sets Are Encrypted with Different Encryption Keys

Features: PROC AUTHLIB statement options
MODIFY statement options:
ENCRYPT=
ENCRYPTKEY=
PW=
REQUIRE_ENCRYPTION
SECUREDLIBRARY=
SECUREDFOLDER=
TABLES statement option:
ENCRYPTKEY=

Details

This example is similar to the previous example. The difference is that the library is already bound to metadata, so the MODIFY statement is used to change the binding to require AES encryption.

Program

```
proc authlib lib=abcde;

    modify  seclib="ABCDEEmps"
        securedfolder="Department XYZZY"
        pw=secret
        require_encryption=yes
        encrypt=aes
        encryptkey=new;

    tables employee /
        encryptkey=abc;
    tables empinfo /
        encryptkey=def;
    tables deptname ;
run;
quit;
```

Program Description

Library ABCDE has three data sets: Employees, EmpInfo, and DeptName. In this library, the Employees data set has the encryption key value `abc`. The EmpInfo data set has the encryption key value `def`. The DeptName data set is not AES-encrypted.

```
proc authlib lib=abcde;
```

Using the MODIFY statement, enter the name of the metadata folder and name the secured library object in the SAS Metadata Server. You use the REQUIRE_ENCRYPTION=YES option to require that all data sets in the metadata-bound library have AES encryption. Note that the name of the secured library object and the name of the metadata folder are optional, but can be specified to ensure that the library is bound to that secured library object before making the change.

```
      modify  seclib="ABCDEEmps"
          securedfolder="Department XYZZY"
          pw=secret
          require_encryption=yes
          encrypt=aes
          encryptkey=new;
```

Using the TABLES statement, specify the encrypt key for each data set. TABLES statements are required for each data set.

```
      tables employee /
          encryptkey=abc;
      tables empinfo /
          encryptkey=def;
      tables deptname ;
run;
quit;
```

Results: The library ABCDE remains bound. The MODIFY statement changed the binding to require AES encryption. All three data sets are copied-in-place to encrypt the data sets with the required encrypt key and the specified encryption key algorithm, AES in this case.

Log Examples

Example Code 8.16 *Library ABCDE Requiring AES Encryption and Changing the Encryption Key Values of Each Data Set to a Recorded Encryption Key Value*

```
628  proc authlib lib=abcde;
629  modify seclib="ABCDEEmps"
630  securedfolder="Department XYZZY"
631  pw=XXXXXX
632  require_encryption=yes
633  encrypt=aes
634  encryptkey=XXX;
635  tables employee /
636  encryptkey=XXX;
637  tables empinfo /
638  encryptkey=XXX;
639  tables deptname ;
640  run;

NOTE: Changing library to require encryption.
NOTE: Required encryption will use AES encryption with the recorded key.

NOTE: The passwords on ABCDE.EMPLOYEE.DATA do not require modification.
NOTE: Copying data set ABCDE.EMPLOYEE in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.EMPLOYEE to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPLOYEE.
NOTE: There were 5 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPLOYEE has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.EMPINFO.DATA do not require modification.
NOTE: Copying data set ABCDE.EMPINFO in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.EMPINFO to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPINFO.
NOTE: There were 5 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPINFO has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords on ABCDE.DEPTNAME.DATA do not require modification.
NOTE: Copying data set ABCDE.DEPTNAME in place to do required encryption with the library's required
encryption key and
      passwords.
NOTE: Renaming the data set ABCDE.DEPTNAME to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.DEPTNAME.
NOTE: There were 4 observations read from the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.DEPTNAME has 4 observations and 2 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The passwords and/or encryption options for the secured library object with path "/System/
Secured Libraries/Department
      XYZZY/ABCDEEmps" were successfully modified."
641  quit;
```

Example 17: Using the REMOVE Statement on a Metadata-Bound Library with Required AES Encryption

Features: PROC AUTHLIB statement options
REMOVE statement options:
PW=
ENCRYPT=

Details

This example demonstrates how to unbind a metadata-bound library. The code does the following:

- deletes metadata that describes the library and its tables from the SAS Metadata Repository
- removes security bindings from the physical library and data sets
- removes the assigned password and encryption from the data sets, leaving them unprotected

The slash (/) after the password is optional and is used to remove or replace the password from the data sets. If a library is bound with READ=, WRITE=, and ALTER= passwords, as in Example 4 on page 173, then you must specify all of the passwords, and they must each have a slash (/).

Program

```
proc authlib lib=abcde;

    remove
        pw=currntpw/
        encrypt=no;
run;
quit;
```

Program Description

Unbinding the metadata-bound library ABCDE.

```
proc authlib lib=abcde;
```

Use the REMOVE statement to unbind the metadata-bound library. The slash (/) after the password is used to remove the password from the data sets. ENCRYPT=NO specifies that encryption is removed from all data sets.

```
    remove
        pw=currntpw/
        encrypt=no;
run;
quit;
```

Results: The library ABCDE and all the data sets bound to it are no longer bound. All passwords and encryption are removed from the unbound data sets making them unprotected.

Example Code 8.17 *Using the REMOVE Statement on a Metadata-Bound Library with Required AES Encryption*

```
642  proc authlib lib=abcde;
643  remove
644  pw=XXXXXX/
645  encrypt=no;
646  run;

NOTE: Copying data set ABCDE.DEPTNAME in place to remove encryption.
NOTE: Renaming the data set ABCDE.DEPTNAME to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.DEPTNAME.
NOTE: There were 4 observations read from the data set
ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.DEPTNAME has 4 observations and 2 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
WARNING: Some or all the passwords on ABCDE.DEPTNAME.DATA were removed along with
the secured library object location,
         leaving the data set unprotected.
NOTE: The secured table object location for ABCDE.DEPTNAME.DATA was successfully
removed.
NOTE: Copying data set ABCDE.EMPINFO in place to remove encryption.
NOTE: Renaming the data set ABCDE.EMPINFO to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPINFO.
NOTE: There were 5 observations read from the data set
ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPINFO has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
WARNING: Some or all the passwords on ABCDE.EMPINFO.DATA were removed along with the
secured library object location, leaving
         the data set unprotected.
NOTE: The secured table object location for ABCDE.EMPINFO.DATA was successfully
removed.
NOTE: Copying data set ABCDE.EMPLOYEE in place to remove encryption.
NOTE: Renaming the data set ABCDE.EMPLOYEE to ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: Copying the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__ to ABCDE.EMPLOYEE.
NOTE: There were 5 observations read from the data set
ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
NOTE: The data set ABCDE.EMPLOYEE has 5 observations and 6 variables.
NOTE: Deleting the data set ABCDE.__TEMP_ENCRYPT_FILE_NAME__.
WARNING: Some or all the passwords on ABCDE.EMPLOYEE.DATA were removed along with
the secured library object location,
         leaving the data set unprotected.
NOTE: The secured table object location for ABCDE.EMPLOYEE.DATA was successfully
removed.
NOTE: Successfully deleted the secured library object that was located at:
           SecuredFolder:      /System/Secured Libraries/Department XYZZY
           SecuredLibrary:     ABCDEEmps
           SecuredLibraryGUID: 157F7ACD-5B71-4BC3-A490-DCED4BD275E8
NOTE: Successfully deleted the recorded location of the secured library object for
the physical library ABCDE.
647  quit;
```

Example 18: Resetting Credentials on Imported SecuredLibrary Objects

Features: PROC AUTHLIB statement options
MODIFY statement options:
LIBRARY=
PW=
ENCRYPT=
ENCRYPTKEY=

Details

This example shows how to reset the passwords and encryption key on SecuredLibrary objects that are imported from a backup package.

- The LIBNAME statement without the AUTHADMIN=YES option fails because there are no associated password values restored by the import.
- The AUTHADMIN=YES option is used to enable the AUTHLIB procedure to execute with the binding information in the physical library.
- The MODIFY statement is used to reset the metadata-bound library passwords and encryption key value on the library from "Example 13: Binding a Library with Required AES Encryption When Existing Data Sets Are Encrypted with the Same Encryption Key" on page 192 assuming that the SecuredLibrary object was imported from a backup package without those values.

Program

```
libname abcde "sas-library" ;

libname abcde "sas-library" authadmin=yes;

proc authlib lib=abcde;
    modify
        pw=secret
        encrypt=aes
        encryptkey=value;
run;
quit;

libname abcde "sas-library";
```

Program Description

Library ABCDE has three data sets: Employees, EmpInfo, and DeptName. This LIBNAME statement fails because there are no associated password values.

```
libname abcde "sas-library" ;
```

Use the AUTHADMIN=YES option. The AUTHADMIN=YES option enables the AUTHLIB procedure to execute with the binding information in the physical library.

```
libname abcde "sas-library" authadmin=yes;
```

Use the MODIFY statement to reset the metadata-bound library passwords and encryption key value. The PW= option resets the password. The ENCRYPTKEY= option resets the encryption key value.

```
proc authlib lib=abcde;
    modify
        pw=secret
        encrypt=aes
        encryptkey=value;
run;
quit;
```

Reissue the LIBNAME statement without the AUTHADMIN=YES option . It is good practice to reassign the library without AUTHADMIN=YES as soon as your administrative need is complete, so that any other access that you make to the library is not in administrative mode. In this case, it also ensures that the credentials are reset.

```
libname abcde "sas-library";
```

Example Code 8.18 *Resetting Credentials*

```
253 libname abcde "library-name" ;
ERROR: The secured library object information for library ABCDE could not be obtained
       from the metadata server or has invalid data.
ERROR: Association not found.
ERROR: Error in the LIBNAME statement.
254  libname abcde "library-name" authadmin=yes;
NOTE: Libref ABCDE was successfully assigned as follows:
      Engine:             V9
      Physical Name:      library-name
      Secured Library:    /System/Secured Libraries/Department XYZZY/ABCDEEmps
      Authenticated ID:   user-id@site as user-id
      Encryption Key:     YES
      Require Encryption: YES
255  proc authlib lib=abcde;
256  modify
257        pw=XXXXXX
258        encrypt=aes
259        encryptkey=XXX ;
260  run;

NOTE: Required encryption will use AES encryption with the recorded key.

NOTE: The passwords on ABCDE.DEPTNAME.DATA do not require modification.
NOTE: The passwords on ABCDE.EMPINFO.DATA do not require modification.
NOTE: The passwords on ABCDE.EMPLOYEE.DATA do not require modification.
261  quit;
```

9

CALENDAR Procedure

Overview: CALENDAR Procedure

What Does the CALENDAR Procedure Do?

The CALENDAR procedure displays data from a SAS data set in a monthly calendar format. You can produce a *schedule calendar*, which schedules events around holidays and nonwork periods, or you can produce a *summary calendar*, which summarizes data and displays only one-day events and holidays. When you use PROC CALENDAR, you can perform the following tasks:

- schedule work around holidays and other nonwork periods
- display holidays
- process data about *multiple calendars* in a single step and print them in a separate, mixed, or combined format
- apply different holidays, weekly work schedules, and daily work shifts to multiple calendars in a single PROC step
- produce a mean and a sum for variables based on either the number of days in a month or the number of observations

PROC CALENDAR also contains features that are specifically designed to work with PROC CPM in SAS/OR software, a project management scheduling tool.

What Types of Calendars Can PROC CALENDAR Produce?

Simple Schedule Calendar

The following output illustrates the simplest type of schedule calendar that you can produce. This calendar output displays activities that are planned by a banking executive. The following statements produce Output 9.30 on page 214.

```
proc calendar data=allacty;
   start date;
   dur long;
run;
```

For the activities data set shown that is in this calendar, see “Example 1: Schedule Calendar with Holidays: 5-Day Default” on page 261.

The following calendar uses one of the two default calendars, the 24-hour-day, 7-day-week calendar.

Output 9.1 *Simple Schedule Calendar*

The SAS System

July 2002

Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday
	1 +Dist. Mtg./+	2 +Mgrs. Meeting/	3 +Interview/J+ District 6=+	4	5 +VIP Banquet+	6

28	29	30	31			

Advanced Schedule Calendar

The following output is an advanced schedule calendar produced by PROC CALENDAR. The statements that create this calendar can perform the following tasks:

- schedule activities around holidays
- identify separate calendars
- print multiple calendars in the same report
- apply different holidays to different calendars
- apply different work patterns to different calendars

For an explanation of the program that produces this calendar, see "Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278.

Output 9.2 *Advanced Schedule Calendar*

Well Drilling Work Schedule: Combined Calendars

July 2002

	Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday
CAL1		1	2	3	4	5	6
					Independence	+Assemble T>	
						+Lay Power >	
		+========Drill Well/$1,000.00========>				<Drill Well+	
CAL2				+================Excavate/$3,500.00================>			
	7	8	9	10	11	12	13

		<Install Pipe/$1,000.00=+					
	28	29	30	31			
CAL1		<Erect Towe+					

Simple Summary Calendar

The following output shows a simple summary calendar that displays the number of meals served daily in a hospital cafeteria:

```
proc calendar data=meals;
   start date;
   sum brkfst lunch dinner;
   mean brkfst lunch dinner;
run;
```

In a summary calendar, each piece of information for a given day is the value of a variable for that day. The variables can be either numeric or character, and you can format them as necessary. You can use the SUM and MEAN options to calculate sums and means for any numeric variables. These statistics appear in a box below the calendar, as shown in the following output. The data set that is shown in this calendar is created in "Example 7: Summary Calendar with MEAN Values by Observation" on page 295.

Output 9.3 *Simple Summary Calendar*

The SAS System

December 2008

Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday
	1 123 234 238	2 188 188 198	3 123 183 176	4 200 267 243	5 176 165 177	6

14	15 176 165 177	16 156 . 167	17 198 143 167	18 178 198 187	19 165 176 187	20
21	22 187 187 123	23	24	25	26	27
28	29	30	31			

	Sum	Mean
Brkfst	2763	172.688
Lunch	2830	188.667
Dinner	2990	186.875

Advanced Scheduling and Project Management Tasks

For more complex scheduling tasks, consider using the CPM procedure in SAS/OR software. PROC CALENDAR requires that you specify the starting date of each activity. When the beginning of one task depends on the completion of others and a date slips in a schedule, recalculating the schedule can be time-consuming. Instead of manually recalculating dates, you can use PROC CPM to calculate dates for project activities based on an initial starting date, activity durations, and which tasks are identified as *successors* to others. For an example, see "Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks" on page 287.

Concepts: CALENDAR Procedure

Types of Calendars

PROC CALENDAR can produce two types of calendars: schedule and summary.

Table 9.1 *Summary of Schedule and Summary Calendars*

Type of Calendar	Task	Restriction
Schedule calendar	Schedule activities around holidays and nonwork periods	Cannot calculate sums and means
Schedule calendar	Schedule activities that last more than one day	
Summary calendar	Calculate sums and means	Activities can last only one day

Note: PROC CALENDAR produces a summary calendar if you do not use a DUR or FIN statement in the PROC step.

Schedule Calendar

Definition

A report in calendar format that shows when activities and holidays start and end.

Required Statements

You must supply a START statement and either a DUR or FIN statement. If you do not use a DUR or FIN statement, then PROC CALENDAR assumes that you want to create a summary calendar report.

Table 9.2 *Required Statements*

Statement	Variable Value
"START Statement" on page 256	Starting date of an activity
"DUR Statement" on page 248	Duration of an activity
"FIN Statement" on page 249	Ending date of an activity

Examples

- "Simple Schedule Calendar" on page 213
- "Advanced Schedule Calendar" on page 215
- "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261
- "Example 2: Schedule Calendar Containing Multiple Calendars" on page 266
- "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271
- "Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278
- "Example 5: Schedule Calendar, Blank or with Holidays" on page 284
- "Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks" on page 287

Summary Calendar

Definition

A report in calendar format that displays activities and holidays that last only one day and that can provide summary information in the form of sums and means.

Required Statements

You must supply a START statement. This statement identifies the variable in the activities data set that contains an activity's starting date.

Multiple Events on a Single Day

A summary calendar report can display only one activity on a given date. Therefore, if more than one activity has the same START value, then only the last observation that was read is used. In such situations, you might find PROC SUMMARY useful in collapsing your data set to contain one activity per starting date.

Examples

- "Simple Summary Calendar" on page 216
- "Example 7: Summary Calendar with MEAN Values by Observation" on page 295
- "Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

The Default Calendars

Description

PROC CALENDAR provides two default calendars for simple applications. You can produce calendars without having to specify detailed work shifts and weekly work patterns if your application can use one of two simple work patterns. Consider using a default calendar if the following conditions are true:

- your application uses a 5-day work week with 8-hour days or a 7-day work week with 24-hour days, as shown in the following table
- you want to print all activities on the same calendar
- you do not need to identify separate calendars

Table 9.3 *Default Calendar Settings and Examples*

Scheduled Work Days	INTERVAL=	Default DAYLENGTH=	Work Period Length	Example
7 (M-Sun)	DAY	24	24-hour days	2
5 (M-F)	WORKDAY	8	8-hour days	1

When You Unexpectedly Produce a Default Calendar

If you want to produce a specialized calendar but do not provide all the necessary information, then PROC CALENDAR attempts to produce a default calendar. These errors cause PROC CALENDAR to produce a calendar with default features:

- If the activities data set does not contain a CALID variable, then PROC CALENDAR produces a default calendar.
- If *both* the holidays and calendar data sets do not contain a CALID variable, then PROC CALENDAR produces a default calendar *even if the activities data set contains a CALID variable*.
- If the activities and calendar data sets contain the CALID variable, but the holidays data set does not, then the default holidays are used.

Examples

- See the 7-day default calendar in Output 9.30 on page 214
- See the 5-day default calendar in “Example 1: Schedule Calendar with Holidays: 5-Day Default” on page 261

Calendars and Multiple Calendars

Definitions

calendar
: a logical entity that represents a weekly work pattern, which consists of weekly work schedules and daily shifts. PROC CALENDAR contains two default work patterns: 5-day week with an 8-hour day or a 7-day week with a 24-hour day. You can also define your own work patterns by using CALENDAR and WORKDAYS data sets.

calendar report
: a report in calendar format that displays activities, holidays, and nonwork periods. A calendar report can contain multiple calendars in one of three formats:

  separate
  : each identified calendar is printed on separate output pages.

  combined
  : all identified calendars are printed on the same output pages and each is identified.

  mixed
  : all identified calendars are printed on the same output pages but are not identified as belonging to separate calendars.

multiple calendar
: a logical entity that represents multiple weekly work patterns.

Advantages of Creating Multiple Calendars

Create a multiple calendar if you want to print a calendar report that shows activities that follow different work schedules or different weekly work patterns. For example, a construction project report might need to use different work

schedules and weekly work patterns for work crews on different parts of the project.

Another use for multiple calendars is to identify activities so that you can choose to print them in the same calendar report. For example, if you identify activities as belonging to separate departments within a division, then you can choose to print a calendar report that shows all departmental activities on the same calendar.

Finally, using multiple calendars, you can produce separate calendar reports for each calendar in a single step. For example, if activities are identified by department, then you can produce a calendar report that prints the activities of each department on separate pages.

How to Identify Multiple Calendars

Because PROC CALENDAR can process only one data set of each type (activities, holidays, calendar, workdays) in a single PROC step, you must be able to identify for PROC CALENDAR which calendar an activity, holiday, or weekly work pattern belongs to. Use the CALID statement to specify the variable whose values identify the appropriate calendar. This variable can be numeric or character.

You can use the special variable name _CAL_ or you can use another variable name. PROC CALENDAR automatically looks for a variable named _CAL_ in the holiday and calendar data sets, even when the activities data set uses a variable with another name as the CALID variable. Therefore, if you use the name _CAL_ in your holiday and calendar data sets, then you can more easily reuse these data sets in different calendar applications.

Using Holidays or Calendar Data Sets with Multiple Calendars

When using a holidays or calendar data set with multiple calendars, PROC CALENDAR treats the variable values in the following way:

- Every value of the CALID variable that appears in either the holidays or calendar data sets defines a calendar.
- If a CALID value appears in the HOLIDATA= data set but not in the CALEDATA= data set, then the work schedule of the default calendar is used.
- If a CALID value appears in the CALEDATA= data set but not in the HOLIDATA= data set, then the holidays of the default calendar are used.
- If a CALID value does not appear in either the HOLIDATA= or CALEDATA= data set, then the work schedule and holidays of the default calendar are used.
- If the CALID variable is not found in the holiday or calendar data set, then PROC CALENDAR looks for the default variable _CAL_ instead. If neither the CALID variable nor a _CAL_ variable appears in a data set, then the observations in that data set are applied to a default calendar.

Types of Reports That Contain Multiple Calendars

Because you can associate different observations with different calendars, you can print a calendar report that shows activities that follow different work schedules or different work shifts or that contain different holidays. You can perform the following tasks:

- print separate calendars on the same page and identify each one
- print separate calendars on the same page without identifying them
- print separate pages for each identified calendar

For example, consider a calendar that shows the activities of all departments within a division. Each department can have its own calendar identification value and, if necessary, can have individual weekly work patterns, daily work shifts, and holidays.

If you place activities that are associated with different calendars in the same activities data sets, then you use PROC CALENDAR to produce calendar reports that print the following:

- the schedule and events for each department on a separate page (separate output)
- the schedule and events for the entire division, each identified by department (combined output)
- the schedule and events for the entire division, but *not* identified by department (mixed output)

The multiple-calendar feature was added specifically to enable PROC CALENDAR to process the output of PROC CPM in SAS/OR software, a project management tool. See "Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks" on page 287.

How to Identify Calendars with the CALID Statement and the Special Variable _CAL_

To identify multiple calendars, you must use the CALID statement to specify the variable whose values identify which calendar an event belongs with. This variable can be numeric or character.

You can use the special variable name _CAL_ or you can use another variable name. PROC CALENDAR automatically looks for a variable named _CAL_ in the holiday and calendar data sets, even when the activities data set uses a variable with another name as the CALID variable. Therefore, if you use the name _CAL_ in your holiday and calendar data sets, then you can more easily reuse these data sets in different calendar applications.

When You Use Holidays or Calendar Data Sets

When you use a holidays or calendar data set with multiple calendars, PROC CALENDAR treats the variable values in the following way:

- Every value of the CALID variable that appears in either the holidays or calendar data sets defines a calendar.
- If a CALID value appears in the HOLIDATA= data set but not in the CALEDATA= data set, then the work schedule of the default calendar is used.
- If a CALID value appears in the CALEDATA= data set but not in the HOLIDATA= data set, then the holidays of the default calendar are used.
- If a CALID value does not appear in either the HOLIDATA= or CALEDATA= data set, then the work schedule and holidays of the default calendar are used.
- If the CALID variable is not found in the holiday or calendar data sets, then PROC CALENDAR looks for the default variable _CAL_ instead. If neither the CALID variable nor a _CAL_ variable appears in a data set, then the observations in that data set are applied to a default calendar.

Examples

- "Example 2: Schedule Calendar Containing Multiple Calendars" on page 266
- "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271
- "Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278
- "Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

Input Data Sets

You might need several data sets to produce a calendar, depending on the complexity of your application. PROC CALENDAR can process one of each of four data sets, as shown in the following table.

Table 9.4 *Four Possible Input Data Sets for PROC CALENDAR*

Data Set	Description	Option
Activities	Each *observation* contains information about a single activity.	"DATA=*SAS-data-set*" on page 237
Holidays	Each *observation* contains information about a holiday.	"HOLIDATA=*SAS-data-set*" on page 242
Calendar	Each *observation* defines one weekly work schedule.	"CALEDATA=*SAS-data-set*" on page 237
Workdays	Each *variable* represents one daily schedule of alternating work and nonwork periods.	"WORKDATA=*SAS-data-set*" on page 244

Activities Data Set

Purpose

The activities data set, specified with the DATA= option, contains information about the activities to be scheduled by PROC CALENDAR. Each observation describes a single activity.

Requirements and Restrictions

- An activities data set is required. (If you do not specify an activities data set with the DATA= option, then PROC CALENDAR uses the _LAST_ data set.)
- Only one activities data set is allowed.
- The activities data set must always be sorted or indexed by the START variable.
- If you use a CALID (calendar identifier) variable and want to produce output that shows multiple calendars on separate pages, then the activities data set must be sorted by or indexed on the CALID variable and then the START variable.
- If you use a BY statement, then the activities data set must be sorted by or indexed on the BY variables.

Structure

Each *observation* in the activities data set contains information about one activity. One variable must contain the starting date. If you are producing a schedule calendar, then another variable must contain either the activity duration or finishing date. Other variables can contain additional information about an activity.

Table 9.5 *Required Statements*

Variable Content	Statement	Calendar Type
Starting date	"START Statement" on page 256	Schedule Summary
Duration	"DUR Statement" on page 248	Schedule
Finishing date	"FIN Statement" on page 249	Schedule

Multiple Activities per Day in Summary Calendars

A summary calendar can display only one activity on a given date. Therefore, if more than one activity has the same START value, then only the last observation that is read is used. In such situations, you might find PROC SUMMARY useful to collapse your data set to contain one activity per starting date.

Examples

Every example in the Examples section uses an activities data set.

Holidays Data Set

Purpose

You can use a holidays data set, specified with the HOLIDATA= option, to identify the following:

- holidays on your calendar output.
- days that are not available for scheduling work. (In a schedule calendar, PROC CALENDAR does not schedule activities on these days.)

Structure

Each observation in the holidays data set must contain at least the holiday starting date. A holiday lasts only one day unless a duration or finishing date is specified. Supplying a holiday name is recommended, though not required. If you do not specify which variable contains the holiday name, then PROC CALENDAR uses the word **DATE** to identify each holiday.

Table 9.6 *Required Statements*

Variable Content	Statement
Starting date	"HOLISTART Statement" on page 251
Name	"HOLIVAR Statement" on page 252
Duration	"HOLIDUR Statement" on page 250
Finishing date	"HOLIFIN Statement" on page 251

No Sorting Needed

You do not need to sort or index the holidays data set.

Using SAS Date versus SAS Datetime Values

PROC CALENDAR calculates time using SAS datetime values. Even when your data is in DATE. format, the procedure automatically calculates time in minutes and seconds. Therefore, if you specify only date values, then PROC CALENDAR prints messages similar to the following ones to the SAS log:

```
NOTE: All holidays are assumed to start at the
      time/date specified for the holiday variable
      and last one DTWRKDAY.
WARNING: The units of calculation are SAS datetime
         values while all the holiday variables are
         not. All holidays are converted to SAS
         datetime values.
```

Create a Generic Holidays Data Set

If you have many applications that require PROC CALENDAR output, then consider creating a generic holidays data set that contains standard holidays. You can begin with the generic holidays and add observations that contain holidays or nonwork events specific to an application.

Holidays and Nonwork Periods

Do not schedule holidays during nonwork periods. Holidays that are defined in the HOLIDATA= data set cannot occur during any nonwork periods that are defined in the work schedule. For example, you cannot schedule Sunday as a vacation day if the work week is defined as Monday through Friday. When such a conflict occurs, the holiday is rescheduled to the next available working period following the nonwork day.

Examples

Every example in the Examples section uses a holidays data set.

Calendar Data Set

Purpose

You can use a calendar data set, specified with the CALEDATA= option, to specify work schedules for different calendars.

Structure

Each observation in the calendar data set defines one weekly work schedule. The data set created in the DATA step shown below defines weekly work schedules for two calendars, CALONE and CALTWO.

```
data cale;
   input _sun_ $ _mon_ $ _tue_ $ _wed_ $ _thu_ $ /
         _fri_ $ _sat_ $ _cal_ $ d_length time6.;
   datalines;
```

```
holiday workday workday workday workday
workday holiday calone 8:00
holiday shift1 shift1 shift1 shift1
shift2 holiday caltwo 9:00
;
```

These are the variables in this calendar data set:

SUN through _SAT_
the name of each day of the week that appears in the calendar. The values of these variables contain the name of work shifts. These are the valid values for work shifts:

- `WORKDAY` (the default work shift)
- `HOLIDAY` (a nonwork period)
- names of variables in the WORKDATA= data set (in this example, `SHIFT1` and `SHIFT2`)

CAL
the CALID (calendar identifier) variable. The values of this variable identify different calendars. If this variable is not present, then the first observation in this data set defines the work schedule that is applied to all calendars in the activities data set.

If the CALID variable contains a missing value, then the character or numeric value for the default calendar (`DEFAULT` or 0) is used. For more details, see "The Default Calendars" on page 221.

D_LENGTH
the daylength identifier variable. Values of D_LENGTH indicate the length of the standard workday to be used in calendar calculations. You can set the workday length either by placing this variable in your calendar data set or by using the DAYLENGTH= option.

Missing values for this variable default to the number of hours specified in the DAYLENGTH= option. If the DAYLENGTH= option is not used, then the day length defaults to 24 hours if INTERVAL=DAY, or eight hours if INTERVAL=WORKDAY.

Using Default Work Shifts Instead of a Workdays Data Set

You can use a calendar data set with or without a workdays data set. Without a workdays data set, WORKDAY in the calendar data set is equal to one of two standard workdays, depending on the setting of the INTERVAL= option:

Table 9.7 *Workday Settings*

INTERVAL=	Work-Shift Start	Day Length
DAY	00:00	24 hours

INTERVAL=	Work-Shift Start	Day Length
WORKDAY	9:00	8 hours

You can reset the length of the standard workday with the DAYLENGTH= option or a D_LENGTH variable in the calendar data set. You can define other work shifts in a workdays data set.

Examples

The following examples feature a calendar data set:

- "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271
- "Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278
- "Example 7: Summary Calendar with MEAN Values by Observation" on page 295

Workdays Data Set

Purpose

You can use a workdays data set, specified with the WORKDATA= option, to define the daily work shifts named in a CALEDATA= data set.

Use Default Work Shifts or Create Your Own?

You do not need a workdays data set if your application can use one of two default work shifts:

Table 9.8 *Default Work Shifts*

INTERVAL=	Work-Shift Start	Day Length
DAY	00:00	24 hours
WORKDAY	9:00	8 hours

See the "INTERVAL=DAY | WORKDAY " on page 242.

Structure

Each variable in the workdays data set contains one daily schedule of alternating work and nonwork periods. For example, this DATA step creates a data set that contains specifications for two work shifts:

```
data work;
   input shift1 time6. shift2 time6.;
   datalines;
7:00  7:00
12:00 11:00
13:00   .
17:00   .
;
```

The variable SHIFT1 specifies a 10-hour workday, with one nonwork period (a lunch hour); the variable SHIFT2 specifies a 4-hour workday with no nonwork periods.

How Missing Values Are Treated

The missing values default to 00:00 in the first observation and to 24:00 in all other observations. Two consecutive values of 24:00 define a zero-length time period, which is ignored.

Examples

See "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271

Missing Values in Input Data Sets

The following table summarizes the treatment of missing values for variables in the data sets used by PROC CALENDAR.

Table 9.9 *Treatment of Missing Values in PROC CALENDAR*

Data set	Variable	Treatment of Missing Values
Activities (DATA=)	"_CAL_" on page 230	Default calendar value is used.
	"START Statement" on page 256	Observation is not used.

Data set	Variable	Treatment of Missing Values
	"DUR Statement" on page 248	1.0 is used.
	"FIN Statement" on page 249	START value + daylength is used.
	"VAR Statement" on page 258	If a summary calendar or the MISSING option is specified, then the missing value is used. Otherwise, no value is used.
	"SUM Statement" on page 257 , "MEAN Statement" on page 253	0
Calendar (CALEDATA=)	"_CAL_" on page 230	Default calendar value is used.
	"_SUN_ through _SAT_" on page 230	Corresponding shift for default calendar is used.
	"D_LENGTH" on page 230	If available, DAYLENGTH= value is used, or, if INTERVAL=DAY, 24:00 is used. Otherwise, 8:00 is used.
	"SUM Statement" on page 257 , "MEAN Statement" on page 253	0
Holiday (HOLIDATA=)	"_CAL_" on page 230	All holidays apply to all calendars.
	"HOLISTART Statement" on page 251	Observation is not used.
	"HOLIDUR Statement" on page 250	If available, HOLIFIN value is used instead of HOLIDUR value. Otherwise, 1.0 is used.
	"HOLIFIN Statement" on page 251	If available, HOLIDUR value is used instead of HOLIFIN value. Otherwise, HOLISTART value + day length is used.
	"HOLIVAR Statement" on page 252	No value is used.
Workdays (WORKDATA=)	any	For the first observation, 00:00 is used. Otherwise, 24:00 is used.

Syntax: CALENDAR Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Requirements: You must use a START statement.

For schedule calendars, you must also use a DUR or FIN statement.

Tips: If you use a DUR or FIN statement, then PROC CALENDAR produces a schedule calendar.

You can use the FORMAT, LABEL, and WHERE statements with PROC CALENDAR. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

You can also use any global statement. For a list, see "Global Statements" on page 25 and "Dictionary of SAS Global Statements" in *SAS Global Statements: Reference*.

PROC CALENDAR <*options*>;

START *variable*;

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

CALID *variable*
</ OUTPUT=COMBINE | MIX | SEPARATE>;

DUR *variable*;

FIN *variable*;

HOLISTART *variable*;

HOLIDUR *variable*;

HOLIFIN *variable*;

HOLIVAR *variable*;

MEAN *variable(s)* </ FORMAT=*format-name*>;

OUTSTART *day-of-week*;

OUTDUR *number-of-days*;

OUTFIN *day-of-week*;

SUM *variable(s)* </ FORMAT=*format-name*>;

VAR *variable(s)*;

Statement	Task	Example
PROC CALENDAR	Display data from a SAS data set in a monthly calendar format	Ex. 1, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 8

Statement	Task	Example
BY	Process activities separately for each BY group, producing a separate calendar for each value of the BY variable	
CALID	Process activities in groups defined by the values of a calendar identifier variable	Ex. 2, Ex. 3, Ex. 4, Ex. 6, Ex. 7, Ex. 8
DUR	Specify the variable that contains the duration of each activity	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5
FIN	Specify the variable in the activities data set that contains the finishing date of each activity	Ex. 6
HOLIDUR	Specify the variable in the holidays data set that contains the duration of each holiday for a schedule calendar	Ex. 1, Ex. 5
HOLIFIN	Specify the variable in the holidays data set that contains the finishing date of each holiday	
HOLISTART	Specify a variable in the holidays data set that contains the starting date of each holiday	Ex. 1, Ex. 5
HOLIVAR	Specify a variable in the holidays data set whose values are used to label the holidays	Ex. 1, Ex. 5
MEAN	Specify numeric variables in the activities data set for which mean values are to be calculated for each month	
OUTDUR	Specify in days the length of the week to be displayed	
OUTFIN	Specify the last day of the week to display in the calendar	Ex. 3, Ex. 4, Ex. 8
OUTSTART	Specify the starting day of the week to display in the calendar	Ex. 3, Ex. 4, Ex. 8
START	Specify the variable in the activities data set that contains the starting date of each activity	Ex. 1
SUM	Specify numeric variables in the activities data set to total for each month	Ex. 8
VAR	Specify the variables that you want to display for each activity	Ex. 6

PROC CALENDAR Statement

Displays data from a SAS data set in a monthly calendar format.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Examples:
"Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261
"Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271
"Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278
"Example 5: Schedule Calendar, Blank or with Holidays" on page 284
"Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks" on page 287
"Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

Syntax

PROC CALENDAR <*options*>;

Summary of Optional Arguments

Control printing

FILL
: displays all months, even if no activities exist.

FORMCHAR <(*position(s)*)>='*formatting-character(s)*'
: defines characters used for outlines, dividers, and so on.

HEADER=SMALL | MEDIUM | LARGE
: specifies the type of heading to use in printing the name of the month.

LOCALE
: displays month and weekday names in the local language.

MISSING
: specifies how to show missing values.

WEEKDAYS
: suppresses the display of Saturdays and Sundays in the output.

Control summary information

LEGEND
: prints the names of the variables whose values appear in the calendar.

MEANTYPE=NOBS | NDAYS

specifies the type of mean to calculate for each month.

Specify data sets containing

CALEDATA=*SAS-data-set*
: weekly work schedules

DATA=*SAS-data-set*
: activities

HOLIDATA=*SAS-data-set*
: holidays

WORKDATA=*SAS-data-set*
: unique shift patterns

Specify time or duration

DATETIME
: specifies that START and FIN variables contain values in DATETIME. format.

DAYLENGTH=*hours*
: specifies the number of hours in a standard work day.

INTERVAL=DAY | WORKDAY
: specifies the units of the DUR and HOLIDUR variables.

Optional Arguments

CALEDATA=*SAS-data-set*

specifies the *calendar data set*, a SAS data set that contains weekly work schedules for multiple calendars.

Default: If you omit the CALEDATA= option, then PROC CALENDAR uses a default work schedule.

Tip: A calendar data set is useful if you are using multiple calendars or a nonstandard work schedule.

See: "The Default Calendars" on page 221

"Calendar Data Set " on page 229

Examples: "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271

"Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278

DATA=*SAS-data-set*

specifies the *activities data set*, a SAS data set that contains starting dates for all activities and variables to display for each activity. Activities must be sorted or indexed by starting date.

Default: If you omit the DATA= option, then the most recently created SAS data set is used.

See: "Activities Data Set " on page 226

Example "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261

DATETIME
specifies that START and FIN variables contain values in DATETIME. format.

Default If you omit the DATETIME option, then PROC CALENDAR assumes that the START and FIN values are in the DATE. format.

Examples "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271

"Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278

"Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

DAYLENGTH=*hours*
The hour value must be a SAS TIME value.

Default 24 if INTERVAL=DAY (the default), 8 if INTERVAL=WORKDAY.

Restriction DAYLENGTH= applies only to schedule calendars.

Interactions If you specify the DAYLENGTH= option and the calendar data set contains a D_LENGTH variable, then PROC CALENDAR uses the DAYLENGTH= value only when the D_LENGTH value is missing.

When INTERVAL=DAY and you have no CALEDATA= data set, specifying a DAYLENGTH= value has no effect.

Tips The DAYLENGTH= option is useful when you use the DUR statement and your work schedule contains days of varying lengths (for example, a work week of five half-days). In a work week with varying day lengths, you need to set a standard day length to use in calculating duration times. For example, an activity with a duration of 3.0 workdays lasts 24 hours if DAYLENGTH=8:00 or 30 hours if DAYLENGTH=10:00.

Instead of specifying the DAYLENGTH= option, you can specify the length of the working day by using a D_LENGTH variable in the CALEDATA= data set. If you use this method, then you can specify different standard day lengths for different calendars.

See "Calendar Data Set " on page 229 for more information about setting the length of the standard workday

FILL
displays all months between the first and last activity, start and finish dates inclusive, including months that contain no activities.

Default If you do not specify FILL, then PROC CALENDAR prints only months that contain *activities*. (Months that contain only *holidays* are not printed.)

Example "Example 5: Schedule Calendar, Blank or with Holidays" on page 284

FORMCHAR <(*position(s)*)>='*formatting-character(s)*'

defines the characters to use for constructing the outlines and dividers for the cells in the calendar as well as all identifying markers (such as asterisks and arrows) used to indicate holidays or continuation of activities in PROC CALENDAR output.

position(s)

identifies the position of one or more characters in the SAS formatting-character string. A space or a comma separates the positions.

Default Omitting (*position(s)*) is the same as specifying all 20 possible system formatting characters, in order.

Range PROC CALENDAR uses 17 of the 20 formatting characters that SAS provides.

See Table 9.15 on page 240 shows the formatting characters that PROC CALENDAR uses.

Figure 9.12 on page 240 illustrates their use in PROC CALENDAR output.

formatting-character(s)

lists the characters to use for the specified positions. PROC CALENDAR assigns characters in *formatting-character(s)* to *position(s)*, in the order in which they are listed. For example, the following option assigns an asterisk (*) to the 12th position, assigns a single hyphen (-) to the 13th, and does not alter remaining characters:

```
formchar(12 13)='*-'
```

These new settings change the activity line from this:

```
+=================ACTIVITY===============+
```

to this:

```
*-----------------ACTIVITY--------------*
```

Figure 9.1 Formatting Characters in PROC CALENDAR Output

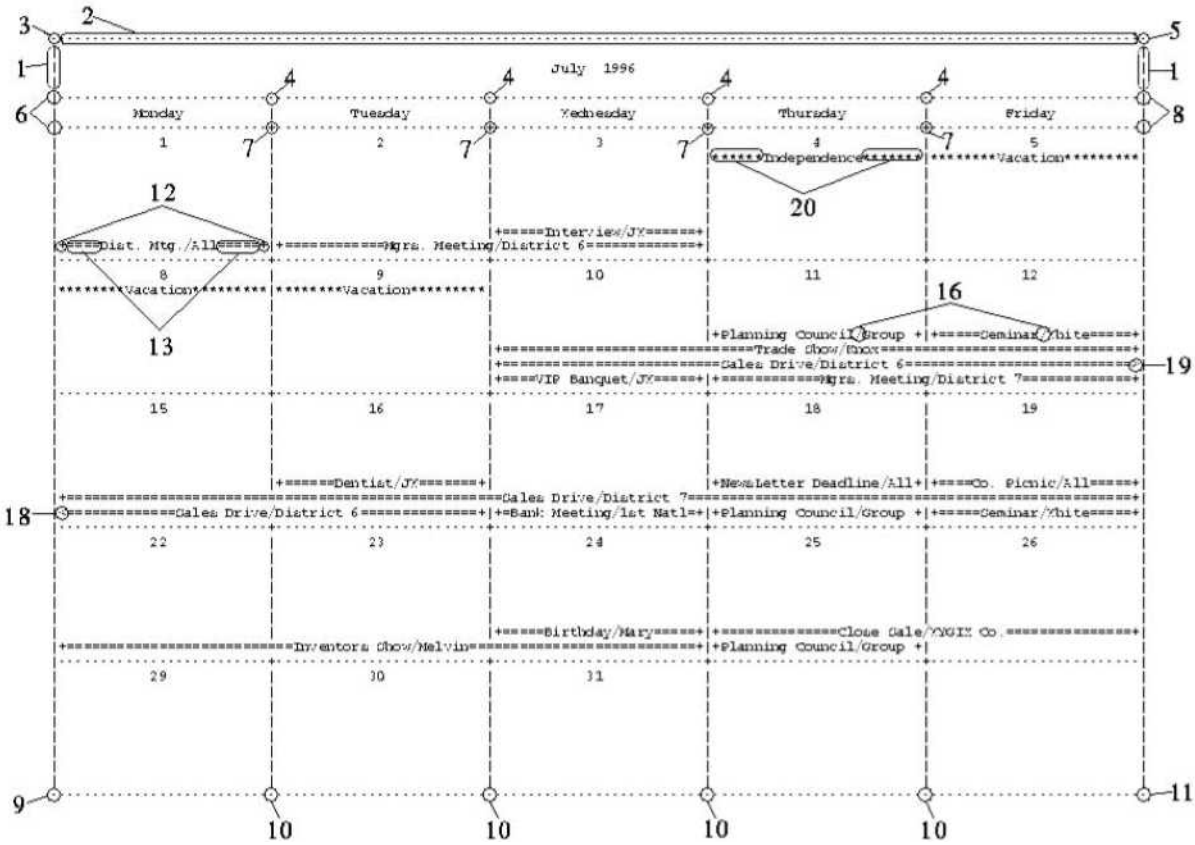

Table 9.10 Formatting Characters Used by PROC CALENDAR

Position	Default	Used to Draw
1	|	Vertical bar
2	-	Horizontal bar
3	-	Cell: upper left corner
4	-	Cell: upper middle intersection
5	-	Cell: upper right corner
6	|	Cell: middle left cell side
7	+	Cell: middle middle intersection
8	|	Cell: middle right cell side
9	-	Cell: lower left corner

Position	Default	Used to Draw
10	-	Cell: lower middle intersection
11	-	Cell: lower right corner
12	+	Activity start and finish
13	=	Activity line
16	/	Activity separator
18	<	Activity continuation from
19	>	Activity continuation to
20	*	Holiday marker

Interaction The SAS system option FORMCHAR= specifies the default formatting characters. The SAS system option defines the entire string of formatting characters. The FORMCHAR= option in a procedure can redefine selected characters.

Tip You can use any character in *formatting-characters*, including hexadecimal characters. If you use hexadecimal characters, then you must put an `x` after the closing quotation mark. For example, the following option assigns the hexadecimal character 2-D to the third formatting character, the hexadecimal character 7C to the seventh character, and does not alter the remaining characters:

```
formchar(3,7)='2D7C'x
```

See For information about which hexadecimal codes to use for which characters, consult the documentation for your hardware.

HEADER=SMALL | MEDIUM | LARGE

specifies the type of heading to use in printing the name of the month.

SMALL

prints the month and year on one line.

MEDIUM

prints the month and year in a box four lines high.

LARGE

prints the month seven lines high using asterisks (*). The year is included if space is available.

Default MEDIUM

HOLIDATA=*SAS-data-set*

specifies the *holidays data set*, a SAS data set that contains the holidays that you want to display in the output. One variable must contain the holiday names and another must contain the starting dates for each holiday. PROC CALENDAR marks holidays in the calendar output with asterisks (*) when space permits.

Interaction Displaying holidays on a calendar requires a holidays data set and a HOLISTART statement. A HOLIVAR statement is recommended for naming holidays. HOLIDUR is required if any holiday lasts longer than one day.

Tip The holidays data set does not require sorting.

See "Holidays Data Set " on page 227

Examples "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261

"Example 5: Schedule Calendar, Blank or with Holidays" on page 284

INTERVAL=DAY | WORKDAY

specifies the units of the DUR and HOLIDUR variables to one of two default day lengths:

DAY

specifies the values of the DUR and HOLIDUR variables in units of 24-hour days and specifies the default 7-day calendar. For example, a DUR value of 3.0 is treated as 72 hours. The default calendar work schedule consists of seven working days, all starting at 00:00 with a length of 24:00.

WORKDAY

specifies the values of the DUR and HOLIDUR variables in units of 8-hour days. WORKDAY also specifies that the default calendar contains five days a week, Monday through Friday, all starting at 09:00 with a length of 08:00. When WORKDAY is specified, PROC CALENDAR treats the values of the DUR and HOLIDUR variables in units of working days, as defined in the DAYLENGTH= option, the CALEDATA= data set, or the default calendar. For example, if the working day is eight hours long, then a DUR value of 3.0 is treated as 24 hours.

Example "Example 5: Schedule Calendar, Blank or with Holidays" on page 284

Default DAY

Interactions If there is no CALEDATA= data set, PROC CALENDAR uses the work schedule defined in a default calendar.

The WEEKDAYS option automatically sets the INTERVAL= value to WORKDAY.

See "Calendars and Multiple Calendars" on page 222 and "Calendar Data Set " on page 229 for more information about the INTERVAL= option and the specification of working days; "The Default Calendars" on page 221

Example "Example 5: Schedule Calendar, Blank or with Holidays" on page 284

LEGEND

prints the names of the variables whose values appear in the calendar. This identifying text, or legend box, appears at the bottom of the page for each month if space permits. Otherwise, it is printed on the following page. PROC CALENDAR identifies each variable by name or by label if one exists. The order of variables in the legend matches their order in the calendar.

Restriction LEGEND applies only to summary calendars.

Interaction If you use the SUM and MEAN statements, then the legend box also contains SUM and MEAN values.

Example "Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

LOCALE

prints the names of months and weekdays in the language that is indicated by the value of the LOCALE= SAS system option. The LOCALE option in PROC CALENDAR does not change the starting day of the week.

Default If LOCALE is not specified, then names of months and weekdays are printed in English.

MEANTYPE=NOBS | NDAYS

specifies the type of mean to calculate for each month.

NOBS

calculates the mean over the number of *observations* displayed in the month.

NDAYS

calculates the mean over the number of *days* displayed in the month.

Default NOBS

Restriction MEANTYPE= applies only to summary calendars.

Interaction Normally, PROC CALENDAR displays all days for each month. However, it might omit some days if you use the OUTSTART statement with the OUTDUR or OUTFIN statement.

Example "Example 7: Summary Calendar with MEAN Values by Observation" on page 295

MISSING

determines how missing values are treated, based on the type of calendar.

Summary Calendar

If there is a day without an activity scheduled, then PROC CALENDAR prints the values of variables for that day by using the SAS or user-defined that is format specified for missing values.

Default If you omit MISSING, then days without activities contain no values.

Schedule Calendar
variables with missing values appear in the label of an activity, using the format specified for missing values.

Default If you do not specify MISSING, then PROC CALENDAR ignores missing values in labeling activities.

See "Missing Values in Input Data Sets" on page 232 for more information about missing values

WEEKDAYS
suppresses the display of Saturdays and Sundays in the output. It also specifies that the value of the INTERVAL= option is WORKDAY.

```
  proc calendar weekdays;
    start date;
run;
proc calendar interval=workday;
    start date;
outstart monday;
outfin friday;
run;
```

Default If you omit WEEKDAYS, then the calendar displays all seven days.

Tip The WEEKDAYS option is an alternative to using the combination of INTERVAL=WORKDAY and the OUTSTART and OUTFIN statements, as shown here:

Example "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261

WORKDATA=*SAS-data-set*
specifies the *workdays data set*, a SAS data set that defines the work pattern during a standard working day. Each numeric variable in the workdays data set denotes a unique work-shift pattern during one working day.

Tip The workdays data set is useful in conjunction with the calendar data set.

See "Workdays Data Set " on page 231 and "Calendar Data Set " on page 229

Examples "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271

"Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278

BY Statement

Processes activities separately for each BY group, producing a separate calendar for each value of the BY variable.

Supports: Summary and schedule calendars

See: "CALID Statement" on page 246
"BY" on page 74 (main discussion)
Example: "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable, but the observations in the data set must be sorted by all the variables that you specify or have an appropriate index. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The observations are grouped in another way (for example, chronological order).

Details

When you use the CALID statement, you can process activities that apply to different calendars, indicated by the value of the CALID variable. Because you can specify only one CALID variable, however, you can create only one level of grouping. For example, if you want a calendar report to show the activities of several departments within a company, then you can identify each department with

the value of the CALID variable and produce calendar output that shows the calendars for all departments.

When you use a BY statement, however, you can further divide activities into related groups. For example, you can print calendar output that groups departmental calendars by division. The observations for activities must contain a variable that identifies which department an activity belongs to and a variable that identifies the division that a department resides in. Specify the variable that identifies the department with the CALID statement. Specify the variable that identifies the division with the BY statement.

CALID Statement

Processes activities in groups defined by the values of a calendar identifier variable.

Supports: Summary and schedule calendars

Tip: CALID is useful for producing multiple schedule calendars and for use with SAS/OR software.

See: "Calendar Data Set " on page 229

Examples: "Example 2: Schedule Calendar Containing Multiple Calendars" on page 266

"Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271

"Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278

"Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks" on page 287

"Example 7: Summary Calendar with MEAN Values by Observation" on page 295

"Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

Syntax

CALID *variable*

</ OUTPUT=COMBINE | MIX | SEPARATE>;

Required Argument

variable

a character or numeric variable that identifies which calendar an observation contains data for.

Requirement If you specify the CALID variable, then both the activities and holidays data sets must contain this variable. If either of these data sets does not contain the CALID variable, then a default calendar is used.

Interaction SAS/OR software uses this variable to identify which calendar an observation contains data for.

Tip You do not need to use a CALID statement to create this variable. You can include the default variable _CALID_ in the input data sets.

See "Calendar Data Set " on page 229

Optional Argument

OUTPUT=COMBINE | MIX | SEPARATE
controls the amount of space required to display output for multiple calendars.

COMBINE
produces one page for each month that contains activities and subdivides each day by the CALID value.

Restriction The input data must be sorted by or indexed on the START variable.

Examples "Example 2: Schedule Calendar Containing Multiple Calendars" on page 266

"Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278

MIX
produces one page for each month that contains activities and does not identify activities by the CALID value.

Restriction The input data must be sorted by or indexed on the START variable.

Tip MIX requires the least space for output.

Example "Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278

SEPARATE
produces a separate page for each value of the CALID variable.

Restriction The input data must be sorted by the CALID variable and then by the START variable or must contain an appropriate composite index.

Examples "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271

"Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

"Example 7: Summary Calendar with MEAN Values by Observation" on page 295

Default COMBINE

DUR Statement

Specifies the variable that contains the duration of each activity.

Alias: DURATION

Interaction: If you use both a DUR statement and a FIN statement, then DUR is ignored.

Supports: Schedule calendars

Tip: To produce a schedule calendar, you must use either a DUR or FIN statement.

Examples:
"Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261
"Example 2: Schedule Calendar Containing Multiple Calendars" on page 266
"Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271
"Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278
"Example 5: Schedule Calendar, Blank or with Holidays" on page 284

Syntax

DUR *variable*;

Required Argument

variable
contains the duration of each activity in a schedule calendar.

Range The duration can be a real or integral value.

Restriction This variable must be in the activities data set.

See For more information about activity durations, see "Activities Data Set " on page 226 and "Calendar Data Set " on page 229

Details

Duration is measured inclusively from the start of the activity (as given in the START variable). In the output, any activity that lasts part of a day is displayed as lasting a full day.

The INTERVAL= option in a PROC CALENDAR statement automatically sets the unit of the duration variable, depending on its own value as follows:

Table 9.11 *INTERVAL= Settings*

INTERVAL=	Default Length of the Duration Unit
DAY (the default)	24 hours
WORKDAY	8 hours

You can override the default length of a duration unit by using one of the following:

- the DAYLENGTH= option
- a D_LENGTH variable in the CALEDATA= data set

FIN Statement

Specifies the variable in the activities data set that contains the finishing date of each activity.

Alias: FINISH

Interaction: If you use both a FIN statement and a DUR statement, then FIN is used.

Supports: Schedule calendars

Tip: To produce a schedule calendar, you must use either a FIN or DUR statement.

Example: "Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks" on page 287

Syntax

FIN *variable*;

Required Argument

variable
contains the finishing date of each activity.

Restrictions The values of *variable* must be either SAS date or datetime values.

If the FIN variable contains datetime values, then you must specify the DATETIME option in the PROC CALENDAR statement.

Both the START and FIN variables must have matching formats. For example, if one contains datetime values, then so must the other.

HOLIDUR Statement

Specifies the variable in the holidays data set that contains the duration of each holiday for a schedule calendar.

Alias: HOLIDURATION

Default: If you do not use a HOLIDUR or HOLIFIN statement, then all holidays last one day.

Restriction: You cannot use the HOLIDUR statement with a HOLIFIN statement.

Supports: Schedule calendars

Examples: "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261
"Example 5: Schedule Calendar, Blank or with Holidays" on page 284

Syntax

HOLIDUR *variable*;

Required Argument

variable
contains the duration of each holiday.

Range: The duration can be a real or integral value.

Restriction: This variable must be in the holidays data set.

Examples: "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271

"Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

Details

- If you use both the HOLIFIN and HOLIDUR statements, then PROC CALENDAR uses the HOLIFIN variable value to define each holiday's duration.
- Set the *unit* of the holiday duration variable in the same way that you set the unit of the duration variable; use either the INTERVAL= and DAYLENGTH= options or the CALEDATA= data set.
- Duration is measured inclusively from the start of the holiday (as given in the HOLISTART variable). In the output, any holiday lasting at least half a day appears as lasting a full day.

HOLIFIN Statement

Specifies the variable in the holidays data set that contains the finishing date of each holiday.

Alias: HOLIFINISH

Default: If you do not use a HOLIFIN or HOLIDUR statement, then all holidays last one day.

Supports: Schedule calendars

Syntax

HOLIFIN *variable*;

Required Argument

variable
contains the finishing date of each holiday.

Restrictions This variable must be in the holidays data set.

Values of *variable* must be in either SAS date or datetime values.

If the HOLIFIN variable contains datetime values, then you must specify the DATETIME option in the PROC CALENDAR statement.

If a HOLIFIN statement or a HOLIDUR statement is not specified, then all holidays last one day.

Details

If you use both the HOLIFIN and HOLIDUR statements, then PROC CALENDAR uses only the HOLIFIN variable.

HOLISTART Statement

Specifies a variable in the holidays data set that contains the starting date of each holiday.

Aliases: HOLISTA
HOLIDAY

Requirement: When you use a holidays data set, HOLISTART is required.

Supports: Summary and schedule calendars

Examples: "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261
"Example 5: Schedule Calendar, Blank or with Holidays" on page 284

Syntax

HOLISTART *variable*;

Required Argument

variable
contains the starting date of each holiday.

Restrictions Values of *variable* must be in either SAS date or datetime values.

If the HOLISTART variable contains datetime values, then specify the DATETIME option in the PROC CALENDAR statement.

Details

- The holidays data set do not need to be sorted.
- All holidays last only one day, unless you use a HOLIFIN or HOLIDUR statement.
- If two or more holidays occur on the same day, then PROC CALENDAR uses only the first observation.

HOLIVAR Statement

Specifies a variable in the holidays data set whose values are used to label the holidays.

Aliases: HOLIVARIABLE
HOLINAME

Default: If you do not use a HOLIVAR statement, then PROC CALENDAR uses the word *DATE* to identify holidays.

Supports: Summary and schedule calendars

Examples: "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261
"Example 5: Schedule Calendar, Blank or with Holidays" on page 284

Syntax

HOLIVAR *variable*;

Required Argument

variable
a variable whose values are used to label the holidays. Typically, this variable contains the names of the holidays.

Range character or numeric.

Restrictions This variable must be in the holidays data set.

If a HOLIVAR statement is not specified, then PROC CALENDAR use the word `DATE` to identify holidays.

Tip You can format the HOLIVAR variable as you like.

MEAN Statement

Specifies numeric variables in the activities data set for which mean values are to be calculated for each month.

Supports: Summary calendars

Tip: You can use multiple MEAN statements.

See: "Example 7: Summary Calendar with MEAN Values by Observation" on page 295

Syntax

MEAN *variable(s)* </ FORMAT=*format-name*>;

Required Argument

variable(s)
numeric variable for which mean values are calculated for each month.

Restriction This variable must be in the activities data set.

Optional Argument

FORMAT=*format-name*
names a SAS or user-defined format to be used in displaying the means requested.

Alias F=

Default BEST. format

Example "Example 7: Summary Calendar with MEAN Values by Observation" on page 295

Details

- The means appear at the bottom of the summary calendar page, if there is room. Otherwise, they appear on the following page.
- The means appear in the **LEGEND** box if you specify the LEGEND option.
- PROC CALENDAR automatically displays variables named in a MEAN statement in the calendar output, even if the variables are not named in the VAR statement.

OUTDUR Statement

Specifies in days the length of the week to be displayed.

Alias: OUTDURATION

Requirement: The OUTSTART statement is required.

Syntax

OUTDUR *number-of-days*;

Required Argument

number-of-days
an integer that expresses the length in days of the week to be displayed.

Details

Use either the OUTDUR or OUTFIN statement to supply the procedure with information about the length of the week to display. If you use both, then PROC CALENDAR ignores the OUTDUR statement.

OUTFIN Statement

Specifies the last day of the week to display in the calendar.

Alias: OUTFINISH

Requirement: The OUTSTART statement is required.

See: "Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

Examples: “Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)” on page 271
“Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)” on page 278
“Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)” on page 300

Syntax

OUTFIN *day-of-week*;

Required Argument

day-of-week
the name of the last day of the week to display. For example,

```
outfin friday;
```

Details

Use either the OUTFIN or OUTDUR statement to supply the procedure with information about the length of the week to display. If you use both, then PROC CALENDAR uses only the OUTFIN statement.

OUTSTART Statement

Specifies the starting day of the week to display in the calendar.

Alias: OUTSTA

Default: If you do not use OUTSTART, then each calendar week begins with Sunday.

See: “Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)” on page 300

Examples: “Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)” on page 271
“Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)” on page 278
“Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)” on page 300

Syntax

OUTSTART *day-of-week*;

Required Argument

day-of-week
the name of the starting day of the week for each week in the calendar. For example,

```
outstart monday;
```

Details

By default, a calendar displays all seven days in a week. Use OUTDUR or OUTFIN, in conjunction with OUTSTART, to control how many days are displayed and which day starts the week.

START Statement

Specifies the variable in the activities data set that contains the starting date of each activity.

Aliases: STA
DATE
ID

Requirement: START is required for both summary and schedule calendars.

Example: "Example 1: Schedule Calendar with Holidays: 5-Day Default" on page 261

Syntax

START *variable*;

Required Argument

variable
contains the starting date of each activity.

Restrictions This variable must be in the activities data set.

Values of *variable* must be in either SAS date or datetime values.

If you use datetime values, then specify the DATETIME option in the PROC CALENDAR statement.

Both the START and FIN variables must have matching formats. For example, if one contains datetime values, then so must the other.

SUM Statement

Specifies numeric variables in the activities data set to total for each month.

Supports: Summary calendars

Tip: To apply different formats to variables that are being summed, use multiple SUM statements.

Examples: "Example 7: Summary Calendar with MEAN Values by Observation" on page 295

"Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

Syntax

SUM *variable(s)* </ FORMAT=*format-name*>;

Required Argument

variable(s)
specifies one or more numeric variables to total for each month.

Restriction This variable must be in the activities data set.

Optional Argument

FORMAT=*format-name*
names a SAS or user-defined format to use in displaying the sums requested.

Alias F=

Default BEST. format

Examples "Example 7: Summary Calendar with MEAN Values by Observation" on page 295

"Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)" on page 300

Details

- The sum appears at the bottom of the calendar page, if there is room. Otherwise, it appears on the following page.
- The sum appears in the **LEGEND** box if you specify the LEGEND option.
- PROC CALENDAR automatically displays variables named in a SUM statement in the calendar output, even if the variables are not named in the VAR statement.

VAR Statement

Specifies the variables that you want to display for each activity.

Alias: VARIABLE

Example: "Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks" on page 287

Syntax

VAR *variable(s)*;

Required Argument

variable(s)
specifies one or more variables that you want to display in the calendar.

Range The values of *variable* can be either character or numeric.

Restriction These variables must be in the activities data set.

Tip You can apply a format to this variable.

Details

When VAR Is Not Used

If you do not use a VAR statement, then the procedure displays all variables in the activities data set in the order in which they occur in the data set, except for the BY, CALID, START, DUR, and FIN variables. However, not all variables are displayed if the LINESIZE= and PAGESIZE= settings do not allow enough space in the calendar.

Display of Variables

- PROC CALENDAR displays variables in the order in which they appear in the VAR statement. Not all variables are displayed, however, if the LINESIZE= and PAGESIZE= settings do not allow enough space in the calendar.
- PROC CALENDAR also displays any variable named in a SUM or MEAN statement for each activity in the calendar output. It displays the variable even if you do not name that variable in a VAR statement.

Results: CALENDAR Procedure

What Affects the Quantity of PROC CALENDAR Output

The quantity of printed calendar output depends on the following variables:

- the range of dates in the activities data set
- whether the FILL option is specified
- the BY statement
- the CALID statement

PROC CALENDAR always prints one calendar for every month that contains any activities. If you specify the FILL option, then the procedure prints every month between the first and last activities, including months that contain no activities. Using the BY statement prints one set of output for each BY value. Using the CALID statement with OUTPUT=SEPARATE prints one set of output for each value of the CALID variable.

How Size Affects the Format of PROC CALENDAR Output

PROC CALENDAR always attempts to fit the calendar within a single page, as defined by the SAS system options PAGESIZE= and LINESIZE=. If the PAGESIZE= and LINESIZE= values do not allow sufficient room, then PROC CALENDAR might print the legend box on a separate page. If necessary, PROC CALENDAR truncates or omits values to make the output fit the page and prints messages to that effect in the SAS log.

What Affects the Lines That Show Activity Duration

In a schedule calendar, the duration of an activity is shown by a continuous line through each day of the activity. Values of variables for each activity are printed on the same line, separated by slashes (/). Each activity begins and ends with a plus sign (+). If an activity continues from one week to the next, then PROC CALENDAR displays arrows (< >) at the points of continuation.

The length of the activity lines depends on the amount of horizontal space available. You can increase the length by specifying the following variables:

- a larger line size with the LINESIZE= option in the OPTIONS statement
- the WEEKDAYS option to suppress the printing of Saturday and Sunday, which provides more space for Monday through Friday

Customizing the Calendar Appearance

PROC CALENDAR uses 17 of the 20 SAS formatting characters to construct the outline of the calendar and to print activity lines and to indicate holidays. You can use the FORMCHAR= option to customize the appearance of your PROC CALENDAR output by substituting your own characters for the default. See Figure 9.12 on page 240 and Table 9.15 on page 240.

If your printer supports an *extended character set* (one that includes graphics characters in addition to the regular alphanumeric characters), then you can greatly improve the appearance of your output by using the FORMCHAR= option to redefine formatting characters with hexadecimal characters. For information about which hexadecimal codes to use for which characters, consult the documentation for your hardware. For an example of assigning hexadecimal values, see *"formatting-character(s)"* on page 239.

Portability of ODS Output with PROC CALENDAR

Under certain circumstances, using PROC CALENDAR with the Output Delivery System produces files that are not portable. If the SAS system option FORMCHAR= in your SAS session uses nonstandard line-drawing characters, then the output might include strange characters instead of lines in operating environments in which the SAS Monospace font is not installed. To avoid this problem, specify the following OPTIONS statement before executing PROC CALENDAR:

```
options formchar="|----|+|---+=|-/\<>*";
```

Examples: CALENDAR Procedure

Example 1: Schedule Calendar with Holidays: 5-Day Default

Features:

PROC CALENDAR statement options
- DATA=
- HOLIDATA=
- WEEKDAYS

Other statements
- DUR statement
- HOLISTART statement
- HOLIVAR statement
- HOLIDUR statement
- START statement

Other features
- PROC SORT statement
- BY statement
- 5-day default calendar

Details

This example does the following:

- creates a schedule calendar
- uses one of the two default work patterns: 8-hour day, 5-day week
- schedules activities around holidays
- displays a 5-day week

Program

12JUL02 Seminar                    White        1
19JUL02 Seminar                    White        1
18JUL02 NewsLetter Deadline        All          1
05JUL02 VIP Banquet                JW           1
19JUL02 Co. Picnic                 All          1
16JUL02 Dentist                    JW           1
24JUL02 Birthday                   Mary         1
25JUL02 Close Sale                 WYGIX Co.    2
;
```

Create the holidays data set.

```
data hol;
   input date : date7. holiday $ 11-25 holilong @27;
   datalines;
05jul02   Vacation        3
04jul02   Independence    1
;
```

Sort the activities data set by the variable that contains the starting date. You are not required to sort the holidays data set.

```
proc sort data=allacty;
   by date;
run;
```

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the schedule calendar. DATA= identifies the activities data set; HOLIDATA= identifies the holidays data set. WEEKDAYS specifies that a week consists of five eight-hour work days.

```
proc calendar data=allacty holidata=hol weekdays;
```

Specify an activity start date variable and an activity duration variable. The START statement specifies the variable in the activities data set that contains the starting date of the activities; DUR specifies the variable that contains the duration of each activity. Creating a schedule calendar requires START and DUR.

```
   start date;
   dur long;
```

Retrieve holiday information. The HOLISTART, HOLIVAR, and HOLIDUR statements specify the variables in the holidays data set that contain the start date, name, and duration of each holiday, respectively. When you use a holidays data set, HOLISTART is required. Because at least one holiday lasts more than one day, HOLIDUR is required.

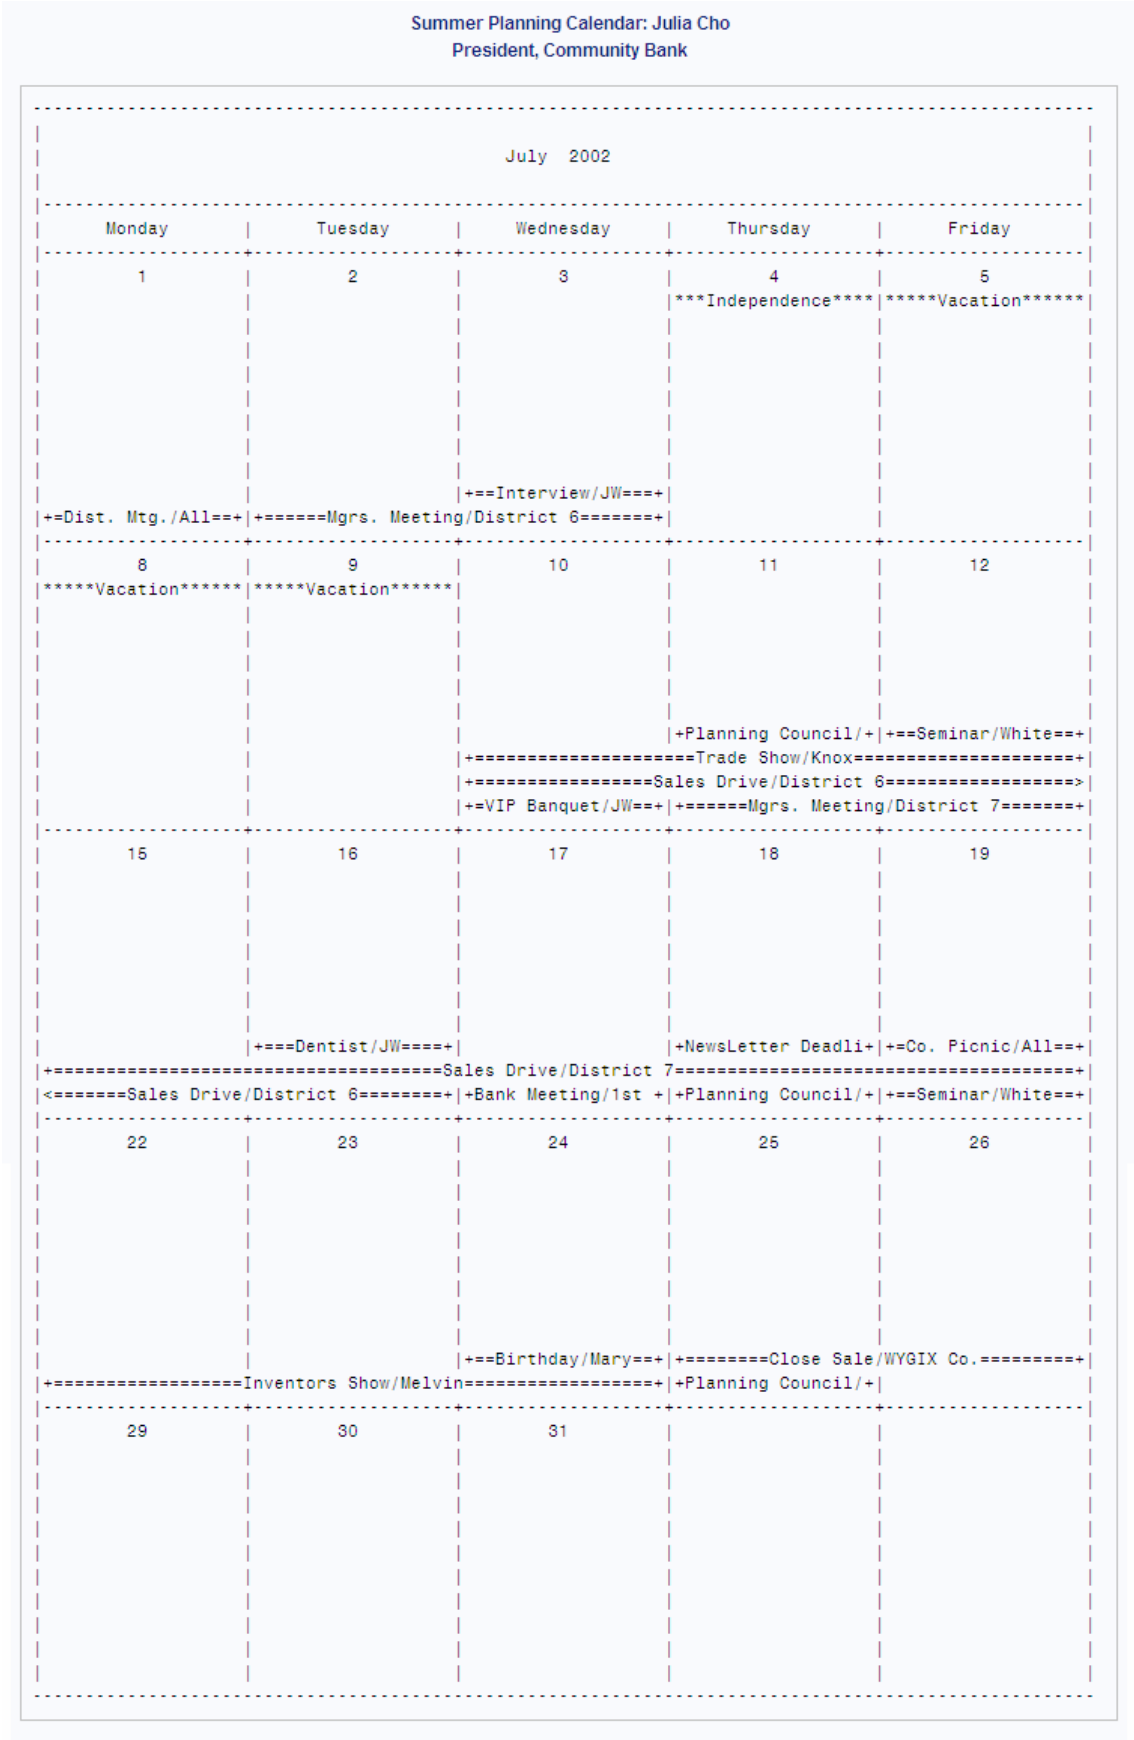
```
   holistart date;
   holivar holiday;
   holidur holilong;
```

Specify the titles.

```
   title1 'Summer Planning Calendar:  Julia Cho';
   title2 'President, Community Bank';
run;
```

Output: HTML

Output 9.4 *Summer Planning Calendar: Julia Cho*



Summer Planning Calendar: Julia Cho
President, Community Bank

Example 2: Schedule Calendar Containing Multiple Calendars

Features:

CALID statement
- _CAL_ variable
- OUTPUT=COMBINE option

Others
- DUR statement
- 24-hour day, 7-day week

Details

This example builds on Example 1 by identifying activities as belonging to one of two calendars, business or personal. This example does the following:

- produces a schedule calendar report
- prints two calendars on the same output page
- schedules activities around holidays
- uses one of the two default work patterns: 24-hour day, 7-day week
- identifies activities and holidays by calendar name

Program

```
data allacty2;

14JUL02  Co. Picnic               All          CAL1   1
14JUL02  Business trip            Fred         CAL2   2
15JUL02  Sales Drive              District 7   CAL1   5
16JUL02  Dentist                  JW           CAL1   1
17JUL02  Bank Meeting             1st Natl     CAL1   1
17JUL02  Real estate agent        Family       CAL2   1
18JUL02  NewsLetter Deadline      All          CAL1   1
18JUL02  Planning Council         Group III    CAL1   1
19JUL02  Seminar                  White        CAL1   1
22JUL02  Inventors Show           Melvin       CAL1   3
24JUL02  Birthday                 Mary         CAL1   1
25JUL02  Planning Council         Group IV     CAL1   1
25JUL02  Close Sale               WYGIX Co.    CAL1   2
27JUL02  Ballgame                 Family       CAL2   1
;
```

Create the holidays data set and identify which calendar a holiday affects. The _CAL_ variable identifies which calendar a holiday belongs to.

```
data vac;
   input hdate:date7.  holiday $ 11-25 _CAL_ $ ;
   datalines;
29JUL02   vacation               CAL2
04JUL02   Independence           CAL1
;
```

Sort the activities data set by the variable that contains the starting date. When creating a calendar with combined output, you sort only by the activity starting date, not by the CALID variable. You are not required to sort the holidays data set.

```
proc sort data=allacty2;
   by date;
run;
```

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the schedule calendar. DATA= identifies the activities data set; HOLIDATA= identifies the holidays data set. By default, the output calendar displays a 7-day week.

```
proc calendar data=allacty2 holidata=vac;
```

Combine all events and holidays on a single calendar. The CALID statement specifies the variable that identifies which calendar an event belongs to. OUTPUT=COMBINE places all events and holidays on the same calendar.

```
   calid _CAL_ / output=combine;
```

Specify an activity start date variable and an activity duration variable. The START statement specifies the variable in the activities data set that contains the starting date of the activities; DUR specifies the variable that contains the duration of each activity. Creating a schedule calendar requires START and DUR.

```
   start date ;
```

```
    dur long;
```

Retrieve holiday information. The HOLISTART and HOLIVAR statements specify the variables in the holidays data set that contain the start date and name of each holiday, respectively. HOLISTART is required when you use a holidays data set.

```
    holistart hdate;
    holivar holiday;
```

Specify the titles.

```
    title1 'Summer Planning Calendar:  Julia Cho';
    title2 'President, Community Bank';
    title3 'Work and Home Schedule';
run;
```

Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)

Features:

PROC CALENDAR statement options
- CALEDATA=
- DATETIME
- WORKDATA=

CALID statement
- _CAL_ variable
- OUTPUT=SEPARATE option

Other statements
- DUR statement
- OUTSTART statement
- OUTFIN statement

Details

This example does the following:

- produces separate output pages for each calendar in a single PROC step
- schedules activities around holidays
- displays an 8-hour day, 5 1/2-day week
- uses separate work patterns and holidays for each calendar

Producing Different Output for Multiple Calendars

This example and "Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)" on page 278 use the same input data for multiple calendars to produce different output. The only differences in these programs are how the activities data set is sorted and how the OUTPUT= option is set.

Table 9.12 Sort and OUTPUT= Settings

Print Options	Sorting Variables	OUTPUT= Settings	Examples
Separate pages for each calendar	Calendar ID and starting date	SEPARATE	3, 8
All activities on the same page and identify each calendar	Starting date	COMBINE	4, 2
All activities on the same page and NOT identify each calendar	Starting date	MIX	4

```

Program Description

Specify a library so that you can permanently store the activities data set.

```
libname well 'SAS-library';
```

Create the activities data set and identify separate calendars. Well.Act is a permanent SAS data set that contains activities for a well construction project. The _CAL_ variable identifies the calendar that an activity belongs to.

```
data well.act;
   input task & $16. dur : 5. date : datetime16.  _cal_ $ cost;
   datalines;
Drill Well          3.50  01JUL02:12:00:00  CAL1   1000
Lay Power Line      3.00  04JUL02:12:00:00  CAL1   2000
Assemble Tank       4.00  05JUL02:08:00:00  CAL1   1000
Build Pump House    3.00  08JUL02:12:00:00  CAL1   2000
Pour Foundation     4.00  11JUL02:08:00:00  CAL1   1500
Install Pump        4.00  15JUL02:14:00:00  CAL1    500
Install Pipe        2.00  19JUL02:08:00:00  CAL1   1000
Erect Tower         6.00  20JUL02:08:00:00  CAL1   2500
Deliver Material    2.00  01JUL02:12:00:00  CAL2    500
Excavate            4.75  03JUL02:08:00:00  CAL2   3500
;
```

Create the holidays data set. The _CAL_ variable identifies the calendar that a holiday belongs to.

```
data well.hol;
   input date date. holiday $ 11-25 _cal_ $;
   datalines;
09JUL02   Vacation            CAL2
04JUL02   Independence        CAL1
;
```

Create the calendar data set. Each observation defines the work shifts for an entire week. The _CAL_ variable identifies to which calendar the work shifts apply. CAL1 uses the default 8-hour work shifts for Monday through Friday. CAL2 uses a half day on Saturday and the default 8-hour work shift for Monday through Friday.

```
data well.cal;
   input _sun_ $ _sat_ $ _mon_ $ _tue_ $ _wed_ $ _thu_ $
         _fri_ $ _cal_ $;
   datalines;
Holiday Holiday  Workday Workday Workday Workday Workday CAL1
Holiday Halfday  Workday Workday Workday Workday Workday CAL2
;
```

Create the workdays data set. This data set defines the daily work shifts that are named in the calendar data set. Each variable (not observation) contains one daily schedule of alternating work and nonwork periods. The HALFDAY work shift lasts 4 hours.

```
data well.wor;
   input halfday time5.;
   datalines;
08:00
12:00
;
```

Sort the activities data set by the variables that contain the calendar identification and the starting date, respectively. You are not required to sort the holidays data set.

```
proc sort data=well.act;
   by _cal_ date;
run;
```

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the schedule calendar. DATA= identifies the activities data set; HOLIDATA= identifies the holidays data set; CALEDATA= identifies the calendar data set; WORKDATA= identifies the workdays data set. DATETIME specifies that the variable specified with the START statement contains values in SAS datetime format.

```
proc calendar data=well.act
              holidata=well.hol
              caledata=well.cal
              workdata=well.wor
              datetime;
```

Print each calendar on a separate page. The CALID statement specifies that the _CAL_ variable identifies calendars. OUTPUT=SEPARATE prints information for each calendar on separate pages.

```
calid _cal_ / output=separate;
```

Specify an activity start date variable and an activity duration variable. The START statement specifies the variable in the activities data set that contains the activity starting date; DUR specifies the variable that contains the activity duration. START and DUR are required for a schedule calendar.

```
start date;
dur dur;
```

Retrieve holiday information. HOLISTART and HOLIVAR specify the variables in the holidays data set that contain the start date and name of each holiday, respectively. HOLISTART is required when you use a holidays data set.

```
holistart date;
holivar holiday;
```

Customize the calendar appearance. OUTSTART and OUTFIN specify that the calendar display a 6-day week, Monday through Saturday.

```
outstart Monday;
outfin Saturday;
```

Specify the title and format the Cost variable.

```
   title1 'Well Drilling Work Schedule: Separate Calendars';
   format cost dollar9.2;
run;
```

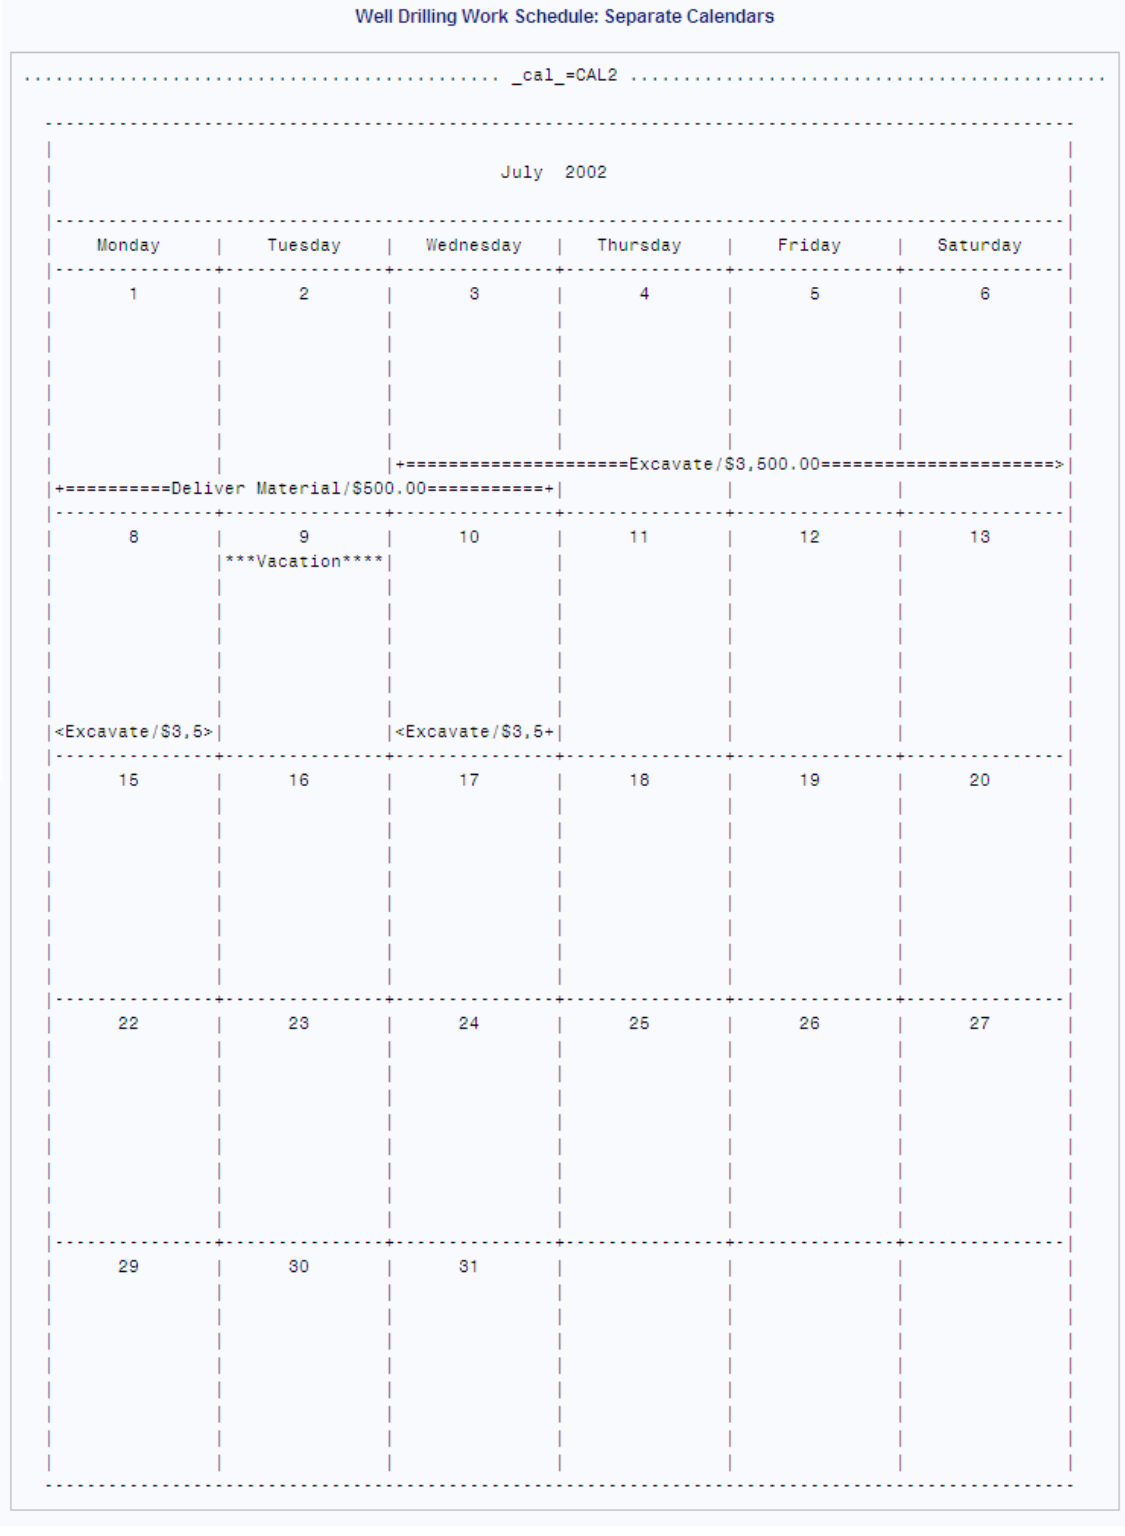
Output 9.7 *Part Two of Well Drilling Work Schedule*



Example 4: Multiple Schedule Calendars with Atypical Work Shifts (Combined and Mixed Output)

Features:

PROC CALENDAR statement options
- CALEDATA=
- DATETIME
- WORKDATA=

CALID statement
- _CAL_ variable
- OUTPUT=COMBINE option
- OUTPUT=MIXED option

Other statement
- DUR statement
- OUTSTART statement
- OUTFIN statement

Data sets:

Well.Aact

Well.Hol

Well.Cal

Well.Wor

Details

This example does the following:

- produces a schedule calendar
- schedules activities around holidays
- uses separate work patterns and holidays for each calendar
- uses an 8-hour day, 5 1/2-day work week
- displays and identifies multiple calendars on each calendar page (combined output)
- displays *but does not identify* multiple calendars on each calendar page (mixed output)

This example creates both combined and mixed output. Producing combined or mixed calendar output requires only one change to a PROC CALENDAR step: the setting of the OUTPUT= option in the CALID statement. Combined output is produced first, then mixed output.

This example and "Example 3: Multiple Schedule Calendars with Atypical Work Shifts (Separated Output)" on page 271 use the same input data for multiple calendars to produce different output. The only differences in these programs are how the activities data set is sorted and how the OUTPUT= option is set.

Table 9.13 *Sort and OUTPUT= Settings*

Print Options	Sorting Variables	OUTPUT= Settings	Examples
Separate pages for each calendar	Calendar ID and starting date	SEPARATE	3, 8
All activities on the same page and identify each calendar	Starting date	COMBINE	4, 2
All activities on the same page and NOT identify each calendar	Starting date	MIX	4

Program for Combined Characters

```
libname well
'SAS-library';

              caledata=well.cal
              workdata=well.wor
              datetime;

   calid _cal_ / output=combine;

   start date;
   dur dur;

   holistart date;
   holivar holiday;

   title1 'Well Drilling Work Schedule: Combined Calendars';
   format cost dollar9.2;
run;
```

Program Description

Specify the SAS library where the activities data set is stored.

```
libname well
'SAS-library';
```

Sort the activities data set by the variable that contains the starting date. Do not sort by the CALID variable when producing combined calendar output.

```
proc sort data=well.act;
   by date;
run;
```

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the schedule calendar. DATA= identifies the activities data set; HOLIDATA= identifies the holidays data set; CALEDATA= identifies the calendar data set; WORKDATA= identifies the workdays data set. DATETIME specifies that the variable specified with the START statement contains values in SAS datetime format.

```
proc calendar data=well.act
              holidata=well.hol
              caledata=well.cal
              workdata=well.wor
              datetime;
```

Combine all events and holidays on a single calendar. The CALID statement specifies that the _CAL_ variable identifies the calendars. OUTPUT=COMBINE prints multiple calendars on the same page and identifies each calendar.

```
   calid _cal_ / output=combine;
```

Specify an activity start date variable and an activity duration variable. The START statement specifies the variable in the activities data set that contains the starting date of the activities; DUR specifies the variable that contains the duration of each activity. START and DUR are required for a schedule calendar.

```
   start date;
   dur dur;
```

Retrieve holiday information. HOLISTART and HOLIVAR specify the variables in the holidays data set that contain the start date and name of each holiday, respectively. HOLISTART is required when you use a holidays data set.

```
   holistart date;
   holivar holiday;
```

Specify the title and format the Cost variable.

```
   title1 'Well Drilling Work Schedule: Combined Calendars';
   format cost dollar9.2;
run;
```

Output: HTML

Output 9.8 *Well Drilling Work Schedule: Combined Calendars*

Program for Mixed Calendars

To produce mixed output instead of combined, use the same program and change the setting of the OUTPUT= option to OUTPUT=MIX:

```
proc calendar data=well.act
              holidata=well.hol
              caledata=well.cal
              workdata=well.wor
              datetime;
   calid _cal_ / output=mix;
   start date;
   dur dur;
   holistart date;
   holivar holiday;
   outstart Monday;
   outfin Saturday;
   title1 'Well Drilling Work Schedule: Mixed Calendars';
   format cost dollar9.2;
run;
```

Output: HTML

Output 9.9 *Well Drilling Work Schedule: Mixed Calendars*

Example 5: Schedule Calendar, Blank or with Holidays

Features:

PROC CALENDAR statement options
- FILL
- HOLIDATA=
- INTERVAL=WORKDAY

Other statements
- DUR statement
- HOLIDUR statement
- HOLISTART statement
- HOLIVAR statement

Details

This example produces a schedule calendar that displays only holidays. You can use this same code to produce a set of blank calendars by removing the HOLIDATA= option and the HOLISTART, HOLIVAR, and HOLIDUR statements from the PROC CALENDAR step.

Program

```
data acts;
   input sta : date7. act $ 11-30 dur;
   datalines;
01JAN03   Start                0
31DEC03   Finish               0
;

data holidays;
   input sta : date7. act $ 11-30 dur;
   datalines;
01JAN03   New Year's           1
30MAR03   Good Friday          1
28MAY03   Memorial Day         1
04JUL03   Independence Day     1
03SEP03   Labor Day            1
22NOV03   Thanksgiving         2
25DEC03   Christmas Break      5
;

options formchar="|----|+|---+=|-/\<>*";

proc calendar data=acts holidata=holidays fill interval=workday;
```

```
   start sta;
   dur dur;

   holistart sta;
   holivar act;
   holidur dur;

   title1 'Calendar of Holidays Only';
run;
```

Program Description

Create the activities data set. Specify one activity in the first month and one in the last, and give each activity a duration of 0. PROC CALENDAR does not print activities with zero durations in the output.

```
data acts;
   input sta : date7. act $ 11-30 dur;
   datalines;
01JAN03   Start                0
31DEC03   Finish               0
;
```

Create the holidays data set.

```
data holidays;
   input sta : date7. act $ 11-30 dur;
   datalines;
01JAN03   New Year's           1
30MAR03   Good Friday          1
28MAY03   Memorial Day         1
04JUL03   Independence Day     1
03SEP03   Labor Day            1
22NOV03   Thanksgiving         2
25DEC03   Christmas Break      5
;
```

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the calendar. DATA= identifies the activities data set; HOLIDATA= identifies the holidays data set. FILL displays all months, even those with no activities. By default, only months with activities appear in the report. INTERVAL=WORKDAY specifies that activities and holidays are measured in 8-hour days and that PROC CALENDAR schedules activities only Monday through Friday.

```
proc calendar data=acts holidata=holidays fill interval=workday;
```

Specify an activity start date variable and an activity duration variable. The START statement specifies the variable in the activities data set that contains the starting date of the activities; DUR specifies the variable that contains the duration of each activity. Creating a schedule calendar requires START and DUR.

```
   start sta;
   dur dur;
```

Retrieve holiday information. The HOLISTART, HOLIVAR, and HOLIDUR statements specify the variables in the holidays data set that contain the start date, name, and duration of each holiday, respectively. When you use a holidays data set, HOLISTART is required. Because at least one holiday lasts more than one day, HOLIDUR (or HOLIFIN) is required.

```
      holistart sta;
      holivar act;
      holidur dur;
```

Specify the title.

```
      title1 'Calendar of Holidays Only';
   run;
```

Output: HTML

The following output shows the December portion of the output. Without the INTERVAL=WORKDAY option, the 5-day Christmas break would be scheduled through the weekend.

Output 9.10 *Calendar of Holidays Only, December*

Calendar of Holidays Only

December 2003

Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday

28	29 Christmas Br	30 Christmas Br	31 Christmas Br			

Example 6: Calculating a Schedule Based on Completion of Predecessor Tasks

Features: PROC CALENDAR procedure features
- PROC CALENDAR statement
- CALID statement
- FIN statement
- VAR statement

PROC CPM step

PROC SORT step

Details

Program Description

This example does the following:

- calculates a project schedule containing multiple calendars (PROC CPM)
- produces a listing of the PROC CPM output data set (PROC PRINT)
- displays the schedule in calendar format (PROC CALENDAR)

This example features PROC CPM's ability to calculate a schedule that meets the following criteria:

- is based on an initial starting date
- applies different non-work periods to different calendars, such as personal vacation days to each employee's schedule
- includes milestones (activities with a duration of 0)

Automating Your Scheduling Task with SAS/OR Software

When changes occur to a schedule, you have to adjust the activity starting dates manually if you use PROC CALENDAR to produce a schedule calendar. Alternatively, you can use PROC CPM in SAS/OR software to reschedule work when dates change. Even more importantly, you can provide only an initial starting date for a project and let PROC CPM calculate starting dates for activities, based on identified successor tasks, that is, tasks that cannot begin until their predecessors end.

In order to use PROC CPM, you must complete the following steps:

1. Create an activities data set that contains activities with durations. (You can indicate nonwork days, weekly work schedules, and work shifts with holidays, calendar, and work-shift data sets.)
2. Indicate which activities are successors to others (precedence relationships).
3. Define resource limitations if you want them considered in the schedule.
4. Provide an initial starting date.

PROC CPM can process your data to generate a data set that contains the start and end dates for each activity. PROC CPM schedules the activities, based on the

duration information, weekly work patterns, work shifts, as well as holidays and nonwork days that interrupt the schedule. You can generate several views of the schedule that is computed by PROC CPM, from a simple listing of start and finish dates to a calendar, a Gantt chart, or a network diagram.

See Also

This example introduces users of PROC CALENDAR to more advanced SAS scheduling tools. For an introduction to project management tasks and tools and several examples, see *Project Management Using the SAS System*. For more examples, see *SAS/OR Software: Project Management Examples*. For complete reference documentation, see *SAS/OR(R) 9.3 User's Guide: Mathematical Programming*.

```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the activities data set and identify separate calendars. This data identifies two calendars: the professor's (the value of _CAL_ is *Prof.*) and the student's (the value of _CAL_ is *Student*). The Succ1 variable identifies which activity cannot begin until the current one ends. For example, *Analyze Exp 1* cannot begin until *Run Exp 1* is completed. The DAYS value of *0* for JOBNUM *3, 6,* and *8* indicates that these jobs are milestones.

```
data grant;
   input jobnum Task $ 4-22 Days Succ1 $ 27-45 aldate : date7. altype $
         _cal_ $;
   format aldate date7.;
   datalines;
1  Run Exp 1          11  Analyze Exp 1       .      .   Student
2  Analyze Exp 1       5  Send Report 1       .      .   Prof.
3  Send Report 1       0  Run Exp 2           .      .   Prof.
4  Run Exp 2          11  Analyze Exp 2       .      .   Student
5  Analyze Exp 2       4  Send Report 2       .      .   Prof.
```

```
6  Send Report 2       0  Write Final Report  .       .   Prof.
7  Write Final Report  4  Send Final Report   .       .   Prof.
8  Send Final Report   0                      .       .   Student
9  Site Visit          1                   18jul07 ms  Prof.
;
```

Create the holidays data set and identify which calendar a nonwork day belongs to. The two holidays are listed twice, once for the professor's calendar and once for the student's. Because each person is associated with a separate calendar, PROC CPM can apply the personal vacation days to the appropriate calendars.

```
data nowork;
   format holista date7. holifin date7.;
   input holista : date7. holifin : date7. name $ 17-32 _cal_ $;
   datalines;
04jul07 04jul07 Independence Day Prof.
03sep07 03sep07 Labor Day        Prof.
04jul07 04jul07 Independence Day Student
03sep07 03sep07 Labor Day        Student
16jul07 17jul07 PROF Vacation    Prof.
16aug07 17aug07 STUDENT Vacation Student
;
```

Calculate the schedule with PROC CPM. PROC CPM uses information supplied in the activities and holidays data sets to calculate start and finish dates for each activity. The DATE= option supplies the starting date of the project. The CALID statement is not required, even though this example includes two calendars, because the calendar identification variable has the special name _CAL_.

```
proc cpm data=grant
         date='01jul07'd
         interval=weekday
         out=gcpm1
         holidata=nowork;
   activity task;
   successor succ1;
   duration days;
   calid _cal_;
   id task;
   aligndate aldate;
   aligntype altype;
   holiday holista / holifin=holifin;
run;
```

Print the output data set that was created with PROC CPM. This step is not required. PROC PRINT is a useful way to view the calculations produced by PROC CPM.

```
proc print data=gcpm1;
   title 'Data Set GCPM1, Created with PROC CPM';
run;
```

Sort GCPM1 by the variable that contains the activity start dates before using it with PROC CALENDAR.

```
proc sort data=gcpm1;
   by e_start;
run;
```

Create the schedule calendar. GCPM1 is the activity data set. PROC CALENDAR uses the S_START and S_FINISH dates, calculated by PROC CPM, to print the schedule. The VAR statement selects only the variable TASK to display on the calendar output.

```
proc calendar data=gcpm1
              holidata=nowork
              interval=workday;
   start e_start;
   fin   e_finish;
   calid _cal_ / output=combine;
   holistart holista;
   holifin   holifin;
   holivar name;
   var task;
   title 'Schedule for Experiment X-15';
   title2 'Professor and Student Schedule';
run;
```

Output: HTML

PROC PRINT displays the observations in GCPM1, showing the scheduling calculations created by PROC CPM.

Output 9.11 *Data Set GCPM1, Created with PROC CPM*

Data Set GCPM1, Created with PROC CPM

Obs	Task	Succ1	Days	_cal_	E_START	E_FINISH	L_START	L_FINISH	T_FLOAT	F_FLOAT

9	Site Visit		1	Prof.	19JUL07	19JUL07	19JUL07	19JUL07	0	0

PROC CALENDAR created the following schedule calendar by using the S_START and S_FINISH dates that were calculated by PROC CPM. The activities on July 25 and August 15, because they are milestones, do not delay the start of a successor activity. Note that Site Visit occurs on July 18, the same day that Analyze Exp 1 occurs. To prevent this overallocation of resources, you can use *resource constrained scheduling*, available in SAS/OR software.

Output 9.12 *Schedule for Experiment X-15, July*

Schedule for Experiment X-15
Professor and Student Schedule

Example 7: Summary Calendar with MEAN Values by Observation

Features:

CALID statement
- _CAL_ variable
- OUTPUT=SEPARATE option

Other statements
- FORMAT statement
- LABEL statement
- MEAN statement
- SUM statement

PROC FORMAT
- PICTURE statement

Details

This example does the following:

- produces a summary calendar
- displays holidays
- produces sum and mean values by business day (observation) for three variables
- prints a legend and uses variable labels
- uses picture formats to display values

To produce MEAN values based on *the number of days in the calendar month*, use MEANTYPE=NDAYS. By default, MEANTYPE=NOBS, which calculates the MEAN values according to *the number of days for which data exists*.

proc calendar data=meals holidata=closed;
   start date;

   holistart date;
   holiname holiday;

   sum brkfst lunch dinner / format=4.0;
   mean brkfst lunch dinner / format=6.2;
   label brkfst = 'Breakfasts Served'
         lunch  = '   Lunches Served'
         dinner = '   Dinners Served';
   format brkfst bfmt.
          lunch lfmt.
          dinner dfmt.;

   title 'Meals Served in Company Cafeteria';
   title2 'Mean Number by Business Day';
run;

title;
```

Program Description

Create the Activities data set. MEALS records how many meals were served for breakfast, lunch, and dinner on the days that the cafeteria was open for business.

```
data meals;
   input date : date7. Brkfst Lunch Dinner;
   datalines;
01Dec08       123 234 238
02Dec08       188 188 198
03Dec08       123 183 176
04Dec08       200 267 243
05Dec08       176 165 177
08Dec08       178 198 187
09Dec08       165 176 187
10Dec08       187 176 231
11Dec08       176 187 222
12Dec08       187 187 123
15Dec08       176 165 177
16Dec08       156   . 167
17Dec08       198 143 167
18Dec08       178 198 187
19Dec08       165 176 187
22Dec08       187 187 123
;
```

Create the Holidays data set.

```
data closed;
   input date date. holiday $ 11-25;
   datalines;
26DEC08   Repairs
29DEC08   Repairs
30DEC08   Repairs
31DEC08   Repairs
23DEC08   Vacation
24DEC08   Christmas Eve
25DEC08   Christmas
;
```

Sort the Activities data set by the activity starting date. You are not required to sort the Holidays data set.

```
proc sort data=meals;
   by date;
run;
```

Create picture formats for the variables that indicate how many meals were served.

```
proc format;
   picture bfmt other = '000 Brkfst';
   picture lfmt other = '000 Lunch ';
   picture dfmt other = '000 Dinner';
run;
```

Set the FORMCHAR and LINESIZE options. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the summary calendar. DATA= identifies the Activities data set; HOLIDATA= identifies the Holidays data set. The START statement specifies the variable in the Activities data set that contains the activity starting date; START is required.

```
proc calendar data=meals holidata=closed;
   start date;
```

Retrieve holiday information. The HOLISTART and HOLIVAR statements specify the variables in the Holidays data set that contain the start date and the name of each holiday, respectively. HOLISTART is required when you use a Holidays data set.

```
   holistart date;
   holiname holiday;
```

Calculate, label, and format the sum and mean values. The SUM and MEAN statements calculate sum and mean values for three variables and print them with the specified format. The LABEL statement prints a legend and uses labels instead of variable names. The FORMAT statement associates picture formats with three variables.

```
   sum brkfst lunch dinner / format=4.0;
   mean brkfst lunch dinner / format=6.2;
   label brkfst = 'Breakfasts Served'
         lunch  = '   Lunches Served'
         dinner = '   Dinners Served';
   format brkfst bfmt.
          lunch lfmt.
          dinner dfmt.;
```

Specify the titles.

```
   title 'Meals Served in Company Cafeteria';
   title2 'Mean Number by Business Day';
run;

title;
```

Output: HTML

Output 9.14 *Meals Served in Company Cafeteria - Mean Number by Business Day*

Meals Served in Company Cafeteria
Mean Number by Business Day

Example 8: Multiple Summary Calendars with Atypical Work Shifts (Separated Output)

Features:

PROC CALENDAR statement options
- DATETIME
- LEGEND

CALID statement
- _CAL_ variable
- OUTPUT=SEPARATE option

Other statements
- OUTSTART statement
- OUTFIN statement
- SUM statement

Data sets: Well.Act

Well.Hol

Details

This example does the following:

- produces a summary calendar for multiple calendars in a single PROC step
- prints the calendars on separate pages
- displays holidays
- uses separate work patterns, work shifts, and holidays for each calendar

Producing Different Output for Multiple Calendars

This example produces separate output for multiple calendars. To produce combined or mixed output for this data, you need to change only the following two things:

- how the Activities data set is sorted
- how the OUTPUT= option is set

Table 9.14 *Sort and OUTPUT= Settings*

Print Options	Sorting Variables	OUTPUT= Settings	Examples
Separate pages for each calendar	Calendar ID and starting date	SEPARATE	3, 8
All activities on the same page and identify each calendar	Starting date	COMBINE	4, 2
All activities on the same page and NOT identify each calendar	Starting date	MIX	4

Program

```
libname well
'SAS-library';
run;

proc sort data=well.act;
   by _cal_ date;
run;

options formchar="|----|+|---+=|-/\<>*" linesize=132;

proc calendar data=well.act
              holidata=well.hol
              datetime legend;

   calid _cal_ / output=separate;

   start date;
   holistart date;
   holivar holiday;

   sum cost / format=dollar10.2;

   outstart Monday;
   outfin Saturday;

   title 'Well Drilling Cost Summary';
   title2 'Separate Calendars';
   format cost dollar10.2;
run;
```

Program Description

Specify the SAS library where the Activities data set is stored.

```
libname well
```

```
'SAS-library';
run;
```

Sort the Activities data set by the variables containing the calendar identification and the starting date, respectively.

```
proc sort data=well.act;
   by _cal_ date;
run;
```

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available. LINESIZE needs to be set in this example to prevent truncating data in the output.

```
options formchar="|----|+|---+=|-/\<>*" linesize=132;
```

Create the summary calendar. DATA= identifies the Activities data set; HOLIDATA= identifies the Holidays data set; CALDATA= identifies the Calendar data set; WORKDATA= identifies the Workdays data set. DATETIME specifies that the variable specified with the START statement contains a SAS datetime value. LEGEND prints text that identifies the variables.

```
proc calendar data=well.act
              holidata=well.hol
              datetime legend;
```

Print each calendar on a separate page. The CALID statement specifies that the _CAL_ variable identifies calendars. OUTPUT=SEPARATE prints information for each calendar on separate pages.

```
   calid _cal_ / output=separate;
```

Specify an activity start date variable and retrieve holiday information. The START statement specifies the variable in the Activities data set that contains the activity starting date. The HOLISTART and HOLIVAR statements specify the variables in the Holidays data set that contain the start date and name of each holiday, respectively. These statements are required when you use a Holidays data set.

```
   start date;
   holistart date;
   holivar holiday;
```

Calculate sum values. The SUM statement totals the COST variable for all observations in each calendar.

```
   sum cost / format=dollar10.2;
```

Display a 6-day week. OUTSTART and OUTFIN specify that the calendar display a 6-day week, Monday through Saturday.

```
   outstart Monday;
   outfin Saturday;
```

Specify the titles and format the Cost variable.

```
   title 'Well Drilling Cost Summary';
   title2 'Separate Calendars';
   format cost dollar10.2;
run;
```

Output: HTML

Output 9.15 *Part One of Well Drilling Cost Summary*

CATALOG Procedure

Overview: CATALOG Procedure

What Does the CATALOG Procedure Do?

The CATALOG procedure manages entries in SAS catalogs. PROC CATALOG is an interactive, statement-driven procedure that enables you to do the following:

- create a listing of the contents of a catalog
- copy a catalog or selected entries within a catalog
- rename, exchange, or delete entries within a catalog
- change the name of a catalog entry
- modify, by changing or deleting, the description of a catalog entry

For more information about SAS libraries and catalogs, see *SAS Language Reference: Concepts*.

Concepts: CATALOG Procedure

Concepts: CATALOG Procedure

To learn how to use the SAS windowing environment to manage entries in a SAS catalog, see the SAS online Help for the Explorer window. You might prefer to use the Explorer window instead of using PROC CATALOG. You can do most of what the procedure does using the Explorer window.

Syntax: CATALOG Procedure

Tips: The CATALOG procedure supports RUN-group processing.

You can perform similar functions with the SAS Explorer window and with DICTIONARY tables in the SQL procedure. For information about the Explorer window, see the online Help. For information about PROC SQL, see *SAS SQL Procedure User's Guide*.

See: CATALOG Procedure under Windows, UNIX, z/OS

PROC CATALOG CATALOG=<*libref.*>*catalog* <ENTRYTYPE=*entry-type*> <FORCE> <KILL>;

CONTENTS <OUT=*SAS-data-set*> <FILE=*fileref*>;

COPY OUT=<*libref.*>*catalog* <*options*>;

SELECT *entry-1* <*entry-2 ...*> </ ENTRYTYPE=*entry-type* >;

EXCLUDE *entry-1* <*entry-2 ...*> </ ENTRYTYPE=*entry-type*>;

CHANGE *old-name-1=new-name-1*
<*old-name-2=new-name-2 ...*>
</ ENTRYTYPE=*entry-type*>;

EXCHANGE *name-1=other-name-1*
<*name-2=other-name-2 ...*>
</ ENTRYTYPE=*entry-type*>;

DELETE *entry-1* <*entry-2 ...*> </ ENTRYTYPE=*entry-type*>;

MODIFY *entry* (DESCRIPTION=<<'>*entry-description*<'>>)
</ ENTRYTYPE=*entry-type*>;

SAVE *entry-1* <*entry-2 ...*> </ ENTRYTYPE=*entry-type* >;

Statement	Task	Example
Chapter 10, "CATALOG Procedure,"	Copy entries from one SAS catalog to another	Ex. 1, Ex. 2, Ex. 3
CHANGE	Change the names of catalog entries	Ex. 2
CONTENTS	Print the contents of a catalog	Ex. 2
COPY	Copy some or all of the entries in one catalog to another catalog	Ex. 1
DELETE	Delete specified entries	Ex. 1
EXCHANGE	Switch the names of two catalog entries	
EXCLUDE	Exclude entries from being copied	Ex. 1
MODIFY	Change the description of a catalog entry	Ex. 2
SAVE	Delete all except the entries specified	
SELECT	Copy only selected entries	Ex. 1

PROC CATALOG Statement

Copies entries from one SAS catalog to another.

Syntax

PROC CATALOG CATALOG=<*libref*.>*catalog* <ENTRYTYPE=*entry-type*> <FORCE> <KILL>;

Summary of Optional Arguments

ENTRYTYPE=*entry-type*
: restricts processing of the current PROC CATALOG step to one entry type.

FORCE
: forces statements to execute on a catalog that is opened by another resource environment.

KILL

Required Argument

CATALOG=<*libref*.>*catalog*
: specifies the SAS catalog to process.

Aliases: CAT=, C=

Default: PROC CATALOG processes all entries in the catalog.

Example: "Example 3: Using the FORCE Option with the KILL Option" on page 331

Optional Arguments

ENTRYTYPE=*entry-type*
: restricts processing of the current PROC CATALOG step to one entry type.

Alias: ET=

Default: PROC CATALOG processes all entries in a catalog.

Interactions The specified entry type applies to any one-level entry names that are used in a subordinate statement. You cannot override this specification in a subordinate statement.

The ENTRYTYPE= option does not restrict the effects of the KILL option.

Tip In order to process multiple entry types in a single PROC CATALOG step, use the ENTRYTYPE= option in a subordinate statement, not in the PROC CATALOG statement.

See "Specifying an Entry Type" on page 320

Examples "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

"Example 2: Displaying Contents, Changing Names, and Changing a Description" on page 329

FORCE

forces statements to execute on a catalog that is opened by another resource environment.

Some CATALOG statements and arguments require exclusive access to the catalog that they operate on if the statement can radically change the contents of a catalog. If exclusive access cannot be obtained, then the action fails. Here are the statements and arguments and the catalogs that are affected by the FORCE option:

COPY	affects the OUT= catalog.
COPY MOVE	affects the IN= catalog and the OUT= catalog.
SAVE	affects the specified catalog.

Tip Use the FORCE option to execute the statement, even if exclusive access cannot be obtained.

Example "Example 3: Using the FORCE Option with the KILL Option" on page 331

KILL

affects the specified catalog and deletes all entries in a SAS catalog.

deletes all entries in a SAS catalog.

CAUTION

Do not attempt to limit the effects of the KILL option. This option deletes all entries in a SAS catalog before any option or other statement takes effect.

Interactions The KILL option deletes all catalog entries even when the ENTRYTYPE= option is specified.

The SAVE statement has no effect because the KILL option deletes all entries in a SAS catalog before any other statements are processed.

Tip The KILL option deletes all entries but does not remove an empty catalog from the SAS library. You must use another method, such as PROC DATASETS or the DIR window to delete an empty SAS catalog.

Example "Example 3: Using the FORCE Option with the KILL Option" on page 331

CHANGE Statement

Renames one or more catalog entry names.

Tip: You can change multiple entry names in a single CHANGE statement or use multiple CHANGE statements.

Example: "Example 2: Displaying Contents, Changing Names, and Changing a Description" on page 329

Syntax

CHANGE *old-name-1=new-name-1*
<*old-name-2=new-name-2 ...*>
</ ENTRYTYPE=*entry-type*>;

Required Argument

old-name=new-name
specifies the current name of a catalog entry and the new name that you want to assign to it. Specify any valid SAS name.

Restriction You must designate the type of the entry, either with the name (*entry-name.entry-type*) or with the ENTRYTYPE= option.

Optional Argument

ENTRYTYPE=*entry-type*
restricts processing to one entry type.

Alias ET=

See "The ENTRYTYPE= Option" on page 322

"Specifying an Entry Type" on page 320

CONTENTS Statement

Lists the contents of a catalog in the procedure output or writes a list of the contents to a SAS data set, an external file, or both.

Note: The ENTRYTYPE= option is not available for the CONTENTS statement.

Example: "Example 2: Displaying Contents, Changing Names, and Changing a Description" on page 329

Syntax

CONTENTS <CATALOG=<*libref.*>*catalog* > <OUT=*SAS-data-set*> <FILE=*fileref*>;

Without Arguments

The output is sent to the procedure output.

Optional Arguments

CATALOG=<*libref.*>*catalog*
specifies the SAS catalog to process.

Aliases CAT=

C=

Default None

FILE=*fileref*
sends the contents to an external file that is identified with a SAS fileref.

Interaction If *fileref* has not been previously assigned to a file, then the file is created and named according to operating environment-dependent rules for external files.

OUT=*SAS-data-set*
sends the contents to a SAS data set. When the statement executes, a message in the SAS log reports that a data set has been created. The data set contains six variables in the following order:

Table 10.1 *OUT= Outpput*

LIBNAME	the libref
MEMNAME	the catalog name

NAME	the names of entries
TYPE	the types of entries
DESC	the descriptions of entries
DATE	the dates entries were last modified

COPY Statement

Copies some or all of the entries in one catalog to another catalog.

Restriction: A COPY statement's effect ends at a RUN statement or at the beginning of a statement other than the SELECT or EXCLUDE statement.

Tips: Use the SELECT or EXCLUDE statement, but not both, after the COPY statement to limit which entries are copied.

You can copy entries from multiple catalogs in a single PROC step, not just the one specified in the PROC CATALOG statement.

The ENTRYTYPE= option does not require a forward slash (/) in the COPY statement.

Example: "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

Syntax

COPY OUT=<*libref.*>*catalog* <*options*>;

Required Argument

OUT=<*libref.*>*catalog*
names the catalog to which entries are copied.

Optional Arguments

ENTRYTYPE=*entry-type*
restricts processing to one entry type for the current COPY statement and any subsequent SELECT or EXCLUDE statements.

Alias ET=

See "The ENTRYTYPE= Option" on page 322

"Specifying an Entry Type" on page 320

IN=<*libref*.>*catalog*
specifies the catalog to copy.

Interaction The IN= option overrides a CATALOG= argument that was specified in the PROC CATALOG statement.

Example "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

LOCKCAT=EXCLUSIVE | SHARE
specifies whether to enable more than one user to copy to the same catalog at the same time. Using LOCKCAT=SHARE locks individual entries rather than the entire catalog, which enables greater throughput. The default is LOCKCAT=EXCLUSIVE, which locks the entire catalog to one user. Note that using the LOCKCAT=SHARE option can lessen performance if used in a single-user environment because of the overhead associated with locking and unlocking each entry.

MOVE
deletes the original catalog or entries after the new copy is made.

Interaction When the MOVE option removes all entries from a catalog, the procedure deletes the catalog from the library.

NEW
overwrites the catalog (specified by the OUT= option) if it already exists. If you omit the NEW option , then PROC CATALOG updates the catalog.

See For information about using the NEW option with concatenated catalogs, see "Catalog Concatenation" on page 323.

NOEDIT
prevents the copied version of the following SAS/AF entry types from being edited by the BUILD procedure:

CBT
FRAME
HELP
MENU
PROGRAM
SCL
SYSTEM

Restriction If you specify the NOEDIT option for an entry that is not one of the above types, then it is ignored.

Tip When creating SAS/AF applications for other users, use the NOEDIT option to protect the application by preventing certain catalog entries from being altered.

Example "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

NOSOURCE
omits copying the source lines when you copy a SAS/AF PROGRAM, FRAME, or SCL entry.

Alias NOSRC

Restriction If you specify this option for an entry other than a PROGRAM, FRAME, or SCL entry, then it is ignored.

DELETE Statement

Deletes entries from a SAS catalog.

Restriction: This procedure is not supported on the CAS server.

Tips: Use the DELETE statement to delete only a few entries; use the SAVE option when it is more convenient to specify which entries not to delete.

You can specify multiple entries. You can also use multiple DELETE statements.

See: SAVE Statement on page 317

Example: "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

Syntax

DELETE *entry-1 <entry-2 ...>* </ ENTRYTYPE=*entry-type*>;

Required Argument

entry-1 <entry-2 ...>
specifies the name of one or more SAS catalog entries.

Restriction You must designate the type of the entry, either with the name (*entry-name.entry-type*) or with the ENTRYTYPE= option.

Optional Argument

ENTRYTYPE=*entry-type*
restricts processing to one entry type.

See "The ENTRYTYPE= Option" on page 322

"Specifying an Entry Type" on page 320

EXCHANGE Statement

Switches the name of two catalog entries.

Restriction: When using the EXCHANGE statement, the catalog entries must be of the same type.

Syntax

EXCHANGE *name-1=other-name-1*
<*name-2=other-name-2 ...*>
</ ENTRYTYPE=*entry-type*>;

Required Argument

name=other-name
specifies two catalog entry names that the procedure switches.

Interaction: You can specify only the entry name without the entry type if you use the ENTRYTYPE= option on either the PROC CATALOG statement or the EXCHANGE statement.

See "Specifying an Entry Type" on page 320

Optional Argument

ENTRYTYPE=*entry-type*
restricts processing to one entry type.

Alias: ET=

See "The ENTRYTYPE= Option" on page 322

"Specifying an Entry Type" on page 320

EXCLUDE Statement

Specifies entries that the COPY statement does not copy.

Restrictions: The EXCLUDE statement requires the COPY statement.
Do not use the EXCLUDE statement with the SELECT statement.

Tips: You can specify multiple entries in a single EXCLUDE statement.

You can use multiple EXCLUDE statements with a single COPY statement within a RUN group.

See: COPY Statement on page 312 and SELECT Statement on page 318

Example: "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

Syntax

EXCLUDE *entry-1 <entry-2 ...>* </ ENTRYTYPE=*entry-type*>;

Required Argument

entry-1 <entry-2 ...>
specifies the name of one or more SAS catalog entries.

Restriction: You must designate the type of the entry, either when you specify the name (*entry-name.entry-type*) or with the ENTRYTYPE= option.

See: "Specifying an Entry Type" on page 320

Optional Argument

ENTRYTYPE=*entry-type*
restricts processing to one entry type.

Alias: ET=

See: "The ENTRYTYPE= Option" on page 322

"Specifying an Entry Type" on page 320

MODIFY Statement

Changes the description of a catalog entry.

Example: "Example 2: Displaying Contents, Changing Names, and Changing a Description" on page 329

Syntax

MODIFY *entry* (DESCRIPTION=<<'>*entry-description*<'>>)
</ ENTRYTYPE=*entry-type*>;

Required Arguments

entry
specifies the name of one SAS catalog entry. You can specify the entry type with the name (*entry-name.entry-type*).

Restriction: You must designate the type of the entry, either when you specify the name (*entry-name.entry-type*) or with the ENTRYTYPE= option.

See: "Specifying an Entry Type" on page 320

DESCRIPTION=<<'>*entry-description*<'>>
changes the description of a catalog entry by replacing it with a new description, up to 256 characters long, or by removing it altogether. You can enclose the description in single or double quotation marks.

Alias: DESC

Tip: When using the MODIFY statement with the CATALOG procedure, use the DESCRIPTION= option with no text to remove the current description.

Optional Argument

ENTRYTYPE=*entry-type*
restricts processing to one entry type.

Alias: ET=

See: "The ENTRYTYPE= Option" on page 322

"Specifying an Entry Type" on page 320

SAVE Statement

Specifies entries not to delete from a SAS catalog.

Restriction: The SAVE statement cannot limit the effects of the KILL option.

Tips: Use the SAVE statement to delete all but a few entries in a catalog. Use the DELETE statement when it is more convenient to specify which entries to delete.

You can specify multiple entries and use multiple SAVE statements.

See: DELETE Statement on page 314

Syntax

SAVE *entry-1 <entry-2 ...>* </ ENTRYTYPE=*entry-type* >;

Required Argument

entry-1 <entry-2...>
specifies the name of one or more SAS catalog entries.

Restriction You must designate the type of the entry, either with the name (*entry-name.entry-type*) or with the ENTRYTYPE= option when using the SAVE statement.

Optional Argument

ENTRYTYPE=*entry-type*
restricts processing to one entry type.

Alias ET=

See "The ENTRYTYPE= Option" on page 322

"Specifying an Entry Type" on page 320

SELECT Statement

Specifies entries that the COPY statement copies.

Restrictions: The SELECT statement requires the COPY statement.
The SELECT statement cannot be used with an EXCLUDE statement.

Tips: You can specify multiple entries in a single SELECT statement.
You can use multiple SELECT statements with a single COPY statement within a RUN group.

See: COPY Statement on page 312 and EXCLUDE Statement on page 315

Example: "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

Syntax

SELECT *entry-1 <entry-2 ...>* </ ENTRYTYPE=*entry-type* >;

Required Argument

entry-1 <entry-2 ...>
specifies the name of one or more SAS catalog entries.

Restriction You must designate the type of the entry, either when you specify the name (*entry-name.entry-type*) or with the ENTRYTYPE= option.

Optional Argument

ENTRYTYPE=*entry-type*
restricts processing to one entry type.

Alias ET=

See "The ENTRYTYPE= Option" on page 322.

"Specifying an Entry Type" on page 320.

Usage: CATALOG Procedure

Interactive Processing with RUN Groups

Definition

The CATALOG procedure is interactive. Once you submit a PROC CATALOG statement, you can continue to submit and execute statements or groups of statements without repeating the PROC CATALOG statement.

A set of procedure statements ending with a RUN statement is called a *RUN group*. The changes specified in a given group of statements take effect when a RUN statement is encountered.

How to End a PROC CATALOG Step

In the DATA step and most SAS procedures, a RUN statement is a step boundary and ends the step. However, a simple RUN statement does not end an interactive procedure. The following list contains ways to terminate a PROC CATALOG step:

- submit a QUIT statement
- submit a RUN statement with the CANCEL option
- submit another DATA or PROC statement
- end your SAS session

Note: When you enter a QUIT, DATA, or PROC statement, any statements following the last RUN group execute before the CATALOG procedure terminates. If

you enter a RUN statement with the CANCEL option, then the remaining statements *do not execute* before the procedure ends.

See "Example 2: Displaying Contents, Changing Names, and Changing a Description" on page 329.

Error Handling and RUN Groups

Error handling is based in part on the division of statements into RUN groups. If a syntax error is encountered, then none of the statements in the current RUN group execute, and execution proceeds to the next RUN group.

For example, the following statements contain a misspelled DELETE statement:

```
proc catalog catalog=misc entrytype=help;
      copy out=drink;
         select coffee tea;
      del juices;        /* INCORRECT!!! */
      exchange glass=plastic;
   run;
      change calstats=nutri;
   run;
quit;
```

Because the DELETE statement is incorrectly specified as DEL, no statements in that RUN group execute, except the PROC CATALOG statement itself. The CHANGE statement does execute because it is in a different RUN group.

Note: Be careful when setting up batch jobs in which one RUN group's statements depend on the effects of a previous RUN group, especially when deleting and renaming entries.

Specifying an Entry Type

Four Ways to Supply an Entry Type

There is no default entry type, so if you do not supply one, then PROC CATALOG generates an error. You can supply an entry type in one of four ways, as shown in the following table:

Table 10.2 *Supplying an Entry Type*

Entry Type	Example
Entry name	`delete test1.program test1.log test2.log;`
ET= in parentheses	`delete test1 (et=program);`
ET= after a slash [1]	`delete test1 (et=program) test1 test2 / et=log;`
ENTRYTYPE= without a slash [2]	`proc catalog catalog=mycat et=log; delete test1 test2;`

1 in a subordinate statement
2 in the PROC CATALOG or the COPY statement

Note: All statements, except the CONTENTS statement, accept the ENTRYTYPE= option.

Advantages of Using the ENTRYTYPE= Option

The ENTRYTYPE= option can save keystrokes when you are processing multiple entries of the same type.

To create a default for entry type for all statements in the current step, use the ENTRYTYPE= option in the PROC CATALOG statement. To set the default for only the current statement, use the ENTRYTYPE= option in a subordinate statement.

You can have many entries of one type and a few of other types. You can use the ENTRYTYPE= option to specify a default and then override that for individual entries with (ENTRYTYPE=) *in parentheses* after those entries.

Avoid a Common Error

You cannot specify the ENTRYTYPE= option in both the PROC CATALOG statement and a subordinate statement. For example, these statements generate an error and do not delete any entries because the ENTRYTYPE= option specifications contradict each other:

```
   /* THIS IS INCORRECT CODE. */
proc catalog cat=sample et=help;
   delete a b c / et=program;
run;
quit;
```

The ENTRYTYPE= Option

The ENTRYTYPE= option is available in every statement in the CATALOG procedure except the CONTENTS statement.

ENTRYTYPE=*entry-type*
not in parentheses, sets a default entry type for the entire PROC step when used in the PROC CATALOG statement. In all other statements, this option sets a default entry type for the current statement. If you omit the ENTRYTYPE= option, then PROC CATALOG processes all entries in the catalog.

Alias ET=

Default PROC CATALOG processes all entries in the catalog.

Interactions If you specify the ENTRYTYPE= option in the PROC CATALOG statement, then you do not specify either ENTRYTYPE= or (ENTRYTYPE=) in a subordinate statement.

(ENTRYTYPE=) in parentheses immediately following an entry name overrides the ENTRYTYPE= option in that same statement.

Tips On all statements except the PROC CATALOG and COPY statements, the ENTRYTYPE= option follows a slash.

To process multiple entry types in a single PROC CATALOG step, use the ENTRYTYPE= option in a subordinate statement, not in the PROC CATALOG statement.

See "Specifying an Entry Type" on page 320 and "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325

(ENTRYTYPE=*entry-type*)
in parentheses, identifies the type of the entry just preceding it.

Alias (ET=)

Restriction An (ENTRYTYPE=) option immediately following an entry name in a subordinate statement cannot override an ENTRYTYPE= option in the PROC CATALOG statement. It generates a syntax error.

Interaction The (ENTRYTYPE=) option immediately following an entry name overrides the ENTRYTYPE= option in that same statement.

Tips This form is useful mainly for specifying exceptions to an ENTRYTYPE= option that is used in a subordinate statement. The following statement deletes A.Help, B.Format, and C.Help:

```
delete a b (et=format) c / et=help;
```

For the CHANGE and EXCHANGE statements, specify the (ENTRYTYPE=) option in parentheses only once for each pair of names following the second name in the pair. Here is an example:

```
change old1=new1 (et=log)
       old1=new2 (et=help);
```

See "Specifying an Entry Type" on page 320, "Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs" on page 325 and "Example 2: Displaying Contents, Changing Names, and Changing a Description" on page 329

Catalog Concatenation

About Catalog Concatenation

There are two types of CATALOG concatenation. The first type is specified by the LIBNAME statement and the second type is specified by the global CATNAME statement. All statements and options that can be used on single (unconcatenated) catalogs can be used on catalog concatenations.

Restrictions

When you use the CATALOG procedure to copy concatenated catalogs and you use the NEW option, the following rules apply:

- If the input catalog is a concatenation and if the output catalog exists in any level of the input concatenation, then the copy is not allowed.
- If the output catalog is a concatenation and if the input catalog exists in the first level of the output concatenation, then the copy is not allowed.

For example, the following code demonstrates these two rules, and the copy fails:

```
libname first 'SAS-library-1';
libname second 'SAS-library-2';
   /* create concat.x */
libname concat (first second);

   /* fails rule #1 */
proc catalog c=concat.x;
   copy out=first.x new;
run;
quit;

   /* fails rule #2 */
proc catalog c=first.x;
```

```
   copy out=concat.x new;
run;
quit;
```

In summary, the following table shows when copies are allowed. In the table, A and B are libraries, and each contains catalog X. Catalog C is an automatic concatenation of A and B, and catalog D is an automatic concatenation of B and A.

Table 10.3 *Allowing Copies*

Input Catalog	Output Catalog	Copy Allowed?
C.X	B.X	No
C.X	D.X	No
D.X	C.X	No
A.X	A.X	No
A.X	B.X	Yes
B.X	A.X	Yes
C.X	A.X	No
B.X	C.X	Yes
A.X	C.X	No

Results: CATALOG Procedure

Results: CATALOG Procedure

The CATALOG procedure produces output when the CONTENTS statement is executed without options. The procedure output is assigned a name. You can use this name to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. For more information, see "ODS Table Names Produced by Base SAS Procedures" in *SAS Output Delivery System: Procedures Guide*.

Table 10.4 *ODS Tables Produced by the CATALOG Procedure*

Table Name	Type of Library
Catalog_Random	When the catalog is in a random-access library
Catalog_Sequential	When the catalog is in a sequential library

Examples: CATALOG Procedure

Example 1: Copying, Deleting, and Moving Catalog Entries from Multiple Catalogs

Features: PROC CATALOG statement options
CAT=
COPY statement
DELETE statement

Details

This example demonstrates the following tasks:

- copies entries by excluding a few entries
- copies entries by specifying a few entries
- protects entries from being edited
- moves entries
- deletes entries
- processes entries from multiple catalogs
- processes entries in multiple run groups

The SAS catalog Perm.Sample contains the following entries:

```
DEFAULT     FORM        Default form for printing
FSLETTER    FORM        Standard form for letters (HP Laserjet)
LOAN        FRAME       Loan analysis application
LOAN        HELP        Information about the application
```

```
BUILD       KEYS        Function Key Definitions
LOAN        KEYS        Custom key definitions for application
CREDIT      LOG         credit application log
TEST1       LOG         Inventory program
TEST2       LOG         Inventory program
TEST3       LOG         Inventory program
LOAN        PMENU       Custom menu definitions for applicaticm
CREDIT      PROGRAM     credit application pgm
TEST1       PROGRAM     testing budget applic.
TEST2       PROGRAM     testing budget applic.
TEST3       PROGRAM     testing budget applic.
LOAN        SCL         SCL code for loan analysis application
PASSIST     SLIST       User profile
```

The SAS catalog Perm.Formats contains the following entries:

```
REVENUE    FORMAT      FORMAT:MAXLEN=16,16,12
DEPT       FORMATC     FORMAT:MAXLEN=1,1,14
```

Program

```
libname perm 'SAS-library';

proc catalog cat=perm.sample;
   delete credit.program credit.log;
run;

   copy out=tcatall;
run;

   copy out=testcat;
      exclude test1 test2 test3  passist (et=slist) / et=log;
run;

   copy out=logcat move;
      select test1 test2 test3 / et=log;
run;

   copy out=perm.finance noedit;
      select loan.frame loan.help loan.keys loan.pmenu;
run;

   copy in=perm.formats out=perm.finance;
      select revenue.format dept.formatc;
run;
quit;
```

Program Description

Assign a library reference to a SAS library. The LIBNAME statement assigns the libref Perm to the SAS library that contains a permanent SAS catalog.

```
libname perm 'SAS-library';
```

Delete two entries from the Perm.Sample catalog.

```
proc catalog cat=perm.sample;
   delete credit.program credit.log;
run;
```

Copy all entries in the Perm.Sample catalog to the Work.TCatAll catalog.

```
   copy out=tcatall;
run;
```

Copy everything except three LOG entries and Passist.Slist from Perm.Sample to Work.TestCat. The EXCLUDE statement specifies which entries not to copy. ET= specifies a default type. (ET=) specifies an exception to the default type.

```
   copy out=testcat;
      exclude test1 test2 test3  passist (et=slist) / et=log;
run;
```

Move three LOG entries from Perm.Sample to Work.LogCat. The SELECT statement specifies which entries to move. ET= restricts processing to LOG entries.

```
   copy out=logcat move;
      select test1 test2 test3 / et=log;
run;
```

Copy four SAS/AF software entries from Perm.Sample to Perm.Finance. The NOEDIT option protects these entries in Perm.Finance from further editing with PROC BUILD.

```
   copy out=perm.finance noedit;
      select loan.frame loan.help loan.keys loan.pmenu;
run;
```

Copy two formats from Perm.Formats to Perm.Finance. The IN= option enables you to copy from a different catalog than the one specified in the PROC CATALOG statement. Note the entry types for numeric and character formats: REVENUE.FORMAT is a numeric format and DEPT.FORMATC is a character format. The COPY and SELECT statements execute before the QUIT statement ends the PROC CATALOG step.

```
   copy in=perm.formats out=perm.finance;
      select revenue.format dept.formatc;
run;
quit;
```

The SAS Log

Example Code 10.1 *Copying, Protecting, Removing, Deleting, and Processing Entries Using PROC CATALOG*

```
1    libname perm 'SAS-library';
NOTE: Libref PERM was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library\perm
2    proc catalog cat=perm.sample;
NOTE: Writing HTML Body file: sashtml.htm
3       delete credit.program credit.log;
4    run;

NOTE: Deleting entry CREDIT.PROGRAM in catalog PERM.SAMPLE.
NOTE: Deleting entry CREDIT.LOG in catalog PERM.SAMPLE.
5       copy out=tcatall;
6    run;

NOTE: Copying entry DEFAULT.FORM from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry FSLETTER.FORM from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry LOAN.FRAME from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry LOAN.HELP from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry BUILD.KEYS from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry LOAN.KEYS from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry TEST1.LOG from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry TEST2.LOG from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry TEST3.LOG from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry LOAN.PMENU from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry TEST1.PROGRAM from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry TEST2.PROGRAM from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry TEST3.PROGRAM from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry LOAN.SCL from catalog PERM.SAMPLE to catalog WORK.TCATALL.
NOTE: Copying entry PASSIST.SLIST from catalog PERM.SAMPLE to catalog WORK.TCATALL.
7       copy out=testcat;
8          exclude test1 test2 test3  passist (et=slist) / et=log;
9    run;

NOTE: Copying entry DEFAULT.FORM from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry FSLETTER.FORM from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry LOAN.FRAME from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry LOAN.HELP from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry BUILD.KEYS from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry LOAN.KEYS from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry LOAN.PMENU from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry TEST1.PROGRAM from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry TEST2.PROGRAM from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry TEST3.PROGRAM from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
NOTE: Copying entry LOAN.SCL from catalog PERM.SAMPLE to catalog WORK.TESTCAT.
10      copy out=logcat move;
11         select test1 test2 test3 / et=log;
12   run;

NOTE: Moving entry TEST1.LOG from catalog PERM.SAMPLE to catalog WORK.LOGCAT.
NOTE: Moving entry TEST2.LOG from catalog PERM.SAMPLE to catalog WORK.LOGCAT.
NOTE: Moving entry TEST3.LOG from catalog PERM.SAMPLE to catalog WORK.LOGCAT.
13      copy out=perm.finance noedit;
14         select loan.frame loan.help loan.keys loan.pmenu;
15   run;
```

```
NOTE: Copying entry LOAN.FRAME from catalog PERM.SAMPLE to catalog PERM.FINANCE.
NOTE: Copying entry LOAN.HELP from catalog PERM.SAMPLE to catalog PERM.FINANCE.
NOTE: Copying entry LOAN.KEYS from catalog PERM.SAMPLE to catalog PERM.FINANCE.
NOTE: Copying entry LOAN.PMENU from catalog PERM.SAMPLE to catalog PERM.FINANCE.
16      copy in=perm.formats out=perm.finance;
17         select revenue.format dept.formatc;
18   quit;

NOTE: Copying entry REVENUE.FORMAT from catalog PERM.FORMATS to catalog PERM.FINANCE.
NOTE: Copying entry DEPT.FORMATC from catalog PERM.FORMATS to catalog PERM.FINANCE.
```

Example 2: Displaying Contents, Changing Names, and Changing a Description

Features: PROC CATALOG statement options
- CATALOGS=
- CHANGE statement
- CONTENTS statement
- MODIFY statement

TITLE statement

Details

This example demonstrates the following tasks:

- lists the entries in a catalog and routes the output to a file
- changes entry names
- changes entry descriptions
- processes entries in multiple run groups

Program

```
libname perm 'SAS-library';

proc catalog catalog=perm.finance;
   contents;
title1 'Contents of PERM.FINANCE before changes are made';
run;

   change dept=deptcode (et=formatc);
run;

   modify loan.frame (description='Loan analysis app. - ver1');
   contents;
```

```
title1 'Contents of PERM.FINANCE after changes are made';
run;

quit;
```

Program Description

Assign a library reference. The LIBNAME statement assigns a libref to the SAS library that contains a permanent SAS catalog.

```
libname perm 'SAS-library';
```

List the entries in a catalog and route the output to a file. The CONTENTS statement creates a listing of the contents of the SAS catalog Perm.Finance and routes the output to a file.

```
proc catalog catalog=perm.finance;
   contents;
title1 'Contents of PERM.FINANCE before changes are made';
run;
```

Change entry names. The CHANGE statement changes the name of an entry that contains a user-written character format. (ET=) specifies the entry type.

```
   change dept=deptcode (et=formatc);
run;
```

Process entries in multiple run groups. The MODIFY statement changes the description of an entry. The CONTENTS statement creates a listing of the contents of Perm.Finance after all the changes have been applied. QUIT ends the procedure.

```
   modify loan.frame (description='Loan analysis app. - ver1');
   contents;
title1 'Contents of PERM.FINANCE after changes are made';
run;

quit;
```

Output Examples

Output 10.1 *Contents of Perm.Finance before and After Changes Are Made*

Contents of PERM.FINANCE before changes are made

Contents of Catalog PERM.FINANCE					
#	Name	Type	Create Date	Modified Date	Description
1	REVENUE	FORMAT	10/16/1996 13:48:11	10/16/1996 13:48:11	FORMAT:MAXLEN=16,16,12
2	DEPTCODE	FORMATC	10/30/1996 13:40:42	10/30/1996 13:40:42	FORMAT:MAXLEN=1,1,14
3	LOAN	FRAME	10/30/1996 13:40:43	02/18/2014 13:31:25	Loan analysis app. - ver1
4	LOAN	HELP	10/16/1996 13:48:10	10/16/1996 13:48:10	Information about the application
5	LOAN	KEYS	10/16/1996 13:48:10	10/16/1996 13:48:10	Custom key definitions for application
6	LOAN	PMENU	10/16/1996 13:48:10	10/16/1996 13:48:10	Custom menu definitions for application
7	LOAN	SCL	10/16/1996 13:48:10	10/16/1996 13:48:10	SCL code for loan analysis application

Contents of PERM.FINANCE after changes are made

Contents of Catalog PERM.FINANCE					
#	Name	Type	Create Date	Modified Date	Description
1	REVENUE	FORMAT	10/16/1996 13:48:11	10/16/1996 13:48:11	FORMAT:MAXLEN=16,16,12
2	DEPTCODE	FORMATC	10/30/1996 13:40:42	10/30/1996 13:40:42	FORMAT:MAXLEN=1,1,14
3	LOAN	FRAME	10/30/1996 13:40:43	03/28/2014 10:26:50	Loan analysis app. - ver1
4	LOAN	HELP	10/16/1996 13:48:10	10/16/1996 13:48:10	Information about the application
5	LOAN	KEYS	10/16/1996 13:48:10	10/16/1996 13:48:10	Custom key definitions for application
6	LOAN	PMENU	10/16/1996 13:48:10	10/16/1996 13:48:10	Custom menu definitions for application
7	LOAN	SCL	10/16/1996 13:48:10	10/16/1996 13:48:10	SCL code for loan analysis application

Example 3: Using the FORCE Option with the KILL Option

Features:

PROC CATALOG statement options
- CATALOG=
- FORCE
- KILL

%MACRO statement

%MEND statement

%PUT statement

Details

This example demonstrates the following tasks:

- creates a resource environment
- tries to delete all catalog entries by using the KILL option but receives an error
- specifies the FORCE option to successfully delete all catalog entries by using the KILL option.

Program

```
 %macro matt;
    %put &syscc;
%mend matt;

proc catalog c=work.sasmacr kill;
run;
quit;

proc catalog c=work.sasmacr kill force;
run;
quit;
```

Program Description

Start a process (resource environment). Do this by opening the catalog entry MATT in the Work.Sasmacr catalog.

```
 %macro matt;
    %put &syscc;
%mend matt;
```

Specify the KILL option to delete all catalog entries in Work.SasMacr. Since there is a resource environment (process using the catalog), KILL does not work and an error is sent to the log.

```
proc catalog c=work.sasmacr kill;
run;
quit;
```

Specify the FORCE option to the KILL option to delete the catalog entries.

```
proc catalog c=work.sasmacr kill force;
run;
quit;
```

Log Examples

Example Code 10.2 *KILL Option Causes Error to Be Sent to the SAS Log*

```
1     %macro matt;
2       %put &syscc;
3       %mend matt;
4
5    proc catalog c=work.sasmacr kill;
NOTE: Writing HTML Body file: sashtml.htm
6    run;

ERROR: You cannot open WORK.SASMACR.CATALOG for update access because
WORK.SASMACR.CATALOG is in
use by you in resource environment _O_TAGS.
WARNING: Command CATALOG not processed because of errors noted above.
7    quit;

NOTE: The SAS System stopped processing this step because of errors.
NOTE: PROCEDURE CATALOG used (Total process time):
      real time           6.46 seconds
      cpu time            0.62 seconds
```

Example Code 10.3 *Adding the FORCE Option to the KILL Option to Delete the Catalog Entry*

```
8    proc catalog c=work.sasmacr kill force;
9    run;

NOTE: Deleting entry MATT.MACRO in catalog WORK.SASMACR.
10   quit;

NOTE: PROCEDURE CATALOG used (Total process time):
      real time           0.01 seconds
      cpu time            0.01 seconds
```

11

CHART Procedure

Overview: CHART Procedure

What Does the CHART Procedure Do?

The CHART procedure produces vertical and horizontal bar charts, block charts, pie charts, and star charts. These types of charts graphically display values of a variable or a statistic associated with those values. The charted variable can be numeric or character.

PROC CHART is a useful tool that lets you visualize data quickly, but if you need to produce presentation-quality graphics that include color and various fonts, then use SAS/GRAPH software. The GCHART procedure in SAS/GRAPH software produces the same types of charts as PROC CHART does. In addition, PROC GCHART can produce donut charts.

What Types of Charts Can PROC CHART Create?

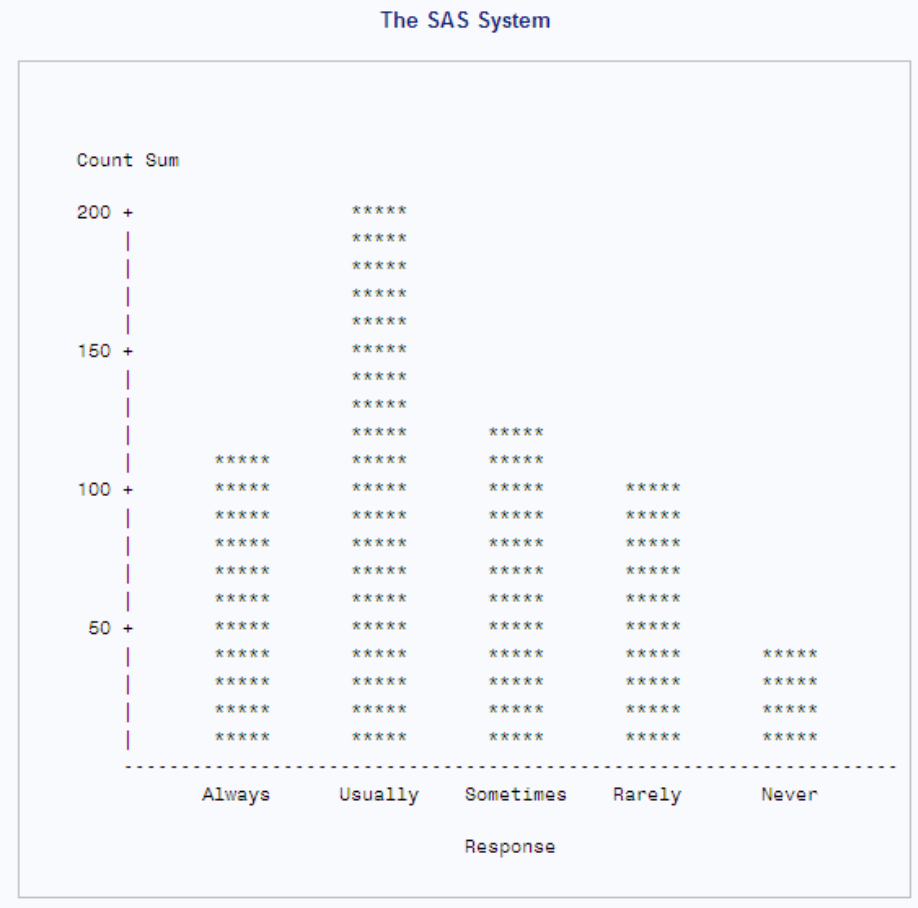
Bar Charts

Horizontal and vertical bar charts display the magnitude of data with bars, each of which represents a category of data. The length or height of the bars represents the value of the chart statistic for each category.

The following output shows a vertical bar chart that displays the number of responses for the five categories from the survey data. The following statements produce the output:

```
proc chart data=survey;
   vbar response / sumvar=count
   axis=0 to 200 by 50
   midpoints='Always' 'Usually'
             'Sometimes' 'Rarely' 'Never';
run;
```

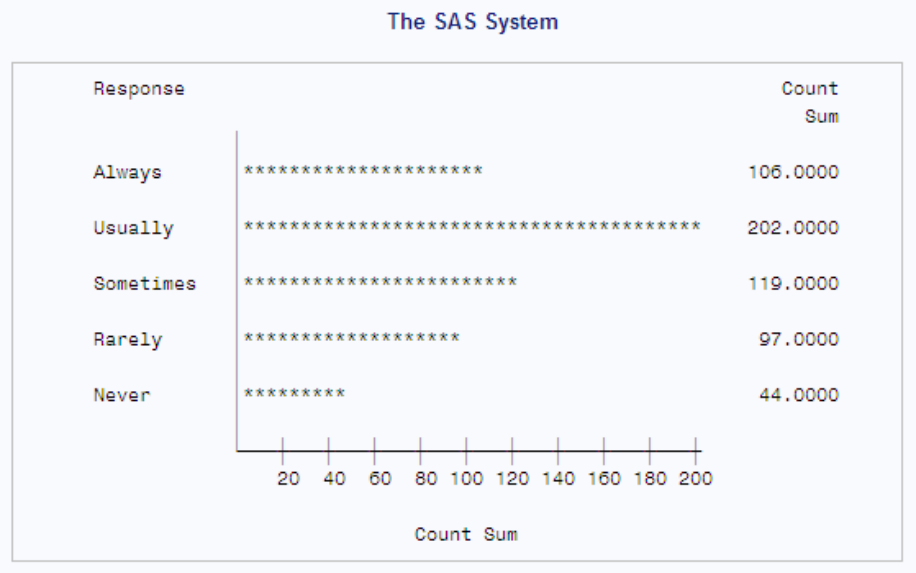
Output 11.1 *Vertical Bar Chart*



The following output shows the same data presented in a horizontal bar chart. The two types of bar charts have essentially the same characteristics, except that horizontal bar charts by default display a table of statistic values to the right of the bars. The following statements produce the output:

```
proc chart data=survey;
   hbar response / sumvar=count
        midpoints='Always' 'Usually'
           'Sometimes' 'Rarely' 'Never';
run;
```

Output 11.2 *Horizontal Bar Chart*

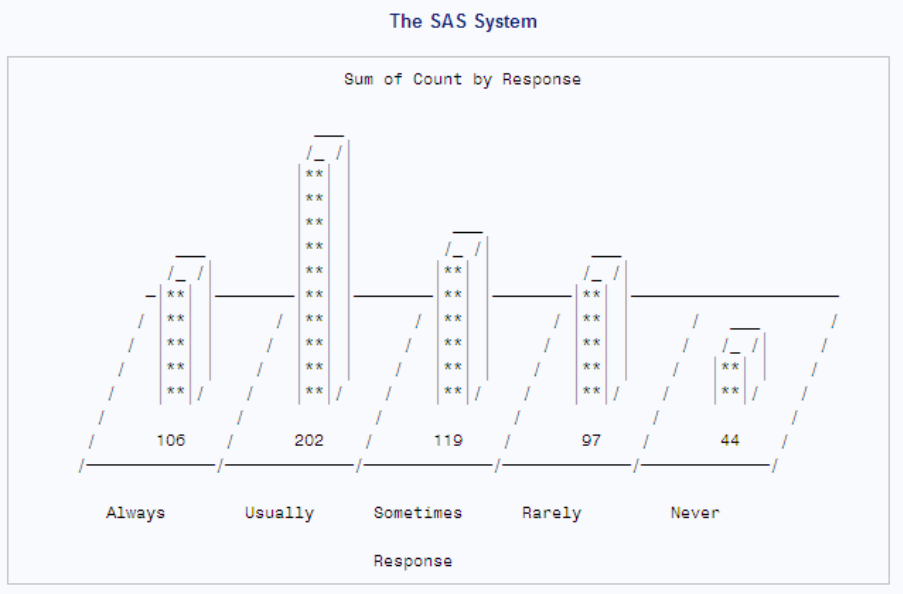


Block Charts

Block charts display the relative magnitude of data by using blocks of varying height, each set in a square that represents a category of data. The following output shows the number of each survey response in the form of a block chart.

```
proc chart data=survey;
    block response / sumvar=count
    midpoints='Always' 'Usually'
              'Sometimes' 'Rarely' 'Never';
run;
```

Output 11.3 *Block Chart*

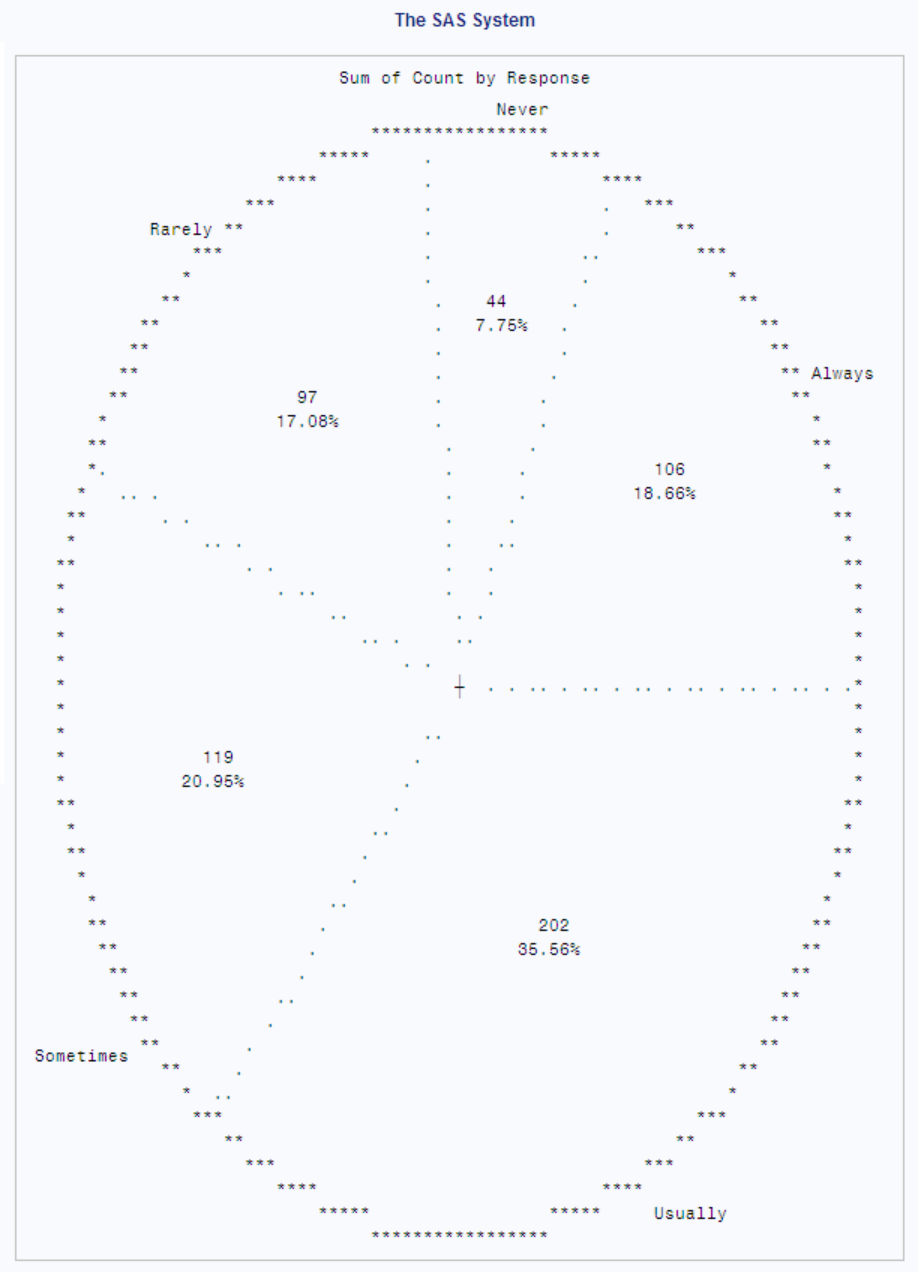


Pie Charts

Pie charts represent the relative contribution of parts to the whole by displaying data as wedge-shaped slices of a circle. Each slice represents a category of the data. The following output shows the survey results divided by response into five pie slices. The following statements produce the output:

```
proc chart data=survey;
   pie response / sumvar=count;
run;
```

Output 11.4 *Pie Chart*



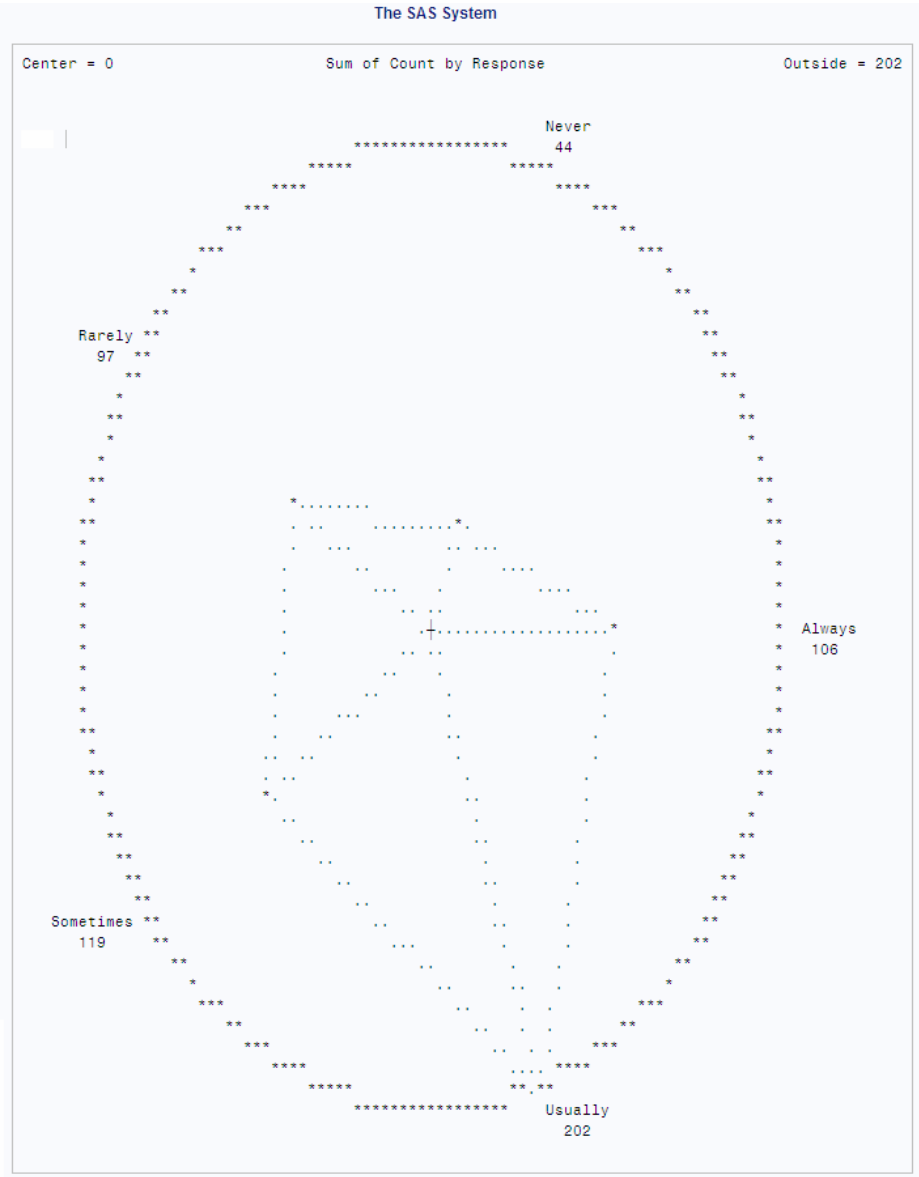
Star Charts

With PROC CHART, you can produce star charts that show group frequencies, totals, or mean values. A star chart is similar to a vertical bar chart, but the bars on a star chart radiate from a center point, like spokes in a wheel. Star charts are commonly used for cyclical data, such as measures taken every month or day or hour. They are also used for data in which the categories have an inherent order ("always" meaning more frequent than "usually," which means more frequent than

"sometimes"). The following output shows the survey data displayed in a star chart. The following statements produce the output:

```
proc chart data=survey;
   star response / sumvar=count;
run;
```

Output 11.5 *Star Chart*



Concepts: CHART Procedure

Concepts: CHART Procedure

Here are characteristics for the CHART procedure:

- Character variables and formats cannot exceed a length of 16.
- For continuous numeric variables, PROC CHART automatically selects display intervals, although you can define interval midpoints.
- For character variables and discrete numeric variables, which contain several distinct values rather than a continuous range, the data values themselves define the intervals.

Syntax: CHART Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Requirement: You must use at least one of the chart-producing statements.

Tips: You can use the ATTRIB, FORMAT, LABEL, and WHERE statements. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

You can also use any global statement. For a list, see "Global Statements" on page 25 and "Dictionary of SAS Global Statements" in *SAS Global Statements: Reference*.

PROC CHART <*options*>;

BLOCK *variable(s)* </ *options*>;

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

HBAR *variable(s)* </ *options*>;

PIE *variable(s)* </ *options*>;

STAR *variable(s)* </ *options*>;

VBAR *variable(s)* </ *options*>;

Statement	Task	Example
PROC CHART	Produce a chart	
BLOCK	Produce a block chart	Ex. 6
BY	Produce a separate chart for each BY group	Ex. 6
HBAR	Produce a horizontal bar chart	Ex. 5
PIE	Produce a PIE chart	
STAR	Produce a STAR chart	
VBAR	Produce a vertical bar chart	Ex. 1, Ex. 2, Ex. 3, Ex. 4

PROC CHART Statement

Produces vertical and horizontal bar charts, block charts, pie charts, and star charts.

Syntax

PROC CHART <*options*>;

Optional Arguments

DATA=*SAS-data-set*
identifies the input SAS data set.

Restriction You cannot use PROC CHART with an engine that supports concurrent access if another user is updating the data set at the same time.

See "Input Data Sets" on page 26

FORMCHAR <(*position(s)*)>='*formatting-character(s)*'
defines the characters to use for constructing the horizontal and vertical axes, reference lines, and other structural parts of a chart. It also defines the symbols to use to create the bars, blocks, or sections in the output.

position(s)
identifies the position of one or more characters in the SAS formatting-character string. A space or a comma separates the positions.

Default Omitting (*position(s)*), is the same as specifying all 20 possible SAS formatting characters, in order.

Note PROC CHART uses 6 of the 20 formatting characters that SAS provides. Table 11.24 on page 344 shows the formatting characters that PROC CHART uses. Figure 11.13 on page 345 illustrates the use of formatting characters commonly used in PROC CHART.

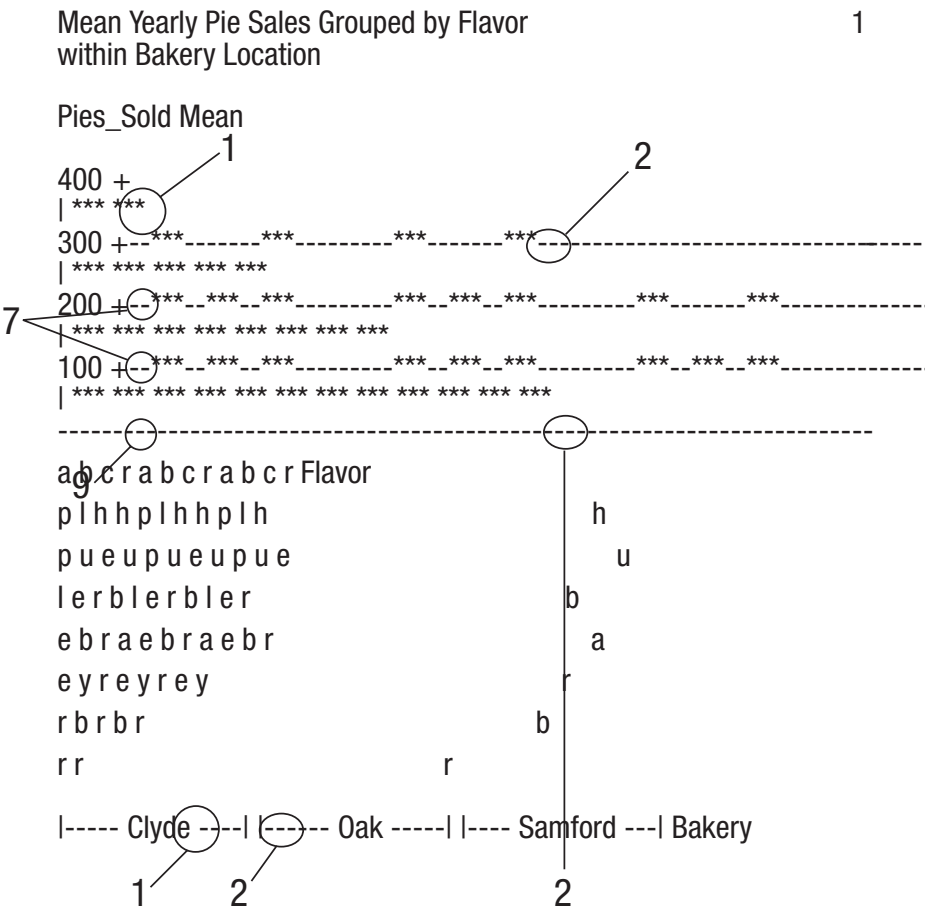
formatting-character(s)
lists the characters to use for the specified positions. PROC CHART assigns characters in *formatting-character(s)* to *position(s)*, in the order which they are listed. For example, the following option assigns the asterisk (*) to the second formatting character, the number sign (#) to the seventh character, and does not alter the remaining characters:

```
formchar(2,7)='*#'
```

Table 11.1 *Formatting Characters Used by PROC CHART*

Position	Default	Used to Draw
1	|	Vertical axes in bar charts, the sides of the blocks in block charts, and reference lines in horizontal bar charts. In side-by-side bar charts, the first and second formatting characters appear around each value of the group variable (below the chart) to indicate the width of each group.
2	-	Horizontal axes in bar charts, the horizontal lines that separate the blocks in a block chart, and reference lines in vertical bar charts. In side-by-side bar charts, the first and second formatting characters appear around each value of the group variable (below the chart) to indicate the width of each group.
7	+	Tick marks in bar charts and the centers in pie and star charts.
9	-	Intersection of axes in bar charts.
16	/	Ends of blocks and the diagonal lines that separate blocks in a block chart.
20	*	Circles in pie and star charts.

Figure 11.1 *Formatting Characters Commonly Used in PROC CHART Output*



Interaction The SAS system option FORMCHAR= specifies the default formatting characters. The system option defines the entire string of formatting characters. The FORMCHAR= option in a procedure can redefine selected characters.

Tip You can use any character in *formatting-characters*, including hexadecimal characters. If you use hexadecimal characters, then you must put an x after the closing quotation mark. For example, the following option assigns the hexadecimal character 2-D to the second formatting character, the hexadecimal character 7C to the seventh character, and does not alter the remaining characters:

```
formchar(2,7)='2D7C'x
```

See For information about which hexadecimal codes to use for which characters, consult the documentation for your hardware.

LPI=*value*

specifies the proportions of PIE and STAR charts. The *value* is determined by

$$(\text{lines per inch} / \text{columns per inch}) * 10$$

For example, if you have a printer with 8 lines per inch and 12 columns per inch, then specify LPI=6.6667.

Default 6

BLOCK Statement

Produces a block chart.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Example: "Example 6: Producing Block Charts for BY Groups" on page 384

Syntax

BLOCK *variable(s)* </ *options*>;

Required Argument

variable(s)
specifies the variables for which PROC CHART produces a block chart, one chart for each variable.

Optional Arguments

AXIS=*value-expression*
specifies the values for the response axis, where *value-expression* is a list of individual values, each separated by a space, or a range with a uniform interval for the values. For example, the following range specifies tick marks on a bar chart from 0 to 100 at intervals of 10: `hbar x / axis=0 to 100 by 10;`

Restrictions Values must be equally spaced, even if you specify them individually.

For frequency charts, values must be integers.

Interactions For BLOCK charts, AXIS= sets the scale of the tallest block. To set the scale, PROC CHART uses the maximum value from the AXIS= list. If no value is greater than 0, then PROC CHART ignores the AXIS= option.

If you use AXIS= and the BY statement, then PROC CHART produces uniform axes over BY groups.

CAUTION **Values in value-expression override the range of the data.** For example, if the data range is 1 to 10 and you specify a range of 3 to 5, then only the data in the range 3 to 5 appears on the chart. Values out of range produce a warning message in the SAS log.

FREQ=*variable*
specifies a data set variable that represents a frequency count for each observation. Normally, each observation contributes a value of one to the frequency counts. With FREQ=, each observation contributes its value of the FREQ= value.

Restriction If the FREQ= values are not integers, then PROC CHART truncates them.

Interaction If you use SUMVAR=, then PROC CHART multiplies the sums by the FREQ= value.

GROUP=*variable*
produces side-by-side charts, with each chart representing the observations that have a common value for the GROUP= variable. The GROUP= variable can be character or numeric and is assumed to be discrete. For example, the following statement produces a frequency bar chart for men and women in each department:

```
vbar gender / group=dept;
```

Missing values for a GROUP= variable are treated as valid levels.

Examples "Example 4: Producing Side-by-Side Bar Charts" on page 379

"Example 5: Producing a Horizontal Bar Chart for a Subset of the Data" on page 382

"Example 6: Producing Block Charts for BY Groups" on page 384

G100
specifies that the sum of percentages for each group equals 100. By default, PROC CHART uses 100% as the total sum. For example, if you produce a bar chart that separates males and females into three age categories, then the six bars, by default, add to 100%. However, with G100, the three bars for females add to 100%, and the three bars for males add to 100%.

Interaction PROC CHART ignores G100 if you omit GROUP=.

LEVELS=*number-of-midpoints*
specifies the number of bars that represent each chart variable when the variables are continuous.

MIDPOINTS=*midpoint-specification* | OLD
defines the range of values that each bar, block, or section represents by specifying the range midpoints.

The value for MIDPOINTS= is one of the following:

midpoint-specification
specifies midpoints, either individually, or across a range at a uniform interval. For example, the following statement produces a chart with five bars. The first bar represents the range of values of X with a midpoint of 10. The second bar represents the range with a midpoint of 20, and so on:

```
vbar x / midpoints=10 20 30 40 50;
```

Here is an example of a midpoint specification for a character variable:

```
vbar x / midpoints='JAN' 'FEB' 'MAR';
```

Here is an example of specifying midpoints across a range at a uniform interval:

```
vbar x / midpoints=10 to 100 by 5;
```

OLD
specifies an algorithm that PROC CHART used in previous versions of SAS to choose midpoints for continuous variables. The old algorithm was based on the work of Nelder (1976). The current algorithm that PROC CHART uses if you omit OLD is based on the work of Terrell and Scott (1985).

Default Without MIDPOINTS=, PROC CHART displays the values in the SAS System's normal sorted order.

MISSING
specifies that missing values are valid levels for the chart variable.

NOHEADER
suppresses the default header line printed at the top of a chart.

Alias NOHEADING

Example "Example 6: Producing Block Charts for BY Groups" on page 384

NOSYMBOL
suppresses printing of the subgroup symbol or legend table.

Alias NOLEGEND

Interaction PROC CHART ignores NOSYMBOL if you omit SUBGROUP=.

SUBGROUP=*variable*
subdivides each bar or block into characters that show the contribution of the values of *variable* to that bar or block. PROC CHART uses the first character of each value to fill in the portion of the bar or block that corresponds to that value, unless more than one value begins with the same first character. In that case, PROC CHART uses the letters A, B, C, and so on, to fill in the bars or blocks. If the variable is formatted, then PROC CHART uses the first character of the formatted value.

The characters used in the chart and the values that they represent are given in a legend at the bottom of the chart. The subgroup symbols are ordered A through Z and 0 through 9 with the characters in ascending order.

PROC CHART calculates the height of a bar or block for each subgroup individually and then rounds the percentage of the total bar up or down. So the total height of the bar can be higher or lower than the same bar without the SUBGROUP= option.

Interaction If you use both TYPE=MEAN and SUBGROUP=, then PROC CHART first calculates the mean for each variable that is listed in the SUMVAR= option. It then subdivides the bar into the percentages that each subgroup contributes.

Example “Example 3: Subdividing the Bars into Categories” on page 376

SUMVAR=*variable*
specifies the variable for which either values or means (depending on the value of TYPE=) PROC CHART displays in the chart.

Interaction If you use SUMVAR= and you use TYPE= with a value other than MEAN or SUM, then TYPE=SUM overrides the specified TYPE= value.

Tip Both HBAR and VBAR charts can print labels for SUMVAR= variables if you use a LABEL statement.

Examples “Example 3: Subdividing the Bars into Categories” on page 376

“Example 4: Producing Side-by-Side Bar Charts” on page 379

“Example 5: Producing a Horizontal Bar Chart for a Subset of the Data” on page 382

“Example 6: Producing Block Charts for BY Groups” on page 384

SYMBOL=*character(s)*
specifies the character or characters that PROC CHART uses in the bars or blocks of the chart when you do not use the SUBGROUP= option.

Default asterisk (*)

Interaction If the SAS system option OVP is in effect and if your printing device supports overprinting, then you can specify up to three characters to produce overprinted charts.

Example “Example 6: Producing Block Charts for BY Groups” on page 384

TYPE=*statistic*
specifies what the bars or sections in the chart represent. The *statistic* is one of the following:

CFREQ
specifies that each bar, block, or section represent the cumulative frequency.

CPERCENT
specifies that each bar, block, or section represent the cumulative percentage.

Alias CPCT

FREQ
specifies that each bar, block, or section represent the frequency with which a value or range occurs for the chart variable in the data.

MEAN
specifies that each bar, block, or section represent the mean of the SUMVAR= variable across all observations that belong to that bar, block, or section.

Interaction With TYPE=MEAN, you can compute only MEAN and FREQ statistics.

Example "Example 4: Producing Side-by-Side Bar Charts" on page 379

PERCENT
specifies that each bar, block, or section represent the percentage of observations that have a given value or that fall into a given range of the chart variable.

Alias PCT

Example "Example 2: Producing a Percentage Bar Chart" on page 373

SUM
specifies that each bar, block, or section represent the sum of the SUMVAR= variable for the observations that correspond to each bar, block, or section.

Default FREQ (unless you use SUMVAR=, which causes a default of SUM)

Interaction With TYPE=SUM, you can compute only SUM and FREQ statistics.

Details

Statement Results

Because each block chart must fit on one output page, you might have to adjust the SAS system options LINESIZE= and PAGESIZE= if you have a large number of charted values for the BLOCK variable and for the variable specified in the GROUP= option.

The following table shows the maximum number of charted values of BLOCK variables for selected LINESIZE= (LS=) specifications that can fit on a 66-line page.

Table 11.2 *Maximum Number of Bars of BLOCK Variables*

GROUP= Value	LS= 132	LS= 120	LS= 105	LS= 90	LS= 76	LS= 64
0,1	9	8	7	6	5	4
2	8	8	7	6	5	4
3	8	7	6	5	4	3
4	7	7	6	5	4	3
5,6	7	6	5	4	3	2

If the value of any GROUP= level is longer than three characters, then the maximum number of charted values for the BLOCK variable that can fit might be reduced by one. BLOCK level values truncate to 12 characters. If you exceed these limits, then PROC CHART produces a horizontal bar chart instead.

BY Statement

Produces a separate chart for each BY group.

See: "BY" on page 74

Example: "Example 6: Producing Block Charts for BY Groups" on page 384

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then the observations in the data set must either be sorted by all the variables that you specify, or they must be indexed appropriately. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The observations are grouped in another way (for example, chronological order).

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

HBAR Statement

Produces a horizontal bar chart.

Tip: HBAR charts can print either the name or the label of the chart variable.

See: "Example 5: Producing a Horizontal Bar Chart for a Subset of the Data" on page 382

Syntax

HBAR *variable(s)* </ *options*>;

Required Argument

variable(s)
specifies the variables for which PROC CHART produces a horizontal bar chart, one chart for each variable.

Optional Arguments

ASCENDING
prints the bars and any associated statistics in ascending order of size within groups.

Alias ASC

AXIS=*value-expression*
specifies the values for the response axis, where *value-expression* is a list of individual values, each separated by a space, or a range with a uniform interval for the values. For example, the following range specifies tick marks on a bar chart from 0 to 100 at intervals of 10: `hbar x / axis=0 to 100 by 10;`

Restrictions Values must be equally spaced, even if you specify them individually.

For frequency charts, values must be integers.

Interactions For HBAR and VBAR charts, AXIS= determines tick marks on the response axis. If the AXIS= specification contains only one value, then the value determines the minimum tick mark if the value is less than 0, or determines the maximum tick mark if the value is greater than 0.

If you use AXIS= and the BY statement, then PROC CHART produces uniform axes over BY groups.

CAUTION **Values in value-expression override the range of the data.** For example, if the data range is 1 to 10 and you specify a range of 3 to 5, then

only the data in the range 3 to 5 appears on the chart. Values out of range produce a warning message in the SAS log.

CFREQ
prints the cumulative frequency.

Restriction Available only in the HBAR statement

CPERCENT
prints the cumulative percentages.

Restriction Available only in the HBAR statement

DISCRETE
specifies that a numeric chart variable is discrete rather than continuous. Without DISCRETE, PROC CHART assumes that all numeric variables are continuous and automatically chooses intervals for them unless you use MIDPOINTS= or LEVELS=.

FREQ
prints the frequency of each bar to the side of the chart.

Restriction Available only in the HBAR statement

FREQ=*variable*
specifies a data set variable that represents a frequency count for each observation. Normally, each observation contributes a value of one to the frequency counts. With FREQ=, each observation contributes its value of the FREQ= value.

Restriction If the FREQ= values are not integers, then PROC CHART truncates them.

Interaction If you use SUMVAR=, then PROC CHART multiplies the sums by the FREQ= value.

GROUP=*variable*
produces side-by-side charts, with each chart representing the observations that have a common value for the GROUP= variable. The GROUP= variable can be character or numeric and is assumed to be discrete. For example, the following statement produces a frequency bar chart for men and women in each department:

```
vbar gender / group=dept;
```

Missing values for a GROUP= variable are treated as valid levels.

Examples "Example 4: Producing Side-by-Side Bar Charts" on page 379

"Example 5: Producing a Horizontal Bar Chart for a Subset of the Data" on page 382

"Example 6: Producing Block Charts for BY Groups" on page 384

GSPACE=*n*
specifies the amount of extra space between groups of bars. Use GSPACE=0 to leave no extra space between adjacent groups of bars.

Interaction PROC CHART ignores GSPACE= if you omit GROUP=

G100
specifies that the sum of percentages for each group equals 100. By default, PROC CHART uses 100% as the total sum. For example, if you produce a bar chart that separates males and females into three age categories, then the six bars, by default, add to 100%. However, with G100, the three bars for females add to 100%, and the three bars for males add to 100%.

Interaction PROC CHART ignores G100 if you omit GROUP=.

LEVELS=*number-of-midpoints*
specifies the number of bars that represent each chart variable when the variables are continuous.

MEAN
prints the mean of the observations represented by each bar.

Restrictions Available only when you use SUMVAR= and TYPE=

Not available when TYPE=CFREQ, CPERCENT, FREQ, or PERCENT

MISSING
specifies that missing values are valid levels for the chart variable.

NOSTATS
suppresses the statistics on a horizontal bar chart.

Alias NOSTAT

NOSYMBOL
suppresses printing of the subgroup symbol or legend table.

Alias NOLEGEND

Interaction PROC CHART ignores NOSYMBOL if you omit SUBGROUP=.

NOZEROS
suppresses any bar with zero frequency.

PERCENT
prints the percentages of observations having a given value for the chart variable.

REF=*value(s)*
draws reference lines on the response axis at the specified positions.

Tip The REF= values should correspond to values of the TYPE= statistic.

Example “Example 4: Producing Side-by-Side Bar Charts” on page 379

SPACE=*n*
specifies the amount of space between individual bars.

Tips Use SPACE=0 to leave no space between adjacent bars.

Use the GSPACE= option to specify the amount of space between the bars within each group.

SUBGROUP=*variable*
subdivides each bar or block into characters that show the contribution of the values of *variable* to that bar or block. PROC CHART uses the first character of each value to fill in the portion of the bar or block that corresponds to that value, unless more than one value begins with the same first character. In that case, PROC CHART uses the letters A, B, C, and so on, to fill in the bars or blocks. If the variable is formatted, then PROC CHART uses the first character of the formatted value.

The characters used in the chart and the values that they represent are given in a legend at the bottom of the chart. The subgroup symbols are ordered A through Z and 0 through 9 with the characters in ascending order.

PROC CHART calculates the height of a bar or block for each subgroup individually and then rounds the percentage of the total bar up or down. So the total height of the bar can be higher or lower than the same bar without the SUBGROUP= option.

Interaction If you use both TYPE=MEAN and SUBGROUP=, then PROC CHART first calculates the mean for each variable that is listed in the SUMVAR= option. It then subdivides the bar into the percentages that each subgroup contributes.

Example “Example 3: Subdividing the Bars into Categories” on page 376

SUM
prints the total number of observations that each bar represents.

Restrictions Available only when you use both SUMVAR= and TYPE=

Not available when TYPE=CFREQ, CPERCENT, FREQ, or PERCENT

SUMVAR=*variable*
specifies the variable for which either values or means (depending on the value of TYPE=) PROC CHART displays in the chart.

Interaction If you use SUMVAR= and you use TYPE= with a value other than MEAN or SUM, then TYPE=SUM overrides the specified TYPE= value.

Tip HBAR charts can print labels for SUMVAR= variables if you use a LABEL statement.

Examples “Example 3: Subdividing the Bars into Categories” on page 376

“Example 4: Producing Side-by-Side Bar Charts” on page 379

"Example 5: Producing a Horizontal Bar Chart for a Subset of the Data" on page 382

"Example 6: Producing Block Charts for BY Groups" on page 384

SYMBOL=*character(s)*
specifies the character or characters that PROC CHART uses in the bars or blocks of the chart when you do not use the SUBGROUP= option.

Default asterisk (*)

Interaction If the SAS system option OVP is in effect and if your printing device supports overprinting, then you can specify up to three characters to produce overprinted charts.

Example "Example 6: Producing Block Charts for BY Groups" on page 384

TYPE=*statistic*
specifies what the bars or sections in the chart represent. The *statistic* is one of the following:

CFREQ
specifies that each bar, block, or section represent the cumulative frequency.

CPERCENT
specifies that each bar, block, or section represent the cumulative percentage.

Alias CPCT

FREQ
specifies that each bar, block, or section represent the frequency with which a value or range occurs for the chart variable in the data.

MEAN
specifies that each bar, block, or section represent the mean of the SUMVAR= variable across all observations that belong to that bar, block, or section.

Interaction With TYPE=MEAN, you can compute only MEAN and FREQ statistics.

Example "Example 4: Producing Side-by-Side Bar Charts" on page 379

PERCENT
specifies that each bar, block, or section represent the percentage of observations that have a given value or that fall into a given range of the chart variable.

Alias PCT

Example "Example 2: Producing a Percentage Bar Chart" on page 373

SUM
specifies that each bar, block, or section represent the sum of the SUMVAR= variable for the observations that correspond to each bar, block, or section.

Default	FREQ (unless you use SUMVAR=, which causes a default of SUM)
Interaction	With TYPE=SUM, you can compute only SUM and FREQ statistics.

WIDTH=*n*
specifies the width of the bars on bar charts.

Details

Statement Results

Each chart occupies one or more output pages, depending on the number of bars; each bar occupies one line, by default.

By default, for horizontal bar charts of TYPE=FREQ, CFREQ, PCT, or CPCT, PROC CHART prints the following statistics: frequency, cumulative frequency, percentage, and cumulative percentage. If you use one or more of the statistics options, then PROC CHART prints only the statistics that you request, plus the frequency.

PIE Statement

Produces a pie chart.

Syntax

PIE *variable(s)* </ *options*>;

Required Argument

variable(s)
specifies the variables for which PROC CHART produces a pie chart, one chart for each variable.

Optional Arguments

FREQ=*variable*
specifies a data set variable that represents a frequency count for each observation. Normally, each observation contributes a value of one to the frequency counts. With FREQ=, each observation contributes its value of the FREQ= value.

Restriction If the FREQ= values are not integers, then PROC CHART truncates them.

Interaction If you use SUMVAR=, then PROC CHART multiplies the sums by the FREQ= value.

LEVELS=*number-of-midpoints*
specifies the number of bars that represent each chart variable when the variables are continuous.

MIDPOINTS=*midpoint-specification* | OLD
defines the range of values that each bar, block, or section represents by specifying the range midpoints.

The value for MIDPOINTS= is one of the following:

midpoint-specification
specifies midpoints, either individually, or across a range at a uniform interval. For example, the following statement produces a chart with five bars. The first bar represents the range of values of X with a midpoint of 10. The second bar represents the range with a midpoint of 20, and so on:

```
vbar x / midpoints=10 20 30 40 50;
```

Here is an example of a midpoint specification for a character variable:

```
vbar x / midpoints='JAN' 'FEB' 'MAR';
```

Here is an example of specifying midpoints across a range at a uniform interval:

```
vbar x / midpoints=10 to 100 by 5;
```

OLD
specifies an algorithm that PROC CHART used in previous versions of SAS to choose midpoints for continuous variables. The old algorithm was based on the work of Nelder (1976). The current algorithm that PROC CHART uses if you omit OLD is based on the work of Terrell and Scott (1985).

Default Without MIDPOINTS=, PROC CHART displays the values in the SAS System's normal sorted order.

MISSING
specifies that missing values are valid levels for the chart variable.

NOHEADER
suppresses the default header line printed at the top of a chart.

Alias NOHEADING

Example "Example 6: Producing Block Charts for BY Groups" on page 384

SUMVAR=*variable*
specifies the variable for which either values or means (depending on the value of TYPE=) PROC CHART displays in the chart.

Interaction If you use SUMVAR= and you use TYPE= with a value other than MEAN or SUM, then TYPE=SUM overrides the specified TYPE= value.

Tip Both HBAR and VBAR charts can print labels for SUMVAR= variables if you use a LABEL statement.

Examples "Example 3: Subdividing the Bars into Categories" on page 376

"Example 4: Producing Side-by-Side Bar Charts" on page 379

"Example 5: Producing a Horizontal Bar Chart for a Subset of the Data" on page 382

"Example 6: Producing Block Charts for BY Groups" on page 384

TYPE=*statistic*

specifies what the bars or sections in the chart represent. The *statistic* is one of the following:

CFREQ

specifies that each bar, block, or section represent the cumulative frequency.

CPERCENT

specifies that each bar, block, or section represent the cumulative percentage.

Alias CPCT

FREQ

specifies that each bar, block, or section represent the frequency with which a value or range occurs for the chart variable in the data.

MEAN

specifies that each bar, block, or section represent the mean of the SUMVAR= variable across all observations that belong to that bar, block, or section.

Interaction With TYPE=MEAN, you can compute only MEAN and FREQ statistics.

Example "Example 4: Producing Side-by-Side Bar Charts" on page 379

PERCENT

specifies that each bar, block, or section represent the percentage of observations that have a given value or that fall into a given range of the chart variable.

Alias PCT

Example "Example 2: Producing a Percentage Bar Chart" on page 373

SUM

specifies that each bar, block, or section represent the sum of the SUMVAR= variable for the observations that correspond to each bar, block, or section.

Default	FREQ (unless you use SUMVAR=, which causes a default of SUM)
Interaction	With TYPE=SUM, you can compute only SUM and FREQ statistics.

Details

Statement Results

PROC CHART determines the number of slices for the pie in the same way that it determines the number of bars for vertical bar charts. Any slices of the pie accounting for less than three print positions are grouped together into an "OTHER" category.

The pie's size is determined only by the SAS system options LINESIZE= and PAGESIZE=. By default, the pie looks elliptical if your printer does not print 6 lines per inch and 10 columns per inch. To make a circular pie chart on a printer that does not print 6 lines and 10 columns per inch, use the LPI= option in the PROC CHART statement. See the description of "LPI=*value*" on page 345 for the formula that gives you the proper LPI= value for your printer.

If you try to create a PIE chart for a variable with more than 50 levels, then PROC CHART produces a horizontal bar chart instead.

STAR Statement

Produces a star chart.

Syntax

STAR *variable(s)* </ *options*>;

Required Argument

variable(s)
specifies the variables for which PROC CHART produces a star chart, one chart for each variable.

Optional Arguments

AXIS=*value-expression*
specifies the values for the response axis, where *value-expression* is a list of individual values, each separated by a space, or a range with a uniform interval

for the values. For example, the following range specifies tick marks on a bar chart from 0 to 100 at intervals of 10: `hbar x / axis=0 to 100 by 10;`

Restrictions Values must be equally spaced, even if you specify them individually.

For frequency charts, values must be integers.

Interactions For STAR charts, a single AXIS= value sets the minimum (the center of the chart) if the value is less than zero, or sets the maximum (the outside circle) if the value is greater than zero. If the AXIS= specification contains more than one value, then PROC CHART uses the minimum and maximum values from the list.

If you use AXIS= and the BY statement, then PROC CHART produces uniform axes over BY groups.

CAUTION **Values in value-expression override the range of the data.** For example, if the data range is 1 to 10 and you specify a range of 3 to 5, then only the data in the range 3 to 5 appears on the chart. Values out of range produce a warning message in the SAS log.

FREQ=*variable*

specifies a data set variable that represents a frequency count for each observation. Normally, each observation contributes a value of one to the frequency counts. With FREQ=, each observation contributes its value of the FREQ= value.

Restriction If the FREQ= values are not integers, then PROC CHART truncates them.

Interaction If you use SUMVAR=, then PROC CHART multiplies the sums by the FREQ= value.

LEVELS=*number-of-midpoints*

specifies the number of bars that represent each chart variable when the variables are continuous.

MIDPOINTS=*midpoint-specification* | OLD

defines the range of values that each bar, block, or section represents by specifying the range midpoints.

The value for MIDPOINTS= is one of the following:

midpoint-specification

specifies midpoints, either individually, or across a range at a uniform interval. For example, the following statement produces a chart with five bars. The first bar represents the range of values of X with a midpoint of 10. The second bar represents the range with a midpoint of 20, and so on:

```
vbar x / midpoints=10 20 30 40 50;
```

Here is an example of a midpoint specification for a character variable:

```
vbar x / midpoints='JAN' 'FEB' 'MAR';
```

Here is an example of specifying midpoints across a range at a uniform interval:

```
vbar x / midpoints=10 to 100 by 5;
```

OLD
specifies an algorithm that PROC CHART used in previous versions of SAS to choose midpoints for continuous variables. The old algorithm was based on the work of Nelder (1976). The current algorithm that PROC CHART uses if you omit OLD is based on the work of Terrell and Scott (1985).

Default Without MIDPOINTS=, PROC CHART displays the values in the SAS System's normal sorted order.

MISSING
specifies that missing values are valid levels for the chart variable.

NOHEADER
suppresses the default header line printed at the top of a chart.

Alias NOHEADING

Example "Example 6: Producing Block Charts for BY Groups" on page 384

SUMVAR=*variable*
specifies the variable for which either values or means (depending on the value of TYPE=) PROC CHART displays in the chart.

Interaction If you use SUMVAR= and you use TYPE= with a value other than MEAN or SUM, then TYPE=SUM overrides the specified TYPE= value.

Tip Both HBAR and VBAR charts can print labels for SUMVAR= variables if you use a LABEL statement.

Examples "Example 3: Subdividing the Bars into Categories" on page 376

"Example 4: Producing Side-by-Side Bar Charts" on page 379

"Example 5: Producing a Horizontal Bar Chart for a Subset of the Data" on page 382

"Example 6: Producing Block Charts for BY Groups" on page 384

TYPE=*statistic*
specifies what the bars or sections in the chart represent. The *statistic* is one of the following:

CFREQ
specifies that each bar, block, or section represent the cumulative frequency.

CPERCENT
specifies that each bar, block, or section represent the cumulative percentage.

Alias CPCT

FREQ
specifies that each bar, block, or section represent the frequency with which a value or range occurs for the chart variable in the data.

MEAN
specifies that each bar, block, or section represent the mean of the SUMVAR= variable across all observations that belong to that bar, block, or section.

Interaction With TYPE=MEAN, you can compute only MEAN and FREQ statistics.

Example "Example 4: Producing Side-by-Side Bar Charts" on page 379

PERCENT
specifies that each bar, block, or section represent the percentage of observations that have a given value or that fall into a given range of the chart variable.

Alias PCT

Example "Example 2: Producing a Percentage Bar Chart" on page 373

SUM
specifies that each bar, block, or section represent the sum of the SUMVAR= variable for the observations that correspond to each bar, block, or section.

Default FREQ (unless you use SUMVAR=, which causes a default of SUM)

Interaction With TYPE=SUM, you can compute only SUM and FREQ statistics.

Details

Statement Results

The number of points in the star is determined in the same way as the number of bars for vertical bar charts.

If all the data values are positive, then the center of the star represents zero and the outside circle represents the maximum value. If any data values are negative, then the center represents the minimum. See the description of the AXIS=*value expression* for more information about how to specify maximum and minimum values. For information about how to specify the proportion of the chart, see the description of the "LPI=*value*" on page 345.

If you try to create a star chart for a variable with more than 24 levels, then PROC CHART produces a horizontal bar chart instead.

VBAR Statement

Produces a vertical bar chart.

Examples:
"Example 1: Producing a Simple Frequency Count" on page 371
"Example 2: Producing a Percentage Bar Chart" on page 373
"Example 3: Subdividing the Bars into Categories" on page 376
"Example 4: Producing Side-by-Side Bar Charts" on page 379

Syntax

VBAR *variable(s)* </ *options*>;

Required Argument

variable(s)
specifies the variables for which PROC CHART produces a vertical bar chart, one chart for each variable.

Optional Arguments

ASCENDING
prints the bars and any associated statistics in ascending order of size within groups.

Alias ASC

AXIS=*value-expression*
specifies the values for the response axis, where *value-expression* is a list of individual values, each separated by a space, or a range with a uniform interval for the values. For example, the following range specifies tick marks on a bar chart from 0 to 100 at intervals of 10: `hbar x / axis=0 to 100 by 10;`

Restrictions Values must be equally spaced, even if you specify them individually.

For frequency charts, values must be integers.

Interactions For HBAR and VBAR charts, AXIS= determines tick marks on the response axis. If the AXIS= specification contains only one value, then the value determines the minimum tick mark if the value is less than 0, or determines the maximum tick mark if the value is greater than 0.

If you use AXIS= and the BY statement, then PROC CHART produces uniform axes over BY groups.

CAUTION **Values in value-expression override the range of the data.** For example, if the data range is 1 to 10 and you specify a range of 3 to 5, then only the data in the range 3 to 5 appears on the chart. Values out of range produce a warning message in the SAS log.

DISCRETE
specifies that a numeric chart variable is discrete rather than continuous. Without DISCRETE, PROC CHART assumes that all numeric variables are continuous and automatically chooses intervals for them unless you use MIDPOINTS= or LEVELS=.

FREQ=*variable*
specifies a data set variable that represents a frequency count for each observation. Normally, each observation contributes a value of one to the frequency counts. With FREQ=, each observation contributes its value of the FREQ= value.

Restriction If the FREQ= values are not integers, then PROC CHART truncates them.

Interaction If you use SUMVAR=, then PROC CHART multiplies the sums by the FREQ= value.

GROUP=*variable*
produces side-by-side charts, with each chart representing the observations that have a common value for the GROUP= variable. The GROUP= variable can be character or numeric and is assumed to be discrete. For example, the following statement produces a frequency bar chart for men and women in each department:

```
vbar gender / group=dept;
```

Missing values for a GROUP= variable are treated as valid levels.

Examples "Example 4: Producing Side-by-Side Bar Charts" on page 379

"Example 5: Producing a Horizontal Bar Chart for a Subset of the Data" on page 382

"Example 6: Producing Block Charts for BY Groups" on page 384

GSPACE=*n*
specifies the amount of extra space between groups of bars. Use GSPACE=0 to leave no extra space between adjacent groups of bars.

Interaction PROC CHART ignores GSPACE= if you omit GROUP=

G100
specifies that the sum of percentages for each group equals 100. By default, PROC CHART uses 100% as the total sum. For example, if you produce a bar chart that separates males and females into three age categories, then the six bars, by default, add to 100%. However, with G100, the three bars for females add to 100%, and the three bars for males add to 100%.

Interaction PROC CHART ignores G100 if you omit GROUP=.

LEVELS=*number-of-midpoints*
specifies the number of bars that represent each chart variable when the variables are continuous.

MIDPOINTS=*midpoint-specification* | OLD
defines the range of values that each bar, block, or section represents by specifying the range midpoints.

The value for MIDPOINTS= is one of the following:

midpoint-specification
specifies midpoints, either individually, or across a range at a uniform interval. For example, the following statement produces a chart with five bars; the first bar represents the range of values of X with a midpoint of 10, the second bar represents the range with a midpoint of 20, and so on:

```
vbar x / midpoints=10 20 30 40 50;
```

Here is an example of a midpoint specification for a character variable:

```
vbar x / midpoints='JAN' 'FEB' 'MAR';
```

Here is an example of specifying midpoints across a range at a uniform interval:

```
vbar x / midpoints=10 to 100 by 5;
```

OLD
specifies an algorithm that PROC CHART used in previous versions of SAS to choose midpoints for continuous variables. The old algorithm was based on the work of Nelder (1976). The current algorithm that PROC CHART uses if you omit OLD is based on the work of Terrell and Scott (1985).

Default Without MIDPOINTS=, PROC CHART displays the values in the SAS System's normal sorted order.

Restriction When the VBAR variables are numeric, the midpoints must be given in ascending order.

MISSING
specifies that missing values are valid levels for the chart variable.

NOSYMBOL
suppresses printing of the subgroup symbol or legend table.

Alias NOLEGEND

Interaction PROC CHART ignores NOSYMBOL if you omit SUBGROUP=.

NOZEROS
suppresses any bar with zero frequency.

REF=*value(s)*
draws reference lines on the response axis at the specified positions.

Tip The REF= values should correspond to values of the TYPE= statistic.

Example "Example 4: Producing Side-by-Side Bar Charts" on page 379

SPACE=*n*
specifies the amount of space between individual bars.

Tips Use SPACE=0 to leave no space between adjacent bars.

Use the GSPACE= option to specify the amount of space between the bars within each group.

SUBGROUP=*variable*
subdivides each bar or block into characters that show the contribution of the values of *variable* to that bar or block. PROC CHART uses the first character of each value to fill in the portion of the bar or block that corresponds to that value, unless more than one value begins with the same first character. In that case, PROC CHART uses the letters A, B, C, and so on, to fill in the bars or blocks. If the variable is formatted, then PROC CHART uses the first character of the formatted value.

The characters used in the chart and the values that they represent are given in a legend at the bottom of the chart. The subgroup symbols are ordered A through Z and 0 through 9 with the characters in ascending order.

PROC CHART calculates the height of a bar or block for each subgroup individually and then rounds the percentage of the total bar up or down. So the total height of the bar can be higher or lower than the same bar without the SUBGROUP= option.

Interaction If you use both TYPE=MEAN and SUBGROUP=, then PROC CHART first calculates the mean for each variable that is listed in the SUMVAR= option. It then subdivides the bar into the percentages that each subgroup contributes.

Example “Example 3: Subdividing the Bars into Categories” on page 376

SUMVAR=*variable*
specifies the variable for which either values or means (depending on the value of TYPE=) PROC CHART displays in the chart.

Interaction If you use SUMVAR= and you use TYPE= with a value other than MEAN or SUM, then TYPE=SUM overrides the specified TYPE= value.

Tip VBAR charts can print labels for SUMVAR= variables if you use a LABEL statement.

Examples “Example 3: Subdividing the Bars into Categories” on page 376

“Example 4: Producing Side-by-Side Bar Charts” on page 379

“Example 5: Producing a Horizontal Bar Chart for a Subset of the Data” on page 382

“Example 6: Producing Block Charts for BY Groups” on page 384

SYMBOL=*character(s)*
specifies the character or characters that PROC CHART uses in the bars or blocks of the chart when you do not use the SUBGROUP= option.

Default asterisk (*)

Interaction If the SAS system option OVP is in effect and if your printing device supports overprinting, then you can specify up to three characters to produce overprinted charts.

Example "Example 6: Producing Block Charts for BY Groups" on page 384

TYPE=*statistic*
specifies what the bars or sections in the chart represent. The *statistic* is one of the following:

CFREQ
specifies that each bar, block, or section represent the cumulative frequency.

CPERCENT
specifies that each bar, block, or section represent the cumulative percentage.

Alias CPCT

FREQ
specifies that each bar, block, or section represent the frequency with which a value or range occurs for the chart variable in the data.

MEAN
specifies that each bar, block, or section represent the mean of the SUMVAR= variable across all observations that belong to that bar, block, or section.

Interaction With TYPE=MEAN, you can compute only MEAN and FREQ statistics.

Example "Example 4: Producing Side-by-Side Bar Charts" on page 379

PERCENT
specifies that each bar, block, or section represent the percentage of observations that have a given value or that fall into a given range of the chart variable.

Alias PCT

Example "Example 2: Producing a Percentage Bar Chart" on page 373

SUM
specifies that each bar, block, or section represent the sum of the SUMVAR= variable for the observations that correspond to each bar, block, or section.

Default FREQ (unless you use SUMVAR=, which causes a default of SUM)

Interaction With TYPE=SUM, you can compute only SUM and FREQ statistics.

WIDTH=*n*
specifies the width of the bars on bar charts.

Details

Statement Results

PROC CHART prints one page per chart. Along the vertical axis, PROC CHART describes the chart frequency, the cumulative frequency, the chart percentage, the cumulative percentage, the sum, or the mean. At the bottom of each bar, PROC CHART prints a value according to the value of the TYPE= option, if specified. For character variables or discrete numeric variables, this value is the actual value represented by the bar. For continuous numeric variables, the value gives the midpoint of the interval represented by the bar.

PROC CHART can automatically scale the vertical axis, determine the bar width, and choose spacing between the bars. However, by using options, you can choose bar intervals and the number of bars, include missing values in the chart, produce side-by-side charts, and subdivide the bars. If the number of characters per line (LINESIZE=) is not sufficient to display all vertical bars, then PROC CHART produces a horizontal bar chart instead.

Results: CHART Procedure

Missing Values

PROC CHART follows these rules when handling missing values:

- Missing values are considered as valid levels for the chart variable when you use the MISSING option.
- Missing values for a GROUP= or SUBGROUP= variable are treated as valid levels.
- PROC CHART ignores missing values for the FREQ= option and the SUMVAR= option.
- If the value of the FREQ= variable is missing, zero, or negative, then the observation is excluded from the calculation of the chart statistic.
- If the value of the SUMVAR= variable is missing, then the observation is excluded from the calculation of the chart statistic.

ODS Table Names

The CHART procedure assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. For more information, see *SAS Output Delivery System: User's Guide*.

Table 11.3 *ODS Tables Produced by the CHART Procedure*

Name	Description	Statement Used
BLOCK	A block chart	BLOCK
HBAR	A horizontal bar chart	HBAR
PIE	A pie chart	PIE
STAR	A star chart	STAR
VBAR	A vertical bar chart	VBAR

Portability of ODS Output with PROC CHART

Under certain circumstances, using PROC CHART with the Output Delivery System produces files that are not portable. If the SAS system option FORMCHAR= in your SAS session uses nonstandard line-drawing characters, then the output might include strange characters instead of lines in operating environments in which the SAS Monospace font is not installed. To avoid this problem, specify the following OPTIONS statement before executing PROC CHART:

```
options formchar="|----|+|---+=|-/\<>*";
```

Examples: CHART Procedure

Example 1: Producing a Simple Frequency Count

Features: VBAR statement

Details

This example produces a vertical bar chart that shows a frequency count for the values of the chart variable.

Program

```
data shirts;
   input Size $ @@;
   datalines;
medium    large
large     large
large     medium
medium    small
small     medium
medium    large
small     medium
large     large
large     small
medium    medium
medium    medium
medium    large
small     small
;

proc chart data=shirts;
   vbar size;

   title 'Number of Each Shirt Size Sold';
run;
```

Program Description

Create the Shirts data set. Shirts contains the sizes of a particular shirt that is sold during a week at a clothing store, with one observation for each shirt that is sold.

```
data shirts;
   input Size $ @@;
   datalines;
medium    large
large     large
large     medium
medium    small
small     medium
medium    large
small     medium
large     large
large     small
medium    medium
medium    medium
medium    large
small     small
;
```

Create a vertical bar chart with frequency counts. The VBAR statement produces a vertical bar chart for the frequency counts of the Size values.

```
proc chart data=shirts;
   vbar size;
```

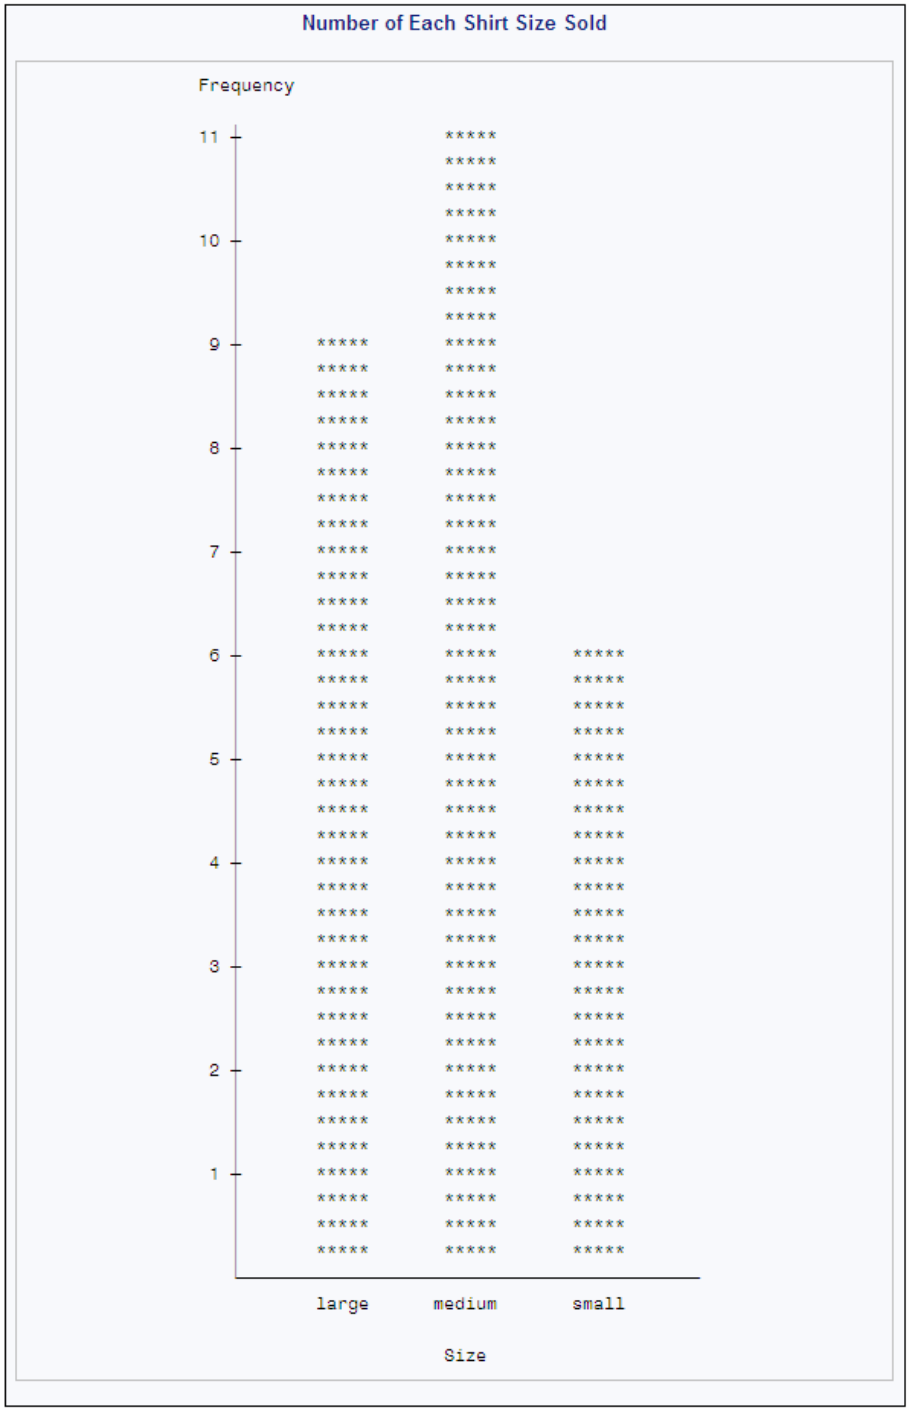
Specify the title.

```
   title 'Number of Each Shirt Size Sold';
run;
```

Output: HTML

The following frequency chart shows the store's sales of each shirt size for the week: 9 large shirts, 11 medium shirts, and 6 small shirts.

Output 11.6 *Number of Each Shirt Size Sold*



Example 2: Producing a Percentage Bar Chart

Features: VBAR statement option
TYPE=

Data set: SHIRTS

Details

This example produces a vertical bar chart. The chart statistic is the percentage for each category of the total number of shirts sold.

Program

```
proc chart data=shirts;
   vbar size / type=percent;

   title 'Percentage of Total Sales for Each Shirt Size';
run;
```

Program Description

Create a vertical bar chart with percentages. The VBAR statement produces a vertical bar chart. TYPE= specifies percentage as the chart statistic for the variable Size.

```
proc chart data=shirts;
   vbar size / type=percent;
```

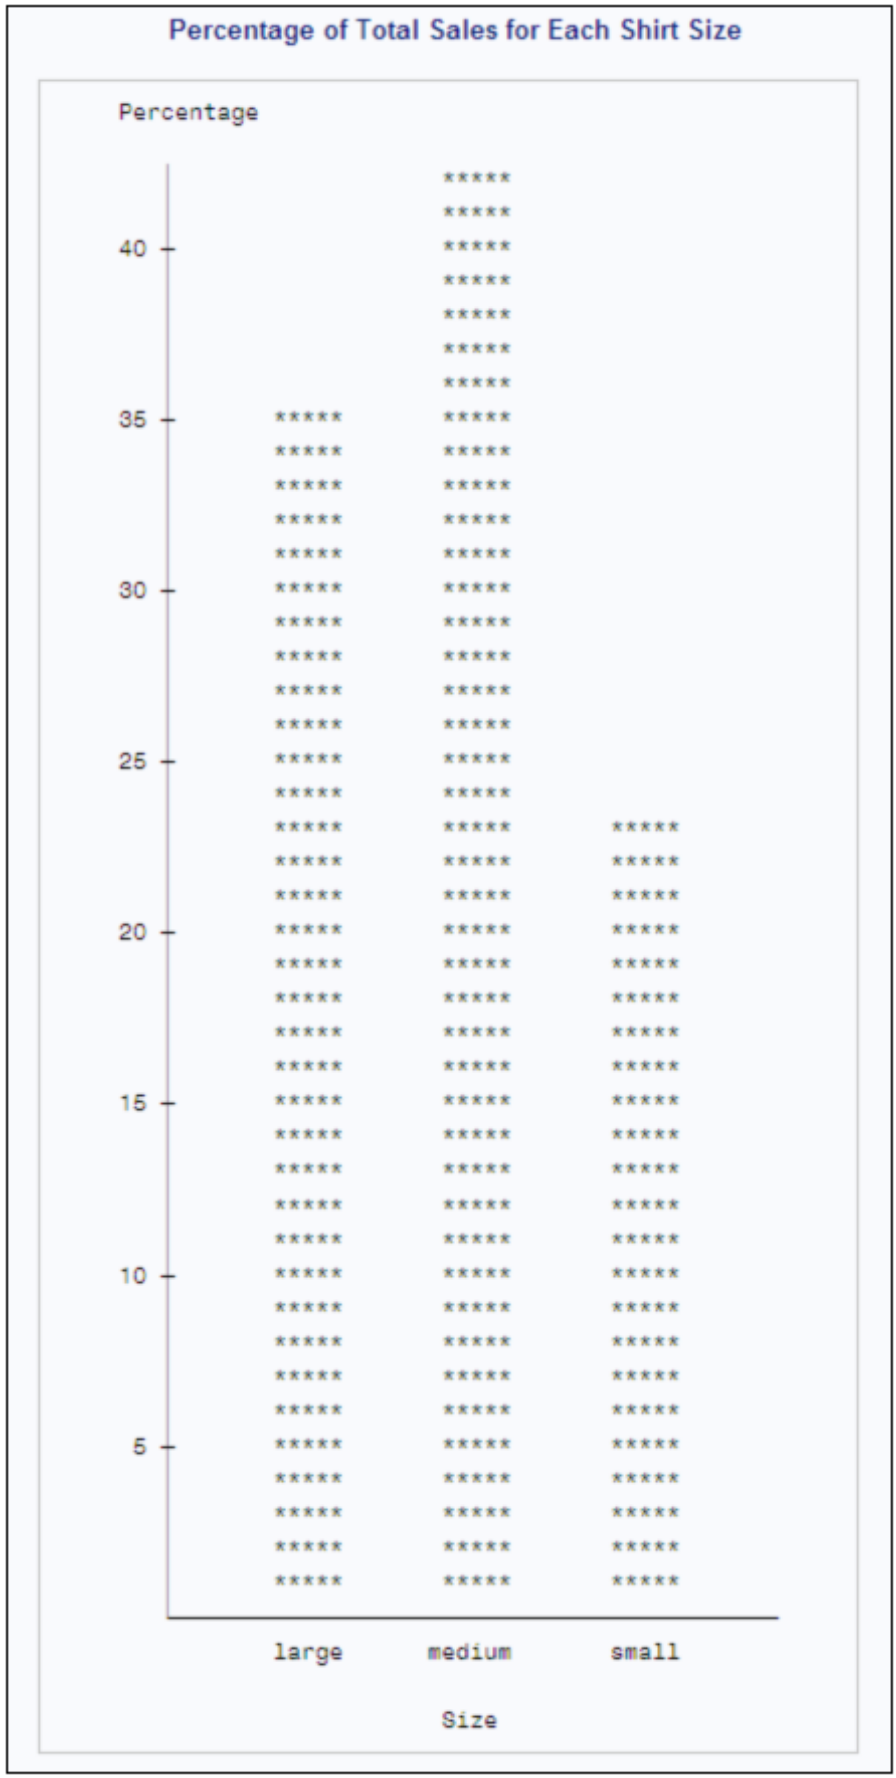
Specify the title.

```
   title 'Percentage of Total Sales for Each Shirt Size';
run;
```

Output: HTML

The following chart shows the percentage of total sales for each shirt size. Of all the shirts sold, about 42.3 percent were medium, 34.6 were large, and 23.1 were small.

Output 11.7 *Percentage of Total Sales for Each Shirt Size*



Example 3: Subdividing the Bars into Categories

Features: VBAR statement options
SUBGROUP=
SUMVAR=

Details

This example does the following:

- produces a vertical bar chart for categories of one variable with bar lengths that represent the values of another variable
- subdivides each bar into categories based on the values of a third variable

Program

```
data piesales;
   input Bakery $ Flavor $ Year Pies_Sold;
   datalines;
Samford  apple      2005  234
Samford  apple      2006  288
Samford  blueberry  2005  103
Samford  blueberry  2006  143
Samford  cherry     2005  173
Samford  cherry     2006  195
Samford  rhubarb    2005   26
Samford  rhubarb    2006   28
Oak      apple      2005  219
Oak      apple      2006  371

Oak      blueberry  2006  206
Oak      cherry     2005  226
Oak      cherry     2006  311
Oak      rhubarb    2005   51
Oak      rhubarb    2006   56
Clyde    apple      2005  213
Clyde    apple      2006  415
Clyde    blueberry  2005  177
Clyde    blueberry  2006  201
Clyde    cherry     2005  230
Clyde    cherry     2006  328
Clyde    rhubarb    2005   60
Clyde    rhubarb    2006   59
;
```

Create a vertical bar chart with the bars that are subdivided into categories. The VBAR statement produces a vertical bar chart with one bar for each pie flavor. SUBGROUP= divides each bar into sales for each bakery.

```
proc chart data=piesales;
   vbar flavor / subgroup=bakery
```

Specify the bar length variable. SUMVAR= specifies Pies_Sold as the variable whose values are represented by the lengths of the bars.

```
                 sumvar=pies_sold;
```

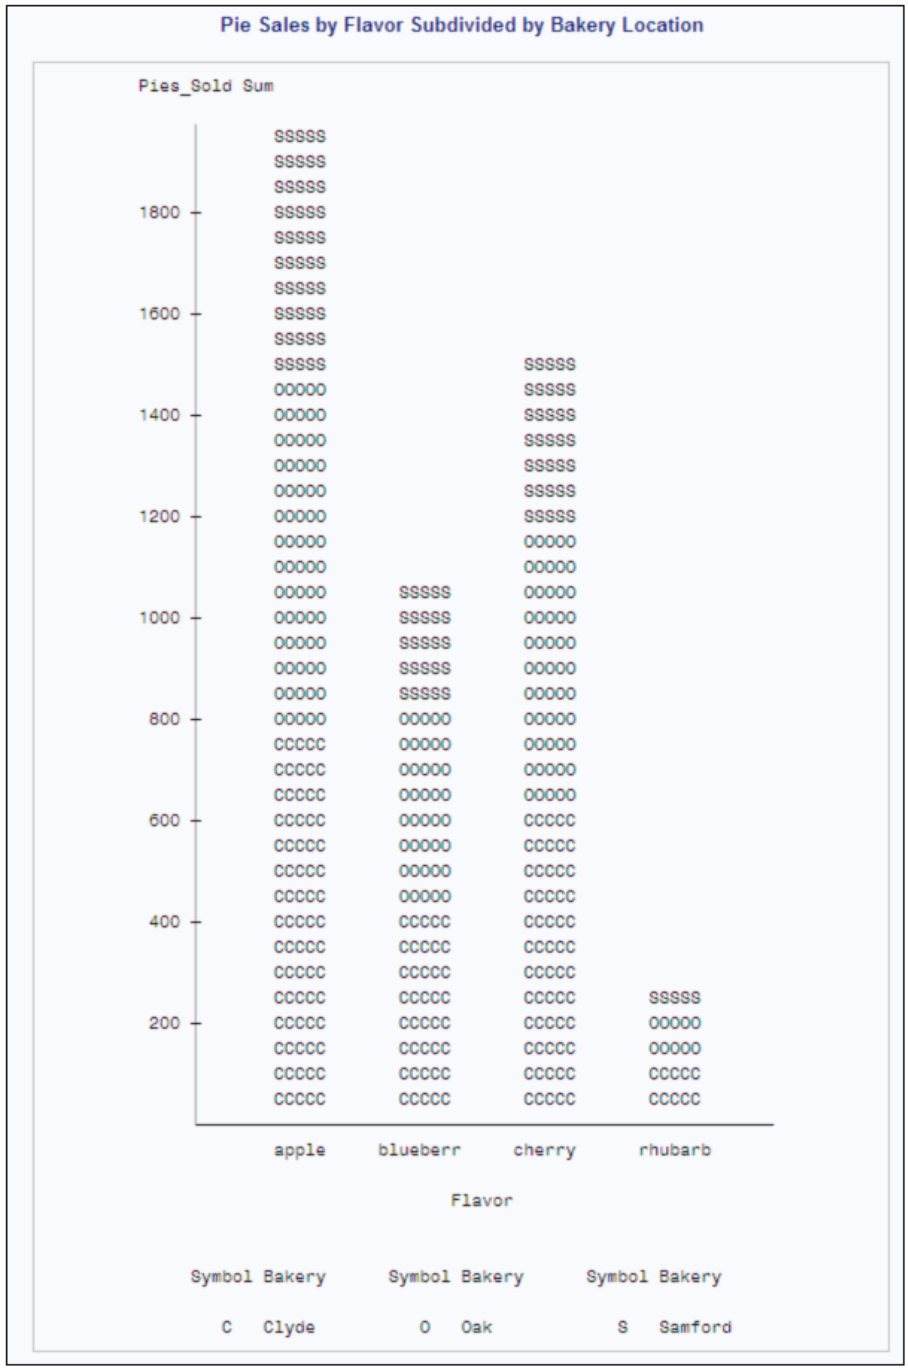
Specify the title.

```
   title 'Pie Sales by Flavor Subdivided by Bakery Location';
run;
```

Output: HTML

In the following output, the bar that represents the sales of apple pies, for example, shows 1,940 total pies across both years and all three bakeries. The symbol for the Samford Avenue bakery represents the 522 pies at the top. The symbol for the Oak Street bakery represents the 690 pies in the middle. The symbol for the Clyde Drive bakery represents the 728 pies at the bottom of the bar for apple pies. By default, the labels along the horizontal axis are truncated to eight characters.

Output 11.8 *Pie Sales by Flavor Subdivided by Bakery Location*



Example 4: Producing Side-by-Side Bar Charts

Features: VBAR statement options
- GROUP=
- REF=
- SUMVAR=

TYPE=

Data set: PIESALES

Details

This example does the following:

- charts the mean values of a variable for the categories of another variable
- creates side-by-side bar charts for the categories of a third variable
- draws reference lines across the charts

Program

```
proc chart data=piesales;
   vbar flavor / group=bakery
                 ref=100 200 300
                 sumvar=pies_sold
                 type=mean;
   title  'Mean Yearly Pie Sales Grouped by Flavor';
   title2 'within Bakery Location';
run;
```

Program Description

Create a side-by-side vertical bar chart. The VBAR statement produces a side-by-side vertical bar chart to compare the sales across values of Bakery, specified by GROUP=. Each Bakery group contains a bar for each Flavor value.

```
proc chart data=piesales;
   vbar flavor / group=bakery
```

Create reference lines. REF= draws reference lines to mark pie sales at 100, 200, and 300.

```
                 ref=100 200 300
```

Specify the bar length variable. SUMVAR= specifies Pies_Sold as the variable that is represented by the lengths of the bars.

```
                 sumvar=pies_sold
```

Specify the statistical variable. TYPE= averages the sales for 2005 and 2006 for each combination of bakery and flavor.

```
                 type=mean;
```

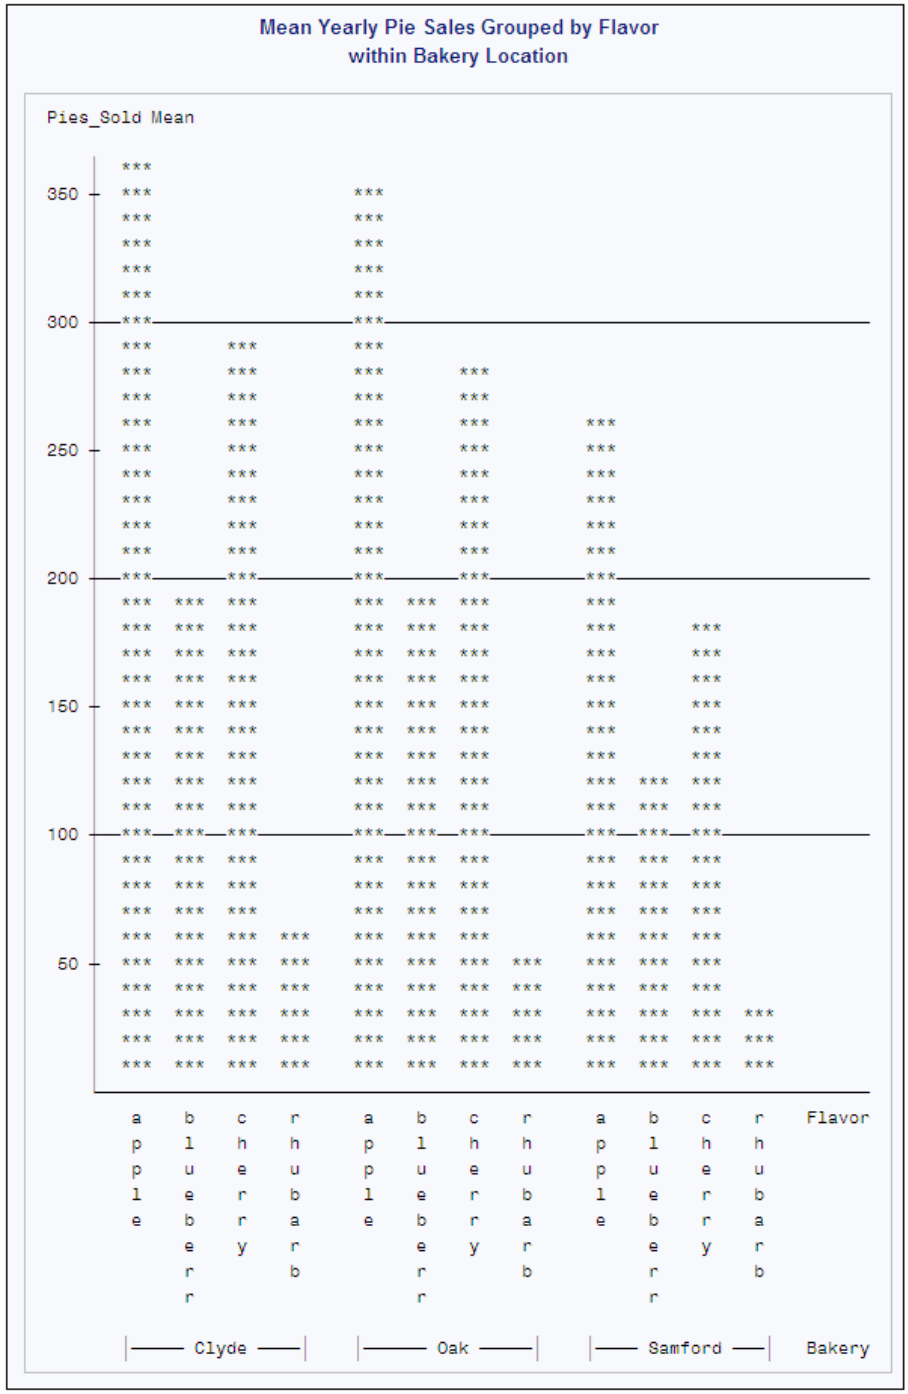
Specify the titles.

```
    title  'Mean Yearly Pie Sales Grouped by Flavor';
    title2 'within Bakery Location';
run;
```

Output: HTML

The following side-by-side bar charts compare the sales of pies by flavor, across bakeries. For example, for apple pie sales, the mean for the Clyde Drive bakery is 364, the mean for the Oak Street bakery is 345, and the mean for the Samford Avenue bakery is 261.

Output 11.9 *Mean Yearly Pie Sales Grouped by Flavor within Bakery Location*



Example 5: Producing a Horizontal Bar Chart for a Subset of the Data

Features: HBAR statement options
GROUP=

SUMVAR=
WHERE= data set option

Data set: PIESALES

Details

This example does the following:

- produces horizontal bar charts only for observations with a common value
- charts the values of a variable for the categories of another variable
- creates side-by-side bar charts for the categories of a third variable

Program

```
proc chart data=piesales(where=(year=2005));
   hbar bakery / group=flavor
   sumvar=pies_sold;
   title '2005 Pie Sales for Each Bakery According to Flavor';
run;
```

Program Description

Specify the variable value limitation for the horizontal bar chart. WHERE= limits the chart to only the 2005 sales totals.

```
proc chart data=piesales(where=(year=2005));
```

Create a side-by-side horizontal bar chart. The HBAR statement produces a side-by-side horizontal bar chart to compare sales across values of Flavor, specified by GROUP=. Each Flavor group contains a bar for each Bakery value.

```
   hbar bakery / group=flavor
```

Specify the bar length variable. SUMVAR= specifies Pies_Sold as the variable whose values are represented by the lengths of the bars.

```
   sumvar=pies_sold;
```

Specify the title.

```
   title '2005 Pie Sales for Each Bakery According to Flavor';
run;
```

Output: HTML

Output 11.10 *2005 Pie Sales for Each Bakery According to Flavor*

2005 Pie Sales for Each Bakery According to Flavor

```
Flavor     Bakery                                   Pies_Sold
                                                          Sum
                     |
apple      Clyde     |*********************      213.0000
           Oak       |**********************     219.0000

                         50  100  150  200

                          Pies_Sold Sum
```

Example 6: Producing Block Charts for BY Groups

Features:

BLOCK statement options
- GROUP=
- NOHEADER=
- SUMVAR=
- SYMBOL=

BY statement

PROC SORT

SAS system options
- NOBYLINE
- OVP

TITLE statement
- #BYVAL specification

Data set: PIESALES

Details

This example does the following:

- sorts the data set
- produces a block chart for each BY group
- organizes the blocks into a three-dimensional chart
- prints BY group-specific titles

Program

```
proc sort data=piesales out=sorted_piesales;
   by year;
run;

options nobyline;

proc chart data=sorted_piesales;
   by year;

   block bakery / group=flavor

                  sumvar=pies_sold

                  noheader

                  symbol='OX';

   title  'Pie Sales for Each Bakery and Flavor';
   title2 '#byval(year)';
run;

options byline;
```

Program Description

Sort the input data set Piesales. PROC SORT sorts Piesales by year. Sorting is required to produce a separate chart for each year.

```
proc sort data=piesales out=sorted_piesales;
   by year;
run;
```

Suppress BY lines and allow overprinted characters in the block charts. NOBYLINE suppresses the usual BY lines in the output.

```
options nobyline;
```

Specify the BY group for multiple block charts. The BY statement produces one chart for 2005 sales and one for 2006 sales.

```
proc chart data=sorted_piesales;
   by year;
```

Create a block chart. The BLOCK statement produces a block chart for each year. Each chart contains a grid (Bakery values along the bottom, Flavor values along the side) of cells that contain the blocks.

```
   block bakery / group=flavor
```

Specify the bar length variable. SUMVAR= specifies Pies_Sold as the variable whose values are represented by the lengths of the blocks.

```
                sumvar=pies_sold
```

Suppress the default header line. NOHEADER suppresses the default header line.

```
                noheader
```

Specify the block symbols. SYMBOL= specifies the symbols in the blocks.

```
                symbol='OX';
```

Specify the titles. The #BYVAL specification inserts the year into the second line of the title.

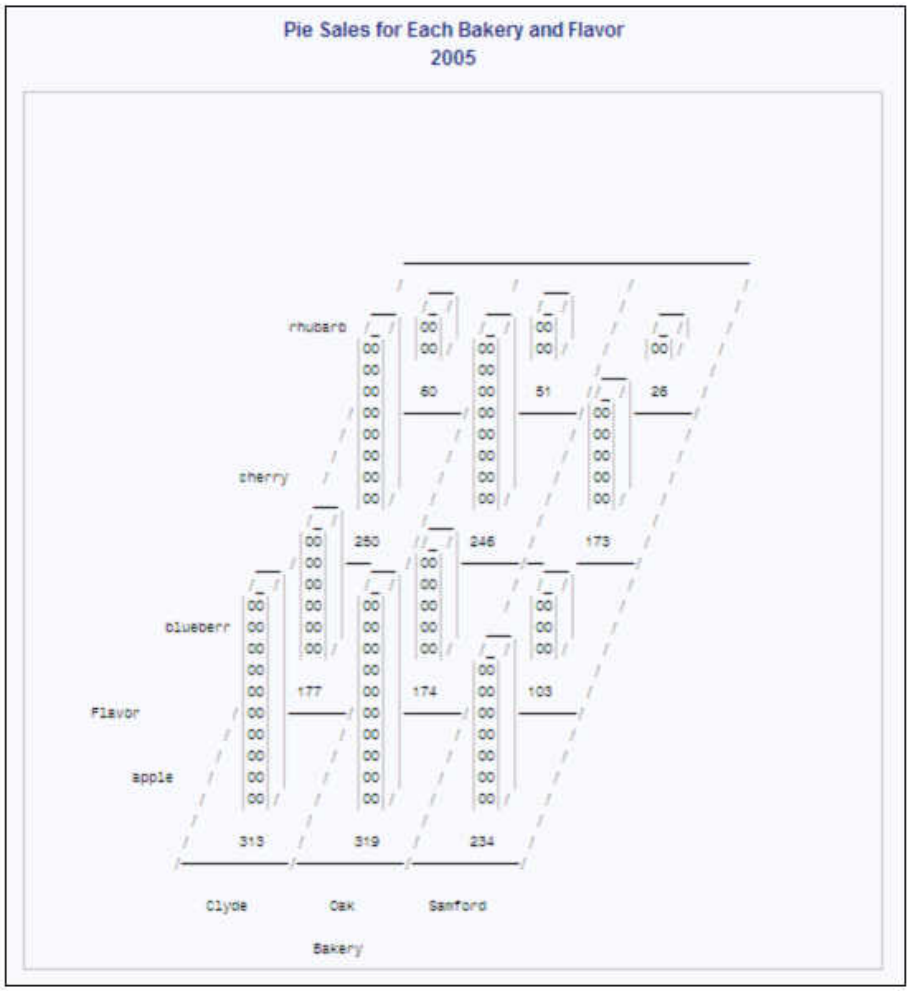
```
   title  'Pie Sales for Each Bakery and Flavor';
   title2 '#byval(year)';
run;
```

Reset the printing of the default BY line. The SAS system option BYLINE resets the printing of the default BY line.

```
options byline;
```

Output: HTML

Output 11.11 *2005 Pie Sales for Each Bakery and Flavor*



Output 11.12 *2006 Pie Sales for Each Bakery and Flavor*

CIMPORT Procedure

Overview: CIMPORT Procedure

What Does the CIMPORT Procedure Do?

The CIMPORT procedure *imports* a transport file that was created (*exported*) by the CPORT procedure. PROC CIMPORT restores the transport file to its original form as a SAS catalog, SAS data set, or SAS library. *Transport files* are sequential files that each contain a SAS library, a SAS catalog, or a SAS data set in transport format. The transport format that PROC CPORT writes is the same for all environments and for many releases of SAS.

PROC CIMPORT also *converts* SAS files, which means that it changes the format of a SAS file from the SAS format appropriate for one version of SAS to the SAS format appropriate for another version. For example, you can use PROC CPORT and PROC CIMPORT to move files from earlier releases of SAS to more recent releases (for example, from SAS 8 to SAS®9) or between the same versions (for example, from one SAS 9 operating environment to another SAS 9 operating environment). PROC CIMPORT automatically converts the transport file as it imports it.

However, PROC CPORT and PROC CIMPORT do not allow file transport from a later version to an earlier version (known as regressing). For example, transporting is not allowed from SAS® 9 to SAS 8.

Note: PROC CIMPORT and PROC CPORT can be used to back up graphic catalogs. PROC COPY cannot be used to back up graphic catalogs.

PROC CIMPORT produces no output, but it does write notes to the SAS log.

Process for Creating and Reading a Transport File

Here is the process to create a transport file at the source computer and to read it at a target computer:

1. A transport file is created at the source computer using PROC CPORT.
2. The transport file is transferred from the source computer to the target computer.
3. The transport file is read at the target computer using PROC CIMPORT.

   Note: Transport files that are created using PROC CPORT are not interchangeable with transport files that are created using the XPORT engine.

For complete details about the steps to create a transport file (PROC CPORT), to transfer the transport file, and to restore the transport file (PROC CIMPORT), see *Moving and Accessing SAS Files*.

Converting Data to UTF-8 for Loading into CAS

The CAS server supports only UTF-8 encoding. If your SAS Viya session encoding is not UTF-8, then the data that is read to a CAS table must be transcoded to UTF-8 before loading your data into CAS. You can set your SAS Viya session to UTF-8 in order to avoid the need to transcode the data.

In SAS Viya 3.5, PROC CIMPORT provides the EXTENDVAR= and the EXTENDFORMAT = options to prevent truncation and to ensure that the SAS supplied format width is sufficient for the transcoded data.

Note: The formats supported are SAS supplied formats only. User-defined formats are not supported.

For more information about migrating data to UTF-8 encoding, see the following resources.

- "UTF-8 Encoding" in *Migrating Data to UTF-8 for SAS Viya*
- "Data Migration to UTF-8 Encoding" in *An Introduction to SAS Viya Programming*
- "Read External Files" in *Migrating Data to UTF-8 for SAS Viya*

Syntax: CIMPORT Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Tip: Use PROC CIMPORT or PROC CPORT when backing up graphic catalogs. PROC COPY cannot be used to back up graphic catalogs.

See: CIMPORT Procedure under Windows, UNIX, z/OS

For complete details about the steps to create a transport file (PROC CPORT), to transfer the transport file, and to restore the transport file (PROC CIMPORT), see *Moving and Accessing SAS Files*

PROC CIMPORT *destination=libref | <libref.> member-name* <*options*>;

EXCLUDE *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*> </ ENTRYTYPE=*entry-type*>;

SELECT *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*> </ ENTRYTYPE=*entry-type*>;

Statement	Task	Example
PROC CIMPORT	Import a transport file	Ex. 1, Ex. 2, Ex. 3
EXCLUDE	Exclude one or more specified files from the import process	
SELECT	Specify one or more files or entries to import process	Ex. 2

PROC CIMPORT Statement

Imports a transport file.

Examples:

Syntax

PROC CIMPORT *destination=libref* | <*libref.*> *member-name* <*options*>;

Summary of Optional Arguments

COMPRESS=NO | CHAR | BINARY
: Specifies how the resulting CIMPORT data set is to be compressed.

FORCE
: enables access to a locked catalog.

NEW
: creates a new catalog for the imported transport file, and deletes any existing catalog with the same name.

NOEDIT
: imports SAS/AF PROGRAM and SCL entries without Edit capability.

NOSRC
: suppresses the importing of source code for SAS/AF entries that contain compiled SCL code.

SORT
: causes the output data set to be re-sorted if necessary when PROC CIMPORT is used to import a sorted data set.

Control the contents of the transport file

EXTENDFORMAT=YES | NO
: specifies whether to extend the character format width.

EXTENDSN=YES | NO
: specifies whether to extend by 1 byte the length of short numerics (less than 8 bytes) when you import them.

EXTENDVAR=*multiplier* | AUTO
: specifies a multiplier value that expands character variable lengths.

UPCASE
: writes the alphabetic characters in uppercase to the output file.

Identify the input transport file

INFILE=*fileref* | '*filename*'
: specifies a previously defined fileref or the filename of the transport file to read.

TAPE
: reads the input transport file from a tape.

Look at the encoding of the transport file

ENCODINGINFO=ALL | *n*
: specifies the number of data set headers to read in order to output the encoding value of the data set to the log.

ISFILEUTF8=YES | NO
: specifies whether the file is encoded in UTF-8 format.

Select files to import

EET=(*etype(s)*)
: excludes specified entry types from the import process.

ET=(*etype(s)*)
: specifies entry types to import.

MEMTYPE=*mtype*
: specifies that only data sets, only catalogs, or both, be moved when a library is imported.

Required Argument

destination=libref | <libref.>member-name
: identifies the type of file to import and specifies the catalog, SAS data set, or SAS library to import.

destination
: identifies the file or files in the transport file as a single catalog, as a single SAS data set, or as the members of a SAS library. The *destination* argument can be one of the following:

CATALOG | CAT | C

DATA | DS | D

LIBRARY | LIB | L

libref
<libref.> member-name
: specifies the specific catalog, SAS data set, or SAS library as the destination of the transport file. If the *destination* argument is CATALOG or DATA, you can specify both a *libref* and a member name. If the *libref* is omitted, PROC CIMPORT uses the default library as the *libref*, which is usually the WORK library. If the *destination* argument is LIBRARY, specify only a *libref*.

See Refer to "Names in the SAS Language" in *SAS Language Reference: Concepts* for naming conventions that you can use for names and member names.

Optional Arguments

COMPRESS=NO | CHAR | BINARY
: specifies whether the resulting CIMPORT data set is compressed. You can specify the compression type that is being used.

NO
: specifies that the data set produced by CIMPORT is not compressed.

Alias OFF | N

CHAR
specifies that the observations in a newly created SAS data set are compressed (producing variable-length records) by using RLE (Run Length Encoding). RLE compresses observations by reducing repeated runs of the same character (including blanks) to two-byte or three-byte representations.

Alias ON | YES | Y

BINARY
specifies that the observations in a newly created SAS data set are compressed (producing variable-length records) by using RDC (Ross Data Compression). RDC combines run-length encoding and sliding-window compression to compress the file by representing repeated byte patterns more efficiently.

Note: This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (character and numeric variables). Because the compression function operates on a single record at a time, the record length needs to be several hundred bytes or larger for effective compression.

See For more information about creating and restoring transport files, see *Moving and Accessing SAS Files*.

Example
```
proc cimport file=transportFile lib=myLib compress=char;
run;
```

EET=(*etype(s)*)
excludes specified entry types from the import process. If the *etype* is a single entry type, then you can omit the parentheses. Separate multiple values with spaces.

Interaction You cannot specify both the EET= option and the ET= option in the same PROC CIMPORT step.

ENCODINGINFO=ALL | *n*
specifies the number of data set headers to read in order to output the encoding value of the data set to the log.

ALL
specifies that all data set headers are read. The encoding value stored for the data set header is output to the SAS log.

n
specifies an integer greater than zero. This value represents the number of data set headers to read. The encoding value stored for the data set header is output to the SAS log.

Range Specify an integer greater than zero. The upper limit is dependent on system contraints. All data is still processed when *n* is larger than the number of data sets in the transport file.

Note If catalogs are encountered in the library during the process of reading the data set headers, they are skipped. Catalog headers do not contain encoding values.

See For more information about creating and restoring transport files, see *Moving and Accessing SAS Files*.

Example
```
proc cimport lib=work file='mixed' encodinginfo=3;
run;
```

```
NOTE: The CPORTed data set ASCII transport file encoding=us-ascii.
NOTE: The CPORTed data set JISDS transport file encoding=wlatin1.
NOTE: The CPORTed data set UTF8 transport file encoding=wlatin1.
NOTE: The CPORTed data set WLATIN1DS transport file encoding=wlatin1.
```

ET=(*etype(s)*)
specifies the entry types to import. If the *etype* is a single entry type, then you can omit the parentheses. Separate multiple values with spaces.

Interaction You cannot specify both the EET= option and the ET= option in the same PROC CIMPORT step.

EXTENDSN=YES | NO
specifies whether to extend by 1 byte the length of short numerics (fewer than 8 bytes) when you import them. You can avoid a loss of precision when you transport a short numeric in IBM format to IEEE format if you extend its length. You cannot extend the length of an 8-byte short numeric.

Default YES

Restriction This option applies only to data sets.

Tip Do not store fractions as short numerics.

EXTENDFORMAT=YES | NO
specifies whether to extend the character format width.

Note: The EXTENDFORMAT= option is used in conjunction with the EXTENDVAR= option.

Alias Y, N

Default YES

Restrictions This option is supported in SAS Viya 3.5 but is not supported in SAS 9.

The EXTENDFORMAT= option is used in conjunction with the EXTENDVAR= option. If you set EXTENDVAR= to specify a larger variable length and then set EXTENDFORMAT= to NO, the text might be truncated.

EXTENDVAR=*multiplier* | AUTO

specifies a multiplier value that expands character variable lengths when you are processing a SAS data file that requires transcoding. The expanded length helps to ensure that character data is not truncated.

multiplier

Specify a multiplier value from 1 to 5 or you can specify AUTO. The lengths for character variables are increased by multiplying the current length by the specified value. The default value is 1. When 1 is used, the variable length is not extended. When AUTO is specified, the multiplier is set automatically.

Auto

AUTO is used to set the *multiplier*. This value is dependant on the encoding of the session and the data set in the transport file. When the file that is specified by INFILE= is in ANSI encoding or has no character encoding ID (CEI) information, a multiplier value of one is used. Otherwise, the extended length is calculated for you.

When the string is truncated, a warning message is generated. The message prompts you to use the EXTENDVAR option.

Default 1. When the default is used, the variable length is not extended.

Restrictions This option is supported in SAS Viya 3.5 but is not supported in SAS 9.

This option applies only to data sets.

This option does not take affect when the NOTRANSCODE attribute is specified for data types for SAS character variables.

PROC CIMPORT does not support VARCHAR.

Note If the ASIS option is specified in PROC CPORT, the EXTENDVAR= option is ignored.

Tip Do not store fractions as short numerics.

ISFILEUTF8=YES | NO

explicitly designates the encoding of a data set that is contained in a transport file as UTF-8. Although data set encodings are recorded (or stamped) in SAS 9.2 transport files, encodings are not stamped in transport files created using SAS releases before 9.2. Therefore, designating the UTF-8 encoding is useful under these conditions:

- The data set in the transport file was created using a SAS release before 9.2.
- The data set is known to be encoded as UTF-8.

The person who restores the transport file in the target environment should have a description of the transport file in advance of the restore operation.

yes

specifies that the data set in the transport file is encoded as UTF-8.

Alias YES, Y, y, TRUE, true, T, t

no
specifies that the data set in the transport file is not encoded as UTF-8. NO is the default.

Alias NO, N, n, FALSE, false, F, f

In order to successfully import a transport file in the target SAS session, you should have this information about the transport file:

- source operating environment. **`Windows`** for example.
- SAS release. **`SAS 9.2`** for example.
- name of the transport file. **`tport.dat`** for example.
- encoding of the character data.**`wlatin1`** for example.
- national language of the character data. For example, American English (or **`en_US`**)

Default NO

Restriction PROC CIMPORT uses this option only if the transport file is not stamped with the encoding of the data set. Encodings were not recorded in SAS releases before 9.2. If an encoding is recorded in the transport file and the ISFILEUTF8= option is specified in PROC CIMPORT, ISFILEUTF8= is ignored.

See "CIMPORT Problems: Importing Transport Files" on page 402

For more information about creating and restoring transport files, see *Moving and Accessing SAS Files*.

FORCE
enables access to a locked catalog. By default, PROC CIMPORT locks the catalog that it is updating to prevent other users from accessing the catalog while it is being updated. The FORCE option overrides this lock, which allows other users to access the catalog while it is being imported, or enables you to import a catalog that is currently being accessed by other users.

CAUTION
The FORCE option can lead to unpredictable results. The FORCE option allows multiple users to access the same catalog entry simultaneously.

INFILE=*fileref* | '*filename*'
specifies a previously defined fileref or the filename of the transport file to read. If you omit the INFILE= option, then PROC CIMPORT attempts to read from a transport file with the fileref SASCAT. If a fileref SASCAT does not exist, then PROC CIMPORT attempts to read from a file named SASCAT.DAT.

Alias FILE=

Example "Example 1: Importing an Entire Library" on page 410

MEMTYPE=*mtype*
specifies that only data sets, only catalogs, or both, be imported from the transport file. Values for *mtype* can be as follows:

ALL	both catalogs and data sets
CATALOG | CAT	catalogs
DATA | DS	SAS data sets

NEW
creates a new catalog to contain the contents of the imported transport file when the destination that you specify has the same name as an existing catalog. NEW deletes any existing catalog with the same name as the one you specify as a destination for the import. If you do not specify NEW, and the destination that you specify has the same name as an existing catalog, PROC CIMPORT appends the imported transport file to the existing catalog.

NOEDIT
imports SAS/AF PROGRAM and SCL entries without Edit capability.

You obtain the same results if you create a new catalog to contain SCL code by using the MERGE statement with the NOEDIT option in the BUILD procedure of SAS/AF software.

Note: The NOEDIT option affects only SAS/AF PROGRAM and SCL entries. It does not affect FSEDIT SCREEN and FSVIEW FORMULA entries.

Alias NEDIT

NOSRC
suppresses the importing of source code for SAS/AF entries that contain compiled SCL code.

You obtain the same results if you create a new catalog to contain SCL code by using the MERGE statement with the NOSOURCE option in the BUILD procedure of SAS/AF software.

Alias NSRC

Interaction PROC CIMPORT ignores the NOSRC option if you use it with an entry type other than FRAME, PROGRAM, or SCL.

SORT
causes the output data set to be re-sorted if necessary when importing a sorted data set using PROC CIMPORT. A re-sort is necessary if the data set to be imported is sorted by one or more character variables and the ordering of character values in the target SAS session is different from that of the source session.

Note: The CIMPORT SORT option has no effect on data sets that do not contain sort information. This applies only to data sets that were sorted previously.

The ordering of character values, or collating sequence, is dependent upon the session encoding and translation tables used by SAS as well as by the options used when invoking the SORT procedure. If necessary, a re-sort is performed during the import, and the data set's sort indicator is preserved.

For more information, see "Collating Sequence" in *SAS National Language Support (NLS): Reference Guide* and Chapter 64, "SORT Procedure," on page 2355.

When PROC CIMPORT re-sorts a data set, the following information is output:

```
NOTE: PROC CIMPORT re-sorted the data set WORK.TEMP because it contained
      character variables in the sort key, and the collating sequence of
      the sort differs from the local host.
```

Example `proc cimport 'transportfile.tpt' lib=library sort; run;`

Example code for z/OS:

```
proc cimport data=file.mwelect inf=CPO sort; run;
```

TAPE

reads the input transport file from a tape.

Default PROC CIMPORT reads from disk.

UPCASE

reads from the transport file and writes the alphabetic characters in uppercase to the output file.

Restriction The UPCASE option is allowed only if SAS is built with a Double-Byte Character Set (DBCS).

Tip PROC CPORT can be used to create a transport file that includes all uppercase characters. See option "OUTTYPE=UPCASE" on page 545 for details.

EXCLUDE Statement

Excludes specified files or entries from the import process.

Interaction: You can use either EXCLUDE statements or SELECT statements in a PROC CIMPORT step, but not both.

Tip: There is no limit to the number of EXCLUDE statements that you can use in one invocation of PROC CIMPORT.

Syntax

EXCLUDE *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*> </ ENTRYTYPE=*entry-type*>;

Required Argument

SAS file(s) | catalog entry(s)
specifies one or more SAS files or one or more catalog entries to be excluded from the import process. Specify SAS filenames if you import a library; specify catalog entry names if you import an individual SAS catalog. Separate multiple filenames or entry names with a space. You can use shortcuts to list many like-named files in the EXCLUDE statement. For more information, see "SAS Data Sets" in *SAS Language Reference: Concepts*.

Optional Arguments

ENTRYTYPE=*entry-type*
specifies a single entry type for one or more catalog entries that are listed in the EXCLUDE statement. See *SAS Language Reference: Concepts* for a complete list of catalog entry types.

Alias ETYPE=, ET=

Restriction ENTRYTYPE= is valid only when you import an individual SAS catalog.

MEMTYPE=*mtype*
specifies a single member type for one or more SAS files listed in the EXCLUDE statement. Values for *mtype* can be

ALL	both catalogs and data sets
CATALOG	catalogs
DATA	SAS data sets

You can also specify the MEMTYPE= option, enclosed in parentheses, immediately after the name of a file. In parentheses, MEMTYPE= identifies the type of the filename that just precedes it. When you use this form of the option, it overrides the MEMTYPE= option that follows the slash in the EXCLUDE statement, but it must match the MEMTYPE= option in the PROC CIMPORT statement.

Alias MTYPE=, MT=

Default ALL

Restriction MEMTYPE= is valid only when you import a SAS library.

SELECT Statement

Specifies individual files or entries to import.

Interaction: You can use either EXCLUDE statements or SELECT statements in a PROC CIMPORT step, but not both.

Tip: There is no limit to the number of SELECT statements that you can use in one invocation of PROC CIMPORT.

Example: "Example 2: Importing Individual Catalog Entries" on page 411

Syntax

SELECT *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*>
</ ENTRYTYPE=*entry-type*>;

Required Argument

SAS file(s) | catalog entry(s)
specifies one or more SAS files or one or more catalog entries to import. Specify SAS filenames if you import a library; specify catalog entry names if you import an individual SAS catalog. Separate multiple filenames or entry names with a space. You can use shortcuts to list many like-named files in the SELECT statement. For more information, see "SAS Data Sets" in *SAS Language Reference: Concepts*.

Optional Arguments

ENTRYTYPE=*entry-type*
specifies a single entry type for one or more catalog entries that are listed in the SELECT statement. See *SAS Language Reference: Concepts* for a complete list of catalog entry types.

Alias ETYPE=, ET=

Restriction ENTRYTYPE= is valid only when you import an individual SAS catalog.

MEMTYPE=*mtype*
specifies a single member type for one or more SAS files listed in the SELECT statement. Valid values are CATALOG or CAT, DATA, or ALL.

You can also specify the MEMTYPE= option, enclosed in parentheses, immediately after the name of a file. In parentheses, MEMTYPE= identifies the type of the filename that just precedes it. When you use this form of the option, it overrides the MEMTYPE= option that follows the slash in the SELECT statement, but it must match the MEMTYPE= option in the PROC CIMPORT statement.

Alias MTYPE=, MT=

Default ALL

Restriction MEMTYPE= is valid only when you import a SAS library.

Usage: CIMPORT Procedure

CIMPORT Problems: Importing Transport Files

About Transport Files and Encodings

The character data in a transport file is created for the following types of encodings:

- the UTF-8 encoding of the SAS session in which the transport file is created.
- the Windows encoding that is associated with the locale of the SAS session in which the transport file is created. However, starting in SAS 9.4M3, PROC CIMPORT supports the ability to import data sets created in non-UTF-8 SAS sessions into UTF-8 SAS sessions.

  Using PROC CIMPORT to import a data set in a UTF-8 session preserves the encoding value of the data set. For example, if a data set with SHIFT-JIS encoding is imported into a UTF-8 session using PROC CIMPORT, PROC CONTENTS shows that the SHIFT-JIS encoding is maintained. However, starting in SAS Viya 3.5, using PROC CIMPORT to import a data set in a UTF-8 session, the UTF-8 encoding is maintained.

  Note: The ENCODINGINFO= option displays the Window's encoding associated with the locale of the SAS Session in which the transport file was created.

- Starting in SAS 9.4, when you use PROC CPORT to create a transport file that is encoded with US-ASCII on an ASCII platform, regardless of the session encoding, the US-ASCII encoding is preserved for that transport file. If you then transport that data set to an ASCII platform using PROC CIMPORT, the US-ASCII encoding for that transport file is preserved and is not d. The data set that is created has the US-ASCII encoding, not the session encoding. For example, if your session encoding is WLATIN1, you use PROC CPORT to create a data set that has an encoding of US-ASCII. The US-ASCII encoding is preserved in the transport file, instead of the WLATIN1 encoding. This preservation also occurs when you use PROC CIMPORT on this data set. The US-ASCII encoding is preserved and is not when you use PROC CIMPORT to transport the data set to an ASCII platform.

Note: The preservation of the US-ASCII encoding occurs only on an ASCII platform, not on z/OS.

- on a z/OS platform, PROC CIMPORT creates data sets using the session encoding.

These examples show how SAS applies an encoding to a transport file:

Table 12.1 *Assignment of Encodings to Transport Files*

Encoding Value of the Transport File	Example of Applying an Encoding in a SAS Invocation	Explanation
utf-8 or us-ascii	sas9 -encoding utf8;	A SAS session is invoked using the UTF-8 encoding. The session encoding is applied to the transport file. Note that starting in SAS 9.4M3, if the data set is US-ASCII, the US-ASCII encoding is preserved, not the session encoding.
wlatin2	sas9 -locale pl_PL;	A SAS session is invoked using the default UNIX encoding, LATIN2, which is associated with the Polish Poland locale.

For a complete list of encodings that are associated with each locale, see Locale Tables in *SAS National Language Support (NLS): Reference Guide*.

In order for a transport file to be imported successfully, the encodings of the source and target SAS sessions must be compatible. Here is an example of compatible source and target SAS sessions:

Table 12.2 *Compatible Encodings*

Source SAS Session			Target SAS Session	
Locale	UNIX SAS Session Encoding	Transport File Encoding	Locale	Windows SAS Session Encoding
es_MX (Spanish Mexico)	latin1	wlatin1	it_IT (Italian Italy)	wlatin1

The encodings of the source and target SAS sessions are compatible because the Windows default encoding for the es_MX locale is WLATIN1 and the encoding of the target SAS session is WLATIN1. For more detailed information about

compatible languages and encodings, see the SAS Press book SAS Encoding: Understanding the Details, by Manfred Kiefer.

However, if the encodings of the source and target SAS sessions are incompatible, a transport file might not be successfully imported. (See the introduction to this section.) Here is an example of incompatible encodings:

Table 12.3 *Incompatible Encodings*

Source SAS Session			Target SAS Session	
Locale	**UNIX SAS Session Encoding**	**Transport File Encoding**	**Locale**	**z/OS Encoding**
cs_CZ (Czech Czechoslovakia)	latin2	wlatin2	de_DE (German Germany)	open_ed-1141

The encodings of the source and target SAS sessions are incompatible because the Windows default encoding for the cs_CZ locale is WLATIN2 and the encoding of the target SAS session is OPEN_ED-1141. A transport file cannot be imported between these locales.

When importing transport files, you can use the ENCODINGINFO= option see the encoding value of the transport file. Otherwise, you are alerted to compatibility problems via warnings and error messages. For more information about the ENCODINGINFO= option, see "ENCODINGINFO=ALL | *n*" on page 394.

Problems with Transport Files Created Using a SAS Release Prior to 9.2

Overview: SAS Releases Prior to 9.2

Transport files that were created by SAS releases before 9.2 are not stamped with encoding values. Therefore, the CIMPORT procedure does not know the identity of the transport file's encoding and cannot report specific warning and error detail. The encoding of the transport file must be inferred when performing recovery actions.

However, using your knowledge about the transport file, you should be able to recover from transport problems. For information that is useful for importing the transport file in the target SAS session, see Tips: for the ISFILEUTF8 option on page 396. For complete details about creating and restoring transport files, see *Moving and Accessing SAS Files*.

Here are the warning and error messages with recovery actions:

- "Error: Transport File Encoding Is Unknown: Use the ISFILEUTF8= Option" on page 405

■ “Warning: Transport File Encoding Is Unknown” on page 405

Error: Transport File Encoding Is Unknown: Use the ISFILEUTF8= Option

The error message provides this information:

- The transport file was created using a SAS release before 9.2.
- Because the encoding is not stamped in the transport file, the encoding is unknown.
- The target SAS session uses the UTF-8 encoding.

Note: In order to perform recovery steps, you must know the encoding of the transport file.

If you know that the transport file is encoded as UTF-8, you can import the file again, and use the ISFILEUTF8=YES option in PROC CIMPORT.

Here is an example of the UTF-8 transport file and UTF-8 target SAS session. The UTF-8 transport file was created using a SAS release before 9.2.

```
filename importin 'transport-file';
libname target 'sas-library';
proc cimport isfileutf8=yes infile=importin library=target
memtype=data;
run;
```

For syntax details, see the ISFILEUTF8= option on page 396.

PROC CIMPORT should succeed.

Warning: Transport File Encoding Is Unknown

The warning message provides this information:

- The transport file was created using a SAS release before 9.2.
- Because the encoding is not stamped in the transport file, the encoding is unknown.

Try to read the character data from the imported data set. If you cannot read the data, you can infer that the locale of the target SAS session is incompatible with the encoding of the transport file.

Note: In order to perform recovery steps, you must know the encoding of the transport file.

For example, the transport file was created in a source SAS session using a SAS release before 9.2. The transport file was also created using a Polish Poland locale. The target SAS session uses a German locale.

1 In the target SAS session, start another SAS session and change the locale to the locale of the source SAS session that created the transport file.

In this example, you start a new SAS session in the Polish Poland locale.

```
sas9 -locale pl_PL;
```

2 Import the file again. Here is an example:

```
filename importin 'transport-file';
libname target 'sas-library';
proc cimport infile=importin library=target memtype=data;
run;
```

PROC CIMPORT should succeed and the data should be readable in the SAS session that uses a Polish_Poland locale.

Problems with Transport Files Created Using SAS Versions 9.2 and Later

Overview

The encoding of the character data is stamped in transport files that are created using SAS versions 9.2 and later. Therefore, the CIMPORT procedure can detect error conditions such as UTF-8 encoded transport files cannot be imported into SAS sessions that do not use the UTF-8 encoding. For example, a UTF-8 transport file cannot be imported into a SAS session that uses the Wlatin2 encoding.

SAS versions 9.2 and later can detect the condition of incompatibility between the encoding of the transport file and the locale of the target SAS session. Because some customers' SAS applications ran successfully using a release prior to SAS 9.2, PROC CIMPORT reports a warning only, but allows the import procedure to continue.

Here are the warning and error messages with recovery actions:

- "Error: Target Session Uses UTF-8: Transport File Is Not UTF-8" on page 406
- "Error: Target Session Does Not Use UTF-8: Transport File Is UTF-8" on page 408
- "Warning: Target Session Does Not Use UTF-8: Transport File Is Not UTF-8" on page 408

Error: Target Session Uses UTF-8: Transport File Is Not UTF-8

This error message should not appear in SAS 9.4M3 and later. The Error message provides the following information:

- The target SAS session uses the UTF-8 encoding.
- The transport file has an identified encoding that is not UTF-8. The encodings of the transport file and the target SAS session are incompatible.

Note: Starting in SAS 9.4M3, PROC CIMPORT supports the ability to import data sets that are created in non-UTF-8 SAS sessions into UTF-8 SAS sessions.

Prior to SAS 9.4M3, transport files are encoded in a Windows encoding that corresponds to the SAS session encoding.

If this error is generated, the encoding of the target SAS session cannot be UTF-8. The locales of the source and target SAS sessions must be identical.

Here is an example of a SAS 9.2 WLATIN2 transport file and UTF-8 target SAS session.

1 To recover, in the target SAS session, start another SAS session and change the locale to the locale that was used in the source SAS session that created the transport file.

   The LOCALE= value is preferred over the ENCODING= value because it sets automatically the default values for the ENCODING=, DFLANG=, DATESTYLE=, and PAPERSIZE= options.

   If you do not know the locale of the source session (or the transport file), you can infer it from the language that is used by the character data in the transport file.

   For example, if you know that Polish is the language, specify the pl_PL (Polish Poland) locale in a new target SAS session. Here are the encoding values that are associated with the pl_PL locale:

   Table 12.4 *LOCALE= Value for the Polish Language*

POSIX Locale	Windows Encoding	UNIX Encoding	z/OS Encoding
.pl_PL (Polish Poland)	wlatin2	latin2	open_ed-870

   Here is an example of specifying the pl_PL locale in a new SAS session:

```
sas9 -locale pl_PL;
```

   For complete details, see Locale Table.

   Note: Verify that you do not have a SAS invocation command that already contains the specification of the UTF-8 encoding. For example: `sas9 -encoding utf8`. If it exists, the UTF-8 encoding would persist regardless of a new locale specification.

2 Import the file again. Here is an example:

```
filename importin 'transport-file';
libname target 'SAS-data-library';
proc cimport infile=importin library=target memtype=data;
run;
```

   PROC CIMPORT should succeed.

Error: Target Session Does Not Use UTF-8: Transport File Is UTF-8

The error message provides this information:

- The target session uses an identified encoding that is not UTF-8.
- The transport file is encoded as UTF-8. The encodings of the transport file and the target SAS session are incompatible.

The encoding of the target SAS session must be changed to UTF-8.

Here is an example of a SAS 9.2 UTF-8 transport file and Wlatin1 target SAS session:

1 To recover, in the target SAS session, start a new SAS session and change the session encoding to UTF-8. Here is an example:

```
sas9 -encoding utf8;
```

2 Import the file again. Here is an example:

```
filename importin 'transport-file';
libname target 'sas-library';
proc cimport infile=importin library=target memtype=data;
run;
```

PROC CIMPORT should succeed.

Warning: Target Session Does Not Use UTF-8: Transport File Is Not UTF-8

The warning message provides this information:

- The target SAS session uses an identified encoding.
- The encoding of the transport file is identified. The encodings of the transport file and the target SAS session are incompatible.

This table shows the locale and encoding values of incompatible source and target SAS sessions. Although the wlatin2 Windows encoding that is assigned to the transport file in the source SAS session is incompatible with the open_ed-1141 encoding of the target SAS session, a warning is displayed and the import continues.

Table 12.5 *Encoding Values for the Czech and German Locales*

SAS Session	POSIX Locale	Windows Encoding	UNIX Encoding	z/OS Encoding
Source SAS Session	cs_CZ (Czech Czechoslovakia)	wlatin2	latin2	open_ed-870

SAS Session	POSIX Locale	Windows Encoding	UNIX Encoding	z/OS Encoding
Target SAS Session	de_DE (German Germany)	wlatin1	latin9	open_ed-1141

The transport file is imported, but the contents of the file are questionable. The message identifies the incompatible encoding formats. To recover, try to read the contents of the imported file. If the file is unreadable, perform these steps:

1 In the target SAS session, start a new SAS session and change the locale (rather than the encoding) to the locale that is used in the source SAS session.

   The LOCALE= value is preferred over the ENCODING= value because it automatically sets the default values for the ENCODING=, DFLANG=, DATESTYLE=, and PAPERSIZE= options.

   If you do not know the locale of the source session (or the transport file), you can infer it from the national language of the transport file.

   For example, if you know that Czech is the national language, specify the **cs_CZ** locale in a new target SAS session.

   Here is an example of specifying the **cs_CZ** locale in a new SAS session:

   ```
   sas9 -locale cs_CZ;
   ```

   The target SAS session and the transport file use compatible encodings. They both use wlatin2.

   For complete details, see the Locale Table in *SAS National Language Support (NLS): Reference Guide*.

2 Import the file again. Here is an example:

   ```
   filename importin 'transport-file';
   libname target 'sas-library';
   proc cimport infile=importin library=target memtype=data;
   run;
   ```

   PROC CIMPORT should succeed.

Problems with Loss of Numeric Precision

PROC CPORT and PROC CIMPORT can lose precision on numeric values that are extremely small and large. Refer to "Loss of Numeric Precision and Magnitude" in *SAS/CONNECT User's Guide* for details.

Examples: CIMPORT Procedure

Example 1: Importing an Entire Library

Features: PROC CIMPORT statement option
INFILE=

Details

This example shows how to use PROC CIMPORT to read from disk a transport file, named TRANFILE, that PROC CPORT created from a SAS library in another operating environment. The transport file was moved to the new operating environment by means of communications software or magnetic medium. PROC CIMPORT imports the transport file to a SAS library, called NEWLIB, in the new operating environment.

Program

```
libname newlib 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;

proc cimport library=newlib infile=tranfile;
run;
```

Program Description

Specify the library name and filename. The LIBNAME statement specifies a LIBNAME for the new SAS library. The FILENAME statement specifies the filename of the transport file that PROC CPORT created and enables you to specify any operating environment options for file characteristics.

```
libname newlib 'sas-library';
filename tranfile 'transport-file';
```

```
host-options-for-file-characteristics;
```

Import the SAS library in the NEWLIB library. PROC CIMPORT imports the SAS library into the library named NEWLIB.

```
proc cimport library=newlib infile=tranfile;
run;
```

Log Examples

Example Code 12.1 *Importing an Entire Library*

```
NOTE: Proc CIMPORT begins to create/update catalog NEWLIB.FINANCE
NOTE: Entry LOAN.FRAME has been imported.
NOTE: Entry LOAN.HELP has been imported.
NOTE: Entry LOAN.KEYS has been imported.
NOTE: Entry LOAN.PMENU has been imported.
NOTE: Entry LOAN.SCL has been imported.
NOTE: Total number of entries processed in catalog NEWLIB.FINANCE: 5

NOTE: Proc CIMPORT begins to create/update catalog NEWLIB.FORMATS
NOTE: Entry REVENUE.FORMAT has been imported.
NOTE: Entry DEPT.FORMATC has been imported.
NOTE: Total number of entries processed in catalog NEWLIB.FORMATS: 2
```

Example 2: Importing Individual Catalog Entries

Features:

PROC CIMPORT statement option
INFILE=

SELECT statement

Details

This example shows how to use PROC CIMPORT to import the individual catalog entries LOAN.PMENU and LOAN.SCL from the transport file TRANS2, which was created from a single SAS catalog.

Program

```
libname newlib 'sas-library';
filename trans2 'transport-file';

host-options-for-file-characteristics;
```

```
proc cimport catalog=newlib.finance infile=trans2;
   select loan.pmenu loan.scl;
run;
```

Program Description

Specify the library name, filename, and operating environment options. The LIBNAME statement specifies a LIBNAME for the new SAS library. The FILENAME statement specifies the filename of the transport file that PROC CPORT created and enables you to specify any operating environment options for file characteristics.

```
libname newlib 'sas-library';
filename trans2 'transport-file';

host-options-for-file-characteristics;
```

Import the specified catalog entries to the new SAS catalog. PROC CIMPORT imports the individual catalog entries from the TRANS2 transport file and stores them in a new SAS catalog called NEWLIB.FINANCE. The SELECT statement selects only the two specified entries from the transport file to be imported into the new catalog.

```
proc cimport catalog=newlib.finance infile=trans2;
   select loan.pmenu loan.scl;
run;
```

Log Examples

Example Code 12.2 *Importing Individual Catalog Entries*

```
NOTE: Proc CIMPORT begins to create/update catalog NEWLIB.FINANCE
NOTE: Entry LOAN.PMENU has been imported.
NOTE: Entry LOAN.SCL has been imported.
NOTE: Total number of entries processed in catalog NEWLIB.FINANCE: 2
```

Example 3: Importing a Single Indexed SAS Data Set

Features: PROC CIMPORT statement option
INFILE=

Details

This example shows how to use PROC CIMPORT to import an indexed SAS data set from a transport file that was created by PROC CPORT from a single SAS data set.

Program

```
libname newdata 'sas-library';
filename trans3 'transport-file';

host-options-for-file-characteristics;

proc cimport data=newdata.times infile=trans3;
run;
```

Program Description

Specify the library name, filename, and operating environment options. The LIBNAME statement specifies a LIBNAME for the new SAS library. The FILENAME statement specifies the filename of the transport file that PROC CPORT created and enables you to specify any operating environment options for file characteristics.

```
libname newdata 'sas-library';
filename trans3 'transport-file';

host-options-for-file-characteristics;
```

Import the SAS data set. PROC CIMPORT imports the single SAS data set that you identify with the DATA= specification in the PROC CIMPORT statement. PROC CPORT exported the data set NEWDATA.TIMES in the transport file TRANS3.

```
proc cimport data=newdata.times infile=trans3;
run;
```

Log Examples

Example Code 12.3 *Importing a Single Indexed SAS Data Set*

```
NOTE: Proc CIMPORT begins to create/update data set NEWDATA.TIMES
NOTE: The data set index x is defined.
NOTE: Data set contains 2 variables and 2 observations.
      Logical record length is 16
```

Example 4: Using PROC CIMPORT to Import a French Data Set into a UTF-8 SAS Session

Features:

PROC CPORT statement option
- DATA=
- FILE=

PROC CIMPORT statement option
- DATA=
- INFILE=
- EXTENDVAR=
- EXTENDFORMAT=

Details

This example shows how to import a French data set into a UTF-8 SAS session. The French data set has an 8-byte character variable 'a' with a character format '$8.'. Using a SAS Viya deployment, we start a French SAS session where we use PROC CPORT to generate a transport file named 'myfile'.

In another SAS Viya window, we start a SAS session that uses UTF-8 encoding. We then import the transport file (non-UTF-8) into a UTF-8 SAS session using PROC CIMPORT. We first show that the imported data set is truncated and then how to extend the variable length using the EXTENDVAR= option to avoid truncation.

Program

Use PROC CPORT to create a transport file using a French data set. From a SAS Viya deployment, bring up a default SAS session using the French language. In the following example, we are using a French data set where the data set has an 8-byte character variable 'a' (the value of 'a' is premiere with an accented e) with a character format set to'$8.'. We use PROC CPORT to create a transport file. In this example, the encoding is wlatin-1, the default.

```
data test;
   a = 'première';
   format a $8.;
run;
proc cport data=test file='myfile';
run;
```

Output 12.1 *French Data Set Used in PROC CPORT File*

Le Système SAS

Obs.	a
1	première

Import the transport file in a UTF-8 SAS session using PROC CIMPORT. From a separate SAS Viya session that is using UTF-8 encoding, import the transport file 'myfile' into the UTF-8 SAS session using PROC CIMPORT. Print the SAS data set and the PROC CONTENTS. Because it takes 2 bytes to store the accented 'e' in UTF-8 encoding, the value premiere needs 9 bytes to display the value. The format is $8. so the value is truncated.

```
proc cimport data=test infile='myfile';
run;
proc print data=test;
run;
proc contents data=test;
run;
```

Output 12.2 *CIMPORT a Non-UTF-8 Transport File to an Encoding Session That Is UTF-8 - Truncated*

Cimport the Transport File Into a UTF-8 SAS Session Showing Truncation

Obs.	a
1	premièr

Cimport the Transport File Into a UTF-8 SAS Session Showing Truncation

#	Variable	Type	Long.	Format
1	a	Texte	8	$8.

Extend the Variable Length to avoid truncation. Because there was truncation, we use the EXTENDVAR= option to extend the variable length and the format width (default for EXTENDFORMAT= is YES).

```
proc cimport data=test infile='myfile' extendvar=1.5;
run;
proc print data=test;
run;
```

```
proc contents data=test;
run;
```

Note that the output data set now contains the entire variable. Also, note in the output of PROC CONTENTS that the variable length and the format width have been extended.

COMPARE Procedure

Overview: COMPARE Procedure

What Does the COMPARE Procedure Do?

The COMPARE procedure compares the contents of two SAS data sets, selected variables in different data sets, or variables within the same data set.

PROC COMPARE compares two data sets: the base data set and the comparison data set. The procedure determines matching variables and matching observations. Matching variables are variables with the same name or variables that you pair by using the VAR and WITH statements. Matching variables must be of the same type. Matching observations are observations that have the same values for all ID variables that you specify or, if you do not use the ID statement, that occur in the same position in the data sets. If you match observations by ID variables, then both data sets must be sorted by all ID variables.

What Information Does PROC COMPARE Provide?

PROC COMPARE generates the following information about the two data sets that are being compared:

- whether matching variables have different values
- whether one data set has more observations than the other
- what variables the two data sets have in common
- how many variables are in one data set but not in the other
- whether matching variables have different formats, labels, or types
- a comparison of the values of matching observations

Note: You can create a view that has two columns with the same variable name. If duplicate variable names exist in the view, PROC COMPARE cannot determine which column in the base data set should be compared to the compare data set. PROC COMPARE issues an error if it finds duplicate variable names.

Further, PROC COMPARE creates two types of output data sets that give detailed information about the differences between observations of variables that it is comparing.

The following example compares the data sets Proclib.One and Proclib.Two, which contain similar data about students:

```
data proclib.one(label='First Data Set');
   input student year $ state $ gr1 gr2;
   label year='Year of Birth';
   format gr1 4.1;
   datalines;
1000 1990 NC 85 87
1042 1991 MS 90 92
1095 1989 TN 78 92
1187 1990 MA 87 94
;

data proclib.two(label='Second Data Set');
   input student $ year $ state $ gr1
         gr2 major $;
   label state='Home State';
   format gr1 5.2;
   datalines;
1000 1990 NC 85 87 Math
1042 1991 MS 90 92 History
1095 1989 TN 78 92 Physics
1187 1990 MA 87 94 Music
1204 1991 NC 82 96 English
;
```

PROC COMPARE does not produce information about values that are the same in each comparison data set. It produces information about values that are different, not the same.

PROC COMPARE does not produce a data set that contains observations that are in one of the comparison data sets but not in the other, or that are in both comparison data sets. The options for the COMPARE statement can produce much of this information, but they do not produce a data set. If you want to produce a data set that contains this information, use a DATA step that contains a MERGE statement. Here is an example of a DATA step that uses a MERGE statement to create a data set:

```
data inone intwo inboth;
   merge a (in=ina) b(in=inb);
   by byvar;
      if ina and not inb then output inone;
      if inb and not ina then output intwo;
      if ina and inb then output inboth;
run;
```

Concepts: COMPARE Procedure

Comparisons Using PROC COMPARE

PROC COMPARE first compares the following:

- data set attributes (set by the data set options TYPE= and LABEL=).
- variables. PROC COMPARE checks each variable in one data set to determine whether it matches a variable in the other data set.
- attributes (type, length, labels, formats, and informats) of matching variables.
- observations. PROC COMPARE checks each observation in one data set to determine whether it matches an observation in the other data set. PROC COMPARE either matches observations by their position in the data sets or by the values of the ID variable.

After making these comparisons, PROC COMPARE compares the values in the parts of the data sets that match. PROC COMPARE either compares the data by the position of observations or by the values of an ID variable.

A Comparison by Position of Observations

The following figure shows two data sets. The data inside the shaded boxes shows the part of the data sets that the procedure compares. Assume that variables with the same names have the same type.

Figure 13.1 Comparison by the Positions of Observations

Data Set ONE

Obs	idnum	name	year	state	grade1	grade2
1	1000	Emily	1990	NC	85.0	87
2	1042	Dan	1991	MS	90.0	92
3	1095	Julia	1989	TN	78.0	92
4	1187	Robin	1990	MA	87.0	94

Data Set TWO

Obs	idnum	name	year	state	grade1	grade2	major
1	1000	Emily	1990	NC	85.00	87	Math
2	1042	Dan	1991	MS	90.00	92	History
3	1095	Julia	1989	TN	78.00	92	Physics
4	1187	Robin	1990	MA	87.00	94	Music
5	1204	Keith	1991	NC	82.00	96	English
6	1198	Ted	1990	PA	84.00	93	Music
7	1054	Lisa	1989	GA	81.00	94	French

When you use PROC COMPARE to compare data set TWO with data set ONE, the procedure compares the first observation in data set ONE with the first observation in data set TWO, and it compares the second observation in the first data set with the second observation in the second data set, and so on. In each observation that it compares, the procedure compares the values of the idnum, name, year, state, grade1, and grade2.

The procedure does not report on the value of the last three observations or the variable major in data set TWO because there is nothing to compare them with in data set ONE.

A Comparison with an ID Variable

In a simple comparison, PROC COMPARE uses the observation number to determine which observations to compare. When you use an ID variable, PROC COMPARE uses the values of the ID variable to determine which observations to compare. ID variables should have unique values and must have the same type.

For the two data sets shown in the following figure, assume that IDNUM is an ID variable and that IDNUM has the same type in both data sets. The procedure compares the observations that have the same value for IDNUM. The data inside the shaded boxes shows the part of the data sets that the procedure compares.

Figure 13.2 Comparison by the Value of the ID Variable

Data Set ONE

Obs	idnum	name	year	state	grade1	grade2
1	1000	Emily	1990	NC	85.0	87
2	1042	Dan	1991	MS	90.0	92
3	1095	Julia	1989	TN	78.0	92
4	1187	Robin	1990	MA	87.0	94

Data Set TWO

Obs	idnum	name	year	state	grade1	grade2	major
1	1000	Emily	1990	NC	85.00	87	Math
2	1042	Dan	1991	MS	90.00	92	History
3	1095	Julia	1989	TN	78.00	92	Physics
4	1187	Robin	1990	MA	87.00	94	Music
5	1204	Keith	1991	NC	82.00	96	English
6	1198	Ted	1990	PA	84.00	93	Music
7	1054	Lisa	1989	GA	81.00	94	French

The data sets contain five matching variables: name, year, state, grade1, and grade2. They also contain four matching observations: the observations with values of `1000`, `1042`, `1095`, and `1187` for idnum.

Data set TWO contains three observations (idnum=`1204`, idnum=`1198`, and idnum=`1054`) for which data set ONE contains no matching observations. Similarly, no variable in data set ONE matches the variable “major” in data set TWO.

See “Example 5: Comparing Observations with an ID Variable” on page 476 for an example that uses an ID variable.

The Equality Criterion

Using the CRITERION= Option

The COMPARE procedure judges numeric values unequal if the magnitude of their difference, as measured according to the METHOD= option, is greater than the value of the CRITERION= option. PROC COMPARE provides four methods for applying CRITERION=:

- The EXACT method tests for exact equality.

- The ABSOLUTE method compares the absolute difference to the value specified by CRITERION=.
- The RELATIVE method compares the absolute relative difference to the value specified by CRITERION=.
- The PERCENT method compares the absolute percent difference to the value specified by CRITERION=.

For a numeric variable compared, let *x* be its value in the base data set and let *y* be its value in the comparison data set. If both *x* and *y* are nonmissing, then the values are judged unequal according to the value of METHOD= and the value of CRITERION= (γ) as follows:

- If METHOD=EXACT, then the values are unequal if *y* does not equal *x*.
- If METHOD=ABSOLUTE, then the values are unequal if

  $$\mathrm{ABS}(y - x) > \gamma$$

- If METHOD=RELATIVE, then the values are unequal if

  $$\mathrm{ABS}(y - x)/((\mathrm{ABS}(x) + \mathrm{ABS}(y))/2 + \delta) > \gamma$$

  The values are equal if *x*=*y*=0.
- If METHOD=PERCENT, then the values are unequal if

  $$100(\mathrm{ABS}(y - x)/\mathrm{ABS}(x)) > \gamma \quad \text{for} \quad x \neq 0$$

  or

  $$y \neq 0 \quad \text{for} \quad \mathrm{x} = 0$$

If *x* or *y* is missing, then the comparison depends on the NOMISSING option. If the NOMISSING option is in effect, then a missing value will always be judged equal to anything. Otherwise, a missing value is judged equal only to a missing value of the same type (that is, .=., .^=.A, .A=.A, .A^=.B, and so on).

If the value that is specified for CRITERION= is negative, then the actual criterion that is used, γ, is equal to the absolute value of the specified criterion multiplied by a very small number, ε (epsilon), that depends on the numerical precision of the computer. This number ε is defined as the smallest positive floating-point value such that, using machine arithmetic, 1−ε<1<1+ε. Round-off or truncation error in floating-point computations is typically a few orders of magnitude larger than ε. CRITERION=−1000 often provides a reasonable test of the equality of computed results at the machine level of precision.

The value δ added to the denominator in the RELATIVE method is specified in parentheses after the method name: METHOD=RELATIVE(δ). If not specified in METHOD=, then δ defaults to 0. The value of δ can be used to control the behavior of the error measure when both *x* and *y* are very close to 0. If δ is not given and *x* and *y* are very close to 0, then any error produces a large relative error (in the limit, 2).

Specifying a value for δ avoids this extreme sensitivity of the RELATIVE method for small values. If you specify METHOD=RELATIVE(δ) CRITERION=γ when both *x* and *y* are much smaller than δ in absolute value, then the comparison is as if you had specified METHOD=ABSOLUTE CRITERION=δγ. However, when either *x* or *y* is much larger than δ in absolute value, the comparison is like METHOD=RELATIVE

CRITERION=γ. For moderate values of *x* and *y*, METHOD=RELATIVE(δ) CRITERION=γ is, in effect, a compromise between METHOD=ABSOLUTE CRITERION=δ γ and METHOD=RELATIVE CRITERION=γ.

For character variables, if one value is longer than the other, then the shorter value is padded with blanks for the comparison. Nonblank character values are judged equal only if they agree at each character. If the NOMISSING option is in effect, then blank character values are judged equal to anything.

Definition of Difference and Percent Difference

In the reports of value comparisons and in the OUT= data set, PROC COMPARE displays difference and percent difference values for the numbers compared. These quantities are defined using the value from the base data set as the reference value. For a numeric variable compared, let *x* be its value in the base data set and let *y* be its value in the comparison data set. If *x* and *y* are both nonmissing, then the difference and percent difference are defined as follows:

- Difference = $y - x$
- Percent Difference = $(y - x)/x * 100 \quad \text{for} \quad x \neq 0$
- Percent Difference = missing for $x = 0$.

How PROC COMPARE Handles Variable Formats

PROC COMPARE compares unformatted values. If you have two matching variables that are formatted differently, then PROC COMPARE lists the formats of the variables. If non-matching values are found in the comparison section of the output, then the formatted values are displayed in the values comparison section.

Syntax: COMPARE Procedure

Restriction: You must use the VAR statement when you use the WITH statement.

Tips: Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

You can use the LABEL, ATTRIB, FORMAT, and WHERE statements. For more information, see “Statements with the Same Function in Multiple Procedures” on page 73.

Ensure that the LINESIZE option in the OPTIONS statement specifies an adequate length to display the label information for the data sets.

If problems occur with the length of CHAR variables when you compare two unequal data sets in CAS, you might need to change the value of the

NCHARMULTIPLIER option of the LIBNAME statement. For more information, see "NCHARMULTIPLIER= LIBNAME Statement Option" in *SAS Cloud Analytic Services: User's Guide* and "CAS LIBNAME Statement" in *SAS Cloud Analytic Services: User's Guide*.

PROC COMPARE <*options*>;

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

ID <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

VAR *variable(s)*;

WITH *variable(s)*;

Statement	Task	Example
PROC COMPARE	Compare the contents of SAS data sets, or compare two variables	Ex. 1, Ex. 2, Ex. 4, Ex. 6, Ex. 7
BY	Produce a separate comparison for each BY group	
ID	Identify variables to use to match observations	Ex. 5
VAR	Restrict the comparison to values of specific variables	Ex. 2, Ex. 3, Ex. 4
WITH	Compare variables of different names	Ex. 2, Ex. 3, Ex. 4
WITH	Compare two variables in the same data set	Ex. 4

PROC COMPARE Statement

Compares the contents of two SAS data sets, selected variables in different data sets, or variables within the same data set.

Restriction: If you omit COMPARE=, then you must use the WITH and VAR statements.

Tips: Ensure that the LINESIZE option in the OPTIONS statement specifies an adequate length to display the label information for the data sets.

If problems occur with the length of CHAR variables when you compare two unequal data sets in CAS, you might need to change the value of the NCHARMULTIPLIER option of the LIBNAME statement. For more information, see "NCHARMULTIPLIER= LIBNAME Statement Option" in *SAS Cloud Analytic Services: User's Guide* and "CAS LIBNAME Statement" in *SAS Cloud Analytic Services: User's Guide*.

You can use data set options with the BASE= and COMPARE= options.

Examples:

"Example 1: Producing a Complete Report of the Differences" on page 463
"Example 2: Comparing Variables in Different Data Sets" on page 470
"Example 4: Comparing Variables That Are in the Same Data Set" on page 474
"Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482
"Example 7: Creating an Output Data Set of Statistics (OUTSTATS=)" on page 486

Syntax

PROC COMPARE <*options*>;

Summary of Optional Arguments

Control the details in the default report

ALLOBS
: includes the values for all matching observations.

ALLSTATS
: prints a table of summary statistics for all pairs of matching variables.

ALLVARS
: includes in the report the values and differences for all matching variables.

BRIEFSUMMARY
: prints only a short comparison summary.

FUZZ=*number*
: changes the report for numbers between 0 and 1.

MAXPRINT=*total* | (*per-variable, total*)
: restricts the number of differences to be printed.

NODATE
: suppresses the printing of creation and last-modified dates.

NOPRINT
: suppresses all printed output.

NOSUMMARY
: suppresses the data set, variable, observation, and values comparison summary reports.

NOVALUES
: suppresses the report of the value comparison results.

PRINTALL
: produces a complete listing of values and differences.

STATS
: prints a table of summary statistics for all pairs of matching numeric variables that are judged unequal.

TRANSPOSE

prints the reports of value differences by observation instead of by variable.

Control the listing of variables and observations

LISTALL
: lists all variables and observations that are found in only one data set.

LISTBASE
: lists all variables and observations found only in the base data set.

LISTBASEOBS
: lists all observations found only in the base data set.

LISTBASEVAR
: lists all variables found in only the base data set.

LISTCOMP
: lists all variables and observations found only in the comparison data set.

LISTCOMPOBS
: lists all observations found only in the comparison data set.

LISTCOMPVAR
: lists all variables found only in the comparison data set.

LISTEQUALVAR
: lists variables whose values are judged equal.

LISTOBS
: lists all observations found in only one data set.

LISTVAR
: list all variables found in only one data set.

Control the output data set

OUT=*SAS-data-set*
: creates an output data set.

OUTALL
: writes an observation for each observation in the BASE= and COMPARE= data sets.

OUTBASE
: writes an observation for each observation in the base data set.

OUTCOMP
: writes an observation for each observation in the comparison data set

OUTDIF
: writes an observation to the output data set for each pair of matching observations.

OUTNOEQUAL
: suppresses the writing of observations when all values are equal.

OUTPERCENT
: writes an observation to the output data set for each pair of matching observations.

Create an output data set that contains summary statistics

OUTSTATS=*SAS-data-set*
: writes summary statistics for all pairs of matching variables to the specified *SAS-data-set*.

Display a warning message in the SAS log

WARNING
: displays a warning message in the SAS log when differences are found.

Display an error message in the SAS log

ERROR
: displays an error message in the SAS log when differences are found.

Specify how the values are compared

CRITERION=γ
: specifies the criterion for judging the equality of numeric values.

METHOD=ABSOLUTE | EXACT | PERCENT | RELATIVE<(δ)>
: specifies the method for judging the equality of numeric values.

NOMISSBASE
: judges a missing value in the base data set equal to any value.

NOMISSCOMP
: judges a missing value in the comparison data set equal to any value.

NOMISSING
: judges missing values in both the base and comparison data sets equal to any value.

Specify the data sets to compare

BASE=*SAS-data-set*
: specifies the data set to use as the base data set.

COMPARE=*SAS-data-set*
: specifies the data set to use as the comparison data set.

Write notes to the SAS log

NOTE
: displays notes in the SAS log that describe the results of the comparison.

Optional Arguments

ALLOBS

includes in the report of value comparison results the values and, for numeric variables, the differences for all matching observations, even if they are judged equal.

Default
: If you omit ALLOBS, then PROC COMPARE prints values only for observations that are judged unequal.

Interaction
: When used with the TRANSPOSE option, ALLOBS invokes the ALLVARS option and displays the values for all matching observations and variables.

ALLSTATS

prints a table of summary statistics for all pairs of matching variables.

See "Table of Summary Statistics" on page 456 for information about the statistics produced

ALLVARS
includes in the report of value comparison results the values and, for numeric variables, the differences for all pairs of matching variables, even if they are judged equal.

Default If you omit ALLVARS, then PROC COMPARE prints values only for variables that are judged unequal.

Interaction When used with the TRANSPOSE option, ALLVARS displays unequal values in context with the values for other matching variables. If you omit the TRANSPOSE option, then ALLVARS invokes the ALLOBS option and displays the values for all matching observations and variables.

BASE=*SAS-data-set*
specifies the data set to use as the base data set.

Alias DATA=

Default the most recently created SAS data set

Tip You can use the WHERE= data set option with the BASE= option to limit the observations that are available for comparison.

BRIEFSUMMARY
produces a short comparison summary and suppresses the four default summary reports (data set summary report, variables summary report, observation summary report, and values comparison summary report).

Alias BRIEF

Tip By default, a listing of value differences accompanies the summary reports. To suppress this listing, use the NOVALUES option.

Example "Example 4: Comparing Variables That Are in the Same Data Set" on page 474

COMPARE=*SAS-data-set*
specifies the data set to use as the comparison data set.

Alias COMP=, C=

Default If you omit COMPARE=, then the comparison data set is the same as the base data set, and PROC COMPARE compares variables within the data set.

Restriction If you omit COMPARE=, then you must use the WITH and VAR statements.

Tip You can use the WHERE= data set option with COMPARE= to limit the observations that are available for comparison.

CRITERION=γ
specifies the criterion for judging the equality of numeric values. Normally, the value of γ (gamma) is positive. In that case, the number itself becomes the

equality criterion. If you use a negative value for γ, then PROC COMPARE uses an equality criterion proportional to the precision of the computer on which SAS is running.

Default 0.00001

See "The Equality Criterion" on page 424

ERROR
displays an error message in the SAS log when differences are found.

Interaction This option overrides the WARNING option.

FUZZ=*number*
alters the values comparison results for numbers less than *number*. PROC COMPARE prints the following:

- 0 for any variable value that is less than *number*
- a blank for difference or percent difference if it is less than *number*
- 0 for any summary statistic that is less than *number*

Default 0

Range 0 - 1

Tip A report that contains many trivial differences is easier to read in this form.

LISTALL
lists all variables and observations that are found in only one data set.

Alias LIST

Interaction using LISTALL is equivalent to using the following four options: LISTBASEOBS, LISTCOMPOBS, LISTBASEVAR, and LISTCOMPVAR.

LISTBASE
lists all observations and variables that are found in the base data set but not in the comparison data set.

Interaction Using LISTBASE is equivalent to using the LISTBASEOBS and LISTBASEVAR options.

LISTBASEOBS
lists all observations that are found in the base data set but not in the comparison data set.

LISTBASEVAR
lists all variables that are found in the base data set but not in the comparison data set.

LISTCOMP
lists all observations and variables that are found in the comparison data set but not in the base data set.

Interaction Using LISTCOMP is equivalent to using the LISTCOMPOBS and LISTCOMPVAR options.

LISTCOMPOBS
lists all observations that are found in the comparison data set but not in the base data set.

LISTCOMPVAR
lists all variables that are found in the comparison data set but not in the base data set.

LISTEQUALVAR
prints a list of variables whose values are judged equal at all observations in addition to the default list of variables whose values are judged unequal.

LISTOBS
lists all observations that are found in only one data set.

Interaction Using LISTOBS is equivalent to using the LISTBASEOBS and LISTCOMPOBS options.

LISTVAR
lists all variables that are found in only one data set.

Interaction Using LISTVAR is equivalent to using both the LISTBASEVAR and LISTCOMPVAR options.

MAXPRINT=*total* | (*per-variable, total*)
specifies the maximum number of differences to be printed, where

total
is the maximum total number of differences to be printed. The default value is 500 unless you use the ALLOBS option (or both the ALLVAR and TRANSPOSE options). In that case, the default is 32000.

per-variable
is the maximum number of differences to be printed for each variable within a BY group. The default value is 50 unless you use the ALLOBS option (or both the ALLVAR and TRANSPOSE options). In that case, the default is 1000.

The MAXPRINT= option prevents the output from becoming extremely large when data sets differ greatly.

METHOD=ABSOLUTE | EXACT | PERCENT | RELATIVE<(δ)>
specifies the method for judging the equality of numeric values. The constant δ (delta) is a number between 0 and 1 that specifies a value to add to the denominator when calculating the equality measure. By default, δ is 0.

Unless you use the CRITERION= option, the default method is EXACT. If you use the CRITERION= option, then the default method is RELATIVE(ϕ), where ϕ (phi) is a small number that depends on the numerical precision of the computer on which SAS is running and on the value of CRITERION=.

See "The Equality Criterion" on page 424

NODATE
suppresses the display in the data set summary report of the creation dates and the last modified dates of the base and comparison data sets.

NOMISSBASE
(By default, a missing value is equal only to a missing value of the same kind, that is .=., .^=.A, .A=.A, .A^=.B, and so on.)

You can use this option to determine the changes that would be made to the observations in the comparison data set if it were used as the master data set and the base data set were used as the transaction data set in a DATA step UPDATE statement. For information about the UPDATE statement, see "UPDATE" in *SAS DATA Step Statements: Reference*.

NOMISSCOMP
judges a missing value in the comparison data set equal to any value. (By default, a missing value is equal only to a missing value of the same kind, that is .=., .^=.A, .A=.A, .A^=.B, and so on.)

You can use this option to determine the changes that would be made to the observations in the base data set if it were used as the master data set and the comparison data set were used as the transaction data set in a DATA step UPDATE statement. For information about the UPDATE statement, see "UPDATE" in *SAS DATA Step Statements: Reference*.

NOMISSING
judges missing values in both the base and comparison data sets equal to any value. By default, a missing value is equal only to a missing value of the same kind, that is .=., .^=.A, .A=.A, .A^=.B, and so on.

Alias NOMISS

Interaction Using NOMISSING is equivalent to using both NOMISSBASE and NOMISSCOMP.

NOPRINT
suppresses all printed output.

Tip You might want to use this option when you are creating one or more output data sets.

Example "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482

NOSUMMARY
suppresses the data set, variable, observation, and values comparison summary reports.

Tip NOSUMMARY produces no output if there are no differences in the matching values.

Example "Example 2: Comparing Variables in Different Data Sets" on page 470

NOTE
displays notes in the SAS log that describe the results of the comparison, if differences were found.

NOVALUES
suppresses the report of the value comparison results.

Example Overview: COMPARE Procedure on page 420

OUT=*SAS-data-set*
names the output data set. If *SAS-data-set* does not exist, then PROC COMPARE creates it. *SAS-data-set* contains the differences between matching variables.

See "Output Data Set (OUT=)" on page 460

Example "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482

OUTALL
writes an observation to the output data set for each observation in the base data set and for each observation in the comparison data set. The option also writes observations to the output data set that contains the differences and percent differences between the values in matching observations.

Tip Using OUTALL is equivalent to using the following four options: OUTBASE, OUTCOMP, OUTDIF, and OUTPERCENT.

See "Output Data Set (OUT=)" on page 460

OUTBASE
writes an observation to the output data set for each observation in the base data set, creating observations in which _TYPE_=BASE.

See "Output Data Set (OUT=)" on page 460

Example "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482

OUTCOMP
writes an observation to the output data set for each observation in the comparison data set, creating observations in which _TYPE_=COMP.

See "Output Data Set (OUT=)" on page 460

Example "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482

OUTDIF
writes an observation to the output data set for each pair of matching observations. The values in the observation include values for the differences between the values in the pair of observations. The value of _TYPE_ in each observation is DIF.

Default The OUTDIF option is the default unless you specify the OUTBASE, OUTCOMP, or OUTPERCENT option. If you use any of these options, then you must specify the OUTDIF option to create _TYPE_=DIF observations in the output data set.

See "Output Data Set (OUT=)" on page 460

Example "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482

OUTNOEQUAL
suppresses the writing of an observation to the output data set when all values in the observation are judged equal. In addition, in observations containing values for some variables judged equal and others judged unequal, the OUTNOEQUAL option uses the special missing value ".E" to represent differences and percent differences for variables judged equal.

See "Output Data Set (OUT=)" on page 460

Example "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482

OUTPERCENT
writes an observation to the output data set for each pair of matching observations. The values in the observation include values for the percent differences between the values in the pair of observations. The value of _TYPE_ in each observation is PERCENT.

See "Output Data Set (OUT=)" on page 460

OUTSTATS=*SAS-data-set*
writes summary statistics for all pairs of matching variables to the specified *SAS-data-set*.

Tip If you want to print a table of statistics in the procedure output, then use the STATS, ALLSTATS, or PRINTALL option.

See "Output Statistics Data Set (OUTSTATS=)" on page 462

"Table of Summary Statistics" on page 456

Example "Example 7: Creating an Output Data Set of Statistics (OUTSTATS=)" on page 486

PRINTALL
invokes the following options: ALLVARS, ALLOBS, ALLSTATS, LISTALL, and WARNING.

Example "Example 1: Producing a Complete Report of the Differences" on page 463

STATS
prints a table of summary statistics for all pairs of matching numeric variables that are judged unequal.

See "Table of Summary Statistics" on page 456 for information about the statistics produced.

TRANSPOSE
prints the reports of value differences by observation instead of by variable.

Interaction If you also use the NOVALUES option, then the TRANSPOSE option lists only the *names* of the variables whose values are judged unequal for each observation, not the values and differences.

See "Comparison Results for Observations (Using the TRANSPOSE Option)" on page 458.

WARNING
displays a warning message in the SAS log when differences are found.

Interaction The ERROR option overrides the WARNING option.

BY Statement

Produces a separate comparison for each BY group.

See: "BY" on page 74

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then the observations in the data set must be sorted by all the variables that you specify. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The observations are grouped in another way (for example, chronological order).

Note The requirement for ordering observations according to the values of BY variables is suspended for BY-group processing when you use the

NOTSORTED option. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

Details

BY Processing with PROC COMPARE

To use a BY statement with PROC COMPARE, you must sort both the base and comparison data sets by the BY variables. The nature of the comparison depends on whether all BY variables are in the comparison data set and, if they are, whether their attributes match the ones of the BY variables in the base data set. The following table shows how PROC COMPARE behaves under different circumstances:

Table 13.1 *Behavior of PROC COMPARE under Different Circumstances*

Condition	Behavior of PROC COMPARE
All BY variables are in the comparison data set and all attributes match exactly	Compares corresponding BY groups
None of the BY variables are in the comparison data set	Compares each BY group in the base data set with the entire comparison data set
Some BY variables are not in the comparison data set	Writes an error message to the SAS log and terminates
Some BY variables have different types in the two data sets	Writes an error message to the SAS log and terminates

Note: Identical BY values might not compare as equal if they are formatted differently.

ID Statement

Lists variables to use to match observations.

See: "A Comparison with an ID Variable" on page 423

Example: "Example 5: Comparing Observations with an ID Variable" on page 476

Syntax

ID <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to match observations. You can specify more than one variable, but the data set must be sorted by the variable or variables that you specify. These variables are *ID variables*. ID variables also identify observations on the printed reports and in the output data set.

Optional Arguments

DESCENDING
specifies that the data set is sorted in descending order by the variable that immediately follows the word DESCENDING in the ID statement.

If you use the DESCENDING option, then you must sort the data sets. SAS does not use an index to process an ID statement with the DESCENDING option. Further, the use of DESCENDING for ID variables must correspond to the use of the DESCENDING option in the BY statement in the PROC SORT step that was used to sort the data sets.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The data are grouped in another way (for example, chronological order).

See "Comparing Unsorted Data" on page 440

Details

Requirements for ID Variables

- ID variables must be in the BASE= data set or PROC COMPARE stops processing.
- If an ID variable is not in the COMPARE= data set, then PROC COMPARE writes a warning message to the SAS log and does not use that variable to match observations in the comparison data set (but does write it to the OUT= data set).
- ID variables must be of the same type in both data sets.
- You should sort both data sets by the common ID variables (within the BY variables, if any) unless you specify the NOTSORTED option.

Comparing Unsorted Data

If you do not want to sort the data set by the ID variables, then you can use the NOTSORTED option. When you specify the NOTSORTED option, or if the ID statement is omitted, PROC COMPARE matches the observations one-to-one. That is, PROC COMPARE matches the first observation in the base data set with the first observation in the comparison data set, the second with the second, and so on. If you use NOTSORTED, and the ID values of corresponding observations are not the same, then PROC COMPARE prints an error message and stops processing.

If the data sets are not sorted by the common ID variables and if you do not specify the NOTSORTED option, then PROC COMPARE writes a warning message to the SAS log and continues to process the data sets as if you had specified NOTSORTED.

Avoiding Duplicate ID Values

The observations in each data set should be uniquely labeled by the values of the ID variables. If PROC COMPARE finds two successive observations with the same ID values in a data set, then it does the following:

- prints the warning `Duplicate Observations` for the first occurrence for that data set
- prints the total number of duplicate observations found in the data set in the observation summary report
- uses the duplicate observations in the base data set and the comparison data set to compare the observations on a one-to-one basis

When the data sets are not sorted, PROC COMPARE detects only those duplicate observations that occur in succession.

VAR Statement

Restricts the comparison of the values of variables to the ones named in the VAR statement.

Examples: "Example 2: Comparing Variables in Different Data Sets" on page 470
"Example 3: Comparing a Variable Multiple Times" on page 472
"Example 4: Comparing Variables That Are in the Same Data Set" on page 474

Syntax

VAR *variable(s)*;

Required Argument

variable(s)
one or more variables that appear in the BASE= and COMPARE= data sets or only in the BASE= data set.

Details

- If you do not use the VAR statement, then PROC COMPARE compares the values of all matching variables except the ones that appear in BY and ID statements.
- If a variable in the VAR statement does not exist in the COMPARE= data set, then PROC COMPARE writes a warning message to the SAS log and ignores the variable.
- If a variable in the VAR statement does not exist in the BASE= data set, then PROC COMPARE stops processing and writes an error message to the SAS log.
- The VAR statement restricts only the comparison of values of matching variables. PROC COMPARE still reports on the total number of matching variables and compares their attributes. However, it produces neither error nor warning messages about these variables.

WITH Statement

Compares variables in the base data set with variables that have different names in the comparison data set, and compares different variables that are in the same data set.

Restriction: You must use the VAR statement when you use the WITH statement.

Examples: "Example 2: Comparing Variables in Different Data Sets" on page 470
"Example 3: Comparing a Variable Multiple Times" on page 472
"Example 4: Comparing Variables That Are in the Same Data Set" on page 474

Syntax

WITH *variable(s)*;

Required Argument

variable(s)
one or more variables to compare with variables in the VAR statement.

Details

Comparing Selected Variables

If you want to compare variables in the base data set with variables that have different names in the comparison data set, then specify the names of the variables in the base data set in the VAR statement and specify the names of the matching variables in the WITH statement. The first variable that you list in the WITH

statement corresponds to the first variable that you list in the VAR statement, the second with the second, and so on. If the WITH statement list is shorter than the VAR statement list, then PROC COMPARE assumes that the extra variables in the VAR statement have the same names in the comparison data set as they do in the base data set. If the WITH statement list is longer than the VAR statement list, then PROC COMPARE ignores the extra variables.

A variable name can appear any number of times in the VAR statement or the WITH statement. By selecting VAR and WITH statement lists, you can compare the variables in any permutation.

If you omit the COMPARE= option in the PROC COMPARE statement, then you must use the WITH statement. In this case, PROC COMPARE compares the values of variables with different names in the BASE= data set.

Usage: COMPARE Procedure

Customizing PROC COMPARE Output

PROC COMPARE produces lengthy output. You can use one or more options to determine the types of comparisons to make and the degree of detail in the report. For example, in the following PROC COMPARE step, the NOVALUES option suppresses the part of the output that shows the differences in the values of matching variables:

```
options nodate pageno=1 linesize=80 pagesize=40;

title 'The SAS System';

proc compare base=proclib.one
             compare=proclib.two novalues;
run;
```

Output 13.1 *Part One of Comparison of WORK.ONE and WORK.TWO*

The SAS System

```
                        The COMPARE Procedure
                  Comparison of WORK.ONE with WORK.TWO
                             (Method=EXACT)

                          Data Set Summary

Dataset            Created          Modified  NVar    NObs  Label

WORK.ONE   16MAR11:16:43:16  16MAR11:16:43:16     5       4  First Data Set
WORK.TWO   16MAR11:16:43:16  16MAR11:16:43:16     6       5  Second Data Set

                          Variables Summary

            Number of Variables in Common: 5.
            Number of Variables in WORK.TWO but not in WORK.ONE: 1.
            Number of Variables with Conflicting Types: 1.
            Number of Variables with Differing Attributes: 3.
```

```
            Listing of Common Variables with Conflicting Types

                     Variable  Dataset   Type  Length

                     student   WORK.ONE  Num        8
                               WORK.TWO  Char       8

"Procedure Output" on page 449 shows the default output for these two data sets. "Example 1: Producing a Complete Report of the Differences" on page 463 shows the complete output for these two data sets.

Results: COMPARE Procedure

Results Reporting

PROC COMPARE reports the results of its comparisons in the following ways:

- the SAS log
- return codes stored in the automatic macro SYSINFO
- procedure output
- output data sets

SAS Log

When you use the WARNING, PRINTALL, or ERROR option, PROC COMPARE writes a description of the differences to the SAS log.

Macro Return Codes (SYSINFO)

PROC COMPARE stores a return code in the automatic macro variable SYSINFO. The value of the return code provides information about the result of the comparison. By checking the value of SYSINFO after PROC COMPARE has run and before any other step begins, SAS macros can use the results of a PROC COMPARE step to determine what action to take or what parts of a SAS program to execute.

The following table is a key for interpreting the SYSINFO return code from PROC COMPARE. For each of the conditions listed, the associated value is added to the return code if the condition is true. Thus, the SYSINFO return code is the sum of the codes listed in the following table for the applicable conditions:

Table 13.2 *Macro Return Codes*

Bit	Condition	Code	Hexadecimal	Description
1	DSLABEL	1	0001X	Data set labels differ
2	DSTYPE	2	0002X	Data set types differ
3	INFORMAT	4	0004X	Variable has different informat
4	FORMAT	8	0008X	Variable has different format
5	LENGTH	16	0010X	Variable has different length
6	LABEL	32	0020X	Variable has different label
7	BASEOBS	64	0040X	Base data set has observation not in comparison
8	COMPOBS	128	0080X	Comparison data set has observation not in base
9	BASEBY	256	0100X	Base data set has BY group not in comparison
10	COMPBY	512	0200X	Comparison data set has BY group not in base

Bit	Condition	Code	Hexadecimal	Description
11	BASEVAR	1024	0400X	Base data set has variable not in comparison
12	COMPVAR	2048	0800X	Comparison data set has variable not in base
13	VALUE	4096	1000X	A value comparison was unequal
14	TYPE	8192	2000X	Conflicting variable types
15	BYVAR	16384	4000X	BY variables do not match
16	ERROR	32768	8000X	Fatal error: comparison not done

These codes are ordered and scaled to enable a simple check of the degree to which the data sets differ. For example, if you want to check that two data sets contain the same variables, observations, and values, but you do not care about differences in labels, formats, and so on, then use the following statements:

```
proc compare base=SAS-data-set
             compare=SAS-data-set;
run;

%if &sysinfo >= 64 %then
   %do;
      handle error;
   %end;
```

Each time you include SYSINFO in your code, the value for each subsequent instance of SYSINFO is added to the previous value. The final value for SYSINFO is the cumulative value for all of the instances of SYSINFO in the code. For example, if you run the following example code, the first instance of SYSINFO produces a return code of 32, and the second instance produces a return code of 4096. The two values are added together to produce the final return code of 4128.

```
   /*diff label -- RC is 32*/
   data class1;
      set sashelp.class;
      label sex='Gender';
   run;

   data class2;
      set sashelp.class;
   run;

   proc compare base=class1 comp=class2;
   run;

   %let rc=&sysinfo
   %put 'RC' &rc

   /*diff label and value -- RC is 4128*/
   data class1;
```

```
      set sashelp.class;
      label sex='Gender';
   run;
   data class2;
      set sashelp.class;
      if name="Jeffrey" then name="Jeff";
   run;

   proc compare base=class1 comp=class2;
   run;

   %let rc=&sysinfo
   %put 'RC' &rc
```

You can examine individual bits in the SYSINFO value by using DATA step bit-testing features to check for specific conditions. For example, to check for the presence of observations in the base data set that are not in the comparison data set, use the following statements:

```
proc compare base=SAS-data-set
             compare=SAS-data-set;
run;

%let rc=&sysinfo;
data _null_;
   /* Test for data set label */
   if &rc = '1'b then
      put '<<<< Data sets have different labels';
/* Test for data set types */
   if &rc = '1.'b then
      put '<<<< Data set types differ';
/* Test for label */
   if &rc = '1.....'b then
      put '<<<< Variable has different label';
/* Test for base observation */
if &rc = '1......'b then
      put '<<<< Base data set has observation not in comparison data set';
/* Test for length */
   if &rc = '1....'b then
      put '<<<< Variable has different lengths between the base data set
      and the comparison data set';
/* Variable in base data set not in compare data set */
   if &rc ='1..........'b then
      put '<<<< Variable in base data set not found in comparison data set';
/* Comparison data set has variable not in base data set */
   if &rc = '1...........'b then
      put '<<<< Comparison data set has variable not contained in the
      base data set';
/* Test for values */
   if &rc = '1............'b then
      put '<<<< A value comparison was unequal';
/* Conflicting variable types */
   if &rc ='1............'b then
      put '<<<< Conflicting variable types between the two data sets
      being compared';
run;
```

PROC COMPARE must run before you check SYSINFO and you must obtain the SYSINFO value before another SAS step starts because every SAS step resets SYSINFO.

Procedure Output

Procedure Output Overview

The following sections show and describe the default output of the two data sets shown in Overview: COMPARE Procedure on page 420. Because PROC COMPARE produces lengthy output, the output is presented in seven pieces.

```
options nodate pageno=1 linesize=80 pagesize=60;
proc compare base=proclib.one compare=proclib.two;
  run;
```

Data Set Summary

This report lists the attributes of the data sets that are being compared. These attributes include the following:

- the data set names
- the data set types, if any
- the data set labels, if any
- the dates created and last modified
- the number of variables in each data set
- the number of observations in each data set

To view the Data Set Summary, see Output 13.65 on page 451.

Note: The COMPARE procedure omits data set labels if the line size is too small for them.

Variables Summary

This report compares the variables in the two data sets. The first part of the report lists the following:

- the number of variables the data sets have in common

- the number of variables in the base data set that are not in the comparison data set and vice versa
- the number of variables in both data sets that have different types
- the number of variables that differ on other attributes (length, label, format, or informat)
- the number of BY, ID, VAR, and WITH variables specified for the comparison

The second part of the report lists matching variables with different attributes and shows how the attributes differ. (The COMPARE procedure omits variable labels if the line size is too small for them.)

The following output shows the Data Set Summary and the Variables Summary.

Output 13.4 *Partial Output Showing the Data Set Summary and Variables Summary*

The SAS System

```
                        The COMPARE Procedure

```

Observation Summary

This report provides information about observations in the base and comparison data sets. First of all, the report identifies the first and last observation in each data set, the first and last matching observations, and the first and last different observations. Then, the report lists the following:

- the number of observations that the data sets have in common

- the number of observations in the base data set that are not in the comparison data set and vice versa
- the total number of observations in each data set
- the number of matching observations for which PROC COMPARE judged some variables unequal
- the number of matching observations for which PROC COMPARE judged all variables equal

The following output shows the Observation Summary.

Output 13.5 *Partial Output Showing the Observation Summary*

```
                        Observation Summary

                    Observation      Base  Compare

Number of Observations in Common: 4.
Number of Observations in WORK.TWO but not in WORK.ONE: 1.
Total Number of Observations Read from WORK.ONE: 4.
Total Number of Observations Read from WORK.TWO: 5.

Number of Observations with Some Compared Variables Unequal: 4.
Number of Observations with All Compared Variables Equal: 0.
```

Values Comparison Summary

This report first lists the following:

- the number of variables compared with all observations equal
- the number of variables compared with some observations unequal
- the number of variables with differences involving missing values, if any
- the total number of values judged unequal
- the maximum difference measure between unequal values for all pairs of matching variables (for differences not involving missing values)

In addition, for the variables for which some matching observations have unequal values, the report lists the following:

- the name of the variable
- other variable attributes
- the number of times PROC COMPARE judged the variable unequal

- the maximum difference measure found between values (for differences not involving missing values)
- the number of differences caused by comparison with missing values, if any

The following output shows the Values Comparison Summary.

Output 13.6 *Partial Output Showing the Values Comparison Summary*

The SAS System

```
                        The COMPARE Procedure
                Comparison of WORK.ONE with WORK.TWO
                            (Method=EXACT)

                     Values Comparison Summary

Number of Variables Compared with All Observations Equal: 1.
Number of Variables Compared with Some Observations Unequal: 3.

state     CHAR    8   Home State        2
gr1       NUM     8                     2    1.000
gr2       NUM     8                     2   20.000
```

Value Comparison Results

This report consists of a table for each pair of matching variables judged unequal at one or more observations.

Note:

- When it is comparing character values, PROC COMPARE displays only the first 20 characters. When you use the TRANSPOSE option, PROC COMPARE displays only the first 12 characters.

  If you are comparing character values, in the output PROC COMPARE displays a plus sign at the end of a character string that is longer than 20 characters. If you specify the TRANSPOSE option PROC COMPARE displays a plus sign in the output at the end of a character string that is longer than 12 characters. In both instances, the plus sign appears in the table-cell border above the character string. Here is an example.

```
                The COMPARE Procedure
            Comparison of WORK.X with WORK.Y
                   (Method=EXACT)

          Value Comparison Results for Variables

__________________________________________________________
          ||  Base Value            Compare Value
      Obs ||  x                      x
 ________ ||  ___________________+  ___________________+
          ||
        1 ||  12345678901234567890  12345678901234567890
__________________________________________________________
```

Note: The plus sign is displayed at the end of the border above the character string.

- If you do not specify an adequate value for the LINESIZE option, SAS might write a warning that indicates the LINESIZE value is too small to print all of the ID variables in the value comparison reports. PROC COMPARE reserves space for the value section based on the formatted width of the data values. The rest of the space is available for ID values. The character ID values use the width that is specified by their format, and numeric variables use approximately 10 spaces.

Each table shows the following:

- the number of the observation or, if you use the ID statement, the values of the ID variables
- the value of the variable in the base data set
- the value of the variable in the comparison data set
- the difference between these two values (numeric variables only)
- the percent difference between these two values (numeric variables only)

The following output shows the Value Comparison Results for Variables.

Output 13.7 *Partial Output Showing the Value Comparison Results for Variables*

Value Comparison Results for Variables

Obs	Home State Base Value state	Compare Value state
2	MD	MA
4	MA	MD

Obs	Base gr1	Compare gr1	Diff.	% Diff
1	85.0	84.00	-1.0000	-1.1765
3	78.0	79.00	1.0000	1.2821

Obs	Base gr2	Compare gr2	Diff.	% Diff
3	72.0000	73.0000	1.0000	1.3889
4	94.0000	74.0000	-20.0000	-21.2766

You can suppress the value comparison results with the NOVALUES option. If you use both the NOVALUES and TRANSPOSE options, then PROC COMPARE lists for each observation the names of the variables with values judged unequal but does not display the values and differences.

The display limits of PROC COMPARE and the TRANSPOSE option apply only to the printed output generated by PROC COMPARE. To see the entire value, you have to use the following options to create an output data set with PROC COMPARE:

- OUT= specifies the name of the output data set.
- OUTNOEQUAL suppresses writing observations where all variables match.
- OUTBASE and OUTCOMP include the observations from the BASE= and COMPARE= data sets.
- NOPRINT suppresses the default printed reports.

The following example produces a Differences data set and then runs PROC PRINT.

```
data x;
a='aaaaaaaaaaaaaaaaaaaaa';
```

```
data y;
a='aaaaaaaaaaaaaaaaaaaab';
run;
proc compare base=x comp=y out=dif outbase outcomp outdif outnoequal;
run;
proc print data=dif;
run;
```

Figure 13.3 *Differences Data Set*

The SAS System

Obs	_TYPE_	_OBS_	a
1	BASE	1	aaaaaaaaaaaaaaaaaaaaa
2	COMPARE	1	aaaaaaaaaaaaaaaaaaaab
3	DIF	1	X

Table of Summary Statistics

If you use the STATS, ALLSTATS, or PRINTALL option, then the Value Comparison Results for Variables section contains summary statistics for the numeric variables that are being compared. The STATS option generates these statistics for only the numeric variables whose values are judged unequal. The ALLSTATS and PRINTALL options generate these statistics for all numeric variables, even if all values are judged equal. Here is the formula that is used to generate the statistics for the ALLSTATS section.

```
(ystat-xstat)/x*100
```

Note: In all cases PROC COMPARE calculates the summary statistics based on all matching observations that do not contain missing values, not just on those containing unequal values.

The following output shows the following summary statistics for base data set values, comparison data set values, differences, and percent differences:

N
: the number of nonmissing values.

  Note: The value of the N statistic is always the count of nonmissing observations for all four of the columns in the output. The Diff and %Diff columns do not perform any calculations on the N statistic.

MEAN
: the mean, or average, of the values.

STD
: the standard deviation.

MAX
the maximum value.

MIN
the minimum value.

MISSDIFF
the number of missing values in either a base or compare data set.

STDERR
the standard error of the mean.

T
the T ratio (MEAN/STDERR).

PROB> | T |
the probability of a greater absolute T value if the true population mean is 0.

NDIF
the number of matching observations judged unequal, and the percent of the matching observations that were judged unequal.

DIFMEANS
the difference between the mean of the base values and the mean of the comparison values. This line contains three numbers. The first is the mean expressed as a percentage of the base values mean. The second is the mean expressed as a percentage of the comparison values mean. The third is the difference in the two means (the comparison mean minus the base mean).

R
the correlation of the base and comparison values for matching observations that are nonmissing in both data sets.

RSQ
the square of the correlation of the base and comparison values for matching observations that are nonmissing in both data sets.

The following output is from the ALLSTATS option using the two data sets shown in Overview: COMPARE Procedure on page 420.:

```
options nodate pageno=1
   linesize=80 pagesize=60;
proc compare base=proclib.one
     compare=proclib.two allstats;
   title 'Comparing Two Data Sets: Default Report';
run;
```

Output 13.8 *Partial Output Showing Value Comparison Results for Variables*

Value Comparison Results for Variables

Obs	Home State Base Value state	Compare Value state
2	MD	MA
4	MA	MD

Obs	Base gr1	Compare gr1	Diff.	% Diff
1	85.0	84.00	-1.0000	-1.1765
3	78.0	79.00	1.0000	1.2821
N	4	4	4	4
Mean	85.5000	85.5000	0	0.0264
Std	5.8023	5.4467	0.8165	1.0042
Max	92.0000	92.0000	1.0000	1.2821
Min	78.0000	79.0000	-1.0000	-1.1765
StdErr	2.9011	2.7234	0.4082	0.5021
t	29.4711	31.3951	0.0000	0.0526
Prob>|t|	<.0001	<.0001	1.0000	0.9614
Ndif	2	50.000%		
DifMeans	0.000%	0.000%	0	
r, rsq	0.991	0.983		

Note: If you use a wide line size with PRINTALL, then PROC COMPARE prints the value comparison result for character variables next to the result for numeric variables. In that case, PROC COMPARE calculates only NDIF for the character variables.

Comparison Results for Observations (Using the TRANSPOSE Option)

The TRANSPOSE option prints the comparison results by observation instead of by variable. The comparison results precede the observation summary report. By

default, the source of the values for each row of the table is indicated by the following label:

```
_OBS_1=number-1  _OBS_2=number-2
```

where *number-1* is the number of the observation in the base data set for which the value of the variable is shown, and *number-2* is the number of the observation in the comparison data set.

The following output shows the differences in PROCLIB.ONE and PROCLIB.TWO by observation instead of by variable.

```
options nodate pageno=1
   linesize=80 pagesize=60;
proc compare base=proclib.one
     compare=proclib.two transpose;
   title 'Comparing Two Data Sets: Default Report';
run;
```

Output 13.9 *Partial Output Showing Comparison Results for Observations*

Comparing Two Data Sets: Default Report

```
                        The COMPARE Procedure
                  Comparison of WORK.ONE with WORK.TWO
                              (Method=EXACT)

                  Comparison Results for Observations

_OBS_1=3 _OBS_2=3:
Variable    Base Value       Compare         Diff.        % Diff
     gr1          78.0         79.00      1.000000      1.282051
     gr2     72.000000     73.000000      1.000000      1.388889

_OBS_1=4 _OBS_2=4:
Variable    Base Value       Compare         Diff.        % Diff
     gr2     94.000000     74.000000    -20.000000    -21.276596
   state            MA            MD
```

If you use an ID statement, then the identifying label has the following form:

```
ID-1=ID-value-1 ... ID-n=ID-value-n
```

where *ID* is the name of an ID variable and *ID-value* is the value of the ID variable.

Note: When you use the TRANSPOSE option, PROC COMPARE prints only the first 12 characters of the value.

ODS Table Names

The COMPARE procedure assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS)

to select tables and create output data sets. For more information, see *SAS Output Delivery System: User's Guide*.

Table 13.3 *ODS Tables Produced by the COMPARE Procedure*

Table Name	Description	Conditions When Table Is Generated
CompareData sets	Information about the data set or data sets	By default, unless NOSUMMARY or NOVALUES option is specified
CompareDetails (Comparison Results for Observations)	A listing of observations that the base data set and the compare data set do not have in common	If PRINTALL option is specified
CompareDetails (ID variable notes and warnings)	A listing of notes and warnings concerning duplicate ID variable values	If ID statement is specified and duplicate ID variable values exist in either data set
CompareDifferences	A report of variable value differences	By default unless NOVALUES option is specified
CompareSummary	Summary report of observations, values, and variables with unequal values	By default
CompareVariables	A listing of differences in variable types or attributes between the base data set and the compare data set	By default, unless the variables are identical or the NOSUMMARY option is specified

Note: The ODS output tables contain the same information as that written to the Output window. These tables do not contain any additional information, and they do not provide a different format for the information. The ODS output tables might be of some use to you, but it depends on the task that you are performing. For an example of the format produced in the Output window, see the outputs in "Customizing PROC COMPARE Output" on page 442.

Output Data Set (OUT=)

By default, the OUT= data set contains an observation for each pair of matching observations. The OUT= data set contains the following variables from the data sets you are comparing:

- all variables named in the BY statement

- all variables named in the ID statement
- all matching variables or, if you use the VAR statement, all variables listed in the VAR statement

In addition, the data set contains two variables created by PROC COMPARE to identify the source of the values for the matching variables: _TYPE_ and _OBS_.

TYPE
is a character variable of length 8. Its value indicates the source of the values for the matching (or VAR) variables in that observation. (For ID and BY variables, which are not compared, the values are the values from the original data sets.) _TYPE_ has the label `Type of Observation`. The four possible values of this variable are as follows:

BASE
the values in this observation are from an observation in the base data set. PROC COMPARE writes this type of observation to the OUT= data set when you specify the OUTBASE option.

COMPARE
the values in this observation are from an observation in the comparison data set. PROC COMPARE writes this type of observation to the OUT= data set when you specify the OUTCOMP option.

DIF
the values in this observation are the differences between the values in the base and comparison data sets.

For character variables, PROC COMPARE uses a period (.) to represent equal characters and an X to represent unequal characters.

For numeric variables, an E means that there is no difference. Otherwise, the numeric difference is shown.

PROC COMPARE writes this type of observation to the OUT= data set by default. However, if you request any other type of observation with the OUTBASE, OUTCOMP, or OUTPERCENT option, then you must specify the OUTDIF option to generate observations of this type in the OUT= data set.

For an example output that shows the use of the period, X, and E to represent equal and different values, see "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482.

PERCENT
the values in this observation are the percent differences between the values in the base and comparison data sets. For character variables the values in observations of type PERCENT are the same as the values in observations of type DIF.

OBS
is a numeric variable that contains a number further identifying the source of the OUT= observations.

For observations with _TYPE_ equal to BASE, _OBS_ is the number of the observation in the base data set from which the values of the VAR variables were copied. Similarly, for observations with _TYPE_ equal to COMPARE, _OBS_ is the number of the observation in the comparison data set from which the values of the VAR variables were copied.

For observations with _TYPE_ equal to DIF or PERCENT, _OBS_ is a sequence number that counts the matching observations in the BY group.

OBS has the label `Observation Number`.

The COMPARE procedure takes variable names and attributes for the OUT= data set from the base data set except for the length of the VAR variable. The COMPARE procedure uses the longer length for the VAR variable regardless of which data set contains that length is from. This behavior has two important repercussions:

- If you use the VAR and WITH statements, then the names of the variables in the OUT= data set come from the VAR statement. Thus, observations with _TYPE_ equal to `BASE` contain the values of the VAR variables, whereas observations with _TYPE_ equal to `COMPARE` contain the values of the WITH variables.
- If you include a variable more than once in the VAR statement in order to compare it with more than one variable, then PROC COMPARE can include only the first comparison in the OUT= data set because each variable must have a unique name. Other comparisons produce warning messages.

For an example of the OUT= option, see "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482.

Output Statistics Data Set (OUTSTATS=)

When you use the OUTSTATS= option, PROC COMPARE calculates the same summary statistics as the ALLSTATS option for each pair of numeric variables that are compared. For more information, see "Table of Summary Statistics" on page 456). The OUTSTATS= data set contains an observation for each summary statistic for each pair of variables. The data set also contains the BY variables used in the comparison and several variables created by PROC COMPARE:

VAR
is a character variable that contains the name of the variable from the base data set for which the statistic in the observation was calculated.

WITH
is a character variable that contains the name of the variable from the comparison data set for which the statistic in the observation was calculated. The _WITH_ variable is not included in the OUTSTATS= data set unless you use the WITH statement.

TYPE
is a character variable that contains the name of the statistic contained in the observation. Values of the _TYPE_ variable are `N`, `MEAN`, `STD`, `MIN`, `MAX`, `STDERR`, `T`, `PROBT`, `NDIF`, `DIFMEANS`, and `R`, `RSQ`.

BASE
is a numeric variable that contains the value of the statistic calculated from the values of the variable named by _VAR_ in the observations in the base data set with matching observations in the comparison data set.

COMP
is a numeric variable that contains the value of the statistic calculated from the values of the variable named by the _VAR_ variable (or by the _WITH_ variable if you use the WITH statement) in the observations in the comparison data set with matching observations in the base data set.

DIF
is a numeric variable that contains the value of the statistic calculated from the differences of the values of the variable named by the _VAR_ variable in the base data set and the matching variable (named by the _VAR_ or _WITH_ variable) in the comparison data set.

PCTDIF
is a numeric variable that contains the value of the statistic calculated from the percent differences of the values of the variable named by the _VAR_ variable in the base data set and the matching variable (named by the _VAR_ or _WITH_ variable) in the comparison data set.

Note: For both types of output data sets, PROC COMPARE assigns one of the following data set labels:

```
Comparison of base-SAS-data-set
with comparison-SAS-data-set

Comparison of variables in base-SAS-data-set
```

Labels are limited to 40 characters.

See "Example 7: Creating an Output Data Set of Statistics (OUTSTATS=)" on page 486 for an example of an OUTSTATS= data set.

Examples: COMPARE Procedure

Example 1: Producing a Complete Report of the Differences

Features: PROC COMPARE statement options
BASE=
PRINTALL
COMPARE=

Data set: Proclib.One, Proclib.Two

Details

This example shows the most complete report that PROC COMPARE produces as procedure output.

Program

```
libname proclib 'SAS-library';

options nodate pageno=1 linesize=80 pagesize=40;

proc compare base=proclib.one compare=proclib.two printall;
   title 'Comparing Two Data Sets: Full Report';
run;
```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib 'SAS-library';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Create a complete report of the differences between two data sets. BASE= and COMPARE= specify the data sets to compare. PRINTALL prints a full report of the differences.

```
proc compare base=proclib.one compare=proclib.two printall;
   title 'Comparing Two Data Sets: Full Report';
run;
```

Output: HTML

A > in the output marks information that is in the full report but not in the default report. The additional information includes a listing of variables found in one data set but not the other, a listing of observations found in one data set but not the other, a listing of variables with all equal values, and summary statistics. For an explanation of the statistics, see “Table of Summary Statistics” on page 456.

Output 13.10 *Part One of Comparing Two Data Sets: Full Report*

Comparing Two Data Sets: Full Report

```

Example 2: Comparing Variables in Different Data Sets

Features: PROC COMPARE statement option NOSUMMARY
VAR statement
WITH statement

Data set: Proclib.One, Proclib.Two

Details

This example compares a variable from the base data set with a variable in the comparison data set. All summary reports are suppressed.

Program

```
libname proclib 'SAS-library';

options nodate pageno=1 linesize=80 pagesize=40;

proc compare base=proclib.one compare=proclib.two nosummary;

   var gr1;
   with gr2;
   title 'Comparison of Variables in Different Data Sets';
run;
```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib 'SAS-library';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Suppress all summary reports of the differences between two data sets. BASE= specifies the base data set and COMPARE= specifies the comparison data set. NOSUMMARY suppresses all summary reports.

```
proc compare base=proclib.one compare=proclib.two nosummary;
```

Specify one variable from the base data set to compare with one variable from the comparison data set. The VAR and WITH statements specify the variables to compare. This example compares GR1 from the base data set with GR2 from the comparison data set.

```
   var gr1;
   with gr2;
   title 'Comparison of Variables in Different Data Sets';
run;
```

Output: HTML

Output 13.16 *Comparison of Variables in Different Data Sets*

Comparison of Variables in Different Data Sets

```
                        The COMPARE Procedure
                    Comparison of WORK.ONE with WORK.TWO
                              (Method=EXACT)

NOTE: Data set WORK.TWO contains 1 observations not in WORK.ONE.
NOTE: Values of the following 1 variables compare unequal: gr1^=gr2
```

Value Comparison Results for Variables

Obs	Base gr1	Compare gr2	Diff.	% Diff
1	85.0	87.0000	2.0000	2.3529
3	78.0	73.0000	-5.0000	-6.4103
4	87.0	74.0000	-13.0000	-14.9425

Example 3: Comparing a Variable Multiple Times

Features: VAR statement
WITH statement

Data set: Proclib.One, Proclib.Two

Details

This example compares one variable from the base data set with two variables in the comparison data set.

Program

```
libname proclib 'SAS-library';
options nodate pageno=1 linesize=80 pagesize=40;
```

```
proc compare base=proclib.one compare=proclib.two nosummary;
   var gr1 gr1;
   with gr1 gr2;
   title 'Comparison of One Variable with Two Variables';
run;
```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib 'SAS-library';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Suppress all summary reports of the differences between two data sets. BASE= specifies the base data set and COMPARE= specifies the comparison data set. NOSUMMARY suppresses all summary reports.

```
proc compare base=proclib.one compare=proclib.two nosummary;
```

Specify one variable from the base data set to compare with two variables from the comparison data set. The VAR and WITH statements specify the variables to compare. This example compares GR1 from the base data set with GR1 and GR2 from the comparison data set.

```
   var gr1 gr1;
   with gr1 gr2;
   title 'Comparison of One Variable with Two Variables';
run;
```

Output: HTML

The Value Comparison Results section shows the result of the comparison.

Output 13.17 *Comparison of One Variable with Two Variables*

Comparison of One Variable with Two Variables

```
                        The COMPARE Procedure
                   Comparison of WORK.ONE with WORK.TWO
                              (Method=EXACT)

NOTE: Data set WORK.TWO contains 1 observations not in WORK.ONE.
NOTE: Values of the following 2 variables compare unequal: gr1^=gr1 gr1^=gr2
```

Value Comparison Results for Variables

Obs	Base gr1	Compare gr1	Diff.	% Diff
1	85.0	84.00	-1.0000	-1.1765
3	78.0	79.00	1.0000	1.2821

Obs	Base gr1	Compare gr2	Diff.	% Diff
1	85.0	87.0000	2.0000	2.3529
3	78.0	73.0000	-5.0000	-6.4103
4	87.0	74.0000	-13.0000	-14.9425

Example 4: Comparing Variables That Are in the Same Data Set

Features: PROC COMPARE statement options
- ALLSTATS
- BRIEFSUMMARY

VAR statement

WITH statement

Data set: Proclib.One

Details

This example shows that PROC COMPARE can compare two variables that are in the same data set.

Program

```
libname proclib 'SAS-library';

options nodate pageno=1 linesize=80 pagesize=40;

proc compare base=proclib.one allstats briefsummary;

   var gr1;
   with gr2;
   title 'Comparison of Variables in the Same Data Set';
run;
```

Program Description

Declare the Proclib SAS library.

```
libname proclib 'SAS-library';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Create a short summary report of the differences within one data set. ALLSTATS prints summary statistics. BRIEFSUMMARY prints only a short comparison summary.

```
proc compare base=proclib.one allstats briefsummary;
```

Specify two variables from the base data set to compare. The VAR and WITH statements specify the variables in the base data set to compare. This example compares GR1 with GR2. Because there is no comparison data set, the variables GR1 and GR2 must be in the base data set.

```
   var gr1;
   with gr2;
   title 'Comparison of Variables in the Same Data Set';
run;
```

Output: HTML

Output 13.18 *Comparison of One Variable with Two Variables*

Comparison of One Variable with Two Variables

```
                        The COMPARE Procedure
                    Comparisons of variables in WORK.ONE
                              (Method=EXACT)

NOTE: Values of the following 1 variables compare unequal: gr1^=gr2
```

Value Comparison Results for Variables

r, rsq	0.898	0.807		

Example 5: Comparing Observations with an ID Variable

Features: ID statement

Data sets: Proclib.Emp95
Proclib.Emp96

Details

In this example, PROC COMPARE compares only the observations that have matching values for the ID variable.

Program

```
libname proclib 'SAS-library';

options nodate pageno=1 linesize=80 pagesize=40;

data proclib.emp95;
   input #1 idnum $4. @6 name $15.

```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib 'SAS-library';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Create the Proclib.Emp95 and Proclib.Emp96 data sets. Proclib.Emp95 and Proclib.Emp96 contain employee data. IDNUM works well as an ID variable because it has unique values. The first DATA step creates Proclib.Emp95. The second DATA step creates Proclib.Emp96.

```
data proclib.emp95;
   input #1 idnum $4. @6 name $15.
         #2 address $42.
         #3 salary 6.;
   datalines;

6544 Roger Monday
```

```
3004 Crepe Myrtle Court Raleigh NC 27604
47007
;
```

Sort the data sets by the ID variable. Both data sets must be sorted by the variable that will be used as the ID variable in the PROC COMPARE step. OUT= specifies the location of the sorted data.

```
proc sort data=proclib.emp95 out=emp95_byidnum;

 by idnum;
run;

proc sort data=proclib.emp96 out=emp96_byidnum;
   by idnum;
run;
```

Create a summary report that compares observations with matching values for the ID variable. The ID statement specifies IDNUM as the ID variable.

```
proc compare base=emp95_byidnum compare=emp96_byidnum;
   id idnum;
   title 'Comparing Observations that Have Matching IDNUMs';
run;
```

Output: HTML

PROC COMPARE identifies specific observations by the value of IDNUM. In the `Value Comparison Results for Variables` section, PROC COMPARE prints the nonmatching addresses and nonmatching salaries. For salaries, PROC COMPARE computes the numerical difference and the percent difference. Because ADDRESS is a character variable, PROC COMPARE displays only the first 20 characters. For addresses where the observation has an IDNUM of `0987`, `2776`, or `3888`, the differences occur after the 20th character and the differences do not appear in the output. The plus sign in the output indicates that the full value is not shown. To see the entire value, create an output data set. See "Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)" on page 482.

Output 13.19 *Part One of Comparing Observations That Have Matching IDNUMs*

Example 6: Comparing Values of Observations Using an Output Data Set (OUT=)

Features: PROC COMPARE statement options
- NOPRINT
- OUT=
- OUTBASE
- OUTCOMP
- OUTDIF
- OUTNOEQUAL

PRINT procedure

Data sets: Proclib.Emp95
Proclib.Emp96

Details

This example creates and prints an output data set that shows the differences between matching observations.

In "Example 5: Comparing Observations with an ID Variable" on page 476, the output does not show the differences past the 20th character. The output data set in this example shows the full values. Further, it shows the observations that occur in only one of the data sets.

Program

```
libname proclib 'SAS-library';

options nodate pageno=1 linesize=120 pagesize=40;

proc sort data=proclib.emp95 out=emp95_byidnum;

 by idnum;
run;

proc sort data=proclib.emp96 out=emp96_byidnum;
   by idnum;
run;

proc compare base=emp95_byidnum compare=emp96_byidnum

             out=result outnoequal outbase outcomp outdif
     noprint;

   id idnum;
run;

proc print data=result noobs;
   by idnum;
   id idnum;
   title 'The Output Data Set RESULT';
run;
```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib 'SAS-library';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=120 pagesize=40;
```

Sort the data sets by the ID variable. Both data sets must be sorted by the variable that will be used as the ID variable in the PROC COMPARE step. OUT= specifies the location of the sorted data.

```
proc sort data=proclib.emp95 out=emp95_byidnum;

 by idnum;
run;

proc sort data=proclib.emp96 out=emp96_byidnum;
   by idnum;
run;
```

Specify the data sets to compare. BASE= and COMPARE= specify the data sets to compare.

```
proc compare base=emp95_byidnum compare=emp96_byidnum
```

Create the Result output data set and include all unequal observations and their differences. OUT= names and creates the output data set. NOPRINT suppresses the printing of the procedure output. OUTNOEQUAL includes only observations that are judged unequal. OUTBASE writes an observation to the output data set for each observation in the base data set. OUTCOMP writes an observation to the output data set for each observation in the comparison data set. OUTDIF writes an observation to the output data set that contains the differences between the two observations.

```
                out=result outnoequal outbase outcomp outdif
      noprint;
```

Specify the ID variable. The ID statement specifies IDNUM as the ID variable.

```
   id idnum;
run;
```

Print the Result output data set and use the BY and ID statements with the ID variable. PROC PRINT prints the output data set. Using the BY and ID statements with the same variable makes the output easy to read. See the PRINT procedure for more information about this technique.

```
proc print data=result noobs;
   by idnum;
   id idnum;
   title 'The Output Data Set RESULT';
run;
```

Output: HTML

The differences for character variables are noted with an X or a period (.). An X shows that the characters do not match. A period shows that the characters do match. For numeric variables, an E means that there is no difference. Otherwise, the numeric difference is shown. By default, the output data set shows that two observations in the comparison data set have no matching observation in the base data set. You do not have to use an option to make those observations appear in the output data set.

Output 13.22 *Part One of the Output Data Set RESULT*

Example 7: Creating an Output Data Set of Statistics (OUTSTATS=)

Features: PROC COMPARE statement options
NOPRINT
OUTSTATS=

Data sets: Proclib.Emp95
Proclib.Emp96

Details

This example creates an output data set that contains summary statistics for the numeric variables that are compared.

Program

```
libname proclib 'SAS-library';

options nodate pageno=1 linesize=80 pagesize=40;

proc sort data=proclib.emp95 out=emp95_byidnum;
   by idnum;
run;

proc sort data=proclib.emp96 out=emp96_byidnum;
   by idnum;
run;

proc compare base=emp95_byidnum compare=emp96_byidnum
             outstats=diffstat noprint;
   id idnum;
run;

proc print data=diffstat noobs;
   title 'The DIFFSTAT Data Set';
run;
```

Program Description

Declare the Proclib SAS library.

```
libname proclib 'SAS-library';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Sort the data sets by the ID variable. Both data sets must be sorted by the variable that will be used as the ID variable in the PROC COMPARE step. OUT= specifies the location of the sorted data.

```
proc sort data=proclib.emp95 out=emp95_byidnum;
   by idnum;
run;

proc sort data=proclib.emp96 out=emp96_byidnum;
   by idnum;
run;
```

Create the output data set of statistics and compare observations that have matching values for the ID variable. BASE= and COMPARE= specify the data sets to compare. OUTSTATS= creates the output data set Diffstat.Noprint and suppresses the procedure output. The ID statement specifies IDNUM as the ID variable. PROC COMPARE uses the values of IDNUM to match observations.

```
proc compare base=emp95_byidnum compare=emp96_byidnum
             outstats=diffstat noprint;
   id idnum;
run;
```

Print the output data set Diffstat. PROC PRINT prints the output data set Diffstat.

```
proc print data=diffstat noobs;
   title 'The DIFFSTAT Data Set';
run;
```

Output: HTML

The variables are described in "Output Statistics Data Set (OUTSTATS=)" on page 462.

Output 13.24 *The Diffstat Data Set*

The DIFFSTAT Data Set

CONTENTS Procedure

Overview: CONTENTS Procedure

What Does the CONTENTS Procedure Do?

The CONTENTS procedure shows the contents of a SAS data set and prints the directory of the SAS library.

Generally, the CONTENTS procedure functions the same as the CONTENTS statement in the DATASETS procedure. The differences between the CONTENTS procedure and the CONTENTS statement in PROC DATASETS are as follows:

- The default for *libref* in the DATA= option in PROC CONTENTS is Work. For the CONTENTS statement, the default is the libref of the procedure input library.

- PROC CONTENTS can read sequential files. The CONTENTS statement cannot.

Concepts: CONTENTS Procedure

Concepts: CONTENTS Procedure

See Concepts for the CONTENTS Statement on page 603.

PROC CONTENTS reports metadata about the table and the metadata about the variables. The CAS engine is the only engine supporting VARCHAR. If there is a VARCHAR data type in the table, PROC CONTENTS shows the Length in bytes and characters as well as maximum bytes used.

Just like with Base engine data sets, the top portion of PROC CONTENTS reports the information about the table. The Encoding shows the encoding of the CAS table. The same for the Data Representation.

The bottom portion of PROC CONTENTS (related to the variable metadata reports) is the metadata that is represented in the SAS session. Based on what type of transcoding that might or might not be needed to go from the CAS UTF–8 encoding to the SAS session encoding, The variable byte length used in the SAS session may differ from the byte length in the CAS table depending on the encoding of the SAS session.

Output 14.1 *Output of Mycas.French2 with VARCHAR*

Data Set Name	MYCAS.FRENCH2	Observations	11
Member Type	DATA	Variables	2
Engine	CAS	Indexes	0
Created	08/16/2017 18:05:10	Observation Length	40
Last Modified	08/16/2017 18:05:10	Deleted Observations	0
Protection		Compressed	NO
Data Set Type		Sorted	NO
Label			
Data Representation	SOLARIS_X86_64, LINUX_X86_64, ALPHA_TRU64, LINUX_IA64		
Encoding	utf-8 Unicode (UTF-8)		

Engine/Host Dependent Information	
Data Limit	100MB
Caslib	CASUSER,
Scope	Session

Alphabetic List of Variables and Attributes					
#	Variable	Type	Len		Max Bytes Used
			Bytes	Chars	
1	nterm	Varchar	80	20	19
2	term	Char	19		

The following PROC CONTENTS shows the output from the Hadoop engine.

Output 14.2 *PROC CONTENTS for the Hadoop Engine*

The CONTENTS Procedure

Data Set Name	X.CLASS	Observations	.
Member Type	DATA	Variables	5
Engine	HADOOP	Indexes	0
Created	.	Observation Length	0
Last Modified	.	Deleted Observations	0
Protection		Compressed	NO
Data Set Type		Sorted	NO
Label			
Data Representation	Default		
Encoding	Default		

Engine/Host Dependent Information	
Table Type	MANAGED_TABLE
Location	hdfs://hdp26p1/apps/hive/warehouse/accesstesting.db/class
SerDe Library	org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe
Input Format	org.apache.hadoop.mapred.TextInputFormat
Output Format	org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat

Alphabetic List of Variables and Attributes

#	Variable	Type	Len	Format	Informat	Label
3	age	Num	8			age
4	height	Num	8			height
1	name	Char	8	$8.	$8.	name
2	sex	Char	1	$1.	$1.	sex
5	weight	Num	8			weight

CAUTION

Do not confuse the GENNUM variable value in CONTENTS' OUT= data set with the GEN variable value from DICTIONARY tables. GENNUM from a CONTENTS procedure or statement refers to a specific generation of a data set. GEN from DICTIONARY tables refers to the total number of generations for a data set. Each SAS procedure is designed and architected to deliver specific information. The output from DICTIONARY.TABLES and PROC CONTENTS are not interchangeable.

Syntax: CONTENTS Procedure

Restrictions: You cannot use the WHERE option to affect the output because PROC CONTENTS does not process any observations.

When a SAS data file reaches the maximum observation count, SAS procedures that return an observation count (such as the PRINT procedure or the CONTENTS procedure) return a missing value, which is represented by a period (.), for the number of observations. For more information, see "Understanding the Observation Count in a SAS Data File" in *SAS Language Reference: Concepts*.

When using a SAS/ACCESS LIBNAME engine to access a database, some of the information that is available in the header of a SAS data set is not available. Procedures like CONTENTS and DATASETS don't query the system tables so indexes, integrity constraints, number of observations, and so on will not be displayed. For more information, see "Differences in the DATASETS Procedure Output When Using SAS/ACCESS LIBNAME Engines" on page 572.

Note: The ATTRIB statement does not affect the PROC CONTENTS output. PROC CONTENTS reports the labels, informats, and formats on the actual member.

Tips: Complete documentation for the CONTENTS procedure is in CONTENTS Statement on page 603. The links in the table below are to the DATASETS procedure documentation, which explains these options.

When using PROC CONTENTS, you can use data set options with the DATA=, OUT=, and OUT2= options.

The ORDER= option does not affect the order of the OUT= and OUT2= data sets.

See: CONTENTS Procedure under Windows, UNIX, z/OS

PROC CONTENTS <*options*>;

Statement	Task	Example
CONTENTS	List the contents of one or more SAS data sets and print the directory of the SAS library	Ex. 1, Ex. 2, Ex. 3, Ex. 4

PROC CONTENTS Statement

Describes the contents of one or more SAS data sets and prints the directory of the SAS library.

Restriction: You cannot use the WHERE option to affect the output because PROC CONTENTS does not process any observations.

Notes: The ATTRIB statement does not affect the CONTENTS statement output. CONTENTS reports the labels, informats, and formats on the actual member.

When using the CONTENTS statement with SAS/ACCESS LIBNAME engines, "Differences in the DATASETS Procedure Output When Using SAS/ACCESS LIBNAME Engines" on page 572.

Tip: You can use data set options with the DATA=, OUT=, and OUT2= options. You can use any global statements as well.

Example: "Example 1: Describing a SAS Data Set" on page 501.

Syntax

PROC CONTENTS<*options*>

Optional Arguments

CENTILES
prints centiles information for indexed variables.

The following additional fields are printed in the default report of PROC CONTENTS when the CENTILES option is selected and an index exists on the data set. Note that the additional fields depend on whether the index is simple or complex.

#	number of the index on the data set.
Index	name of the index.
Update Centiles	percentage of the data values that must be changed before the CENTILES for the indexed variables are automatically updated.
Current Update Percentage	percentage of index updated since CENTILES were refreshed.
# of Unique Values	number of unique indexed values.
Variables	names of the variables used to make up the index. Centile information is listed below the variables.

DATA=*SAS-file-specification*
specifies an entire library or a specific SAS data set within a library. *SAS-file-specification* can take one of the following forms:

<libref.>SAS-data-set
names one SAS data set to process. The default for libref is the libref of the procedure input library. For example, to obtain the contents of the SAS data set HtWt from the procedure input library, use the following CONTENTS statement:

```
contents data=HtWt;
```

To obtain the contents of a specific version from a generation group, use the GENNUM= data set option as shown in the following CONTENTS statement:

```
contents data=HtWt(gennum=3);
```

<*libref.*>_ALL_
gives you information about all SAS data sets that have the type or types specified by the MEMTYPE= option. *libref* refers to the SAS library. The default for libref is the libref of the procedure input library.

- If you are using the _ALL_ keyword, you need Read access to all read-protected SAS data sets in the SAS library.
- DATA=_ALL_ automatically prints a listing of the SAS files that are contained in the SAS library. Note that for SAS views, all librefs that are associated with the views must be assigned in the current session in order for them to be processed for the listing.

Default most recently created data set in your job or session, from any SAS library.

Tip If you specify a read-protected data set in the DATA= option but do not give the Read password, by default the procedure looks in the PROC DATASETS statement for the Read password. However, if you do not specify the DATA= option and the default data set (last one created in the session) is Read protected, the procedure does not look in the PROC DATASETS statement for the Read password.

Example "Example 5: Describing a SAS Data Set" on page 707

DETAILS | NODETAILS
includes information in the output about the number of observations, number of variables, number of indexes, and data set labels. DETAILS includes these additional columns of information in the output, but only if DIRECTORY is also specified.

Default If neither DETAILS nor NODETAILS is specified, the defaults are as follows: for the CONTENTS procedure, the default is the system option setting, which is NODETAILS; for the CONTENTS statement, the default is whatever is specified in the PROC DATASETS statement, which also defaults to the system option setting.

See a description of the additional columns in the Optional Argument section of PROC DATASETS Statement on page 579

DIRECTORY
prints a list of all SAS files in the specified SAS library. If DETAILS is also specified, using DIRECTORY causes the additional columns described in DETAILS | NODETAILS on page 495 to be printed.

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption.

See "Appending AES-Encrypted Data Sets" on page 592

FMTLEN
prints the length of the informat or format. If you do not specify a length for the informat or format when you associate it with a variable, the length does not appear in the output of the CONTENTS statement unless you use the FMTLEN

option. The length also appears in the FORMATL or INFORML variable in the output data set.

MEMTYPE=(*member-type(s)*)
restricts processing to one or more member types. The CONTENTS statement produces output only for member types DATA, VIEW, and ALL, which includes DATA and VIEW.

MEMTYPE= in the CONTENTS statement differs from MEMTYPE= in most of the other statements in the DATASETS procedure in the following ways:

- A slash does not precede the option.
- You cannot enclose the MEMTYPE= option in parentheses to limit its effect to only the SAS file immediately preceding it.

MEMTYPE= results in a directory of the library in which the DATA= member is located. However, MEMTYPE= does not limit the types of members whose contents are displayed unless the _ALL_ keyword is used in the DATA= option. For example, the following statements produce the contents of only the SAS data sets with the member type DATA:

```
proc datasets memtype=data;
   contents data=_all_;
run;
```

Aliases MTYPE=

MT=

Default DATA

NODS
suppresses printing the contents of individual files when you specify _ALL_ in the DATA= option. The CONTENTS statement prints only the SAS library directory. You cannot use the NODS option when you specify only one SAS data set in the DATA= option.

NODETAILS
See “DETAILS|NODETAILS” on page 495.

NOPRINT
suppresses printing the output of the CONTENTS statement.

ORDER=COLLATE | CASECOLLATE | IGNORECASE | VARNUM

COLLATE	prints a list of variables in alphabetical order beginning with uppercase and then lowercase names.
CASECOLLATE	prints a list of variables in alphabetical order even if they include mixed-case names and numerics.
IGNORECASE	prints a list of variables in alphabetical order ignoring the case of the letters.
VARNUM	is the same as the VARNUM option.

Note The ORDER= option does not affect the order of the OUT= and OUT2= data sets.

See "VARNUM" on page 497

Example See "Example 4: Using the ORDER= Option" on page 515 to compare the default and the four options for ORDER=.

OUT=*SAS-data-set*
names an output SAS data set.

Tip OUT= does not suppress the printed output from the statement. If you want to suppress the printed output, you must use the NOPRINT option.

See "The OUT= Data Set" on page 683 for a description of the variables in the OUT= data set.

OUT2=*SAS-data-set*
names the output data set to contain information about indexes and integrity constraints.

Note When you use the OUT2=*PermanentLibrary*_ALL_ option within PROC CONTENTS or PROC DATASETS with the CONTENTS statement, you must also set the REPLACE=YES data set option or the REPLACE system option.

Tips If UPDATECENTILES was not specified in the index definition, then the default value of 5 is used in the re-create variable of the OUT2 data set.

OUT2= does not suppress the printed output from the statement. To suppress the printed output, use the NOPRINT option.

See "The OUT2= Data Set" on page 689 for a description of the variables in the OUT2= data set.

SHORT
prints only the list of variable names, the index information, and the sort information for the SAS data set.

Restriction If the list of variables is more than 32,767 characters, the list is truncated and a WARNING is written to the SAS log. To get a complete list of the variables, request an alphabetical listing of the variables.

VARNUM
prints a list of the variable names in the order of their logical position in the data set. By default, the CONTENTS statement lists the variables alphabetically. The physical position of the variable in the data set is engine-dependent.

Details

Using the CONTENTS Procedure Instead of the CONTENTS Statement

The only difference between the CONTENTS procedure and the CONTENTS statement in PROC DATASETS is the default for libref in the DATA= option. For PROC CONTENTS, the default is Work. For the CONTENTS statement, the default is the libref of the procedure input library.

Printing Variables

The CONTENTS statement prints an alphabetical listing of the variables by default, except for variables in the form of a numbered range list. Numbered range lists, such as x1–x100, are printed in incrementing order, that is, x1–x100. For more information, see "Alphabetic List of Variables and Attributes" on page 678.

Note: If a label is changed after a view is created from a data set with variable labels, the CONTENTS or DATASETS procedure output shows the original labels. The view must be recompiled in order for the CONTENTS or DATASETS procedure output to reflect the new variable labels.

Displaying the ICU Revision Number

The CONTENTS statement prints the International Components for Unicode (ICU) revision number when you use the SORT procedure for a linguistic sort on a data set. For more information about linguistic sorting, see Chapter 64, "SORT Procedure," on page 2355.

Library Contents and AES Encryption

When requesting the contents of all data files in a library, use the _ALL_ option. If the library contains data files that are AES -encrypted, the ENCRYPTKEY= data set option must be used to access the data files. Here is an example using the ENCRYPTKEY= option:

```
proc contents data=MyLib._all_ (encryptkey=key-value);
run;
```

If the key value does not match the key value for a particular data file in the library, then you will be prompted to enter the correct key value.

For more information about AES encryption, see "AES Encryption" in *SAS Programmer's Guide: Essentials*. For more information about the ENCRYPTKEY= data set option, see "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*.

Observation Length, Alignment, and Padding for a SAS Data Set

There are three different cases for alignment.

- Observations within a SAS data set are aligned on double-byte boundaries whenever possible. As a result, 8-byte and 4-byte numeric variables are positioned at 8-byte boundaries at the front of the data set. They are followed by character variables in the order in which they are encountered. If the data set contains only 4-byte numeric data, the alignment is based on 4-byte boundaries. Since numeric doubles can be operated upon directly rather than being moved and aligned before doing comparisons or increments, the boundaries cause better performance.

  Since there are many observations contained within a given disk data page buffer, there might be padding between observations. The padding is to let each observation be aligned on a double-byte boundary. See the following example:

```
data a;
   length aa 7 bb 6 cc $10 dd 8 ee 3;
   aa = 1;
   bb = 2;
   cc = 'abc';
   dd = 3;
   ee = 4;
   ff = 5;
   output;
run;

proc contents data=a out=a1;
run;

proc print data=a1(keep=name length varnum npos);
run;
```

Figure 14.1 *Observation Length*

The CONTENTS Procedure

Data Set Name	WORK.A	**Observations**	1
Member Type	DATA	**Variables**	6
Engine	V9	**Indexes**	0
Created	08/16/2016 12:08:25	**Observation Length**	48
Last Modified	08/16/2016 12:08:25	**Deleted Observations**	0
Protection		**Compressed**	NO
Data Set Type		**Sorted**	NO
Label			
Data Representation	WINDOWS_64		
Encoding	wlatin1 Western (Windows)		

PROC CONTENTS shows an observation length of 48. PROC PRINT displays the internal layout of the variables within the observation where NPOS is the zero-based offset for each variable.

Figure 14.2 *Observation and Variable Boundaries*

Obs	NAME	LENGTH	VARNUM	NPOS
1	aa	7	1	16
2	bb	6	2	23
3	cc	10	3	32
4	dd	8	4	0
5	ee	3	5	29
6	ff	8	6	8

Variables DD and FF, the only true numeric doubles, are at offsets 0 and 8, respectively, so they are automatically aligned. The rest of the observation contains the remaining numeric variables and then character variables.

The last physical variable in this layout is CC with an offset of 32 and a length of 10. This gives you an internal length of 42, even though PROC CONTENTS reports the observation length as 48. The difference is the 6 bytes of padding so that the next observation is aligned on a double-byte boundary within the disk page buffer.

- No alignment is done when the observation does not contain 8-byte numeric variables as demonstrated in the next example, which gives you an observation length of 7 and no padding between observations within disk page buffers:

```
data b;
   length aa 6 cc $1;
   aa = 1;
   cc = 'x';
   output;
run;

proc contents data=b out=b1;
run;

proc print data=b1(keep=name length varnum npos);
run;
```

Figure 14.3 *Variables and Attributes*

Obs	NAME	LENGTH	VARNUM	NPOS
1	aa	6	1	0
2	cc	1	2	6

- Observations for compressed data sets are not aligned within the disk page buffer, but the same algorithm is used for positioning the variables within the observations. Compressed observations must be uncompressed and moved into a work buffer. The 8-byte numeric values will be aligned and ready for use immediately after uncompressing. The observation length in the PROC CONTENTS output might be larger due to operating system-specific overhead.

Usage: CONTENTS Procedure

Using PROC CONTENTS

For information on using PROC CONTENTS with SAS data sets, see "CONTENTS Statement" on page 603.

For more information, see Chapter 5, "CAS Processing of Base Procedures," on page 93.

Examples: CONTENTS Procedure

Example 1: Describing a SAS Data Set

Features: PROC CONTENTS statement options
DATA=
OUT=
OPTIONS statement
TITLE statement

Details

This example shows the output from the CONTENTS procedure for the Group data set. The output shows the modifications made to the Group data set in "Example 4: Modifying SAS Data Sets" on page 704 and the contents of the Grpout data set.

Program

```
options pagesize=40 linesize=80 nodate pageno=1;

LIBNAME health 'SAS-library';

proc datasets library=health nolist;
run;

proc contents data=health.group (read=green) out=health.grpout;
   title  'The Contents of the GROUP Data Set';
run;

proc contents data=health.grpout;
   title  'The Contents of the GRPOUT Data Set';
run;
```

Program Description

Set the system options. The PAGESIZE= option specifies the number of lines that compose a page of the SAS log and SAS output. The LINESIZE= option specifies the line size for the SAS log and for the SAS procedure output. The NODATE option specifies that the date and the time are not printed. The PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=40 linesize=80 nodate pageno=1;
```

Set your libref.

```
LIBNAME health 'SAS-library';
```

Specify Health as the procedure input library, and suppress the directory listing.

```
proc datasets library=health nolist;
run;
```

Create the output data set Grpout from the data set Group. Specify Group as the data set to describe, give Read access to the Group data set, and create the output data set Grpout.

```
proc contents data=health.group (read=green) out=health.grpout;
   title  'The Contents of the GROUP Data Set';
run;
```

Display the contents of the Grpout data set.

```
proc contents data=health.grpout;
   title  'The Contents of the GRPOUT Data Set';
run;
```

Example 2: Using the DIRECTORY Option

Features:

PROC CONTENTS statement options
- DATA=
- DIRECTORY
- OUT=

OPTIONS statement

TITLE statement

Details

This example shows the output from the CONTENTS procedure for the Group data set using the DIRECTORY option. This option prints a list of all SAS files that are in the specified SAS library.

Program

```
options pagesize=40 linesize=80 nodate pageno=1;

LIBNAME health 'SAS-library';

proc datasets library=health nolist;
run;

proc contents data=health.group (read=green) directory;
title 'Contents Using the DIRECTORY Option';
run;
```

Program Description

Set the system options. The PAGESIZE= option specifies the number of lines that compose a page of the SAS log and the SAS output. The LINESIZE= option specifies the line size for the SAS log and for the SAS procedure output. The NODATE option specifies that the date and the time are not printed. The PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=40 linesize=80 nodate pageno=1;
```

Set your libref.

```
LIBNAME health 'SAS-library';
```

Specify Health as the procedure input library, and suppress the directory listing.

```
proc datasets library=health nolist;
run;
```

Specify Group as the data set to describe, and give Read access to the Group data set. Use the DIRECTORY option to print a listing of all the data sets that are in the HEALTH library.

```
proc contents data=health.group (read=green) directory;
title 'Contents Using the DIRECTORY Option';
run;
```

Features:

PROC CONTENTS statement options
- DATA=
- DETAILS
- DIRECTORY
- OUT=

OPTIONS statement

TITLE statement

Details

This example shows the output from the CONTENTS procedure for the Group data set using the DIRECTORY option. This option prints a list of all SAS files that are in the specified SAS library. The DETAILS option includes information in the output about the number of observations, number of variables, number of indexes, and data set labels.

Program

```
options pagesize=40 linesize=80 nodate pageno=1;

LIBNAME health 'SAS-library';

proc datasets library=health nolist;
run;

proc contents data=health.groupdirectory details;
title 'Contents Using the DIRECTORY and DETAILS Options';
run;
```

Program Description

Set the system options. The PAGESIZE= option specifies the number of lines that compose a page of the SAS log and the SAS output. The LINESIZE= option specifies the line size for the SAS log and for the SAS procedure output. The NODATE option specifies that the date and the time are not printed. The PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=40 linesize=80 nodate pageno=1;
```

Set your libref.

```
LIBNAME health 'SAS-library';
```

Specify Health as the procedure input library, and suppress the directory listing.

```
proc datasets library=health nolist;
run;
```

Specify Group as the data set. Use the DIRECTORY option to print a listing of all the data sets that are in the HEALTH library. Use the DETAILS options for additional columns of information in the Group output.

```
proc contents data=health.groupdirectory details;
title 'Contents Using the DIRECTORY and DETAILS Options';
run;
```

Example 4: Using the ORDER= Option

Features:

PROC CONTENTS statement options
- DATA=
- ORDER=
- OUT=

OPTIONS statement

TITLE statement

Details

This example shows the output from the CONTENTS procedure for the Grpout data set using the ORDER= option, which prints a list of variables in different orders.

Program

```
options pagesize=40 linesize=80 nodate pageno=1;

LIBNAME health 'SAS-library';

proc contents data=health.grpout order=collate;
title 'Contents Using the ORDER= Option';
run;

proc contents data=health.grpout order=varnum;
title 'Contents Using the ORDER= Option';
run;
```

Program Description

Set the system options. The PAGESIZE= option specifies the number of lines that compose a page of the SAS log and the SAS output. The LINESIZE= option specifies the line size for the SAS log and for the SAS procedure output. The NODATE option specifies that the date and the time are not printed. The PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=40 linesize=80 nodate pageno=1;
```

Set your libref.

```
LIBNAME health 'SAS-library';
```

Specify the Grpout data set. Use the ORDER=COLLATE option to print a listing of all variables in alphabetical order.

```
proc contents data=health.grpout order=collate;
title 'Contents Using the ORDER= Option';
run;
```

Specify the Grpout data set. Use the ORDER=VARNUM option to print a listing of all variables in number order.

```
proc contents data=health.grpout order=varnum;
title 'Contents Using the ORDER= Option';
run;
```

Output Examples

Output 14.7 *Using the ORDER=COLLATE Option*

15

COPY Procedure

Overview: COPY Procedure

What Does the COPY Procedure Do?

The COPY procedure copies one or more tables from one SAS library to another.

Generally, the COPY procedure functions the same as the COPY statement in the DATASETS procedure. The differences are as follows:

- The IN= argument is required with PROC COPY. In the COPY statement, IN= is optional. If IN= is omitted, the default value is the libref of the procedure input library.

- PROC DATASETS cannot work with libraries that allow only sequential data access.
- The COPY statement honors the NOWARN option but PROC COPY does not.

Note: The MIGRATE procedure is available specifically for migrating a SAS library from a previous release to the most recent release. For migration, PROC MIGRATE offers benefits that PROC COPY does not. For more information, see MIGRATE Procedure on page 1559.

With the ACCEL option, PROC COPY executes a CAS action to copy a CAS table from one caslib to another caslib in the same CAS session.

Syntax: COPY Procedure

Restrictions: PROC COPY ignores concatenations with catalogs. Use PROC CATALOG COPY to copy concatenated catalogs.

PROC COPY does not support data set options.

PROC COPY does not back up graphic catalogs. Use PROC CPORT or PROC CIMPORT when doing back ups with graphic catalogs.

Interaction: The International Components for Unicode (ICU) version is used to sort data sets with a linguistic collating sequence. If a linguistically sorted data set has a different ICU version number than that of the current SAS session, the following occurs: PROC COPY retains the data set's sort order in the OUT= destination library. However, the data set is no longer marked as sorted, and a message is written to the SAS log. For more information about linguistic sorting, see Chapter 64, "SORT Procedure," on page 2355.

Notes: Data set names and variable names that end with large numeric values that are larger than a long integer cannot be used in numbered-range lists. For more information, see "Restriction for Numbered Range Lists" in *SAS Language Reference: Concepts*.

PROC COPY uses a CAS action to provide the copy operation in the CAS server when both the IN= and OUT= values use the CAS libname engine and both libnames use the same CAS session. See "Copying a CAS Table to Another CAS Table" on page 620 and "CAS Processing for PROC COPY" on page 523.

Tips: Complete documentation for the COPY procedure is in COPY Statement on page 610.

For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

PROC COPY <ACCEL | NOACCEL>

OUT=*libref-1* <CLONE | NOCLONE>
<CONSTRAINT=YES | NO>
<DATECOPY>
<ENCRYPTKEY=*key-value*>

<FORCE>
IN=*libref-2*
<INDEX=YES | NO>
<MEMTYPE=(*member-type(s)*)>
<MOVE <ALTER=*alter-password*>>
<OVERRIDE=(*ds-option-1=value-1 <ds-option-2=value-2 ...>*) >;
<SELECT *SAS-file(s)*>
</ <ENCRYPTKEY=*key-value*> <ALTER=*alter-password*>
<MEMTYPE=*member-type*>>;

Statement	Task	Example
COPY	Copy one or more files	Ex. 1, Ex. 3
EXCLUDE	Exclude files or memtypes	Ex.
SELECT	Select files or memtypes	Ex. 1, Ex. 2

Usage: COPY Procedure

CAS Processing for PROC COPY

When the IN= option and OUT= option both reference a CAS engine library and both libraries use the same CAS session, the COPY procedure can use a CAS action to copy tables within the server.

PROC COPY options are valid when using a CAS LIBNAME engine except for the following:

- ENCRYPTKEY=
- OVERRIDE=
- PW=

When a copy occurs on the CAS server, the MVA session system options (like VALIDMEMNAME and VALIDVARNAME) will not be used.

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. The CAS LIBNAME engine can connect a SAS 9.4 session to an existing SAS Cloud Analytic Services session through the CAS session name or the CAS session UUID. The libref then becomes your handle to communicate from SAS with the specific session. The following example shows how to use PROC COPY with CAS processing.

Here is an example of how to run PROC COPY with CAS.

```
/* Connect to a CAS server */
cas casauto host="cloud.example.com" port=5570;

/*Specify the LIBNAME statements*/
libname foo cas caslib=casuserhdfs;
libname bar cas caslib=casuser;

/*Loading data to Casuserhdfs. Note that you can specify OUTCASLIB=
on the PROC CASUTIL statement and it will apply to all statements
that follow (up to the quit). */
proc casutil;
load data=sashelp.class outcaslib=casuserhdfs;
load data=sashelp.class compress casout="class_comp"
outcaslib=casuserhdfs;
load data=sashelp.class promote casout="class_prom"
outcaslib=casuserhdfs;
quit;

/*Execute the PROC COPY statement*/
title 'Copy with CLONE;
proc copy in=foo out=bar;
run;
```

For information about how to use the CAS LIBNAME statement, see “Getting Started” in *SAS Cloud Analytic Services: User’s Guide*.

Using CLONE | NOCLONE on a CAS Table

The CLONE | NOCLONE option specifies whether to copy data set attributes. The only attribute that can be used with the CAS engine is COMPRESS.

Attributes are specified with data set options, system options, or LIBNAME statement options. The CAS engine supports only the COMPRESS=YES | NO option. No other attributes are supported by the CAS engine.

The following table summarizes how the COPY statement works:

Table 15.1 *CLONE Interaction with Attributes*

Attribute	To	CLONE or NOCLONE	Description
BUFSIZE= CAS engine does not support.	SAS data set to CAS table		
	CAS table to SAS data set	CLONE	OVERRIDE=(BUFSIZE=*value other than default*)

Attribute	To	CLONE or NOCLONE	Description
		NOCLONE	Uses setting of BUFSIZE= system option
	CAS table to CAS table		
COMPRESS= SAS data set - COMPRESS=BINARY | CHAR | NO CAS table - COMPRESS=NO | YES	SAS data set to CAS table	CLONE	A compressed SAS data set becomes a compressed CAS table unless OVERRIDE= is used. An uncompressed SAS data set becomes an uncompressed CAS table unless OVERRIDE= is used.
		NOCLONE	Follows the CAS LIBNAME setting.
	CAS table to SAS data set	CLONE	Compressed CAS table becomes a SAS data set CHAR unless the OVERRIDE= is used.
		NOCLONE	The COMPRESS= system option or LIBNAME option value is used.
	CAS table to CAS table	CLONE	Keeps the current setting.
		NOCLONE	Set using the CAS LIBNAME setting for the OUT= libref.
REUSE= CAS engine does not support.	SAS data set to CAS table		
	CAS table to SAS data set	CLONE	REUSE=NO unless OVERRIDE= or REUSE=YES system option is used.
		NOCLONE	Uses the REUSE= system option value.

Attribute	To	CLONE or NOCLONE	Description
	CAS table to CAS table		
POINTOBS= CAS engine does not support.	SAS data set to CAS table		
	CAS table to SAS data set	CLONE	POINTOBS=NO unless OVERRIDE= is used.
		NOCLONE	POINTOBS=NO, if the CAS table is compressed and the LIBNAME statement has POINTOBS=NO. POINTOBS=YES, if the CAS table is compressed and the LIBNAME option is missing.
	CAS table to CAS table		
OUTREP= CAS engine does not support.	SAS data set to CAS table	CLONE	Converts to LINUX_86_64 if needed. (A warning is sent to the log if the OVERRIDE= option is used.)
		NOCLONE	Converts to LINUX_86_64 if needed.
	CAS table to SAS data set		
		CLONE	Keeps data representation. (A warning is sent to the log if the OVERRIDE= option is used.)
	CAS table to CAS table		
ENCODING=	SAS data set to CAS table	CLONE	Converts to UTF-8 if needed. (A warning is sent to the log if the

Attribute	To	CLONE or NOCLONE	Description
CAS engine supports UTF-8 only. Changing encoding is not implemented for the CAS engine.			OVERRIDE= option is used.)
		NOCLONE	Converts to UTF-8 if needed.
	CAS table to SAS data set	CLONE	Keeps the UTF-8 encoding unless OVERRIDE= is used.
		NOCLONE	Keeps the UTF-8 encoding unless OUTENCODING= is used in the output data set LIBNAME is used.
	CAS table to CAS table		

Compressing Output CAS Tables

When copying previously compressed tables, the following occurs:

- if a SAS data set is compressed, then it retains the COMPRESS=YES value on the CAS table.
- if a CAS table is compressed, then it converts to a SAS data set with the COMPRESS=CHAR value.
- if a CAS table is copied to another CAS table, the COMPRESS=YES attribute is maintained.

Using the COPY Procedure

Copying Select Files from a Large Directory of Files

When using the COPY procedure, an in-memory directory of the library is obtained. This can be a performance issue if the library has thousands of members and only a few members are being copied. To resolve this performance issue, use a combination of the MEMTYPE= option in the COPY statement with a SELECT statement. The following is an example of this process:

```
proc copy in=work out=mylib memtype=(data catalog);
   select mydata x1-x10 data2;
run;
```

Note: If either MEMTYPE=ALL or a wildcard specification (":") is used, the performance code cannot be used.

TIP If the MSGLEVEL=I option is set, and the SELECT performance code can be used, the following message is sent to the SAS log:

```
INFO: COPY with SELECT performance is in use.
```

Transporting SAS Data Sets between Hosts

The COPY procedure, along with the XPORT engine and the XML engine, can create and read transport files that can be moved from one host to another. PROC COPY can create transport files only with SAS data sets, not with catalogs or other types of SAS files.

Transporting is a three-step process:

1. Use PROC COPY to copy one or more SAS data sets to a file that is created with either the transport (XPORT) engine or the XML engine. This file is referred to as a transport file and is always a sequential file.
2. After the file is created, you can move it to another operating environment via communications software, such as FTP, or tape. If you use communications software, be sure to move the file in binary format to avoid any type of conversion. If you are moving the file to a mainframe, the file must have certain

attributes. Consult the SAS documentation for your operating environment and the SAS Technical Support web page for more information.

3 After you have successfully moved the file to the receiving host, use PROC COPY to copy the data sets from the transport file to a SAS library.

For an example, see "Example 1: Copying SAS Data Sets between Hosts" on page 530.

For details about transporting files, see *Moving and Accessing SAS Files*.

The CPORT and CIMPORT procedures also provide a way to transport SAS files. For more information, see Chapter 16, "CPORT Procedure," on page 537 and Chapter 12, "CIMPORT Procedure," on page 389.

If you need to migrate a SAS library from a previous release of SAS, see the Migration focus area at http://support.sas.com/migration.

For more information, see the Details on page 618 section of the CONTENTS statement in PROC DATASETS.

Copying AES-Encrypted Data Files

You must use the ENCRYPTKEY= data set option when copying an AES-encrypted data file. An error occurs when you copy an AES-encrypted file to a library that does not support AES encryption. For more information about AES encryption, see "AES Encryption" in *SAS Programmer's Guide: Essentials* and see "Copying AES-Encrypted Data Files" on page 623.

The following is an example using the ENCRYPTKEY= data set option:

```
proc copy in=Lib1 out=Lib2;
select My-Data1 (encryptkey=key-value1) <My-Data2 (encryptkey=key-value2) ...>;
run;
```

To copy AES-encrypted data files containing referential integrity constraints, see "Copying AES-Encrypted Data Files Containing Referential Integrity Constraints " on page 624.

Compressing Output Data Files

The COPY procedure does not support data set options. Therefore, you cannot use the COMPRESS= data set option in PROC COPY or a COPY statement from PROC DATASETS. To compress an OUTPUT data set generated by PROC COPY, you can use the COMPRESS=YES system option before the PROC COPY statement with the NOCLONE option.

```
options compress=yes;
proc copy in=work out=new noclone;
select x;
run;
```

Examples: COPY Procedure

Example 1: Copying SAS Data Sets between Hosts

Features:

PROC COPY statement options
- IN=
- MEMTYPE=
- OUT=
- SELECT statement

XPORT engine

Details

This example demonstrates how to create a transport file on a host and read it on another host.

In order for this example to work correctly, the transport file must have certain characteristics, as described in the SAS documentation for your operating environment. In addition, the transport file must be moved to the receiving operating system in binary format.

Program

```
libname source 'SAS-library-on-sending-host';

libname xptout xport 'filename-on-sending-host';

proc copy in=source out=xptout memtype=data;
   select bonus budget salary;
run;

libname insource xport 'filename-on-receiving-host';
```

```
proc copy in=insource out=work;
run;
```

Program Description

Assign library references. Assign a libref, such as Source, to the SAS library that contains the SAS data set that you want to transport. Also, assign a libref to the transport file and use the XPORT keyword to specify the XPORT engine.

```
libname source 'SAS-library-on-sending-host';

libname xptout xport 'filename-on-sending-host';
```

Copy the SAS data sets to the transport file.

```
proc copy in=source out=xptout memtype=data;
   select bonus budget salary;
run;
```

Enable the procedure to read data from the transport file. The XPORT engine in the LIBNAME statement enables the procedure to read the data from the transport file.

```
libname insource xport 'filename-on-receiving-host';
```

Copy the SAS data sets to the receiving host. After you copy the files, use PROC COPY to copy the SAS data sets to the Work data library on the receiving host. You could use FTP in binary mode to the Windows host.

```
proc copy in=insource out=work;
run;
```

Log Examples

Example Code 15.1 *Source Library Log*

```
1    LIBNAME source 'SAS-library-on-sending-host ';
NOTE: Libref SOURCE was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library-on-sending-host
2    LIBNAME xptout xport 'filename-on-sending-host';
NOTE: Libref XPTOUT was successfully assigned as follows:
      Engine:        XPORT
      Physical Name: filename-on-sending-host
3    proc copy in=source out=xptout memtype=data;
4    select bonus budget salary;
5    run;

NOTE: Copying SOURCE.BONUS to XPTOUT.BONUS (memtype=DATA).
NOTE: The data set XPTOUT.BONUS has 1 observations and 3 variables.
NOTE: Copying SOURCE.BUDGET to XPTOUT.BUDGET (memtype=DATA).
NOTE: The data set XPTOUT.BUDGET has 1 observations and 3 variables.
NOTE: Copying SOURCE.SALARY to XPTOUT.SALARY (memtype=DATA).
NOTE: The data set XPTOUT.SALARY has 1 observations
```

Example Code 15.2 *Insource Library Log*

```
1     LIBNAME insource xport 'filename-on-receiving-host';
NOTE: Libref INSOURCE was successfully assigned as follows:
       Engine:      XPORT
       Physical Name: filename-on-receiving-host
2     proc copy in=insource out=work;
3     run;
NOTE: Input library INSOURCE is sequential.
NOTE: Copying INSOURCE.BUDGET to WORK.BUDGET (memtype=DATA).
NOTE: BUFSIZE is not cloned when copying across different engines.
      System Option for BUFSIZE was used.
NOTE: The data set WORK.BUDGET has 1 observations and 3 variables.
NOTE: Copying INSOURCE.BONUS to WORK.BONUS (memtype=DATA).
NOTE: BUFSIZE is not cloned when copying across different engines.
      System Option for BUFSIZE was used.
NOTE: The data set WORK.BONUS has 1 observations and 3 variables.
NOTE: Copying INSOURCE.SALARY to WORK.SALARY (memtype=DATA).
NOTE: BUFSIZE is not cloned when copying across different engines.
      System Option for BUFSIZE was used.
NOTE: The data set WORK.SALARY has 1 observations and 3 variables.
```

Example 2: Converting SAS Data Sets Encodings

Features: PROC COPY statement options
- IN=
- NOCLONE
- OUT=
- SELECT statement

CVP engine

Details

This example demonstrates how to convert encoding from one type to another type. In order for this example to work correctly, the two encodings must be compatible. For documentation, see "Compatible and Incompatible Encodings" in *SAS National Language Support (NLS): Reference Guide*.

Program

Assign library references. The two encodings must be compatible.

```
LIBNAME inlib cvp 'SAS-library';
LIBNAME outlib 'SAS-library' outencoding="encoding value for output";
proc copy noclone in=inlib out=outlib;
   select car;
run;
```

Log Examples

Example Code 15.3 *InLib Library Log*

```
1    LIBNAME inlib cvp  'SAS-library';
NOTE: Libref INLIB was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library
2    LIBNAME outlib 'SAS-library' outencoding="encoding value for output";
NOTE: Libref OUTLIB was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library
3    proc copy noclone in=inlib out=outlib;
4    select car;
5    run;

NOTE: Copying INLIB.CAR to OUTLIB.CAR (memtype=DATA).
NOTE: System Options for BUFSIZE and REUSE were used at user's request.

NOTE: Libname and/or system options for compress, pointobs, data representation and
encoding attributes were used at user's request.
NOTE: Data file OUTLIB.CAR.DATA is in a format that is native to another host, or
the file encoding does not match the session encoding. Cross Environment Data Access
will be used, which might require additional CPU resources and might reduce
performance.

NOTE: There were 25 observations read from the data set INLIB.CAR.

NOTE: The data set OUTLIB.CAR has 25 observations and 2 variables.
```

Example 3: Using PROC COPY to Migrate from a 32-bit to a 64-bit Machine

Features:

PROC COPY statement options
- IN=
- OUT=
- NOCLONE
- SELECTstatement

OUTREP= data set option

Details

This example demonstrates how to use PROC COPY to migrate from a 32-bit to a 64-bit environment. PROC MIGRATE does not support item stores when you migrate from a 32-bit to a 64-bit environment.

Program

```
libname source 'SAS-library';
libname target 'SAS-library'
    outrep=windows_64;

proc copy in=source out=target NOCLONE;
    select data-set-name;
run;
```

Program Description

Assign library resources. Use the OUTREP= option when changing from a 32-bit to a 64-bit machine.

```
libname source 'SAS-library';
libname target 'SAS-library'
    outrep=windows_64;
```

Copy data set from a 32-bit to a 64-bit machine.

```
proc copy in=source out=target NOCLONE;
    select data-set-name;
run;
```

Example 4: Copy a SAS Data Set to a CAS Table

Features: PROC COPY statement options
- IN=
- OUT=
- SELECT statement

Details

This example demonstrates how to copy a SAS data set into a CAS table.

Program

```
libname mycas cas;
libname mylib 'BASE-engine-library';

proc copy in=mylib out=mycas;
   select monthly;
run;
quit;
```

Program Description

Assign library references. Select the data set that you want to copy into a CAS table.

```
libname mycas cas;
libname mylib 'BASE-engine-library';
```

Use PROC COPY and the SELECT statement. Copy a SAS data set into a CAS table.

```
proc copy in=mylib out=mycas;
   select monthly;
run;
quit;
```

Log Examples

Example Code 15.4 *MyLib Library Log*

```
57         libname mycas cas;
 NOTE: Libref MYCAS was successfully assigned as follows:
       Engine:        CAS
       Physical Name: 1f436ced
 58         libname mylib 'BASE-engine-library';
 NOTE: Libref MYLIB was successfully assigned as follows:
       Engine:        V9
       Physical Name: BASE-engine-library
 59
 60         proc copy in=mylib out=mycas;
 61            select monthly;
 62         run;

 NOTE: Copying MYLIB.MONTHLY to MYCAS.MONTHLY (memtype=DATA).
 NOTE: There were 12012 observations read from the data set MYLIB.MONTHLY.
 NOTE: The data set MYCAS.MONTHLY has 12012 observations and 7 variables.
 NOTE: PROCEDURE COPY used (Total process time):
       real time           0.06 seconds
       cpu time            0.02 seconds
```

16

CPORT Procedure

Overview: CPORT Procedure

What Does the CPORT Procedure Do?

The CPORT procedure writes SAS data sets, SAS catalogs, or SAS libraries to sequential file formats (transport files). Use PROC CPORT with the CIMPORT procedure to move files from one environment to another. *Transport files* are sequential files that each contain a SAS library, a SAS catalog, or a SAS data set in transport format. The transport format that PROC CPORT writes is the same for all

environments and for many releases of SAS. In PROC CPORT, *export* means to put a SAS library, a SAS catalog, or a SAS data set into transport format. PROC CPORT exports catalogs and data sets, either singly or as a SAS library. PROC CIMPORT restores (*imports*) the transport file to its original form as a SAS catalog, SAS data set, or SAS library.

PROC CPORT also *converts* SAS files, which means that it changes the format of a SAS file from the format appropriate for one version of SAS to the format appropriate for another version. For example, you can use PROC CPORT and PROC CIMPORT to move files from earlier releases of SAS to more recent releases. PROC CIMPORT automatically converts the transport file as it imports it.

Note: PROC CPORT and PROC CIMPORT can be used to back up graphic catalogs. PROC COPY cannot be used to back up graphic catalogs.

PROC CPORT produces no output (other than the transport files), but it does write notes to the SAS log.

Process for Creating and Reading a Transport File

Here is the process to create a transport file at the source computer and to read it at a target computer:

1. A transport file is created at the source computer using PROC CPORT.
2. The transport file is transferred from the source computer to the target computer via communications software or a magnetic medium.
3. The transport file is read at the target computer using PROC CIMPORT.

   Note: Transport files that are created using PROC CPORT are not interchangeable with transport files that are created using the XPORT engine.

For complete details about the steps to create a transport file (PROC CPORT), to transfer the transport file, and to restore the transport file (PROC CIMPORT), see *Moving and Accessing SAS Files*.

Syntax: CPORT Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Tip: Use PROC CPORT or PROC CIMPORT when backing up graphic catalogs. PROC COPY cannot be used to back up graphic catalogs.

See: CPORT Procedure under Windows, UNIX , z/OS

For complete details about the steps to create a transport file (PROC CPORT), to transfer the transport file, and to restore the transport file (PROC CIMPORT), see *Moving and Accessing SAS Files*

PROC CPORT *source-type=libref* | <*libref.*>*member-name* <*options*>;

EXCLUDE *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*> </ ENTRYTYPE=*entry-type*>;

SELECT *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*> </ ENTRYTYPE=*entry-type*> ;

TRANTAB NAME=*translation-table-name* <*options*>;

Statement	Task	Example
PROC CPORT	Create a transport file	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5
EXCLUDE	Exclude one or more specified files from the transport file	
SELECT	Specify one or more files or entries to include in the transport file	Ex. 2
TRANTAB	Specify one or more translation tables for characters in catalog entries to be exported	Ex. 4

PROC CPORT Statement

Creates a transport file.

Examples:

"Example 1: Exporting Multiple Catalogs" on page 553
"Example 2: Exporting Individual Catalog Entries" on page 555
"Example 3: Exporting a Single SAS Data Set" on page 556
"Example 4: Applying a Translation Table" on page 557
"Example 5: Exporting Entries Based on Modification Date" on page 558

Syntax

PROC CPORT *source-type=libref* | <*libref.*>*member-name* <*options*>;

Summary of Optional Arguments

NOEDIT

exports SAS/AF PROGRAM and SCL entries without Edit capability when you import them.

NOSRC
: specifies that exported catalog entries contain compiled SCL code, but not the source code.

OUTLIB=*libref*
: specifies a libref associated with a SAS library.

Control the contents of the transport file

ASIS
: suppresses the conversion of displayed character data to transport format.

CONSTRAINT=YES | NO
: controls the exportation of integrity constraints.

DATECOPY
: copies the created and modified date and time to the transport file.

INDEX=YES | NO
: controls the exportation of indexes with indexed SAS data sets.

INTYPE=*DBCS-type*
: specifies the type of DBCS data stored in the SAS files to be exported.

NOCOMPRESS
: suppresses the compression of binary zeros and blanks in the transport file.

OUTTYPE=UPCASE
: writes all alphabetic characters to the transport file in uppercase.

TRANSLATE=(*translation-list*)
: translates specified characters from one ASCII or EBCDIC value to another.

Identify the transport file

FILE=*fileref* | '*filename*'
: specifies the transport file to write to.

TAPE
: directs the output from PROC CPORT to a tape.

Select files to export

AFTER=*date*
: exports copies of all data sets or catalog entries that have a modification date equal to or later than the date that you specify.

EET=(*etype(s)*)
: excludes specified entry types from the transport file.

ET=(*etype(s)*)
: includes specified entry types in the transport file.

GENERATION=YES | NO
: specifies whether to export all generations of a data set.

MEMTYPE=*mtype*
: specifies that only data sets, only catalogs, or both, be moved when a library is exported.

Required Argument

source-type=libref | <libref.>member-name
identifies the type of file to export and specifies the catalog, SAS data set, or SAS library to export.

source-type
identifies one or more files to export as a single catalog, as a single SAS data set, or as the members of a SAS library. The *source-type* argument can be one of the following:

CATALOG | CAT | C
DATA | DS | D
LIBRARY | LIB | L

Note If you specify a password-protected data set as the source type, you must also include the password when creating its transport file. For details, see "READ= Data Set Option in the PROC CPORT Statement " on page 549.

libref
<libref.>member-name
specifies the specific catalog, SAS data set, or SAS library to export. If *source-type* is CATALOG or DATA, you can specify both a libref and a member name. If the *libref* is omitted, PROC CPORT uses the default library as the *libref*, which is usually the WORK library. If the *source-type* argument is LIBRARY, specify only a *libref*. If you specify a library, PROC CPORT exports only data sets and catalogs from that library. You cannot export other types of files.

See Refer to "Names in the SAS Language" in *SAS Language Reference: Concepts* for naming conventions that you can use for names and member names.

Optional Arguments

AFTER=*date*
exports copies of all data sets or catalog entries that have a modification date later than or equal to the date that you specify. The modification date is the most recent date when the contents of the data set or catalog entry changed. Specify date as a SAS date literal or as a numeric SAS date value.

Tip You can determine the modification date of a catalog entry by using the CATALOG procedure.

Example "Example 5: Exporting Entries Based on Modification Date" on page 558

ASIS
suppresses the conversion of displayed character data to transport format. Use this option when you move files that contain DBCS (double-byte character set) data from one operating environment to another if both operating environments use the same type of DBCS data.

Interactions The ASIS option invokes the NOCOMPRESS option.

You cannot use both the ASIS option and the OUTTYPE= options in the same PROC CPORT step.

CONSTRAINT=YES | NO
controls the exportation of integrity constraints that have been defined on a data set. When you specify CONSTRAINT=YES, all types of integrity constraints are exported for a library; only general integrity constraints are exported for a single data set. When you specify CONSTRAINT=NO, indexes created without integrity constraints are ported, but neither integrity constraints nor any indexes created with integrity constraints are ported. For more information about integrity constraints, see the section on SAS files in *SAS Language Reference: Concepts*.

Alias CON=

Default YES

Interactions You cannot specify both CONSTRAINT= and INDEX= in the same PROC CPORT step.

If you specify INDEX=NO, no integrity constraints are exported.

DATECOPY
copies the SAS internal date and time at which the SAS file was created and the date and time at which it was last modified to the resulting transport file. Note that the operating environment date and time are not preserved.

Restriction DATECOPY can be used only when the destination file uses the V8 or V9 engine.

Note If the file that you are transporting has attributes that require additional processing, then the last modified date might be changed to the current date and time.

Tips The DATECOPY option must be specified to transport data sets with time zone offsets.

You can alter the file creation date and time with the DTC= option in the MODIFY statement in a PROC DATASETS step. For details, see "MODIFY Statement" on page 644.

EET=(*etype(s)*)
excludes specified entry types from the transport file. If *etype* is a single entry type, then you can omit the parentheses. Separate multiple values with a space.

Interaction You cannot use both the EET= option and the ET= option in the same PROC CPORT step.

ET=(*etype(s)*)
includes specified entry types in the transport file. If *etype* is a single entry type, then you can omit the parentheses. Separate multiple values with a space.

Interaction You cannot use both the EET= option and the ET= option in the same PROC CPORT step.

FILE=*fileref* | '*filename*'
specifies a previously defined fileref or the filename of the transport file to write to. If you omit the FILE= option, then PROC CPORT writes to the fileref SASCAT, if defined. If the fileref SASCAT is not defined, PROC CPORT writes to SASCAT.DAT in the current directory.

Note The behavior of PROC CPORT when SASCAT is undefined varies from one operating environment to another. For details, see the SAS documentation for your operating environment.

Example All examples.

GENERATION=YES | NO
specifies whether to export all generations of a SAS data set. To export only the base generation of a data set, specify GENERATION=NO in the PROC CPORT statement. To export a specific generation number, use the GENNUM= data set option when you specify a data set in the PROC CPORT statement. For more information about generation data sets, see *SAS Language Reference: Concepts*.

Alias GEN=

Default YES for libraries; NO for single data sets

Note PROC CIMPORT imports all generations of a data set that are present in the transport file. It deletes any previous generation set with the same name and replaces it with the imported generation set, even if the number of generations does not match.

INDEX=YES | NO
specifies whether to export indexes with indexed SAS data sets.

Default YES

Interactions You cannot specify both INDEX= and CONSTRAINT= in the same PROC CPORT step.

If you specify INDEX=NO, no integrity constraints are exported.

INTYPE=*DBCS-type*
specifies the type of DBCS data stored in the SAS files to be exported. Double-byte character set (DBCS) data uses up to two bytes for each character in the set. *DBCS-type* must be one of the following values:

IBM | HITAC | FACOM	for z/OS
IBM	for VSE
DEC | SJIS	for OpenVMS
PCIBM | SJIS	for OS/2

Default If the INTYPE= option is not used, the DBCS type defaults to the value of the SAS system option DBCSTYPE=.

Restriction The INTYPE= option is allowed only if SAS is built with Double-Byte Character Set (DBCS) extensions. Because these extensions require significant computing resources, there is a special distribution for those sites that require it. An error is reported if this option is used at a site for which DBCS extensions are not enabled.

Interactions Use the INTYPE= option in conjunction with the OUTTYPE= option to change from one type of DBCS data to another.

The INTYPE= option invokes the NOCOMPRESS option.

You cannot use the INTYPE= option and the ASIS option in the same PROC CPORT step.

Tip You can set the value of the SAS system option DBCSTYPE= in your configuration file.

MEMTYPE=*mtype*
restricts the type of SAS file that PROC CPORT writes to the transport file. MEMTYPE= restricts processing to one member type. Values for *mtype* can be

ALL
both catalogs and data sets

CATALOG
CAT
catalogs

DATA
DS
SAS data sets

Alias MT=

Default ALL

Example “Example 1: Exporting Multiple Catalogs” on page 553

NOCOMPRESS
suppresses the compression of binary zeros and blanks in the transport file.

Alias NOCOMP

Default By default, PROC CPORT compresses binary zeros and blanks to conserve space.

Interaction The ASIS, INTYPE=, and OUTTYPE= options invoke the NOCOMPRESS option.

Note Compression of the transport file does not alter the flag in each catalog and data set that indicates whether the original file was compressed.

NOEDIT
exports SAS/AF PROGRAM and SCL entries without Edit capability when you import them.

The NOEDIT option produces the same results as when you create a new catalog to contain SCL code by using the MERGE statement with the NOEDIT option in the BUILD procedure of SAS/AF software.

Alias NEDIT

Note The NOEDIT option affects only SAS/AF PROGRAM and SCL entries. It does not affect FSEDIT SCREEN or FSVIEW FORMULA entries.

NOSRC
specifies that exported catalog entries contain compiled SCL code but not the source code.

The NOSRC option produces the same results as when you create a new catalog to contain SCL code by using the MERGE statement with the NOSOURCE option in the BUILD procedure of SAS/AF software.

Alias NSRC

OUTLIB=*libref*
specifies a libref associated with a SAS library. If you specify the OUTLIB= option, PROC CIMPORT is invoked automatically to re-create the input library, data set, or catalog in the specified library.

Alias OUT=

Tip Use the OUTLIB= option when you change SAS files from one DBCS type to another within the same operating environment if you want to keep the original data intact.

OUTTYPE=UPCASE
writes all displayed characters to the transport file and to the OUTLIB= file in uppercase.

Interaction The OUTTYPE= option invokes the NOCOMPRESS option.

TAPE
directs the output from PROC CPORT to a tape.

Default The output from PROC CPORT is sent to disk.

TRANSLATE=(*translation-list*)
translates specified characters from one ASCII or EBCDIC value to another. Each element of *translation-list* has the following form:

- *ASCII-value-1* TO *ASCII-value-2*
- *EBCDIC-value-1* TO *EBCDIC-value-2*

You can use hexadecimal or decimal representation for ASCII values. If you use the hexadecimal representation, values must begin with a digit and end with an x. Use a leading zero if the hexadecimal value begins with an alphabetic character.

For example, to translate all left brackets to left braces, specify the TRANSLATE= option as follows (for ASCII characters):

```
translate=(5bx to 7bx)
```

The following example translates all left brackets to left braces and all right brackets to right braces:

```
translate=(5bx to 7bx 5dx to 7dx)
```

EXCLUDE Statement

Excludes specified files or entries from the transport file.

Interaction: You can use either EXCLUDE statements or SELECT statements in a PROC CPORT step, but not both.

Tip: There is no limit to the number of EXCLUDE statements that you can use in one invocation of PROC CPORT.

Syntax

EXCLUDE *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*> </ ENTRYTYPE=*entry-type*>;

Required Argument

SAS file(s) | catalog entry(s)
specifies one or more SAS files or one or more catalog entries to be excluded from the transport file. Specify SAS filenames when you export a SAS library; specify catalog entry names when you export an individual SAS catalog. Separate multiple filenames or entry names with a space. You can use shortcuts to list many like-named files in the EXCLUDE statement. For more information, see "SAS Data Sets" in *SAS Language Reference: Concepts*.

Optional Arguments

ENTRYTYPE=*entry-type*
specifies a single entry type for the catalog entries listed in the EXCLUDE statement. See *SAS Language Reference: Concepts* for a complete list of catalog entry types.

Alias: ETYPE=, ET=

Restriction: ENTRYTYPE= is valid only when you export an individual SAS catalog.

MEMTYPE=*mtype*
specifies a single member type for one or more SAS files listed in the EXCLUDE statement. Valid values are CATALOG, DATA, or ALL. If you do not specify the

MEMTYPE= option in the EXCLUDE statement, then processing is restricted to those member types specified in the MEMTYPE= option in the PROC CPORT statement.

You can also specify the MEMTYPE= option, enclosed in parentheses, immediately after the name of a file. In parentheses, MEMTYPE= identifies the type of the filename that immediately precedes it. When you use this form of the option, it overrides the MEMTYPE= option that follows the slash in the EXCLUDE statement, but it must match the MEMTYPE= option in the PROC CPORT statement:

Alias MTYPE=, MT=

Default If you do not specify MEMTYPE= in the PROC CPORT statement or in the EXCLUDE statement, the default is MEMTYPE=ALL.

Restrictions MEMTYPE= is valid only when you export a SAS library.

If you specify a member type for MEMTYPE= in the PROC CPORT statement, it must agree with the member type that you specify for MEMTYPE= in the EXCLUDE statement.

See Refer to "Names in the SAS Language" in *SAS Language Reference: Concepts* for naming conventions that you can use for names and member names.

SELECT Statement

Includes specified files or entries in the transport file.

Interaction: You can use either EXCLUDE statements or SELECT statements in a PROC CPORT step, but not both.

Tip: There is no limit to the number of SELECT statements that you can use in one invocation of PROC CPORT.

Examples: "Example 2: Exporting Individual Catalog Entries" on page 555

"Example 4: Using PROC CIMPORT to Import a French Data Set into a UTF-8 SAS Session" on page 414

Syntax

SELECT *SAS file(s) | catalog entry(s)* </ MEMTYPE=*mtype*>
</ ENTRYTYPE=*entry-type*> ;

Required Argument

SAS file(s) | catalog entry(s)
specifies one or more SAS files or one or more catalog entries to be included in the transport file. Specify SAS filenames when you export a SAS library; specify catalog entry names when you export an individual SAS catalog. Separate multiple filenames or entry names with a space. You can use shortcuts to list many like-named files in the SELECT statement. For more information, see "SAS Data Sets" in *SAS Language Reference: Concepts*.

Optional Arguments

ENTRYTYPE=*entry-type*
specifies a single entry type for the catalog entries listed in the SELECT statement. See *SAS Language Reference: Concepts* for a complete list of catalog entry types.

Alias ETYPE=, ET=

Restriction ENTRYTYPE= is valid only when you export an individual SAS catalog.

MEMTYPE=*mtype*
specifies a single member type for one or more SAS files listed in the SELECT statement. Valid values are CATALOG, DATA, or ALL. If you do not specify the MEMTYPE= option in the SELECT statement, then processing is restricted to those member types specified in the MEMTYPE= option in the PROC CPORT statement.

You can also specify the MEMTYPE= option, enclosed in parentheses, immediately after the name of a member. In parentheses, MEMTYPE= identifies the type of the member name that immediately precedes it. When you use this form of the option, it overrides the MEMTYPE= option that follows the slash in the SELECT statement, but it must match the MEMTYPE= option in the PROC CPORT statement.

Alias MTYPE=, MT=

Default If you do not specify MEMTYPE= in the PROC CPORT statement or in the SELECT statement, the default is MEMTYPE=ALL.

Restrictions MEMTYPE= is valid only when you export a SAS library.

If you specify a member type for MEMTYPE= in the PROC CPORT statement, it must agree with the member type that you specify for MEMTYPE= in the SELECT statement.

See Refer to "Names in the SAS Language" in *SAS Language Reference: Concepts* for naming conventions that you can use for names and member names.

TRANTAB Statement

Specifies translation tables for characters in catalog entries that you export.

Restriction: The TRANTAB statement does not support DBCS or UTF-8 SAS sessions.

Tip: You can specify only one translation table for each TRANTAB statement. However, you can use more than one translation table in a single invocation of PROC CPORT.

See: The TRANTAB Statement for the CPORT Procedure and the UPLOAD and DOWNLOAD Procedures in *SAS National Language Support (NLS): Reference Guide*.

Example: "Example 4: Applying a Translation Table" on page 557

Syntax

TRANTAB NAME=*translation-table-name* <*options*>;

Usage: CPORT Procedure

READ= Data Set Option in the PROC CPORT Statement

To be authorized to create the transport file for a read-protected data set, you must include the password (clear-text or encoded). If the password is not included, the transport file cannot be created.

If you are working with a password protected data set, you can supply that password using the READ= option. If you do not supply the password using the READ= option for a read-protected data set, you are prompted for the password.

Use the READ= data set option to include the appropriate password for the read-protected data set when creating a transport file. In Example 1, PROC CPORT copies the input file that is named SOURCE.GRADES, includes the password ADMIN with the data set, and creates the transport file named GRADESOUT.

Example 1: Clear-Text Password:

```
proc cport data=source.grades(read=admin) file=gradesout;
```

In Example 2, an encoded password is specified with the READ= option. An encoded password is generated via the PWENCODE procedure. For details, see Chapter 54, "PWENCODE Procedure," on page 1939.

Example 2: Encoded Password

```
proc cport
data=source.grades(read={sas003}6EDB396015B96DBD9E80F0913A543819A8E5)
   file=gradesout;
```

If the password is omitted when referring to a password protected data set, SAS prompts for the password. If an invalid password is specified, an error message is sent to the log. Here is an example error:

```
ERROR: Invalid or missing READ password on member WORK.XYZ.DATA
```

If the data set is transported as part of a library or named in a SELECT statement, a password is not required. However, if a data set with a password is transported and the target SAS engine does not support passwords, the transport file cannot be imported.

For details about the READ= data set option, see *SAS Data Set Options: Reference*, and for details about password-protected data sets, see *SAS Language Reference: Concepts*.

Note: PROC CIMPORT does not require a password in order to restore the transport file in the target environment. However, other SAS procedures that use the password-protected data set must include the password.

CPORT Problems: Creating Transport Files

About Transport Files and Encodings

The character data in a transport file is created for the following types of encodings:

- the UTF-8 encoding of the SAS session in which the transport file is created.
- the Windows encoding that is associated with the locale of the SAS session in which the transport file is created. However, starting in SAS 9.4M3, PROC CIMPORT supports the ability to import data sets that are created in non-UTF-8 SAS sessions into UTF-8 SAS sessions.

  Using PROC CIMPORT to import a data set in a UTF-8 session preserves the encoding value of the data set. For example, if a data set with SHIFT-JIS encoding is imported into a UTF-8 session using PROC CIMPORT, PROC CONTENTS shows that the SHIFT-JIS encoding is maintained.

Note: The ENCODINGINFO= option displays the Window's encoding associated with the locale of the SAS session in which the transport file was created.

- In SAS 9.4, when you use PROC CPORT to create a transport file that is encoded with US-ASCII on an ASCII platform, regardless of the session encoding, the US-ASCII encoding is preserved for that transport file. If you then transport that data set to an ASCII platform using PROC CIMPORT, the US-ASCII encoding for that transport file is preserved and is not transcoded. The data set that is created has the US-ASCII encoding, not the session encoding. For example, if your session encoding is WLATIN1, you use PROC CPORT to create a data set that has an encoding of US-ASCII. The US-ASCII encoding is preserved in the transport file, instead of the WLATIN1 encoding. This preservation also occurs when you use PROC CIMPORT on this data set. The US-ASCII encoding is preserved and is not transcoded when you use PROC CIMPORT to transport the data set to an ASCII platform.

  Note: The preservation of the US-ASCII encoding occurs only on an ASCII platform, not on z/OS.

- on a z/OS platform, PROC CIMPORT creates data sets using the session encoding.

These examples show how SAS applies an encoding to a transport file:

Table 16.1 *Assignment of Encodings to Transport Files*

Encoding Value of the Transport File	Example of Applying an Encoding in a SAS Invocation	Explanation
utf-8 or us-ascii	sas9 -encoding utf8;	A SAS session is invoked using the UTF-8 encoding. The session encoding is applied to the transport file. Note that starting in SAS 9.4M3, if the data set is US-ASCII, the US-ASCII encoding is preserved, not the session encoding.
wlatin2	sas9 -locale pl_PL;	A SAS session is invoked using the default UNIX encoding, LATIN2, which is associated with the Polish Poland locale.

For a complete list of encodings that are associated with each locale, see Locale Tables in *SAS National Language Support (NLS): Reference Guide*.

In order for a transport file to be imported successfully, the encodings of the source and target SAS sessions must be compatible. Here is an example of compatible source and target SAS sessions:

Table 16.2 Compatible Encodings

Source SAS Session			Target SAS Session	
Locale	**UNIX SAS Session Encoding**	**Transport File Encoding**	**Locale**	**Windows SAS Session Encoding**
es_MX (Spanish Mexico)	latin1	wlatin1	it_IT (Italian Italy)	wlatin1

The encodings of the source and target SAS sessions are compatible because the Windows default encoding for the es_MX locale is WLATIN1 and the encoding of the target SAS session is WLATIN1. For more detailed information about compatible languages and encodings, see the SAS Press book SAS Encoding: Understanding the Details, by Manfred Kiefer.

However, if the encodings of the source and target SAS sessions are incompatible, a transport file might not be successfully imported. (See the introduction to this section.) Here is an example of incompatible encodings:

Table 16.3 Incompatible Encodings

Source SAS Session			Target SAS Session	
Locale	**UNIX SAS Session Encoding**	**Transport File Encoding**	**Locale**	**z/OS Encoding**
cs_CZ (Czech Czechoslovakia)	latin2	wlatin2	de_DE (German Germany)	open_ed-1141

The encodings of the source and target SAS sessions are incompatible because the Windows default encoding for the cs_CZ locale is WLATIN2 and the encoding of the target SAS session is OPEN_ED-1141. A transport file cannot be imported between these locales.

When importing transport files, you can use the ENCODINGINFO= option to see the encoding value of the transport file. Otherwise, you are alerted to compatibility problems via warnings and error messages. For more information about the ENCODINGINFO= option, see "ENCODINGINFO=ALL | *n*" on page 394.

Data Control Blocks Characteristics

A common problem when you create or import a transport file under the z/OS environment is a failure to specify the correct Data Control Block (DCB)

characteristics. When you reference a transport file, you must specify the following DCB characteristics:

- LRECL=80
- BLKSIZE=8000
- RECFM=FB
- DSORG=PS

Another common problem can occur if you use communications software to move files from another environment to z/OS. In some cases, the transport file does not have the proper DCB characteristics when it arrives on z/OS. If the communications software does not allow you to specify file characteristics, try the following approach for z/OS:

1. Create a file under z/OS with the correct DCB characteristics and initialize the file.
2. Move the transport file from the other environment to the newly created file under z/OS using binary transfer.

Loss of Numeric Precision

PROC CPORT and PROC CIMPORT can lose precision on numeric values that are extremely small and large. Refer to "Loss of Numeric Precision and Magnitude" in *SAS/CONNECT User's Guide* for details.

Examples: CPORT Procedure

Example 1: Exporting Multiple Catalogs

Features: PROC CPORT statement options
FILE=
MEMTYPE=

Details

This example shows how to use PROC CPORT to export entries from all of the SAS catalogs in the SAS library that you specify.

Program

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;

proc cport library=source file=tranfile memtype=catalog;
run;
```

Program Description

Specify the library reference for the SAS library that contains the source files to be exported and the file reference to which the output transport file is written. The LIBNAME statement assigns a libref for the SAS library. The FILENAME statement assigns a fileref and any operating environment options for file characteristics for the transport file that PROC CPORT creates.

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;
```

Create the transport file. The PROC CPORT step executes on the operating environment where the source library is located. MEMTYPE=CATALOG writes all SAS catalogs in the source library to the transport file.

```
proc cport library=source file=tranfile memtype=catalog;
run;
```

Log Examples

Example Code 16.1 *Exporting Multiple Catalogs*

```
NOTE: Proc CPORT begins to transport catalog SOURCE.FINANCE
NOTE: The catalog has 5 entries and its maximum logical record length is 866.
NOTE: Entry LOAN.FRAME has been transported.
NOTE: Entry LOAN.HELP has been transported.
NOTE: Entry LOAN.KEYS has been transported.
NOTE: Entry LOAN.PMENU has been transported.
NOTE: Entry LOAN.SCL has been transported.

NOTE: Proc CPORT begins to transport catalog SOURCE.FORMATS
NOTE: The catalog has 2 entries and its maximum logical record length is 104.
NOTE: Entry REVENUE.FORMAT has been transported.
NOTE: Entry DEPT.FORMATC has been transported.
```

Example 2: Exporting Individual Catalog Entries

Features: PROC CPORT statement option
FILE=
SELECT statement

Details

This example shows how to use PROC CPORT to export individual catalog entries, rather than all of the entries in a catalog.

Program

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;

proc cport catalog=source.finance file=tranfile;
select loan.scl;
run;
```

Program Description

Assign library references. The LIBNAME and FILENAME statements assign a libref for the source library and a fileref for the transport file, respectively.

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;
```

Write an entry to the transport file. SELECT writes only the LOAN.SCL entry to the transport file for export.

```
proc cport catalog=source.finance file=tranfile;
select loan.scl;
run;
```

Log Examples

Example Code 16.2 *Exporting Individual Catalog Entries*

```
NOTE: Proc CPORT begins to transport catalog SOURCE.FINANCE
NOTE: The catalog has 5 entries and its maximum logical record length is 866.
NOTE: Entry LOAN.SCL has been transported.
```

Example 3: Exporting a Single SAS Data Set

Features: PROC CPORT statement option
FILE=

Details

This example shows how to use PROC CPORT to export a single SAS data set.

Program

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;

proc cport data=source.times file=tranfile;
```

```
run;
```

Program Description

Assign library references. The LIBNAME and FILENAME statements assign a libref for the source library and a fileref for the transport file, respectively.

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;
```

Specify the type of file that you are exporting. The DATA= specification in the PROC CPORT statement tells the procedure that you are exporting a SAS data set rather than a library or a catalog.

```
proc cport data=source.times file=tranfile;
run;
```

Log Examples

Example Code 16.3 *Exporting a Single SAS Data Set*

```
NOTE: Proc CPORT begins to transport data set SOURCE.TIMES
NOTE: The data set contains 2 variables and 2 observations.
      Logical record length is 16.
NOTE: Transporting data set index information.
```

Example 4: Applying a Translation Table

Features:

PROC CPORT statement option
FILE=

TRANTAB statement option
TYPE=

Details

This example shows how to apply a customized translation table to the transport file before PROC CPORT exports it. For this example, assume that you have already created a customized translation table called TTABLE1.

Program

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;

proc cport catalog=source.formats file=tranfile;
   trantab name=ttable1 type=(format);
run;
```

Program Description

Assign library references. The LIBNAME and FILENAME statements assign a libref for the source library and a fileref for the transport file, respectively.

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;
```

Apply the translation specifics. The TRANTAB statement applies the translation that you specify with the customized translation table TTABLE1. TYPE= limits the translation to FORMAT entries.

```
proc cport catalog=source.formats file=tranfile;
   trantab name=ttable1 type=(format);
run;
```

Log Examples

Example Code 16.4 *Applying a Translation Table*

```
NOTE: Proc CPORT begins to transport catalog SOURCE.FORMATS
NOTE: The catalog has 2 entries and its maximum logical record length is 104.
NOTE: Entry REVENUE.FORMAT has been transported.
NOTE: Entry DEPT.FORMATC has been transported.
```

Example 5: Exporting Entries Based on Modification Date

Features: PROC CPORT statement options
AFTER=
FILE=

Details

This example shows how to use PROC CPORT to transport only the catalog entries with modification dates equal to or later than the date that you specify in the AFTER= option.

Program

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;

proc cport catalog=source.finance file=tranfile
           after='09sep1996'd;
run;
```

Program Description

Assign library references. The LIBNAME and FILENAME statements assign a libref for the source library and a fileref for the transport file, respectively.

```
libname source 'sas-library';
filename tranfile 'transport-file';

host-options-for-file-characteristics;
```

Specify the catalog entries to be written to the transport file. AFTER= specifies that only catalog entries with modification dates on or after September 9, 1996, should be written to the transport file.

```
proc cport catalog=source.finance file=tranfile
           after='09sep1996'd;
run;
```

Log Examples

PROC CPORT writes messages to the SAS log to inform you that it began the export process for all the entries in the specified catalog. However, PROC CPORT wrote only the entries LOAN.FRAME and LOAN.HELP in the FINANCE catalog to the transport file because only those two entries had a modification date equal to or later than September 9, 1996. That is, of all the entries in the specified catalog, only two met the requirement of the AFTER= option.

Example Code 16.5 *Exporting Entries Based on Modification Date*

```
NOTE: Proc CPORT begins to transport catalog SOURCE.FINANCE
NOTE: The catalog has 5 entries and its maximum logical record length is 866.
NOTE: Entry LOAN.FRAME has been transported.
NOTE: Entry LOAN.HELP has been transported.
```

17

DATASETS Procedure

Overview: DATASETS Procedure

Managing Data Sets Using the DATASETS Procedure

The DATASETS procedure is a utility procedure that manages your SAS files. With PROC DATASETS, you can do the following:

- copy SAS files from one SAS library to another
- rename SAS files
- repair SAS files
- delete SAS files
- list the SAS files that are contained in a SAS library
- list the attributes of a SAS data set:
  - the date on which the data was last modified
  - whether the data is compressed
  - whether the data is indexed
- manipulate passwords on SAS files
- append SAS data sets
- modify attributes of SAS data sets and variables within the data sets
- create and delete indexes on SAS data sets
- create and manage audit files for SAS data sets
- create and delete integrity constraints on SAS data sets
- create and manage extended attributes of data sets

Notes

- Although the DATASETS procedure can perform some operations on catalogs, generally the CATALOG procedure is the best utility to use for managing catalogs.
- The term *member* often appears as a synonym for *SAS file*. If you are unfamiliar with SAS files and SAS libraries, see "SAS Files Concepts" in *SAS Language Reference: Concepts*.
- If the NOLIST option is specified, then the PROC DATASETS statement does not list the SAS files. However, if you are using the ODS LISTING statement the result is displayed in the Results window. To view the output only in the SAS log, use the ODS EXCLUDE statement with the LISTING destination.
- PROC DATASETS cannot work with sequential data libraries.
- You cannot change the length of a variable using the LENGTH statement or the LENGTH= option in an ATTRIB statement.
- There can be a discrepancy between the modified date in PROC DATASETS, PROC CONTENTS, and other components of SAS, such as SAS Explorer. The two modified dates and times are distinctly different:
  - Operating-environment modified date and time is reported by the SAS Explorer and the PROC DATASETS LIST option.
  - The modified date and time reported by the CONTENTS statement is the date and time that the data within the data set was actually modified.

- If you have a library containing a large number of members, the DATASETS procedure might show an increase in process time. You might want to reorganize your library into smaller libraries for better performance.
- Beginning in the SAS 9.4 release, extended attributes are supported.
- If you want to use the KILL functionality of the DATASETS procedure and the DBMS=Redshift, then you need to use a SCHEMA= option in the LIBNAME statement.

Concepts: DATASETS Procedure

Procedure Execution

Execution of Statements

When you start the DATASETS procedure, you specify the procedure input library in the PROC DATASETS statement. If you omit a procedure input library, the procedure processes the current default SAS library (usually the Work library). To specify a new procedure input library, issue the DATASETS procedure again.

Statements execute in the order in which they are written. Use CONTENTS, COPY, CONTENTS if you want to see the contents of a data set, copy a data set, and then visually compare the contents of the second data set with the first.

RUN-Group Processing

PROC DATASETS supports RUN-group processing. RUN-group processing enables you to submit RUN groups without ending the procedure.

The DATASETS procedure supports four types of RUN groups. Each RUN group is defined by the statements that compose it and by what causes it to execute.

Some statements in PROC DATASETS act as implied RUN statements because they cause the RUN group preceding them to execute.

The following list discusses what statements compose a RUN group and what causes each RUN group to execute:

- The PROC DATASETS statement always executes immediately. No other statement is necessary to cause the PROC DATASETS statement to execute. Therefore, the PROC DATASETS statement alone is a RUN group.
- The MODIFY statement, and any of its subordinate statements, form a RUN group. These RUN groups always execute immediately. No other statement is necessary to cause a MODIFY RUN group to execute.
- The APPEND, CONTENTS, and COPY statements (including EXCLUDE and SELECT, if present), form their own separate RUN groups. Every APPEND statement forms a single-statement RUN group; every CONTENTS statement forms a single-statement RUN group; and every COPY step forms a RUN group. Any other statement in the procedure, except those that are subordinate to either the COPY or MODIFY statement, causes the RUN group to execute.
- One or more of the following statements form a RUN group:
  - AGE
  - CHANGE
  - DELETE
  - EXCHANGE
  - REPAIR
  - SAVE

  If any of these statements appear in sequence in the PROC step, the sequence forms a RUN group. For example, if a REPAIR statement appears immediately after a SAVE statement, the REPAIR statement does not force the SAVE statement to execute; it becomes part of the same RUN group. To execute the RUN group, submit one of the following statements:
  - PROC DATASETS
  - APPEND
  - CONTENTS
  - COPY
  - MODIFY
  - QUIT
  - RUN
  - another DATA or PROC step

SAS reads the program statements that are associated with one task until it reaches a RUN statement or an implied RUN statement. SAS executes all of the preceding statements immediately and continues reading until it reaches another RUN statement or implied RUN statement. To execute the last task, you must use a RUN statement or a statement that stops the procedure.

The following PROC DATASETS step contains five RUN groups:

```
LIBNAME dest 'SAS-library';
   /* RUN group */

proc datasets;
      /* RUN group */
```

```
      change nutr=fatg;
      delete bldtest;
      exchange xray=chest;
         /* RUN group */
      copy out=dest;
         select report;
         /* RUN group */
      modify bp;
         label dias='Taken at Noon';
         rename weight=bodyfat;
         /* RUN group */
      append base=tissue data=newtiss;
   quit;
```

Note: If you are running in interactive line mode, you can receive messages that statements have already executed before you submit a RUN statement. Plan your tasks carefully if you are using this environment for running PROC DATASETS.

Error Handling

Generally, if an error occurs in a statement, the RUN group containing the error does not execute. RUN groups preceding or following the one containing the error execute normally. The MODIFY RUN group is an exception. If a syntax error occurs in a statement subordinate to the MODIFY statement, only the statement containing the error fails. The other statements in the RUN group execute.

Note: If the first word of the statement (the statement name) is in error and the procedure cannot recognize it, the procedure treats the statement as part of the preceding RUN group.

Password Errors

If there is an error involving an incorrect or omitted password in a statement, the error affects only the statement containing the error. The other statements in the RUN group execute.

Forcing a RUN Group with Errors to Execute

The FORCE option in the PROC DATASETS statement forces execution of the RUN group even if one or more of the statements contain errors. Only the statements that are error-free execute.

Ending the Procedure

To stop the DATASETS procedure, you must issue a QUIT statement, a RUN CANCEL statement, a new PROC statement, or a DATA statement. Submitting a QUIT statement executes any statements that have not executed. Submitting a RUN CANCEL statement cancels any statements that have not executed.

Extended Attributes

Extended attributes are customized metadata for your SAS files. They are user-defined characteristics that you associate with a SAS data set or variable. Whereas common SAS attributes, such as length for variables for data sets are predefined SAS system attributes, extended attributes are attributes that you define yourself. Extended attributes are organized into (name, value) pairs.

Use the MODIFY statement to add, delete, remove, set, and update extended attributes. When using the COPY statement, if the OUT= library engine supports extended attributes, they are copied. Extended attributes are not appended when using the APPEND statement, unless the BASE= data set does not exist.

Extended attributes can be used to automate tasks that require a custom attribute to be associated with a variable or a data set.

An extended attribute can have numeric or character values. There is no maximum length to an extended attribute character value. By default, each value is stored in 256-byte segments. The length of the segment can be changed with the SEGLEN= option of the XATTR OPTIONS statement. This option indicates the length of the storage element that will hold the character attribute value. Should the segment size not be large enough for some particular character attribute value, another segment is allocated. To minimize processing time, choose a length that would accommodate most attribute values for the data set.

The following output shows a data set and variables with extended attributes.

Output 17.1 *Contents of a Data Set with Extended Attributes*

Alphabetic List of Variables and Attributes			
#	Variable	Type	Len
2	age	Num	8
5	cars	Num	8
3	income	Num	8
4	kids	Num	8
1	purchase	Char	3

Alphabetic List of Data Set Extended Attributes		
Extended Attribute	Numeric Value	Character Value
attrib	.	table
role	.	train

Alphabetic List of Extended Attributes on Variables			
Extended Attribute	Attribute Variable	Numeric Value	Character Value
level	income	.	interval
level	purchase	.	nominal
role	age	.	reject
role	income	.	input
role	purchase	.	target

For information about using extended attributes, see "XATTR ADD Statement" on page 660, "XATTR DELETE Statement" on page 661, "XATTR REMOVE Statement" on page 662, "XATTR SET Statement" on page 663, and "XATTR UPDATE Statement" on page 664.

Contents of a Library at the Directory Level

In a concatenated library, each physical piece of the library is a level. Level 1 is the first location in the libref definition, Level 2 is the second location, and so on. PROC DATASETS reports the number of levels in the library as a value under the LEVEL specification.

The following example shows that there are 6 Levels in the libref named Samp.

The SAS System

Directory	
Libref	SAMP
Levels	6

Level 1	
Engine	V9
Physical Name	C:\Program Files\SASHome\SASFoundation\9.4\core\sample
Filename	C:\Program Files\SASHome\SASFoundation\9.4\core\sample

Level 2	
Engine	V9
Physical Name	C:\Program Files\SASHome\SASFoundation\9.4\access\sample
Filename	C:\Program Files\SASHome\SASFoundation\9.4\access\sample

Level 3	
Engine	V9
Physical Name	C:\Program Files\SASHome\SASFoundation\9.4\accesssample\sample
Filename	C:\Program Files\SASHome\SASFoundation\9.4\accesssample\sample

Level 4	
Engine	V9
Physical Name	C:\Program Files\SASHome\SASFoundation\9.4\connect\sample
Filename	C:\Program Files\SASHome\SASFoundation\9.4\connect\sample

Level 5	
Engine	V9
Physical Name	C:\Program Files\SASHome\SASFoundation\9.4\eis\sample
Filename	C:\Program Files\SASHome\SASFoundation\9.4\eis\sample

Level 6	
Engine	V9
Physical Name	C:\Program Files\SASHome\SASFoundation\9.4\ets\sample
Filename	C:\Program Files\SASHome\SASFoundation\9.4\ets\sample

CONTENTS Statement with VARCHAR

If there is a VARCHAR data type in the table, PROC CONTENTS or PROC DATASETS CONTENTS statement shows the Length in bytes and characters, as well as the max bytes used. PROC CONTENTS reports metadata about the table and the metadata about the variables. The CAS engine is the only engine supporting VARCHAR.

The bottom portion of PROC CONTENTS (related to the variable metadata) is the metadata that is represented in the SAS session. Based on what type of transcoding that might or might not be needed to go from the CAS UTF–8 encoding to the SAS session encoding. The variable byte length used in SAS is dependent on the encoding of the SAS session. The variable byte length used in the SAS session might differ from the byte length.

Output 17.2 *Contents of Mycas.French2 Table*

Data Set Name	MYCAS.FRENCH2	**Observations**	11
Member Type	DATA	**Variables**	2
Engine	CAS	**Indexes**	0
Created	08/16/2017 18:05:10	**Observation Length**	40
Last Modified	08/16/2017 18:05:10	**Deleted Observations**	0
Protection		**Compressed**	NO
Data Set Type		**Sorted**	NO
Label			
Data Representation	SOLARIS_X86_64, LINUX_X86_64, ALPHA_TRU64, LINUX_IA64		
Encoding	utf-8 Unicode (UTF-8)		

Engine/Host Dependent Information	
Data Limit	100MB
Caslib	CASUSER,
Scope	Session

Alphabetic List of Variables and Attributes

#	Variable	Type	Len		Max Bytes Used
			Bytes	Chars	
1	nterm	Varchar	80	20	19
2	term	Char	19		

Use the following code to show the contents of the Mycas library:

```
proc datasets lib=mycas;
contents data=cars;
run;
```

Output 17.3 *Mycas Library and Mycas.Cars Table*

Data Set Name	MYCAS.CARS	Observations	428
Member Type	DATA	Variables	15
Engine	CAS	Indexes	0
Created	08/16/2017 17:55:43	Observation Length	160
Last Modified	08/16/2017 17:55:43	Deleted Observations	0
Protection		Compressed	NO
Data Set Type		Sorted	NO
Label			
Data Representation	SOLARIS_X86_64, LINUX_X86_64, ALPHA_TRU64, LINUX_IA64		
Encoding	utf-8 Unicode (UTF-8)		

Engine/Host Dependent Information	
Data Limit	100MB
Caslib	CASUSER
Scope	Session

Alphabetic List of Variables and Attributes

#	Variable	Type	Len	Format	Label
9	Cylinders	Num	8		
5	DriveTrain	Char	5		
8	EngineSize	Num	8		Engine Size (L)
10	Horsepower	Num	8		
7	Invoice	Num	8	DOLLAR8.	
15	Length	Num	8		Length (IN)
11	MPG_City	Num	8		MPG (City)
12	MPG_Highway	Num	8		MPG (Highway)
6	MSRP	Num	8	DOLLAR8.	
1	Make	Char	13		
2	Model	Char	40		
4	Origin	Char	6		
3	Type	Char	8		
13	Weight	Num	8		Weight (LBS)
14	Wheelbase	Num	8		Wheelbase (IN)

Use the following code to show the contents of the Mycas library:

```
proc datasets lib=mycas;
contents data=mycs.cars directory details;
run;
```

Using the DIRECTORY and DETAILS Option

Directory	
Libref	MYCAS
Engine	CAS
Physical Name	eb4545e1
Session UUID	eb4545e1
Session Name	SASCAS1
Server Host	rdoesx
Server Port	55
Caslib	CASUSER

#	Name	Member Type	Obs, Entries or Indexes	Vars	Label	Number of Rows	Number of Columns	Last Modified	Data Encoding	Scope
1	CARS	DATA	428	15		428	15	08/16/2017 19:29:50	utf-8	Session
2	LASTMONTH	DATA	12	7		12	7	08/16/2017 18:56:09	utf-8	Session

Differences in the DATASETS Procedure Output When Using SAS/ACCESS LIBNAME Engines

When you use a SAS/ACCESS LIBNAME engine to access a database, some of the information that is available in the header of a SAS data set is not available to the procedure. Therefore, the procedure does not have the information to display. The CONTENTS procedure, the DATASETS COPY statement, and the DATASETS CONTENTS statement do not provide information about the indexes, integrity constraints, and number of observations. For example, copying a table with indexes and integrity constraints results in a table with no indexes or integrity constraints if the engine used to access the table is a SAS/ACCESS LIBNAME engine. In the following code, the output from the CONTENTS statement displays a `0` (zero) in the index field although the database has indexes, and displays a `.` (period) for the unknown number of observations.

```
proc datasets lib=mylib details;
   contents data=table-name;
run;
quit;
```

To obtain the number of observations, run an SQL query to obtain the count using the LIBNAME engine or explicit-pass through on the DBMS table.

To obtain the information about indexes and integrity constraints, you can use explicit pass-through of database-specific syntax to query the system tables. For documentation on explicit pass-through, see "Connecting to a DBMS By Using the SQL Procedure Pass-Through Facility" in *SAS SQL Procedure User's Guide*.

CAS Processing for the DATASETS Procedure

Accessing CAS tables through the CAS LIBNAME engine with the DATASETS procedure results in some behavior that differs from other LIBNAME engines. The following is a summary of these behavior differences:

- Indexes, integrity constraints, and extended attributes are not supported in CAS tables.
- The MODIFY statement results in an error because UPDATE access is not supported.
- If there is a VARCHAR data type in the table, the CONTENTS statement shows the length in bytes, length in characters, and maximum bytes used.
- The encoding shown by the CONTENTS statement is the encoding of the CAS table.
- The block I/O method cannot be used when appending a CAS table to a SAS data set.
- You cannot use the APPEND statement to add data to a CAS table because UPDATE access is not supported. Data from a CAS table can be appended to a SAS data set.
- If the CAS LIBNAME engine is used for both the input and output libraries with the COPY statement, the COPY task is executed on the CAS server. The NOACCEL option disables this behavior, causing the COPY task to be executed in the SAS session.

PROC DATASETS and the Output Delivery System (ODS)

Most procedures send their messages to the log and their procedure results to the output. PROC DATASETS is unique because it sends procedure results to both the log and the procedure output table. When the interface to ODS was created, it was decided that all procedure results (from both the log and the procedure output table) should be available to ODS. In order to implement this feature and maintain compatibility with earlier releases, the interface to ODS had to be slightly different from the usual interface.

By default, the PROC DATASETS statement itself produces two output objects: Members and Directory. These objects are routed to the log. The CONTENTS statement produces three output objects by default: Attributes, EngineHost, and Variables. (The use of various options adds other output objects.) These objects are routed to the procedure output table. If you open an ODS destination (such as HTML, RTF, or PRINTER), all of these objects are, by default, routed to that destination.

You can use the ODS SELECT and ODS EXCLUDE statements to control which objects go to which destination, just as you can for any other procedure.

PROC DATASETS and PROC CONTENTS assign a name to each table that they create. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output tables.

PROC CONTENTS generates the same ODS tables as PROC DATASETS with the CONTENTS statement.

Table 17.1 *ODS Tables Produced by the DATASETS Procedure without the CONTENTS Statement*

ODS Table	Description	Generates Table
Directory	General library information	Unless you specify the NOLIST option
Members	Library member information	Unless you specify the NOLIST option

Table 17.2 *ODS Table Names Produced by PROC CONTENTS and PROC DATASETS with the CONTENTS Statement*

ODS Table	Description	Generates Table
Attributes	Data set attributes	Unless you specify the SHORT option
Directory	General library information	If you specify DATA=<*libref*.>_ALL_ or the DIRECTORY option
Members	Library member information	If you specify DATA=<*libref*.>_ALL_ or the DIRECTORY option
Position	A detailed listing of variables by logical position in the table	If you specify the VARNUM option and you do not specify the SHORT option
PositionShort	A concise listing of variables by logical position in the table	If you specify the VARNUM option and the SHORT option
Variables	A detailed listing of variables in alphabetical order	Unless you specify the SHORT option
VariablesShort	A concise listing of variables in alphabetical order	If you specify the SHORT option

Syntax: DATASETS Procedure

Notes: Data set names and variable names that end with large numeric values that are larger than a long integer cannot be used in numbered-range lists. For more information, see "Restriction for Numbered Range Lists" in *SAS Language Reference: Concepts*.

NOTE: _LAST_ is the name of the last data set that is created in your session. When the BASE= data set does not exist and PROC APPEND creates it, PROC APPEND sets _LAST_ to the name of the BASE= data set.

Tips: Supports RUN-group processing.

Supports the Output Delivery System. For details, see "Output Delivery System: Basic Concepts" in *SAS Output Delivery System: User's Guide*.

See: For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

<*variable-name-2* (*attribute-name-1=attribute-value-1*
<*attribute-name-2=attribute-value-2*> ...)>;

XATTR UPDATE DS *attribute-name-1=attribute-value-1*
<*attribute-name-2=attribute-value-2 ...*>;

or

XATTR UPDATE VAR *variable-name-1* (*attribute-name-1=attribute-value-1*
<*attribute-name-2=attribute-value-2 ...*>)
<*variable-name-2* (*attribute-name-1=attribute-value-1*
<*attribute-name-2=attribute-value-2 ...*>)>;

REBUILD *SAS-file* </ <ENCRYPTKEY=*key-value*>
<ALTER=*password*> <GENNUM=*n*> <MEMTYPE=*member-type*>
<NOINDEX>>;

REPAIR </ <ENCRYPTKEY=*key-value*>
<ALTER=*alter-password*> <GENNUM=*integer*> <MEMTYPE=*member-type*>>;

SAVE *SAS-file(s)* </ MEMTYPE=*member-type*>;

Statement	Task	Example
PROC DATASETS	Manage SAS files	
AGE	Rename a group of related SAS files	Ex. 7
APPEND	Add observations from one SAS data set to the end of another SAS data set	Ex. 6
ATTRIB	Associate a format, informat, or label with variables in the SAS data set specified in the MODIFY statement	Ex. 1
AUDIT	Initiate, control, suspend, resume, or terminate event logging to an audit file	
CHANGE	Rename one or more SAS files	Ex. 2

Statement	Task	Example
CONTENTS	Describe the contents of one or more SAS data sets and prints a directory of the SAS library	Ex. 5
COPY	Copy all or some of the SAS files	Ex. 2
DELETE	Delete SAS files	Ex. 2
EXCHANGE	Exchange the names of two SAS files	Ex. 2
EXCLUDE	Exclude SAS files from copying	Ex. 2
FORMAT	Permanently assign, change, and remove variable formats	Ex. 4
IC CREATE	Create an integrity constraint	
IC DELETE	Delete an integrity constraint	
IC REACTIVATE	Reactivate a foreign key integrity constraint	
INDEX CENTILES	Update centiles statistics for indexed variables	
INDEX CREATE	Create simple or composite indexes	Ex. 4
INDEX DELETE	Delete one or more indexes	
INFORMAT	Permanently assign, change, and remove variable informats	Ex. 4
INITIATE	Create an audit file that has the same name as the SAS data file and a data set type of AUDIT	Ex. 8
LABEL	Assign, change, and remove variable labels	Ex. 4
LOG	Specify the settings for an audit file	Ex. 8
MODIFY	Change the attributes of a SAS file and the attributes of variables	Ex. 4
REBUILD	Specify whether to restore or delete the disabled indexes and integrity constraints	
RENAME	Rename variables in the SAS data set	Ex. 4
REPAIR	Attempt to restore damaged SAS data sets or catalogs	
RESUME	Resume event logging to the audit file, if the audit file was suspended	Ex. 8
SAVE	Delete all the SAS files except the ones listed in the SAVE statement	Ex. 3
SELECT	Select SAS files for copying	Ex. 2
SUSPEND	Suspend event logging to the audit file	Ex. 8

Statement	Task	Example
TERMINATE	Terminate event logging and deletes the audit file	Ex. 8
USER_VAR	Define optional variables to be logged in the audit file with each update to an observation	Ex. 8
XATTR ADD	Add an extended attribute to a variable or a data set	Ex. 9
XATTR DELETE	Delete all of the extended attributes from a data set	
XATTR OPTIONS	Specify options as needed for extended attributes	Ex. 9
XATTR REMOVE	Remove an extended attribute from a variable or a data set	
XATTR SET	Update or add an extended attribute to a variable or a data set	
XATTR UPDATE	Update an extended attribute of a variable or a data set	Ex. 9

PROC DATASETS Statement

Manages SAS files.

Syntax

PROC DATASETS <*options*>;

Summary of Optional Arguments

ALTER=*alter-password*
: provides Alter access to any alter-protected SAS file in the SAS library.

DETAILS

NODETAILS
: includes information in the log about the number of observations, number of variables, number of indexes, and data set labels.

ENCRYPTKEY=*key-value*
: specifies the key value for AES encryption.

FORCE

forces either a RUN group to execute even when there are errors or forces an Append operation.

GENNUM=ALL | HIST | REVERT | *integer*
: restricts processing for generation data sets.

KILL
: deletes SAS files.

LIBRARY=*libref*
: specifies the procedure input/output library.

MEMTYPE=(*member-type(s)*)
: restricts processing to a certain type of SAS file.

NODETAILS
: see the description of DETAILS | NODETAILS.

NOLIST
: suppresses the printing of the directory.

NOPRINT
: suppresses the printing of the output to the log and listing.

NOWARN
: suppresses error processing.

PW= *password*
: provides Read, Write, or Alter access.

READ=*read-password*
: provides Read access.

Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files in the SAS library.

See "Using Passwords with the DATASETS Procedure" on page 665

DETAILS | NODETAILS
determines whether the following columns are written to the log:

Obs, Entries, or Indexes	gives the number of observations for SAS files of type AUDIT, DATA, and VIEW; the number of entries for type CATALOG; and the number of files of type INDEX that are associated with a data file, if any. If SAS cannot determine the number of observations in a SAS data set, the value in this column is set to missing. For example, in a very large data set, if the number of observations or deleted observations exceeds the number that can be stored in a double-precision integer, the count shows as missing. The value for type CATALOG is the total number of entries. For other types, this column is blank.
Vars	gives the number of variables for types AUDIT, DATA, and VIEW. If SAS cannot determine the number of variables in the SAS data set, the value in this column is set to missing. For other types, this column is blank.
Label	contains the label associated with the SAS data set. This column prints a label only for the type DATA.

> **TIP** The value for files of type INDEX includes both user-defined indexes and indexes created by integrity constraints. To view index ownership and attribute information, use PROC DATASETS with the CONTENTS statement and the OUT2 option.

Note: The DETAILS option affects output only when a directory is specified and requires Read access to all read-protected SAS files in the SAS library. If you do not supply the Read password, the directory listing contains missing values for the columns produced by the DETAILS option.

Default If neither DETAILS or NODETAILS is specified, the default is the system option setting. The default system option setting is NODETAILS.

Tip If you are using the SAS windowing environment and specify the DETAILS option for a library that contains read-protected SAS files, a dialog box prompts you for each Read password that you do not specify in the PROC DATASETS statement. Therefore, you might want to assign the same Read password to all SAS files in the same SAS library.

Example "Example 2: Manipulating SAS Files" on page 696

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption.

See "Appending AES-Encrypted Data Sets" on page 592

FORCE
performs two separate actions:

- forces a RUN group to execute even if errors are present in one or more statements in the RUN group. See "RUN-Group Processing" on page 564 for a discussion of RUN-group processing and error handling.
- forces all APPEND statements to concatenate two data sets even when the variables in the data sets are not exactly the same. The APPEND statement drops the extra variables and issues a warning message to the SAS log unless the NOWARN option is specified (either with the APPEND statement or PROC DATASETS). For more information about the FORCE option, see APPEND statement on page 586.

GENNUM=ALL | HIST | REVERT | *integer*
restricts processing for generation data sets. Valid values are as follows:

ALL for subordinate CHANGE and DELETE statements, refers to the base version and all historical versions in a generation group.

HIST for a subordinate DELETE statement, refers to all historical versions, but excludes the base version in a generation group.

REVERT | 0
: for a subordinate DELETE statement, refers to the base version in a generation group and changes the most current historical version, if it exists, to the base version.

integer
: for subordinate AUDIT, CHANGE, MODIFY, DELETE, and REPAIR statements, refers to a specific version in a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set name (that is, **gennum=2** specifies MYDATA#002). Specifying a negative number is a relative reference to a historical version in relation to the base version, from the youngest to the oldest (that is, **gennum=-1** refers to the youngest historical version).

See "Restricting Processing for Generation Data Sets" on page 667

KILL
deletes all SAS files in the SAS library that are available for processing. The MEMTYPE= option subsets the member types that the statement deletes. The following example deletes all the data files in the Work library:

```
proc datasets lib=work kill memtype=data; run; quit;
```

CAUTION
The KILL option deletes the SAS files immediately after you submit the statement. If the SAS file has an ALTER= password assigned, it must be specified in order to delete the SAS file.

LIBRARY=*libref*
names the library that the procedure processes. This library is the *procedure input/output library*.

Aliases
: DDNAME=
: DD=
: LIB=

Default
: Work or User

Note
: A SAS library that is accessed via a sequential engine (such as a tape format engine) cannot be specified as the value of the LIBRARY= option.

See
: For information about the Work and User libraries, see "One-level SAS Data Set Names" in *SAS Language Reference: Concepts*.

Example
: "Example 2: Manipulating SAS Files" on page 696

MEMTYPE=(*member-type(s)*)
restricts processing to one or more member types and restricts the listing of the data library directory to SAS files of the specified member types. For example, the following PROC DATASETS statement limits processing to SAS data sets in the default data library and limits the directory listing in the SAS log to SAS files of member type DATA:

```
proc datasets memtype=data;
```

Aliases MTYPE=

MT=

Default ALL

See "Restricting Member Types for Processing" on page 668

NODETAILS

See "DETAILS|NODETAILS" on page 580.

NOLIST

suppresses the printing of the directory of the SAS files in the SAS log and any open non-LISTING destination.

Note If you have ODS LISTING turned on and open a non-LISTING ODS destination, PROC DATASETS output goes to both the SAS log and the ODS destination. The NOLIST option suppresses output to both. To see the output in the SAS log only, use the ODS EXCLUDE statement by specifying the Members and Directory output objects. For example, if the RTF and LISTING destinations are both open and Directory and Members information is desired in the LOG window only, use the following:

```
ods rtf file="listing_nolist.rtf";
ods trace on;
ods rtf exclude directory members;

proc datasets lib=work;
run;
quit;

ods rtf close;
```

Example "Example 4: Modifying SAS Data Sets" on page 704

NOPRINT

suppresses the printing of the output and the printing of the directory of the SAS files in the log and any open non-LISTING destination. The NOPRINT option is a combination of the NOLIST option and the NOPRINT option in the CONTENTS statement.

NOWARN

suppresses the error processing that occurs when a SAS file that is specified in a SAVE, CHANGE, EXCHANGE, REPAIR, DELETE, or COPY statement or listed as the first SAS file in an AGE statement, is not in the procedure input library. When an error occurs and the NOWARN option is in effect, PROC DATASETS continues processing that RUN group. If NOWARN is not in effect, PROC DATASETS stops processing that RUN group and issues a warning for all operations except DELETE, for which it does not stop processing.

PW= ***password***
provides the password for any protected SAS files in the SAS library. PW= can act as an alias for READ=, WRITE=, or ALTER=.

See "Using Passwords with the DATASETS Procedure" on page 665

READ=*read-password*
provides the Read password for any read-protected SAS files in the SAS library.

See "Using Passwords with the DATASETS Procedure" on page 665

AGE Statement

Renames a group of related SAS files in a library.

Example: "Example 7: Aging SAS Data Sets" on page 713

Syntax

AGE *current-name related-SAS-file(s)*
</ <ALTER=*alter-password*> <MEMTYPE=*member-type*>>;

Required Arguments

current-name
is a SAS file that the procedure renames. *current-name* receives the name of the first name in *related-SAS-file(s)*.

related-SAS-file(s)
is one or more SAS files in the SAS library.

Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files named in the AGE statement. Because an AGE statement renames and deletes SAS files, you need Alter access to use the AGE statement. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

See "Using Passwords with the DATASETS Procedure" on page 665

MEMTYPE=*member-type*
restricts processing to one member type. All of the SAS files that you name in the AGE statement must be the same member type. You can use the option after a forward slash after the name of each SAS file.

Aliases MTYPE=

MT=

Default If you do not specify MEMTYPE= in the PROC DATASETS statement, the default is DATA.

See "Restricting Member Types for Processing" on page 668

Details

The AGE statement renames the *current-name* to the name of the first name in the *related-SAS-files*, renames the first name in the *related-SAS-files* to the second name in the *related-SAS-files*, and so on, until it changes the name of the next-to-last SAS file in the *related-SAS-files* to the last name in the *related-SAS-files*. The AGE statement then deletes the last file in the *related-SAS-files*.

If the first SAS file named in the AGE statement does not exist in the SAS library, PROC DATASETS stops processing the RUN group containing the AGE statement and issues an error message. The AGE statement does not age any of the *related-SAS-files*. To override this behavior, use the NOWARN option in the PROC DATASETS statement.

If one of the *related-SAS-files* does not exist, the procedure prints a warning message to the SAS log but continues to age the SAS files that it can.

If you age a data set that has an index, the index continues to correspond to the data set.

You can age only entire generation groups. For example, if data sets A and B have generation groups, then the following statement deletes generation group B and ages (renames) generation group A to the name B:

```
age a b;
```

For example, suppose the generation group for data set A has three historical versions and the generation group for data set B has two historical versions. Then aging A to B has this effect:

Table 17.3 *Generation Groups*

Old Name	Version	New Name	Version
A	base	B	base
A	1	B	1
A	2	B	2
A	3	B	3
B	base	is deleted	

Old Name	Version	New Name	Version
B	1	is deleted	
B	2	is deleted	

APPEND Statement

Adds the observations from one SAS data set to the end of another SAS data set.

Default: If the BASE= data set is accessed through a SAS server and if no other user has the data set open at the time the APPEND statement begins processing, the BASE= data set defaults to CNTLLEV=MEMBER (member-level locking). When this behavior happens, no other user can update the file while the data set is processed.

Restriction: The BASE= option cannot be an existing CAS table.

Requirement: The BASE= data set must be a member of a SAS library that supports update processing.

Note: If you use the DROP=, KEEP=, or RENAME= options on the BASE= data set, the options ONLY affect the APPEND processing and does not change the variables in the appended BASE= data set. Variables that are dropped or not kept using the DROP= and KEEP= options still exist in the appended BASE= data set. Variables that are renamed using the RENAME= option remain with their original name in the appended BASE= data set. The CAS engine does not support update processing and therefore an existing CAS table cannot be specified with BASE=.

Tips: You can specify most data set options for the BASE= argument and DATA= option. However, if you specify DROP=, KEEP=, or RENAME= data set option for the BASE= data set, the option is ignored. You can use any global statements as well.

If a failure occurs during processing, the data set is marked as damaged and is reset to the pre-append condition at the next REPAIR statement. If the data set has an index, the index is not updated with each observation but is updated once at the end. (This behavior is Version 7 and later, as long as APPENDVER=V6 is not set.)

Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Example: "Example 6: Concatenating Two SAS Data Sets" on page 710

Syntax

APPEND BASE=<*libref.*>*SAS-data-set*
<APPENDVER=V6>
<DATA=<*libref.*>*SAS-data-set*>
<ENCRYPTKEY=*key-value*>
<FORCE>

<GETSORT>
<NOWARN>;

Required Argument

BASE=<*libref.*> *SAS-data-set*
names the data set to which you want to add observations.

libref
specifies the library that contains the SAS data set. If you omit the libref, the default is the libref for the procedure input library. If you are using PROC APPEND, the default for libref is either Work or User.

SAS-data-set
names a SAS data set. If the APPEND statement cannot find an existing data set with this name, it creates a new data set in the library. That is, you can use the APPEND statement to create a data set by specifying a new data set name in the BASE= argument.

Whether you are creating a new data set or appending to an existing data set, the BASE= data set is the current SAS data set after all Append operations.

Alias OUT=

Example "Example 6: Concatenating Two SAS Data Sets" on page 710

Optional Arguments

APPENDVER=V6
uses the Version 6 behavior for appending observations to the BASE= data set, which is to append one observation at a time. Beginning in Version 7, to improve performance, the default behavior changed so that all observations are appended after the data set is processed.

See "Appending to an Indexed Data Set — Fast-Append Method" on page 593

DATA=<*libref.*> *SAS-data-set*
names the SAS data set containing observations that you want to append to the end of the SAS data set specified in the BASE= argument.

libref
specifies the library that contains the SAS data set. If you omit libref, the default is the libref for the procedure input library. The DATA= data set can be from any SAS library. You must use the two-level name if the data set resides in a library other than the procedure input library.

SAS-data-set
names a SAS data set. If the APPEND statement cannot find an existing data set with this name, it stops processing.

Alias NEW=

Default the most recently created SAS data set, from any SAS library

See "Appending with Generation Groups" on page 596

Example "Example 6: Concatenating Two SAS Data Sets" on page 710

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption.

See "Appending AES-Encrypted Data Sets" on page 592

FORCE
forces the APPEND statement to concatenate data sets when the DATA= data set contains variables that meet one of the following criteria:

- are not in the BASE= data set
- do not have the same type as the variables in the BASE= data set
- are longer than the variables in the BASE= data set

Tip You can use the GENNUM= data set option to append to or from a specific version in a generation group. Here are some examples:

```
/* appends historical version to base A */
proc datasets;
   append base=a
      data=a (gennum=2);

/* appends current version of A to historical version */
proc datasets;
   append base=a (gennum=1)
      data=a;
```

See "Appending to Data Sets with Different Variables" on page 594 and "Appending to Data Sets That Contain Variables with Different Attributes" on page 595

Example "Example 6: Concatenating Two SAS Data Sets" on page 710

GETSORT
copies the sort indicator from the DATA= data set to the BASE= data set. The sort indicator is established by either a PROC SORT or an ORDERBY clause in PROC SQL if the following criteria are met:

- The BASE= data set must meet the following criteria:
  - be SAS Version 7 or later
  - contain no observations
  - accept sort indicators

CAUTION
Any pre-existing sort indicator on the BASE= data set is overwritten with no warning, even if the DATA= data set is not sorted at all.

- The DATA= data set must meet the following criteria:
  - contain a sort indicator established by PROC SORT
  - be the same data representation as the BASE= data set

Restrictions The GETSORT option has no effect on the data sets if the BASE= data set has an audit trail associated with it. This restriction causes a WARNING in the output while the APPEND process continues.

The GETSORT option has no effect on the data sets if there are dropped, kept, or renamed variables in the DATA= data file.

NOWARN
suppresses the warning when used with the FORCE option to concatenate two data sets with different variables.

Details

Using the APPEND Procedure Instead of the APPEND Statement

The only difference between the APPEND procedure and the APPEND statement in PROC DATASETS, is the default for libref in the BASE= and DATA= arguments. For PROC APPEND, the default is either Work or User. For the APPEND statement, the default is the libref of the procedure input library.

You can use the WHERE= data set option with the DATA= data set to restrict the observations that are appended. Similarly, you can use the WHERE statement to restrict the observations from the DATA= data set. The WHERE statement has no effect on the BASE= data set.

CAUTION
If there is a WHERE option used on an existing BASE= data set, it is used only if the WHEREUP= option is set to YES. If the BASE= data set does not exist, then no WHEREUP= option is needed for the WHERE option to take effect.

Appending Sorted Data Sets

You can append sorted data sets and maintain the sort using the following guidelines:

- The DATA= data set and the BASE= data set contain sort indicators from the SORT procedure.
- The DATA= data set and the BASE= data set are sorted using the same variables.
- The observations added from the DATA= data set do not violate the sort order of the BASE= data set.

The sort indicator from the BASE= data set is retained.

Using the Block I/O Method to Append

Note: The block I/O method cannot be used when appending a CAS table to a SAS data set.

The block I/O method is used to append blocks of data instead of one observation at a time. This method increases performance when you are appending large data sets. SAS determines whether to use the block I/O method. Not all data sets can use the block I/O method. There are restrictions set by the APPEND statement and the Base SAS engine.

To display information in the SAS log about the append method that is being used, you can specify the MSGLEVEL= system option as follows:

```
options msglevel=i;
```

The following message is written to the SAS log, if the block I/O method is not used:

```
INFO: Data set block I/O cannot be used because:
```

If the APPEND statement determines that the block I/O will not be used, one of the following explanations is written to the SAS log:

```
INFO: - The data sets use different engines, have different variables
or have attributes that might differ.

INFO: - There is a WHERE clause present.

INFO: - There is no member level locking.

INFO: - The OBS option is active.

INFO: - The FIRSTOBS option is active.
```

If the Base SAS engine determines that the block I/O method will not be used, one of the following explanations is written to the SAS log:

```
INFO: - Referential Integrity Constraints exist.

INFO: - Cross Environment Data Access is being used.

INFO: - The file is compressed.

INFO: - The file has an audit file which is not suspended.
```

Restricting the Observations That Are Appended

You can use the WHERE= data set option with the DATA= data set in order to restrict the observations that are appended. Likewise, you can use the WHERE statement in order to restrict the observations from the DATA= data set. The WHERE statement has no effect on the BASE= data set. If you use the WHERE= data set option with the BASE= data set, WHERE= has no effect.

CAUTION

For an existing BASE= data set: If there is a WHERE statement in the BASE= data set, it takes effect only if the WHEREUP= option is set to YES.

CAUTION
For the non-existent BASE= data set: If there is a WHERE statement in the non-existent BASE= data set, regardless of the WHEREUP option setting, you use the WHERE statement.

Note: You cannot append a data set to itself by using the WHERE= data set option.

Choosing between the SET Statement and the APPEND Statement

If you use the SET statement in a DATA step to concatenate two data sets, SAS must process all the observations in both data sets to create a new one. The APPEND statement bypasses the processing of data in the original data set and adds new observations directly to the end of the original data set. Using the APPEND statement can be more efficient than using a SET statement if any of the following occurs:

- The BASE= data set is large.
- All variables in the BASE= data set have the same length and type as the variables in the DATA= data set and if all variables exist in both data sets.

  Note: You can use the CONTENTS statement to see the variable lengths and types.

The APPEND statement is especially useful if you frequently add observations to a SAS data set (for example, in production programs that are constantly appending data to a journal-type data set).

Appending Password-Protected SAS Data Sets

In order to use the APPEND statement, you need Read access to the DATA= data set and Write access to the BASE= data set. To gain access, use the READ= and WRITE= data set options in the APPEND statement in parentheses immediately after the data set name. When you are appending password-protected data sets, use the following guidelines:

- If you do not give the Read password for the DATA= data set in the APPEND statement, by default the procedure looks for the Read password for the DATA= data set in the PROC DATASETS statement. However, the procedure does not look for the Write password for the BASE= data set in the PROC DATASETS statement. Therefore, you must specify the Write password for the BASE= data set in the APPEND statement.
- If the BASE= data set is read-protected only, you must specify its Read password in the APPEND statement.

Appending AES-Encrypted Data Sets

When appending two AES-encrypted data sets, you must use the ENCRYPTKEY= data set option for access to the data sets. Here is an example using the ENCRYPTKEY= option on both data sets:

```
proc datasets;
   append base=a (encryptkey=secret)
      data=a (encryptkey=jlgh56);
run;
```

When appending to a non-encrypted data set, you must specify the ENCRYPTKEY= on the DATA= data set. Then, you can append to the data set even if the BASE= data set engine does not support AES encryption. The data appended will not be encrypted.

```
proc datasets;
   append base=a
      data=a (encryptkey=key-value);
run;
```

For more information about AES encryption, see "AES Encryption" in *SAS Programmer's Guide: Essentials*. For more information about the ENCRYPTKEY= data set option, see "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*.

Appending to a Compressed Data Set

You can concatenate compressed SAS data sets. Either or both of the BASE= and DATA= data sets can be compressed. If the BASE= data set allows the reuse of space from deleted observations, the APPEND statement might insert the observations into the middle of the BASE= data set to use available space.

Either or both of the BASE= SAS data set and DATA= data set or CAS table can be compressed. If the BASE= data set allows the reuse of space from deleted rows, the APPEND statement might insert the rows into the middle of the BASE= data set.

For information about the COMPRESS= and REUSE= data set and system options, see *SAS Data Set Options: Reference* and *SAS System Options: Reference*.

PROC APPEND places all of the new observations at the end of the BASE= data-set and tries to reuse space, which is part of the fast-append behavior that was added in SAS 7. The fast-append behavior was added for better performance writing to the BASE data set and updating indexes. If you want to reuse space, then you need to add the APPENDVER=v6 option to the PROC DATASETS APPEND statement. PROC DATASETS APPEND reuses space only when the new observations fit into the space previously occupied by the deleted observations.

```
proc append base=libref.data-set data=librefdata-set appendver=v6;
run;
```

Appending to Data Sets That Contain Variables with Different Attributes

If a variable has different attributes in the BASE= SAS data set than it does in the DATA= data set or table, the attributes in the BASE= data set prevail.

If the formats in the DATA= SAS data set or CAS table are different from those in the BASE= SAS data set, then the formats in the BASE= data set are used. However, the data from the DATA= data set or table is not converted in order to be consistent with the formats in the BASE= data set. The result could be data that seems to be incorrect. A warning message is displayed in the log.

Use the FORCE option if one of the following occurs:

- if the length of a variable is longer in the DATA= SAS data set or CAS table than in the BASE= data set
- if the same variable is a character variable in one data set or table and a numeric variable in the other

Using FORCE has the following consequences:

- The length of the variables in the BASE= SAS data set takes precedence. The values might be truncated from the DATA= data set or CAS table to fit them into the length that is specified in the BASE= data set.
- The type of the variables in the BASE= data set takes precedence. The APPEND statement replaces values of the wrong type (all values for the variable in the DATA= data set or table) with missing values.

Appending to an Indexed Data Set — Fast-Append Method

Beginning with Version 7, the behavior of appending to an indexed data set changed to improve performance.

- In Version 6, when you appended to an indexed data set, the index was updated for each added observation. Index updates tend to be random. Therefore, disk I/O could have been high.
- Currently, SAS does not update the index until all observations are added to the data set. After the append, SAS internally sorts the observations and inserts the data into the index sequentially. The behavior reduces most of the disk I/O and results in a faster append method.

The fast-append method is used by default when the following requirements are met. Otherwise, the Version 6 method is used:

- The BASE= data set is open for member-level locking. If CNTLLEV= is set to record, then the fast-append method is not used.
- The BASE= data set does not contain referential integrity constraints.
- The BASE= data set is not accessed using the Cross Environment Data Access (CEDA) facility.
- The BASE= data set is not using a WHERE= data set option.

To display information in the SAS log about the append method that is being used, you can specify the MSGLEVEL= system option as follows:

```
options msglevel=i;
```

Either a message appears if the fast-append method is in use, or a message or messages appear as to why the fast-append method is not in use.

The current append method initially adds observations to the BASE= data set regardless of the restrictions that are determined by the index. For example, a variable that has an index that was created with the UNIQUE option does not have its values validated for uniqueness until the index is updated. Then, if a nonunique value is detected, the offending observation is deleted from the data set. After observations are appended, some of them might subsequently be deleted.

For a simple example, consider that the BASE= data set has ten observations numbered from 1 to 10 with a UNIQUE index for the variable ID. You append a data set that contains five observations numbered from 1 to 5, and observations 3 and 4 both contain the same value for ID. The following actions occur:

1. After the observations are appended, the BASE= data set contains 15 observations numbered from 1 to 15.
2. SAS updates the index for ID, validates the values, and determines that observations 13 and 14 contain the same value for ID.
3. SAS deletes one of the observations from the BASE= data set, resulting in 14 observations that are numbered from 1 to 15. For example, observation 13 is deleted. Note that you cannot predict which observation is deleted, because the internal sort might place either observation first. (In Version 6, you could predict that observation 13 would be added and observation 14 would be rejected.)

If you do not want the current behavior (which could result in deleted observations) or if you want to be able to predict which observations are appended, request the Version 6 append method by specifying the APPENDVER=V6 option:

```
proc datasets;
   append base=a data=b appendver=v6;
run;
```

Note: In Version 6, deleting the index and then re-creating it after the append could improve performance. The current method might eliminate the need to do that. However, the performance depends on the nature of your data.

Appending to Data Sets with Different Variables

If the DATA= data set contains variables that are not in the BASE= data set, use the FORCE option in the APPEND statement to force the concatenation of the two data sets. The APPEND statement drops the extra variables and issues a warning message. You can use the NOWARN option to suppress the warning message.

If the BASE= data set contains a variable that is not in the DATA= data set, the APPEND statement concatenates the data sets, but the observations from the DATA= data set have a missing value for the variable that was not present in the DATA= data set. The FORCE option is not necessary in this case.

If you use the DROP=, KEEP=, or RENAME= options on the BASE= data set, the options ONLY affect the APPEND processing and does not change the variables in

the appended BASE= data set. Variables that are dropped or not kept using the DROP= and KEEP= options still exist in the appended BASE= data set. Variables that are renamed using the RENAME= option remain with their original name in the appended BASE= data set.

Appending to Data Sets That Contain Variables with Different Attributes

If a variable has different attributes in the BASE= data set than it does in the DATA= data set, the attributes in the BASE= data set prevail.

If the SAS formats in the DATA= data set are different from those in the BASE= data set, then the SAS formats in the BASE= data set are used. However, SAS does not convert the data from the DATA= data set in order to be consistent with the SAS formats in the BASE= data set. The result could be data that seems to be incorrect. A warning message is displayed in the SAS log. The following example illustrates appending data by using different SAS formats:

```
data format1;
   input Date date9.;
   format Date date9.;
datalines;
24sep1975
22may1952
;

data format2;
   input Date datetime20.;
   format Date datetime20.;
datalines;
25aug1952:11:23:07.4
;

proc append base=format1 data=format2;
run;
```

The following messages are displayed in the SAS log.

```
NOTE: Appending WORK.FORMAT2 to WORK.FORMAT1.
WARNING: Variable Date has format DATE9. on the BASE data set
   and format DATETIME20. on the DATA data set. DATE9. used.
NOTE: There were 1 observations read from the data set WORK.FORMAT2.
NOTE: 1 observations added.
NOTE: The data set WORK.FORMAT1 has 3 observations and 1 variables.
```

If the length of a variable is longer in the DATA= data set than in the BASE= data set, or if the same variable is a character variable in one data set and a numeric variable in the other, use the FORCE option. Using FORCE has the following consequences:

- The length of the variables in the BASE= data set takes precedence. SAS truncates values from the DATA= data set to fit them into the length that is specified in the BASE= data set.

- The type of the variables in the BASE= data set takes precedence. The APPEND statement replaces values of the wrong type (all values for the variable in the DATA= data set) with missing values.

Note: If a character variable's transcoding attribute is opposite in the BASE= and DATA= data sets (for example, one is YES and the other is NO), then a warning is issued. To determine the transcoding attributes, use the CONTENTS procedure for each data set. You set the transcoding attribute with the TRANSCODE= option in the ATTRIB statement or with the TRANSCODE= column modifier in PROC SQL.

Appending Data Sets That Contain Integrity Constraints

If the DATA= data set contains integrity constraints and the BASE= data set does not exist, the APPEND statement copies the general constraints. Note that the referential constraints are not copied. If the BASE= data set exists, the APPEND action copies only observations.

Appending to a Data Set with Integrity Constraints or Indexes

Here is a simple way to get the indexes and integrity constraints from an existing data set and then apply them to another data set. Note that Work.Model should already exist and have observations:

```
Proc contents data=sashelp.zipcode out2=work.ConstraintsIndexes;
run;

proc sql noprint;
   select recreate into :macroVarCIs separated by ' '
          from work.ConstraintsIndexes;
quit;

data work.test_zipcode;
   set sashelp.zipcode;
run;

proc datasets lib=work nolist;
   modify test_zipcode;
   &macroVarCIs
quit;

proc contents data=work.test_zipcode;
run;
```

Appending with Generation Groups

You can use the GENNUM= data set option to append to a specific version in a generation group. Here are examples:

Table 17.4 *Appending with Generation Groups*

SAS Statements	Result

`proc datasets;`
`  append base=a`
`  data=b(gennum=2);`
	Appends historical version B#002 to base A

`proc datasets;`
`  append base=a(gennum=2)`
`  data=b(gennum=2);`
	Appends historical version B#002 to historical version A#002

System Failures

If a system failure or some other type of interruption occurs while the procedure is executing, the Append operation might not be successful; it is possible that not all, perhaps none, of the observations are added to the BASE= data set. In addition, the BASE= data set might suffer damage. The Append operation performs an update in place, which means that it does not make a copy of the original data set before it begins to append observations. If you want to be able to restore the original observations, you can initiate an audit trail for the base data file and choose to store a before-update image of the observations. Then you can write a DATA step to extract and reapply the original observations to the data file. For information about initiating an audit trail, see "AUDIT Statement" on page 598.

ATTRIB Statement

Associates a format, informat, or label with variables in the SAS data set specified in the MODIFY statement.

Restriction: The ATTRIB statement must appear in a MODIFY RUN group

Note: The ATTRIB statement does not affect the CONTENTS statement output. CONTENTS reports the labels, informats, and formats on the actual member.

Example: AUDIT statement on page 691

Syntax

ATTRIB *variable-list(s) attribute-list(s)*;

Required Arguments

variable-list(s)
names the variables that you want to associate with the attributes. You can list the variables in any form that SAS allows.

attribute-list(s)
specifies one or more attributes to assign to *variable-list*. Specify one or more of the following attributes in the ATTRIB statement:

FORMAT=*format*
associates a format with variables in *variable-list.*

Tip The format can be either a standard SAS format or a format that is defined with the FORMAT procedure.

INFORMAT=*informat*
associates an informat with variables in *variable-list.*

Tip The informat can be either a standard SAS informat or an informat that is defined with the FORMAT procedure.

LABEL='*label*'
associates a label with variables in the *variable-list.*

Details

Within the DATASETS procedure, the ATTRIB statement must be used in a MODIFY RUN group and can use only the FORMAT, INFORMAT, and LABEL options. The ATTRIB statement is the simplest way to remove or change all variable labels, formats, or informats in a data set using the keyword _ALL_. For an example, see "Example 1: Removing All Labels and Formats in a Data Set" on page 691.

If you are not deleting or changing all attributes, it is easier to use the following statements, LABEL statement on page 642 , FORMAT Statement on page 632, and INFORMAT statement on page 640.

AUDIT Statement

Initiates and controls event logging to an audit file as well as suspends, resumes, or terminates event logging in an audit file.

Tips: The AUDIT statement takes one of two forms, depending on whether you are initiating the audit trail or suspending, resuming, or terminating event logging in an audit file.

You can define attributes such as format and informat for the user variables in the data file by using the PROC DATASETS MODIFY statement.

See: "Understanding an Audit Trail" in *SAS Language Reference: Concepts*

Syntax

AUDIT *SAS-file* <(*SAS-password* <ENCRYPTKEY=*key-value*>
<GENNUM=*integer*>)>;

INITIATE <AUDIT_ALL=NO | YES>;

LOG<ADMIN_IMAGE=YES | NO>
<BEFORE_IMAGE=YES | NO>
<DATA_IMAGE=YES | NO>
<ERROR_IMAGE=YES | NO>;

<SUSPEND | RESUME | TERMINATE; >

<USER_VAR *variable(s)* >;

Required Argument

SAS-file
specifies the SAS data file in the procedure input library that you want to audit.

Optional Arguments

SAS-password
specifies the password for the SAS data file, if one exists. The parentheses are required.

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption.

GENNUM=*integer*
specifies that the SUSPEND, RESUME, or TERMINATE action be performed on the audit trail of a generation file. You cannot initiate an audit trail on a generation file. Valid values for GENNUM= are *integers*, which is a number that references a specific version from a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set's name (that is, `gennum=2` specifies MYDATA#002). Specifying a negative number is a relative reference to a historical version in relation to the base version, from the youngest to the oldest (that is, `gennum=-1` refers to the youngest historical version). Specifying 0, which is the default, refers to the base version. The parentheses are required.

Restriction The GENNUM= option cannot be specified before an INITIATE or USER_VAR statement.

Details

Creating an Audit File

Note: The initiation of an audit trail is possible only with the Base SAS engine.

The following example creates the audit file MyLib.MyFile.audit to log updates to the data file MyLib.MyFile.data, storing all available record images:

```
proc datasets library=mylib;
   audit myfile (alter=password);
   initiate;
run;
```

The following example creates the same audit file but stores only error record images:

```
proc datasets library=mylib;
   audit myfile (alter=password);
   initiate;
      log data_image=no
          before_image=no
          data_image=no;
run;
```

The following example initiates an audit file using AUDIT_ALL=YES:

```
proc datasets lib=mylib;  /* all audit image types will be logged
                             and the file cannot be suspended */
     audit myfile (alter=password);
     initiate audit_all=yes;
quit;
```

The following example terminates an audit file:

```
proc datasets lib=mylib;
     audit myfile (alter=password);
     terminate;
quit;
```

The AUDIT statement starts an *audit run group* for a file. Multiple audit run groups for that file can be submitted in the following ways:

- in the same PROC DATASETS step
- in separate PROC DATASETS steps
- in separate SAS sessions

All audit file related statements (INITIATE, USER_VAR, LOG, SUSPEND, RESUME, TERMINATE) must be preceded by an AUDIT statement, which identifies the file that they apply to.

The INITIATE statement creates an audit file and must be submitted in the first AUDIT statement occurrence. No other audit-related statement, such as USER_VAR, LOG, SUSPEND, RESUME, or TERMINATE will be valid for that audit file until the INITIATE statement has been submitted. You can initiate an audit file on a generation data set, but it must be the latest generation of the generation group. You cannot specify a GENNUM to identify the latest generation. You will get the latest generation by default.

Here is an example of the AUDIT statement in the first AUDIT RUN group for a given file:

```
AUDIT file <(SAS-password)>;
```

Once an audit file has been initiated, the AUDIT statements that follow the INITIATE statement for that file can specify a GENNUM:

```
AUDIT file <(<SAS-password><GENNUM=integer>)>;
```

The USER_VAR statement must directly follow the INITIATE statement in the same AUDIT RUN group.

CHANGE Statement

Renames one or more SAS files in the same SAS library.

Example: "Example 2: Manipulating SAS Files" on page 696

Syntax

CHANGE *old-name-1=new-name-1*
<*old-name-2=new-name-2* ...>
</ <ENCRYPTKEY=*key-value*>
<ALTER=*alter-password*> <GENNUM=ALL | *integer*> <MEMTYPE=*member-type*>>;

Required Argument

old-name=new-name
changes the name of a SAS file in the input data library. *old-name* must be the name of an existing SAS file in the input data library.

Example "Example 2: Manipulating SAS Files" on page 696

Optional Arguments

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption. This option is needed only if RELATIVE GENNUM is specified. For more information, see "Library Contents and AES Encryption" on page 607.

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files named in the CHANGE statement. Because a CHANGE statement changes the names of SAS files, you need Alter access to use the CHANGE statement for *new-name*. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

See "Using Passwords with the DATASETS Procedure" on page 665

GENNUM=ALL | *integer*
restricts processing for generation data sets. You can use the option either in parentheses after the name of each SAS file or after a forward slash. The following list shows valid values:

ALL
0
refers to the base version and all historical versions of a generation group.

integer
refers to a specific version from a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set's name (that is, **gennum=2** specifies MYDATA#002). Specifying a negative number is a relative reference to a historical version in relation to the base version, from the youngest to the oldest (that is, **gennum=-1** refers to the youngest historical version).

For example, the following statements change the name of version A#003 to base B:

```
proc datasets;
   change A=B / gennum=3;

proc datasets;
   change A(gennum=3)=B;
```

The following CHANGE statement produces an error:

```
proc datasets;
   change A(gennum=3)=B(gennum=3);
```

See "Restricting Processing for Generation Data Sets" on page 667 and "Understanding Generation Data Sets" in *SAS Language Reference: Concepts*

MEMTYPE=*member-type*
restricts processing to one member type. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

Aliases MTYPE=

MT=

Default If you do not specify MEMTYPE= in the PROC DATASETS statement, the default is MEMTYPE=ALL.

See "Restricting Member Types for Processing" on page 668

Details

The CHANGE statement changes names by the order in which the *old-names* occur in the directory listing, not in the order in which you list the changes in the CHANGE statement.

If the *old-name* SAS file does not exist in the SAS library, PROC DATASETS stops processing the RUN group containing the CHANGE statement and issues an error message. To override this behavior, use the NOWARN option in the PROC DATASETS statement.

If you change the name of a data set that has an index, the index continues to correspond to the data set.

CONTENTS Statement

Describes the contents of one or more SAS data sets and prints the directory of the SAS library.

Restriction: You cannot use the WHERE option to affect the output because PROC CONTENTS does not process any observations.

Notes: The ATTRIB statement does not affect the CONTENTS statement output. CONTENTS reports the labels, informats, and formats on the actual member.

When using the CONTENTS statement with SAS/ACCESS LIBNAME engines, see "Differences in the DATASETS Procedure Output When Using SAS/ACCESS LIBNAME Engines" on page 572.

Tip: You can use data set options with the DATA=, OUT=, and OUT2= options. You can use any global statements as well.

Example: "Example 5: Describing a SAS Data Set" on page 707

Syntax

CONTENTS <*options*>;

Optional Arguments

CENTILES
prints centiles information for indexed variables.

The following additional fields are printed in the default report of PROC CONTENTS when the CENTILES option is selected and an index exists on the data set. Note that the additional fields depend on whether the index is simple or complex.

#	number of the index on the data set.
Index	name of the index.
Update Centiles	percentage of the data values that must be changed before the CENTILES for the indexed variables are automatically updated.
Current Update Percentage	percentage of index updated since CENTILES were refreshed.
# of Unique Values	number of unique indexed values.
Variables	names of the variables used to make up the index. Centile information is listed below the variables.

DATA=*SAS-file-specification*

specifies an entire library or a specific SAS data set within a library. *SAS-file-specification* can take one of the following forms:

<libref.>SAS-data-set

names one SAS data set to process. The default for libref is the libref of the procedure input library. For example, to obtain the contents of the SAS data set HtWt from the procedure input library, use the following CONTENTS statement:

```
contents data=HtWt;
```

To obtain the contents of a specific version from a generation group, use the GENNUM= data set option as shown in the following CONTENTS statement:

```
contents data=HtWt(gennum=3);
```

***<libref.>*_ALL_**

gives you information about all SAS data sets that have the type or types specified by the MEMTYPE= option. *libref* refers to the SAS library. The default for libref is the libref of the procedure input library.

- If you are using the _ALL_ keyword, you need Read access to all read-protected SAS data sets in the SAS library.
- DATA=_ALL_ automatically prints a listing of the SAS files that are contained in the SAS library. Note that for SAS views, all librefs that are associated with the views must be assigned in the current session in order for them to be processed for the listing.

Default most recently created data set in your job or session, from any SAS library.

Tip If you specify a read-protected data set in the DATA= option but do not give the Read password, by default the procedure looks in the PROC DATASETS statement for the Read password. However, if you do not specify the DATA= option and the default data set (last one created in the session) is Read protected, the procedure does not look in the PROC DATASETS statement for the Read password.

Example "Example 5: Describing a SAS Data Set" on page 707

DETAILS | NODETAILS

includes information in the output about the number of observations, number of variables, number of indexes, and data set labels. DETAILS includes these additional columns of information in the output, but only if DIRECTORY is also specified.

Default If neither DETAILS nor NODETAILS is specified, the defaults are as follows: for the CONTENTS procedure, the default is the system option setting, which is NODETAILS; for the CONTENTS statement, the default is whatever is specified in the PROC DATASETS statement, which also defaults to the system option setting.

See a description of the additional columns in the Optional Argument section of PROC DATASETS Statement on page 579

DIRECTORY
prints a list of all SAS files in the specified SAS library. If DETAILS is also specified, using DIRECTORY causes the additional columns described in DETAILS | NODETAILS on page 604 to be printed.

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption. For more information, see "Library Contents and AES Encryption" on page 607.

FMTLEN
prints the length of the informat or format. If you do not specify a length for the informat or format when you associate it with a variable, the length does not appear in the output of the CONTENTS statement unless you use the FMTLEN option. The length also appears in the FORMATL or INFORML variable in the output data set.

MEMTYPE=(*member-type(s)*)
restricts processing to one or more member types. The CONTENTS statement produces output only for member types DATA, VIEW, and ALL, which includes DATA and VIEW.

MEMTYPE= in the CONTENTS statement differs from MEMTYPE= in most of the other statements in the DATASETS procedure in the following ways:

- A slash does not precede the option.
- You cannot enclose the MEMTYPE= option in parentheses to limit its effect to only the SAS file immediately preceding it.

MEMTYPE= results in a directory of the library in which the DATA= member is located. However, MEMTYPE= does not limit the types of members whose contents are displayed unless the _ALL_ keyword is used in the DATA= option. For example, the following statements produce the contents of only the SAS data sets with the member type DATA:

```
proc datasets memtype=data;
   contents data=_all_;
run;
```

Aliases MTYPE=
MT=

Default DATA

NODS
suppresses printing the contents of individual files when you specify _ALL_ in the DATA= option. The CONTENTS statement prints only the SAS library directory. You cannot use the NODS option when you specify only one SAS data set in the DATA= option.

NODETAILS
See "DETAILS|NODETAILS" on page 604.

NOPRINT
suppresses printing the output of the CONTENTS statement.

ORDER=COLLATE | CASECOLLATE | IGNORECASE | VARNUM

COLLATE	prints a list of variables in alphabetical order beginning with uppercase and then lowercase names.
CASECOLLATE	prints a list of variables in alphabetical order even if they include mixed-case names and numerics.
IGNORECASE	prints a list of variables in alphabetical order ignoring the case of the letters.
VARNUM	is the same as the VARNUM option.

Note The ORDER= option does not affect the order of the OUT= and OUT2= data sets.

See "VARNUM" on page 607

Example See "Example 4: Using the ORDER= Option" on page 515 to compare the default and the four options for ORDER=.

OUT=*SAS-data-set*

names an output SAS data set.

Tip OUT= does not suppress the printed output from the statement. If you want to suppress the printed output, you must use the NOPRINT option.

See "The OUT= Data Set" on page 683 for a description of the variables in the OUT= data set.

OUT2=*SAS-data-set*

names the output data set to contain information about indexes and integrity constraints.

Note When you use the OUT2=*PermanentLibrary*_ALL_ option within PROC CONTENTS or PROC DATASETS with the CONTENTS statement, you must also set the REPLACE=YES data set option or the REPLACE system option.

Tips If UPDATECENTILES was not specified in the index definition, then the default value of 5 is used in the re-create variable of the OUT2 data set.

OUT2= does not suppress the printed output from the statement. To suppress the printed output, use the NOPRINT option.

See "The OUT2= Data Set" on page 689 for a description of the variables in the OUT2= data set.

SHORT

prints only the list of variable names, the index information, and the sort information for the SAS data set.

Restriction If the list of variables is more than 32,767 characters, the list is truncated and a WARNING is written to the SAS log. To get a complete list of the variables, request an alphabetical listing of the variables.

VARNUM
prints a list of the variable names in the order of their logical position in the data set. By default, the CONTENTS statement lists the variables alphabetically. The physical position of the variable in the data set is engine-dependent.

Details

Using the CONTENTS Procedure Instead of the CONTENTS Statement

The only difference between the CONTENTS procedure and the CONTENTS statement in PROC DATASETS is the default for libref in the DATA= option. For PROC CONTENTS, the default is Work. For the CONTENTS statement, the default is the libref of the procedure input library.

Printing Variables

The CONTENTS statement prints an alphabetical listing of the variables by default, except for variables in the form of a numbered range list. Numbered range lists, such as x1–x100, are printed in incrementing order, that is, x1–x100. For more information, see "Alphabetic List of Variables and Attributes" on page 678.

Note: If a label is changed after a view is created from a data set with variable labels, the CONTENTS or DATASETS procedure output shows the original labels. The view must be recompiled in order for the CONTENTS or DATASETS procedure output to reflect the new variable labels.

Displaying the ICU Revision Number

The CONTENTS statement prints the International Components for Unicode (ICU) revision number when you use the SORT procedure for a linguistic sort on a data set. For more information about linguistic sorting, see Chapter 64, "SORT Procedure," on page 2355.

Library Contents and AES Encryption

When requesting the contents of all data files in a library, use the _ALL_ option. If the library contains data files that are AES -encrypted, the ENCRYPTKEY= data set option must be used to access the data files. Here is an example using the ENCRYPTKEY= option:

```
proc contents data=MyLib._all_ (encryptkey=key-value);
run;
```

If the key value does not match the key value for a particular data file in the library, then you will be prompted to enter the correct key value.

For more information about AES encryption, see "AES Encryption" in *SAS Programmer's Guide: Essentials*. For more information about the ENCRYPTKEY=

data set option, see "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*.

Observation Length, Alignment, and Padding for a SAS Data Set

There are three different cases for alignment.

- Observations within a SAS data set are aligned on double-byte boundaries whenever possible. As a result, 8-byte and 4-byte numeric variables are positioned at 8-byte boundaries at the front of the data set. They are followed by character variables in the order in which they are encountered. If the data set contains only 4-byte numeric data, the alignment is based on 4-byte boundaries. Since numeric doubles can be operated upon directly rather than being moved and aligned before doing comparisons or increments, the boundaries cause better performance.

  Since there are many observations contained within a given disk data page buffer, there might be padding between observations. The padding is to let each observation be aligned on a double-byte boundary. See the following example:

```
data a;
   length aa 7 bb 6 cc $10 dd 8 ee 3;
   aa = 1;
   bb = 2;
   cc = 'abc';
   dd = 3;
   ee = 4;
   ff = 5;
   output;
run;

proc contents data=a out=a1;
run;

proc print data=a1(keep=name length varnum npos);
run;
```

Figure 17.1 Observation Length

The CONTENTS Procedure

Data Set Name	WORK.A	Observations	1
Member Type	DATA	Variables	6
Engine	V9	Indexes	0
Created	08/16/2016 12:08:25	Observation Length	48
Last Modified	08/16/2016 12:08:25	Deleted Observations	0
Protection		Compressed	NO
Data Set Type		Sorted	NO
Label			
Data Representation	WINDOWS_64		
Encoding	wlatin1 Western (Windows)		

PROC CONTENTS shows an observation length of 48. PROC PRINT displays the internal layout of the variables within the observation where NPOS is the zero-based offset for each variable.

Figure 17.2 Observation and Variable Boundaries

Obs	NAME	LENGTH	VARNUM	NPOS
1	aa	7	1	16
2	bb	6	2	23
3	cc	10	3	32
4	dd	8	4	0
5	ee	3	5	29
6	ff	8	6	8

Variables DD and FF, the only true numeric doubles, are at offsets 0 and 8, respectively, so they are automatically aligned. The rest of the observation contains the remaining numeric variables and then character variables.

The last physical variable in this layout is CC with an offset of 32 and a length of 10. This gives you an internal length of 42, even though PROC CONTENTS reports the observation length as 48. The difference is the 6 bytes of padding so that the next observation is aligned on a double-byte boundary within the disk page buffer.

- No alignment is done when the observation does not contain 8-byte numeric variables as demonstrated in the next example, which gives you an observation length of 7 and no padding between observations within disk page buffers:

```
data b;
   length aa 6 cc $1;
   aa = 1;
   cc = 'x';
   output;
run;

proc contents data=b out=b1;
run;

proc print data=b1(keep=name length varnum npos);
run;
```

Figure 17.3 *Variables and Attributes*

Obs	NAME	LENGTH	VARNUM	NPOS
1	aa	6	1	0
2	cc	1	2	6

- Observations for compressed data sets are not aligned within the disk page buffer, but the same algorithm is used for positioning the variables within the observations. Compressed observations must be uncompressed and moved into a work buffer. The 8-byte numeric values will be aligned and ready for use immediately after uncompressing. The observation length in the PROC CONTENTS output might be larger due to operating system-specific overhead.

COPY Statement

Copies all or some of the SAS files in a SAS library.

Restriction: The COPY statement does not support data set options.

Notes: When using the COPY statement with SAS/ACCESS LIBNAME engines, see "Differences in the DATASETS Procedure Output When Using SAS/ACCESS LIBNAME Engines" on page 572.

For CAS engine specifics, see "CAS Processing for PROC COPY" on page 523.

Tips: See the example in PROC COPY on page 534 to migrate from a 32-bit machine to a 64-bit machine.

The COPY statement defaults to the encoding and data representation of the output library when you use Remote Library Services (RLS) such as SAS/SHARE or SAS/CONNECT. If you are not using RLS, you must use the PROC COPY option NOCLONE for the output files to take on the encoding and data representation of

the output library. Using the NOCLONE option results in a copy with the data representation of the data library (if specified in the OUTREP= LIBNAME option) or the native data representation of the operating environment.

Example: "Example 2: Manipulating SAS Files" on page 696

Syntax

COPY <ACCEL | NOACCEL>OUT=*libref-1*
<CLONE | NOCLONE>
<CONSTRAINT=YES | NO>
<DATECOPY>
<ENCRYPTKEY=*key-value*>
<FORCE>
IN=*libref-2*
<INDEX=YES | NO>
<MEMTYPE=(*member-type(s)*)>
<MOVE <ALTER=*alter-password*>>
<OVERRIDE=(*ds-option-1=value-1 <ds-option-2=value-2 ...>*) >;

Required Argument

OUT=*libref-1*
names the SAS library to copy SAS files to.

Alias OUTLIB= and OUTDD=

Example "Example 2: Manipulating SAS Files" on page 696

Optional Arguments

ACCEL | NOACCEL
specifies whether to perform the copy operation in CAS. Both the IN= and OUT= libraries must be CAS engine libraries and they must use the same CAS session.

Default ACCEL

See "Copying a CAS Table to Another CAS Table" on page 620

CLONE | NOCLONE
specifies whether to copy the following data set attributes:

- size of input/output buffers
- whether the data set is compressed
- whether free space is reused
- data representation of input data set, library, or operating environment
- encoding value
- whether a compressed data set can be randomly accessed by an observation number

These attributes are specified with data set options, SAS system options, and LIBNAME statement options:

- BUFSIZE= value for the size of the input/output buffers
- COMPRESS= value for whether the data set is compressed
- REUSE= value for whether free space is reused
- OUTREP= value for data representation
- ENCODING= or INENCODING= for encoding value
- POINTOBS= value for whether a compressed data set can be randomly accessed by an observation number

For the BUFSIZE= attribute, the following table summarizes how the COPY statement works:

Table 17.5 *CLONE and the Buffer Page Size Attribute*

Option	COPY Statement
CLONE	Uses the BUFSIZE= value from the input data set for the output data set. However, specifying BUFSIZE= value in the OVERRIDE= option list results in a copy that uses the specified value.
NOCLONE	Uses the current setting of the SAS system option BUFSIZE= for the output data set.
Neither	Determines the type of access method, sequential or random, used by the engine for the input data set and the engine for the output data set. If both engines use the same type of access, the COPY statement uses the BUFSIZE= value from the input data set for the output data set. If the engines do not use the same type of access, the COPY statement uses the setting of SAS system option BUFSIZE= for the output data set.

For the COMPRESS= attribute, the following table summarizes how the COPY statement works:

Table 17.6 *CLONE and the Compression Attribute*

Option	COPY Statement
CLONE	Uses the values from the input data set for the output data set. However, specifying COMPRESS= value in the OVERRIDE= option list results in a copy that uses the specified encoding.

Option	COPY Statement
NOCLONE	Results in a copy with the compression of the operating environment or, if specified, the value of the COMPRESS= option in the LIBNAME statement for the library.
Neither	Defaults to CLONE.

For the REUSE= attribute, the following table summarizes how the COPY statement works:

Table 17.7 *CLONE and the Reuse Space Attribute*

Option	COPY Statement
CLONE	Uses the values from the input data set for the output data set. If the engine for the input data set does not support the reuse space attribute, then the COPY statement uses the current setting of the corresponding SAS system option. However, specifying REUSE= value in the OVERRIDE= option list results in a copy that uses the specified value.
NOCLONE	Uses the current setting of the SAS system options COMPRESS= and REUSE= for the output data set.
Neither	Defaults to CLONE.

For the OUTREP= attribute, the following table summarizes how the COPY statement works:

Table 17.8 *CLONE and the Data Representation Attribute*

Option	COPY Statement
CLONE	Results in a copy with the same data representation of the input data set. However, if you specify an OUTREP= value in the OVERRIDE= option list, the data representation is changed, and its encoding will change to an encoding that is compatible with the data representation and the locale of the current session. The encoding will also change if it is specified in the OVERRIDE= option list.
NOCLONE	Results in a copy with the data representation of the operating environment or, if specified, the value of the OUTREP= option in the LIBNAME statement for the OUT= library.

Option	COPY Statement
Neither	Defaults to CLONE.

Data representation is the form in which data is stored in a particular operating environment. Different operating environments use the following different standards or conventions:

- for storing floating-point numbers (for example, IEEE or IBM 390)
- for character encoding (ASCII or EBCDIC)
- for the ordering of bytes in memory (big Endian or little Endian)
- for word alignment (4-byte boundaries or 8-byte boundaries)
- for data-type length (16-bit, 32-bit, or 64-bit)

Native data representation is when the data representation of a file is the same as the CPU operating environment. For example, a file in Windows data representation is native to the Windows operating environment.

For the ENCODING= attribute, the following table summarizes how the COPY statement works.

Table 17.9 *CLONE and the Encoding Attribute*

Option	COPY Statement
CLONE	Results in a copy that uses the encoding of the input data set or, if specified, the value of the INENCODING= option in the LIBNAME statement for the input library. However, specifying ENCODING= value in the OVERRIDE= option list results in a copy that uses the specified encoding.
NOCLONE	Results in a copy that uses the encoding of the current session encoding or, if specified, the value of the OUTENCODING= option in the LIBNAME statement for the output library.
Neither	Defaults to CLONE.

All text (character) data that is stored, transmitted, or processed by a computer is in an encoding. An encoding maps each character to a unique numeric representation. An encoding is a combination of a character set with an encoding method. A character set is the repertoire of characters and symbols that are used by a language or group of languages. An encoding method is the set of rules that are used to assign the numbers to the set of characters that are used in an encoding.

For the POINTOBS= attribute, the following table summarizes how the COPY statement works. To use POINTOBS=, the output data set must be compressed.

Table 17.10 CLONE and the POINTOBS= Attribute

Option	COPY Statement
CLONE	Uses the POINTOBS= value from the input data set for the output data set. However, specifying POINTOBS= value in the OVERRIDE= option list results in a copy that uses the specified value.
NOCLONE	Uses the LIBNAME statement if the output data set is compressed and the POINTOBS= option is specified and supported by the output engine. If the LIBNAME statement is not specified and the data set is compressed, the default is POINTOBS=YES when supported by the output engine.
Neither	Defaults to CLONE.

CONSTRAINT=YES | NO

specifies whether to copy all integrity constraints when copying a data set.

Default NO

Tip For data sets with integrity constraints that have a foreign key, the COPY statement copies the general and referential constraints if CONSTRAINT=YES is specified and the entire library is copied. If you use the SELECT or EXCLUDE statement to copy the data sets, then the referential integrity constraints are not copied. For more information, see "Understanding Integrity Constraints" in *SAS Language Reference: Concepts*.

DATECOPY

copies the SAS internal date and time at which the SAS file was created and when it was last modified to the resulting copy of the file. Note that the operating environment date and time are not preserved.

Restrictions DATECOPY cannot be used with encrypted files or catalogs.

DATECOPY can be used only when the resulting SAS file uses the V8 or V9 engine.

Tips You can alter the file creation date and time with the DTC= option in the MODIFY statement. See MODIFY statement on page 644.

If the file that you are copying has attributes that require additional processing, the last modified date is changed to the current date. For example, when you copy a data set that has an index, the index must be rebuilt, and the last modified date changes to the current date. Other attributes that require additional processing and that could affect the last modified date include integrity constraints and a sort indicator.

ENCRYPTKEY= *key-value*
specifies the key value needed to copy data sets in the IN= library that have AES encryption.

Note If the output library does not support AES-encryption and the input data set is AES-encrypted, the COPY process will produce an error.

See "Copying AES-Encrypted Data Files Containing Referential Integrity Constraints " on page 624

FORCE
enables you to use the MOVE option for a SAS data set on which an audit trail exists.

Note The AUDIT file is not moved with the audited data set.

IN=*libref-2*
names the SAS library containing SAS files to copy.

Alias INLIB= and INDD=

Default the libref of the procedure input library

Interaction To copy only selected members, use the SELECT or EXCLUDE statements.

INDEX=YES | NO
specifies whether to copy all indexes for a data set when copying the data set to another SAS library.

Default YES

MEMTYPE=(*member-type(s)*)
restricts processing to one or more member types.

Aliases MTYPE=

MT=

Default If you omit MEMTYPE= in the PROC DATASETS statement, the default is MEMTYPE=ALL.

Note When PROC COPY processes a SAS library on tape and the MEMTYPE= option is not specified, it scans the entire sequential library for entries until it reaches the end-of-file. If the sequential library is a multivolume tape, all tape volumes are mounted. This behavior is also true for single-volume tape libraries.

See "Specifying Member Types When Copying or Moving SAS Files" on page 620 and "Member Types" on page 669

Example "Example 2: Manipulating SAS Files" on page 696

MOVE
moves SAS files from the input data library (named with the IN= option) to the output data library (named with the OUT= option). And deletes the original files from the input data library.

See "Using Passwords with the DATASETS Procedure" on page 665

Restriction The MOVE option can be used to delete a member of a SAS library only if the IN= engine supports the deletion of tables. A tape format engine does not support table deletion. If you use a tape format engine, SAS suppresses the MOVE operation and prints a warning.

Example "Example 2: Manipulating SAS Files" on page 696

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files that you are moving from one data library to another. Because the MOVE option deletes the SAS file from the original data library, you need Alter access to move the SAS file.

OVERRIDE=(*ds-option-1=value-1 <ds-option-2=value-2> ...*)
overrides specified output data set options copied from the input data set. Some data set options might not be appropriate in the output data set context of COPY.

Restriction The OVERRIDE option is ignored if the NOCLONE option is specified. However, it can be used to modify data set attributes other than those controlled by the NOCLONE option.

Interaction When you specify an OUTREP= value in the OVERRIDE= option, the default encoding is based on the operating environment that is represented by the OUTREP= value and the locale of the current SAS session. To assign a nondefault encoding such as UTF-8, you must also specify an ENCODING= value in the OVERRIDE=option. For more information about locale and encoding, see *SAS National Language Support (NLS): Reference Guide*.

Tip The default (or CLONE) behavior is to preserve many attributes, including the data representation and encoding, from the input data set. If instead you want the data representation and encoding of the SAS session that is executing the procedure, then specify OVERRIDE=(OUTREP=SESSION ENCODING=SESSION) in PROC COPY or in the COPY statement. If you do not want to preserve any attributes from the input data set, then specify NOCLONE instead.

NOCLONE
See the description of "CLONE|NOCLONE" on page 611.

Details

Performance Improvement Using SELECT with MEMTYPE

When using the COPY statement, an in-memory directory of the library is obtained. This can be a performance issue if the library has thousands of members and only a few members are being copied. To resolve this performance issue, use a combination of the MEMTYPE= option in the COPY statement with a SELECT statement. Here is an example of this process:

```
proc datasets lib=work;
    copy out=mylib memtype=(data catalog);
    select mydata x1-x10 data2;
run;
```

Note: If either MEMTYPE=ALL or a wildcard specification (":") is used, the performance code cannot be used.

Using the Block I/O Method to Copy

The block I/O method is used to copy blocks of data instead of one observation at a time. This method can increase performance when you are copying large data sets. SAS determines whether to use this method. Not all data sets can use the block I/O method. There are restrictions set by the COPY statement and the Base SAS engine.

To display information in the SAS log about the copy method that is being used, you can specify the MSGLEVEL= system option as follows:

```
options msglevel=i;
```

The following message is written to the SAS log, if the block I/O method is not used:

```
INFO: Data set block I/O cannot be used because:
```

If the COPY statement determines that the block I/O will not be used, one of the following explanations is written to the SAS log:

```
INFO: - The data sets use different engines, have different variables
or have attributes that might differ.

INFO: - There is no member level locking.

INFO: - The OBS option is active.

INFO: - The FIRSTOBS option is active.
```

If the Base SAS engine determines that the block I/O method will not be used, one of the following explanations is written to the SAS log:

```
INFO: - Referential Integrity Constraints exist.

INFO: - Cross Environment Data Access is being used.

INFO: - The file is compressed.
```

```
INFO: - The file has an audit file which is not suspended.
```

If you are having performance issues and want to create a subset of a large data set for testing, you can use the OBS=0 option. In this case, you want to reduce the use of system resources by disabling the block I/O method.

The following example uses the OBS=0 option to reduce the use of system resources:

```
options obs=0 msglevel=i;
proc copy in=old out=lib;
select a;
run;
```

You get the same results when you use the SET statement:

```
data lib.new;
    if 0 then set old.a;
    stop;
run;
```

Copying an Entire Library

To copy an entire SAS library, simply specify an input data library and an output data library following the COPY statement. For example, the following statements copy all the SAS files in the Source data library into the Dest data library:

```
proc datasets library=source;
   copy out=dest;
run;
```

Copying Selected SAS Files

To copy selected SAS files, use a SELECT or EXCLUDE statement. For more discussion of using the COPY statement with a SELECT statement or an EXCLUDE statement, see "Specifying Member Types When Copying or Moving SAS Files" on page 620 and see Manipulating SAS Files on page 696 for an example. Also, see EXCLUDE statement on page 631 and SELECT statement on page 656.

You can also select or exclude an abbreviated list of members. For example, the following statement selects members Tabs, Test1, Test2, and Test3:

```
select tabs test1-test3;
```

Also, you can select a group of members whose names begin with the same letter or letters by entering the common letters followed by a colon (:). For example, you can select the four members in the previous example and all other members having names that begin with the letter T by specifying the following statement:

```
select t:;
```

You specify members to exclude in the same way that you specify those to select. That is, you can list individual member names, use an abbreviated list, or specify a common letter or letters followed by a colon (:). For example, the following statement excludes the members Stats, Teams1, Teams2, Teams3, Teams4 and all the members that begin with the letters RBI from the copy operation:

```
exclude stats teams1-teams4 rbi:;
```

Note that the MEMTYPE= option affects which types of members are available to be selected or excluded.

When a SELECT or EXCLUDE statement is used with CONSTRAINT=YES, only the general integrity constraints on the data sets are copied. Any referential integrity constraints are not copied. For more information, see "Understanding Integrity Constraints" in *SAS Language Reference: Concepts*.

Copying a CAS Table to Another CAS Table

When PROC COPY IN= and OUT= options are set to a CAS libref, and the same CAS session is used by both librefs by default the copy occurs in CAS.

This is a change to the default behavior. If options MSGLEVEL=I system option is set, when the COPY occurs in CAS, an INFO message is sent to the log: `INFO: Running COPY in Cloud Analytic Services.`

The PROC COPY option ACCEL | NOACCEL determines where the COPY procedure executes. ACCEL is the default, which means the COPY operation runs on the CAS server. If the COPY procedure fails on the CAS server, it does not attempt to copy the file by pulling the observations into V9 SAS.

If the OVERRIDE option is specified on the PROC COPY invocation, the option is ignored, and a note is sent to the log.

You cannot copy between sessions with PROC COPY. If the CAS libraries are defined with two different sessions, the following error is displayed: `ERROR: The CAS sessions SESS1 and SESS2 used for this action do not match.`

Specifying Member Types When Copying or Moving SAS Files

The MEMTYPE= option in the COPY statement differs from the MEMTYPE= option in other statements in the procedure in several ways:

- A slash does not precede the option.
- You cannot limit its effect to the member immediately preceding it by enclosing the MEMTYPE= option in parentheses.
- The SELECT and EXCLUDE statements and the IN= option (in the COPY statement) affect the behavior of the MEMTYPE= option in the COPY statement according to the following rules:

  1. MEMTYPE= in a SELECT or EXCLUDE statement takes precedence over the MEMTYPE= option in the COPY statement. The following statements copy only Vision.catalog and Nutr.data from the default data library to the Dest data library; the MEMTYPE= value in the first SELECT statement overrides the MEMTYPE= value in the COPY statement.

```
proc datasets;
   copy out=dest memtype=data;
      select vision(memtype=catalog) nutr;
run;
```

  2. If you do not use the IN= option, or you use it to specify the library that happens to be the procedure input library, the value of the MEMTYPE= option in the PROC DATASETS statement limits the types of SAS files that

are available for processing. The procedure uses the order of precedence described in rule 1 to further subset the types available for copying. The following statements do not copy any members from the default data library to the Dest data library. Instead, the procedure issues an error message because the MEMTYPE= value specified in the SELECT statement is not one of the values of the MEMTYPE= option in the PROC DATASETS statement.

```
      /* This step fails! */
proc datasets memtype=(data program);
   copy out=dest;
      select apples / memtype=catalog;
run;
```

3 If you specify an input data library in the IN= option other than the procedure input library, the MEMTYPE= option in the PROC DATASETS statement has no effect on the copy operation. Because no subsetting has yet occurred, the procedure uses the order of precedence described in rule 1 to subset the types available for copying. The following statements successfully copy Bodyfat.data to the Dest data library because the Source library specified in the IN= option in the COPY statement is not affected by the MEMTYPE= option in the PROC DATASETS statement.

```
proc datasets library=work memtype=catalog;
   copy in=source out=dest;
      select bodyfat / memtype=data;
run;
```

When using the COPY statement, an in-memory directory of the library is obtained. This can be a performance issue if the library has thousands of members and only a few members are being copied. To resolve this performance issue, use a combination of the MEMTYPE= option in the COPY statement with a SELECT statement. Here is an example of this process:

```
proc datasets lib=work;
    copy out=mylib memtype=(data catalog);
    select mydata x1-x10 data2;
run;
```

Note: If either MEMTYPE=ALL or a wildcard specification (":") is used, the performance code cannot be used.

Copying Views

The COPY statement with NOCLONE specified supports the OUTREP= and ENCODING= LIBNAME options for SQL views, DATA step views, and some views (Oracle and Sybase). When you use the COPY statement with Remote Library Services (RLS) such as SAS/SHARE or SAS/CONNECT, the COPY statement defaults to the encoding and data representation of the output library.

CAUTION
If you use the DATA statement's SOURCE=NOSAVE option when creating a DATA step view, the view cannot be copied from one version of SAS to another version.

Copying Password-Protected SAS Files

You can copy a password-protected SAS file without specifying the password. In addition, because the password continues to correspond to the SAS file, you must know the password in order to access and manipulate the SAS file after you copy it.

Copying Data Sets with Long Variable Names

If the VALIDVARNAME=V6 system option is set and the data set has long variable names, the long variable names are truncated, unique variables names are generated, and the copy succeeds. The same is true for index names. If VALIDVARNAME=ANY, the copy fails with an error if the OUT= engine does not support long variable names.

When a variable name is truncated, the variable name is shortened to eight bytes. If this name has already been defined in the data set, the name is shortened and a digit is added, starting with the number 2. The process of truncation and adding a digit continues until the variable name is unique. For example, a variable named LONGVARNAME becomes LONGVARN, provided that a variable with that name does not already exist in the data set. In that case, the variable name becomes LONGVAR2.

CAUTION

Truncated variable names can collide with names already defined in the input data set. This behavior is possible when the variable name that is already defined is exactly eight bytes long and ends in a digit. In the following example, the truncated name is defined in the output data set and the name from the input data set is changed:

```
options validvarname=any;
data test;
   longvar10='aLongVariableName';
   retain longvar1-longvar5 0;
run;

options validvarname=v6;
proc copy in=work out=sasuser;
   select test;
run;
```

In this example, LONGVAR10 is truncated to LONGVAR1 and placed in the output data set. Next, the original LONGVAR1 is copied. Its name is no longer unique. Therefore, it is renamed LONGVAR2. The other variables in the input data set are also renamed according to the renaming algorithm. The following example is from the SAS log:

```
1    options validvarname=any;
2    data test;
3       longvar10='aLongVariableName';
4       retain longvar1-longvar5 0;
5    run;

NOTE: The data set WORK.TEST has 1 observations and 6 variables.
NOTE: DATA statement used (Total process time):
      real time           2.60 seconds
      cpu time            0.07 seconds
```

```
6
7    options validvarname=v6;
8    proc copy in=work out=sasuser;
9       select test;
10   run;

NOTE: Copying WORK.TEST to SASUSER.TEST (memtype=DATA).
NOTE: The variable name longvar10 has been truncated to longvar1.
NOTE: The variable longvar1 now has a label set to longvar10.
NOTE: Variable LONGVAR1 already exists on file SASUSER.TEST, using LONGVAR2
instead.
NOTE: The variable LONGVAR2 now has a label set to LONGVAR1.
NOTE: Variable LONGVAR2 already exists on file SASUSER.TEST, using LONGVAR3
instead.
NOTE: The variable LONGVAR3 now has a label set to LONGVAR2.
NOTE: Variable LONGVAR3 already exists on file SASUSER.TEST, using LONGVAR4
instead.
NOTE: The variable LONGVAR4 now has a label set to LONGVAR3.
NOTE: Variable LONGVAR4 already exists on file SASUSER.TEST, using LONGVAR5
instead.
NOTE: The variable LONGVAR5 now has a label set to LONGVAR4.
NOTE: Variable LONGVAR5 already exists on file SASUSER.TEST, using LONGVAR6
instead.
NOTE: The variable LONGVAR6 now has a label set to LONGVAR5.
NOTE: There were 1 observations read from the data set WORK.TEST.
NOTE: The data set SASUSER.TEST has 1 observations and 6 variables.
NOTE: PROCEDURE COPY used (Total process time):
      real time           13.18 seconds
      cpu time            0.31 seconds

11
12   proc print data=test;
13   run;

ERROR: The value LONGVAR10 is not a valid SAS name.
NOTE: The SAS System stopped processing this step because of errors.
NOTE: PROCEDURE PRINT used (Total process time):
      real time           0.15 seconds
      cpu time            0.01 seconds
```

Copying AES-Encrypted Data Files

In order to copy data files with AES encryption, you must specify the ENCRYPTKEY=*key-value* in one of two ways:

- if all the AES-encrypted data sets in the library have the same ENCRYPTKEY=*key-value*, use the following example:

```
proc copy in=lib1 out=lib2 encryptkey=key-value;
run;
```

- if the ENCRYPTKEY=*key-value* is different for each data set, use the SELECT statement as shown in the following example:

```
proc copy in=lib1 out=lib2;
    select mydata1 (encryptkey=key-value1) mydata2 (encryptkey=key-value2);
run;
```

For more information about AES encryption, see "AES Encryption" in *SAS Programmer's Guide: Essentials*. For more information about the ENCRYPTKEY= data set option, see "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*.

Copying AES-Encrypted Data Files Containing Referential Integrity Constraints

In order to copy data files with AES encryption and with referential integrity constraints, you must do the following:

- copy the entire contents of the IN=library
- specify the CONSTRAINT=YES statement option
- specify the ENCRYPTKEY=*key-value* option or the library must be metadata bound with the encryption key recorded for the library

```
proc copy in=Lib1 out=Lib2 constraint=yes encryptkey=key-value;
run;
```

However, the above code will not work if there are multiple data primary key and referential data set pairs in the IN=LIB and each pair has different ENCYPTKEY= values. For example, if there are two pairs:

```
primarydset1/foreigndset1 having ENCRYPTKEY=secret1
primarydset2/foreigndset2 having ENCRYPTKEY=secret2
```

then the above scheme would work for only one pair. All pairs must have the same key value.

For more information, see "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference*.

Copying Generation Groups

You can use the COPY statement to copy an entire generation group. However, you cannot copy a specific version in a generation group.

Transporting SAS Data Sets between Hosts

You use the COPY procedure, along with the XPORT engine or a REMOTE engine, to transport SAS data sets between hosts. For more information, see "Strategies for Moving and Accessing SAS Files" in *Moving and Accessing SAS Files*.

Using the COPY Procedure Instead of the COPY Statement

Generally, the COPY procedure functions the same as the COPY statement in the DATASETS procedure. Here is a list of differences:

- The IN= argument is required with PROC COPY. In the COPY statement, IN= is optional. If omitted, the default value is the libref of the procedure input library.

- PROC DATASETS cannot work with libraries that allow only sequential data access.
- The COPY statement honors the NOWARN option but PROC COPY does not.

DELETE Statement

Deletes SAS files from a SAS library.

Example: "Example 2: Manipulating SAS Files" on page 696

Syntax

DELETE *SAS-file(s)*
</ <ALTER=*alter-password*>
<ENCRYPTKEY=*key-value*>
<GENNUM=ALL | HIST | REVERT | *integer*>
<MEMTYPE=*member-type*>>;

Required Argument

SAS-file(s)
specifies one or more SAS files that you want to delete. If the SAS file has an ALTER= password assigned, it must be specified in order to delete the SAS file. You can also use a numbered range list or colon list. For more information, see "Data Set Name Lists" in *SAS Programmer's Guide: Essentials*.

Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files that you want to delete. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

See "Using Passwords with the DATASETS Procedure" on page 665

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption. This option is required when specifying GENNUM=REVERT (which is the same as GENNUM=0) or GENNUM=*relative-generation-number*. The key value for the ENCRYPTKEY= option must be the key value for the base version. For more information, see "Library Contents and AES Encryption" on page 607.

GENNUM=ALL | HIST | REVERT | *integer*
restricts processing for generation data sets. You can use the option either in parentheses after the name of each SAS file or after a forward slash. Here is a list of valid values:

ALL	refers to the base version and all historical versions in a generation group.
HIST	refers to all historical versions, but excludes the base version in a generation group.
REVERT | 0	deletes the base version and changes the most current historical version, if it exists, to the base version.
integer	is a number that references a specific version from a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set's name (that is, `gennum=2` specifies MYDATA#002). Specifying a negative number is a relative reference to a historical version in relation to the base version, from the youngest to the oldest (that is, `gennum=-1` refers to the youngest historical version).

See "Understanding Generation Data Sets" in *SAS Language Reference: Concepts* and "Restricting Processing for Generation Data Sets" on page 667

MEMTYPE=*member-type*

restricts processing to one member type. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

Aliases MTYPE=

MT=

Default DATA

See "Restricting Member Types for Processing" on page 668

Example "Example 2: Manipulating SAS Files" on page 696

Details

The Basics

SAS immediately deletes SAS files when the RUN group executes. You do not have an opportunity to verify the Delete operation before it begins.

If the SAS file has an ALTER= password assigned, it must be specified in order to delete the SAS file.

If you attempt to delete a SAS file that does not exist in the procedure input library, PROC DATASETS issues a message and continues processing. If NOWARN is used, no message is issued.

When you use the DELETE statement to delete a data set that has indexes associated with it, the statement also deletes the indexes.

You cannot use the DELETE statement to delete a data file that has a foreign key integrity constraint or a primary key with foreign key references. For data files that have foreign keys, you must remove the foreign keys before you delete the data file. For data files that have primary keys with foreign key references, you must remove the foreign keys that reference the primary key before you delete the data file.

If you attempt to delete a CAS table that does not exist in the input CAS engine libref, a message is written to the log and processing continues. If NOWARN is used, no message is issued.

Working with Generation Groups

Overview of Working with Generation Groups

When you are working with generation groups, you can use the DELETE statement to delete the following versions:

- delete the base version and all historical versions
- delete the base version and rename the youngest historical version to the base version
- delete an absolute version
- delete a relative version
- delete all historical versions and leave the base version

Deleting the Base Version and All Historical Versions

The following statements delete the base version and all historical versions where the data set name is A:

```
proc datasets;
   delete A(gennum=all);

proc datasets;
   delete A / gennum=all;

proc datasets gennum=all;
   delete A;
```

The following statements delete the base version and all historical versions where the data set name begins with the letter A:

```
proc datasets;
   delete A:(gennum=all);

proc datasets;
   delete A: / gennum=all;

proc datasets gennum=all;
   delete A:;
```

Deleting the Base Version and Renaming the Youngest Historical Version to the Base Version

The following statements delete the base version and rename the youngest historical version to the base version, where the data set name is A:

```
proc datasets;
   delete A(gennum=revert);

proc datasets;
   delete A / gennum=revert;

proc datasets gennum=revert;
   delete A;
```

The following statements delete the base version and rename the youngest historical version to the base version, where the data set name begins with the letter A:

```
proc datasets;
   delete A:(gennum=revert);

proc datasets;
   delete A: / gennum=revert;

proc datasets gennum=revert;
   delete A:;
```

Deleting a Version with an Absolute Number

The following statements use an absolute number to delete the first historical version:

```
proc datasets;
   delete A(gennum=1);

proc datasets;
   delete A / gennum=1;

proc datasets gennum=1;
   delete A;
```

The following statements delete a specific historical version, where the data set name begins with the letter A:

```
proc datasets;
   delete A:(gennum=1);

proc datasets;
   delete A: / gennum=1;

proc datasets gennum=1;
   delete A:;
```

Deleting a Version with a Relative Number

The following statements use a relative number to delete the youngest historical version, where the data set name is A:

```
proc datasets;
   delete A(gennum=-1);

proc datasets;
   delete A / gennum=-1;

proc datasets gennum=-1;
   delete A;
```

The following statements use a relative number to delete the youngest historical version, where the data set name begins with the letter A:

```
proc datasets;
   delete A:(gennum=-1);

proc datasets;
   delete A: / gennum=-1;

proc datasets gennum=-1;
   delete A:;
```

Deleting All Historical Versions and Leaving the Base Version

The following statements delete all historical versions and leave the base version, where the data set name is A:

```
proc datasets;
   delete A(gennum=hist);

proc datasets;
   delete A / gennum=hist;

proc datasets gennum=hist;
   delete A;
```

The following statements delete all historical versions and leave the base version, where the data set name begins with the letter A:

```
proc datasets;
   delete A:(gennum=hist);

proc datasets;
   delete A: / gennum=hist;

proc datasets gennum=hist;
   delete A:;
```

EXCHANGE Statement

Exchanges the names of two SAS files in a SAS library.

Example: "Example 2: Manipulating SAS Files" on page 696

Syntax

EXCHANGE *name-1=other-name-1* <*name-2=other-name-2* ...>
</ <ALTER=*alter-password*> <MEMTYPE=*member-type*>>;

Required Argument

name=other-name
exchanges the names of SAS files in the procedure input library. Both *name* and *other-name* must already exist in the procedure input library.

Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files whose names you want to exchange. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

See "Using Passwords with the DATASETS Procedure" on page 665

MEMTYPE=*member-type*
restricts processing to one member type. You can exchange only the names of SAS files of the same type. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

Default If you do not specify MEMTYPE= in the PROC DATASETS statement, the default is ALL.

See "Restricting Member Types for Processing" on page 668

Details

When you exchange more than one pair of names in one EXCHANGE statement, PROC DATASETS performs the exchanges in the order in which the names of the SAS files occur in the directory listing, not in the order in which you list the exchanges in the EXCHANGE statement.

If the *name* SAS file does not exist in the SAS library, PROC DATASETS stops processing the RUN group that contains the EXCHANGE statement and issues an error message. To override this behavior, specify the NOWARN option in the PROC DATASETS statement.

The EXCHANGE statement also exchanges the associated indexes so that they correspond with the new name.

The EXCHANGE statement allows only two existing generation groups to exchange names. You cannot exchange a specific generation number with either an existing base version or another generation number.

EXCLUDE Statement

Excludes SAS files from copying.

Restrictions: The EXCLUDE statement must follow a COPY statement

The EXCLUDE statement cannot appear in the same COPY step with a SELECT statement

Example: "Example 2: Manipulating SAS Files" on page 696

Syntax

EXCLUDE *SAS-file(s)* </ MEMTYPE=*member-type*>;

Required Argument

SAS-file(s)
specifies one or more SAS files to exclude from the copy operation. All SAS files you name in the EXCLUDE statement must be in the library that is specified in the IN= option in the COPY statement. If the SAS files are generation groups, the EXCLUDE statement allows only selection of the base versions.

You can use the following shortcuts to list several SAS files in the EXCLUDE statement:

Table 17.11 *Using the EXCLUDE Statement*

Notation	Meaning
x1–xn	Specifies files X1 through Xn. The numbers must be consecutive.
x:	Specifies all files that begin with the letter X.

Optional Argument

MEMTYPE=*member-type*
restricts processing to one member type. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

Aliases MTYPE=

MT=

Default If you do not specify MEMTYPE= in the PROC DATASETS statement, the COPY statement, or in the EXCLUDE statement, the default is MEMTYPE=ALL.

See "Specifying Member Types When Copying or Moving SAS Files" on page 620 and "Restricting Member Types for Processing" on page 668

Details

Excluding Several Like-Named Files

You can use shortcuts for listing several SAS files in the EXCLUDE statement.

FORMAT Statement

Assigns, changes, and removes variable formats in the SAS data set specified in the MODIFY statement permanently.

Restriction: The FORMAT statement must appear in a MODIFY RUN group

Example: "Example 4: Modifying SAS Data Sets" on page 704

Syntax

FORMAT *variable-1* <*format-1*>
<*variable-2* <*format-2*> ...>;

Required Argument

variable
specifies one or more variables whose format you want to assign, change, or remove. If you want to disassociate a format with a variable, list the variable last in the list with no format following:

```
format x1-x3 4.1 time hhmm2.2 age;
```

Optional Argument

format
specifies a format to apply to the variable or variables listed before it. If you do not specify a format, the FORMAT statement removes any format associated with the variables in *variable-list*.

Tip To remove all formats from a data set, use the ATTRIB Statement on page 597 and the _ALL_ keyword.

IC CREATE Statement

Creates an integrity constraint.

Restriction: The IC CREATE statement must appear in a MODIFY RUN group

Note: In order for a referential constraint to be established, the foreign key must specify the same number of variables as the primary key, in the same order, and the variables must be of the same type (character or numeric) and length.

See: "Understanding Integrity Constraints" in *SAS Language Reference: Concepts*

Syntax

IC CREATE <*constraint-name=*> *constraint* <MESSAGE='*message-string*' <MSGTYPE=USER>>;

Required Argument

constraint
is the type of constraint. Here is a list of valid values:

NOT NULL (*variable*)	specifies that *variable* does not contain a SAS missing value, including special missing values.
UNIQUE (*variables*)	specifies that the values of *variables* must be unique. This constraint is identical to DISTINCT.
DISTINCT (*variables*)	specifies that the values of *variables* must be unique. This constraint is identical to UNIQUE.
CHECK (WHERE-*expression*)	limits the data values of variables to a specific set, range, or list of values. This behavior is accomplished with a WHERE expression.
PRIMARY KEY (*variables*)	specifies a primary key, that is, a set of variables that do not contain missing values and whose values are unique.

When defining overlapping primary key and foreign key constraints, which means that variables in a data file are part of both a primary key and a foreign key definition, if you use exactly the same variables, then the variables must be defined in a different order.

A primary key affects the values of an individual data file until it has a foreign key referencing it.

Note: If a not null constraint exists for a variable that is being used to define a new primary key constraint, then the primary key constraint replaces the existing not null constraint.

FOREIGN KEY (*variables*) REFERENCES *table-name* <ON DELETE *referential-action*> <ON UPDATE *referential-action*>
: specifies a foreign key, that is, a set of variables whose values are linked to the values of the primary key variables in another data file. The referential actions are enforced when updates are made to the values of a primary key variable that is referenced by a foreign key. There are three types of referential actions: RESTRICT, SET NULL, and CASCADE:

The following operations can be done with the RESTRICT referential action:

a delete operation
: deletes the primary key row, but only if no foreign key values match the deleted value.

an update operation
: updates the primary key value, but only if no foreign key values match the current value to be updated.

The following operations can be done with the SET NULL referential action:

a delete operation
: deletes the primary key row and sets the corresponding foreign key values to NULL.

an update operation
: modifies the primary key value and sets all matching foreign key values to NULL.

The following operations can be done with the CASCADE referential action:

an update operation
: modifies the primary key value, and also modifies any matching foreign key values to the same value. CASCADE is not supported for Delete operations.

Default
: RESTRICT is the default action if no referential action is specified.

Requirements
: When defining overlapping primary key and foreign key constraints, which means that variables in a data file are part of both a primary key and a foreign key definition, the following actions are required:

  If you use exactly the same variables, then the variables must be defined in a different order.

  The foreign key's update and delete referential actions must both be RESTRICT.

Interaction
: Before it enforces a SET NULL or CASCADE referential action, SAS checks to see whether there are other foreign keys that reference the primary key and that specify RESTRICT for the intended operation. If RESTRICT is specified, or if the constraint reverts to the default values, then RESTRICT is enforced for all

foreign keys, unless no foreign key values match the values to updated or deleted.

Optional Arguments

<*constraint-name*=>
is an optional name for the constraint. The name must be a valid SAS name. When you do not supply a constraint name, a default name is generated. This default constraint name has the following form:

Table 17.12 *Using RESTRICT=*

Default Name	Constraint Type
NM*xxxx*	Not Null
UN*xxxx*	Unique
CK*xxxx*	Check
PK*xxxx*	Primary key
FK*xxxx*	Foreign key

xxxx is a counter beginning at 0001.

Note: The names PRIMARY, FOREIGN, MESSAGE, UNIQUE, DISTINCT, CHECK, and NOT cannot be used as values for *constraint-name*.

<MESSAGE='*message-string*' <MSGTYPE=USER>>
message-string is the text of an error message to be written to the log when the data fails the constraint:

```
ic create not null(socsec)
   message='Invalid Social Security number';
```

<MSGTYPE=USER> controls the format of the integrity constraint error message. By default when the MESSAGE= option is specified, the message that you define is inserted into the SAS error message for the constraint, separated by a space. MSGTYPE=USER suppresses the SAS portion of the message.

Length The maximum length of the message is 250 characters.

Example The following examples show how to Create integrity constraints:

```
ic create a = not null(x);
ic create Unique_D = unique(d);
ic create Distinct_DE = distinct(d e);
ic create E_less_D = check(where=(e < d or d = 99));
ic create primkey = primary key(a b);
ic create forkey = foreign key (a b) references table-name
  on update cascade on delete set null;
```

```
ic create not null (x);
```

IC DELETE Statement

Deletes an integrity constraint.

Restriction: IC DELETE must be in a MODIFY RUN group

See: "Understanding Integrity Constraints" in *SAS Language Reference: Concepts*

Syntax

IC DELETE *constraint-name(s)* | _ALL_;

Required Arguments

constraint-name(s)
names one or more constraints to delete. For example, to delete the constraints Unique_D and Unique_E, use the following statement: `ic delete Unique_D Unique_E;`

ALL
deletes all constraints for the SAS data file specified in the preceding MODIFY statement.

IC REACTIVATE Statement

Reactivates a foreign key integrity constraint that is inactive.

Restriction: IC REACTIVATE must be in a MODIFY RUN group

See: "Understanding Integrity Constraints" in *SAS Language Reference: Concepts*

Syntax

IC REACTIVATE *foreign-key-name* REFERENCES *libref*;

Required Arguments

foreign-key-name
is the name of the foreign key to reactivate.

libref
refers to the SAS library containing the data set that contains the primary key that is referenced by the foreign key.

Example

Suppose that you have the foreign key FKEY defined in data set MyLib.MyOwn and that FKEY is linked to a primary key in data set MainLib.Main. If the integrity constraint is inactivated by a copy or move operation, you can reactivate the integrity constraint by using the following code:

```
proc datasets library=mylib;
   modify myown;
   ic reactivate fkey references mainlib;
run;
```

INDEX CENTILES Statement

Updates centiles statistics for indexed variables.

Restriction: INDEX CENTILES must be in a MODIFY RUN group

See: "Understanding SAS Indexes" in *SAS Language Reference: Concepts*

Syntax

INDEX CENTILES *index(s)*
</ <REFRESH> <UPDATECENTILES=ALWAYS | NEVER | *integer*>>;

Required Argument

index(s)
names one or more indexes.

Optional Arguments

REFRESH
updates centiles immediately, regardless of the value of UPDATECENTILES.

UPDATECENTILES=ALWAYS | NEVER | *integer*
specifies when centiles are to be updated. It is not practical to update centiles after every data set update. Therefore, you can specify as the value of UPDATECENTILES the percentage of the data values that can be changed before centiles for the indexed variables are updated.

Here is a list of valid values:

ALWAYS | 0	updates centiles when the data set is closed if any changes have been made to the data set index. You can specify ALWAYS or 0 and produce the same results.
NEVER | 101	does not update centiles. You can specify NEVER or 101 and produce the same results.
integer	is the percentage of values for the indexed variable that can be updated before centiles are refreshed. The alias is UPDCEN. The default is 5 (percent).

INDEX CREATE Statement

Creates simple or composite indexes for the SAS data set specified in the MODIFY statement.

Restriction: INDEX CREATE must be in a MODIFY RUN group

See: "Understanding SAS Indexes" in *SAS Language Reference: Concepts*

Example: "Example 4: Modifying SAS Data Sets" on page 704

Syntax

INDEX CREATE *index-specification(s)*
</ <NOMISS> <UNIQUE> <UPDATECENTILES=ALWAYS | NEVER | *integer*>>;

Required Argument

index-specification(s)
can be one or both of the following forms:

variable
creates a simple index on the specified variable.

index=(variables)
creates a composite index. The name that you specify for *index* is the name of the composite index. It must be a valid SAS name and cannot be the same as any variable name or any other composite index name. You must specify at least two variables.

Note The index name must follow the same rules as a SAS variable name, including avoiding the use of reserved names for automatic variables, such as _N_, and special variable list names, such as _ALL_. For more information, see "Words in the SAS Language" in *SAS Language Reference: Concepts*.

Optional Arguments

NOMISS
excludes from the index all observations with missing values for all index variables.

When you create an index with the NOMISS option, SAS uses the index only for WHERE processing and only when missing values fail to satisfy the WHERE expression. For example, if you use the following WHERE statement, SAS does not use the index, because missing values satisfy the WHERE expression:

```
where dept ne '01';
```

For more information, see *SAS Language Reference: Concepts*.

BY-group processing ignores indexes that are created with the NOMISS option.

Example "Example 4: Modifying SAS Data Sets" on page 704

UNIQUE
specifies that the combination of values of the index variables must be unique. If you specify UNIQUE and multiple observations have the same values for the index variables, the index is not created.

Example "Example 4: Modifying SAS Data Sets" on page 704

UPDATECENTILES=ALWAYS | NEVER | *integer*
specifies when centiles are to be updated. It is not practical to update centiles after every data set update. Therefore, you can specify the percentage of the data values that can be changed before centiles for the indexed variables are updated. Here is a list of valid values:

ALWAYS | 0	updates centiles when the data set is closed if any changes have been made to the data set index. You can specify ALWAYS or 0 and produce the same results.
NEVER | 101	does not update centiles. You can specify NEVER or 101 and produce the same results.
integer	specifies the percentage of values for the indexed variable that can be updated before centiles are refreshed. The alias is UPDCEN and the default is 5 (percent).

INDEX DELETE Statement

Deletes one or more indexes associated with the SAS data set specified in the MODIFY statement.

Restriction: The INDEX DELETE statement must appear in a MODIFY RUN group

Note: You can use the CONTENTS statement to produce a list of all indexes for a data set.

Syntax

INDEX DELETE *index(s)* | _ALL_;

Required Arguments

index(s)
names one or more indexes to delete. The index(es) must be for variables in the SAS data set that is named in the preceding MODIFY statement. You can delete both simple and composite indexes.

ALL
deletes all indexes, except for indexes that are owned by an integrity constraint. When an index is created, it is marked as owned by the user, by an integrity constraint, or by both. If an index is owned by both a user and an integrity constraint, the index is not deleted until both an IC DELETE statement and an INDEX DELETE statement are processed.

INFORMAT Statement

Assigns, changes, and removes variable informats in the data set specified in the MODIFY statement permanently.

Restriction: The INFORMAT statement must appear in a MODIFY RUN group

Example: "Example 4: Modifying SAS Data Sets" on page 704

Syntax

INFORMAT *variable-1* <*informat-1*>
<*variable-2* <*informat-2*> ...>;

Required Argument

variable
specifies one or more variables whose informats you want to assign, change, or remove. If you want to disassociate an informat with a variable, list the variable last in the list with no informat following:

```
informat a b 2. x1-x3 4.1 c;
```

Optional Argument

informat
specifies an informat for the variables immediately preceding it in the statement. If you do not specify an informat, the INFORMAT statement removes any existing informats for the variables in *variable-list*.

Tip To remove all informats from a data set, use the ATTRIB statement on page 597 and the _ALL_ keyword.

INITIATE Statement

Creates an audit file that has the same name as the SAS data file and a data set type of AUDIT.

Restrictions: The INITIATE statement must appear in an AUDIT RUN group.

An INITIATE statement is a required statement that can occur only once per audit file and must be placed directly after the AUDIT statement in the first AUDIT RUN group for that file.

Example: "Example 8: Initiating an Audit File" on page 715

Syntax

INITIATE <AUDIT_ALL=NO | YES>;

Optional Argument

AUDIT_ALL=NO | YES
specifies whether logging can be suspended and audit settings can be changed. AUDIT_ALL=YES specifies that all images are logged and cannot be suspended. That is, you cannot use the LOG statement to turn off logging of particular images, and you cannot suspend event logging by using the SUSPEND statement. To turn off logging, you must use the TERMINATE statement, which terminates event logging and deletes the audit file.

Default NO

Example "Example 8: Initiating an Audit File" on page 715

Details

The audit file logs additions, deletions, and updates to the SAS data file. You must initiate an audit trail before you can suspend, resume, or terminate it. Although the AUDIT statement immediately preceding the INITIATE statement cannot specify a GENNUM= option, if the specified file identifies a generation data set group, the audit file created by the INITIATE statement will be attached to the most recently created generation in the generation group.

The following example creates the audit file MyLib.MyFile.audit to log updates to the data file MyLib.MyFile.data, storing all available record images:

```
proc datasets library=mylib;
   audit myfile (alter=password);
```

```
   initiate;
run;
```

The following example initiates an audit file using AUDIT_ALL=YES:

```
proc datasets lib=mylib;  /* all audit image types will be logged
                             and the file cannot be suspended */
     audit myfile (alter=password);
     initiate audit_all=yes;
quit;
```

LABEL Statement

Assigns, changes, and removes variable labels for the SAS data set specified in the MODIFY statement.

Restriction: The LABEL statement must appear in a MODIFY RUN group

Example: "Example 4: Modifying SAS Data Sets" on page 704

Syntax

LABEL *variable-1=<'label-1' | ' '>*
<variable-2=<'label-2' | ' '> ...>;

Required Argument

variable=<'label'>
specifies a text string of up to 256 characters. If the label text contains single quotation marks, use double quotation marks around the label, or use two single quotation marks in the label text and enclose the string in single quotation marks. To remove a label from a data set, assign a label that is equal to a blank that is enclosed in quotation marks.

Range 1 - 256 characters

Tip To remove all variable labels in a data set, use the ATTRIB statement on page 597 and the _ALL_ keyword.

LOG Statement

specifies the audit file settings.

Restriction: The LOG statement must appear after the INITIATE statement in an AUDIT RUN group.

Example: "Example 8: Initiating an Audit File" on page 715

Syntax

LOG <ADMIN_IMAGE=YES | NO>
<BEFORE_IMAGE=YES | NO>
<DATA_IMAGE=YES | NO>
<ERROR_IMAGE=YES | NO>;

Optional Arguments

ADMIN_IMAGE=YES | NO
specifies whether the administrative events are logged to the audit file (that is, the SUSPEND and RESUME actions).

Default YES

Tip If you do not want to log a particular image, specify NO for the image type. For example, the following code turns off logging the error images, but the administrative, before, and data images continue to be logged: `log error_image=no;`

BEFORE_IMAGE=YES | NO
specifies whether the before-update record images are logged to the audit file.

Default YES

DATA_IMAGE=YES | NO
specifies whether the added, deleted, and after-update record images are logged to the audit file.

Default YES

ERROR_IMAGE=YES | NO
specifies whether the after-update record images are logged to the audit file.

Default YES

Details

The following example creates the same audit file but stores only error record images:

```
proc datasets library=mylib;
   audit myfile (alter=password);
   initiate;
      log admin_image=no
          before_image=no
          data_image=no;
run;
```

MODIFY Statement

Changes the attributes of a SAS file and, through the use of subordinate statements, the attributes of variables in the SAS file.

Restriction: You cannot change the length of a variable using the LENGTH= option in an ATTRIB statement.

Example: "Example 4: Modifying SAS Data Sets" on page 704

Syntax

MODIFY *SAS-file* <(*options*)>
</ <CORRECTENCODING=*encoding-value*> <DTC=*SAS-date-time*>
<GENNUM=*integer*> <MEMTYPE=*member-type*>>;

Required Argument

SAS-file
specifies a SAS file that exists in the procedure input library.

Optional Arguments

ALTER=*password-modification*
assigns, changes, or removes an Alter password for the SAS file named in the MODIFY statement. *password-modification* is one of the following:

- *new-password*
- *old-password* / *new-password*
- / *new-password*
- *old-password* /
- /

See "Manipulating Passwords" on page 648

CORRECTENCODING=*encoding-value*
enables you to change the encoding indicator, which is recorded in the file's descriptor information, in order to match the actual encoding of the file's data.

See "CORRECTENCODING= Option Statement" in *SAS National Language Support (NLS): Reference Guide*

ENCRYPTKEY=*key-value*
specifies a key value for AES encryption.

Requirement ENCRYPTKEY= data set option is required if the data file has AES encryption.

DTC=*SAS-date-time*

specifies a date and time to substitute for the date and time stamp placed on a SAS file at the time of creation. You cannot use this option in parentheses after the name of each SAS file; you must specify DTC= after a forward slash:

```
modify mydata / dtc='03MAR00:12:01:00'dt;
```

Restrictions A SAS file's creation date and time cannot be set later than the date and time the file was actually created.

DTC= cannot be used with encrypted files or sequential files.

DTC= can be used only when the resulting SAS file uses the V8 or V9 engine.

Tip Use DTC= to alter a SAS file's creation date and time before using the DATECOPY option in the COPY procedure, CPORT procedure, SORT procedure, and the COPY statement in the DATASETS procedure.

GENMAX=*number-of-generations*

specifies the maximum number of versions. Use this option in parentheses after the name of SAS file.

Default 0

Range 0 to 1,000

GENNUM=*integer*

restricts processing for generation data sets. You can specify GENNUM= either in parentheses after the name of each SAS file or after a forward slash. Valid value is *integer*, which is a number that references a specific version from a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set's name (that is, `gennum=2` specifies MYDATA#002). Specifying a negative number is a relative reference to a historical version in relation to the base version, from the youngest to the oldest (that is, `gennum=-1` refers to the youngest historical version). Specifying 0, which is the default, refers to the base version.

See "Understanding Generation Data Sets" in *SAS Language Reference: Concepts*

LABEL='*data-set-label*' | ' '

assigns, changes, or removes a data set label for the SAS data set named in the MODIFY statement. If a single quotation mark appears in the label, write it as two single quotation marks. LABEL= or LABEL=' ' removes the current label.

Range 1 - 256 characters

Restriction A view label cannot be updated after the label is created.

Tip To remove all variable labels in a data set, use the ATTRIB statement on page 597.

See "Example 4: Modifying SAS Data Sets" on page 704

MEMTYPE=*member-type*
restricts processing to one member type. You cannot specify MEMTYPE= in parentheses after the name of each SAS file; you must specify MEMTYPE= after a forward slash.

Aliases MTYPE=

MT=

Default If you do not specify the MEMTYPE= option in the PROC DATASETS statement or in the MODIFY statement, the default is MEMTYPE=DATA.

PW=*password-modification*
assigns, changes, or removes a Read, Write, or Alter password for the SAS file named in the MODIFY statement. *password-modification* is one of the following:

- *new-password*
- *old-password* / *new-password*
- / *new-password*
- *old-password* /
- /

READ=*password-modification*
assigns, changes, or removes a Read password for the SAS file named in the MODIFY statement. *password-modification* is one of the following:

- *new-password*
- *old-password* / *new-password*
- / *new-password*
- *old-password* /
- /

See "Manipulating Passwords" on page 648

Example "Example 4: Modifying SAS Data Sets" on page 704

SORTEDBY=*sort-information*
specifies how the data are currently sorted. SAS stores the sort information with the file but does not verify that the data are sorted the way you indicate. *sort-information* can be one of the following:

by-clause </ *collate-name*> indicates how the data are currently sorted. Values for *by-clause* are the variables and options that you can use in a BY statement in a PROC SORT step. *collate-name* names the collating sequence used for the sort. By default, the

collating sequence is that of your host operating environment.

NULL removes any existing sort indicator.

Restriction The data must be sorted in the order in which you specify. If the data is not in the specified order, SAS does not sort it for you.

Tip When using the MODIFY SORTEDBY option, you can also use a numbered range list or colon list. For more information, see "Data Set Name Lists" in *SAS Programmer's Guide: Essentials*.

Example "Example 4: Modifying SAS Data Sets" on page 704

TYPE=*special-type*
assigns or changes the special data set type of a SAS data set. SAS does not verify the following:

- the SAS data set type that you specify in the TYPE= option (except to check if it has a length of eight or fewer characters)
- that the SAS data set's structure is appropriate for the type that you have designated

Note Do not confuse the TYPE= option with the MEMTYPE= option. The TYPE= option specifies a type of special SAS data set. The MEMTYPE= option specifies one or more types of SAS files in a SAS library.

Tip Most SAS data sets have no special type. However, certain SAS procedures, like the CORR procedure, can create a number of special SAS data sets. In addition, SAS/STAT software and SAS/EIS software support special data set types.

WRITE=*password-modification*
assigns, changes, or removes a Write password for the SAS file named in the MODIFY statement. *password-modification* is one of the following:

- *new-password*
- *old-password* / *new-password*
- / *new-password*
- *old-password* /
- /

See "Manipulating Passwords" on page 648

Details

Changing Data Set Labels and Variable Labels

The LABEL option can change either the data set label or a variable label within the data set. To change a data set label, use the following syntax:

```
modify datasetname(label='Label for Data Set');
run;
```

You can change one or more variable labels within a data set. To change a variable label within the data set, use the following syntax:

```
modify datasetname;
    label  variablename='Label for Variable';
run;
```

For an example of changing both a data set label and a variable label in the same PROC DATASETS, see "Example 4: Modifying SAS Data Sets" on page 704.

Manipulating Passwords

In order to assign, change, or remove a password, you must specify the password for the highest level of protection that currently exists on that file.

Assigning Passwords

```
/* assigns a password to an unprotected file */
modify colors (pw=green);

/* assigns an Alter password to an already read-protected SAS data set */
modify colors (read=green alter=red);
```

Changing Passwords

```
/* changes the Write password from YELLOW to BROWN */
modify cars (write=yellow/brown);

/* uses Alter access to change unknown Read password to BLUE */
modify colors (read=/blue alter=red);
```

Removing Passwords

```
/* removes the Alter password RED from STATES */
modify states (alter=red/);

/* uses Alter access to remove the Read password */
modify zoology (read=green/ alter=red);

/* uses PW= as an alias for either WRITE= or ALTER= to remove unknown
   Read password */
modify biology (read=/ pw=red);
```

Working with Generation Groups

Changing the Number of Generations

```
/* changes the number of generations on data set A to 99 */
modify A (genmax=99);
```

Removing Passwords

```
/* removes the Alter password RED from STATES#002 */
modify states (alter=red/) / gennum=2;
```

REBUILD Statement

Specifies whether to restore or delete the disabled indexes and integrity constraints.

Default: Rebuild indexes and integrity constraints

Restriction: The REBUILD statement applies only to data sets created in Version 7 or later

Syntax

REBUILD *SAS-file* </ <ENCRYPTKEY=*key-value*>
<ALTER=*password*> <GENNUM=*n*> <MEMTYPE=*member-type*> <NOINDEX>>;

Required Argument

SAS-file
specifies a SAS data file that contains the disabled indexes and integrity constraints. You can also use a numbered range list or colon list.

See "Data Set Name Lists" in *SAS Programmer's Guide: Essentials*.

Optional Arguments

ENCRYPTKEY=*key-value*
specifies a key value for AES encryption.

Requirement ENCRYPTKEY= data set option is required if the data file has AES encryption.

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files that are named in the REBUILD statement. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

GENNUM=*integer*
restricts processing for generation data sets. You can use the option either in parentheses after the name of each SAS file or after a forward slash. Valid value is *integer*, which is a number that references a specific version from a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set's name (that is, `gennum=2` specifies MYDATA#002). Specifying a negative number is a relative reference to a historical version in relation to the base version, from the youngest to the oldest (that is, `gennum=-1` refers to the youngest historical version). Specifying 0, which is the default, refers to the base version.

See "Understanding Generation Data Sets" in *SAS Language Reference: Concepts*

MEMTYPE=*member-type*
restricts processing to one member type.

Aliases MTYPE=

MT=

Default If you do not specify the MEMTYPE= option in the PROC DATASETS statement or in the REBUILD statement, the default is MEMTYPE=ALL.

NOINDEX
specifies to delete the disabled indexes and integrity constraints.

Restriction The NOINDEX option cannot be used for data files that contain one or more referential integrity constraints.

Details

When the DLDMGACTION=NOINDEX data set or system option is specified and SAS encounters a damaged data file, SAS does the following:

- repairs the data file without indexes and integrity constraints
- deletes the index file
- updates the data file to reflect the disabled indexes and integrity constraints
- limits the data file to be opened only in INPUT mode
- writes the following warning to the SAS log:

```
WARNING: SAS data file MYLIB.MYFILE.DATA was damaged and
         has been partially repaired. To complete the repair,
         execute the DATASETS procedure REBUILD statement.
```

The REBUILD statement completes the repair of a damaged SAS data file by rebuilding or deleting all of the data file's disabled indexes and integrity constraints. The REBUILD statement establishes and uses member-level locking in order to process the new index file and to restore the indexes and integrity constraints.

To rebuild the index file and restore the indexes and integrity constraints, use the following code:

```
proc datasets library=mylib;
rebuild myfile
/alter=password
 gennum=n
 memtype=mytype;
```

To delete the disabled indexes and integrity constraints, use the following code:

```
proc datasets library=mylib;
rebuild myfile /noindex;
```

After you execute the REBUILD statement, the data file is no longer restricted to INPUT mode.

The REBUILD statement default is to rebuild the indexes and integrity constraints and the index file.

If a data file contains one or more referential integrity constraints and you use the NOINDEX option with the REBUILD statement, the following error message is written to the SAS log:

```
Error: Unable to rebuild data file MYLIB.MYFILE.DATA using the
             NOINDEX option because the data file contains referential
             constraints. Resubmit the REBUILD statement without the
             NOINDEX option to restore the data file.
```

RENAME Statement

Renames variables in the SAS data set specified in the MODIFY statement.

Restriction: The RENAME statement must appear in a MODIFY RUN group

Example: "Example 4: Modifying SAS Data Sets" on page 704

Syntax

RENAME *old-name-1=new-name-1*
<*old-name-2=new-name-2* ...>;

Required Argument

old-name=new-name
changes the name of a variable in the data set specified in the MODIFY statement. *old-name* must be a variable that already exists in the data set. *new-name* cannot be the name of a variable that already exists in the data set or the name of an index, and the new name must be a valid SAS name.

For example, assume the Oxygen data set includes a variable named OXYGEN. The following code renames the OXYGEN variable to intake:

```
modify oxygen;
      rename oxygen=intake;
```

Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Label
1	AGE	Num	8	
6	MAXPULSE	Num	8	
4	RSTPULSE	Num	8	
5	RUNPULSE	Num	8	
3	RUNTIME	Num	8	
2	WEIGHT	Num	8	
7	intake	Num	8	Intake Measurement

See "Rules for Words and Names in the SAS Language" in *SAS Language Reference: Concepts*

Details

If *old-name* does not exist in the SAS data set or *new-name* already exists, PROC DATASETS stops processing the RUN group containing the RENAME statement and issues an error message.

When you use the RENAME statement to change the name of a variable for which there is a simple index, the statement also renames the index.

If the variable that you are renaming is used in a composite index, the composite index automatically references the new variable name. However, if you attempt to rename a variable to a name that has already been used for a composite index, you receive an error message.

REPAIR Statement

Attempts to restore damaged SAS data sets or catalogs, in permanent libraries, to a usable condition.

Note: The REPAIR statement is not a replacement for having a current backup.

Syntax

REPAIR *SAS-file(s)*
</ <ENCRYPTKEY=*key-value*>
<ALTER=*alter-password*> <GENNUM=*integer*> <MEMTYPE=*member-type*>>;

Required Argument

SAS-file(s)
specifies one or more SAS data sets or catalogs in the procedure input library. You can also use a numbered range list or colon list.

See "Data Set Name Lists" in *SAS Programmer's Guide: Essentials*

Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files that are named in the REPAIR statement. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

See "Using Passwords with the DATASETS Procedure" on page 665

ENCRYPTKEY=*key-value*
specifies a key value for AES encryption.

Requirement ENCRYPTKEY= data set option is required if the data file has AES encryption.

GENNUM=*integer*
restricts processing for generation data sets. You can use the option either in parentheses after the name of each SAS file or after a forward slash. Valid value is *integer*, which is a number that references a specific version from a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set's name (that is, `gennum=2` specifies MYDATA#002). Specifying a negative number is a relative reference to a historical version in relation to the base version, from the youngest to the oldest (that is, `gennum=-1` refers to the youngest historical version). Specifying 0, which is the default, refers to the base version.

See "Restricting Processing for Generation Data Sets" on page 667 and "Understanding Generation Data Sets" in *SAS Language Reference: Concepts*

MEMTYPE=*member-type*
restricts processing to one member type.

Aliases MTYPE=

MT=

Default If you do not specify the MEMTYPE= option in the PROC DATASETS statement or in the REPAIR statement, the default is MEMTYPE=ALL.

See "Restricting Member Types for Processing" on page 668

Details

CAUTION
If you have extensive damage to your data set, the REPAIR statement will not correct it. If the device on which a SAS data set or an auxiliary file (index, audit, or

extended attribute file) resides is damaged, then you must restore the damaged data set and auxiliary files from a backup device.

The most common situations where the REPAIR statement might be helpful are as follows:

- A system failure occurs while you are updating a SAS data set or catalog.

  When you use the REPAIR statement for SAS data sets, it re-creates all indexes for the data set. It also attempts to restore the data set to a usable condition, but the restored data set might not include the last several updates that occurred before the system failed. You cannot use the REPAIR statement to re-create indexes that were destroyed by using the FORCE option in a PROC SORT step.

- An I/O error occurs while you are writing a SAS data set or catalog entry.

  If the disk that stores the SAS data set becomes full before the file is completely written to disk, the step that writes the data set will fail, and an error is written to the SAS log. The REPAIR statement can repair the data set header and perhaps offer a workable data set. The data set will likely be incomplete and its integrity questionable. The best recourse is to re-create the data set from a backup.

Note that observations might be lost during the repair process.

When you use the REPAIR statement for a catalog, you receive a message stating whether the REPAIR statement restored the entry. If the entire catalog is potentially damaged, the REPAIR statement attempts to restore all the entries in the catalog. If only a single entry is potentially damaged, for example, when a single entry is being updated and a disk-full condition occurs, on most systems only the entry that is open when the problem occurs is potentially damaged. In this case, the REPAIR statement attempts to repair only that entry. Some entries within the restored catalog might not include the last updates that occurred before a system crash or an I/O error. The REPAIR statement issues warning messages for entries that might have truncated data.

To repair a damaged catalog, you must use a version of SAS that can update the catalog. A damaged SAS 9 catalog can be repaired with SAS 9 only.

If you issue a REPAIR statement for a SAS file that does not exist in the specified library, PROC DATASETS stops processing the run group that contains the REPAIR statement, and issues an error message. To override this behavior, use the NOWARN option in the PROC DATASETS statement.

If you are using Cross-Environment Data Access (CEDA) to process a foreign SAS data set that has become damaged, you must move the data set back to its native environment before you attempt to repair it using the PROC DATASETS REPAIR statement. CEDA does not support update processing, which is required in order to repair a damaged data set.

For more information about CEDA, see “Definitions for Cross-Environment Data Access (CEDA)” in *SAS Programmer’s Guide: Essentials*.

RESUME Statement

resumes event logging to the audit file, if it was suspended.

Restriction: The RESUME statement must appear in an AUDIT RUN group.

Example: "Example 8: Initiating an Audit File" on page 715

Syntax

RESUME;

Details

No other audit-related statement, such as RESUME, SUSPEND, TERMINATE, USER_VAR, or LOG, will be valid for an audit file until the INITIATE statement has been submitted. For more information, see "INITIATE Statement" on page 641.

The RESUME statement requires the LOG statement ADMIN_IMAGE=YES option. This option specifies whether the administrative events are logged to the audit file (that is, the SUSPEND and RESUME actions). For more information, see "LOG Statement" on page 642.

SAVE Statement

Deletes all the SAS files in a library except the ones listed in the SAVE statement.

Example: "Example 3: Saving SAS Files from Deletion" on page 701

Syntax

SAVE *SAS-file(s)* </ MEMTYPE=*member-type*>;

Required Argument

SAS-file(s)
specifies one or more SAS files that you do not want to delete from the SAS library.

Note: If a SAS file has an ALTER= password assigned, it must be specified in order to delete the SAS file.

Optional Argument

MEMTYPE=*member-type*
restricts processing to one member type. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

Aliases MTYPE=

MT=

Default If you do not specify the MEMTYPE= option in the PROC DATASETS statement or in the SAVE statement, the default is MEMTYPE=ALL.

See "Restricting Member Types for Processing" on page 668

Example "Example 3: Saving SAS Files from Deletion" on page 701

Details

If one of the SAS files in *SAS-file* does not exist in the procedure input library, PROC DATASETS stops processing the RUN group containing the SAVE statement and issues an error message. To override this behavior, specify the NOWARN option in the PROC DATASETS statement.

When the SAVE statement deletes SAS data sets, it also deletes any indexes associated with those data sets. (If the SAS data set that is to be deleted has an ALTER= password assigned to it, the ALTER= password must be specified in order to delete the SAS data set.)

CAUTION
SAS immediately deletes libraries and library members when you submit a RUN group. You are not asked to verify the Delete operation before it begins. The SAVE statement deletes many SAS files in one operation. Make sure that you understand how the MEMTYPE= option affects which types of SAS files are saved and which types are deleted.

When you use the SAVE statement with generation groups, the SAVE statement treats the base version and all historical versions as a unit. You cannot save a specific version.

SELECT Statement

Selects SAS files for copying.

Restrictions: The SELECT statement must follow a COPY statement

The SELECT statement cannot appear with an EXCLUDE statement in the same COPY step

Example: "Example 2: Manipulating SAS Files" on page 696

Syntax

SELECT *SAS-file(s)*
</ <ENCRYPTKEY=*key-value*> <ALTER=*alter-password*> <MEMTYPE=*member-type*>>;

Required Argument

SAS-file(s)
specifies one or more SAS files that you want to copy. All of the SAS files that you name must be in the data library that is referenced by the libref named in the IN= option in the COPY statement. If the SAS files have generation groups, all the generations are copied because the SELECT statement does not allow you to select specific versions.

Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files that you are moving from one data library to another. Because you are moving and thus deleting a SAS file from a SAS library, you need Alter access. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

See "Using Passwords with the DATASETS Procedure" on page 665

ENCRYPTKEY=*key-value*
specifies the key value for AES encryption.

See "Appending AES-Encrypted Data Sets" on page 592

MEMTYPE=*member-type*
restricts processing to one member type. You can use the option either in parentheses after the name of each SAS file or after a forward slash.

Aliases MTYPE=

MT=

Default If you do not specify the MEMTYPE= option in the PROC DATASETS statement, in the COPY statement, or in the SELECT statement, the default is MEMTYPE=ALL.

See "Specifying Member Types When Copying or Moving SAS Files" on page 620 and "Restricting Member Types for Processing" on page 668

Example “Example 2: Manipulating SAS Files” on page 696

Details

Selecting Several Like-Named Files

You can use shortcuts for listing several SAS files in the SELECT statement:

Table 17.13 *Using the SELECT Statement*

Notation	Meaning
x1–xn	Specifies files X1 through Xn. The numbers must be consecutive.
x:	Specifies all files that begin with the letter X.

SUSPEND Statement

suspends event logging to the audit file, but does not delete the audit file.

Restriction: The SUSPEND statement must appear in an AUDIT RUN group.

Example: “Example 8: Initiating an Audit File” on page 715

Syntax

SUSPEND;

Details

No other audit-related statement, such as SUSPEND, RESUME, TERMINATE, USER_VAR, or LOG, will be valid for an audit file until the INITIATE statement has been submitted. For more information, see “INITIATE Statement” on page 641.

The SUSPEND statement requires the LOG statement ADMIN_IMAGE=YES option. This option specifies whether the administrative events are logged to the audit file (that is, the SUSPEND and RESUME actions). For more information, see “LOG Statement” on page 642.

TERMINATE Statement

terminates event logging and deletes the audit file.

Restriction: The TERMINATE statement must appear in an AUDIT RUN group.

Example: "Example 8: Initiating an Audit File" on page 715

Syntax

TERMINATE;

Details

No other audit-related statement, such as TERMINATE, SUSPEND, RESUME, USER_VAR, or LOG, will be valid for an audit file until the INITIATE statement has been submitted. For more information, see "INITIATE Statement" on page 641.

USER_VAR Statement

defines optional variables to be logged in the audit file with each update to an observation. When you use USER_VAR, it must follow an INITIATE statement.

Restrictions: The USER_VAR statement must appear in an AUDIT RUN group.

The USER_VAR statement is optional. If specified, the USER_VAR statement must immediately follow the INITIATE statement for the applicable audit file.

Example: "Example 8: Initiating an Audit File" on page 715

Syntax

USER_VAR *variable-name-1* <$> <*length*> <LABEL='*variable-label*' > <*variable-name-2* <$> <*length*> <LABEL='*variable-label*' > ...>;

Required Argument

variable-name
is a name for the variable.

Optional Arguments

$
indicates that the variable is a character variable.

length
specifies the length of the variable.

Default 8

LABEL='*variable-label*'
specifies a label for the variable.

XATTR ADD Statement

Adds an extended attribute to a variable or a data set.

Restrictions: The XATTR ADD statement must appear in a MODIFY RUN group

Generation data sets do not support extended attributes.

Supports: V9 engine only

Notes: An extended attribute can have numeric or character values.

A blank space in a character value indicates a missing value. Missing numeric values are also allowed.

An extended attribute name must conform to SAS naming rules. A SAS name can be up to 32 characters long. For more information, see "Rules for User-Supplied SAS Names" in *SAS Language Reference: Concepts* and "SAS Variable Attributes" in *SAS Language Reference: Concepts*.

Example: "Example 9: Extended Attributes" on page 721

Syntax

XATTR ADD DS *attribute-name-1=attribute-value-1*
<*attribute-name-2=attribute-value-2 ...*>;

or

XATTR ADD VAR *variable-name-1* (*attribute-name-1=attribute-value-1*
< attribute-name-2=attribute-value-2 ...>)
<*variable-name-2* (*attribute-name-1=attribute-value-1*
<*attribute-name-2=attribute-value-2 ...*>) >;

Required Arguments

Note that for character values, *attribute-value* must be in quotation marks, such as *"attribute-value"*.

XATTR ADD DS *attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>*
adds an extended attribute to a data set. If the extended attribute already exists, an error will be returned.

XATTR ADD VAR *variable-name-1 (attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>) <variable-name-2 (attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>)>*
adds an extended attribute to a variable. If the extended attribute already exists, an error will be returned.

Details

Extended attributes are organized into (name, value) pairs. If you try to add a new attribute and the attribute already exists, an error is written to the SAS log.

XATTR DELETE Statement

Deletes all extended attributes from a SAS file.

Restriction: The XATTR DELETE statement must appear in a MODIFY RUN group

Supports: V9 engine only

Example: "Example 9: Extended Attributes" on page 721

Syntax

XATTR DELETE;

Required Argument

XATTR DELETE
deletes all extended attributes from a data set.

Details

Use the XATTR DELETE statement to delete all of the extended attributes from a data set. None of the extended attributes will exist after using this command. The following example deletes all extended attributes from a data set:

```
proc datasets lib=library_name nolist;
   modify dataset_name;
      xattr delete;
   run;
quit;
```

XATTR OPTIONS Statement

Specifies options as needed for extended attributes. Currently, only SEGLEN= is a valid option.

Restriction: The XATTR OPTIONS statement must appear in a MODIFY RUN group

Supports: V9 engine only

Example: "Example 9: Extended Attributes" on page 721

Syntax

XATTR OPTIONS <SEGLEN=*number-of-bytes*>;

Required Argument

XATTR OPTIONS SEGLEN=*number-of-bytes*
Indicates the length of the storage element that will hold the character extended attribute value. The value can be 1 to 32,760 bytes.

Default 256

XATTR REMOVE Statement

Removes an extended attribute from a variable or a data set.

Restriction: The XATTR REMOVE statement must appear in a MODIFY RUN group

Supports: V9 engine only

Example: "Example 9: Extended Attributes" on page 721

Syntax

XATTR REMOVE DS *attribute-name(s)* ;

or

XATTR REMOVE VAR *variable-name-1* (*attribute-name(s)*)

<variable-name-2 (attribute-name(s) ...)>;

Required Arguments

XATTR REMOVE DS *attribute-name(s)*
removes an extended attribute from a data set.

XATTR REMOVE VAR *variable-name-1* (*attribute-name(s)*) <*variable-name-2* (*attribute-name(s)*)>
removes an extended attribute from a variable.

Details

If you no longer need an extended attribute that you created, use the XATTR REMOVE statement to remove it from a variable or a data set. The XATTR REMOVE statement deletes only the extended attribute that you specify.

XATTR SET Statement

Updates or adds extended attributes to variables or data sets.

Restrictions: The XATTR SET statement must appear in a MODIFY RUN group

Generation data sets do not support extended attributes.

Supports: V9 engine only

Notes: An extended attribute can have numeric or character values.

A blank space in a character value indicates a missing value. Missing numeric values are also allowed.

An extended attribute name must conform to SAS naming rules. A SAS name can be up to 32 characters long. For more information, see "Rules for User-Supplied SAS Names" in *SAS Language Reference: Concepts* and "SAS Variable Attributes" in *SAS Language Reference: Concepts*.

Example: "Example 9: Extended Attributes" on page 721

Syntax

XATTR SET DS *attribute-name-1=attribute-value-1*
<attribute-name-2="attribute-value-2" ...>;

or

XATTR SET VAR *variable-name-1 (attribute-name-1=attribute-value-1*
<attribute-name-2=attribute-value-2 ... >)
<variable-name-2 (attribute-name-1=attribute-value-1
<attribute-name-2=attribute-value-2> ...)>;

Required Arguments

Note that for character values, *attribute-value* must be in quotation marks, such as *"attribute-value"*.

XATTR SET DS *attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>*
updates or adds an extended attribute to a data set. If the data set extended attribute does not exist, it will be added. If it does exist, it will be updated with the value specified.

XATTR SET VAR *variable-name-1* (*attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>*) *<variable-name-2* (*attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>*)>
updates or adds an extended attribute to a variable. If the variable and extended attribute combination does not exist, the extended attribute will be added. If it does exist, the extended attribute will be updated with the one specified.

Details

Use the XATTR SET statement if you are not sure if an extended attribute exists. If an extended attribute does exist, it will be updated. If the extended attribute does not exist, it added. The XATTR SET statement defines the variable or data set extended attribute even if it does not exist yet. When using XATTR ADD, an error occurs if there is an existing extended attribute using that value. You also get an error if you try to use XATTR UPDATE on an extended attribute that does not exist yet. Using XATTR SET defines the variable or data set extended attributes. If the extended attribute did not exist, it does now. If the extended attribute did exist, then it has a new value.

XATTR UPDATE Statement

Updates an extended attribute to a variable or a data set.

Restriction: The XATTR UPDATE statement must appear in a MODIFY RUN group

Supports: V9 engine only

Notes: A blank space in a character value indicates a missing value. Missing numeric values are also allowed.

An extended attribute name must conform to SAS naming rules. A SAS name can be up to 32 characters long. For more information, see "Rules for User-Supplied SAS Names" in *SAS Language Reference: Concepts* and "SAS Variable Attributes" in *SAS Language Reference: Concepts*.

Example: "Example 9: Extended Attributes" on page 721

Syntax

XATTR UPDATE DS *attribute-name-1=attribute-value-1*
<attribute-name-2=attribute-value-2 ...>;

or

XATTR UPDATE VAR *variable-name-1 (attribute-name-1=attribute-value-1*
<attribute-name-2=attribute-value-2 ...>)
<variable-name-2 (attribute-name-1=attribute-value-1
<attribute-name-2=attribute-value-2 ...>)>;

Required Arguments

Note that for character values, *attribute-value* must be in quotation marks, such as *"attribute-value"*.

XATTR UPDATE DS *attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>*
updates an extended attribute in a data set. If the extended attribute does not exist, an error is written to the SAS log.

XATTR UPDATE VAR *variable-name-1 (attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>) <variable-name-2 (attribute-name-1=attribute-value-1 <attribute-name-2=attribute-value-2 ...>)>*
updates an extended attribute for a variable. If the variable and extended attribute combination is not found, an error message is written to the SAS log.

Details

To make changes to an existing extended attribute, use the XATTR UPDATE statement. If you try to update an extended attribute that does not exist, an error is written to the SAS log.

Usage: DATASETS Procedure

Using Passwords with the DATASETS Procedure

Several statements in the DATASETS procedure support options that manipulate passwords on SAS files. These options, ALTER=, PW=, READ=, and WRITE=, are also data set options.[1] If you do not know how passwords affect SAS files, see "Assigning Passwords" in *SAS Programmer's Guide: Essentials*.

When you are working with password-protected SAS files in the AGE, CHANGE, DELETE, EXCHANGE, REPAIR, or SELECT statement, you can specify ALTER= and PW= password options in the PROC DATASETS statement or in the subordinate statement.

Note: The ALTER= option works slightly different for the COPY (when moving a file) and MODIFY statements. For more information, see COPY statement on page 610 and the MODIFY statement on page 644.

SAS searches for passwords in the following order:

1 in parentheses after the name of the SAS file in a subordinate statement. When used in parentheses, the option refers only to the name immediately preceding the option. If you are working with more than one SAS file in a data library and each SAS file has a different password, you must specify password options in parentheses after individual names.

   In the following statement, the ALTER= option provides the password `red` for the SAS file Bones only:

```
delete xplant bones(alter=red);
```

2 after a forward slash (/) in a subordinate statement. When you use a password option following a slash, the option refers to all SAS files named in the statement unless the same option appears in parentheses after the name of a SAS file. This method is convenient when you are working with more than one SAS file and they all have the same password.

   In the following statement, the ALTER= option in parentheses provides the password `red` for the SAS file Chest, and the ALTER= option after the slash provides the password `blue` for the SAS file Virus:

```
delete chest(alter=red) virus / alter=blue;
```

3 in the PROC DATASETS statement. Specifying the password in the PROC DATASETS statement can be useful if all the SAS files that you are working with in the library have the same password. Do not specify the option in parentheses.

   In the following PROC DATASETS step, the PW= option provides the password `red` for the SAS files Insulin and Abneg:

```
proc datasets pw=red;
   delete insulin;
   contents data=abneg;
run;
```

Note: For the password for a SAS file in a SELECT statement, SAS looks in the COPY statement before it looks in the PROC DATASETS statement.

1. In the APPEND and CONTENTS statements, you use these options just as you use any SAS data set option, in parentheses after the SAS data set name.

Restricting Processing for Generation Data Sets

Several statements in the DATASETS procedure support the GENNUM= option to restrict processing for generation data sets. GENNUM= is also a data set option.[1] If you do not know how to request and use generation data sets, see "Generation Data Sets" in "Understanding Generation Data Sets" in *SAS Language Reference: Concepts*.

When you are working with a generation group for the AUDIT, CHANGE, DELETE, MODIFY, and REPAIR statements, you can restrict processing in the PROC DATASETS statement or in the subordinate statement to a specific version.

Note: The GENNUM= option works slightly different for the MODIFY statement. See MODIFY statement on page 644.

Note: You cannot restrict processing to a specific version for the AGE, COPY, EXCHANGE, and SAVE statements. These statements apply to the entire generation group.

SAS searches for a generation specification in the following order:

1. in parentheses after the name of the SAS data set in a subordinate statement. When used in parentheses, the option refers only to the name immediately preceding the option. If you are working with more than one SAS data set in a data library and you want a different generation version for each SAS data set, then you must specify GENNUM= in parentheses after individual names.

   In the following statement, the GENNUM= option specifies the version of a generation group for the SAS data set Bones only:

   ```
   delete xplant bones (gennum=2);
   ```

2. after a forward slash (/) in a subordinate statement. When you use the GENNUM= option following a slash, the option refers to all SAS data sets named in the statement unless the same option appears in parentheses after the name of a SAS data set. This method is convenient when you are working with more than one file and you want the same version for all files.

   In the following statement, the GENNUM= option in parentheses specifies the generation version for SAS data set Chest, and the GENNUM= option after the slash specifies the generation version for SAS data set Virus:

   ```
   delete chest (gennum=2) virus / gennum=1;
   ```

3. in the PROC DATASETS statement. Specifying the generation version in the PROC DATASETS statement can be useful if you want the same version for all

1. For the APPEND and CONTENTS statements, use GENNUM= just as you use any SAS data set option, in parentheses after the SAS data set name.

of the SAS data sets you are working with in the library. Do not specify the option in parentheses.

In the following PROC DATASETS step, the GENNUM= option specifies the generation version for the SAS files Insulin and Abneg:

```
proc datasets gennum=2;
   delete insulin;
   contents data=abneg;
run;
```

Note: For the generation version for a SAS file in a SELECT statement, SAS looks in the COPY statement before it looks in the PROC DATASETS statement.

Restricting Member Types for Processing

In the PROC DATASETS Statement

If you reference more than one member type in subordinate statements and you have a specified member type in the PROC DATASETS statement, then include all of the member types in the PROC DATASETS statement. Only the member type or types in the original PROC DATASETS statement is in effect. The following example lists multiple member types:

```
proc datasets lib=library memtype=(data view);
```

In Subordinate Statements

Use the MEMTYPE= option in the following subordinate statements to limit the member types that are available for processing:

AGE CHANGE DELETE EXCHANGE

EXCLUDE REPAIR SAVE SELECT

Note: The MEMTYPE= option works slightly differently for the CONTENTS, COPY, and MODIFY statements. For more information, see CONTENTS statement on page 603, COPY Statement on page 610, and MODIFY statement on page 644.

The procedure searches for MEMTYPE= in the following order:

1 in parentheses immediately after the name of a SAS file. When used in parentheses, the MEMTYPE= option refers only to the SAS file immediately preceding the option. For example, the following statement deletes House.data,

Lot.catalog, and Sales.data because the default member type for the DELETE statement is DATA. (For more information, see Table 17.52 on page 670 for the default types for each statement.)

```
delete house lot(memtype=catalog) sales;
```

2 after a slash (/) at the end of the statement. When used following a slash, the MEMTYPE= option refers to all SAS files named in the statement unless the option appears in parentheses after the name of a SAS file. For example, the following statement deletes Lotpix.catalog, Regions.data, and Appl.catalog:

```
delete lotpix regions(memtype=data) appl / memtype=catalog;
```

3 in the PROC DATASETS statement. For example, this DATASETS procedure deletes Appl.catalog:

```
proc datasets memtype=catalog;
   delete appl;
run;
```

Note: When you use the EXCLUDE and SELECT statements, the procedure looks in the COPY statement for the MEMTYPE= option before it looks in the PROC DATASETS statement. For more information, see "Specifying Member Types When Copying or Moving SAS Files" on page 620.

4 for the default value. If you do not specify a MEMTYPE= option in the subordinate statement or in the PROC DATASETS statement, the default value for the subordinate statement determines the member type available for processing.

Member Types

The following list gives the possible values for the MEMTYPE= option:

ACCESS
: access descriptor files (created by SAS/ACCESS software)

ALL
: all member types

CATALOG
: SAS catalogs

DATA
: SAS data files

FDB
: financial database

MDDB
: multidimensional database

PROGRAM
: stored compiled SAS programs

VIEW
SAS views

The following table shows the member types that you can use in each statement:

Table 17.14 *Subordinate Statements and Appropriate Member Types*

Statement	Appropriate Member Types	Default Member Type
AGE	ACCESS, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	DATA
CHANGE	ACCESS, ALL, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	ALL
CONTENTS	ALL, DATA, VIEW	DATA [1]
COPY	ACCESS, ALL, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	ALL
DELETE	ACCESS, ALL, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	DATA
EXCHANGE	ACCESS, ALL, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	ALL
EXCLUDE	ACCESS, ALL, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	ALL
MODIFY	ACCESS, DATA, VIEW	DATA
REPAIR	ALL, CATALOG, DATA	ALL [2]
SAVE	ACCESS, ALL, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	ALL
SELECT	ACCESS, ALL, CATALOG, DATA, FDB, MDDB, PROGRAM, VIEW	ALL

1 When DATA=_ALL_ in the CONTENTS statement, the default is ALL. ALL includes only DATA and VIEW.
2 ALL includes only DATA and CATALOG.

Sample PROC DATASETS Output

The DATASETS procedure includes the following:

- copies all data sets from the Control library to the Health library
- lists the contents of the Health library
- deletes the Syndrome data set from the Health library
- changes the name of the Prenat data set to Infant

The SAS log is shown in the following output.

```
LIBNAME control 'SAS-library-1';
LIBNAME health 'SAS-library-2';

proc datasets memtype=data;
   copy in=control out=health;
run;

proc datasets library=health memtype=data details;
   delete syndrome;
   change prenat=infant;
run;
quit;
```

Example Code 17.1 *Log from PROC DATASETS*

```
744  proc datasets library=health memtype=data details;
                                Directory

Libref         HEALTH

Results: DATASETS Procedure

Directory Listing to the SAS Log

The PROC DATASETS statement lists the SAS files in the procedure input library unless the NOLIST option is specified. The NOLIST option prevents the creation of the procedure results that go to the log. If you specify the MEMTYPE= option, only specified types are listed. If you specify the DETAILS option, PROC DATASETS prints these additional columns of information: **`Obs, Entries or Indexes`**, **`Vars`**, and **`Label`**.

Directory Listing as SAS Output

The CONTENTS statement lists the directory of the procedure input library if you use the DIRECTORY option or specify DATA=_ALL_.

If you want only a directory, use the NODS option and the _ALL_ keyword in the DATA= option. The NODS option suppresses the description of the SAS data sets; only the directory appears in the output.

Note: The CONTENTS statement does not put a directory in an output data set. If you try to create an output data set using the NODS option, you receive an empty output data set. Use the SQL procedure to create a SAS data set that contains information about a SAS library.

Note: If you specify the ODS RTF destination, the PROC DATASETS output goes to both the SAS log and the ODS output area. The NOLIST option suppresses output to both. To see the output only in the SAS log, use the ODS EXCLUDE statement by specifying the member directory as the exclusion.

Procedure Output

The CONTENTS Statement

The only statement in PROC DATASETS that produces procedure output is the CONTENTS statement. This section shows the output from the CONTENTS statement for the Health library and the Group data set, which is shown in the following output.

Only the items in the output that require explanation are discussed.

The Health Library Contents

The following is the list of all the files and catalogs in the Health library.

Directory	
Libref	HEALTH
Engine	V9
Physical Name	c:\procdatasets1\health
Filename	c:\procdatasets1\health
Owner Name	BUILTIN\Administrators
File Size	12KB
File Size (bytes)	12288

25	WGHT	DATA	24KB	09/03/2014 10:35:03

Data Set Attributes

Here are descriptions of selected fields shown in the following output:

Member Type
is the type of library member (DATA or VIEW).

Created
indicates the date and time that the data set was created. The date and time reflect the setting of the TIMEZONE= system option. If the TIMEZONE= system option is not set, then the local time zone in which the SAS session is running is used.

Last Modified
indicates the date and time that the data set was last modified. The date and time reflect the setting of the TIMEZONE= system option. If the TIMEZONE= system option is not set, then the local time zone in which the SAS session is running is used.

Protection
indicates whether the SAS data set is Read, Write, or Alter password protected.

Data Set Type
names the special data set type (such as CORR, COV, SSPC, EST, or FACTOR), if any.

Observations
is the total number of observations currently in the file. Note that for a very large data set, if the number of observations exceeds the largest integer value that can be represented in a double precision floating point number, the count is shown as missing.

Deleted Observations
is the number of observations marked for deletion. These observations are not included in the total number of observations, shown in the **Observations** field. Note that for a very large data set, if the number of deleted observations exceeds the number that can be stored in a double-precision integer, the count is shown as missing. Also, the count for **Deleted Observations** shows a missing value if you use the COMPRESS=YES option with one or both of the REUSE=YES and POINTOBS=NO options.

Compressed
indicates whether the data set is compressed. If the data set is compressed, the output includes an additional item, **Reuse Space** (with a value of YES or NO). This item indicates whether to reuse space that is made available when observations are deleted.

Sorted
indicates whether the data set is sorted. If you sort the data set with PROC SORT, PROC SQL, or specify sort information with the SORTEDBY= data set option, a value of YES appears here, and there is an additional section to the output. See "Sort Information" on page 680 for details.

Data Representation
is the format in which data is represented on a computer architecture or in an operating environment. For example, on an IBM PC, character data is represented by its ASCII encoding and byte-swapped integers. Native data representation refers to an environment for which the data representation compares with the CPU that is accessing the file. For example, a file that is in Windows data representation is native to the Windows operating environment.

Encoding
is the encoding value. Encoding is a set of characters (letters, logograms, digits, punctuation, symbols, control characters, and so on) that have been mapped to numeric values (called code points) that can be used by computers. The code points are assigned to the characters in the character set when you apply an encoding method.

Output 17.4 *Attributes of the Group Data Set*

Data Set Name	HEALTH.GROUP	Observations	148
Member Type	DATA	Variables	11
Engine	V9	Indexes	0
Created	09/03/2014 10:35:02	Observation Length	96
Last Modified	09/03/2014 10:35:02	Deleted Observations	0
Protection		Compressed	NO
Data Set Type		Sorted	NO
Label			
Data Representation	WINDOWS_32		
Encoding	wlatin1 Western (Windows)		

Engine and Operating Environment-Dependent Information

The CONTENTS statement produces operating environment-specific and engine-specific information. This information differs depending on the operating environment. The following output is from the Windows operating environment.

Output 17.5 *Engine/Host Dependent Information for the Group Data Set*

Engine/Host Dependent Information	
Data Set Page Size	8192
Number of Data Set Pages	3
First Data Page	1
Max Obs per Page	84
Obs in First Data Page	63
Number of Data Set Repairs	0
ExtendObsCounter	YES
Filename	c:\procdatasets\health\group.sas7bdat
Release Created	9.0401M3
Host Created	W32_7PRO
Owner Name	BUILTIN\Administrators
File Size	32KB
File Size (bytes)	32768

Alphabetic List of Variables and Attributes

Here are descriptions of selected columns in the following output:

#
is the logical position of each variable in the observation. This number is assigned to the variable when the variable is defined.

Variable
is the name of each variable. By default, variables appear alphabetically.

Note: Variable names are sorted such that X1, X2, and X10 appear in that order and not in the true collating sequence of X1, X10, and X2. Variable names that contain an underscore and digits might appear in a nonstandard sort order. For example, P25 and P75 appear before P2_5.

Type
specifies the type of variable: character or numeric.

Len
specifies the variable's length, which is the number of bytes used to store each of a variable's values in a SAS data set.

Transcode
specifies whether a character variable is transcoded. If the attribute is NO, then transcoding is suppressed. By default, character variables are transcoded when

required. For more information about transcoding, see *SAS National Language Support (NLS): Reference Guide*.

Note: If none of the variables in the SAS data set has a format, informat, or label associated with it, or if all of the variables are set to TRANSCODE=YES, then the column for the attribute is NOT displayed.

Output 17.6 *Listing of Variables and Attributes of the Group Data Set*

Alphabetic List of Variables and Attributes

#	Variable	Type	Len	Format	Informat
9	BIRTH	Num	8		
4	CITY	Char	15		
3	FNAME	Char	15		
10	HIRED	Num	8	DATE7.	DATE7.
11	HPHONE	Char	12		
1	IDNUM	Char	4		
7	JOBCODE	Char	4		
2	LNAME	Char	15		
8	SALARY	Num	8	COMMA8.	
6	SEX	Char	2		
5	STATE	Char	3		

Alphabetic List of Indexes and Attributes

The section shown in the following output appears only if the data set has indexes associated with it.

#
indicates the number of each index. The indexes are numbered sequentially as they are defined.

Index
displays the name of each index. For simple indexes, the name of the index is the same as a variable in the data set.

Unique Option
indicates whether the index must have unique values. If the column contains YES, the combination of values of the index variables is unique for each observation.

Nomiss Option
indicates whether the index excludes missing values for all index variables. If the column contains YES, the index does not contain observations with missing values for all index variables.

# of Unique Values
gives the number of unique values in the index.

Variables
names the variables in a composite index.

Output 17.7 *Listing of Indexes and Attributes of the Group Data Set*

Alphabetic List of Indexes and Attributes

#	Index	Unique Option	NoMiss Option	# of Unique Values	Variables
1	vital	YES	YES	148	BIRTH SALARY

Sort Information

The section shown in the following output appears only if the **Sorted** field has a value of YES.

Sortedby
indicates how the data are currently sorted. This field contains either the variables and options that you use in the BY statement in PROC SORT, the column name in PROC SQL, or the values that you specify in the SORTEDBY= option.

Validated
indicates whether the data was sorted using PROC SORT or SORTEDBY. If PROC SORT or PROC SQL sorted the data set, the value is YES. If you assigned the sort indicator with the SORTEDBY= data set option, the value is NO.

Character Set
is the character set used to sort the data. The value for this field can be ASCII, EBCDIC, or PASCII.

Collating Sequence
is the collating sequence used to sort the data set, which can be a translation table name, an encoding value, or LINGUISTIC if the data set is sorted linguistically. This field does not appear if you do not specify a collating sequence that is different from the character set.

If the data set is sorted linguistically, additional linguistic collating sequence information appears after **Collating Sequence**, such as the locale, collation style, and so on. For a list of the collation rules that can be specified for linguistic collation.

Sort Option
indicates whether PROC SORT used the NODUPKEY option when sorting the data set. This field does not appear if you did not use this option in a PROC SORT statement (not shown).

Output 17.8 *Group Data Set Sort Information*

Sort Information	
Sortedby	LNAME
Validated	NO
Character Set	ANSI

PROC DATASETS and the Output Delivery System (ODS)

Most SAS procedures send their messages to the SAS log and their procedure results to the output. PROC DATASETS is unique because it sends procedure results to both the SAS log and the procedure output file. When the interface to ODS was created, it was decided that all procedure results (from both the log and the procedure output file) should be available to ODS. In order to implement this feature and maintain compatibility with earlier releases, the interface to ODS had to be slightly different from the usual interface.

By default, the PROC DATASETS statement itself produces two output objects: Members and Directory. These objects are routed to the SAS log. The CONTENTS statement produces three output objects by default: Attributes, EngineHost, and Variables. (The use of various options adds other output objects.) These objects are routed to the procedure output file. If you open an ODS destination (such as HTML, RTF, or PRINTER), all of these objects are, by default, routed to that destination.

You can use ODS SELECT and ODS EXCLUDE statements to control which objects go to which destination, just as you can for any other procedure. However, because of the unique interface between PROC DATASETS and ODS, when you use the keyword LISTING in an ODS SELECT or ODS EXCLUDE statement, you affect both the log and the listing.

ODS Table Names

PROC DATASETS and PROC CONTENTS assign a name to each table that they create. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets.

PROC CONTENTS generates the same ODS tables as PROC DATASETS with the CONTENTS statement.

Table 17.15 *ODS Tables Produced by the DATASETS Procedure without the CONTENTS Statement*

ODS Table	Description	Generates Table
Directory	General library information	Unless you specify the NOLIST option
Members	Library member information	Unless you specify the NOLIST option

Table 17.16 *ODS Table Names Produced by PROC CONTENTS and PROC DATASETS with the CONTENTS Statement*

ODS Table	Description	Generates Table
Attributes	Data set attributes	Unless you specify the SHORT option
Directory	General library information	If you specify DATA=<*libref*.>_ALL_ or the DIRECTORY option [1]
EngineHost	Engine and operating environment information	Unless you specify the SHORT option
IntegrityConstraints	A detailed listing of integrity constraints	If the data set has integrity constraints and you do not specify the SHORT option
IntegrityConstraintsShort	A concise listing of integrity constraints	If the data set has integrity constraints and you specify the SHORT option
Indexes	A detailed listing of indexes	If the data set is indexed and you do not specify the SHORT option
IndexesShort	A concise listing of indexes	If the data set is indexed and you specify the SHORT option
Members	Library member information	If you specify DATA=<*libref*.>_ALL_ or the DIRECTORY option [1]
Position	A detailed listing of variables by logical position in the data set	If you specify the VARNUM option and you do not specify the SHORT option
PositionShort	A concise listing of variables by logical position in the data set	If you specify the VARNUM option and the SHORT option

ODS Table	Description	Generates Table
PositionVarchar	Position including varchar type	If a varchar is in the data set, you specify VARNUM and you do not specify the SHORT option
Sortedby	Detailed sort information	If the data set is sorted and you do not specify the SHORT option
SortedbyShort	Concise Sort information	If the data set is sorted and you specify the SHORT option
Variables	A detailed listing of variables in alphabetical order	Unless you specify the SHORT option
VariablesShort	A concise listing of variables in alphabetical order	If you specify the SHORT option
VariablesVarchar	Variables including varchar type	If a varchar is in the data set, unless the SHORT option is specified

1 For PROC DATASETS, if both the NOLIST option and either the DIRECTORY option or DATA=<*libref*.>_ALL_ are specified, then the NOLIST option is ignored.

Output Data Sets

The CONTENTS Statement

The CONTENTS statement is the only statement in the DATASETS procedure that generates output data sets.

The OUT= Data Set

The OUT= option in the CONTENTS statement creates an output data set. Each variable in each DATA= data set has one observation in the OUT= data set. Here are the variables in the output data set:

CHARSET
: the character set used to sort the data set. The value is ASCII, EBCDIC, or PASCII. A blank appears if the data set does not have a sort indicator stored with it.

COLLATE
the collating sequence used to sort the data set. A blank appears if the sort indicator for the input data set does not include a collating sequence.

COMPRESS
indicates whether the data set is compressed.

CRDATE
date the data set was created.

DELOBS
number of observations marked for deletion in the data set. (Observations can be marked for deletion but not actually deleted when you use the FSEDIT procedure of SAS/FSP software.)

ENCRYPT
indicates whether the data set is encrypted.

ENGINE
name of the method used to read from and write to the data set.

FLAGS
indicates whether the variables in an SQL view are protected (**P**) or contribute (**C**) to a derived variable.

P
indicates the variable is protected. The value of the variable can be displayed but not updated.

C
indicates whether the variable contributes to a derived variable.

The value of FLAG is blank if **P** or **C** does not apply to an SQL view or if it is a data set view.

FORMAT
variable format. The value of FORMAT is a blank if you do not associate a format with the variable.

FORMATD
number of decimals that you specify when you associate the format with the variable. The value of FORMATD is 0 if you do not specify decimals in the format.

FORMATL
format length. If you specify a length for the format when you associate the format with a variable, the length that you specify is the value of FORMATL. If you do not specify a length for the format when you associate the format with a variable, the value of FORMATL is the default length of the format if you use the FMTLEN option and 0 if you do not use the FMTLEN option.

GENMAX
maximum number of versions for the generation group.

GENNEXT
the next generation number for a generation group.

GENNUM
the version number.

IDXCOUNT
number of indexes for the data set.

IDXUSAGE
use of the variable in indexes. Possible values are

NONE
the variable is not part of an index.

SIMPLE
the variable has a simple index. No other variables are included in the index.

COMPOSITE
the variable is part of a composite index.

BOTH
the variable has a simple index and is part of a composite index.

INFORMAT
variable informat. The value is a blank if you do not associate an informat with the variable.

INFORMD
number of decimals that you specify when you associate the informat with the variable. The value is 0 if you do not specify decimals when you associate the informat with the variable.

INFORML
informat length. If you specify a length for the informat when you associate the informat with a variable, the length that you specify is the value of INFORML. If you do not specify a length for the informat when you associate the informat with a variable, the value of INFORML is the default length of the informat if you use the FMTLEN option and 0 if you do not use the FMTLEN option.

JUST
justification (0=left, 1=right).

LABEL
variable label (blank if none given).

LENGTH
variable length.

LIBNAME
libref used for the data library.

MEMLABEL
label for this SAS data set (blank if no label).

MEMNAME
SAS data set that contains the variable.

MEMTYPE
library member type (DATA or VIEW).

MODATE
date the data set was last modified.

NAME
variable name.

NOBS
number of observations in the data set.

NODUPKEY
indicates whether the NODUPKEY option was used in a PROC SORT statement to sort the input data set.

NODUPREC
indicates whether the NODUPREC option was used in a PROC SORT statement to sort the input data set.

NPOS
physical position of the first character of the variable in the data set.

POINTOBS
indicates whether the data set can be addressed by observation.

PROTECT
the first letter of the level of protection. The value for PROTECT is one or more of the following:

A
indicates the data set is alter-protected.

R
indicates the data set is read-protected.

W
indicates the data set is write-protected.

REUSE
indicates whether the space made available when observations are deleted from a compressed data set should be reused. If the data set is not compressed, the REUSE variable has a value of NO.

SORTED
the value depends on the sorting characteristics of the input data set. Here are the possible values:

. (period)
for not sorted.

0
for sorted but not validated.

1
for sorted and validated.

SORTEDBY
the value depends on that variable's role in the sort. Here are the possible values:

. (period)
if the variable was not used to sort the input data set.

n
where *n* is an integer that denotes the position of that variable in the sort. A negative value of *n* indicates that the data set is sorted by the descending order of that variable.

TRANSCOD
indicates whether the variable is transcoded.

TYPE
type of the variable (1=numeric, 2=character).

TYPEMEM
special data set type (blank if no TYPE= value is specified).

VARNUM
variable number in the data set. Variables are numbered in the order in which they appear.

The output data set is sorted by the variables LIBNAME and MEMNAME.

Note: The variable names are sorted so that the values X1, X2, and X10 are listed in that order, not in the true collating sequence of X1, X10, X2. Therefore, if you want to use a BY statement on MEMNAME in subsequent steps, run a PROC SORT step on the output data set first. You can also use the NOTSORTED option in the BY statement.

Here is an example of an output data set created from the Group data set, which is shown in "Example 5: Describing a SAS Data Set" on page 707 and in "Procedure Output" on page 674.

Due to the size of the Health.Grpout, the following output is in five sections.

Output 17.9 *An Example of an Output Data Set — Section 1*

Obs	LIBNAME	MEMNAME	MEMLABEL	TYPEMEM	NAME	TYPE	LENGTH	VARNUM
1	HEALTH	GROUP			BIRTH	1	8	9
2	HEALTH	GROUP			CITY	2	15	4
3	HEALTH	GROUP			FNAME	2	15	3
4	HEALTH	GROUP			HIRED	1	8	10
5	HEALTH	GROUP			HPHONE	2	12	11
6	HEALTH	GROUP			IDNUM	2	4	1
7	HEALTH	GROUP			JOBCODE	2	4	7
8	HEALTH	GROUP			LNAME	2	15	2
9	HEALTH	GROUP			SALARY	1	8	8
10	HEALTH	GROUP			SEX	2	2	6
11	HEALTH	GROUP			STATE	2	3	5

Output 17.10 *An Example of an Output Data Set — Section 2*

		NO	NO	NO	YES	0	.	.	YES
		NO	NO	NO	YES	0	.	.	YES

The OUT2= Data Set

The OUT2= option in the CONTENTS statement creates an output data set that contains information about indexes and integrity constraints. Here are the variables in the output data set:

IC_OWN
: contains YES if the index is owned by the integrity constraint.

INACTIVE
: contains YES if the integrity constraint is inactive.

LIBNAME
libref used for the data library.

MEMNAME
SAS data set that contains the variable.

MG
the value of MESSAGE=, if it is used, in the IC CREATE statement.

MSGTYPE
the value is blank unless an integrity constraint is violated and you specified a message.

NAME
the name of the index or integrity constraint.

NOMISS
contains YES if the NOMISS option is defined for the index.

NUMVALS
the number of distinct values in the index (displayed for centiles).

NUMVARS
the number of variables involved in the index or integrity constraint.

ONDELETE
for a foreign key integrity constraint, contains RESTRICT or SET NULL if applicable (the ON DELETE option in the IC CREATE statement).

ONUPDATE
for a foreign key integrity constraint, contains RESTRICT or SET NULL if applicable (the ON UPDATE option in the IC CREATE statement).

RECREATE
the SAS statement necessary to re-create the index or integrity constraint.

REFERENCE
for a foreign key integrity constraint, contains the name of the referenced data set.

TYPE
the type. For an index, the value is “Index” while for an integrity constraint, the value is the type of integrity constraint (Not Null, Check, Primary Key, and so on).

UNIQUE
contains YES if the UNIQUE option is defined for the index.

UPERC
the percentage of the index that has been updated since the last refresh (displayed for centiles).

UPERCMX
the percentage of the index update that triggers a refresh (displayed for centiles).

WHERE
for a check integrity constraint, contains the WHERE statement.

Examples: DATASETS Procedure

Example 1: Removing All Labels and Formats in a Data Set

Features:

PROC DATASETS statement options
- LIB=
- MEMTYPE=

CONTENTS statement

MODIFY statement

CONTENTS procedure

FORMAT procedure

OPTIONS statement

TITLE statement

Details

This example demonstrates the following tasks:

- sets system options
- creates a user defined FORMAT
- creates a data set
- deletes labels and format from the data set
- uses PROC CONTENTS to show data set with and without labels and format

Program

```
options ls=79 nodate center;
title ;

libname mylib 'c:\mylib';

proc format;
   value clsfmt 1='Freshman' 2='Sophomore' 3='Junior' 4='Senior';
```

```
run;

data mylib.class;
   format z clsfmt.;
   label x='ID NUMBER'
      y='AGE'
      z='CLASS STATUS';
   input x y z;
datalines;
1 20 4
2 18 1
;

proc contents data=mylib.class;
run;

proc datasets lib=mylib memtype=data;
   modify class;
     attrib _all_ label=' ';
     attrib _all_ format=;
contents data=mylib.class;
run;
quit;
```

Program Description

Set the system options and the LIBNAME statement. In this example, the LIBNAME is MyLib. The CENTER option specifies to align SAS procedure output in the center. The NODATE option specifies that the date and the time are not printed. The LS= option specifies the line size for the SAS log and for the output. The TITLE statement followed by a blank space removes any existing title in your SAS session.

```
options ls=79 nodate center;
title ;

libname mylib 'c:\mylib';
```

Create a user-defined format with a value of CLSFMT.

```
proc format;
   value clsfmt 1='Freshman' 2='Sophomore' 3='Junior' 4='Senior';
run;
```

Create a data set named Class. Use the CLSFMT format on variable Z. Create labels for variables, X, Y, and Z.

```
data mylib.class;
   format z clsfmt.;
   label x='ID NUMBER'
      y='AGE'
      z='CLASS STATUS';
   input x y z;
datalines;
1 20 4
2 18 1
;
```

Use PROC CONTENTS to view the contents of the data set before removing the labels and format.

```
proc contents data=mylib.class;
run;
```

Within PROC DATASETS, remove all the labels and formats using the MODIFY statement and the ATTRIB option. Use the CONTENTS statement within PROC DATASETS to view the contents of the data set without the labels and format.

```
proc datasets lib=mylib memtype=data;
   modify class;
     attrib _all_ label=' ';
     attrib _all_ format=;
contents data=mylib.class;
run;
quit;
```

Example 2: Manipulating SAS Files

Features:

PROC DATASETS statement options
- DETAILS
- LIBRARY=
- COPY statement
- CHANGE statement
- DELETE statement
- EXCHANGE statement

COPY procedure

EXCLUDE statement

OPTIONS statement

Details

This example demonstrates the following tasks:

- changes the names of SAS files
- copies SAS files between SAS libraries
- deletes SAS files
- selects SAS files to copy
- exchanges the names of SAS files
- excludes SAS files from a copy operation

Program

```
options pagesize=60 linesize=80 nodate pageno=1 source;

LIBNAME dest1 'SAS-library-1';
LIBNAME dest2 'SAS-library-2';
LIBNAME health 'SAS-library-3';

proc datasets library=health details;
```

```
   delete tension a2(mt=catalog);
   change a1=postdrug;
   exchange weight=bodyfat;

   copy out=dest1 move memtype=view;

      select spdata;

      select etest1-etest5 / memtype=catalog;

   copy out=dest2;
      exclude d: mlscl oxygen test2 vision weight;
quit;
```

Program Description

Set the system options. The SOURCE system option writes the programming statements to the SAS log. PAGESIZE= option specifies the number of lines that compose a page of the SAS log and SAS output. LINESIZE= option specifies the line size for the SAS log and for SAS procedure output. NODATE option specifies that the date and the time are not printed. PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=60 linesize=80 nodate pageno=1 source;

LIBNAME dest1 'SAS-library-1';
LIBNAME dest2 'SAS-library-2';
LIBNAME health 'SAS-library-3';
```

Specify the procedure input library, and add more details to the directory. DETAILS prints these additional columns in the directory: **Obs**, **Entries** or **Indexes**, **Vars**, and **Label**. All member types are available for processing because the MEMTYPE= option does not appear in the PROC DATASETS statement.

```
proc datasets library=health details;
```

Delete two files in the library, and modify the names of a SAS data set and a catalog. The DELETE statement deletes the Tension data set and the A2 catalog. MT=CATALOG applies only to A2 and is necessary because the default member type for the DELETE statement is DATA. The CHANGE statement changes the name of the A1 catalog to Postdrug. The EXCHANGE statement exchanges the names of the Weight and Bodyfat data sets. MEMTYPE= is not necessary in the CHANGE or EXCHANGE statement because the default is MEMTYPE=ALL for each statement.

```
   delete tension a2(mt=catalog);
   change a1=postdrug;
   exchange weight=bodyfat;
```

Restrict processing to one member type and delete and move data views. MEMTYPE=VIEW restricts processing to SAS views. MOVE specifies that all SAS views named in the SELECT statements in this step be deleted from the Health data library and moved to the Dest1 data library.

```
   copy out=dest1 move memtype=view;
```

Move the SAS view Spdata from the Health data library to the Dest1 data library.

```
      select spdata;
```

Move the catalogs to another data library. The SELECT statement specifies that the catalogs Etest1 through Etest5 be moved from the Health data library to the Dest1 data library. MEMTYPE=CATALOG overrides the MEMTYPE=VIEW option in the COPY statement.

```
      select etest1-etest5 / memtype=catalog;
```

Exclude all files with specified criteria from processing. The EXCLUDE statement excludes from the COPY operation all SAS files that begin with the letter D and the other SAS files listed. All remaining SAS files in the Health data library are copied to the Dest2 data library.

```
   copy out=dest2;
      exclude d: mlscl oxygen test2 vision weight;
quit;
```

Log Examples

Example Code 17.2 *SAS Log for Dest1*

```
117    options pagesize=60 linesize=80 nodate pageno=1 source;
118  LIBNAME dest1 'SAS-library-1';
NOTE: Libref DEST1 was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library-1\dest1
119  LIBNAME dest2 'SAS-library-2';
NOTE: Libref DEST2 was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library-2\dest2
120  LIBNAME health 'SAS-library-3';
NOTE: Libref HEALTH was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library-3\health

121  proc datasets library=health details;
                                Directory

Libref         HEALTH
Engine         V9
Physical Name  \myfiles\health
Filename       \myfiles\health

      cpu time            0.60 seconds
```

Example 3: Saving SAS Files from Deletion

Features: PROC DATASETS statement options
LIB=

SAVE statement
OPTIONS statement

Details

This example demonstrates how to use the SAVE statement to save some SAS files from deletion and to delete other SAS files.

Program

```
options pagesize=40 linesize=80 nodate pageno=1 source;
LIBNAME elder 'SAS-library';
proc datasets lib=elder;
      save chronic aging clinics / memtype=data;
   run;
```

Program Description

Set the system options and the LIBNAME statement. The SOURCE system option writes the programming statements to the SAS log. LINESIZE= option specifies the line size for the SAS log and for SAS procedure output. NODATE option specifies that the date and the time are not printed.

```
options pagesize=40 linesize=80 nodate pageno=1 source;
LIBNAME elder 'SAS-library';
```

Specify the procedure input library to process.

```
proc datasets lib=elder;
```

Save the data sets Chronic, Aging, and Clinics, and delete all other SAS files (of all types) in the Elder library. MEMTYPE=DATA is necessary because the Elder library has a catalog named Clinics and a data set named Clinics.

```
      save chronic aging clinics / memtype=data;
   run;
```

Log Examples

Example Code 17.3 *SAS Log for Elder Library*

```
6    options pagesize=40 linesize=80 nodate pageno=1 source;
7    LIBNAME elder 'c:\procdatasets\elder';
NOTE: Libref ELDER was successfully assigned as follows:
      Engine:        V9
      Physical Name: c:\procdatasets\elder
8    proc datasets lib=elder;
9       save chronic aging clinics / memtype=data;
10   run;

NOTE: Saving ELDER.CHRONIC (memtype=DATA).
NOTE: Saving ELDER.AGING (memtype=DATA).
NOTE: Saving ELDER.CLINICS (memtype=DATA).
11   quit;

NOTE: PROCEDURE DATASETS used (Total process time):
      real time           0.06 seconds
      cpu time            0.01 seconds
```

Output 17.16 *Elder Library before and After Using the SAVE Statement*

Example 4: Modifying SAS Data Sets

Features:

PROC DATASETS statement options
- LIB=
- NOLIST
- MODIFY statement

OPTIONS statement

Details

This example modifies two SAS data sets using the MODIFY statement and statements subordinate to it. "Example 5: Describing a SAS Data Set" on page 707 shows the modifications to the Group data set.

This example demonstrates the following tasks:

- modifying SAS files
- labeling a SAS data set
- adding a Read password to a SAS data set
- indicating how a SAS data set is currently sorted
- creating an index for a SAS data set
- assigning informats and formats to variables in a SAS data set
- renaming variables in a SAS data set

- labeling variables in a SAS data set

Program

```
options pagesize=40 linesize=80 nodate pageno=1 source;

LIBNAME health 'SAS-library';

proc datasets library=health nolist;

   modify group (label='Test Subjects' read=green sortedby=lname);

      index create vital=(birth salary) / nomiss unique;

      informat birth date7.;
      format birth date7.;

      label salary='current salary excluding bonus';

   modify oxygen;
      rename oxygen=intake;
      label intake='Intake Measurement';
quit;
```

Program Description

Set the system options and LIBNAME statement. The SOURCE system option writes the programming statements to the SAS log. PAGESIZE= option specifies the number of lines that compose a page of the SAS log and SAS output. LINESIZE= option specifies the line size for the SAS log and for SAS procedure output. NODATE option specifies that the date and the time are not printed. PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=40 linesize=80 nodate pageno=1 source;

LIBNAME health 'SAS-library';
```

Specify Health as the procedure input library to process. NOLIST suppresses the directory listing for the Health data library.

```
proc datasets library=health nolist;
```

Add a label to a data set, assign a Read password, and specify how to sort the data. LABEL= adds a data set label to the data set Group. READ= assigns `green` as the Read password. The password appears as Xs in the SAS log. SAS issues a warning message if you specify a level of password protection on a SAS file that does not include alter protection. SORTEDBY= specifies how the data is sorted.

```
   modify group (label='Test Subjects' read=green sortedby=lname);
```

Create the composite index VITAL on the variables BIRTH and SALARY for the Group data set. NOMISS excludes all observations that have missing values for BIRTH and SALARY from the index. UNIQUE specifies that the index is created only if each observation has a unique combination of values for BIRTH and SALARY.

```
        index create vital=(birth salary) / nomiss unique;
```

Assign an informat and format, respectively, to the BIRTH variable.

```
        informat birth date7.;
        format birth date7.;
```

Assign a label to the variable SALARY.

```
        label salary='current salary excluding bonus';
```

Rename a variable, and assign a label. Modify the data set Oxygen by renaming the variable OXYGEN to INTAKE and assigning a label to the variable INTAKE.

```
    modify oxygen;
       rename oxygen=intake;
       label intake='Intake Measurement';
quit;
```

Log Examples

Example Code 17.4 *SAS Log for Health Library*

```
169  options pagesize=40 linesize=80 nodate pageno=1 source;
170  LIBNAME health 'SAS-library';
NOTE: Libref HEALTH was successfully assigned as follows:
      Engine:        V9
      Physical Name: SAS-library\health

NOTE: PROCEDURE DATASETS used (Total process time):
      real time           8:06.11
      cpu time            0.54 seconds

171  proc datasets library=health nolist;
172   modify group (label='Test Subjects' read=XXXXX sortedby=lname);
WARNING: The file HEALTH.GROUP.DATA is not ALTER protected.  It could be
         deleted or replaced without knowing the password.
173   index create vital=(birth salary) / nomiss unique;
NOTE: Composite index vital has been defined.
NOTE: MODIFY was successful for HEALTH.GROUP.DATA.
174  informat birth date7.;
175  format birth date7.;
176  label salary='current salary excluding bonus';
177  modify oxygen;
178  rename oxygen=intake;
NOTE: Renaming variable oxygen to intake.
179  label intake='Intake Measurement';
180  quit;

NOTE: MODIFY was successful for HEALTH.OXYGEN.DATA.
NOTE: PROCEDURE DATASETS used (Total process time):
      real time           15.09 seconds
      cpu time            0.06 seconds
```

Example 5: Describing a SAS Data Set

Features:

PROC DATASETS statement options
- LIB=
- NOLIST
- CONTENTS statement

OPTIONS statement

Details

This example demonstrates the output from the CONTENTS statement for the Group data set. The output shows the modifications made to the Group data set in "Example 4: Modifying SAS Data Sets" on page 704.

Program

```
options pagesize=40 linesize=80 nodate pageno=1;

LIBNAME health 'SAS-library';

proc datasets library=health nolist;

   contents data=group (read=green) out=grpout;
   title  'The Contents of the GROUP Data Set';
run;
quit;
```

Program Description

Set the system options and LIBNAME statement. PAGESIZE= option specifies the number of lines that compose a page of the SAS log and SAS output. LINESIZE= option specifies the line size for the SAS log and for SAS procedure output. NODATE option specifies that the date and the time are not printed. PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=40 linesize=80 nodate pageno=1;

LIBNAME health 'SAS-library';
```

Specify Health as the procedure input library, and suppress the directory listing with the NOLIST option.

```
proc datasets library=health nolist;
```

Create the output data set Grpout from the data set Group. Specify Group as the data set to describe, give Read access to the Group data set, and create the output data set Grpout, which appears in the OUT= data set.

```
   contents data=group (read=green) out=grpout;
   title  'The Contents of the GROUP Data Set';
run;
quit;
```

Output Examples

Output 17.17 *Contents of Group Data Set*

The Contents of the GROUP Data Set

The DATASETS Procedure

Data Set Name	HEALTH.GROUP	**Observations**	148
Member Type	DATA	**Variables**	11

level	1	
region	.	NorthEast

Alphabetic List of Extended Attributes on Variables			
Extended Attribute	**Attribute Variable**	**Numeric Value**	**Character Value**
classification	jobcode	.	local
length	idnum	4	

Example 6: Concatenating Two SAS Data Sets

Features: PROC DATASETS statement options
- LIBRARY=
- NOLIST
- APPEND statement

PRINT procedure

OPTIONS statement

Data set: EXP Library

Details

This example demonstrates the following tasks:

- suppresses the printing of a library
- appends two data sets
- prints the data sets before appending and prints the new data set after appending

To create the Exp.Results and Exp.Sur data sets and print them out before using this example to concatenate them, see "EXP Library" on page 2789.

Program

```
options pagesize=40 linesize=64 nodate pageno=1;
```

```
LIBNAME exp 'SAS-library';

proc datasets library=exp nolist;

   append base=exp.results data=exp.sur force;
run;

proc print data=exp.results noobs;
   title 'The RESULTS Data Set';
run;
```

Program Description

This example appends one data set to the end of another data set.

This example appends one data set to the end of another data set.

The data set Exp.Sur contains the variable Wt6Mos, but the Exp.Results data set does not.

Set the system options. The NODATE option suppresses the display of the date and time in the output. The PAGENO= option specifies the starting page number. The LINESIZE= option specifies the output line length, and the PAGESIZE= option specifies the number of lines on an output page.

```
options pagesize=40 linesize=64 nodate pageno=1;
```

The LIBNAME statement assigns the library.

```
LIBNAME exp 'SAS-library';
```

Suppress the printing of the Exp library. LIBRARY= specifies Exp as the procedure input library. NOLIST suppresses the directory listing for the Exp library.

```
proc datasets library=exp nolist;
```

Append the data set Exp.Sur to the Exp.Results data set. The APPEND statement appends the data set Exp.Sur to the data set Exp.Results. FORCE causes the APPEND statement to carry out the Append operation even though Exp.Sur has a variable that Exp.Results does not. APPEND does not add the Wt6Mos variable to Exp.Results.

```
   append base=exp.results data=exp.sur force;
run;
```

Print the data set.

```
proc print data=exp.results noobs;
   title 'The RESULTS Data Set';
run;
```

Output: Concatenating Two Data Sets

Output 17.21 *The Results Data Set*

The RESULTS Data Set

ID	TREAT	INITWT	WT3MOS	AGE
1	Other	166.28	146.98	35

Example 7: Aging SAS Data Sets

Features:

PROC DATASETS statement options
- LIBRARY=
- NOLIST

AGE statement

OPTIONS statement

Details

This example demonstrates how the AGE statement ages SAS files.

Program

```
options pagesize=40 linesize=80 nodate pageno=1 source;
```

```
LIBNAME daily 'SAS-library';

proc datasets library=daily nolist;

   age today day1-day7;
run;
```

Program Description

Set the system options. The SOURCE system option writes the programming statements to the SAS log. PAGESIZE= option specifies the number of lines that compose a page of the SAS log and SAS output. LINESIZE= option specifies the line size for the SAS log and for SAS procedure output. NODATE option specifies that the date and the time are not printed. PAGENO= option specifies a beginning page number for the next page of output.

```
options pagesize=40 linesize=80 nodate pageno=1 source;

LIBNAME daily 'SAS-library';
```

Specify Daily as the procedure input library and suppress the directory listing.

```
proc datasets library=daily nolist;
```

Delete and age. Delete the last SAS file in the list, Day7, and then age (or rename) Day6 to Day7, Day5 to Day6, and so on, until it ages Today to Day1.

```
   age today day1-day7;
run;
```

Log Examples

Example Code 17.5 *SAS Log*

```
6  options pagesize=40 linesize=80
nodate pageno=1 source;
7
8     proc datasets library=daily nolist;
9
10        age today day1-day7;
11     run;
NOTE: Deleting DAILY.DAY7 (memtype=DATA).
NOTE: Ageing the name DAILY.DAY6 to DAILY.DAY7 (memtype=DATA).
NOTE: Ageing the name DAILY.DAY5 to DAILY.DAY6 (memtype=DATA).
NOTE: Ageing the name DAILY.DAY4 to DAILY.DAY5 (memtype=DATA).
NOTE: Ageing the name DAILY.DAY3 to DAILY.DAY4 (memtype=DATA).
NOTE: Ageing the name DAILY.DAY2 to DAILY.DAY3 (memtype=DATA).
NOTE: Ageing the name DAILY.DAY1 to DAILY.DAY2 (memtype=DATA).
NOTE: Ageing the name DAILY.TODAY to DAILY.DAY1 (memtype=DATA).
```

Example 8: Initiating an Audit File

Features:

PROC DATASETS statement options
- LIB=
- AUDIT statement
- INITIATE statement
- LOG statement
- RESUME statement
- SUSPEND statement
- TERMINATE statement
- USER_VAR statement

SQL procedure

Details

This example demonstrates the following tasks:

- initiates an audit file
- updates the data set
- suspends audit file
- terminates audit file

Program

```
libname mylib "SAS-library";

data mylib.inventory;
input vendor $10. +1 item $4. +1 description $11. +1 units 4.;
datalines;
SmithFarms F001 Apples      10
Tropicana  B002 OrangeJuice 45
UpperCrust C215 WheatBread  25
;
run;

proc datasets lib=mylib;
   audit inventory;
   initiate;
   user_var reason $ 30;
quit;

proc sql;
```

```
   Insert into mylib.inventory values ('Bordens','B132', 'Milk', 100,
                                       'increase on hand');
   Update mylib.inventory    set units=10, reason='recounted inventory'
                             where item='B002';
quit;

proc datasets lib=mylib;
audit inventory;
log admin_image=no;
suspend;
quit;

proc sql;
select * from mylib.inventory(type=audit);
quit;

proc datasets lib=mylib;
audit inventory;
resume;
quit;

proc datasets lib=mylib;
audit inventory;
terminate;
quit;
```

Program Description

Initiates an audit file using USER_VAR.

```
libname mylib "SAS-library";

data mylib.inventory;
input vendor $10. +1 item $4. +1 description $11. +1 units 4.;
datalines;
SmithFarms F001 Apples      10
Tropicana  B002 OrangeJuice 45
UpperCrust C215 WheatBread  25
;
run;

proc datasets lib=mylib;
   audit inventory;
   initiate;
   user_var reason $ 30;
quit;
```

Update the data set.

```
proc sql;
   Insert into mylib.inventory values ('Bordens','B132', 'Milk', 100,
                                       'increase on hand');
   Update mylib.inventory    set units=10, reason='recounted inventory'
                             where item='B002';
quit;
```

Discontinue the logging of ADMIN images and suspend audit file.

```
proc datasets lib=mylib;
audit inventory;
log admin_image=no;
suspend;
quit;
```

View the audit file.

```
proc sql;
select * from mylib.inventory(type=audit);
quit;
```

Resume the audit file.

```
proc datasets lib=mylib;
audit inventory;
resume;
quit;
```

Terminate the audit file.

```
proc datasets lib=mylib;
audit inventory;
terminate;
quit;
```

DATEKEYS Procedure

Overview: DATEKEYS Procedure

Overview: The DATEKEYS Procedure

The DATEKEYS procedure enables you to process a single date or a set of dates in a time series using a name to reference the dates. For example, the DATEKEYS procedure can be used to identify time periods that are associated with a datekey, read and write datekeys, and provide details about datekey definitions.

The DATEKEYS procedure can be used to identify time periods that are associated with a datekey.

Some common uses of the DATEKEYS procedure are to define datekeys that identify holiday periods, sales events, or changes to operating hours.

Concepts: DATEKEYS Procedure

Concepts: The DATEKEYS Procedure

A SAS datekey describes a date or time interval that is associated with special events such as holidays and sale periods and time computations.

A datekey has a name, a date or set of dates that are associated with the datekey, and a set of qualifiers.

The DATEKEYS procedure provides results in output data sets that can be interpreted in other SAS procedures. It enables you to define datekeys that can be specified as SAS predefined datekeys when used in conjunction with the SAS system option EVENTDS=. The datekeys that you define can be used as date keywords, just as SAS predefined datekeys are used.

The following example creates datekeys, and then writes the datekey definitions to an output data set named MyHolidays. The datekey definitions are automatically available to SAS High-Performance Forecasting procedures by setting the SAS system option EVENTDS=.

```
proc datekeys;
   datekeydef SuperBowl=
                '15JAN1967'd '14JAN1968'd '12JAN1969'd '11JAN1970'd
   '17JAN1971'd '16JAN1972'd '14JAN1973'd '13JAN1974'd '12JAN1975'd
   '18JAN1976'd '09JAN1977'd '15JAN1978'd '21JAN1979'd '20JAN1980'd
   '25JAN1981'd '24JAN1982'd '30JAN1983'd '22JAN1984'd '20JAN1985'd
   '26JAN1986'd '25JAN1987'd '31JAN1988'd '22JAN1989'd '28JAN1990'd
   '27JAN1991'd '26JAN1992'd '31JAN1993'd '30JAN1994'd '29JAN1995'd
   '28JAN1996'd '26JAN1997'd '25JAN1998'd '31JAN1999'd '30JAN2000'd
   '28JAN2001'd '03FEB2002'd '26JAN2003'd '01FEB2004'd '06FEB2005'd
   '05FEB2006'd '04FEB2007'd '03FEB2008'd '01FEB2009'd '07FEB2010'd
   '06FEB2011'd '05FEB2012'd '03FEB2013'd '02FEB2014'd '01FEB2015'd
...'07FEB2016'd '05FEB2017'd '04FEB2018'd '03FEB2019'd '02FEB2020'd
   / PULSE=DAY ;

   datekeydef GoodFriday=Easter / shift=-2 pulse=day;
   datekeykey EasterMonday=Easter / shift=1 pulse=day;
   datekeydata out=MyHolidays condense;
run;

options eventds=(MyHolidays);

proc hpfevents data=sashelp.citiday;
   id date interval=day start='27JAN1991'd end='01APR1991'd;
   eventkey SuperBowl;
   eventkey GoodFriday;
   eventkey EasterMonday;
   eventdata out=MyHolidayEvents condense;
   eventdummy out=MyHolidayDates;
run;
```

The following output shows the results:

Figure 18.1 *Event Definition Data Set Based on User-Defined Datekeys*

The SAS System

Obs	_NAME_	_KEYNAME_
1	SuperBowl	SUPERBOWL
2	GoodFriday	GOODFRIDAY
3	EasterMonday	EASTERMONDAY

The following statements display an output data set that shows variables for the Super Bowl, Good Friday, and Easter Monday events. The first output shows the results when Month=1. The second output shows the results when Month GE 3.

```
proc print data=MyHolidayDates(where=(month(date)=1));
   var date SuperBowl GoodFriday EasterMonday;
run;

proc print data=MyHolidayDates(where=(month(date) GE 3));
   var date SuperBowl GoodFriday EasterMonday;
```

```
run;
```

Statement	Task	Example
PROC DATEKEYS	Creates and manages datekeys that are associated with time computations	Ex. 1, Ex. 2, Ex. 3, Ex. 4
BY	Obtains separate calendar variables for groups of observations that are defined by the BY variables	
DATEKEYCALENDAR	Writes variables that indicate the active time periods for datekeys	Ex. 3, Ex. 4
DATEKEYDATA	Inputs and outputs datekeys	Ex. 1, Ex. 2, Ex. 3, Ex. 4
DATEKEYDEF	Defines a datekey that can be used in other SAS procedures	Ex. 1, Ex. 2, Ex. 3, Ex. 4
DATEKEYDSOPT	Limits input and output processing of data sets to a specified locale	Ex. 4
DATEKEYKEY	Alters a user-defined or predefined SAS datekey, or creates a new datekey from another datekey	Ex. 1, Ex. 2, Ex. 3, Ex. 4
DATEKEYPERIODS	Writes variables that list the active time periods in the input time ID for datekeys	Ex. 1
ID	Names a numeric variable containing SAS date, datetime or time values that identifies	Ex. 1, Ex. 2, Ex. 4

Statement	Task	Example
	observations by time period in input and output data sets	
VAR	Copies input variables to the output calendar variables data set	

PROC DATEKEYS Statement

Creates and manages datekeys that are associated with time computations.

Syntax

PROC DATEKEYS <*options*>;

Optional Argument

option

The following options are available:

DATA=*SAS-data-set*

names the SAS data set that contains the variables that are used in the VAR, ID, and BY statements.

Tip If the DATA= option is not specified, the most recently created SAS data set is used.

LEAD=*number-of-periods*

specifies the number of periods to extend the calendar variables beyond the input time ID. The LEAD= value is relative to the last observation in the input data set. If BY variables are specified, the LEAD= value is relative to the last observation in each BY group.

Default 0

MAXERROR=*number*

specifies the maximum number of warning and error messages that are produced during the execution of the procedure.

Default 25

Tip This option is particularly useful in BY-group processing, where it can be used to suppress the recurring messages.

SORTNAMES

specifies that the datekeys and variables in the output data sets be written in alphabetical order. Variables are sorted within their groups. Variables that

are listed in the VAR statement are sorted with respect to other variables that are listed in the VAR statement. Calendar variables are sorted with respect to other calendar variables.

BY Statement

Obtains separate calendar variables for groups of observations that are defined by the BY variables.

Syntax

BY *variable(s)*;

Required Argument

variable
specifies a variable that is used to obtain separate calendar variables for groups of observations that are defined by the BY variables.

Tip When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If your input data set is not sorted in ascending order, use one of the following alternatives: Sort the data by using the SORT procedure with a similar BY statement, or create an index for the BY variables by using the DATASETS procedure. For more information, see the DATASETS procedure in *Base SAS Procedures Guide*.

DATEKEYCALENDAR Statement

Writes variables that indicate the active time periods for datekeys. The active periods are indicated with a value of 1, and the inactive periods are indicated with a value of 0.

Syntax

DATEKEYCALENDAR OUT=*SAS-data-set* <SUMMARY=*SAS-variable-name*>;

Summary of Optional Arguments

SUMMARY | SUM=*SAS-variable-name*

Required Argument

OUT=*SAS-data-set*
names the output data set to contain the calendar variables for the specified datekeys based on the ID information as specified in the ID statement.

Tip *SAS-data-set* also includes variables that are specified in the VAR, BY, and ID statements.

Optional Argument

SUMMARY | SUM=*SAS-variable-name*
specifies that the datekey calendar variables be summed and that the result be placed in the specified variable in the DATEKEYCALENDAR OUT= data set.

The SUM= variable can be interpreted as the number of keydates that are active for each time interval. If the SUM= option is not specified, no such variable is included in the OUT= data set.

DATEKEYDATA Statement

Inputs datekeys from a datekeys data set or writes datekeys to a datekeys data set. You can specify multiple DATEKEYDATA statements.

Syntax

DATEKEYDATA IN=*SAS-data-set* | OUT=*SAS-data-set* <*options*>;

Summary of Optional Arguments

option

Required Arguments

IN=*SAS-data-set*
names an input data set that contains datekey definitions.

Note: The IN= or OUT= argument is required.

OUT=*SAS-data-set*
names the output data set to contain the datekey definitions that are specified in the DATEKEYDATA IN= data sets and in the DATEKEYDEF and DATEKEYKEY statements.

Note: The IN= or OUT= argument is required.

Tip If the LIST option is not specified, the OUT= data set can then be used in other SAS procedures and system options to define datekeys.

Optional Argument

option

The following options are available:

CONDENSE

specifies that the DATEKEYDATA OUT= data set be condensed. Any variables that contain only default values are omitted from the data set.

The DATEKEYDATA IN= option reads both condensed data sets and data sets that have not been condensed. For more information, see "Identifying Variables in the DATEKEYDATA OUT= Data Set" on page 757.

LIST

specifies that the DATEKEYDATA OUT= data set contain only a list of the available datekeys. When you specify the LIST option, the output data set does not contain the parameters that are required for datekey definition.

NODEFAULTS

specifies that the DATEKEYDATA OUT= data set not contain any SAS predefined datekeys.

DATEKEYDEF Statement

Defines a datekey that can be interpreted in other SAS procedures. You can specify multiple DATEKEYDEF statements.

Note: These datekeys can be used to create events that can be included in forecasting models.

Syntax

DATEKEYDEF *SAS-variable-name*=*timing-value* </*qualifier-options*>;

Summary of Optional Arguments

qualifier-options

Required Arguments

SAS-variable-name
specifies a name in the DATEKEYDEF statement.

timing-value list
specifies one or more datekeys, dates, datetime values, or observation numbers. You can also specify a *value-list*.

The way you specify *value-list* depends on the type of variable:

integer value-list
For integer variables, *integer value-list* is either an explicit list of one or more integers or a starting value and an ending value with an interval increment, or a combination of both forms:

- *n* <*...n*>

  Here is an example:

```
10,11,12
```

- *n* TO *n* <BY *increment*>

  Here is an example:

```
10 to 12 by 1
```

- *n* <*...n*> TO *n* TO *n* <BY increment> <*n*<*...n*> >

  Here is an example:

```
11 to 5, 5 to 10 by 1;
```

SAS keyword value-list
For character variables, *SAS keyword value-list* is a list of one or more unique character values that are separated by blanks:

"value-1" <"value-2"..."value-n">

Here is an example:

```
"INDEPENDENCE"
or
"INDEPENDENCE" "EASTER" "NEWYEARS"
```

SAS date value-list* and *SAS datetime value-list
For date and time values, *value-list* can have the following forms:

- *"SAS-value"i<..."SAS-value"i>*

  Here are some examples:

```
'01Jan2000'd,'01Feb2000'd, '01Mar2000'd
or
'01Mar1990:15:03:00'dt
or
'01Jan:15:03:00'dt,'1Feb:15:03:00'dt, '01Mar:15:03:00'dt
```

- *"SAS-value"i* TO *"SAS-value"i*< BY *interval>*

Note: *"SAS-value"i* TO *"SAS-value"i* must be integers, dates, datetime, or time values. Do not mix types.

Here are some examples:

```
'01Jan2000'd TO '01Mar2000'd BY month
or
'01Jan1990:15:03:00'dt TO '01Mar1990:15:03:00'd
```

Optional Argument

qualifier-options

The following qualifier options are available:

AFTER=(<DURATION=*value*>)
specifies options that control the datekey definition after the timing value. The DURATION= suboption is used within the parentheses in the AFTER= ( ) option. DURATION specifies the datekey duration after the timing value.

BEFORE=(<DURATION=*value*>)
specifies options that control the datekey definition before the timing value. The DURATION= suboption is used within the parentheses in the BEFORE= ( ) option. DURATION specifies the datekey duration before the timing value.

LABEL='*SAS-label*'
specifies a label that is associated with the datekey. '*SAS-label*' is a text string that is enclosed in quotation marks and can be up to 256 characters.

The default label is '*SAS-variable-name* where *SAS-variable-name* is the name that is specified in the DATEKEYDEF statement. The label is stored in the DATEKEYDATA OUT= data set.

LOCALE='*POSIX locale*'
specifies a locale that is associated with the datekey. The locale should be a POSIX locale value. There is no default for the locale value.

PERIOD=*interval*
specifies the interval for the frequency of the datekey. For example, PERIOD=YEAR produces a datekey that is periodic in a yearly pattern.

If the PERIOD= option is omitted, the datekey is not periodic. The PERIOD= option does not apply to observation numbers, which are not periodic, or to date keywords, which have their own periodicity. For intervals that you can specify, see Chapter 4, "Date Intervals, Formats, and Functions" in *SAS/ETS User's Guide*.

PULSE=*interval*
specifies the interval to be used with the DURATION= option to determine the width of the datekey.

If the datekey is evaluated with respect to a time ID variable, then the default pulse is one observation. When no DURATION= values are specified and the PULSE= option is specified, the DURATION= values are set to zero. For intervals that you can specify, see Chapter 4, "Date Intervals, Formats, and Functions" in *SAS/ETS User's Guide*.

RULE=*value*

specifies the action to take when the defined datekey has multiple timing values that include at least one datekey.

When the datekey timing values consist only of SAS date, SAS datetime values, and observation numbers, the RULE= option does not apply. The RULE= option also does not apply when the timing value list consists of a single datekey. The RULE= option accepts the values AND and OR. The default is RULE=OR.

The following examples demonstrate the RULE= option:

```
datekeykey JANUARY               / pulse=month;
datekeydef RainyDays='11JUL2013'd '13JUL2013'd '21JUL2013'd;
datekeydef HotDays=  '11JUL2013'd '16JUL2013'd '17JUL2013'd
                     '18JUL2013'd '19JUL2013'd;
datekeydef FridaysInJanuary=JANUARY FRIDAY / rule=and;
datekeydef JanuaryPlusFridays=JANUARY FRIDAY / rule=or;
datekeydef HotandRainyDays=RainyDays HotDays / rule=and;
```

The RULE= option does not apply to the first statement because the timing value list consists of a single datekey. The RULE= option does not apply to the second and third statements because the timing value list consists only of SAS date values. The operation between two SAS date, datetime, or observation values is always OR. In the fourth statement, the RULE=AND option identifies only dates where the month is January and the day of the week is Friday. In the fifth statement, the RULE=OR option identifies all dates in January and all dates where the day of the week is Friday. In the sixth statement, the RULE=AND option identifies days that are both rainy and hot. The RULE=AND applies to the two datekeys, RainyDays and HotDays.

Usually, the result of an AND operation between two discrete time periods is an empty value. Therefore, the OR operation is always used between discrete time periods. An example is '13JUL2013'd, '01Mar1990:15:03:00'dt, 3.

The following table explains how the RULE= option is interpreted for each observation:

Table 18.1 *Definition of RULE= Option Values*

RULE= option	Name	Definition
AND	and	identifies time periods that are identified by all datekeys and the group of discrete timing values
OR	or	identifies time periods that are identified by any datekeys or the group of discrete timing values

SHIFT=*number*
specifies the number of pulses to shift the timing value δ. The default is not to shift the timing value (δ= 0). When the SHIFT= option is used, all timing values in the list (including those that are generated by date keywords) are shifted. Therefore, SHIFT= can be used with EASTER to specify ecclesiastical holidays that are based on Easter. For example, the following statement specifies Good Friday, which is defined as two days before Easter (Montes 2001).

```
datekeydef GoodFriday=EASTER / shift=-2 pulse=day;
```

DATEKEYDSOPT Statement

Limits the input and output processing of data sets to a specified locale.

Syntax

DATEKEYDSOPT LOCALE= '*POSIX locale*'<(ONLY)>;

Summary of Optional Arguments

(ONLY)

Required Arguments

LOCALE=
specifies a locale that is used to filter input and output data sets.

'POSIX locale'
specifies a POSIX locale value. There is no default for the locale value.

Optional Argument

(ONLY)
specifies to process only the specified locale, both for input and output data sets. If (ONLY) is not specified, the specified locale and defaults (no specified locale) are processed, both for input and output data sets.

DATEKEYKEY Statement

Alters a user-defined or predefined SAS datekey, or creates a new datekey from another datekey. You can specify multiple DATEKEYKEY statements.

See: "Using the DATEKEYKEY Statement" on page 753

Syntax

DATEKEYKEY <*SAS-variable-name=*> *datekey-keyword* </*qualifier-options*>;

Summary of Optional Arguments

qualifier-option

SAS-variable-name

Required Argument

datekey-keyword
specifies the default SAS variable name for a user-defined or predefined datekey.

Optional Arguments

SAS-variable-name
specifies the name of the new datekey keyword.

> **TIP** If you specify the DATEKEYCALENDAR option, a variable by this name is created and indicates the active and inactive periods of the keyword. If this option is not specified, then *datekey-keyword* is the name of the altered datekey.

qualifier-option
The following options are available:

AFTER=(<DURATION=*value*>)
specifies options that control the datekey definition after the timing value. The DURATION= suboption is used within the parentheses in the AFTER ( ) option.

DURATION specifies the datekey duration after the timing value when used in the AFTER= option.

BEFORE=(<DURATION=*value*>)
specifies options that control the datekey definition before the timing value. The DURATION= suboption is used within the parentheses in the BEFORE ( ) option.

DURATION specifies the datekey duration before the timing value when used in the BEFORE= option.

LABEL='*SAS-label*'
specifies a label that is associated with the datekey. 'SAS-label' is a text string that is enclosed in quotation marks and can be up to 256 characters. The default label is '*SAS-variable-name* , where *SAS-variable-name* is the name that is specified in the DATEKEYKEY statement. If *SAS-variable-name* is not specified in the DATEKEYKEY statement, then the label is the default label for the SAS predefined datekey. The label is stored in the DATEKEYDATA OUT= data set.

LOCALE='*POSIX locale*'
specifies a locale that is associated with the datekey. The locale should be a POSIX locale value. There is no default for the locale value.

PERIOD=*interval*
specifies the interval for the frequency of the datekey. For example, PERIOD=YEAR produces a datekey that is periodic in a yearly pattern. If the PERIOD= option is omitted, the datekey is not periodic. The PERIOD= option does not apply to observation numbers, which are not periodic, or to date keywords, which have their own periodicity. For intervals that can be specified, see Chapter 4, "Date Intervals, Formats, and Functions" in *SAS/ETS User's Guide*.

PULSE=*interval*
specifies the interval to be used with the DURATION= option to determine the width of the datekey. If the datekey is evaluated with respect to a time ID variable, then the default pulse is one observation. When no DURATION= values are specified and the PULSE= option is specified, the DURATION= values are set to zero. For intervals that can be specified, see Chapter 4, "Date Intervals, Formats, and Functions" in *SAS/ETS User's Guide*.

RULE=*value*
specifies the action to take when the defined datekey has multiple timing values that include at least one datekey. When the datekey timing values consist only of SAS date, SAS datetime, and observation numbers, the RULE= option does not apply. The RULE= option also does not apply when the timing value list consists of a single datekey. The RULE= option accepts the values AND and OR. The default is RULE=OR. The following examples demonstrate the RULE= option:

```
datekeykey JANUARY / pulse=month;
datekeydef RainyDays='11JUL2013'd '13JUL2013'd '21JUL2013'd;
datekeydef HotDays=  '11JUL2013'd '16JUL2013'd '17JUL2013'd
                     '18JUL2013'd '19JUL2013'd;
datekeydef FridaysInJanuary=JANUARY FRIDAY / rule=and;
datekeydef JanuaryPlusFridays=JANUARY FRIDAY / rule=or;
datekeydef HotandRainyDays=RainyDays HotDays / rule=and;
```

The RULE= option does not apply to the first statement because the timing value list consists of a single datekey. The RULE= option does not apply to the second and third statements because the timing value list consists only of SAS date values. The operation between two SAS date, datetime, or observation values is always OR. In the fourth statement, the RULE=AND option identifies dates that are both in January and the day of the week is Friday. In the fifth statement, the RULE=OR option identifies all dates in January and all dates where the day of the week is Friday. In the sixth

statement, the RULE=AND option identifies days that are both rainy and hot. The RULE=AND applies to the two datekeys, RainyDays and HotDays.

Usually, the result of an AND operation between two discrete time periods is an empty value. Therefore, the OR operation is always used between discrete time periods. An example is '13JUL2013'D, '01Mar1990:15:03:00'DT, 3.

Table 18.55 on page 739 explains how the RULE= option is interpreted for each observation.

SHIFT=*number*
specifies the number of pulses to shift the timing value δ. The default is not to shift the timing value (δ=0). When the SHIFT= option is used, all timing values in the list (including those generated by date keywords) are shifted.

DATEKEYPERIODS Statement

Writes variables that list the active time periods in the input time ID for datekeys. The active period dates, datetime values, or observation numbers, are listed with the associated datekey.

Syntax

DATEKEYPERIODS OUT=*SAS-data-set*;

Required Argument

OUT=*SAS-data-set*
names the output data set to contain the active dates, datetime values, or observations for the specified datekeys based on the ID information that is specified in the ID statement. The OUT= data set also includes variables that are specified in the BY and ID statements.

ID Statement

Specifies a numeric variable that identifies observations in the input and output data sets.

See: "Details for the ID Statement" on page 756

Syntax

ID *SAS-variable-name* INTERVAL=*interval* <*options*>;

Summary of Optional Arguments

Required Arguments

SAS-variable-name
specifies a numeric variable that identifies observations in the input and output data sets. *SAS-variable-name* can be a SAS date, time, datetime value, or an observation number.

INTERVAL=*interval*
specifies the frequency of the input time ID. For example, if the time ID in the input data set consists of quarterly observations, then use INTERVAL=QTR. For intervals that can be specified, see Chapter 4, "Date Intervals, Formats, and Functions" in *SAS/ETS User's Guide*.

Optional Argument

option
The following options are available:

ALIGN=*option*
controls the alignment of SAS dates that are used to identify output observations. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E.

Default BEGINNING

END=*option*
specifies a SAS date, datetime, or time value that represents the end of the data. If the last time ID variable value is less than the END= value, the variables in the VAR statement are extended with missing values. If the last time ID variable value is greater than the END= value, the variables are truncated. For example, END="&sysdate"d uses the automatic macro variable SYSDATE to extend or truncate the variables to the current date. This option and the START= option can be used to ensure that data associated with each BY group contains the same number of observations.

FORMAT=*format*
specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied from the INTERVAL= option.

START=*option*
specifies a SAS date, datetime, or time value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the variables in the VAR statement are prefixed with missing values. If the first time ID variable value is less than the START= value, the variables are truncated. This option and the END= option can be used to ensure that data associated with each BY group contains the same number of observations.

VAR Statement

Copies input variables to the output calendar variables data set. If the VAR statement is omitted, all numeric variables are selected except those that appear in a BY or ID statement.

Syntax

VAR *variable(s)*;

Required Argument

variable
specifies numeric input variables to be copied to the output calendar variables data set.

Usage: DATEKEYS Procedure

Using the DATEKEYS Procedure

Functional Summary of the DATEKEYS Procedure

The following table summarizes the statements and options that control the DATEKEYS procedure.

Description	Statement	Option
Statements		
Specifies BY-group processing	BY	Not applicable
Specifies a calendar variable data set	DATEKEYCALENDAR	Not applicable
Specifies a datekey data set	DATEKEYDATA	Not applicable

Description	Statement	Option
Specifies a datekey definition	DATEKEYDEF	Not applicable
Specifies a datekey definition based on an existing datekey	DATEKEYKEY	Not applicable
Specifies a data set that contains a list of active periods by datekey	DATEKEYPERIODS	Not applicable
Specifies the time ID variable	ID	Not applicable
Specifies the variables to be copied to the calendar variable data set	VAR	Not applicable
Data Set Options		
Specifies the input data set	PROC DATEKEYS	DATA=
Specifies an output data set that contains calendar variables for datekeys	DATEKEYCALENDAR	OUT=
Specifies a datekeys input data set	DATEKEYDATA	IN=
Specifies a datekeys output data set	DATEKEYDATA	OUT=
Specifies that the datekeys output data set is to be condensed	DATEKEYDATA	CONDENSE
Specifies that the datekeys output data set contain only a list of datekeys	DATEKEYDATA	LIST
Specifies that the datekeys output data set contain no SAS predefined datekeys	DATEKEYDATA	NODEFAULTS
Specifies that input and output data sets process the specified locale	DATEKEYDSOPT	LOCALE=
Specifies an output data set that contains active dates for datekeys	DATEKEYPERIODS	OUT=
Specifies a starting time ID value	ID	START=
Specifies an ending time ID value	ID	END=
Specifies the format of the ID variable	ID	FORMAT=

Description	Statement	Option
Calendar Variable Format Options		
Extends the calendar variables past the end of the input time ID	PROC DATEKEYS	LEAD=
Specifies the frequency of the time ID variables	ID	INTERVAL=
Specifies the interval alignment	ID	ALIGN=
Miscellaneous Options		
Specifies that variables in output data sets are to be in sorted order	PROC DATEKEYS	SORTNAMES
Limits error and warning messages	PROC DATEKEYS	MAXERROR=

Datekey Definitions

The purpose of a datekey definition is to define time periods that are associated with the reference datekey. These time periods are then interpreted in other SAS procedures that define time-dependent features such as events. The time period of the datekey definition is compared to the time period of interest. If the time period of interest falls within the range of the datekey definition, then appropriate action is taken. The datekey definitions can be written to an output file by using the OUT= option of the DATEKEYDATA statement.

Once a datekey has been defined, it is referenced using its SAS variable name. When the datekey definition is written to an output file by using the DATEKEYDATA statement, the datekey is identified by its SAS variable name. As with SAS predefined datekeys, when an event is specified using a user-defined datekey name, a dummy variable is created using the datekey definition. The dummy variable name is the same as the datekey SAS reference name.

Each datekey must have a unique SAS variable name. If two datekey definitions have the same name, the following rules apply:

- If two DATEKEYDEF statements exist using the same name, the second statement is used.
- If a datekey is defined in both a DATEKEYDEF statement and in a data set specified using the DATEKEYDATA statement, the definition in the DATEKEYDEF statement is used.
- Any datekey that is defined using a DATEKEYDEF, DATEKKEYKEY, or DATEKEYDATA statement is used, rather than a predefined SAS datekey.

Details of the Timing Value List Specification

Each DATEKEYDEF statement must be defined using one or more timing values. The timing values can be specified using a list. Each item in the list can be a predefined SAS date keyword, an integer, a SAS date, a SAS datetime value, or a *value-list*. For example, the following DATEKEYDEF statement specifies timing values that use each of these methods in the order listed:

```
datekeydef datekey1=USINDEPENDENCE 10 '25Dec2000'd
                    '01Mar1990:15:03:00'dt
                    '01Jan2000'd to '01Mar2000'd by month;
```

The timing values are interpreted as follows: July 4 of any relevant year; the 10th observation in a time series or data set; December 25, 2000; March 1, 1990 at 3:03PM; January 1, 2000; February 1, 2000; and March 1, 2000.

The following two DATEKEYDEF statements specify identical timing values:

```
datekeydef MyFirstDATEKEY='01Jan2000'd to '01Mar2000'd by month;
datekeydef MyNextDATEKEY=('01Jan2000'd, '01Feb2000'd, '01Mar2000'd );
```

The *timing-value list* can be enclosed in parentheses, and commas can separate the items in the list. Numbers must be integers and are always interpreted as observation numbers. The *value-list* can be based on observation numbers, SAS dates, or SAS datetime values. However, the first and second values in the list must be of the same type. SAS always expects the type of the second value to be the same as the type of the first value, and tries to interpret the statement in that way. The following statement yields erratic results:

```
datekeydef baddatekey='01Jan2000'd to '01Mar2000:00:00:00'dt by month;
```

Either the DATEKEYS procedure produces a list much longer than expected or the procedure does not have enough memory to execute.

Note: Do not mix date, datetime, integer, and value types in a *value-list*.

The following table shows the holiday date keywords that can be used in a *timing-value list*, and their definitions:

Table 18.2 *Holiday Date Keywords and Definitions*

Date Keyword	Definition
BOXING	December 26
CANADA	July 1
CANADAOBSERVED	July 1, or July 2, if July 1 is a Sunday
CHRISTMAS	December 25

Date Keyword	Definition
COLUMBUS	second Monday in October
EASTER[1]	Easter Sunday
FATHERS	third Sunday in June
HALLOWEEN	October 31
LABOR	first Monday in September
MLK	third Monday in January
MEMORIAL	last Monday in May
MOTHERS	second Sunday in May
N<*n*>W<*w*><MON>YR	date specified by NWKDOM(*n*, *w*, *m*, *year*), where *m* corresponds to the month that is specified by MON, and *year* is any year relevant to the data. Example: N4W5NOVYR is the same as THANKSGIVING
NEWYEAR	January 1
THANKSGIVING	fourth Thursday in November
THANKSGIVINGCANADA	second Monday in October
USINDEPENDENCE	July 4
USPRESIDENTS	third Monday in February (since 1971)
VALENTINES	February 14
VETERANS	November 11
VETERANSUSG	U.S. government observed date for Monday–Friday schedule
VETERANSUSPS	U.S. government observed date for Monday–Saturday schedule (U.S. Post Office)
VICTORIA	Monday on or preceding May 24

1. The date for Easter is calculated using a method described by Montes (2001).

The following table shows the seasonal date keywords that can be used in a *timing value list*, and their definitions:

Table 18.3 *Seasonal Date Keywords and Definitions*

Date Keyword	Definition
SECOND_1, ...SECOND_60	the specified second.
MINUTE_1, ...MINUTE_60	the beginning of the specified minute.
HOUR_1, ...HOUR_24	the beginning of the specified hour.
SUNDAY, ...SATURDAY	all Sundays, and so on, in the time series.
WEEK_1, ...WEEK_53	the first day of the *n*th week of the year. PULSE=WEEK.*n* shifts this date for *n* NE 1.
TENDAY_1, ...TENDAY_36	the 1st, 11th, or 21st day of the appropriate month.
SEMIMONTH_1, ...SEMIMONTH_24	the 1st or 16th day of the appropriate month.
JANUARY, ...DECEMBER	the 1st day of the specified month.
QTR_1, QTR_2, QTR_3, QTR_4	the first date of the quarter. PULSE=QTR.*n* shifts this date for *n* NE 1.
SEMIYEAR_1, SEMIYEAR_2	the first date of the semiyear. PULSE=SEMIYEAR.*n* shifts this date for *n* NE 1.

Timing values are evaluated with respect to the application and relevant time specified by the user. Select the timing values that are consistent with the usage. In particular, date and datetime timing values are ignored when no date or time information is specified, and only observation numbers are available for analysis.

Details of Modifying Timing Values Using Options

The qualifier options define functional modifications to be applied at each timing value. The options are applied in the following order:

1. If a SHIFT= value is specified, the timing values in the list are shifted using the SHIFT= value, and the PULSE= value, if specified.
2. If a DURATION= value is specified in the BEFORE= or AFTER= options, then a continuous interval is defined around the shifted timing values based on the DURATION= and PULSE= values.

3 If PERIOD= values are specified, then periodic values are generated based on the timing values that result from steps 1 and 2.

Details of Identifying Active Intervals Based on Timing Values and Options

When a datekey is evaluated with respect to a time ID, active intervals are identified with respect to the time ID intervals. Therefore, the active periods are dependent on both the time ID and the datekey definition.

The observation that is specified by the shifted timing value, t_i, is the observation that contains the date that is generated by `INTNX(interval,timing_value,s,'same')`, where SHIFT=*s* and PULSE=*interval*. If no PULSE= value is specified, the default is PULSE=OBS, which is equivalent to PULSE=*interval*, where *interval* is the interval of the time ID.

Table 18.4 *Calculating the Beginning and Ending Observations for Datekeys When Applied to Time Series*

BEFORE=(DURATION=*value*)	**PULSE=*value***	**Definition of t_b**
ALL	Not available	t_b=1, the first observation in the data set, or t_b= the observation specified by START=
m=0	Not specified	$t_b=t_i$, the observation specified by the shifted timing value
m>0	Not specified	$t_b=t_i-m$
m>=0	*interval*	t_b= the observation specified by the date `INTNX(interval, timing-value,-m, 'begin')`
AFTER=(DURATION=*value*	PULSE=*value*	Definition of t_e
ALL	Not available	t_e= the last observation in the data set, or t_e= the observation specified by END=

BEFORE=(DURATION=*value*)	PULSE=*value*	Definition of t_b
n=0	Not specified	$t_e=t_i$, the observation specified by the shifted timing value
n>0	Not specified	$t_e=t_i+n$
n>=0	*interval*	t_e= the observation specified by the date `INTNX(interval, timing-value,n,'end')`

The following table shows active time periods for datekey definitions:

Table 18.5 *Active Time Periods for Datekey Definitions*

BEFORE=(DURATION=*m*)	AFTER=(DURATION=*n*)	Active Observation
m=ALL	*n*=ALL	ξ_{it}, for all *t*
m=finite	*n*=ALL	ξ_{it}, for all $t>=t_b$
m=ALL	*n*=finite	ξ_{it}, for all $t<=t_e$
m=finite	*n*=finite	ξ_{it}, if $t_b<=t<=t_e$

If an observation is not within an active period for a datekey, then it is not altered by the datekey action.

The active period always occurs at the shifted timing value. You specify three observations before the timing value, one observation at the timing value, and four after the timing value. The total would be 3+1+4=8 observations as follows:

```
datekeydef E1='01JAN1950'd / before=(duration=3)
                                  after=(duration=4);
```

In this example, you specify three weeks before the timing value, the week of the timing value, and four weeks after the timing value by using a combination of the BEFORE=, AFTER=, and PULSE= options as follows:

```
datekeydef E1='01JAN1950'd / before=(duration=3)
                                  after=(duration=4)
                                  pulse=week;
```

DURATION=ALL implies that the active period should be extended to the beginning (BEFORE=) or end (AFTER=) of time. If only one DURATION= value is specified, the other value is assumed to be zero. When neither DURATION= value is specified, both DURATION= values are set to zero. DURATION=ALL is represented in the

datekey definition data set as a special missing value displayed as "A". For more information, see "Missing Values" in *SAS Language Reference: Concepts*.

Using the DATEKEYKEY Statement

Creating New Datekeys from Existing Datekey Definitions

A DATEKEYKEY statement can be used with PROC DATEKEYS to create new datekeys from existing datekey definitions and make them available for processing. SAS events that are based on user-defined datekeys are also available directly through PROC HPFDIAGNOSE and PROC HPFENGINE by specifying the EVENTDS= system option.

A user-defined datekey variable has timing values and qualifiers that are defined by the user. A DATEKEYKEY variable that is defined using a predefined SAS datekey has a predefined set of timing values and qualifiers that are associated with the predefined datekey keyword. You can redefine the qualifiers by using the statement options. The options are the same as in the DATEKEYDEF statement. In "Concepts: The DATEKEYS Procedure" on page 728, the default SAS variable name for an event based on a datekey is the datekey keyword. However, you can specify a different SAS name for the datekey. For example, you can rename the CHRISTMAS predefined datekey to XMAS by using the following statement:

```
datekeykey xmas=christmas;
```

If you redefine the qualifiers that are associated with a predefined SAS datekey and do not rename the datekey, then that has the impact of redefining the predefined SAS datekey. This redefinition occurs because any user definition takes precedence over a SAS predefined definition. The following example produces an event named FALLHOLIDAYS with a pulse of 1 day at Halloween and a pulse of 1 month at Thanksgiving:

```
datekeykey thanksgiving / pulse=month;
eventcomb fallholidays=halloween thanksgiving;
```

The following table describes how to construct a predefined SAS datekey keyword. It also gives the default qualifier options for those predefined datekeys.

Table 18.6 *Definitions for DATEKEYKEY Predefined Event Keywords*

Variable Name or Variable Name Format	Description	Qualifier Option
AO<obs>OBS	outlier	BEFORE=(DURATION=0)
AO<date>D		AFTER=(DURATION=0)
AO<datetime>DT		

Variable Name or Variable Name Format	Description	Qualifier Option
LS<obs>OBS LS<date>D LS<datetime>DT	level shift	BEFORE=(DURATION=0) AFTER=(DURATION=ALL)
TLS<obs>OBS<n> TLS<date>D<n> TLS<datetime>DT<n>	temporary level shift	BEFORE=(DURATION=0) AFTER=(DURATION=<n>)
NLS<obs>OBS NLS<date>D NLS<datetime>DT	negative level shift	BEFORE=(DURATION=0) AFTER=(DURATION=ALL)
CBLS<obs>OBS CBLS<date>D CBLS<datetime>DT	U.S. Census Bureau level shift	SHIFT=–1 BEFORE=(DURATION=ALL) AFTER=(DURATION=0)
TC<obs>OBS TC<date>D TC<datetime>DT	temporary change	BEFORE=(DURATION=0) AFTER=(DURATION=ALL)
<date keyword>	date pulse	BEFORE=(DURATION=0) AFTER=(DURATION=0)
LINEAR QUAD CUBIC	polynomial trends	BEFORE=(DURATION=ALL) AFTER=(DURATION=ALL) default timing value is 0 observation
INVERSE LOG	trends	BEFORE=(DURATION=0) AFTER=(DURATION=ALL) default timing value is 0 observation

Variable Name or Variable Name Format	Description	Qualifier Option
<seasonal keywords>	seasonal	PULSE= depends on keyword BEFORE=(DURATION=0) AFTER=(DURATION=0) timing values based on keyword

Modifying or Cloning a User-Defined Datekey

A DATEKEYKEY statement can be used in a similar manner to modify or clone a user-defined datekey. In the following example, the DATEKEYDEF statement is used to define a simple event named SPRING. The DATEKEYKEY statement is used to modify the SPRING event definition. Then the DATEKEYKEY statement is used to create a new event named SPRINGBREAK that is based on the previously defined user event named SPRING. Therefore, the example defines a total of two datekeys, SPRING and SPRINGBREAK. The DATEKEYKEY statement can be used to modify the qualifiers. It cannot be used to modify the timing values.

```
datekeydef spring='20mar2005'd;
datekeykey spring / pulse=day;
datekeykey SPRINGBREAK=spring / pulse=week;
```

If the preceding datekeys are stored in a data set named SPRINGHOLIDAYS, the first DATEKEYKEY statement in the following example clones SPRING as a datekey named FirstDayOfSpring. The second DATEKEYKEY statement changes the case of the SPRINGBREAK datekey name.

```
datekeydata in=springholidays;
datekeykey FirstDayOfSpring=spring;
datekeykey Springbreak=springbreak;
```

Datekey names that refer to a previously defined datekey are not case sensitive. However, datekey names that are used to create a new datekey preserve the casing in the _NAME_ variable of the DATEKEYDATA OUT= data set.

SAS Datekey Keywords

The date keywords that are described in Table 18.56 on page 748 can be used in the DATEKEYDEF statement as predefined SAS datekey keywords. The timing values are as defined in Table 18.56 on page 748. The default qualifiers are as shown in Table 18.60 on page 753. Table 18.57 on page 750 shows the seasonal keywords that can be used as predefined SAS datekey keywords. The default qualifiers for seasonal keywords are shown in Table 18.60 on page 753. Table 18.61 on page 756

describes how date and observation numbers are encoded into AO, LS, TLS, NLS, CBLS, and TC enter predefined datekeys.

SAS predefined date keywords have only active periods.

Table 18.7 *Encoding Data Information into AO, LS, TLS, NLS, CBLS, and TC Type DATEKEYKEY Variable Names*

Variable Name Format	Example	Refers To
AO<int>OBS	AO15OBS	15th observation
AO<date>D	AO01JAN2000D	'01JAN2000'D
AO<date>h<hr>m<min>s<sec>DT	AO01Jan2000h12m34s56DT	'01Jan2000:12:34:56'DT
TLS<int>OBS<n>	TLS15OBS10	15th observation
TLS<date>D<n>	TLS01JAN2000D10	'01JAN2000'D
TLS<date>h<hr>m<min>s<sec>DT<n>	TLS01Jan2000h12m34s56DT10	'01Jan2000:12:34:56'DT

Details for the ID Statement

The ID statement accepts a SAS variable name and an interval. The ID variable's values are assumed to be SAS date, time, datetime values, or observation numbers. In addition, the ID statement specifies the desired frequency for examining active and inactive time periods. The information that is specified affects all variables that are generated by using the DATEKEYCALENDAR and DATEKEYPERIODS statements. If no DATEKEYCALENDAR or DATEKEYPERIODS statements are specified, the ID statement has no impact on processing, because the DATEKEYDEF definitions are independent of the time identification values and frequencies. If the ID statement is specified, the INTERVAL= option must also be specified. If an ID statement is not specified, the observation number (with respect to the BY group) is used as the time ID. In this case, only datekey timing values that are based on observation numbers are applied to the input time ID to create calendar variables. Timing values that are based on SAS date or datetime values are ignored.

Data Set Output

Creating Data Set Output

The DATEKEYS procedure can create the DATEKEYCALENDAR OUT=, DATEKEYDATA OUT=, and DATEKEYPERIODS OUT= data sets. The DATEKEYDATA OUT= data set contains the datekey definitions that can be used for input to another SAS procedure. If the LIST option is specified in the DATEKEYDATA OUT= statement, then the output data set contains a list of available datekeys. The DATEKEYCALENDAR OUT= data set contains calendar indicator variables that show the active periods for the datekeys relative to the input time ID. The DATEKEYPERIODS OUT= data set contains information about datekeys that are active for the input time ID and the associated dates.

Identifying Variables in the DATEKEYCALENDAR OUT= Data Set

The DATEKEYCALENDAR OUT= data set contains the variables that are listed in the BY statement, the ID variable, any variables that are defined by the VAR statement, and any calendar variables that are generated by the procedure. The calendar indicator variables show the active periods for the datekeys relative to the input time ID. You can specify the SUM= option in the DATEKEYCALENDAR statement. In this case, the variable that is specified in the SUM= option is included in the DATEKEYCALENDAR OUT= data set and contains the sum of the calendar indicator variables.

Identifying Variables in the DATEKEYDATA OUT= Data Set

The DATEKEYDATA OUT= data set contains the following variables. The default values for the CONDENSE option are also given. When all the observations in the variable are equal to the default value, the variable can be omitted from the datekey definition data set.

CLASS
: specifies that the class for all datekeys is DATEKEY. The default for _CLASS_ is DATEKEY.

DATEINTRVL
: specifies the interval for the date *value-list*. The default for _DATEINTRVL_ is no interval, designated by ".".

DTINTRVL
specifies the interval for the datetime *value-list*. The default for _DTINTRVL_ is no interval, designated by ".".

_DUR_AFTER_
specifies the number of durations after the timing value. The default for _DUR_AFTER_ is 0.

_DUR_BEFORE_
specifies the number of durations before the timing value. The default for _DUR_BEFORE_ is 0.

ENDDATE
specifies the last date timing value to use in a *value-list*. The default for _ENDDATE_ is no date, designated by a missing value.

ENDDT
specifies the last datetime timing value to use in a *value-list*. The default for _ENDDT_ is no datetime, designated by a missing value.

ENDOBS
specifies the last observation number timing value to use in a *value-list*. The default for _ENDOBS_ is no observation number, designated by a missing value.

KEYNAME
specifies either a predefined datekey keyword or a user-defined datekey keyword. All _KEYNAME_ values are displayed in uppercase. However, if the _KEYNAME_ value refers to a user-defined keyword, then the actual name can be mixed case. The default for _KEYNAME_ is no keyname, designated by ".".

LABEL
specifies a label or description for the datekey. If you do not specify a label, then the default label value is displayed as ".". For more information, see the LABEL system option in *SAS System Options: Reference*.

LOCALE
specifies the locale for the datekey. _LOCALE_ values are the valid POSIX locale values. For more information, see the LOCALE system option in *SAS National Language Support (NLS): Reference Guide*. There is no default.

NAME
specifies a datekey reference name. _NAME_ is displayed with the case preserved. Because _NAME_ is a SAS variable name, the datekey can be referenced using any case. The _NAME_ variable is required. There is no default.

OBSINTRVL
specifies the interval length of the observation number *value-list*. The default for _OBSINTRVL_ is no interval, designated by ".".

PERIOD
specifies the frequency interval at which the datekey should be repeated. If this value is missing, then the datekey is not periodic. The default for _PERIOD_ is no interval, designated by ".".

PULSE
specifies an interval that defines the units for the DURATION values. The default for _PULSE_ is no interval (one observation), designated by ".".

RULE
specifies the rule to use when you combine the timing values of a datekey. The default for _RULE_ for datekeys is OR.

SHIFT
specifies the number of PULSE= intervals to shift the timing value. The shift can be positive (forward in time) or negative (backward in time). If PULSE= is not specified, then the shift occurs in observations. The default for _SHIFT_ is 0.

STARTDATE
specifies either the date timing value or the first date timing value to use in a *value-list*. The default for _STARTDATE_ is no date, designated by a missing value.

STARTDT
specifies either the datetime timing value or the first datetime timing value to use in a *value-list*. The default for _STARTDT_ is no datetime, designated by a missing value.

STARTOBS
specifies either the observation number timing value or the first observation number timing value to use in a *value-list*. The default for _STARTOBS_ is no observation number, designated by a missing value.

Identifying Variables in the DATEKEYPERIODS OUT= Data Set

The DATEKEYPERIODS OUT= data set contains the following variables.

LOCALE
specifies the locale for the datekey. _LOCALE_ values are the valid POSIX locale values. For more information, see the LOCALE system option in *SAS National Language Support (NLS): Reference Guide*. There is no default.

NAME
specifies a datekey reference name. _NAME_ is displayed with the case preserved. Because _NAME_ is a SAS variable name, the datekey can be referenced using any case. The _NAME_ variable is required. There is no default.

STARTDATE
specifies either the date timing value or the first date timing value to use in a *value-list*. The default for _STARTDATE_ is no date, designated by a missing value.

TIME ID
specifies the date.

Listing the Datekeys By Using the LIST Option

You can use the LIST option in the DATEKEYDATA statement to list datekeys. Specifying the LIST option in the DATEKEYDATA OUT= statement alters the output data set. The purpose of the LIST option is to create a data set that lists the available datekeys that are defined by the data set. When the LIST option is specified, the data set contains only the _LOCALE_, _NAME_, and _LABEL_ variables. The data set contains one observation for each datekey.

Creating a Data Set of BY Statement Variables

You can create a data set of BY statements by using the DATEKEYPERIODS statement. The DATEKEYPERIODS OUT= data set contains the following items:

- variables that are listed in the BY statement
- a list of active datekeys that are associated with the input time ID
- the ID variable dates that are associated with the active datekeys
- the starting date, datetime, or observation value that is associated with the active time ID period

In addition to the BY variables and the ID variable, the DATEKEYPERIODS OUT= data set contains the following variables:

NAME
: specifies a datekey reference name. _NAME_ is displayed with the case preserved. The datekey that is displayed is active on the dates that are specified by the ID variable and the _STARTDATE_, _STARTDT_, or _STARTOBS_ values for the observation.

One of the following variables is included, based on the time ID variable:

STARTDATE
: specifies the date that is associated with the beginning of the period that is specified by the INTERVAL= option relative to the value of the time ID variable.

STARTDT
: specifies the datetime that is associated with the beginning of the period that is specified by the INTERVAL= option relative to the value of the time ID variable.

STARTOBS
: specifies the observation number that is associated with the beginning of the period that is specified by the INTERVAL= option relative to the value of the time ID variable.

Written Output

The DATEKEYS procedure has no written output other than warning and error messages as recorded in the log.

Examples: DATEKEYS Procedure

Example 1: Methods for Constructing a Datekeys Definition Data Set

Features:

PROC DATEKEYS statement options
- ID
- DATEKEYDEF
- DATEKEYKEY
- DATEKEYDATA
- DATEKEYPERIODS

Details

This example uses two methods to construct a datekeys definition data set. The first method uses the DATA step to construct a datekey data set for Fridays when an item was on sale. The second method uses the DATEKEYS procedure to construct the datekey definition data set. The TimeSeriesDates data set contains the time ID variable for the time series.

The same dates that are defined in WhiteSaleDates in the DATA step can be defined using the DATEKEYS procedure. The active dates are the same as in the data set that is shown in Output 18.121 on page 763. However, the definitions in the DATEKEYS procedure are continuous.

Program: Using the DATA Step

```
options eventds=(nodefaults);
```

```
data TimeSeriesDates(keep=date);
   set sashelp.citiday;
   format date date.;
run;

data WhiteSaleDates(keep=_name_ _startdate_);
   set TimeSeriesDates;
   _name_='WhiteSale';
   if (month(date)=1) then do;
      if (year(date)=1991 or year(date)=1992) then do;
         if (weekday(date)=6) then do;
            _startdate_=date;
         end;
         else delete;
         end;
      else delete;
      end;
   else delete;
   format _startdate_ date.;
run;

proc print data=WhiteSaleDates;
run;
```

Program Description

Set the EVENTDS= system option. The EVENTDS= system option specifies the data set that defines the event. The NODEFAULTS option specifies not to use default event definitions. The only events that are used are specified by the event-data-set list.

```
options eventds=(nodefaults);
```

Create the TimeSeriesDates data set. The DATA step uses sashelp.citiday to create the data set for this example:

```
data TimeSeriesDates(keep=date);
   set sashelp.citiday;
   format date date.;
run;
```

Construct a datekeys data set, WhiteSalesDates, for use with the EVENTDS= system option. When you construct a datekeys data set using a DATA step, all observations that define a specific datekey must be consecutive. If necessary, use the SORT procedure to sort the data set by the _NAME_ variable. The DATA step describes an item that was on sale during January 1991 and January 1992. The user-defined datekeys identify the Fridays that the item was on sale.

```
data WhiteSaleDates(keep=_name_ _startdate_);
   set TimeSeriesDates;
   _name_='WhiteSale';
   if (month(date)=1) then do;
      if (year(date)=1991 or year(date)=1992) then do;
         if (weekday(date)=6) then do;
            _startdate_=date;
         end;
```

```
         else delete;
         end;
      else delete;
      end;
   else delete;
   format _startdate_ date.;
run;

proc print data=WhiteSaleDates;
run;
```

Output: HTML

Output 18.1 *User-Defined Datekeys Data Set*

The SAS System

Obs	_NAME_	_STARTDATE_
1	WhiteSale	04JAN91
2	WhiteSale	11JAN91
3	WhiteSale	18JAN91
4	WhiteSale	25JAN91
5	WhiteSale	03JAN92
6	WhiteSale	10JAN92
7	WhiteSale	17JAN92
8	WhiteSale	24JAN92
9	WhiteSale	31JAN92

Program: Using the DATEKEYS Procedure

```
proc datekeys data=sashelp.citiday;
   id date interval=day;
   datekeydef Years1991_1992='01JAN1991'd / pulse=year
after=(duration=1);
   datekeykey January / pulse=month;
   datekeydef WhiteSale=JANUARY FRIDAY Years1991_1992 / rule=and;
   datekeydata out=WhiteSaleDefinitions condense;
   datekeyperiods out=WhiteSaleActiveDates;
run;
```

```
proc print data=WhiteSaleActiveDates(where=(_name_='WhiteSale'));
run;

proc print data=WhiteSaleDefinitions;
run;
```

Program Description

Begin the DATEKEYS procedure. The DATA= option contains the variables that are used in the ID statement.

```
proc datekeys data=sashelp.citiday;
```

Specify the time ID variable. The ID statement names a numeric variable that identifies observations in the data set. If you use the ID statement, the INTERVAL= option must be used. In this case, INTERVAL=day.

```
    id date interval=day;
```

Define a datekey. The DATEKEYDEF statement defines a datekey. PULSE= specifies the interval to be used with the DURATION= option to determine the width of the datekey.

```
    datekeydef Years1991_1992='01JAN1991'd / pulse=year
after=(duration=1);
```

Alter or create a new datekey. Because January is used in the timing value list, it represents the first day of January. Using DATEKEYKEY with PULSE=MONTH creates a datekey for the entire month of January.

```
    datekeykey January / pulse=month;
```

Define a datekey. The DATEKEYDEF statement defines a datekey. The RULE=AND option identifies days in January that are Fridays.

```
    datekeydef WhiteSale=JANUARY FRIDAY Years1991_1992 / rule=and;
```

Write the datekey to an output data set. The DATEKEYDATA OUT= data set contains the definitions for the WhiteSale datekey. The CONDENSE option specifies that the output data set be condensed. Any variables that contain only default values are omitted from the data set.

```
    datekeydata out=WhiteSaleDefinitions condense;
```

Write variables that list the active time periods in the input time ID for datekeys. The DATEKEYPERIODS OUT= data set contains the active time periods for the WhiteSale datekey, as shown in Output 18.122 on page 765.

```
    datekeyperiods out=WhiteSaleActiveDates;
```

Execute the example. The RUN statement causes the program to execute.

```
run;
```

Write the active sales dates data set. The results are shown in Output 18.122 on page 765.

```
proc print data=WhiteSaleActiveDates(where=(_name_='WhiteSale'));
run;
```

Write the definitions for the WhiteSale datekey. The results are shown in Output 18.123 on page 765.

```
proc print data=WhiteSaleDefinitions;
run;
```

HTML Output

Output 18.2 *Datekeys Active Periods Data Set Output*

The SAS System

Obs	_LOCALE_	DATE	_NAME_	_STARTDATE_

Example 2: Using User-Defined SAS Datekey Keywords Directly in Other SAS Procedures

Features:

PROC DATEKEYS statements
- DATEKEYDEF
- DATEKEYKEY
- DATEKEYDATA

System option
- EVENTDS=

Other Procedures
- HPFDIAGNOSE

Details

If a procedure supports an EVENT statement, then you can use either data set that is shown in "Example 1: Methods for Constructing a Datekeys Definition Data Set" on page 761 without using PROC HPFEVENTS. PROC HPFEVENTS enables you to use a user-defined datekey. However, when the user-defined datekey is specified as an event, the event is created automatically, provided that the user-defined datekey definition data set has been specified using the EVENTDS= system option. This example uses the data set from "Example 1: Methods for Constructing a Datekeys Definition Data Set" on page 761 and the EVENT statement in PROC HPFDIAGNOSE.

The output from PROC HPFDIAGNOSE shows that a model that included the WhiteSale event was selected. The event was a poor fit, but REQUIRED=YES was specified. REQUIRED=YES specifies that the events be included in the model as long as the model does not fail to be diagnosed.

Program

```
proc datekeys;

   datekeydef Years1991_1992='01JAN1991'd / pulse=year
after=(duration=1);

   datekeykey JANUARY / pulse=month;

   datekeydef WhiteSale=JANUARY FRIDAY Years1991_1992 / rule=and;

   datekeydata out=WhiteSaleDefinitions condense;

run;

options eventds=(WhiteSaleDefinitions);
```

```
proc hpfdiagnose data=sashelp.citiday
     print=all;

   id date interval=day;

   forecast snysecm;

   event WhiteSale / required=yes;

   arimax;

run;
```

Program Description

Begin the DATEKEYS procedure.

```
proc datekeys;
```

Define a datekey. The DATEKEYDEF statement defines a datekey. PULSE= specifies the interval to be used with the DURATION= option to determine the width of the datekey.

```
   datekeydef Years1991_1992='01JAN1991'd / pulse=year
after=(duration=1);
```

Alter or create a new datekey. The DATEKEYKEY statement alters a user-defined or predefined SAS datekey, or creates a new datekey from another datekey. PULSE= specifies the interval to be used with the DURATION= option to determine the width of the datekey.

```
   datekeykey JANUARY / pulse=month;
```

Define a datekey. The DATEKEYDEF statement defines a datekey. The RULE=AND option identifies days in January 1991 and 1992 that are Fridays.

```
   datekeydef WhiteSale=JANUARY FRIDAY Years1991_1992 / rule=and;
```

Write the datekey to an output data set. The CONDENSE option specifies that the output data set be condensed. Any variables that contain only default values are omitted from the data set.

```
   datekeydata out=WhiteSaleDefinitions condense;
```

Execute the DATEKEYS procedure.

```
run;
```

Set the EVENTDS= system option. The EVENTDS= system option specifies the data set that defines the event.

```
options eventds=(WhiteSaleDefinitions);
```

Begin the HPFDIAGNOSE procedure. The HPFDIAGNOSE procedure automatically diagnoses the statistical characteristics of time series and identifies appropriate models.

```
proc hpfdiagnose data=sashelp.citiday
     print=all;
```

Specify the ID statement. The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are SAS date values. In addition, the ID statement specifies the desired frequency that is associated with the time series. The INTERVAL= option specifies the frequency of the input time ID.

```
id date interval=day;
```

List the variables in the data set that you want to diagnose. The FORECAST statement lists the variables to be diagnosed in the data set that is specified by the DATA= option. The variables are dependent variables or response variables that you want to forecast in the HPFENGINE procedure.

```
forecast snysecm;
```

Name the event. The EVENT statement name identifies the events. The REQUIRED option specifies that the events be included in the model as long as the model does not fail to be diagnosed.

```
event WhiteSale / required=yes;
```

Find an appropriate ARIMAX specification. An ARIMAX model specifies trend factors, seasonal factors, and regression variables, including events. The HPFDIAGNOSE procedure performs the intermittency test first. If the series is not intermittent, an ARIMAX model is fitted to the data.

```
arimax;
```

Execute the HPFDIAGNOSE procedure.

```
run;
```

HTML Output

The following output shows the results:

Output 18.4 *Using the EVENT Statement in PROC HPFDIAGNOSE*

Example 3: Obtaining a Calendar Variable By Using the DATEKEYS Procedure

Features:

PROC DATEKEYS statements
- DATEKEYDEF
- DATEKEYKEY
- DATEKEYDATA
- ID
- DATEKEYCALENDAR

System option
- EVENTDS=

Details

Consider the datekey definitions that are shown in "Concepts: The DATEKEYS Procedure" on page 728. The DATEKEYS procedure can be used to create a calendar variable that indicates the active periods of the datekey definitions that are defined in the data set MyHolidays.

Program

```
options eventds=(nodefaults);

data Year2010;
   do date='01JAN2010'd to '31DEC2010'd;
      output;
   end;
   format date date.;
run;

proc datekeys;

   datekeydef SuperBowl=
                '15JAN1967'd '14JAN1968'd '12JAN1969'd '11JAN1970'd
    '17JAN1971'd '16JAN1972'd '14JAN1973'd '13JAN1974'd '12JAN1975'd
    '18JAN1976'd '09JAN1977'd '15JAN1978'd '21JAN1979'd '20JAN1980'd
    '25JAN1981'd '24JAN1982'd '30JAN1983'd '22JAN1984'd '20JAN1985'd
    '26JAN1986'd '25JAN1987'd '31JAN1988'd '22JAN1989'd '28JAN1990'd
    '27JAN1991'd '26JAN1992'd '31JAN1993'd '30JAN1994'd '29JAN1995'd
    '28JAN1996'd '26JAN1997'd '25JAN1998'd '31JAN1999'd '30JAN2000'd
    '28JAN2001'd '03FEB2002'd '26JAN2003'd '01FEB2004'd '06FEB2005'd
    '05FEB2006'd '04FEB2007'd '03FEB2008'd '01FEB2009'd '07FEB2010'd
    '06FEB2011'd '05FEB2012'd '03FEB2013'd '02FEB2014'd
                         / pulse=day;
```

```
   datekeydef GoodFriday=Easter / shift=-2 pulse=day;
   datekeykey EasterMonday=Easter / shift=1 pulse=day;
   datekeydata out=MyHolidays condense;
run;
options eventds=(MyHolidays);
proc datekeys data=Year2010;
   id date interval=day;
   datekeycalendar out=MyHolidaysIn2010;
run;
proc print data=MyHolidaysIn2010(where=(month(date)=2));
run;
proc print data=MyHolidaysIn2010(where=(month(date)=4));
run;
```

Program Description

Set the EVENTDS= system option. The EVENTDS= system option specifies the data set that defines the event. The NODEFAULTS option specifies not to use default event definitions. The only events that are used are specified by the event-data-set list.

```
options eventds=(nodefaults);
```

Create a SAS data set. Create the Year2010 data set, which contains a series of dates.

```
data Year2010;
   do date='01JAN2010'd to '31DEC2010'd;
      output;
   end;
   format date date.;
run;
```

Begin the DATEKEYS procedure.

```
proc datekeys;
```

Define a datekey. The DATEKEYDEF statement defines a datekey. PULSE= specifies the interval to be used with the DURATION= option to determine the width of the datekey.

```
   datekeydef SuperBowl=
                '15JAN1967'd '14JAN1968'd '12JAN1969'd '11JAN1970'd
    '17JAN1971'd '16JAN1972'd '14JAN1973'd '13JAN1974'd '12JAN1975'd
    '18JAN1976'd '09JAN1977'd '15JAN1978'd '21JAN1979'd '20JAN1980'd
    '25JAN1981'd '24JAN1982'd '30JAN1983'd '22JAN1984'd '20JAN1985'd
    '26JAN1986'd '25JAN1987'd '31JAN1988'd '22JAN1989'd '28JAN1990'd
    '27JAN1991'd '26JAN1992'd '31JAN1993'd '30JAN1994'd '29JAN1995'd
    '28JAN1996'd '26JAN1997'd '25JAN1998'd '31JAN1999'd '30JAN2000'd
    '28JAN2001'd '03FEB2002'd '26JAN2003'd '01FEB2004'd '06FEB2005'd
    '05FEB2006'd '04FEB2007'd '03FEB2008'd '01FEB2009'd '07FEB2010'd
```

```
'06FEB2011'd '05FEB2012'd '03FEB2013'd '02FEB2014'd
                    / pulse=day;
```

Define a datekey. The DATEKEYDEF statement defines a datekey named GoodFriday and makes it equal to the datekey timing value named Easter. When you specify the PULSE= option, DURATION= values are set to zero. SHIFT= specifies the number of pulses to shift the timing value. When the SHIFT= option is used, all timing values are shifted.

```
datekeydef GoodFriday=Easter / shift=-2 pulse=day;
```

Alter or create a new datekey. The value of the DATEKEYKEY statement with the datekey name EasterMonday is equal to the datekey named Easter. When Easter is treated as a datekey timing value, only the timing value definition is used, and qualifiers (such as SHIFT or PULSE) are not part of the definition. When Easter is treated as a datekey, the qualifiers that you select (such as SHIFT and PULSE) are part of the new definition. When you specify the PULSE= option, DURATION= values are set to zero. SHIFT= specifies the number of pulses to shift the timing value. When the SHIFT= option is used, all timing values are shifted.

```
datekeykey EasterMonday=Easter / shift=1 pulse=day;
```

Write the datekey to an output data set. The DATEKEYDATA statement writes datekeys to an output data set named MyHolidays. The CONDENSE option specifies that the output data set be condensed. Any variables that contain only default values are omitted from the data set.

```
datekeydata out=MyHolidays condense;
```

Execute the DATEKEYS procedure.

```
run;
```

Set the EVENTSDS= system option. The EVENTSDS system option specifies the data set that defines the event.

```
options eventds=(MyHolidays);
```

Begin the DATEKEYS procedure. The DATA= option names the data set that contains the variables that are used in the ID statement.

```
proc datekeys data=Year2010;
```

Specify the time ID variable. The ID statement names a numeric variable that identifies observations in the data set. If you use the ID statement, then the INTERVAL= option must be used. In this case, INTERVAL= day.

```
id date interval=day;
```

Create a data set that contains variables that indicate the active time periods for datekeys. The DATEKEYCALENDAR OUT= statement specifies the data set that is created, and contains calendar variables that are based on the information that is specified in the ID statement. The DATEKEYCALENDAR OUT= data set contains calendar variables that identify the holidays that are defined in the MyHolidays data set. Values for the month in which of February 2010 are shown Output 18.125 on page 774.Values for the month in which of April 2010 are shown Output 18.126 on page 775. Only the active and inactive periods that correspond to the input time ID are contained in the DATEKEYCALENDAR OUT= data set MyHolidaysIn2010. Because the input time ID has a daily frequency and spans the year 2010, the results are calendar variables for the year 2010.

```
   datekeycalendar out=MyHolidaysIn2010;
run;
```

Write the output for the MyHolidaysIn2010 data set for February. The results are shown in Output 18.125 on page 774.

```
proc print data=MyHolidaysIn2010(where=(month(date)=2));
```

Execute the DATEKEYS procedure.

```
run;
```

Write the output for the MyHolidaysIn2010 data set for April. The results are shown in Output 18.126 on page 775.

```
proc print data=MyHolidaysIn2010(where=(month(date)=4));
run;
```

HTML Output

Output 18.5 *Holiday Calendar from the Daily 2010 Time ID for February*

Example 4: Filtering Data Sets By Using the DATEKEYDSOPT Statement

Features:

PROC DATEKEYS statements
- DATEKEYKEY
- DATEKEYDEF
- DATEKEYDATA
- ID
- DATEKEYDSOPT
- DATEKEYCALENDAR

System option
- EVENTDS=

Details

The DATEKEYS procedure can be used to filter input data sets and create data sets that contain only datekey data that is associated with a specified locale. The DATEKEYDSOPT statement applies to the data sets that are specified in the DATEKEYDATA, DATEKEYPERIODS, and DATEKEYCALENDAR statements.

This example creates the datekey definitions for the following English Canadian holidays: Canada, CanadaObserved, and Boxing. It also creates an English U.S. datekey definition for USINDEPENDENCE. The definition for NewYearsEve does not have a specified locale.

Program

```
options eventds=(nodefaults);

data December2010;
   do date='01DEC2010'd to '31DEC2010'd;
      output;
   end;
   format date date.;
run;

proc datekeys;

   datekeykey Canada / locale=en_CA;
   datekeykey CanadaObserved / locale=en_CA;
   datekeykey Boxing / locale='en_CA';
   datekeykey USINDEPENDENCE / locale=en_US;

   datekeydef NewYearsEve=NEWYEAR / shift=-1 pulse=day;
```

```
   datekeydata out=MyHolidays condense;
run;
options eventds=(MyHolidays);
proc datekeys data=December2010;
   id date interval=day;
  datekeydsopt locale=en_CA;
   datekeycalendar out=AllCAHolidaysInDecember2010;
run;
proc datekeys data=December2010;
   id date interval=day;
   datekeydsopt locale=(ONLY)en_CA;
   datekeycalendar out=OnlyCAHolidaysInDecember2010;
run;
proc print data=MyHolidays;
run;
proc print data=AllCAHolidaysInDecember2010;
run;
proc print data=OnlyCAHolidaysInDecember2010;
run;
```

Program Description

Set the EVENTDS= system option. The EVENTDS= system option specifies the data set that defines the event. The NODEFAULTS option specifies not to use default event definitions. The only events that are used are specified by the event-data-set list.

```
options eventds=(nodefaults);
```

Create a SAS data set. Create the December2010 data set, which contains a series of dates:

```
data December2010;
   do date='01DEC2010'd to '31DEC2010'd;
      output;
   end;
   format date date.;
run;
```

Begin the DATEKEYS procedure.

```
proc datekeys;
```

Create a new datekey. The DATEKEYKEY statement creates a new datekey. The LOCALE= option specifies a locale that is associated with the datekey. The locale should be a POSIX locale value.

```
   datekeykey Canada / locale=en_CA;
```

```
datekeykey CanadaObserved / locale=en_CA;
datekeykey Boxing / locale='en_CA';
datekeykey USINDEPENDENCE / locale=en_US;
```

Define a datekey. The DATEKEYDEF statement identifies a datekey. The SHIFT= option specifies the number of pulses to shift the timing value 6. When this option is used, all timing values in the list (including those that are generated by date keywords) are shifted. The PULSE= option specifies the interval to be used.

```
datekeydef NewYearsEve=NEWYEAR / shift=-1 pulse=day;
```

Write the datekey to an output data set. The DATEKEYDATA statement creates an output data set. The CONDENSE option specifies that the output data set be condensed. Any variables that contain only default values are omitted from the data set.

```
datekeydata out=MyHolidays condense;
```

Execute the DATEKEYS procedure.

```
run;
```

Set the EVENTDS= system option. The EVENTDS= system option specifies the data set that defines the event.

```
options eventds=(MyHolidays);
```

Begin the DATEKEYS procedure. The DATEKEYS procedure creates datekeys that are associated with time computations. The DATA= option contains the variables that are used in the ID statement.

```
proc datekeys data=December2010;
```

Specify the ID statement. The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are SAS date values. In addition, the ID statement specifies the desired frequency that is associated with the time series.

```
id date interval=day;
```

Create a data set for a specific locale. The DATEKEYDSOPT statement limits the processing of data sets to a specified locale. When you use this statement, only the datekey definitions with a locale value of en_CA, and datekey definitions with no specified locale, are used to create the AllCAHolidaysInDecember2010 data set.

```
datekeydsopt locale=en_CA;
```

Create a data set that contains variables that indicate the active time periods for datekeys. The DATEKEYCALENDAR statement writes variables that indicate the active time periods for datekeys. The OUT= option is the data set that is created, and contains calendar variables based on the information that is specified in the ID statement.

```
datekeycalendar out=AllCAHolidaysInDecember2010;
```

Execute the DATEKEYS procedure.

```
run;
```

Begin the DATEKEYS procedure. The DATA= option contains the variables that are used in the ID statement.

```
proc datekeys data=December2010;
```

Specify the ID statement. The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are SAS date values. In addition, the ID statement specifies the desired frequency that is associated with the time series.

```
id date interval=day;
```

Create a data set for a specific locale. The DATEKEYDSOPT statement creates a data set that contains only datekey data that is associated with a specified locale. If you specify LOCALE=(ONLY)en_CA, then only the specified locale is processed for both input and output data sets. The locale should be a POSIX locale value.

```
datekeydsopt locale=(ONLY)en_CA;
```

Create a data set that contains variables that indicate the active time periods for datekeys. The DATEKEYCALENDAR statement writes variables that indicate the active time periods for datekeys. The OUT= option specifies the data set that is created, and contains calendar variables based on the information that is specified in the ID statement.

```
datekeycalendar out=OnlyCAHolidaysInDecember2010;
```

Execute the DATEKEYS procedure.

```
run;
```

Write the MyHolidays data set. For results, see Output 18.127 on page 780.

```
proc print data=MyHolidays;
run;
```

Write the AllCAHolidaysInDecember2010 data set. For results, see Output 18.128 on page 781.

```
proc print data=AllCAHolidaysInDecember2010;
run;
```

Write the OnlyCAHolidaysInDecember2010 data set. For results, see Output 18.129 on page 782.

```
proc print data=OnlyCAHolidaysInDecember2010;
run;
```

HTML Output

Output 18.7 *All Holiday Definitions That Are Specified in MyHolidays*

The SAS System

DELETE Procedure

Overview: DELETE Procedure

What Does the DELETE Procedure Do?

The DELETE procedure deletes members in a SAS library. Use PROC DELETE to do the following:

- delete either permanent or temporary SAS files

- delete loaded CAS tables from a caslib. It does not delete the original files from the data source specified by the caslib.
- delete a list of data sets with the same name and a numeric suffix, such as

```
proc delete data=x1-x3;
run;
```

- delete a member type.
- delete generation data sets using the GENNUM= option.
- delete AES-encrypted data sets when using GENNUM=ALL and ENCRYPTKEY= options.

Concepts: DELETE Procedure

Concepts: DELETE Procedure

One of the benefits of using PROC DELETE instead of the DELETE statement in the DATASETS procedure is that it does not use the in-memory directory to delete SAS data sets. As a result, the DELETE procedure is faster.

Syntax: DELETE Procedure

Tip: You can perform similar functions with the DELETE statement in the DATASETS procedure.

PROC DELETE DATA=*SAS-file(s)* <*options*>;

Statement	Task	Example
PROC DELETE	Delete SAS files from SAS libraries	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5

PROC DELETE Statement

Deletes SAS files from SAS libraries.

Syntax

PROC DELETE <LIBRARY=*libref*> DATA=*SAS-file(s)*
(<GENNUM=ALL | HIST | REVERT | *integer*>
<MEMTYPE=*member-type*>
<ENCRYPTKEY=*key-value*>
<ALTER=*alter-password*>);

Summary of Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files.

ENCRYPTKEY=*key-value*
The ENCRYPTKEY= option unlocks the data sets that are protected by an AES-encrypted key value.

GENNUM=ALL | HIST | REVERT | *integer*
restricts processing for generation data sets.

LIBRARY=*libref*
specifies the SAS library that contains members to be deleted.

MEMTYPE=(*member-type(s)*)
restricts deletion to a certain type of SAS file.

Required Argument

DATA= *SAS-file(s)*
specifies one or more SAS files that you want to delete.

Note: You can also use a numbered range list. For more information, see "Data Set Name Lists" in *SAS Programmer's Guide: Essentials*. You cannot use a colon list.

TIP If you want to delete all files in a library, use the PROC DATASETS KILL option. Use `PROC DATASETS LIB=library name KILL` to delete all files including catalogs. For more information, see "KILL" on page 582.

Optional Arguments

ALTER=*alter-password*
provides the Alter password for any alter-protected SAS files.

See "Using Passwords with the DATASETS Procedure" on page 665

ENCRYPTKEY=*key-value*
The ENCRYPTKEY= option unlocks the data sets that are protected by an AES-encrypted key value. The ENCRYPTKEY= option is needed only when a data set must be opened.

See "Example 7: Using the ENCRYPTKEY= Option" on page 793

GENNUM=ALL | HIST | REVERT | *integer*
restricts processing for generation data sets. You use the option in parentheses after the name of each SAS file. The following is a list of valid values:

ALL	refers to the base version and all historical versions in a generation group.
HIST	refers to all historical versions, but excludes the base version in a generation group.
REVERT | 0	deletes the base version and changes the most current historical version, if it exists, to the base version.
integer	is a number that references a specific version from a generation group. Specifying a positive number is an absolute reference to a specific generation number that is appended to a data set's name (that is, `gennum=2` specifies MYDATA#002).

See "Understanding Generation Data Sets" in *SAS Language Reference: Concepts*

"Restricting Processing for Generation Data Sets" on page 667

Examples "Example 1: Deleting Several SAS Data Sets" on page 790

"Example 2: Deleting the Base Version and All Historical Versions" on page 791

"Example 3: Deleting the Base Version and Renaming the Youngest Historical Version to the Base Version" on page 791

"Example 4: Deleting a Version with an Absolute Number" on page 792

"Example 5: Deleting All Historical Versions and Leaving the Base Version" on page 792

LIBRARY=*libref*
specifies the SAS library that contains members to be deleted.

Alias LIB=

MEMTYPE=(*member-type(s)*)
restricts deleting one or more member types. For example, if you have a data set and a catalog named MyFile in the MyLib library and you want to delete only the catalog, then use the MEMTYPE= option.

```
proc delete lib=MyLib data=MyFile (memtype=catalog);
run;
```

ACCESS
access descriptor files (created by SAS/ACCESS software)

CATALOG
SAS catalogs

DATA
SAS data files

FDB
financial database

MDDB
multidimensional database

PROGRAM
stored compiled SAS programs

VIEW
SAS views

Aliases MTYPE=

MT=

Default DATA

Example "Example 6: Using the MEMTYPE= Option" on page 793

Details

Working with Generation Groups

When you are working with generation groups, you can use PROC DELETE to delete the following versions:

- delete the base version and all historical versions. See "Example 2: Deleting the Base Version and All Historical Versions" on page 791.
- delete the base version and rename the youngest historical version to the base version. See "Example 3: Deleting the Base Version and Renaming the Youngest Historical Version to the Base Version" on page 791.
- delete an absolute version. See "Example 4: Deleting a Version with an Absolute Number" on page 792.
- delete all historical versions and leave the base version. See "Example 5: Deleting All Historical Versions and Leaving the Base Version" on page 792.

Deleting Specific Member Types

With the MEMTYPE= option, you can specify the member type that you want to delete. The default for the MEMTYPE= option is DATA. For more information, see "MEMTYPE=(*member-type(s)*)" on page 789.

Working with Integrity Constraints

You cannot use the DELETE procedure to delete a data file that has a foreign key integrity constraint or a primary key with foreign key references. For data files that have foreign keys, you must remove the foreign keys before you delete the data file. For data files that have primary keys with foreign key references, you must remove the foreign keys that reference the primary key before you delete the data file.

Examples: DELETE Procedure

Example 1: Deleting Several SAS Data Sets

Features: PROC DELETE statement options
DATA=
GENNUM=

Details

This example demonstrates the following tasks:

- deletes data sets from a library
- deletes all historical versions of each data set

Program

Delete SAS data sets named A, B, and C from a SAS library named MyLib. The GENNUM= option deletes all the historical versions for each of the data sets.

```
proc delete data=MyLib.A MyLib.B MyLib.C (gennum=all);
run;
```

Example 2: Deleting the Base Version and All Historical Versions

Features: PROC DELETE statement options
DATA=
GENNUM=

Details

This example demonstrates the following tasks:

- deletes a data set from a library
- deletes all historical versions of the data set

Program

Deletes the data set named MyLib.A and all the historical versions.

```
proc delete data=MyLib.A (gennum=all);
run;
```

Example 3: Deleting the Base Version and Renaming the Youngest Historical Version to the Base Version

Features: PROC DELETE statement options
DATA=
GENNUM=

Details

This example demonstrates the following tasks:

- deletes a data set from a library

- renames the youngest historical version

The following statement deletes the data set named MyLib.A and renames the youngest historical version.

Program

Deletes the data set named MyLib.A and renames the youngest historical version.

```
proc delete data=MyLib.A(gennum=revert1);
run;
```

Example 4: Deleting a Version with an Absolute Number

Features: PROC DELETE statement options
DATA=
GENNUM=

Details

This example deletes the first historical version of the data set.

Program

GENNUM= option deletes the first historical version of the data set names MyLib.A. You use GENNUM=*integer* to select the historical version that you want to delete.

```
proc delete data=MyLib.A(gennum=1);
run;
```

Example 5: Deleting All Historical Versions and Leaving the Base Version

Features: PROC DELETE statement options
DATA=
GENNUM=

Details

This example deletes all historical versions except the base version of a data set.

Program

Use the GENNUM=HIST option to delete all historical versions and retain the base version of the data set MyLib.A.

```
proc delete data=MyLib.A(gennum=hist);
run;
```

Example 6: Using the MEMTYPE= Option

Features: PROC DELETE statement options
DATA=
MEMTYPE=

Details

This example deletes the CATALOG file in a specific SAS library.

Program

The MEMTYPE= option names the type of file to delete in a SAS library. If you have other member types named MyFile in the MyLib library, they will not be deleted.

```
proc delete lib=MyLib data=MyFile (memtype=catalog);
run;
```

Example 7: Using the ENCRYPTKEY= Option

Features: PROC DELETE statement options
DATA=

ENCRYPTKEY=
GENNUM=

Details

This example demonstrates the following tasks:

- unlocks an AES encrypted data set
- deletes all historical versions and the base AES data set named MyLib.A.

Program

Deletes the base AES data set named MyLib.A and all historical versions. The ENCRYPTKEY= option must be used if the data set is AES encrypted.

```
proc delete data=MyLib.A (gennum=ALL encryptkey=key-value);
run;
```

Example 8: Using the ALTER= Option

Features:

PROC DELETE statement options
ALTER=
DATA=

Details

This example deletes a password protected data set.

Program

Deletes a password protected data set named MyLib.A. If the data set is password protected, you must supply the password.

```
proc delete data=MyLib.A (alter=alter-password);
run;
```

Example 9: Using the DATA= List Feature

Features: PROC DELETE statement options
DATA=

Program

Deletes multiple data sets named X1, X2, X3, X4, and X5. To use the list feature, the data sets must have the same name and end with a numeric suffix. If a LIBRARY= option is not specified, the data sets are deleted from the Work library.

```
proc delete data=X1-X5;
run;
```

Example 10: Using the LIBRARY= Option

Features: PROC DELETE statement options
DATA=
LIB=

Details

The following statement deletes a data set from a specific SAS library.

Program

Deletes the A data set that is in the specified SAS library named MyLib. The alias for the LIBRARY= option is LIB=.

```
proc delete lib=MyLib data=A;
run;
```

Example 11: Using the LIBRARY= Option and List Feature

Features: PROC DELETE statement options
DATA=
LIB=

Details

This example deletes data sets X1, X2, X3, X4, and X5 in the specified SAS library named MyLib. The alias for the LIBRARY= option is LIB=.

Note: The data sets must end with a numeric suffix.

Program

Deletes data sets X1, X2, X3, X4, and X5 from the specified SAS library named MyLib. When using the list feature, all the data sets must have the same name and end with a numeric suffix. The alias for the LIBRARY= option is LIB=.

```
proc delete lib=MyLib data=X1-X5;
run;
```

20

DISPLAY Procedure

Overview: DISPLAY Procedure

What Does the DISPLAY Procedure Do?

The DISPLAY procedure executes SAS/AF applications. These applications consist of a variety of entries that are stored in a SAS catalog and that have been built with the BUILD procedure in SAS/AF software. For complete documentation on building SAS/AF applications, see *Guide to SAS/AF Applications Development*.

Syntax: DISPLAY Procedure

PROC DISPLAY CATALOG=*libref.catalog.entry.type* <BATCH>;

PROC DISPLAY Statement

Executes a SAS/AF application.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Example: "Example: Executing a SAS/AF Application" on page 799

Syntax

PROC DISPLAY CATALOG=*libref.catalog.entry.type* <BATCH>;

Required Argument

CATALOG=*libref.catalog.entry.type*
specifies a four-level name for the catalog entry.

libref
specifies the SAS library where the catalog is stored.

catalog
specifies the name of the catalog.

entry
specifies the name of the entry.

type
specifies the entry's type, which is one of the following. For details, see the description of catalog entry types in the BUILD procedure in online Help.

- CBT
- FRAME
- HELP
- MENU
- PROGRAM
- SCL

Optional Argument

BATCH
runs PROGRAM and SCL entries in batch mode. If a PROGRAM entry contains a display, then it will not run, and you will receive the following error message:

```
ERROR: Cannot allocate window.
```

Restriction PROC DISPLAY cannot pass arguments to a PROGRAM, a FRAME, or an SCL entry.

Usage: DISPLAY Procedure

Using the DISPLAY Procedure

You can use the DISPLAY procedure to execute an application that runs in NODMS batch mode. Be aware that any SAS programming statements that you submit with the DISPLAY procedure through the SUBMIT block in SCL are not submitted for processing until PROC DISPLAY has executed.

If you use the SAS windowing environment, you can use the AF command to execute an application. SUBMIT blocks execute immediately when you use the AF command. You can use the AFA command to execute multiple applications concurrently.

Example: Executing a SAS/AF Application

Features: PROC DISPLAY statement
CATALOG= argument

Details

Suppose that your company has developed a SAS/AF application that compiles statistics from an invoice database. Further, suppose that this application is stored in the SASUSER library, as a FRAME entry in a catalog named INVOICES.WIDGETS. You can execute this application using the following SAS code.

```
proc display catalog=sasuser.invoices.widgets.frame;
run;
```

21

DS2 Procedure

Overview: DS2 Procedure

What Does the DS2 Procedure Do?

The DS2 procedure enables you to submit DS2 language statements from a Base SAS session. The DS2 procedure is supported in both SAS 9.4 and SAS Viya.

DS2 is a SAS programming language that is appropriate for advanced data manipulation. DS2 is included with Base SAS software and SAS Viya software and shares core features with the SAS DATA step. DS2 exceeds the DATA step by adding variable scoping, user-defined methods, ANSI SQL data types, and user-defined packages. The DS2 SET statement accepts embedded FedSQL syntax, and the runtime-generated queries can exchange data interactively between DS2 and any supported database. This allows SQL preprocessing of input tables, which effectively combines the power of the two languages. For more information about the DS2 language, see *SAS DS2 Language Reference* and *SAS DS2 Programmer's Guide*.

Using the DS2 procedure, you can submit DS2 language statements to SAS and third-party data sources that are accessed with SAS and SAS/ACCESS library engines. If you have SAS Cloud Analytic Services (CAS) configured, you can also submit DS2 language statements to the CAS server.

To execute DS2 jobs in a SAS library, specify the PROC DS2 statement followed by DS2 language statements. Qualify table names in your DS2 language statements with a libref. If you do not specify a libref, the request is executed in the SAS Work library.

To execute DS2 jobs on the CAS server, specify the SESSREF= (or SESSUUID=) option and a CAS session name in the procedure statement. Then, either create tables in the CAS session, load tables from external data sources into the CAS session, or qualify table names in your DS2 language statements with caslibs. A caslib enables you to dynamically load external data into your CAS session for processing.

Note: Do not use a CAS engine libref with PROC DS2. When SESSREF= (or SESSUUID=) are specified, PROC DS2 makes a direct connection to the CAS server. The procedure does not need the CAS engine. The procedure silently passes requests to the DS2.runDS2 action and the action executes your DS2 program on the CAS server.

Concepts: DS2 Procedure

Benefits of the DS2 Language

DS2 programs are written for applications that

- require the precision that results from using the additional data types that are available with the language
- benefit from using the new expressions or write methods or packages available in the DS2 syntax
- need to execute the SAS FedSQL language from within the DS2 program
- execute outside of a SAS session (for example, on SAS Federation Server or the CAS server)
- take advantage of threaded processing in products such as SAS Enterprise Miner and the CAS server.

Data Source Support

When submitting DS2 statements to a SAS library, the DS2 procedure can read and write from the following data sources. Unless noted otherwise, availability starts with SAS 9.4 and SAS Viya 3.3. See SAS/ACCESS documentation for supported operating environments.

Table 21.1 *Data Sources for Which DS2 Supports SAS Library Access*

Data Source	SAS V9	SAS Viya 3.5	Release Notes
Amazon Redshift	*	*	Added in SAS 9.4M5
Aster	*	*	Added in SAS 9.4M1
DB2	*	*	DB2
Greenplum	*	*	

Data Source	SAS V9	SAS Viya 3.5	Release Notes
Google BigQuery	*	*	Added in August 2019, on SAS 9.4M6 and SAS Viya 3.4
Hadoop (Hive)	*	*	Added in SAS 9.4M2
HAWQ	*	*	Added in SAS 9.4M3
Impala	*	*	Added in SAS 9.4M3
databases that are compliant with JDBC	*	*	Added in February 2019, on SAS Viya 3.4 and SAS 9.4M6
Microsoft SQL Server	*	*	Added in SAS 9.4M5
MongoDB	*	*	Read-only support available on SAS 9.4M6, starting in April 2019. Write support available starting in November 2019. Read-and-write support available in SAS Viya 3.5.
MySQL	*	*	
Netezza	*	*	
ODBC-compliant databases	*	*	
Oracle	*	*	
PostgreSQL	*	*	Added in SAS 9.4M2
Salesforce	*	*	Read-only support available on SAS 9.4M6, starting in April 2019. Write support available starting in November 2019.

Data Source	SAS V9	SAS Viya 3.5	Release Notes
			Read-and-write support available in SAS Viya 3.5.
SAP	*	*	Read-only
SAP HANA	*	*	Added in SAS 9.4M1
SAP IQ	*	*	
SAS data sets	*	*	Added in SAS Viya 3.1
SAS Scalable Performance Data (SPD) Engine data sets	*	*	
SAS Scalable Performance Data (SPD) Server tables	*	*	Added in SAS 9.4M4 SPD Server SAS Viya access is client only
Snowflake	*	*	Added in August 2019, on SAS 9.4M6 and SAS Viya 3.4
Spark	*		Spark execution of PROC DS2 with the SAS Code Accelerator for Hadoop can be enabled by setting the HADOOPPLATFORM =SPARK system option starting in SAS 9.4M6. SAS/ACCESS to Spark is available on Linux only in SAS 9.4M7.
Teradata	*	*	Teradata
Vertica	*	*	Added in SAS 9.4M5
Yellowbrick	*		SAS/ACCESS to Yellowbrick is limited

Data Source	SAS V9	SAS Viya 3.5	Release Notes
			availability for SAS 9.4 only, starting in SAS 9.4M7.

When submitting DS2 statements to the CAS server, the procedure reads data from files and in-memory tables and creates CAS session tables. A caslib uses a SAS Data Connector (or SAS Data Connector Accelerator) to access data from a corresponding data source for processing in CAS. For information about available SAS Data Connectors, see *SAS Cloud Analytic Services: User's Guide*. DS2 output tables in CAS are in-memory tables. You must use other actions to persist data to caslib data sources.

For information about how to connect to a data source with PROC DS2, see "Data Source Connection" on page 814.

Syntax: DS2 Procedure

PROC DS2 <*connection-option*><*processing-options*>;

...DS2 language statements

RUN;

RUN CANCEL;

QUIT;

Statement	Task	Example
PROC DS2	Specify that the subsequent input is DS2 language statements.	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5
RUN CANCEL	Cancel the previous DS2 language statements.	Ex. 3

PROC DS2 Statement

Specifies that the subsequent input is DS2 language statements.

Requirement: Follow the PROC DS2 statement with DS2 language statements. See *SAS DS2 Language Reference* for information about DS2 language statements.

Interactions: The DS2 procedure requires the RUN statement to submit DS2 statements. That is, SAS reads the program statements that are associated with one task until it reaches a RUN statement.

By default, the procedure processes non-existent numeric values as SAS missing values. To request that non-existent values are processed as ANSI SQL null values, specify ANSIMODE.

When creating tables with PROC DS2, note that by default, you cannot overwrite an existing table. To specify that an output table should be deleted before a replacement output table is created, use the OVERWRITE=YES table option. For information about the OVERWRITE= table option, see *SAS DS2 Language Reference*.

Note: As of September 2023, Microsoft Azure Active Directory (Azure AD) was renamed to Microsoft Entra ID.

Examples:

"Example 1: Introducing DS2 Code" on page 826

"Example 2: Creating a SAS Data Set" on page 828

"Example 3: Terminating the Current Step in Line Prompt Mode" on page 830

"Example 4: Routing Data to Tables Based on Values" on page 831

"Example 5: Run a DS2 Program in CAS" on page 833

Syntax

PROC DS2 <*connection-option* ><*processing-options*>;

Summary of Optional Arguments

Connection

LIBS=*libref* | (*libref1libref2 ...librefn*)
: restricts the default data source connection to the specified libref(s). All other librefs are ignored.

SESSREF=*session-name*
: specifies to run the DS2 statements in a CAS session. The CAS session is identified by its session name.

SESSUUID="*session-uuid*"
: specifies to run the DS2 statements in a CAS session. The CAS session is identified by its universally unique identifier (UUID).

General Processing

ANSIMODE
: specifies that nonexistent values in CHAR and DOUBLE columns are processed as ANSI SQL null values.

BYPARTITION=YES | NO
: determines whether the input data for the DS2 program is automatically re-partitioned when executed inside the database with in-database processing.

DS2ACCEL=NO | YES
: determines whether DS2 code is enabled for parallel processing in supported environments using the SAS In-Database Code Accelerator.

ERRORSTOP | NOERRORSTOP
: specifies whether the procedure stops executing if it encounters an error.

LABEL | NOLABEL
: specifies whether to use the column label or the column name as the column heading.

MEMSIZE=n | nM | nG
: specifies a limit for the amount of memory that is used for an underlying query (such as a SELECT statement), so that allocated memory is available to support other PROC DS2 operations.

NUMBER
: specifies to include a column named Row, which is the row (observation) number of the data as the rows are retrieved.

SCOND=WARNING | NONE | NOTE | ERROR
: specifies the level of messages that PROC DS2 displays in the SAS log for the DS2 variable declaration strict mode, which requires that every variable must be declared in the DS2 program.

STIMER
: specifies to write a subset of system performance statistics, such as time-elapsed statistics, to the SAS log.

XCODE=ERROR | WARNING | IGNORE
: controls the behavior of the SAS session when an NLS transcoding failure occurs.

Optional Arguments

ANSIMODE
specifies that nonexistent values in CHAR and DOUBLE columns are processed as ANSI SQL null values. By default, PROC DS2 processes nonexistent values in CHAR and DOUBLE columns as missing values. This is how SAS processes nonexistent values. The ANSIMODE option specifies to process nonexistent values in CHAR and DOUBLE columns as ANSI SQL null values. It is important to understand the differences, or data can be lost. For information about processing differences, see “How DS2 Processing Nulls and SAS Missing Values” in *SAS DS2 Programmer’s Guide*. All other data types use ANSI NULL semantics all of the time.

Default SAS mode

BYPARTITION=YES | NO
determines whether the input data for the DS2 program is automatically re-partitioned when executed inside the database with in-database processing.

YES
specifies that the input data is automatically re-partitioned by the first BY variable. All of the BY groups are in the same data partition and processed by the same thread. Each thread does the BY processing for the entire group of data.

NO
specifies that the input data is not re-partitioned even if there is a BY statement in the DS2 program. Each group of data resides on different data partitions and is processed by different DS2 threads. Each thread gets partial

data from a group, and each group is processed by multiple threads. The DS2 program must request the final aggregation of data.

Default YES

Restrictions BYPARTITION= is supported only for SAS libraries.

BYPARTITION= is not supported in SAS Viya.

BYPARTITION=NO is not supported in SAS In-Database Code Accelerator for Hadoop.

DS2ACCEL=NO | YES

determines whether DS2 code is enabled for parallel processing in supported environments using the SAS In-Database Code Accelerator. The SAS In-Database Code Accelerator enables you to publish a DS2 thread program to the database and execute the thread program in parallel inside the database. If you are using Hadoop or Teradata, then the DS2 data program is also published and executed inside the database.

NO

disables DS2 code from executing in supported parallel environments. The DS2 code is executed in the Base SAS session.

YES

enables DS2 code to execute in supported parallel environments.

Alias INDB=

Default The default value is determined by the DS2ACCEL= system option. The default value for the system option is NO. The SAS In-Database Code Accelerator is not automatically executed in supported parallel environments. For information about the DS2ACCEL= system option, see *SAS DS2 Language Reference*.

Restrictions DS2ACCEL= is supported for SAS libraries only.

DS2ACCEL= is not supported in SAS Viya.

DS2ACCEL= is not supported for all data sources.

Interaction The DS2ACCEL= procedure option takes precedence over the DS2ACCEL= system option.

Notes The INDB= option was added in SAS 9.4M1 and was renamed to DS2ACCEL= in SAS 9.4M2.

The DS2ACCEL= system option can be restricted by a site administrator. If the system option is restricted, then it cannot be overridden by the DS2ACCEL= procedure option.

See “Threaded Processing” and “SAS In-Database Code Accelerator” in *SAS DS2 Programmer’s Guide*

“Using the SAS In-Database Code Accelerator” in *SAS In-Database Products: User’s Guide*

ERRORSTOP | NOERRORSTOP

specifies whether the procedure stops executing if it encounters an error. In a batch or noninteractive session, ERRORSTOP instructs the procedure to stop executing the statements but to continue checking the syntax after it has encountered an error. NOERRORSTOP instructs the procedure to execute the statements and to continue checking the syntax after an error occurs.

Default NOERRORSTOP in an interactive SAS session; ERRORSTOP in a batch or noninteractive session

Tips ERRORSTOP has an effect only when SAS is running in a batch or noninteractive execution mode.

NOERRORSTOP is useful if you want a batch job to continue executing procedure statements after an error is encountered.

LABEL | NOLABEL

specifies whether to use the column label or the column name as the column heading.

Default LABEL

Interactions If a column does not have a label, the procedure uses the column's name as the column heading.

A column alias overwrites the label or column name as the column heading.

LIBS=*libref* | (*libref1libref2 ...librefn*)

restricts the default data source connection to the specified libref(s). All other librefs are ignored. When you specify a list of librefs, the order of the list defines the library order.

Alias LIBNAMES=

Restriction LIBS= is supported only for SAS libraries.

Interactions If both LIBS= and SESSREF= (or SESSUID=) are specified in the procedure statement, SESSREF= is applied and the other option is ignored.

If LIBS= is specified multiple times, the last one on the procedure statement is applied.

Note LIBS= is available starting in SAS 9.4M3

Tips LIBS= is useful when multiple LIBNAME statements are defined in a SAS session, to limit the scope of the DS2 program to only the LIBNAME statement(s) to which the program applies. It can also avoid duplicate catalog errors when connecting to data sources that support native catalogs, such as Netezza.

If you are curious about how LIBS= affects library assignments, set the MSGLEVEL=i system option before running a PROC DS2 request with LIBS=. The option produces Include and Ignore

messages for each of the LIBNAME statements that are processed in the procedure request.

See "Data Source Connection" on page 814

"About the LIBS= Procedure Option" on page 815

Example The following PROC DS2 procedure statement specifies to create a data source connection that uses only librefs MyLib3 and MyLib4.

```
proc ds2 libs=(mylib3 mylib4);
```

MEMSIZE=n | nM | nG

specifies a limit for the amount of memory that is used for an underlying query (such as a SELECT statement), so that allocated memory is available to support other PROC DS2 operations. Specify the memory limit in multiples of 1 (bytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). For example, the value 23M specifies 24,117,248 bytes of memory. The value 16G specifies 17,179,869,184 bytes of memory.

Default The procedure optimizes the setting based on the amount of memory on the host.

Note On the CAS server, MEMSIZE= specifies the memory for a single worker.

Tip Generally, specifying a memory limit is not necessary unless DS2 reports a memory problem error.

NUMBER

specifies to include a column named Row, which is the row (observation) number of the data as the rows are retrieved.

Default No row numbers.

SCOND=WARNING | NONE | NOTE | ERROR

specifies the level of messages that PROC DS2 displays in the SAS log for the DS2 variable declaration strict mode, which requires that every variable must be declared in the DS2 program. For more information about the DS2 variable declaration strict mode, see the *SAS DS2 Language Reference*.

WARNING

writes warning messages to the SAS log.

NONE

no messages are written to the SAS log.

NOTE

writes notes to the SAS log.

ERROR

writes error messages to the SAS log.

Default The default is determined by the DS2SCOND= system option. The default for DS2SCOND= is WARNING. For information about the DS2SCOND= system option, see *SAS DS2 Language Reference*.

Interaction Specifying the SCOND= option in the PROC DS2 statement takes precedence over the DS2SCOND= system option.

SESSREF=*session-name*
specifies to run the DS2 statements in a CAS session. The CAS session is identified by its session name.

Requirements A CAS server must be configured for your system.

The CAS session must have been previously established by using the CAS statement. If the specified CAS session does not exist, the procedure terminates.

Interactions Use SESSREF= (or SESSUUID=) to connect to the CAS session. If both options are specified, the last option in the procedure statement is applied.

If both SESSREF= and LIBS= are specified in the procedure statement, SESSREF= is applied and the other option is ignored.

Note This option is supported in SAS Viya 3.1 and later and in SAS 9.4M5 and later.

See “Connecting to the CAS Server” on page 816

“Using PROC DS2 in SAS Cloud Analytic Services” on page 817

“Example 5: Run a DS2 Program in CAS” on page 833

SESSUUID="*session-uuid*"
specifies to run the DS2 statements in a CAS session. The CAS session is identified by its universally unique identifier (UUID).

Requirements A CAS server must be configured for your system.

The CAS session must have been previously established by using the CAS statement. The CAS statement generates a UUID value. If the specified CAS session does not exist, the procedure terminates.

Interactions Use SESSUUID= (or SESSREF=) to connect to the CAS session. If both options are specified, the last option in the procedure statement is applied.

If both SESSUUID= and LIBS= are specified in the procedure statement, SESSUUID= is applied and the other option is ignored.

Note This option is supported in SAS Viya 3.1 and later and in SAS 9.4M5 and later.

See “Connecting to the CAS Server” on page 816

“Using PROC DS2 in SAS Cloud Analytic Services” on page 817

Example Here is a PROC DS2 procedure statement that specifies SESSUUID=:

```
proc ds2 sessuuid="76904741-fb09-554d-a8de-6cbce2a0e0e5";
```

The UUID value can be enclosed in single or double quotation marks.

STIMER
specifies to write a subset of system performance statistics, such as time-elapsed statistics, to the SAS log. When STIMER is in effect, the procedure writes to the SAS log a list of computer resources used for each step and the entire SAS session.

Default No performance statistics are written to the SAS log.

Interaction If the SAS system option FULLSTIMER is in effect, the complete list of computer resources is written to the SAS log.

XCODE=ERROR | WARNING | IGNORE
controls the behavior of the SAS session when an NLS transcoding failure occurs. Transcoding failures can occur during row input or output operations, or during string assignment. Transcoding is the process of converting character data from one encoding to another encoding.

ERROR
specifies that a run-time error occurs, which causes row processing to halt. An error message is written to the SAS log. This is the default behavior.

WARNING
specifies that the incompatible character is set to a substitution character. A warning message is written to the SAS log.

IGNORE
specifies that the incompatible character is set to a substitution character. No messages are written to the SAS log.

Default ERROR

Note This option was added in SAS 9.4M2.

RUN CANCEL Statement

Cancels the previous DS2 language statements.

Tip: The RUN CANCEL statement is useful if you enter a typographical error.

Example: "Example 3: Terminating the Current Step in Line Prompt Mode" on page 830

Syntax

RUN CANCEL;

Usage: DS2 Procedure

Data Source Connection

PROC DS2 can execute programs in SAS libraries (librefs) and on the CAS server. By default, PROC DS2 connects to a data source by using available librefs. You can override this default behavior by specifying CAS connection options. The DS2 procedure is not affected by the CASNAME= system option.

Understanding the Default Data Source Connection

PROC DS2 connects to a data source by using the attributes of currently assigned librefs. These librefs are defined by LIBNAME statements. Attributes include the physical location of the data, and for some data sources, access information such as network information used to access the data server, and user identification and password.

1 You first submit the LIBNAME statement for a SAS engine. For information to define a LIBNAME statement, see:

SAS data sets
SAS Global Statements: Reference

Relational DBMS data sources
SAS/ACCESS for Relational Databases: Reference

MongoDB and Salesforce
SAS/ACCESS for Nonrelational Databases: Reference

SPD Engine data sets
SAS Scalable Performance Data Engine: Reference

SPD Server tables
SAS Scalable Performance Data Server: User's Guide

2 In your DS2 program, use a two-part name in the form *libref.table-name* to refer to tables. The libref tells the program where to create or locate a table.

3 Then, submit the DS2 procedure.

This example illustrates how PROC DS2 accesses a data source by using the attributes of a previously assigned libref. The LIBNAME statement assigns the libref MyFiles, specifies the BASE engine, and then specifies the physical location

for the SAS data set. The DS2 program then creates the SAS data set MyFiles.Table1 at the location specified in the LIBNAME statement.

```
libname myfiles base 'C:\myfiles';

proc ds2;
   data myfiles.table1;
      dcl double j j2;
      method run();
         do j = 1 to 1000;
            j2 = 2*j;
            output;
         end;
      end;
   enddata;
run;
quit;
```

The DS2 procedure builds a data source connection string that includes all active librefs and sends it to the DS2 program. You reference a particular library by specifying its libref in a two-part table name in the form *libref.table-name*. If you do not specify a libref, the table is created in the SAS Work library.

PROC DS2 uses libref attributes for connection information only (such as physical location). PROC DS2 generally does not use libref attributes that define behavior. For example, if a previously submitted LIBNAME statement for the BASE engine specifies that SAS data sets are to be compressed, the compression attribute is not used by the procedure. There are exceptions. For example, the MAX_BINARY_LEN= and MAX_CHAR_LEN= for Google BigQuery are included in the internal connection string.

You can determine which LIBNAME options are used by the procedure by setting the MSGLEVEL=i system option before submitting a LIBNAME statement. For many data sources, you can specify a DS2 table option to override a LIBNAME option. For example, the COMPRESS= table option can be used to request compression of SAS data sets. The SCANSTRINGCOLUMNS= table option can be used to override the MAX_CHAR_LEN= LIBNAME option. Not all LIBNAME statement options have a corresponding table option.

Note: PROC DS2 connects immediately, so an error is generated if the LIBNAME statement includes the DEFER=YES option.

z/OS Specifics: The physical location for the libref must be an HFS path specification.

About the LIBS= Procedure Option

When multiple librefs are active in the SAS session, you might want to include the LIBS= option in the PROC DS2 statement. LIBS= restricts the data source connection to the specified libref or librefs and the default library. Work is the default library unless a User library is assigned.

You must continue to qualify table names with a libref, even when LIBS= specifies only one library; otherwise, the default library is used.

The following example illustrates the use of the LIBS= option. In the example, two librefs are assigned in the SAS session: AllFiles and MyFiles. The LIBS= option specifies to use libref MyFiles only.

```
libname allfiles 'C:\sharedfiles';
libname myfiles base 'C:\myfiles;

proc ds2 libs=myfiles;
   data myfiles.table1;
      dcl double j j2;
      method run();
         do j = 1 to 1000;
            j2 = 2*j;
            output;
         end;
      end;
   enddata;
run;
quit;
```

For more information, see "LIBS=*libref* | (*libref1 libref2 ...librefn*)" on page 810.

Connecting to the CAS Server

You connect to a CAS session on the CAS server by specifying the SESSREF= (or SESSUUID=) procedure option with a CAS session name. When SESSREF= (or SESSUUID=) is specified, both the default connection mechanism and the LIBS=option are ignored. Instead, the procedure connects to the specified CAS session.

Note: You must have a CAS server configured. You must first submit the CAS statement to establish the CAS session. To interact with data in a CAS session, you need a caslib. You must first define a caslib or use a pre-defined caslib. You define a caslib and list the caslibs that are available to your CAS session by using the CASLIB statement. For syntax information, see *SAS Cloud Analytic Services: User's Guide*. A caslib uses a SAS Data Connector (or SAS Data Connector Accelerator) to access data. For information about SAS Data Connectors, see *SAS Cloud Analytic Services: User's Guide*.

Use a two-part name in the form *caslib.table-name* to identify tables in your DS2 statements. The following example illustrates a PROC DS2 request to the CAS server.

```
options cashost="cloud.example.com" casport=5570;
cas mysess;

caslib castera desc='Teradata Caslib'
   datasource=(srctype='teradata'
      username='myname'
```

```
      password='mypw'
      server='testserver',
      db='testdb');

proc ds2 sessref=mysess;
   data newtable;
     method run();
       set {select * from castera.employees};
     end;
enddata;
run;
quit;
```

This example establishes a CAS session named MySess on a CAS server on CAS host cloud.example.com. It then uses the CASLIB statement to assign caslib CASTERA. The PROC DS2 statement specifies the SESSREF= procedure option and the CAS session name MySess. The FedSQL SELECT statement in the DS2 SET statement identifies table Employees using the CASTERA caslib.

SAS Viya data connectors support explicit and automatic (shown here) loading of data into CAS. For an example that explicitly loads data, see "Example 5: Run a DS2 Program in CAS" on page 833.

The tables that you create with PROC DS2 are in-memory CAS tables. That is, the tables are available for the duration of the CAS session and are accessible only to the current session. PROC DS2 does not provide a way to persist a table to a data source or to share the table with other CAS sessions. To persist or share a CAS table, use the CASUTIL procedure.

Note: Although CAS tables are in-memory tables, you must specify the OVERWRITE= table option to overwrite an initial output table with a replacement output table.

For more information, see:

- *SAS Cloud Analytic Services: Fundamentals*
- CAS statement, CASLIB statement, and CASUTIL procedure in *SAS Cloud Analytic Services: User's Guide*

Using PROC DS2 in SAS Cloud Analytic Services

SAS Cloud Analytic Services is an alternative environment for processing DS2 requests. When you specify the SESSREF= (or SESSUUID=) option, PROC DS2 prepares and executes your DS2 programs on a CAS server. When you run PROC DS2 with SESSREF= or SESSUUID=, you are actually using the runDS2 action. Unless you are using Lua, Python, or R, it is recommended that you use PROC DS2 to submit your DS2 programs to the CAS server instead of the runDS2 action. There are advantages of using PROC DS2. For more information, see the runDS2 action in the *SAS Viya: System Programming Guide*.

The CAS server is a symmetric multiprocessing (SMP) server. A DS2 program executing on the CAS server can perform manipulations on multiple data observations concurrently, thereby reducing the time required to process large data sets. Based on the structure of the DS2 program, the DS2 compiler determines which operations can be performed on multiple observations concurrently. It also determines which operations must be applied to each observation sequentially.

A DS2 program is classified as either a serial program, a parallel program, or a parallel-serial program. In order to benefit from the CAS server, the DS2 program must be structured as either a DS2 parallel program or a DS2 parallel-serial program.

- A DS2 parallel program contains no operations with data dependencies across observations. Therefore, multiple data observations can be processed in parallel. Each CAS worker can process a subset of the input data and generate a subset of the result set.
- A DS2 parallel-serial program contains some operations with data dependencies across observations and some operations without data dependencies. The processing of the operations is divided into two stages: a parallel stage and a serial stage. During the parallel stage, each CAS worker processes a subset of the input data set and generates a subset of an intermediate data set. During the serial stage, one CAS worker processes the complete intermediate data set and generates the complete result set.

Most of the functionality of the DS2 language is supported for use on the CAS server. However, there are some exceptions. For information about the DS2 functionality that is supported in CAS, see *SAS DS2 Programmer's Guide*.

For an example of how a DS2 parallel program is submitted to the CAS server, see "Example 5: Run a DS2 Program in CAS" on page 833.

DS2 output tables in CAS are in-memory tables. The tables are created in the user's CAS session. You must use other CAS actions to promote the output tables for global use in CAS or to store data to caslib data sources.

RUN-Group Processing

PROC DS2 supports RUN-group processing. RUN-group processing enables you to submit RUN groups without ending the procedure.

To use RUN-group processing, you start the procedure and then submit multiple RUN-groups. A RUN-group is a group of statements that contains at least one action statement and ends with a RUN statement. As long as you do not terminate the procedure, it remains active and you do not need to resubmit the PROC statement.

Note: When using PROC DS2, DS2 programs are delimited by RUN statements. If additional DS2 code is found after a RUN statement, then this code composes a new, distinct DS2 program from the DS2 program before the previous RUN statement.

To end RUN-group processing, submit a RUN CANCEL statement. Statements that have not been submitted are terminated. To stop the procedure, submit a QUIT statement. Statements that have not been submitted are terminated as well.

Applying DS2 Table Options

When you access a data source with PROC DS2, you can apply DS2 table options in the subsequent DS2 statements. A table option specifies actions that enable you to perform operations on a table such as assigning buffer page size or specifying passwords. A DS2 table option performs much of the same functionality as a Base SAS data set option.

DS2 table options are used to apply options when you access a data source within PROC DS2. For example, the following code applies a table option to the SAS data set to specify the size of a permanent buffer page for the new table:

```
libname myfiles base 'C:\myfiles';

proc ds2;
   data myfiles.table1 (bufsize=16k);
      dcl double j j2;
      method run();
         do j = 1 to 1000;
            j2 = 2*j;
            output;
         end;
      end;
enddata;
run;
quit;
```

For a list of available table options, see *SAS DS2 Language Reference*.

Using Macro Variables in a Literal String

Note: The information in this section applies to PROC DS2 use in a libref.

Macro variables enable you to dynamically modify text in a program through symbolic substitution. When you reference a macro variable in a program, the macro processor replaces the reference with the value of the specified macro variable.

With PROC DS2, you can use a macro variable on a subsequent DS2 statement. However, if a macro variable occurs within a literal string, you cannot enclose the string in double quotation marks. The macro processor requires double quotation marks to resolve the macro variable reference. DS2 statements consider a string enclosed in double quotation marks to be a delimited (case sensitive) identifier such as a table or column name.

To reference a macro variable in a literal string, use the SAS macro function %TSLIT. %TSLIT overrides the need for double quotation marks around the literal string and puts single quotation marks around the input value. For example, the following statement includes the %TSLIT function to specify the &SYSHOSTNAME macro variable, which returns the host name of the computer on which it is executed:

```
if hostname = %tslit(&syshostname) then ...
```

The %TSLIT macro function is stored in the default autocall macro library. For more information, see “Referencing a Macro Variable in a Delimited Identifier” in the *SAS DS2 Programmer’s Guide*.

DS2 Automatic Variables

The DS2 language sets up automatic variables with certain values after it executes each statement. These automatic variables are useful for subsetting a problem across DS2 threads. They are also useful for providing context when debugging with PUT statements.

Table 21.2 *DS2 Automatic Variables*

Variable	Description
HOSTNAME	Returns the name of the worker node or host on which the DS2 program is running.
NTHREADS	Returns the total number of DS2 threads running in the program. In a parallel environment, _NTHREADS_ is the total number of DS2 threads across all nodes on which the DS2 program is running.
THREADID	Returns the _THREADID_. A serial program (which does not contain a thread component) is assigned _THREADID_ = 0. In a parallel program, the executing data program is assigned _THREADID_ = 0 and each executing thread program is assigned a unique _THREADID_ from 1 to the number of threads.

Here is an example of how the automatic variables might be used:

```
proc ds2;
thread thd / overwrite = yes;
  dcl double x;
  method init();
    put 'THREAD: thread' _threadid_ 'on' _hostname_;
  end;
endthread;

data _null_;
  dcl thread thd t;
  method init();
```

```
      put 'DATA: thread' _threadid_ 'on' _hostname_;
    end;
    method run();
      set from t threads=8;
    end;
  enddata;
  run;
  quit;
```

Passwords

SAS software enables you to restrict access to SAS data sets and SPD Engine data sets by assigning SAS passwords to the files. You can specify three levels of protection: read, write, and alter.

With PROC DS2, you assign or specify a password for a data source using the DS2 table options ALTER=, PW=, READ=, and WRITE=. For example, the following code applies the DS2 table option PW= in order to assign READ, WRITE, and ALTER passwords to a SAS data set:

```
libname myfiles base 'C:\myfiles';

proc ds2;
   data myfiles.table1 (pw=luke);
      dcl double j j2;
      method run();
         do j = 1 to 1000;
            j2 = 2*j;
            output;
         end;
      end;
enddata;
run;
quit;
```

A SAS password does not control access to a SAS file beyond SAS. You should use the operating system-supplied utilities and file system security controls to control access to SAS files outside SAS. For more information about SAS passwords, see "Assigning Passwords" in *SAS Programmer's Guide: Essentials*..

CAS tables do not support SAS passwords. Therefore, you cannot assign a password for a CAS table. When accessing password-protected data from CAS, passwords are specified in the CAS language element used to access the data. For example, passwords are supported in the CASUTIL procedure, which loads data into CAS, as well as in the CASLIB statement and in the Table.addCaslib action. For more information, see the SAS Viya SAS Data Connector documentation in *SAS Cloud Analytic Services: User's Guide*.

Encryption

SAS software enables you to encrypt the contents of a SAS data set, SPD Engine data set, and SPD Server table. SAS supports SAS proprietary encryption and AES encryption.

SAS proprietary encryption is performed by specifying the ENCRYPT= table option with the PW= or READ= table option. A data set or table encrypted with SAS proprietary encryption must be decrypted by specifying the PW= or READ= table option with the appropriate password.

AES encryption is performed by specifying the ENCRYPT= table option with the ENCRYPTKEY= table option. A data set or table encrypted with AES encryption is later decrypted by specifying the ENCRYPTKEY= table option with the appropriate key value.

Beginning with SAS 9.4M5, SAS supports two levels of AES encryption: AES and AES2. The new AES2 option provides AES encryption to meet newer and more secure encryption standards. You must specify the ENCRYPTKEY= table option when using AES or AES2 encryption. AES2 encryption is initially supported for SAS data sets only. For more information, see "ENCRYPT=" in *SAS DS2 Language Reference*.

DS2 currently does not support the encryption attribute for CAS tables. When accessing SAS and AES encrypted data sets from CAS, passwords and encryption keys are specified in the CAS language element that is used to access the data. For example, passwords and encryption keys are supported in the CASUTIL procedure, which loads data into CAS, as well as in the CASLIB statement and in the Table.addCaslib action. For more information, see the SAS Viya SAS Data Connector documentation in *SAS Cloud Analytic Services: User's Guide*.

DS2 Data Type Support for SAS Data Sets

In PROC DS2, when you submit DS2 statements, all DS2 language data types are supported. For information about the DS2 data types, see *SAS DS2 Language Reference*. However, when reading and creating data, the DS2 data types are translated to and from the data types of the target data source. When submitting statements to read or to create a Base SAS data set, DS2 data types are translated to and from the SAS numeric and SAS character data types. The following table lists the DS2 data types and how they are translated to and from SAS data types:

Table 21.3 *DS2 Data Type Translation for SAS Data Sets*

DS2 Data Type	Legacy SAS Data Type	Description
BIGINT	SAS numeric	Because a SAS numeric is a DOUBLE, there is potential for loss of precision. DOUBLE is an approximate numeric data type rather than an exact numeric data type
BINARY(*n*)	SAS character	Applies the SAS format $n.
CHAR(*n*)	SAS character	Applies the SAS format $n.
DATE	SAS numeric	Applies the SAS format DATE9. Valid SAS date values are in the range from 1582-01-01 to 9999-12-31. Dates outside the SAS date range are not supported and are treated as invalid dates.
DECIMAL| NUMERIC(*p*,*s*)	SAS numeric	
DOUBLE	SAS numeric	
FLOAT	SAS numeric	
INTEGER	SAS numeric	
NCHAR(*n*)	SAS character	Applies the SAS format $n.
NVARCHAR(*n*)	SAS character	Applies the SAS format $n.
REAL	SAS numeric	
SMALLINT	SAS numeric	
TIME(*p*)	SAS numeric	Applies the SAS format TIME8.
TIMESTAMP(*p*)	SAS numeric	Applies the SAS format DATETIME19.2.
TINYINT	SAS numeric	
VARBINARY(*n*)	SAS character	Applies the SAS format $n.
VARCHAR(*n*)	SAS character	Applies the SAS format $n.

DS2 Data Type Support for CAS Tables

Beginning with SAS Viya 3.5, DS2 can create, read, and write VARBINARY columns in CAS, in addition to BIGINT, CHAR(n), DOUBLE, INTEGER, and VARCHAR columns. When writing data to the CAS server, some DS2 data types are translated to and from these data types, but not all of them. The following table lists the DS2 data types and how they are translated to and from CAS data types.

Table 21.4 *DS2 Data Type Translation for CAS Tables*

DS2 Data Type	CAS Data Type	Description
BIGINT[1]	INT64	Large signed, exact whole number.
BINARY(*n*)	Not supported[3]	
CHAR(*n*)	CHAR	Applies the SAS format $*n*. Stores a fixed-length character string, where *n* is the maximum number of characters to store. The maximum number of characters is required to store each value regardless of the actual size of the value. If char(10) is specified and the character string is only five characters long, the value is right-padded with spaces.
DATE	DOUBLE	Applies the SAS format DATE9. Valid SAS date values are in the range from 1582-01-01 to 9999-12-31. Dates outside of the SAS date range are not supported and are treated as invalid dates.
DECIMAL| NUMERIC(*p*,*s*)	Not supported	
DOUBLE	DOUBLE	Stores a signed, approximate, double-precision, floating-point number. Allows numbers of large magnitude and permits computations that require many digits of precision to the right of the decimal point. For SAS Cloud Analytic Services, this is a 64-bit double precision, floating-point number.
FLOAT	DOUBLE	

DS2 Data Type	CAS Data Type	Description
INTEGER[1]	INT32	Regular signed, exact whole number.
NCHAR(*n*)	CHAR	Applies the SAS format $*n*.
NVARCHAR(*n*)	VARCHAR	
REAL	DOUBLE	
SMALLINT	INT32	Small signed, exact whole number.
TIME(*p*)	DOUBLE	Applies the SAS format TIME8.
TIMESTAMP(*p*)	DOUBLE	Applies the SAS format DATETIME25.6.
TINYINT	INT32	Very small signed, exact whole number.
VARBINARY(*n*)[2]	VARBINARY	Varying-length binary opaque data. This data type is used to store image data, audio, documents, and other unstructured data.
VARCHAR(*n*)	VARCHAR	Stores a varying-length character string.

1 Support for the integer data types starts with SAS Viya 3.3.

2 Beginning with SAS Viya 3.5, a DS2 program that runs in CAS can read and create a column with a VARBINARY data type in a CAS table. It can also write to an existing VARBINARY column in a CAS table. In earlier SAS Viya releases, DS2 does not return an error when reading VARBINARY columns. However, the data is incorrectly treated as character data.

3 Beginning with SAS Viya 3.5, a DS2 program that runs in CAS can create a column with a BINARY data type. However, it cannot read a BINARY data column from a CAS table or write to an existing BINARY column in a CAS table. DS2 returns an error if an attempt is made to do so. Use the DROP data set option to exclude BINARY columns when reading or writing to a CAS table that contains a BINARY column. In earlier SAS Viya releases, no error was reported when reading BINARY columns. However, the data was not read correctly.

CAS tables use the UTF-8 character set by default.

Date, time, and timestamp values in CAS tables are supported as DOUBLEs, with a SAS format applied. When SAS Viya Data Connectors read DATE, TIME, and TIMESTAMP columns from an ANSI-compliant data source, they convert the columns to data type DOUBLE. DS2 applies a DATE. SAS format to date values, a TIME. SAS format to time values, and a DATETIME. SAS format to datetime values.

Examples: DS2 Procedure

Example 1: Introducing DS2 Code

Features:
- PROC DS2 statement
- LIBS= procedure option
- QUIT statement
- DS2 language statements

Details

This example uses a simple DS2 program that displays **`Hello World!`** in the SAS log. The example shows basic differences between DS2 and the SAS DATA step. The code looks similar to the SAS DATA step, but there are syntax elements that are different, such as default system methods (INIT, RUN, and TERM). Also, DS2 supports the most common SQL data types such as DECIMAL, INTEGER, and VARCHAR to make operations more native for DBMS data.

Program

```
proc ds2 libs=work;

data _null_;
   method init();
      dcl varchar(16) str;
      str = 'Hello World!';
      put str;
   end;
enddata;

run;

quit;
```

Program Description

Execute the PROC DS2 statement. The LIBS= connection option specifies to execute the request in the SAS Work library. The PROC DS2 statement sets up the environment to submit DS2 language statements.

```
proc ds2 libs=work;
```

Enter the DS2 language statements. _NULL_ on the DS2 DATA statement indicates that there is no automatic output generated. The DS2 PUT statement writes to the SAS log.

```
data _null_;
   method init();
      dcl varchar(16) str;
      str = 'Hello World!';
      put str;
   end;
enddata;
```

Submit the DS2 statements. The RUN statement submits the DS2 statements. The RUN statement is required. SAS reads the program statements that are associated with one task until it reaches a RUN statement.

```
run;
```

Stop the procedure. The QUIT statement stops the procedure.

```
quit;
```

Example Code 21.1 *SAS Log Showing Hello World!*

```
48   proc ds2 libs=work;
49   data _null_;
50      method init();
51         dcl varchar(16) str;
52         str = 'Hello World!';
53         put str;
54      end;
55   enddata;
56   run;
Hello World!
NOTE: Execution succeeded. No rows affected.
57   quit;

NOTE: PROCEDURE DS2 used (Total process time):
      real time           16.38 seconds
      cpu time            0.15 seconds
```

Example 2: Creating a SAS Data Set

Features:
PROC DS2 statement
LIBS= procedure option
QUIT statement
LIBNAME statement
DS2 language statements
PROC PRINT

Details

This example creates a SAS data set in a Base SAS session by submitting the DS2 procedure, and then submitting DS2 language statements. The output shows the first ten rows of the data set.

Program

```
libname myfiles base 'C:\myfiles';
proc ds2 libs=myfiles;

   data myfiles.basetable;
      declare double j j2;
      method run();
         do j = 1 to 1000;
            j2 = 2*j;
            output;
         end;
      end;
   enddata;

run;

quit;

proc print data=myfiles.basetable (obs=10);
run;
```

Program Description

Assign a library reference to the SAS data set to be created. The LIBNAME statement assigns the libref MyFiles, specifies the BASE engine, and specifies the physical location for the SAS data set.

```
libname myfiles base 'C:\myfiles';
```

Execute the PROC DS2 statement. The PROC DS2 statement connects to the data source by using the libref MyFiles and sets up the environment to submit DS2 language statements.

```
proc ds2 libs=myfiles;
```

Enter the DS2 language statements. The DS2 DATA statement creates an output table named Myfiles.BaseTable. The two-level name in the DATA statement specifies the catalog identifier MyFiles. The DECLARE statement assigns the data type DOUBLE to the variables J and J2. The METHOD statement identifies the RUN system method that is used to create output. The OUTPUT statement writes a row to table MyFiles.BaseTable after each execution of the DO loop.

```
data myfiles.basetable;
   declare double j j2;
   method run();
      do j = 1 to 1000;
         j2 = 2*j;
         output;
      end;
   end;
enddata;
```

Submit the DS2 language statements. The RUN statement submits the DS2 statements. The RUN statement is required. SAS reads the program statements that are associated with one task until it reaches a RUN statement.

```
run;
```

Stop the procedure. The QUIT statement stops the procedure.

```
quit;
```

Print the SAS data set. The PRINT procedure prints the observations in the SAS data set. The OBS= data set option limits the output to 10 observations.

```
proc print data=myfiles.basetable (obs=10);
run;
```

Output: Creating a SAS Data Set

Output 21.1 *PROC PRINT Output of MyFiles.BaseTable*

The SAS System

Obs	j	j2
1	1	2
2	2	4
3	3	6
4	4	8
5	5	10
6	6	12
7	7	14
8	8	16
9	9	18
10	10	20

Example 3: Terminating the Current Step in Line Prompt Mode

Features:

PROC DS2 statement
RUN CANCEL statement
QUIT statement
DS2 language statements

Details

The following example shows the usefulness of the RUN CANCEL statement in a line prompt mode session. The sixth statement in the code contains an invalid value for the column (Z instead of Y). RUN CANCEL ends the PROC DS2 step and prevents it from executing.

Program

```
proc ds2;
data xy_data;
   declare double x y;
   method init();
      do x = 1 to 5;
         z = 2*x;
      end;
   end;
enddata;
run cancel;
quit;
```

Example Code 21.2 *SAS Log Showing the Canceled PROC DS2 Step*

```
17   proc ds2 libs=work;
NOTE: Writing HTML Body file: sashtml1.htm
18   data xy_data;
19      dcl double x y;
20      method init();
21         do x = 1 to 5;
22            z = 2*x;
23         end;
24      end;
25   enddata;
26   run cancel;
NOTE: DS2 query cancelled per user request.
27   quit;

NOTE: PROCEDURE DS2 used (Total process time):
      real time           14.33 seconds
      cpu time            0.71 seconds
```

Example 4: Routing Data to Tables Based on Values

Features: PROC DS2 statement
QUIT statement
DS2 language statements

Details

This example illustrates how to create tables based on a condition. Programs 1 and 2 create two tables, Dept1_Items and Dept2_Items, that hold costs for items used by two departments. The third program creates two tables, Highcosts and Lowcosts, based on the costs of the items in the two items tables. Programs 4 and 5 output the contents of the costs tables.

Program

```
proc ds2;
/* Program 1 */
data dept1_items (overwrite=yes);
   dcl varchar(20) item;
   dcl double cost;
   method init();
      item = 'staples';   cost =  1.59; output;
      item = 'pens';      cost =  3.26; output;
      item = 'envelopes'; cost = 11.42; output;
   end;
enddata;
run;
/* Program 2 */
data dept2_items (overwrite=yes);
   dcl varchar(20) item;
   dcl double cost;
   method init();
      item = 'erasers'; cost =  5.43; output;
      item = 'paper';   cost = 26.92; output;
      item = 'toner';   cost = 62.29; output;
   end;
enddata;
run;
/* Program 3 */
data lowCosts (overwrite=yes) highCosts (overwrite=yes);
   method run();
      set dept1_items dept2_items;
      if cost <= 10.00 then
         output lowCosts;
      else
         output highCosts;
      end;
enddata;
run;
/* Program 4 */
data;
   method run();
      set lowCosts;
   end;

Example 5: Run a DS2 Program in CAS

Features:

CAS system options
CAS statement
CASLIB statement
CASUTIL procedure
PROC DS2 statement
SESSREF= procedure option
DS2 language statements

Details

Here is an example of a DS2 parallel program that is run in CAS. A DS2 parallel program is a DS2 program that contains a thread program and a data program and does not contain any data manipulation statements. That is, the data program does not contain any statements besides SET FROM and OUTPUT. Operations in the thread program are applied to multiple data observations in parallel. Each CAS worker processes a subset of the data set and generates a subset of the result set.

Program

```
options cashost="cloud.example.com" casport=5570;

cas mysess;

caslib casdata datasource=(srctype=path)
  path="testdata/cas";

proc casutil;
  load casdata="cars_single.sashdat" incaslib="casdata"
casout="cars_single";
run;

proc ds2 sessref=mysess;

 thread cars_thd / overwrite=yes;
   method run();
     set cars_single;
     if (msrp > 100000) then do;
       put make= model= msrp=;
       output;
     end;
   end;
 endthread;

 data cars_luxury /overwrite=yes;
   dcl thread cars_thd t;
   method run();
     set from t threads=4;
   end;
 enddata;

run;

quit;
```

Program Description

Connect to the CAS server. The CASHOST= and CASPORT= options specify to connect to the CAS server at cloud.example.com using port 5570. This step is not required if your network has a pre-configured CAS server connection.

```
options cashost="cloud.example.com" casport=5570;
```

Establish a CAS session. The CAS statement specifies to start a CAS session named MySess.

```
cas mysess;
```

Define a caslib to access your input data. A file named Cars_Single.sashdat is located in the Testdata/Cas subdirectory of the computer on which the CAS server is running. The CASLIB statement assigns caslib CasData to the directory location. To access a directory on a different computer, specify an absolute pathname.

```
caslib casdata datasource=(srctype=path)
  path="testdata/cas";
```

Load the table into CAS for processing. The CASUTIL procedure is used to load table Cars_Single.sashdat into the CAS session. The CASOUT= parameter assigns the loaded table the name Cars_Single.

```
proc casutil;
  load casdata="cars_single.sashdat" incaslib="casdata"
casout="cars_single";
run;
```

Issue the PROC DS2 statement and specify the SESSREF= procedure option. SESSREF= instructs the procedure to process the request using CAS session MySess.

```
proc ds2 sessref=mysess;
```

Enter the DS2 language statements. The DS2 THREAD statement creates a thread program named Cars_Thd that specifies criteria for selecting data from loaded table Cars_Single. The DS2 DATA statement creates an output table, Cars_Luxury, and specifies to set the results of the thread program as the content of the new table. The data program specifies to use four threads to execute the thread program.

```
thread cars_thd / overwrite=yes;
  method run();
    set cars_single;
    if (msrp > 100000) then do;
      put make= model= msrp=;
      output;
    end;
  end;
endthread;

data cars_luxury /overwrite=yes;
  dcl thread cars_thd t;
  method run();
    set from t threads=4;
  end;
enddata;
```

Submit the DS2 language statements. The RUN statement submits the DS2 statements. The RUN statement is required. SAS reads the program statements that are associated with one task until it reaches a RUN statement.

```
run;
```

Stop the procedure. The QUIT statement stops the procedure.

```
quit;
```

22

DSTODS2 Procedure

Overview: DSTODS2 Procedure

What Does the DSTODS2 Procedure Do?

The DSTODS2 procedure enables you to translate a subset of your SAS DATA step code into DS2 code. Then you can revise your program to take advantage of DS2 features and submit your program using PROC DS2.

Note: PROC DSTODS2 is not supported in the z/OS operating environment.

For more information, see Chapter 21, “DS2 Procedure,” on page 801.

Concepts: DSTODS2 Procedure

Input and Output Files

PROC DSTODS2 works with text files for input and output, and these files are presented either as directly named files or as SAS filerefs.

PROC DSTODS2 requires an input file containing the source to be translated. The input file is specified via the IN= argument. PROC DSTODS2 also requires an output filename where the translated source is to be written. This file is specified via the OUT= argument.

Note: The resulting output file might not be syntactically complete. You might have to clean up the output file to create a DS2 program that can be compiled and executed.

Note: PROC DSTODS2 adds this code lines to your output file. You should not remove it from your .ds2 file during cleanup:

```
_return: ;
```

Supported and Unsupported Syntax

Overview

PROC DSTODS2 cannot translate all possible DATA step syntax. Its main purpose is to support typical SAS Enterprise Miner scoring syntax, which is a subset of the full DATA step syntax.

Supported Syntax

The DATA step syntax that PROC DSTODS2 supports includes the following items.

- The following statements are supported:

  ARRAY statements and array initializers. Implicit arrays give a warning.

  Assignment statements that use arrays and scalars.

  Attribute statements, although they have no semantic meaning in PROC DSTODS2. Only the syntax is supported–that is, you do not get a syntax error for them.

  BY

  Comment

  CONTINUE

  DATA statement and associated data sets

  DO (all forms except DO OVER)

  DROP

  END

  FORMAT (only when a LENGTH statement is also included in the program)

  GOTO

  IF and IF-THEN/ELSE

  KEEP

  LABEL

  LEAVE

  LENGTH

  MERGE

  Null

  OUTPUT

  Basic PUT statement functionality: printing variables, arrays, _ALL_, and formatted values. Other PUT arguments are commented out inline.

  RENAME

  RETAIN

  RETURN

  RUN (syntactically supported but has no semantic meaning)

  SELECT

  SET

  STOP

  Sum

- Partial support for the hash object.
- DROP, IN, KEEP, and RENAME data set options
- All DATA step expressions
- All functions and formats are translated as-is. However, only functions and formats that are supported by DS2 are valid. For more information, see "DS2 Functions" in *SAS DS2 Language Reference*.
- Constant lists (as used in IN clauses)
- Variable lists except for type modifiers in lists, for example, **`x-numeric-a`**

Note: Because of the depth of the DATA step language, this list is not exhaustive.

Unsupported Syntax

The DATA step syntax that PROC DSTODS2 does not support includes the following items:

- The following statements are not supported:

  ABORT
  ATTRIB
  CALL
  CARDS
  CARDS4
  DATALINES
  DATALINES4
  DELETE
  DESCRIBE
  DISPLAY
  DO OVER
  ERROR
  EXECUTE
  FILE
  FORMAT (undeclared variables)
  INFILE
  INFORMAT
  INPUT (all forms)
  LINK
  LIST
  LOSTCARD
  MODIFY
  PUT statement with formatting of any kind
  PUTLOG
  REMOVE
  REPLACE
  UPDATE
  WHERE
  WINDOW

- Data set options other than DROP, IN, KEEP, and RENAME
- DATA step executable options like DEBUG and PASSTHRU
- The following I/O options are not supported:

  CONTROL
  CUROBS
  END
  INDSNAME
  KEY
  NOBS
  OPEN
  POINT
  KEYRESET

- Implicit arrays
- INPUT and PUT modifiers
- All objects other than the Hash object
- Argument tags in any method
- View and stored program syntax
- Constant ranges, such as 1:100, in constant lists
- Format justifiers (L, R, C)

- CALL statements except DMNORM and STREAMINIT
- Bitstring expressions
- Other procedures

Note: Because of the depth of the DATA step language, this list is not exhaustive.

Considerations and Limitations with PROC DSTODS2

- Only one DATA step program can be converted at a time.
- The resulting DS2 program contains two lines of code that should be removed before saving your final DS2 program:

```
ds2_options sas tkgmac;
_return: ;
```

- Existing comments are removed.
- Code lines that cannot be translated are placed in comments.

  These comments are placed in-line in the original position as much as possible to enable you to easily compare the original code with the translated code. But there are situations where comments and other code might be moved to other positions. For example, the code might be moved to the top of a block (the outermost scope).
- The resulting DS2 program might not be syntactically complete. The resulting program can result in one of the following outcomes:
  - compile and execute without error. This is unlikely if any of the new DATA step syntax is used.
  - compile but fail to execute. This is particularly true of any programs that contain commented-out sections.
  - not compile. This could happen because there was a warning, or something that translates syntactically but has no corresponding support in DS2. This could be the case for certain functions and formats. It could happen for some of the variable list features also.
  - produce a fatal syntax error. This could happen for some previously undiscovered feature or for some aspect of the previously mentioned variable list syntax.
- The resulting DS2 program does not invoke the SAS In-Database Code Accelerator. You must take the part of the code that can be run in parallel and create a thread program to accompany the data program.
- If any code line is longer than 32767 characters, it is truncated.
- DATA step fixed-length characters are measured in bytes. DS2 fixed-length characters are measured in characters. If your data has multibyte encoding, you

might have to adjust your LENGTH statement before running PROC DSTODS2 to account for the length of the variable in characters to avoid truncation. There is no issue with single-byte encodings.

- If you run PROC DSTODS2 on a DATA step program with the SESSREF= option to run on the CAS server, you must move the SESSREF= option from the DATA statement to the PROC DS2 statement before running on the CAS server.

Syntax: DSTODS2 Procedure

Restrictions: This procedure is not supported on the CAS server.

PROC DSTODS2 is not supported in the z/OS operating environment.

PROC DSTODS2 IN=*datastep-program-filename* OUT=*ds2-program-filename* <OUTDIR="*output-directory-name*">

RUN;

<QUIT;>

Statement	Task	Example
PROC DSTODS2	Translates DATA step code into DS2 code.	Ex. 1, Ex. 2, Ex. 3

PROC DSTODS2 Statement

Translates DATA step code into DS2 code.

Syntax

PROC DSTODS2 IN=*datastep-program-filename* OUT=*ds2-program-filename* <OUTDIR="*output-directory-name*">

Required Arguments

IN=*datastep-program-filename*
specifies the name of the DATA step file or a SAS fileref.

Interaction If you use a fileref for the *datastep-program-filename*, PROC DSTODS2 does not look at any fileref options (for example, encoding).

Tip You can specify a full pathname.

OUT=*ds2-program-filename*
specifies the name of the DS2 file that is created.

Restriction You must specify only a single, output filename. It cannot include a pathname.

Note You should remove the following two lines from your output .ds2 program:

```
ds2_options sas tkgmac;
_return: ;
```

Tip If you cannot or do not specify the OUTDIR= directory, the output file is automatically written to the current working directory. You can use this code to find your current working directory:

```
data _null_;
file 'name.txt';
put x;
run;
```

OUTDIR="*output-directory-name*"
specifies the output directory name for the file.

Restriction This argument is available only in SAS Viya 3.4.

Requirement For UNIX directories, you must include the final directory separator(/), for example, `outdir="/mydir/files/"`

Examples: DSTODS2 Procedure

Example 1: Data Input

Features: PROC DSTODS2 statement

Details

This example uses PROC DSTODS2 to translate the following DATA step program, dsEx1.sas, that has a SET statement and a BY statement.

```
data _null_;
   length x y z w 8;
   set x;
   by x--z w;
   put x=;
run;
```

Execute the PROC DSTODS2 statement. Without a currently assigned libref, the PROC DSTODS2 statement simply sets up the environment to submit DS2 language statements.

```
proc dstods2 in="dsEx1.sas" out="ds2Ex1.ds2";
```

Submit the DSTODS2 statements. The RUN statement submits the DSTODS2 statements. The RUN statement is required. SAS reads the program statements that are associated with one task until it reaches a RUN statement.

```
run;
```

Example Code 22.1 SAS Log Showing Results

```
4    proc dstods2 in="dsEx1.sas" out="ds2Ex1.ds2";
5    run;

NOTE: PROCEDURE DSTODS2 used (Total process time):
      real time           0.20 seconds
      cpu time            0.07 seconds
```

Output: ds2Ex1.ds2 Program

PROC DSTODS2 translates dsEx1.sas into DS2 code and stores the result in dsEx1.ds2. As you can see, the LENGTH statement has been translated to DECLARE statements, the METHOD statement has been added, and the variable list, **X--Z**, has been commented out.

```
data _NULL_;
dcl double X;
dcl double Y;
dcl double Z;
dcl double W;
method run();
set X;
by  /* X--Z */ W;
put X=;
;
_return: ;
end;
enddata;
```

Example 2: PUT Statement with Line Specifiers

Features: PROC DSTODS2 statement

Details

This example uses PROC DSTODS2 to translate the following DATA step program, dsEx2.sas, that has a DO statement and several PUT statements.

```
data _null_;
   file temp linesize=32600;
   do i = 1 to 5330;
      put i 6. @;
   end;
   put @31990 'N1=72' @;
   put @32580 'N2=32413' @;
   put @32001 'N4=32 N3=783424123' @;
   put @32477 'N5=1977' @;
   put @32222 'N6=1981' ;
run;
```

Execute the PROC DSTODS2 statement. Without a currently assigned libref, the PROC DSTODS2 statement simply sets up the environment to submit DS2 language statements.

```
   proc dstods2 in="dsEx2.sas" out="ds2Ex2.ds2";
```

Submit the DSTODS2 statements. The RUN statement submits the DSTODS2 statements. The RUN statement is required. SAS reads the program statements that are associated with one task until it reaches a RUN statement.

```
   run;
```

Example Code 22.2 *SAS Log Showing Results*

```
4    proc dstods2 in="dsEx2.sas" out="ds2Ex2.ds2";
5    run;

NOTE: PROCEDURE DSTODS2 used (Total process time):
      real time           0.18 seconds
      cpu time            0.06 seconds
```

Output: ds2Ex2.ds2 Program

PROC DSTODS2 translates dsEx2.sas into DS2 code and stores the result in dsEx2.ds2. As you can see, the METHOD statement has been added and the FILE statement has been commented out. The PUT statement is translated but the @ line-hold specifier and constants have been commented out.

```
data _NULL_;
method run();
/* FILE TEMP LINESIZE = 32600 */;
do I = 1.0 to 5330.0;
put I 6. /* Put statement contains unsupported feature(s) @  */ ;
end;
put  /* Put statement contains unsupported feature(s) @  31990  'N1=72'
 @  */ ;
put  /* Put statement contains unsupported feature(s) @  32580  'N2=32413'
 @  */ ;
put  /* Put statement contains unsupported feature(s) @  32001  'N4=32
N3=783424123'
 @  */ ;
put  /* Put statement contains unsupported feature(s) @  32477  'N5=1977'
 @  */ ;
put  /* Put statement contains unsupported feature(s) @  32222  'N6=1981'
 */ ;
;
_return: ;
end;
 enddata;
```

Example 3: Arrays

Features: PROC DSTODS2 statement

Details

This example uses PROC DSTODS2 to translate the following DATA step program, dsEx2.sas, that has an ARRAY statement.

```
data _null_;
   array a(*) a1-a5;
   retain a1-a5 (1*(10 10 10 10 10));
   put _all_;
run;
```

Execute the PROC DSTODS2 statement. Without a currently assigned libref, the PROC DSTODS2 statement simply sets up the environment to submit DS2 language statements.

```
   proc dstods2 in="dsEx3.sas" out="ds2Ex3.ds2";
```

Submit the DSTODS2 statements. The RUN statement submits the DSTODS2 statements. The RUN statement is required. SAS reads the program statements that are associated with one task until it reaches a RUN statement.

```
run;
```

Example Code 22.3 *SAS Log Showing Results*

```
6    proc dstods2 in="dsex3.sas" out="ds2ex3.ds2";
7    run;

NOTE: PROCEDURE DSTODS2 used (Total process time):
      real time           1.83 seconds
      cpu time            1.14 seconds
```

Output: ds2Ex3.ds2 Program

PROC DSTODS2 translates dsEx3.sas into DS2 code and stores the result in dsEx3.ds2. As you can see, the METHOD statement has been added and the ARRAY statement has been translated into a VARARRAY statement.

```
data _NULL_;
retain A1-A5 (1 * (10, 10, 10, 10, 10)) ;
vararray double A[*] A1-A5;
 method run();
put _ALL_;
;
_return: ;
end;
 enddata;
```

23

EXPORT Procedure

Overview: EXPORT Procedure

What Does the EXPORT Procedure Do?

The EXPORT procedure reads data from a SAS data set and writes it to an external data source. In Base SAS 9.4, external data sources include delimited files and JMP files.

In delimited files, a delimiter can be a blank, comma, or tab that separates columns of data values. If you have a license for SAS/ACCESS Interface to PC Files, you can also export to additional file formats, such as to a Microsoft Access database,

Microsoft Excel workbook, DBF file, and Lotus spreadsheets. For more information, see *SAS/ACCESS Interface to PC Files: Reference*.

Starting in SAS 9.4, you can export a SAS data set to a JMP 7 or later file, and JMP variables can be up to 255 characters long. Extended attributes are now used automatically, and the META= statement is no longer supported for JMP files. For more information, see "JMP Files" in *SAS/ACCESS Interface to PC Files: Reference*.

The EXPORT procedure uses one of these methods to export data:

- generated DATA step code
- generated SAS/ACCESS code

You control the results with options and statements that are specific to the output data source. The EXPORT procedure generates the specified output file and writes information about the export to the SAS log. The log displays the DATA step or the SAS/ACCESS code that the EXPORT procedure generates. If a translation engine is used, then no code is submitted.

The **Export Wizard** or the **External File Interface** (EFI) can be used to guide you through the steps to export a SAS data set. The Export Wizard can generate EXPORT procedure statements, which you can save to a file for subsequent use. For more information, see "External File Interface (EFI)" in *SAS/ACCESS Interface to PC Files: Reference*.

The Export Wizard uses EFI methods to read and write data in delimited files, and this can affect the behavior when you use the EXPORT procedure or Export Wizard. For example, when exporting SAS data to a delimited file, the EXPORT procedure discards items that exceed the output line-length. For more information, see the DROPOVER option in the FILE Statement in *SAS DATA Step Statements: Reference*.

To open the Export Wizard, from the SAS windowing environment, select **File** ⇨ **Export Data**. For more information about the Export Wizard, see the Base SAS online Help and documentation. For more detail and an example, see "Using SAS Import and Export Wizards" in *SAS/ACCESS Interface to PC Files: Reference*.

Format Catalog Encodings in SAS Viya

SAS Viya supports only the UTF-8 encoding.

For more information about the encodings of format catalogs, see *Migrating Data to UTF-8 for SAS Viya* and *SAS/ACCESS Interface to PC Files: Reference*.

Support for the VARCHAR Data Type

PROC EXPORT supports the VARCHAR data type in CAS. VARCHAR stores a character variable that can have a varying length. The length that you specify for the variable represents the maximum number of characters that you want to store.

The VARCHAR data type is similar to the CHAR data type. CHAR variables have a length that is measured in terms of bytes. VARCHAR variables have a length that is measured in terms of characters rather than bytes. For information about using VARCHAR, see *SAS Cloud Analytic Services: DATA Step Programming*.

In the following example, the CAS engine is used with the LENGTH statement to create a VARCHAR variable and a CHAR variable. The VARCHAR variable, X, has a length of 30 and the CHAR variable, Y, also has a length of 30.

```
libname mycas cas;
data mycas.string;
   length x varchar(30);
   length y $30;
   x = 'abc'; y = 'def';
run;
proc contents data=mycas.string; run;
```

Here is the output that the code produces.

The CONTENTS Procedure

Data Set Name	MYCAS.STRING	Observations	1
Member Type	DATA	Variables	2
Engine	CAS	Indexes	0
Created	09/11/2016 13:48:30	Observation Length	48
Last Modified	09/11/2016 13:48:30	Deleted Observations	0
Protection		Compressed	NO
Data Set Type		Sorted	NO
Label			
Data Representation	SOLARIS_X86_64, LINUX_X86_64, ALPHA_TRU64, LINUX_IA64		
Encoding	utf-8 Unicode (UTF-8)		

Engine/Host Dependent Information	
Data Limit	100MB

Alphabetic List of Variables and Attributes

#	Variable	Type	Len
1	x	Varchar	30
2	y	Char	30

Syntax: EXPORT Procedure

Restrictions: The EXPORT procedure is available for the following operating environments:

- Windows
- UNIX or Linux

A pathname for a file can have a maximum length of 201 characters.

Tip: Beginning with SAS 9.4M5, PROC EXPORT supports the VARCHAR data type for CAS tables. For more information, see "Support for the VARCHAR Data Type" on page 850.

PROC EXPORT DATA=<*libref*.>*SAS data set* <(*SAS data set options*)>

OUTFILE="*filename*" | OUTTABLE="*tablename*"

<DBMS=*identifier*> <REPLACE> <LABEL>;

statements for exporting to delimited files

DELIMITER=*char* | '*nn*'x;

PUTNAMES=YES | NO;

statements for exporting to JMP files

DBENCODING=*12-char SAS encoding-value*;

FMTLIB=<*libref*.>*format-catalog*;

META=*libref.member-data-set*;

Statement	Task	Example
PROC EXPORT	Export SAS data sets to an external data file	Ex. 1, Ex. 2
DBENCODING	Indicate the encoding used to save data in JMP files	
DELIMITER	Specify the delimiter to separate columns of data in the delimited output file	Ex. 1
FMTLIB	Write SAS format values defined in the format catalog to the JMP file for the value labels	
META	Write SAS metadata information to the JMP file	
PUTNAMES	Write the SAS variable names as column headings to the first row of the exported data file.	Ex. 3

PROC EXPORT Statement

Exports SAS data sets to an external data file.

Tips: Beginning with SAS Viya 3.5, PROC EXPORT supports all access types that are available in the FILENAME statement.

Beginning with SAS 9.4M5, PROC EXPORT supports the VARCHAR data type for CAS tables. For more information, see "Support for the VARCHAR Data Type" on page 850.

See: "FILENAME Statement" in *SAS Global Statements: Reference*

Syntax

PROC EXPORT DATA=<*libref*.>*SAS data set* <(*SAS data set options*)>

OUTFILE="*filename*" | OUTTABLE="*tablename*"
<DBMS=*identifier*> <REPLACE> <LABEL>;

Summary of Optional Arguments

(*SAS data set options*)
specifies SAS data set options.

DBMS=*identifier*
specifies the type of data to export.

LABEL
specifies a variable label name.

REPLACE
overwrites an existing file.

Required Arguments

DATA=<*libref*.>*SAS data set*
identifies the input SAS data set with either a one- or two-level SAS name (library and member name). If you specify a one-level name, by default, the EXPORT procedure uses either the USER library (if assigned) or the WORK library.

The EXPORT procedure can export a SAS data set only if the data target supports the format of a SAS data set. The amount of data must also be within the limitations of the data target. For example, some data files have a maximum number of rows or columns. Some data files cannot support SAS user-defined formats and informats. If the SAS data set that you want to export exceeds the limits of the target file, the EXPORT procedure might not be able to export it correctly. In many cases, the procedure attempts to convert the data to the best of its ability. However, conversion is not possible for some types.

Beginning with SAS 9.4M1 a SAS data set name can contain a single quotation mark when the VALIDMEMNAME=EXTEND system option is also specified. Using VALIDMEMNAME= expands the rules for the names of certain SAS members, such as a SAS data set name. For more information, see “Rules for SAS Data Set Names, View Names, and Item Store Names” in *SAS Language Reference: Concepts*.

Default If you do not specify a SAS data set to export, the EXPORT procedure uses the most recently created SAS data set. SAS keeps track of the data sets with the system variable _LAST_. To be certain that the EXPORT procedure uses the correct data set, you should identify the SAS data set.

Examples “Example 1: Exporting to a Delimited External Data Source” on page 858

“Example 2: Exporting a Subset of Observations to a CSV File” on page 862

OUTFILE="*filename*" | "*fileref*"
specifies the complete path and filename or a fileref for the output PC file, spreadsheet, or delimited external file. A fileref is a SAS name that is associated with the physical location of a file. To assign a fileref, use the FILENAME statement.

If you specify a fileref, or if the complete path and filename do not include special characters (such as the backslash in a path), lowercase characters, or spaces, you can omit the quotation marks.

Alias FILE

Restrictions The EXPORT procedure does not support device types or access methods for the FILENAME statement except for DISK. For example, the EXPORT procedure does not support the TEMP device type, which creates a temporary external file.

PROC EXPORT does not support the DROP|KEEP data set options with Name Range Lists for DBMS=CSV | TAB | DLM.

See *SAS/ACCESS Interface to PC Files: Reference* for more information about PC file formats.

Examples "Example 1: Exporting to a Delimited External Data Source" on page 858

"Example 2: Exporting a Subset of Observations to a CSV File" on page 862

OUTTABLE="*tablename*"
specifies the table name of the output DBMS table. If the name does not include special characters (such as question marks), lowercase characters, or spaces, you can omit the quotation marks. Note that the DBMS table name might be case sensitive.

Requirements You must have a license for SAS/ACCESS Interface to PC Files to export to a DBMS table.

When you export a DBMS table, you must specify the DBMS option.

Optional Arguments

DBMS=*identifier*
specifies the type of data to export. To export to a DBMS table, you must specify the DBMS option by using a valid database identifier. For DBMS=DLM, the default delimiter character is a space. However, you can use DELIMITER='*char*'.

The following values are valid for the DBMS identifier.

Table 23.1 DBMS Identifiers Supported in Base SAS

Identifier	Output Data Source	Extension
CSV	Delimited file (comma-separated values)	.csv
DLM	Delimited file (default delimiter is a blank)	
JMP	JMP files, Version 7 or later format	.jmp
TAB	Delimited file (tab-delimited values)	.txt

Restriction The availability of an output external data source depends on these conditions:

- the operating environment and, in some cases, the platform as specified in the previous table.
- whether your site has a license for SAS/ACCESS Interface to PC Files. If you do not have a license, only delimited and JMP files are available.

See *SAS/ACCESS Interface to PC Files: Reference* for a list of additional DBMS identifiers when using SAS/ACCESS Interface to PC Files.

Example "Example 1: Exporting to a Delimited External Data Source" on page 858

LABEL
specifies a variable label name. SAS writes these to the exported table as column names. If the label names do not already exist, SAS writes them to the exported table.

REPLACE
overwrites an existing file. If you do not specify REPLACE, the EXPORT procedure does not overwrite an existing file.

Example "Example 2: Exporting a Subset of Observations to a CSV File" on page 862

(*SAS data set options*)
specifies SAS data set options. For example, if the data set that you are exporting has an assigned password, you can use the ALTER=, PW=, READ=, or WRITE= data set options. To export a subset of data that meets a specified condition, you can use the WHERE option. For information about SAS data set options, see *SAS Data Set Options: Reference*.

Example "Example 2: Exporting a Subset of Observations to a CSV File" on page 862

DBENCODING Statement

Indicates the encoding used to save data in JMP files.

Interaction: The DBENCODING statement is valid only when DBMS=JMP.

Syntax

DBENCODING=*12-char SAS encoding-value*;

Required Argument

12-char SAS encoding-value
indicates the encoding used to save data in JMP files. Encoding maps each character in a character set to a unique numeric representation, which results in a table of code points. A single character can have different numeric representations in different encodings. This value can be up to 12 characters long.

DELIMITER Statement

Specifies the delimiter to separate columns of data in the output file.

Default: Blank space

Interaction: If you specify DBMS=DLM, you must also specify the DELIMITER statement.

Tip: You can enclose *nn* in single or double quotation marks.

Example: "Example 1: Exporting to a Delimited External Data Source" on page 858

Syntax

DELIMITER=*char | 'nn'*x;

Required Argument

***char | 'nn'*x**
specifies the delimiter to use to separate values in the output file. You can specify the delimiter as a single BYTE character or as a hexadecimal value. For example, if you want columns of data to be separated by an ampersand, specify DELIMITER='&'. A single character which requires two bytes to be represented in a DBCS environment is not valid.

FMTLIB Statement

Write SAS format values defined in the format catalog to the JMP file for the value labels.

Interaction: The FMTLIB statement is valid only when DBMS=JMP.

Syntax

FMTLIB=*<libref> format-catalog*;

Required Argument

<libref.>format-catalog
specifies the format catalog to be written to the JMP file.

META Statement

Writes SAS metadata information to the JMP file. (Deprecated)

Interaction: The META statement is valid only when DBMS=JMP.

Syntax

META=*libref.member-data-set*;

Required Argument

libref.member-data-set
specifies the SAS data set that contains the metadata information to be written to the JMP file.

The META statement is no longer supported and is ignored. Instead, extended attributes are automatically used. When exporting a SAS data set to JMP, PROC EXPORT looks for extended attributes on the SAS data set. If the attributes exist, the procedure uses the attributes to build the new JMP file.

The META statement can remain in your programs, yet it generates a NOTE in the log saying that META has been replaced by extended attributes and is ignored.

PUTNAMES Statement

Writes SAS variable names as column headings to the first row of the exported data file.

Default: YES

Restriction: Valid only for the EXPORT procedure.

Note: If you specify the LABEL= option, the SAS variable labels (not the variable names) are written as column headings.

Example: "Example 3: Exporting to a Tab Delimited File with the PUTNAMES= Statement" on page 865

Syntax

PUTNAMES=YES | NO;

Required Arguments

YES
specifies that the EXPORT procedure is to do the following tasks:

- Write the SAS variable names as column names (or headings) to the first row of the exported data file.
- Write the first row of the SAS data set to the second row of the exported data file.

NO
specifies that the EXPORT procedure is to write the first row of SAS data set values to the first row of the exported data file.

Examples: EXPORT Procedure

Example 1: Exporting to a Delimited External Data Source

Features: PROC EXPORT statement options
DATA=

DBMS=
OUTFILE=
REPLACE

DELIMITER= statement

Details

This example exports the SASHelp.Class data set to a delimited external file. The following example is the SASHelp.Class data set before it is exported:

Output 23.1 *PROC PRINT of SASHelp.Class*

The SAS System

Obs	Name	Sex	Age	Height	Weight
1	Alfred	M	14	69.0	112.5
2	Alice	F	13	56.5	84.0
3	Barbara	F	13	65.3	98.0
4	Carol	F	14	62.8	102.5
5	Henry	M	14	63.5	102.5
6	James	M	12	57.3	83.0
7	Jane	F	12	59.8	84.5
8	Janet	F	15	62.5	112.5
9	Jeffrey	M	13	62.5	84.0
10	John	M	12	59.0	99.5

15	Philip	M	16	72.0	150.0
16	Robert	M	12	64.8	128.0
17	Ronald	M	15	67.0	133.0
18	Thomas	M	11	57.5	85.0
19	William	M	15	66.5	112.0

Program

```
proc export data=sashelp.class
   outfile="c:\myfiles\class"
   dbms=dlm replace;

   delimiter='&';
 run;
```

Program Description

Specify the input data set. Note that the filename does not contain an extension. DBMS=DLM specifies that the output file is a delimited file.

```
proc export data=sashelp.class
   outfile="c:\myfiles\class"
   dbms=dlm replace;
```

The DELIMITER option specifies that an & (ampersand) will delimit data fields in the output file.

```
   delimiter='&';
 run;
```

Log

This partial SAS log displays this information about the successful export, including the generated SAS DATA step.

Example Code 23.1 *SAS Log of Creating a Delimited File*

```
1    proc export data=sashelp.class outfile="c:\myfiles\class" dbms=dlm replace;
1  !                                                              delimiter='&' ; run;

Example 2: Exporting a Subset of Observations to a CSV File

Features: PROC EXPORT statement options
- DATA=
- DBMS=
- OUTFILE=
- REPLACE

Details

This example exports the SAS data set SASHelp.Class to a delimited file.

Program

Specify the data set to be exported. The WHERE option requests a subset of the observations. The OUTFILE= option specifies the output file. The DBMS= option specifies that the output file is a CSV file, and overwrites the target CSV, if it exists.

```
proc export data=sashelp.class (where=(sex='F'))
     outfile="c:\myfiles\Femalelist.csv"
```

```
     dbms=csv
     replace;
run;
```

Log

This partial SAS log displays this information about the successful export, including the generated SAS DATA step.

Example Code 23.2 *Exporting to a CSV File*

```
579  proc export data=sashelp.class (where=(sex='F'))
580       outfile="c:\myfiles\Femalelist.csv"
581       dbms=csv
582       replace;
583  run;

584   /*********************************************************************

596      if _n_ = 1 then        /* write column names or labels */
597       do;
598         put
599            "Name"
600         ','
601            "Sex"
602         ','
603            "Age"
604         ','
605            "Height"
606         ','
607            "Weight"
608         ;
609       end;
610     set  SASHELP.CLASS(where=(sex='F'))   end=EFIEOD;
611         format Name $8. ;
612         format Sex $1. ;
613         format Age best12. ;
614         format Height best12. ;
615         format Weight best12. ;
616       do;
617         EFIOUT + 1;
618         put Name $ @;
619         put Sex $ @;
620         put Age @;
621         put Height @;
622         put Weight ;
623         ;
624       end;
625      if _ERROR_ then call symputx('_EFIERR_',1);  /* set ERROR detection
625! macro variable */
626      if EFIEOD then call symputx('_EFIREC_',EFIOUT);
627      run;

NOTE: The file 'c:\myfiles\Femalelist.csv' is:
      Filename=c:\myfiles\Femalelist.csv,
      RECFM=V,LRECL=32767,File Size (bytes)=0,
      Last Modified=18Apr2014:11:32:07,
      Create Time=18Apr2014:11:32:07
```

Output

The EXPORT procedure produces this external CSV file:

Output 23.3 *CSV File*

Name	Sex	Age	Height	Weight
Alice	F	13	56.5	84
Barbara	F	13	65.3	98
Carol	F	14	62.8	102.5
Jane	F	12	59.8	84.5
Janet	F	15	62.5	112.5
Joyce	F	11	51.3	50.5
Judy	F	14	64.3	90
Louise	F	12	56.3	77
Mary	F	15	66.5	112

Example 3: Exporting to a Tab Delimited File with the PUTNAMES= Statement

Features: PROC EXPORT statement options
- DATA=
- DBMS=
- OUTFILE=
- PUTNAMES=
- REPLACE

Details

This example shows exporting a SAS data set, WORK.INVOICE, to a tab-delimited file. The first program uses PROC EXPORT with the PUTNAMES= statement and the second program does not. They show how the use of this statement affects column headings in a tab-delimited file.

The following display shows the SAS data set, WORK.INVOICE, before it is exported to a tab-delimited file:

Output 23.4 *PROC PRINT of WORK.INVOICE*

Obs	Invoice_ID	Billed_To	Amount_Billed_in_Local_Currency	Country	Amount_Billed_in_US_Dollars	Billed_By	Billed_On	Paid_On

17	12478	15432147	252148.50	USA	252148.50	423286	24DEC2004	02JAN2005

Program

```
PROC PRINT DATA=WORK.INVOICE;
RUN;

PROC EXPORT DATA=WORK.INVOICE
   OUTFILE="c:\temp\invoice_names.txt"
       DBMS=TAB REPLACE;
   PUTNAMES=YES;
RUN;
PROC PRINT;
RUN;

PROC EXPORT DATA=WORK.INVOICE
   OUTFILE="c:\temp\invoice_data_1st.txt"
      DBMS=TAB REPLACE;
   PUTNAMES=NO;
RUN;

PROC PRINT;
RUN;
```

Program Description

Use the PUTNAMES=YES statement in the EXPORT procedure. After WORK.INVOICE is printed, using the PUTNAMES=YES statement writes the SAS variables names as column names to the first row of the exported delimited file,

Invoice_names.txt. The first row of data is then written to the second row of the delimited file.

```
PROC PRINT DATA=WORK.INVOICE;
RUN;

PROC EXPORT DATA=WORK.INVOICE
   OUTFILE="c:\temp\invoice_names.txt"
       DBMS=TAB REPLACE;
   PUTNAMES=YES;
RUN;
PROC PRINT;
RUN;
```

Impact of the PUTNAMES=NO statement. When you set this statement to NO, PROC EXPORT writes the first row of data to the first row of the exported delimited file. Therefore, the SAS variable names are skipped, and the columns are left unlabeled.

```
PROC EXPORT DATA=WORK.INVOICE
   OUTFILE="c:\temp\invoice_data_1st.txt"
      DBMS=TAB REPLACE;
   PUTNAMES=NO;
RUN;

PROC PRINT;
RUN;
```

SAS Log

This SAS log displays information about the successful export, including the generated SAS DATA step. The log is divided into sections only for documentation appearances.

```
490  PROC EXPORT DATA= WORK.INVOICE
491              OUTFILE= "c:\temp\invoice_names.txt"
492              DBMS=TAB REPLACE;
493       PUTNAMES=YES;
494  RUN;

FCMP Procedure

Overview: FCMP Procedure

What Does the FCMP Procedure Do?

The SAS Function Compiler (FCMP) procedure enables you to create, test, and store SAS functions, CALL routines, and subroutines before you use them in other SAS procedures or DATA steps. PROC FCMP provides the ability to build functions, CALL routines, and subroutines using DATA step syntax that is stored in a data set. The procedure accepts slight variations of DATA step statements, and you can use most features of the SAS programming language in functions and CALL routines that are created by PROC FCMP. You can call PROC FCMP functions and CALL routines from the DATA step just as you would any other SAS function, CALL routine, or subroutine. This feature enables programmers to more easily read, write, and maintain complex code with independent and reusable subroutines. You can reuse the PROC FCMP routines in any DATA step or SAS procedure that has access to their storage location.

The FCMP procedure uses the SAS language compiler to compile and execute SAS programs. The compiler subsystem generates machine language code for the computer on which SAS is running. By specifying values with the CMPOPT option, the machine language code can be optimized for efficient execution. For information about the type of code generation optimizations to use in the SAS language compiler, see "CMPOPT= System Option" in *SAS System Options: Reference*.

You can use the functions and subroutines that you create in PROC FCMP with the DATA step, the WHERE statement, the Output Delivery System (ODS), and with the following procedures:

PROC CALIS	PROC OPTMODEL
PROC FORMAT	PROC PHREG
PROC GA	PROC QUANTREG

PROC GENMOD	PROC REPORT COMPUTE blocks
PROC GLIMMIX	SAS Risk Dimensions procedures
PROC MCMC	PROC SEVERITY
PROC MODEL	PROC SIMILARITY
PROC NLIN	PROC SQL (functions with array arguments are not supported)
PROC NLMIXED	PROC SURVEYPHREG
PROC NLP	PROC TMODEL
PROC OPTLSO	PROC VARMAX

Concepts: FCMP Procedure

Creating Functions and Subroutines

PROC FCMP enables you to write functions and CALL routines using DATA step syntax. PROC FCMP functions and CALL routines are stored in a data set and can be called from the DATA step, as well as several SAS/STAT, SAS/ETS, or SAS/OR procedures such as the NLIN, MODEL, and NLP procedures. You can create multiple functions and CALL routines in a single FCMP procedure step.

Functions are equivalent to routines that are used in other programming languages. They are independent computational blocks that require zero or more arguments. A subroutine is a special type of function where return values are optional. All variables that are created within a function or subroutine block are local to that subroutine.

Creating Functions and Subroutines: An Example

This following example defines a function and a subroutine. The function begins with the FUNCTION statement, and the subroutine begins with the SUBROUTINE statement. The DAY_DATE function converts a date to a numeric day of the week,

and the INVERSE subroutine calculates a simple inverse. Each ends with an ENDSUB statement.

```
proc fcmp outlib=sasuser.MySubs.Fncs;
  function day_date(indate);
    wkday=weekday(indate);
    return(wkday);
  endsub;

  subroutine inverse(in, inv);
    outargs inv;
    if in=0
       then inv=.;
       else inv=1/in;
    endsub;
quit;

option cmplib=sasuser.MySubs;

data _null_;
daysDate=day_date(today());
put daysDate=;

CALL inverse(12, inverseValue);
put inverseValue=;
run;
```

These statements produce these results:

```
daysDate=2
inverseValue=0.0833333333
```

Note: The output will change based on the value of "today()".

The function and subroutine follow DATA step syntax. Functions and subroutines that are already defined in the current FCMP procedure step, as well as most DATA step functions, can be called from within these routines as well. In the example above, the DATA step function WEEKDAY is called by DAY_DATE.

The routines in the example are saved to the data set Sasuser.MySubs, inside a package called MathFncs. A package is any collection of related routines that are specified by the user. It is a way of grouping related subroutines and functions within the data set. The OUTLIB= option in the PROC FCMP statement tells PROC FCMP where to store the subroutines that it compiles, and the LIBRARY= option tells it where to read in libraries (C or SAS).

Note: Function and subroutine names must be unique within a package. However, different packages can have subroutines and functions with the same names. To select a specific subroutine when there is ambiguity, use the package name and a period as the prefix to the subroutine name. For example, to access the MthFncs version of INVERSE, use MthFncs.inverse.

Writing Your Own Functions

Advantages of Writing Your Own Functions and CALL Routines

PROC FCMP enables you to write functions and CALL routines by using DATA step syntax. The advantages of writing user-defined functions and CALL routines include the following:

- The function or CALL routine makes a program easier to read, write, and modify.
- The function or CALL routine is independent. A program that calls a routine is not affected by the routine's implementation.
- The function or CALL routine is reusable. Any program that has access to the data set where the function or routine is stored can call the routine.

Note: PROC FCMP routines that you create cannot have the same name as built-in SAS functions. If the names are the same, then SAS generates an error message stating that a built-in SAS function or subroutine already exists with the same name.

Writing a User-Defined Function

The following program shows the syntax that is used to create and call a PROC FCMP function from a DATA step. This example computes the study day during a drug trial.

The example creates a function named STUDY_DAY in a package named TRIAL. A package is a collection of routines that have unique names and is stored in the data set Sasuser.Funcs. STUDY_DAY accepts two numeric arguments, *intervention_date* and *event_date*. The body of the routine uses DATA step syntax to compute the difference between the two dates, where days that occur before *intervention_date* begin at -1 and become smaller, and days that occur after and including *intervention_date* begin at 1 and become larger. This function never returns 0 for a study day.

STUDY_DAY is called from DATA step code as if it were any other function. When the DATA step encounters a call to STUDY_DAY, it does not find this function in its traditional library of functions. Instead, SAS searches each of the libraries or data sets that are specified in the CMPLIB= system option for a package that contains STUDY_DAY. In this example, STUDY_DAY is located in Sasuser.Funcs.Trial. The

program calls the function, passing the variable values for *start_date* and *end_date*, and returns the result in the variable **sd**.

```
proc fcmp outlib=sasuser.funcs.trial;
   function study_day(intervention_date, event_date);
       n=event_date-intervention_date;
       if n <= 0 then
       n=n+1;
       return(n);
   endsub;

options cmplib=sasuser.funcs;
data _null_;
   start_date='15Feb2006'd;
   end_date='27Mar2006'd;
   sd=study_day(start, today);
   put sd=;
run;
```

Example Code 24.1 *Results from the STUDY_DAY User-Defined Function*

```
sd=40
```

Using Library Options

You can use PROC FCMP with the OUTLIB= or INLIB= options. The syntax for this procedure has the following form:

```
proc fcmp
outlib=libname.dataset.package
          inlib=in-libraries;
routine-declarations;
```

The OUTLIB= option is required and specifies the package where routines declared in the *routine-declarations* section are stored.

Routines that are declared in the *routine-declarations* section can call FCMP routines that exist in other packages. To find these routines and to check the validity of the call, SAS searches the data sets that are specified in the INLIB= option. The format for the INLIB= option is as follows:

```
inlib=library.dataset
inlib=(library1.dataset1 library2.dataset2 ... libraryN.datasetN)
inlib=library.datasetM - library.datasetN
```

If the routines that are being declared do not call FCMP routines in other packages, then you do not need to specify the INLIB= option.

Declaring Functions

You declare one or more functions or CALL routines in the *routine-declarations* section of the program. A routine consists of four parts:

- a name
- one or more parameters
- a body of code
- a RETURN statement

You specify these four parts between the FUNCTION or SUBROUTINE keyword and an ENDSUB keyword. For functions, the syntax has the following form:

```
function
name(argument-1 <, argument-2, ...>);
   program-statements;
   return(expression);
endsub;
```

After the FUNCTION keyword, you specify the name of the function and its arguments. Arguments in the function declaration are called formal arguments and can be used within the body of the function. To specify a string argument, place a dollar sign ($) after the argument name. For functions, all arguments are passed by value. This means that the value of the actual argument, variable, or value that is passed to the function from the calling environment is copied before being used by the function. This copying ensures that any modification of the formal argument by the function does not change the original value.

The RETURN statement is used to return a value to a function. The RETURN statement accepts an expression that is enclosed in parentheses, and contains the value that is returned to the calling environment. The function declaration ends with an ENDSUB statement.

Declaring CALL Routines

CALL routines are declared within *routine-declarations* by using the SUBROUTINE keyword instead of the FUNCTION keyword. Functions and CALL routines have the same form, except CALL routines do not return a value, and CALL routines can modify their parameters. You specify the arguments to be modified in an OUTARGS statement. The syntax of a CALL routine declaration is as follows:

```
subroutine
name(<argument-1 , argument-2, ...>);
   outargs <out-argument-1 , out-argument-2, ...>;
   program-statements;
   return;
endsub;
```

The formal arguments that are listed in the OUTARGS statement are passed by reference instead of by value. This means that any modification of the formal

argument by the CALL routine modifies the original variable that was passed. It also means that the value is not copied when the CALL routine is invoked. Reducing the number of copies can improve performance when you pass large amounts of data between a CALL routine and the calling environment.

A RETURN statement is optional within the definition of the CALL routine. When a RETURN statement executes, execution is immediately returned to the caller. A RETURN statement within a CALL routine does not return a value.

Writing Program Statements

The program-statements section of the program is a series of DATA step and or FCMP statements that describe the work to be done by the function or CALL routine. Most DATA step statements and functions are accessible from PROC FCMP routines. The DATA step file and the data set I/O statements (for example, INPUT, FILE, SET, and MERGE) are not available from PROC FCMP routines. However, some functionality of the PUT statement is supported. For more information, see "PROC FCMP and DATA Step Differences" on page 898.

Using Functions as Formats

PROC FCMP enables you to use functions to format values by first performing a function on a value. By using a function to format values, you can create customized formats.

Using DATA Step Statements with PROC FCMP

You can use DATA step statements with PROC FCMP. However, there are some differences in the syntax and functionality for PROC FCMP. For more information, see "PROC FCMP and DATA Step Differences" on page 898.

The behaviors of the DROP, KEEP, FORMAT, and LENGTH statements are the same in PROC FCMP and in the DATA step.

The following DATA step statements are not supported in PROC FCMP:

- DATA
- SET
- MERGE
- UPDATE
- MODIFY
- INPUT
- INFILE

The support for the FILE statement is limited to LOG and PRINT destinations in PROC FCMP. The OUTPUT statement is supported in PROC FCMP, but it is not supported within a function or subroutine.

The following statements are supported in PROC FCMP but not in the DATA step:

- FUNCTION
- STRUCT
- SUBROUTINE
- OUTARGS

Syntax: FCMP Procedure

PROC FCMP *options*;

ABORT;

ARRAY *array-name*[*dimensions*] </NOSYMBOLS> | <*variable(s)*> | <*constant(s)*> | <*initial-values)*>;

ATTRIB *variable(s)* <FORMAT=*format-name* ><LABEL='*label*'>< LENGTH=*length*>;

DELETEFUNC *function-name*;

DELETESUBR *subroutine-name*;

FUNCTION *function-name(argument(s))* <VARARGS> <$> <*length*> <KIND | GROUP='*string*' <LABEL='*string-2*'>>;

LABEL *variable*='*label*';

LISTFUNC *function-name*;

LISTSUBR *subroutine-name*;

STRUCT *structure-name variable*;

SUBROUTINE *subroutine-name (argument(s))* <VARARGS> <LABEL='*label*'> <KIND | GROUP='*string*'>;

OUTARGS *out-argument(s)*;

Statement	Task	Example
PROC FCMP	Create, test, and store SAS functions for use by other SAS procedures	Ex. 1, Ex. 2, Ex. 8, Ex. 7
ABORT	Terminate the execution of the current DATA step, SAS job, or SAS session	
ARRAY	Associate a name with a list of variables and constants	Ex. 8
ATTRIB	Specify format, label, and length information for a variable	

Statement	Task	Example
DELETEFUNC	Delete a function from the function library that is specified in the OUTLIB option	
DELETESUBR	Delete a subroutine from the function library that is specified in the OUTLIB option	
FUNCTION	Return changed variable values	Ex. 1, Ex. 2, Ex. 7
LABEL	Specify a label for variables	
LISTFUNC	Write the source code of a function in the SAS listing	
LISTSUBR	Write the source code for a subroutine in the SAS listing	
STATIC	retains a variable's value from a previous call until the variable is reassigned.	
STRUCT	Declare (create) structure types	
SUBROUTINE	Declare (create) independent computational blocks of code	Ex. 8
OUTARGS	(Use only with the SUBROUTINE statement.) Specify arguments from the argument list that the subroutine should update	Ex. 2, Ex. 8

PROC FCMP Statement

Creates, tests, and stores SAS functions, CALL routines, and subroutines.

Examples:

"Example 1: Creating a Function and Calling the Function from a DATA Step" on page 925

"Example 2: Creating and Saving Functions with PROC FCMP" on page 927

"Example 7: Using Graph Template Language (GTL) with User-Defined Functions" on page 932

"Example 8: Standardizing Each Row of a Data Set" on page 934

Syntax

PROC FCMP *options*;

Optional Arguments

DATA=*filename*
reads an input data set into the PROC FCMP step.

Note: The DATA option can send inputs to a function or subroutine that are defined in the PROC FCMP step. The PROC FCMP step iterates through each observation and calls the function or subroutine during each iteration.

Note: For more information about the DATA= and OUT= options, see "Data Set Input and Output" on page 899.

Note: This example demonstrates using the DATA= and OUT= options in the PROC FCMP statement.

Example

```
proc fcmp outlib=sasuser.funcs.trial;
   function priceWithTax_func(price);
     static taxRate;
      if (taxRate EQ .) then
         taxRate = (7.25 / 100);
     taxedPrice = (price * (1 + taxRate));
      return (taxedPrice);
   endsub;
run;

option CMPLIB=sasuser.funcs;

proc fcmp data=sashelp.cars out=work.carPriceWithTax;
   format msrpWithTax DOLLAR8.;
   msrpWithTax = priceWithTax_func(msrp);
run;

proc print data=work.carPriceWithTax(obs=5 keep=make model
invoice msrp msrpWithTax);
run;
```

ENCRYPT
specifies to encode the source code in a data set. The alias HIDE is also valid.

FLOW
specifies printing a message for each statement in a program as it is executed. This option produces extensive output.

LIBRARY | INLIB=*library.dataset*
LIBRARY | INLIB=(*library-1.dataset library-2.dataset ... library-n.dataset)*
LIBRARY | INLIB=*library.datasetM - library.datasetN*
specifies that previously compiled libraries are to be linked into the program. These libraries are created by a previous PROC FCMP step or by using PROC PROTO (for external C routines).

Tips Libraries are created by the OUTLIB= option and are stored as members of a SAS library that have the type CMPSUB. Only subroutines and functions are read into the program when you use the LIBRARY= option.

If the routines that are being declared do not call PROC FCMP routines in other packages, then you do not need to specify the INLIB= option. Use the *libref.dataset* format to specify the two-level name of a library. The *libref* and *dataset* names must be valid SAS names that are not longer than eight characters.

You can specify a list of files with the LIBRARY= option, and you can specify a range of names by using numeric suffixes. When you specify more than one file, you must enclose the list in parentheses, except in the case of a single range of names. The following are syntax examples:

```
proc fcmp library=sasuser.exsubs;
proc fcmp library=(sasuser.exsubs work.examples);
proc fcmp library=lib1-lib10;
```

LIST
specifies that both the LISTSOURCE and LISTPROG options are in effect.

Tip Printing both the source code and the compiled code and then comparing the two listings of assignment statements is one way of verifying that the assignments were compiled correctly.

LISTALL
specifies that the LISTCODE, LISTPROG, and LISTSOURCE options are in effect.

LISTCODE
specifies that the compiled program code be printed. LISTCODE lists the chain of operations that are generated by the compiler.

Tip Because LISTCODE output is somewhat difficult to read, use the LISTPROG option to obtain a more readable listing of the compiled program code.

LISTFUNCS
specifies that prototypes for all visible FCMP functions or subroutines be written to the SAS listing.

LISTPROG
specifies that the compiled program be printed. The listing for assignment statements is generated from the chain of operations that are generated by the compiler. The source statement text is printed for other statements.

Tip The expressions that are printed by the LISTPROG option do not necessarily represent how the expression is actually calculated, because intermediate results for common subexpressions can be reused. However, the expressions are printed in expanded form by the LISTPROG option. To see how the expression is actually evaluated, see the listing from the LISTCODE option.

LISTSOURCE
specifies that source code statements for the program be printed.

OUT=*filename*
creates an output data set.

OUTFILE=*filename*
writes referenced functions and the main program to a text file. Programs that have been parsed by PROC FCMP, including macro variables, can be exported.

OUTITEMSTORE=*path name*
exports symbols, referenced functions, and the main program to the specified item store. OUTITEMSTORE does not support a fileref. You must use a quoted path.

OUTLIB=*libname.dataset.package*
specifies the three-level name of an output data set to which the compiled subroutines and functions are written when the PROC FCMP step ends. This argument is required. The following are syntax examples:

```
proc fcmp outlib=sasuser.fcmpsubs.pkt1;
```

```
proc fcmp outlib=sasuser.mysubs.math;
```

Tips Use this option when you want to save subroutines and functions in an output library.

Only those subroutines that are declared inside the current PROC FCMP step are saved to the output file. Those subroutines that are loaded by using the LIBRARY= option are not saved to the output file. If you do not specify the OUTLIB= option, then no subroutines that are declared in the current PROC FCMP step are saved.

PRINT
specifies printing the result of each statement in a program as it is executed. This option produces extensive output.

TRACE
specifies printing the results of each operation in each statement in a program as it is executed. These results are produced in addition to the information that is printed by the FLOW option. The TRACE option produces extensive output.

Notes Specifying TRACE is equivalent to specifying FLOW, PRINT, and PRINTALL.

The TRACE option works when the data is contained within PROC FCMP, not when calling FCMP functions from the DATA step. This example and output demonstrate the functionality of the TRACE option.

Example
```
proc fcmp outlib=work.funcs.trial TRACE;
   function study_day(intervention_date, event_date);
   n=event_date - intervention_date;
   if n >= 0 then n=n + 1;
      return(n);
   endsub;
   start='15Feb2010'd;
   today='27Mar2010'd;
   sd=study_day(start, today);
run;
```

```
                                        The FCMP Procedure

--- Program Execution Starting.
    1    1 (20:4)    Executing Stmt            : ASSIGN start =
    1      (20:9)    start = 18308
    1    2 (21:4)    Executing Stmt            : ASSIGN today =
    1      (21:9)    today = 18348
    1    3 (22:4)    Executing Stmt            : ASSIGN sd =

--- Subroutine study_day Execution Starting.
    1    1 (15:4)    Executing Stmt            : FUNCTION
    1    2 (16:4)    Executing Stmt            : ASSIGN n =
    1      (16:17)   n = (event_date=18348) - (intervention_date=18308)
= 40
    1    3 (17:4)    Executing Stmt            : IF
    1      (17:10)   _temp1 = (n=40) >= 0
    1    4 (17:17)   Executing Stmt            : ASSIGN n =
    1      (17:21)   n = (n=41) + 1 = 41
    1    5 (18:7)    Executing Stmt            : RETURN _study_day_ =
    1      (18:14)   _study_day_ = (n=41) = 41
    1    6 (19:4)    Executing Stmt            : ENDSUB
--- Subroutine study_day Execution Finished.

    1      (22:16)   sd = study_day( start=18308, today=18348 ) = 41
--- Program Execution Finished.
```

ABORT Statement

Terminates the current DATA step, job, or SAS session.

Syntax

ABORT;

Without Arguments

The ABORT statement in PROC FCMP has no arguments.

ARRAY Statement

Associates a name with a list of variables and constants.

Example: "Example 8: Standardizing Each Row of a Data Set" on page 934

Syntax

ARRAY *array-name*[*dimensions*] </NOSYMBOLS> | <*variable(s)*> | <*constant(s)*> | <*initial-values*>;

Required Arguments

array-name
specifies the name of the array.

dimensions
is a numeric representation of the number of elements in a one-dimensional array or the number of elements in each dimension of a multidimensional array.

Optional Arguments

/NOSYMBOLS
specifies that an array of numeric or character values be created without the associated element variables. In this case, the only way that you can access elements in the array is by array subscripting.

Tips /NOSYMBOLS is used in exactly the same way as _TEMPORARY_.

You can save memory if you do not need to access the individual array element variables by name.

variable
specifies the variables of the array.

constant
specifies a number or a character string that indicates a fixed value. Enclose character constants in quotation marks.

initial-values
gives initial values for the corresponding elements in the array. You can specify internal values inside parentheses.

Details

ARRAY Statement Basics

The ARRAY statement in PROC FCMP is similar to the ARRAY statement that is used in the DATA step. The ARRAY statement associates a name with a list of variables and constants. You use the array name with subscripts to refer to items in the array.

The ARRAY statement that is used in PROC FCMP does not support all the features of the ARRAY statement in the DATA step. Here is a list of differences that apply only to PROC FCMP:

- All array references must have explicit subscript expressions.

- PROC FCMP uses parentheses after a name to represent a function call. When you reference an array, use square brackets [ ] or braces { }.
- The ARRAY statement in PROC FCMP does not support lower-bound specifications.
- You can use a maximum of six dimensions for an array.

You can use both variables and constants as array elements in the ARRAY statement that is used in PROC FCMP. You cannot assign elements to a constant array. Although dimension specification and the list of elements are optional, you must provide one of these values. If you do not specify a list of elements for the array, or if you list fewer elements than the size of the array, PROC FCMP creates array variables by adding a numeric suffix to the elements of the array to complete the element list.

Passing Array References to PROC FCMP Routines

If you want to pass an array to a CALL routine and the CALL routine modifies the values of the array, you must specify the name for the array argument in an OUTARGS statement in the CALL routine.

Example

Here are some examples of the ARRAY statement:

```
array spot_rate[3] 1 2 3;
array spot_rate[3] (1 2 3);
array y[4] y1-y4;
array xx[2,3] x11 x12 x13 x21 x22 x23;
array pp p1-p12;
array q[1000] /nosymbols;
```

ATTRIB Statement

Specifies format, label, and length information for variables.

Syntax

ATTRIB *variable(s)* <FORMAT=*format-name* LABEL='*label*' LENGTH=*length*>;

Required Argument

variable
specifies the variables that you want to associate with attributes.

Optional Arguments

FORMAT=*format-name*
associates a format with variables in the *variable* argument.

LABEL='*label*'
associates a label with variables in the *variable* argument.

LENGTH=*length*
specifies the length of the variable in the *variable* argument.

Example

Here are some examples of the ATTRIB statement:

```
attrib x1 format=date7. label='variable x1' length=5;

attrib x1 format=date7. label='variable x1' length=5
       x2 length=5
       x3 label='var x3' format=4.
       x4 length=$2 format=$4.;
```

DELETEFUNC Statement

Causes a function to be deleted from the function library that is specified in the OUTLIB option.

Syntax

DELETEFUNC *function-name*;

Required Argument

function-name
specifies the name of a function to be deleted from the function library that is specified in the OUTLIB option.

DELETESUBR Statement

Causes a subroutine to be deleted from the function library that is specified in the OUTLIB option.

Syntax

DELETESUBR *subroutine-name*;

Required Argument

subroutine-name
specifies the name of a subroutine to be deleted from the function library that is specified in the OUTLIB option.

FUNCTION Statement

Specifies a subroutine declaration for a routine that returns a value.

Examples:
"Example 1: Creating a Function and Calling the Function from a DATA Step" on page 925
"Example 2: Creating and Saving Functions with PROC FCMP" on page 927
"Example 3: Using Numeric Data in the FUNCTION Statement" on page 929
"Example 4: Using Character Data with the FUNCTION Statement" on page 929
"Example 5: Using Variable Arguments with an Array" on page 930
"Example 7: Using Graph Template Language (GTL) with User-Defined Functions" on page 932

Syntax

FUNCTION *function-name*(*argument-1* <, *argument-2, ...*>) <VARARGS> <$> <*length*>
<KIND | GROUP='*string*' ><LABEL='*string-2*'>;

... more-program-statements ...

RETURN (*expression*);

ENDSUB;

Required Arguments

function-name
specifies the name of the function.

argument
specifies one or more arguments for the function. You specify character arguments by placing a dollar sign ($) after the argument name. In the following example, `function myfunct(arg1, arg2 $, arg3, arg4 $);` arg1 and arg3 are numeric arguments, and arg2 and arg4 are character arguments.

expression
specifies the value that is returned from the function.

Optional Arguments

VARARGS
specifies that the function supports a variable number of arguments. If you specify VARARGS, then the last argument in the function must be an array.

Restriction You must specify a numeric variable with the VARARGS argument.

See "Example 5: Using Variable Arguments with an Array" on page 930

$
specifies that the function returns a character value. If $ is not specified, the function returns a numeric value.

length
specifies the length of a character value.

Default 8

KIND='*string*'
GROUP='*string*'
specifies a collection of items that have specific attributes and is limited to 32 characters.

LABEL='*string-2*'
specifies a label of up to 256 characters, including blanks.

Details

The FUNCTION statement is a special case of the subroutine declaration that returns a value. You do not use a CALL statement to call a function. The definition of a function begins with the FUNCTION statement and ends with an ENDSUB statement.

LABEL Statement

Specifies a label of up to 256 characters.

Syntax

LABEL *variable*='*label*';

Required Arguments

variable
names the variable that you want to label.

'label'
specifies a label of up to 256 characters, including blanks.

Example

Here are some examples of the LABEL statement:

```
label date='Maturity Date';
label bignum='Very very large numeric value';
```

LISTFUNC Statement

Causes the source code for a function to be written to the SAS listing.

Syntax

LISTFUNC *function-name* </NODEPENDENTS>;

Required Argument

function-name
specifies the name of the function for which source code is written to the SAS listing.

Note: All dependent functions are returned in addition to the specified function by default.

Optional Argument

/NODEPENDENTS
specifies that only the functions specified by *function-name* be returned and not any dependent functions.

Alias /NODEPS

LISTSUBR Statement

Causes the source code for a subroutine to be written to the SAS listing.

Syntax

LISTSUBR *subroutine-name*;

Required Argument

subroutine-name
specifies the name of the subroutine for which source code is written to the SAS listing.

OUTARGS Statement

Specifies arguments in an argument list that you want a subroutine to update.

Restriction: Many SAS analytical procedures perform analytical differentiation on FCMP functions. If you plan to use the function in this way, do not use the OUTARGS statement. In most cases, use the OUTARGS statement only with the SUBROUTINE statement.

Examples: "Example 2: Creating and Saving Functions with PROC FCMP" on page 927
"Example 8: Standardizing Each Row of a Data Set" on page 934
"Example 6: Using the SUBROUTINE Statement with a CALL Statement" on page 931

Syntax

OUTARGS *out-argument-1* <, *out-argument-2*, ...>;

Required Argument

out-argument
specifies arguments from the argument list that you want the subroutine to update.

Tip If an array is listed in the OUTARGS statement within a routine, then the array is passed "by reference." Otherwise, it is passed "by value."

Example See "SUBROUTINE Statement" on page 896 for an example of how to use the OUTARGS statement in a subroutine

STATIC Statement

Retains a variable's value from a previous call until the variable is reassigned.

Syntax

STATIC *variables*, <*initial-value(s)*>;

Required Argument

variables
specifies variable names, variable lists, or array names whose values you want to retain.

Optional Argument

initial-values
specifies an initial value, numeric or character, for one or more of the preceding elements.

Details

The STATIC statement can be used to initialize variables.

Local variables in a function or subroutine are usually not retained between calls to the function or subroutine. If there is an expensive initialization required, a STATIC variable can be used to perform the initialization. STATIC variables are not allocated on the stack, so they can be used for large local arrays to avoid reallocations and overflows on the stack.

Examples

Example 1

Here is a numeric static example:

```
proc fcmp;
   function fdef1(in);
      static x1  1;
      if x1 = 1 then do;
         x1 = 2;
      return(in);
   end;

      return (in*2);
   endsub;

   ans = fdef1( 1);
   put "Answer should be 1" ans=;
   ans = fdef1( 1);
   put "Answer should be 2" ans=;
```

```
run;
```

Example 2

Here is a character static example:

```
proc fcmp;
   function char_func( in $) $;
   length c1 $ 32;
   static c1  "Elephant";
      if c1 = "Elephant" then
         do;
          c1 = in || c1;
    return (c1);
    end;
    return( in);
   endsub;
   length ans $ 32;
   ans = char_func( "Big ");
   put "Answer should be >>Big Elephant<<" ans=;
   ans = char_func( "Big ");
   put "Answer should be >>Big<<" ans=;
run;
quit;
```

Example 3

Here is an array static example:

```
proc fcmp ;
  function array_func( in ) ;
  array a[5] ;
  array foo[5];
  static a  first 1;
  put a[1]= foo[1]=;
     If first  then do;
       do i=1 to dim(a);
          a[i]=i;
          foo[i]=i;
  end;
  first =0;
  end;
  else do;
    do i=1 to dim(a);
       a[i]=a[i]+1;
   end;
   end;
   put a[5];
   return( in);

  endsub;
```

```
  ans = array_func( 4);

/* should increase by 1 */
   ans = array_func( 4);

run;
```

STRUCT Statement

Declares (creates) structure types that are defined in C-Language packages.

Syntax

STRUCT *structure-name variable*;

Required Arguments

structure-name
specifies the name of a structure that is defined in a C-language package and declared in PROC FCMP.

variable
specifies the variable that you want to declare as this structure type.

Example

Here is an example of the STRUCT statement.

```
struct DATESTR matdate;
matdate.month=3;
matdate.day=22;
matdate.year=2009;
```

SUBROUTINE Statement

Declares (creates) an independent computational block of code that you can call using a CALL statement.

Examples: "Example 8: Standardizing Each Row of a Data Set" on page 934
"Example 2: Creating and Saving Functions with PROC FCMP" on page 927

Syntax

SUBROUTINE *subroutine-name* (*argument-1* <, *argument-2*, ...>) <VARARGS> <KIND | GROUP='*string*'>;

OUTARGS *out-argument-1* <, *out-argument-2*, ...>;

... more-program-statements ...

ENDSUB;

Required Arguments

subroutine-name
specifies the name of a subroutine.

argument
specifies one or more arguments for the subroutine. Character arguments are specified by placing a dollar sign ($) after the argument name. In the following example, `subroutine mysub(arg1, arg2 $, arg3, arg4 $);` arg1 and arg3 are numeric arguments, and arg2 and arg4 are character arguments.

OUTARGS
specifies arguments from the argument list that the subroutine should update.

out-argument
specifies arguments from the argument list that you want the subroutine to update.

Optional Arguments

VARARGS
specifies that the subroutine supports a variable number of arguments. If you specify VARARGS, then the last argument in the subroutine must be an array.

GROUP='*string*'
KIND='*string*'
specifies a collection of items that have specific attributes and is limited to 32 characters.

Details

The SUBROUTINE statement enables you to declare (create) an independent computational block of code that you can call with a CALL statement. The definition of a subroutine begins with the SUBROUTINE statement and ends with an ENDSUB statement. You can use the OUTARGS statement in a SUBROUTINE statement to specify arguments from the argument list that the subroutine should update.

Usage: FCMP Procedure

PROC FCMP and DATA Step Differences

Overview of PROC FCMP and DATA Step Differences

PROC FCMP was originally developed as a programming language for several SAS/STAT, SAS/ETS, and SAS/OR procedures. Because the implementation is not identical to the DATA step, differences exist between the two languages. The following section describes some of the differences between PROC FCMP and the DATA step.

Differences between PROC FCMP and the DATA Step

ABORT Statement

The ABORT statement in PROC FCMP does not accept arguments.

The ABORT statement is not valid within functions or subroutines in PROC FCMP. It is valid only in the main body of the procedure.

Arrays

PROC FCMP uses parentheses after a name to represent a function call. When referencing an array, the recommended practice is to use square brackets [ ] or braces { }. For an array named ARR, the code would be `ARR[i]` or `ARR{i}`. PROC FCMP limits the number of dimensions for an array to six.

For more information about the differences in the ARRAY statement for PROC FCMP, see “Details” on page 887.

Data Set Input and Output

PROC FCMP supports the DATA and OUTPUT statements for creating and writing to an output data set. The PROC FCMP statement supports the DATA= and OUT= options for specifying data input and output data sets. It does not support the SET, MERGE, UPDATE, or MODIFY statements for data set input. Data is typically transferred into and out of PROC FCMP routines by using parameters. If a large amount of data needs to be transferred, you can pass arrays to a PROC FCMP routine.

DATA Step Debugger

When you use the DATA step debugger, PROC FCMP routines perform like any other routine. That is, it is not possible to step into the function when debugging. Instead, use a PUT statement within the routine.

DO Statement

The following type of DO statement is supported by PROC FCMP:

```
do i=1, 2, 3;
```

The DO statement in PROC FCMP does not support character loop control variables. You can execute the following code in the DATA step, but not in PROC FCMP:

```
do i='a', 'b', 'c';
```

The DO statement does not support a character index variable. Therefore, the following code is not supported in PROC FCMP:

```
do i='one', 'two', 'three';
```

File Input and Output

PROC FCMP supports the PUT and FILE statements, but the FILE statement is limited to LOG and PRINT destinations. There are no INFILE or INPUT statements in PROC FCMP.

IF Expressions

An IF expression enables IF-THEN/ELSE conditions to be evaluated within an expression. IF expressions are supported by PROC FCMP but not by the DATA step. You can simplify some expressions with IF expressions by not having to split the expression among IF-THEN/ELSE statements. For example, the following two pieces of code are equivalent, but the IF expression (the first example) is not as complex:

```
x=if y < 100 then 1 else 0;
```

```
if y < 100 then
   x=1;
else
   x=0;
```

The alternative to IF expressions is expressions. This means that parentheses are used to group operations instead of DO/END blocks.

PUT Statement

The syntax of the PUT statement is similar in PROC FCMP and in the DATA step, but their operations can be different. In PROC FCMP, the PUT statement is typically used for program debugging. In the DATA step, the PUT statement is used as a report or file creation tool, as well as a debugging tool. The following list describes other differences:

- The PUT statement in PROC FCMP writes output to the SAS Output Window by default. The PUT statement in the DATA step writes output to the SAS log by default.
- The PUT statement in PROC FCMP does not support line pointers, format modifiers, column output, factored lists, iteration factors, overprinting, the _INFILE_ option, or the special character $. It does not support features that are provided by the FILE statement options, such as DLM= and DSD.
- The PUT statement in PROC FCMP supports evaluating an expression and writing the result by placing the expression in parentheses. The DATA step, however, does not support the evaluation of expressions in a PUT statement. In the following example for PROC FCMP, the expressions `x/100` and `sqrt(y)/2` are evaluated and the results are written to the SAS log:

  ```
  put (x/100) (sqrt(y)/2);
  ```

  Because parentheses are used for expression evaluation in PROC FCMP, they cannot be used for variable or format lists as in the DATA step.
- The PUT statement in PROC FCMP does not support subscripted array names unless they are enclosed in parentheses. For example, the statement `put (A[i]);` writes the i-th element of the array A, but the statement `put A[i];` results in an error message.
- An array name can be used in a PUT statement without subscripts. Therefore, the following statements are valid:
  - `put A=;` (when A is an array), writes all of the elements of array A with each value labeled with the name of the element variable.
  - `put (A)*=;` writes the same output as `put A=;`.
  - `put A;` writes all of the elements of array A.
- The PUT statement in PROC FCMP follows the output of each item with a space, which is similar to list mode output in the DATA step. Detailed control over column and line position are supported to a lesser extent than in the DATA step.
- The PUT statement in PROC FCMP supports the print item _PDV_, and prints a formatted listing of all of the variables in the routine's program data vector. The statement `put _PDV_;` prints a much more readable listing of the variables than is printed by the statement `put _ALL_;`.

WHEN and OTHERWISE Statements

The WHEN and OTHERWISE statements allow more than one target statement. That is, DO/END groups are not necessary for multiple WHEN statements. Here is an example:

```
SELECT;
   WHEN(expression-1)
   statement-1;
   statement-2;
   WHEN (expression-2)
   statement-3;
   statement-4;
END;
```

Additional Features in PROC FCMP

PROC REPORT and Compute Blocks

PROC REPORT uses the DATA step to evaluate compute blocks. Because the DATA step can call PROC FCMP routines, you can also call these routines from PROC REPORT compute blocks.

The FCmp Function Editor

The FCmp Function Editor is an application for traversing packages of functions and is built into the SAS Explorer. You can access the FCmp Function Editor from the **Solutions** menu in a traditional DMS session.

Computing Implicit Values of a Function

PROC FCMP uses a SOLVE function for computing implicit values of a function.

PROC FCMP and Microsoft Excel

Many Microsoft Excel functions, not typically available in SAS, are implemented in PROC FCMP. You can find these functions in the sashelp.slkwxl data set. You can view these functions at Excel functions in SAS.

You can also view these functions by using the following SAS code:

```
proc fcmp inlib=sashelp.slkwxl listall;
run;
```

The following example uses the ODD_SLK function:

```
options cmplib=sashelp.slkwxl;
data _null_;
   num    =4.2;
   odd_num=odd_slk(num);
   put 'Odd number nearest to' num ' is ' odd_num;
```

```
run;
```

```
Odd number nearest to 4.2  is 5
```

Working with Arrays

Passing Arrays

By default, PROC FCMP passes arrays "by value" between routines. However, if an array is listed in the OUTARGS statement within the routine, the array is passed "by reference."

This means that a modification to the formal parameter by the function modifies the array that is passed. Passing arrays by reference helps to efficiently pass large amounts of data between the function and the calling environment because the data does not need to be copied. The syntax for specifying a formal array has the following form:

```
function
name(numeric-array-parameter[*],
character-array-parameter[*] $);
```

You can pass DATA step temporary arrays to PROC FCMP routines.

Resizing Arrays

You can resize arrays in PROC FCMP routines by calling the built-in CALL routine DYNAMIC_ARRAY. The syntax for this CALL routine has the following form:

```
call dynamic_array(array, new-dim1-size <, new-dim2-size, ...>);
```

SAS passes to the DYNAMIC_ARRAY CALL routine both the array that is to be resized and a new size for each dimension of the array. A dynamic array enables the routine to allocate the amount of memory that is needed, instead of having to create an array that is large enough to handle all possible cases.

Support for dynamic arrays is limited to PROC FCMP routines. When an array is resized, the array is available only in the routine that resized it. It is not possible to resize a DATA step array or to return a PROC FCMP dynamic array to a DATA step.

Using Macros with PROC FCMP Routines

You can use the %SYSFUNC and %SYSCALL macros to call routines that you create with PROC FCMP. All SAS CALL routines are accessible with %SYSCALL except LABEL, VNAME, SYMPUT, and EXECUTE. %SYSFUNC and %SYSCALL macros support SAS function names up to 32 characters.

Variable Scope in PROC FCMP Routines

The Concept of Variable Scope

A critical part of keeping routines and programs independent of one another is variable scope. A variable's scope is the section of code where a variable's value can be used. In the case of PROC FCMP routines, variables that are declared outside a routine are not accessible inside a routine. Variables that are declared inside a routine is not accessible outside the routine. Variables that are created within a routine are called local variables because their scope is "local" to the routine.

Functions use local variables as scratch variables during computations, and the variables are not available when the function returns. When a function is called, space for local variables is pushed on the call stack. When the function returns, the space used by local variables is removed from the call stack.

When Local Variables in Different Routines Have the Same Name

The concept of variable scope can be confusing when local variables in different routines have the same name. When this occurs, each local variable is distinct. In the following example, the DATA step and CALL routines subA and subB contain a local variable named x. Each x is distinct from the other x variables. When the program executes, the DATA step calls subA and subA calls subB. Each environment writes the value of x to the log. The log output shows how each x is distinct from the others.

```
proc fcmp outlib=sasuser.funcs.math;
   subroutine subA();
      x=5;
      call subB();
      put 'In subA: ' x=;
   endsub;
```

```
   subroutine subB();
      x='subB';
      put 'In subB: ' x=;
   endsub;
run;

options cmplib=sasuser.funcs;
data _null_;
   x=99;
   call subA();
   put 'In DATA step: ' x=;
run;
```

Example Code 24.2 *Local Variables in Different Routines That Have the Same Name*

```
In subB:  x=subB
In subA:  x=5
In DATA step: x=99
```

Recursion

PROC FCMP routines can be recursive. Recursion is a problem-solving technique that reduces a problem to a smaller one that is simpler to solve and then combines the results of the simpler solution to form a complete solution. A recursive function is a function that calls itself, either directly or indirectly.

Each time a routine is called, space for the local variables is pushed on the call stack. The space on the call stack ensures independence of local variables for each call. When the routine returns, the space allocated on the call stack is removed, freeing the space used by local variables. Recursion relies on the call stack to store progress toward a complete solution.

When a routine calls itself, both the calling routine and the routine that is being called must have their own set of local variables for intermediate results. If the calling routine was able to modify the local variables of the routine that is being called, it would be difficult to program a recursive solution. A call stack ensures the independence of local variables for each call.

In the following example, the ALLPERMK routine in PROC FCMP has two arguments, *n* and *k*, and writes all `C(n, k) = n! /(n - k)!` combinations that contain exactly *k* out of the *n* elements. The elements are represented as binary values (0, 1). The function ALLPERMK calls the recursive function PERMK to traverse the entire solution space and output only the items that match a particular filter:

```
proc fcmp outlib=sasuser.funcs.math;
   subroutine allpermk(n, k);
      array scratch[1] / nosymbols;
      call dynamic_array(scratch, n);
      call permk(n, k, scratch, 1,0);
   endsub;
```

```
subroutine permk(n, k, scratch[*], m, i);
   outargs scratch;
   if m-1=n then do;
      if i=k then
         put scratch[*];
      end;
   else do;
      scratch[m]=1;
      call permk(n, k, scratch, m+1, i+1);
      scratch[m]=0;
      call permk(n, k, scratch, m+1, i);
   end;
endsub;
run;
quit;

options cmplib=sasuser.funcs;
data _null_;
   call allpermk(5,3);
run;
```

Example Code 24.3 *Recursion Example Results*

```
1 1 1 0 0
1 1 0 1 0
1 1 0 0 1
1 0 1 1 0
1 0 1 0 1
1 0 0 1 1
0 1 1 1 0
0 1 1 0 1
0 1 0 1 1
0 0 1 1 1
```

This program uses the /NOSYMBOLS option in the ARRAY statement to create an array without a variable for each array element. A /NOSYMBOLS array can be accessed only with an array reference, `scratch[m]`, and is equivalent to a DATA step _temporary_ array. A /NOSYMBOLS array uses less memory than a regular array because no space is allocated for variables. ALLPERMK also uses PROC FCMP dynamic arrays.

Directory Traversal

Overview of Directory Traversal

Implementing functionality that enables functions to traverse a directory hierarchy is difficult if you use the DATA step or macros. With the DATA step and macro code recursion or pseudo-recursion is not easy to code. This section describes how to develop a routine named DIR_ENTRIES that fills an array with the full pathname of all of the files in a directory hierarchy. This example shows the similarity between

PROC FCMP and DATA step syntax and underscores how PROC FCMP routines simplify a program and produce independent, reusable code. DIR_ENTRIES uses as input the following parameters:

- a starting directory
- a result array to fill with pathnames
- an output parameter that is the number of pathnames placed in the result array
- an output parameter that indicates whether the complete result set was truncated because the result array was not large enough

The flow of control for DIR_ENTRIES is as follows:

1. Open the starting directory.
2. For each entry in the directory, do one of the following tasks:
   - If the entry is a directory, call DIR_ENTRIES to fill the result array with the subdirectory's pathnames.
   - Otherwise, the entry is a file, and you must add the file's path to the result array.
3. Close the starting directory.

Directory Traversal Example

Opening and Closing a Directory

Opening and closing a directory are handled by the CALL routines DIROPEN and DIRCLOSE. DIROPEN accepts a directory path and has the following flow of control:

1. Create a fileref for the path by using the FILENAME function.
2. If the FILENAME function fails, write an error message to the log and then return.
3. Otherwise, use the DOPEN function to open the directory and retrieve a directory ID.
4. Clear the directory fileref.
5. Return the directory ID.

The DIRCLOSE CALL routine is passed a directory ID, which is passed to DCLOSE. DIRCLOSE sets the passed directory ID to missing so that an error occurs if a program tries to use the directory ID after the directory has been closed. The following code implements the DIROPEN and DIRCLOSE CALL routines:

```
proc fcmp outlib=sasuser.funcs.dir;
   function diropen(dir $);
   length dir $ 256 fref $ 8;
```

```
      rc=filename(fref, dir);
      if rc=0 then do;
         did=dopen(fref);
         rc=filename(fref);
      end;
      else do;
         msg=sysmsg();
         put msg '(DIROPEN(' dir= ')';
         did=.;
      end;
      return(did);
   endsub;

   subroutine dirclose(did);
      outargs did;
      rc=dclose(did);
      did=.;
   endsub;
```

Gathering Filenames

File paths are collected by the DIR_ENTRIES CALL routine. DIR_ENTRIES uses the following arguments:

- a starting directory
- a result array to fill
- an output parameter to fill with the number of entries in the result array
- an output parameter to set to 0 if all pathnames fit in the result array; or an output parameter to set to 1 if some of the pathnames do not fit into the array

The body of DIR_ENTRIES is almost identical to the code that is used to implement this functionality in a DATA step. Also, DIR_ENTRIES is a CALL routine that is easily reused in several programs.

DIR_ENTRIES calls DIROPEN to open a directory and retrieve a directory ID. The routine then calls DNUM to retrieve the number of entries in the directory. For each entry in the directory, DREAD is called to retrieve the name of the entry. Now that the entry name is available, the routine calls MOPEN to determine whether the entry is a file or a directory.

If the entry is a file, then MOPEN returns a positive value. In this case, the full path to the file is added to the result array. If the result array is full, the truncation output argument is set to 1.

If the entry is a directory, then MOPEN returns a value that is less than or equal to 0. In this case, DIR_ENTRIES gathers the pathnames for the entries in this subdirectory. It gathers the pathnames by recursively calling DIR_ENTRIES and passing the subdirectory's path as the starting path. When DIR_ENTRIES returns, the result array contains the paths of the subdirectory's entries.

```
   subroutine dir_entries(dir $, files[*] $, n, trunc);
      outargs files, n, trunc;
      length dir entry $ 256;

      if trunc then return;
```

```
   did=diropen(dir);
   if did <= 0 then return;

   dnum=dnum(did);
   do i=1 to dnum;
      entry=dread(did, i);
         /* If this entry is a file, then add to array, */
         /* else entry is a directory, recurse.         */
      fid=mopen(did, entry);
      entry=trim(dir) || '\' || entry;
      if fid > 0 then do;
         rc=fclose(fid);
         if n < dim(files) then do;
            trunc=0;
            n=n + 1;
            files[n]=entry;
         end;
         else do;
            trunc=1;
            call dirclose(did);
            return;
         end;
      end;
      else
         call dir_entries(entry, files, n, trunc);
   end;

   call dirclose(did);
   return;
endsub;
```

Calling DIR_ENTRIES from a DATA Step

You invoke DIR_ENTRIES like any other DATA step CALL routine. Declare an array with enough entries to hold all the files that might be found. Then call the DIR_ENTRIES routine. When the routine returns, the result array is looped over and each entry in the array is written to the SAS log.

```
options cmplib=sasuser.funcs;
data _null_;
   array files[1000] $ 256 _temporary_;
   dnum=0;
   trunc=0;
   call dir_entries("c:\logs", files, dnum, trunc);
   if trunc then put 'ERROR: Not enough result array entries. Increase
array
size.';
   do i=1 to dnum;
      put files[i];
   end;
run;
```

Example Code 24.4 *Results from Calling DIR_ENTRIES from a DATA Step*

```
c:\logs\2004\qtr1.log
c:\logs\2004\qtr2.log
c:\logs\2004\qtr3.log
c:\logs\2004\qtr4.log
c:\logs\2005\qtr1.log
c:\logs\2005\qtr2.log
c:\logs\2005\qtr3.log
c:\logs\2005\qtr4.log
c:\logs\2006\qtr1.log
c:\logs\2006\qtr2.log
```

This example shows the similarity between PROC FCMP syntax and the DATA step. For example, numeric expressions and flow of control statements are identical. The abstraction of DIROPEN into a PROC FCMP function simplifies DIR_ENTRIES. All of the PROC FCMP routines that are created can be reused by other DATA steps without any need to modify the routines to work in a new context.

Identifying the Location of Compiled Functions and Subroutines: The CMPLIB= System Option

Overview of the CMPLIB= System Option

The SAS system option CMPLIB= specifies where to look for previously compiled functions and subroutines. All procedures (including FCMP) that support the use of FCMP functions and subroutines use this system option.

Instead of specifying the LIBRARY= option on every procedure statement that supports functions and subroutines, you can use the CMPLIB= system option to set libraries that can be used by all procedures.

The _DISPLAYLOC_ option writes to the log the name of the data set from where SAS loaded a function. The _NO_DISPLAYLOC_ option prevents the data set name from being written to the log.

Syntax of the CMPLIB= System Option

The syntax for the CMPLIB= option has the following form:

OPTIONS CMPLIB=*library*

OPTIONS CMPLIB=*(library-1 <, library-2, ...>)*

OPTIONS CMPLIB=*list-1 <, list-2, ...*

OPTIONS CMPLIB=_DISPLAYLOC_

OPTIONS CMPLIB=_NO_DISPLAYLOC_

The following descriptions refer to the preceding syntax:

OPTIONS
identifies the statement as an OPTIONS statement.

library
specifies that the previously compiled libraries be linked into the program.

list
specifies a list of libraries.

DISPLAYLOC
when using PROC FCMP, specifies to display in the SAS log the data set from where SAS loaded the function.

Default _NO_DISPLAYLOC_

_NO_DISPLAYLOC_
when using PROC FCMP, specifies to not display in the SAS log the data set from where SAS loaded the function, and removes any library specifications as CMPLIB= option values.

Default _NO_DISPLAYLOC_

Tip When you specify CMPLIB=library-specification without the _DISPLAYLOC_ option, SAS does not display the data set name in the SAS log.

Example 1: Setting the CMPLIB= System Option

The following example shows how to set the CMPLIB= system option.

```
options cmplib=sasuser.funcs;
options cmplib=(sasuser.funcs work.functions mycat.funcs);
options cmplib=(sasuser.func1 - sasuser.func10);
```

Example 2: Compiling and Using Functions

In the following example, PROC FCMP compiles the SIMPLE function and stores it in the Sasuser.Models data set. Then the CMPLIB= system option is set, and the function is called by PROC MODEL.

The output from this example spans several pages. The output is divided into five parts.

```
proc fcmp outlib=sasuser.models.yval;
   function simple(a, b, x);
      y=a+b*x;
      return(y);
   endsub;
run;
```

```
options cmplib=sasuser.models nodate ls=80;

data a;
   input y @@;
   x=_n_;
   datalines;
08 06 08 10 08 10
;

proc model data=a;
   y=simple(a, b, x);
   fit y / outest=est1 out=out1;
quit;
```

Output 24.1 *Compiling and Using Functions: Part 1*

Example 3: Identifying the Data Set Name from Where SAS Loaded a Function

The following example uses the _DISPLAYLOC_ and _NO_DISPLAYLOC_ options. When you use the _DISPLAYLOC_ option, SAS writes to the log the name of the data set from where SAS loaded a function. With the _NO_DISPLAYLOC_ option, the name of the data set is not written to the log.

```
proc fcmp outlib=work.myfuncs1.pkg;
   function myfunc();
      return(1);
   endsub;
run;

proc fcmp outlib=work.myfuncs2.pkg;
   function myfunc();
      return(2);
   endsub;
run;

proc fcmp outlib=work.myfuncs3.pkg;
   function myfunc();
```

```
      return(3);
   endsub;
run;

option CMPLIB=(myfuncs1-myfuncs3 _DISPLAYLOC_);

proc fcmp;

  a = myfunc();
  put a=;
run;

/*- turning _DISPLAYLOC_ off -*/
option CMPLIB=(myfuncs1-myfuncs3);

proc fcmp;

  a = myfunc();
  put a=;
run;

option CMPLIB=(myfuncs1 myfuncs2 _DISPLAYLOC_);

proc fcmp;

  a = myfunc();
  put a=;
run;

option CMPLIB=_DISPLAYLOC_;

proc fcmp inlib=work.myfuncs1;
  a = myfunc();
  put a=;
run;

option CMPLIB=_NO_DISPLAYLOC_;

proc fcmp inlib=work.myfuncs1;
  a = myfunc();
  put a=;
run;
```

The following results show a partial SAS log. The _DISPLAYLOC_ and _NO_DISPLAYLOC options produce different results:

```
116  option CMPLIB=(myfuncs1-myfuncs3 _DISPLAYLOC_);
117
118  proc fcmp;
119
120    a = myfunc();
121    put a=;
122  run;

NOTE: Function 'myfunc' loaded from WORK.myfuncs3.PKG.
NOTE: PROCEDURE FCMP used (Total process time):
      real time           0.06 seconds
      cpu time            0.04 seconds

123
124  /*- turning _DISPLAYLOC_ off -*/
125  option CMPLIB=(myfuncs1-myfuncs3);
126
127
128  proc fcmp;
129
130    a = myfunc();
131    put a=;
132  run;

NOTE: PROCEDURE FCMP used (Total process time):
      real time           0.06 seconds
      cpu time            0.06 seconds

133
134  option CMPLIB=(myfuncs1 myfuncs2 _DISPLAYLOC_);
135
136  proc fcmp;
137
138    a = myfunc();
139    put a=;
140  run;

NOTE: Function 'myfunc' loaded from WORK.myfuncs2.PKG.
NOTE: PROCEDURE FCMP used (Total process time):

Using PROC FCMP Component Objects

Hash Object and Hash Iterator Object

Starting with SAS 9.3, hashing is available in user-defined subroutines through the FCMP procedure. Hashing enables you to extend the scope of your programs so that you can solve larger problems without sacrificing simplicity. Embedding a hash object in PROC FCMP functions and subroutines can improve performance and streamline existing programs.

For more information about hash and hash iterator component objects, see "Using the PROC FCMP Hash Object and PROC FCMP Hash Iterator Object" in *SAS Component Objects: Reference*.

Dictionaries

Dictionaries create references to numeric and character data, and they also give you fast in-memory hashing to arrays, other dictionaries, and PROC FCMP hash objects.

For information about how to use dictionaries in PROC FCMP, and to review examples, see "Using FCMP Dictionary Objects" in *SAS Component Objects: Reference* and Dictionaries: Referencing a New PROC FCMP Data Type.

PROC FCMP and ASTORE

CMP supports ASTORE (Analytic Store) scoring models. Data movement is reduced by performing the score and the computations together within the same TKCMP program. PROC FCMP supports ASTORE models on the SAS client.

What is an Analytic Store?

An analytic store is a binary file that contains the state from a predictive analytic procedure. This state from a predictive analytic procedure, such as a random forest, is created using the results from the training phase of model development. A key feature of an analytic store is that it is easily transported from one host to another. An analytic store is a compact and universal file form. The store names the only SAS component that can restore the state of the computation (memory) that can restore the post training memory. It is also called a warm restart for scoring.

What is a State?

State is a copy of all the memory items that are relevant to the next task, for example, scoring. SAVESTATE takes a snapshot of this information:

- Public information (that is, information common to all analytic engines). Examples of public information include the list of input variables, the list of output variables, the formats, and other elements.
- Private information (that is, information specific to that particular analysis, for example, random forests). Examples of private information include the number of trees, the trees themselves, the scores, and other types.

What is Scoring?

Historic data is where the outcomes are known. You train your model with this historic data, and then you score the new data by using the input variables. Scoring new data is predicting the outcome with new data, using the model that is built using the historic data.

What Does PROC ASTORE Do?

PROC ASTORE scores an input data set and produces an output data set using the analytic store that you specify. It is an interactive procedure in which each statement runs immediately. PROC ASTORE produces these outputs:

- Types of DS2 scoring code that can run locally using the DS2 procedure
- DS2 scoring code that can run in SAS Viya.

PROC ASTORE can also move analytic stores between the client and the server and it can provide descriptive information about the analytic store. The syntax is shown below:

SCORE
Scores the model.

DESCRIBE
Specifies the name of the analytic store and produces DS2 basic scoring code.

DOWNLOAD
Retrieves from the CAS session the specified analytic store and stores it in the local file system

UPLOAD
Moves the specified analytic store from the local file system into a data table in CAS.

Note: See The ASTORE Procedure for more information about PROC ASTORE.

Example: Using ASTORE in PROC FCMP

This example demonstrates using ASTORE in PROC FCMP. It also demonstrates TKCMP scoring of ASTORE models.

Note: The code for declaring a CMP object is the same for all platforms:

```
declare object myscore(astore);
```

Note: In a SAS client, the score() method takes a single parameter file path:

- Windows:

```
call myscore.score("C:\models\_va_model208");
```

- UNIX:

```
call myscore.score("/userid/models/_va_model208");
```

Note: In CAS, the score() method requires two arguments, the caslib and the CAS table name:

```
call myscore.score('CASUSER','_va_model208');
```

Note: The score object also supports the describe() method, which prints the input/output variables from the ASTORE to the log. The method takes no arguments:

```
call myscore.describe();
```

This code runs a previously created SVM CAS action in FCMP.

Example Code 24.1 *ASTORE.SAS*

```
title 'CMP ASTORE Test 1';

libname mydata "C:\project\my_data";
libname mymodel "C:\project\my_models";

/* Test a simple object model using the describe method */
/* Note: No input dataset is specified.   */
proc fcmp;
   declare object myscore(astore);
   call myscore.score("C:\project\my_models\_va_model208");

   /* Can use Proc FCMP to describe the local model */
   call myscore.describe();
run;quit;

/* Run the ASTORE model over an input dataset.  */
/* Write the results to an output dataset.      */
proc fcmp data=mydata.hmeq out=astore_fcmp_out;
   declare object myscore(astore);
   call myscore.score("C:\project\my_models\_va_model208");
run;quit;

proc print data=astore_fcmp_out(obs=10);
run;

title 'CMP ASTORE Test 2';

/* Using ASTORE scoring from a FCMP function */
proc fcmp outlib=work.score.funcs;

/* Return the probability value */
function astore(clage, clno, debtinc, delinq, ninq, value);
   declare object myscore(astore);
   call myscore.score("C:\project\my_models\_va_model208");
   return(_P_);
endsub;

/* Pass input values as arguments into the function */
/* Return all probability values from the score     */
subroutine astore2(clage, clno, debtinc, delinq, ninq, value,
                   _P_, P__EVENT_0, P__EVENT_1, I__EVENT_ $, _WARN_ $);
   outargs _P_, P__EVENT_0, P__EVENT_1, I__EVENT_, _WARN_;

   declare object myscore(astore);
   call myscore.score("C:\project\my_models\_va_model208");
endsub;
run;
quit;

/* Call these functions from Proc FCMP */

title 'CMP ASTORE Test 3';

proc fcmp data=mydata.hmeq inlib=work.score out=astore_fcmp_out2;
```

```
ds_p2 = astore(clage, clno, debtinc, delinq, ninq, value);
run;
quit;
proc print data=astore_fcmp_out2(obs=10);
run;

title 'CMP ASTORE Test 4';

proc fcmp data=mydata.hmeq(obs=10) inlib=work.score
out=astore_fcmp_out3;
_P_=.;
P__EVENT_0=.;
P__EVENT_1=.;
I__EVENT_="";
_WARN_="";

call astore2(clage, clno, debtinc, delinq, ninq, value,
             _P_, P__EVENT_0, P__EVENT_1, I__EVENT_, _WARN_);
run;
quit;
proc print data=astore_fcmp_out3(obs=10);
run;

title 'CMP ASTORE Test 5';

/* You can call the function from the data step   */
/* We can perform ASTORE scoring using the data step */
options cmplib=work.score;
data astore_ds_out;
set mydata.hmeq;
ds_p = astore(clage, clno, debtinc, delinq, ninq, value);
run;
proc print data=astore_ds_out(obs=10);
run;
```

PROC ASTORE transports data from CAS into a local analytic store (local file). Once in that form, the data is used by CMP and the new ASTORE object.

Example Code 24.2 *ASTORE_CAS.SAS*

```
title 'CMP ASTORE Test 1';

/* CASPORT=0 means generate a port number for session connection */
/*options casuser=<userid> cashost="<machine>" casport=<port>;*/
options casuser=<userid> cashost="<machine>" casport=<port>;

/* This is how to start a CAS session */
/* CAS sessions live for the life of the SAS session, unless redefined or closed. */
/* Unix: cas mysession AUTHINFO='/userid/.authinfo';*/
/* Windows */
cas mysession authinfo='/userid/.authinfo';
libname sascas1 cas sessref="mysession" caslib="CASUSER";

libname mydata "C:\project\my_data";
libname mymodel "C:\project\my_models";
```

```
/* Our input data for SVM; Load into CAS */
data sascas1.hmeq;
set mydata.hmeq;
run;

/* Run action from VDMML */
proc cas;
    action builtins.loadactionset / actionSet='tkaasvm';
    action tkaasvm.svmtrain result=r /
c=1.0,
code={comment=false,fmtWdth=15,lineSize=200},
includeMissing=false,
maxiter=25,
noscale=false,
savestate={caslib="CASUSER",name="_va_model208"},
table={caslib="CASUSER",compOnDemand="false",compPgm="_va_calculated_208_1=round('BAD'n,1
.0);
if (('_va_calculated_208_1'n = 0.0))then do;
_va_calculated_208_11= 0.0;
end;
else do;
_va_calculated_208_11= 1.0;
end;
;
_EVENT_=_va_calculated_208_11;
_va_FILTER_=(NOT(MISSING('_va_calculated_208_1'n))
AND NOT(MISSING('CLAGE'n)) AND NOT(MISSING('CLNO'n)) AND NOT(MISSING('DEBTINC'n))
AND NOT(MISSING('DELINQ'n)) AND NOT(MISSING('NINQ'n)) AND NOT(MISSING('VALUE'n)));
_va_calculated_208_14=NOT(('_va_FILTER_'n = 0.0));;",compVars={"_va_calculated_208_1","
_va_calculated_208_11","_EVENT_","_va_FILTER_","_va_calculated_208_14"},name="HMEQ",
onDemand="false",where="NOT('_va_calculated_208_14'n = 0)"},
emtarget={name="_EVENT_",options={levelType="BINARY"}},
tolerance=1.0E-6,
var={"CLAGE","CLNO","DEBTINC","DELINQ","NINQ","VALUE"}
outputTables={names={nobs="NObs",modelinfo="ModelInfo"}, replace="TRUE"};
run;

quit;

/* Use Proc ASTORE to describe the model in CAS */
/* Download the model locally                   */
proc astore;
   describe rstore=sascas1._va_model208;
   download rstore=sascas1._va_model208;
 store="C:\project\my_models\_va_model208";
   describe store="C:\project\my_models\_va_model208";
run;
quit;

options pagesize=max;
proc cas;
    loadactionset "table";
   table.fetch
   format=false
   maxRows=1
   sasTypes=TRUE
```

```
   table = {
      compOnDemand=TRUE
      caslib="CASUSER"
       name="hmeq"
      compPgm=
"declare object myscore(astore);
call myscore.score('CASUSER','_va_model208');"
       singlePass=TRUE
       compVars={"_P_", "P__EVENT_0" , "P__EVENT_1" , "I__EVENT_" ,"_WARN_"}
   };
run;
quit;
```

The SETOPTION Method

The CMP ASTORE method, SETOPTION, passes options to ASTORE objects that take different option values. Here is code using PROC FCMP:

```
routineCode = "
   declare object model_glmstore(astore);
   call model_glmstore.setoption('alpha', 0.05);
   call model_glmstore.setoption('COMPUTE_CONFIDENCE_LIMIT', 1);
   call model_glmstore.score('CASUSER','glmstore');
"
;
run;
quit;
```

Here is code using the FCMPACT action:

```
routineCode = "
declare object model_glmstore(astore);
call model_glmstore.setoption('alpha', 0.05);
call model_glmstore.setoption('COMPUTE_CONFIDENCE_LIMIT', 1);
call model_glmstore.score('CASUSER','glmstore');
"
;
run;
quit;
```

Using Python Functions in PROC FCMP

Starting with SAS 9.4M6, PROC FCMP supports submitting and executing functions written in Python by using the Python object. A complete guide for using the Python object is located in the Using Python Objects chapter in the SAS Component Objects: Reference.

Examples: FCMP Procedure

Example 1: Creating a Function and Calling the Function from a DATA Step

Features: PROC FCMP statement option
OUTLIB=
DATA step

Details

This example shows how to compute a study day during a drug trial by creating a function in PROC FCMP and using that function in a DATA step.

Program

```
proc fcmp outlib=sasuser.funcs.trial;

   function study_day(intervention_date, event_date);

      n=event_date - intervention_date;
         if n >= 0 then
            n=n + 1;
         return(n);
   endsub;

options cmplib=sasuser.funcs;

data _null_;
   start='15Feb2010'd;
   today='27Mar2010'd;
   sd=study_day(start, today);

   put sd=;

run;
```

Program Description

Specify the name of an output package to which the compiled function and CALL routine are written. The package is stored in the data set Sasuser.Funcs.

```
proc fcmp outlib=sasuser.funcs.trial;
```

Create a function called STUDY_DAY. STUDY_DAY is created in a package called Trial, and contains two numeric input arguments.

```
   function study_day(intervention_date, event_date);
```

Use a DATA step IF statement to calculate EVENT_DATE. Use DATA step syntax to compute the difference between EVENT_DATE and INTERVENTION_DATE. The days before INTERVENTION_DATE begin at -1 and become smaller. The days after and including INTERVENTION_DATE begin at 1 and become larger. (This function never returns 0 for a study date.)

```
      n=event_date - intervention_date;
         if n >= 0 then
            n=n + 1;
         return(n);
   endsub;
```

Use the CMPLIB= system option to specify a SAS data set that contains the compiler subroutine to include during program compilation.

```
options cmplib=sasuser.funcs;
```

Create a DATA step to produce a value for the function STUDY_DAY. The function uses a start date and today's date to compute the value. STUDY_DAY is called from the DATA step. When the DATA step encounters a call to STUDY_DAY, it does not find this function in its traditional library of functions. It searches each of the data sets that are specified in the CMPLIB system option for a package that contains STUDY_DAY. In this case, it finds STUDY_DAY in Sasuser.Funcs.Trial.

```
data _null_;
   start='15Feb2010'd;
   today='27Mar2010'd;
   sd=study_day(start, today);
```

Write the output to the SAS log.

```
   put sd=;
```

Execute the SAS program.

```
run;
```

Log

Example Code 24.5 *Results from Creating and Calling a Function from a DATA Step*

```
sd=41
```

Example 2: Creating and Saving Functions with PROC FCMP

Features: PROC FCMP statement option
OUTLIB=
OUTARGS statement

Details

This example shows how to use PROC FCMP to create and save the functions that are used in the example.

Program

```
proc fcmp outlib=sasuser.exsubs.pkt1;

   subroutine calc_years(maturity, current_date, years);
      outargs years;
      years=(maturity - current_date) / 365.25;
   endsub;

function garkhprc(type$, buysell$, amount,E, t, S, rd, rf, sig);
      if buysell="Buy" then sign=1.;
      else do;
         if buysell="Sell" then sign=-1.;
         else sign=.;
      end;

      if type="Call" then
         garkhprc=sign * amount * garkhptprc(E, t, S, rd, rf, sig);
      else do;
         if type="Put" then
            garkhprc=sign * amount * garkhptprc(E, t, S, rd, rf, sig);
         else garkhprc=.;
      end;

return(garkhprc);

run;

endfunc;
```

Program Description

Specify the entry where the function package information is saved. The package is a three-level name.

```
proc fcmp outlib=sasuser.exsubs.pkt1;
```

Create a function to calculate years to maturity. A generic function called CALC_YEARS is declared to calculate years to maturity from date variables that are stored as the number of days. The OUTARGS statement specifies the variable that is updated by CALC_YEARS.

```
subroutine calc_years(maturity, current_date, years);
   outargs years;
   years=(maturity - current_date) / 365.25;
endsub;
```

Create a function for Garman-Kohlhagen pricing for FX options. A function called GARKHPRC is declared, which calculates Garman-Kohlhagen pricing for FX options. The function uses the SAS functions GARKHCLPRC and GARKHPTPRC.

```
function garkhprc(type$, buysell$, amount,E, t, S, rd, rf, sig);
      if buysell="Buy" then sign=1.;
      else do;
         if buysell="Sell" then sign=-1.;
         else sign=.;
      end;

      if type="Call" then
         garkhprc=sign * amount * garkhptprc(E, t, S, rd, rf, sig);
      else do;
         if type="Put" then
            garkhprc=sign * amount * garkhptprc(E, t, S, rd, rf, sig);
         else garkhprc=.;
      end;
```

The RETURN statement returns the value of the GARKHPRC function.

```
return(garkhprc);
```

Execute the FCMP procedure. The RUN statement executes the FCMP procedure.

```
run;
```

Close the function. The endfunc statement closes the function.

```
endfunc;
```

Log

Example Code 24.6 *Location of Functions That Are Saved*

```
NOTE: Function garkhprc saved to sasuser.exsubs.pkt1.
NOTE: Function calc_years saved to sasuser.exsubs.pkt1.
```

Example 3: Using Numeric Data in the FUNCTION Statement

Details

The following example uses numeric data as input to the FUNCTION statement of PROC FCMP.

Program

```
proc fcmp;
   function inverse(in);
      if in=0 then inv=.;
      else inv=1/in;
      return(inv);
   endfunc;
run;
```

Example 4: Using Character Data with the FUNCTION Statement

Details

The following example uses character data as input to the FUNCTION statement of PROC FCMP. The output from FUNCTION TEST is assigned a length of 12 bytes.

Program

```
options cmplib=work.funcs;

proc fcmp outlib=work.funcs.math;
   function test(x $) $ 12;
```

```
   if x='yes' then
      return('si si si');
      else
      return('no');
   endfunc;
run;

data _null_;
   spanish=test('yes');
   put spanish=;
run;
```

Log

Example Code 24.7 *Results from Using Character Data with the FUNCTION Statement in PROC FCMP*

```
spanish=si si si
```

Example 5: Using Variable Arguments with an Array

Details

The following example shows an array that accepts variable arguments. The example implies that the summation function can be called as follows:
`sum=summation(1,2,3,4,5);`

Note: When calling this function from a DATA step, you must provide the *VARARGS* as an array.

Program

```
options cmplib=sasuser.funcs;

proc fcmp outlib=sasuser.funcs.temp;
function summation (b[*]) varargs;
    total=0;
    do i=1 to dim(b);
        total=total + b[i];
    end;
return(total);
```

```
endfunc;
sum=summation(1, 2, 3, 4, 5);
   put sum=;
run;
```

Example 6: Using the SUBROUTINE Statement with a CALL Statement

Details

Here is an example of the SUBROUTINE statement. The SUBROUTINE statement creates an independent computational block of code that can be used with a CALL statement.

Program

```
proc fcmp outlib=sasuser.funcs.temp;
subroutine inverse(in,inv) group="generic";
   outargs inv;
   if in=0 then inv=.;
   else inv=1/in;
endsub;

options cmplib=sasuser.funcs;
data _null_;
   x=5;
   call inverse(x, y);
   put x= y=;
run;
```

Log

Example Code 24.8 *Results from Using the SUBROUTINE Statement in PROC FCMP*

```
x=5 y=0.2
```

Example 7: Using Graph Template Language (GTL) with User-Defined Functions

Features:

PROC FCMP functions
- OSCILLATE
- OSCILLATEBOUND

Other procedures
- PROC TEMPLATE
- PROC SGRENDER

Details

The following example shows how to use functions in a GTL EVAL function. It shows how to define functions that define new curve types (oscillate and oscillateBound). These functions can be used in a GTL EVAL function to compute new columns that are presented with a seriesplot and bandplot.

Program

```
proc fcmp outlib=sasuser.funcs.curves;
   function oscillate(x,amplitude,frequency);
         if amplitude le 0 then amp=1; else amp=amplitude;
            if frequency le 0 then freq=1; else freq=frequency;
         y=sin(freq*x)*constant("e")**(-amp*x);
         return (y);
  endfunc;

 function oscillateBound(x,amplitude);
       if amplitude le 0 then amp=1; else amp=amplitude;
       y=constant("e")**(-amp*x);
       return(y);
  endfunc;
 run;

 options cmplib=sasuser.funcs;

data range;
   do time=0 to 2 by .01;
   output;
   end;
run;

proc template ;
```

```
   define statgraph damping;
   dynamic X AMP FREQ;
   begingraph;
       entrytitle "Damped Harmonic Oscillation";
       layout overlay / yaxisopts=(label="Displacement");
          if (exists(X) and exists(AMP) and exists(FREQ))
                bandplot x=X  limitlower=eval(-oscillateBound(X,AMP))
                limitupper=eval(oscillateBound(X,AMP));
                seriesplot x=X y=eval(oscillate(X,AMP,FREQ));
          endif;
        endlayout;
   endgraph;
   end;
   run;

proc sgrender data=range template=damping;
     dynamic x="Time" amp=10 freq=50 ;
run;
```

Program Description

Create the OSCILLATE function.

```
proc fcmp outlib=sasuser.funcs.curves;
   function oscillate(x,amplitude,frequency);
         if amplitude le 0 then amp=1; else amp=amplitude;
            if frequency le 0 then freq=1; else freq=frequency;
         y=sin(freq*x)*constant("e")**(-amp*x);
         return (y);
  endfunc;
```

Create the OSCILLATEBOUND function.

```
 function oscillateBound(x,amplitude);
       if amplitude le 0 then amp=1; else amp=amplitude;
       y=constant("e")**(-amp*x);
       return(y);
  endfunc;
 run;
```

Create a data set called Range that is used by PROC SGRENDER.

```
 options cmplib=sasuser.funcs;

data range;
   do time=0 to 2 by .01;
   output;
   end;
run;
```

Use the TEMPLATE procedure to customize the appearance of your SAS output.

```
proc template ;
   define statgraph damping;
   dynamic X AMP FREQ;
   begingraph;
```

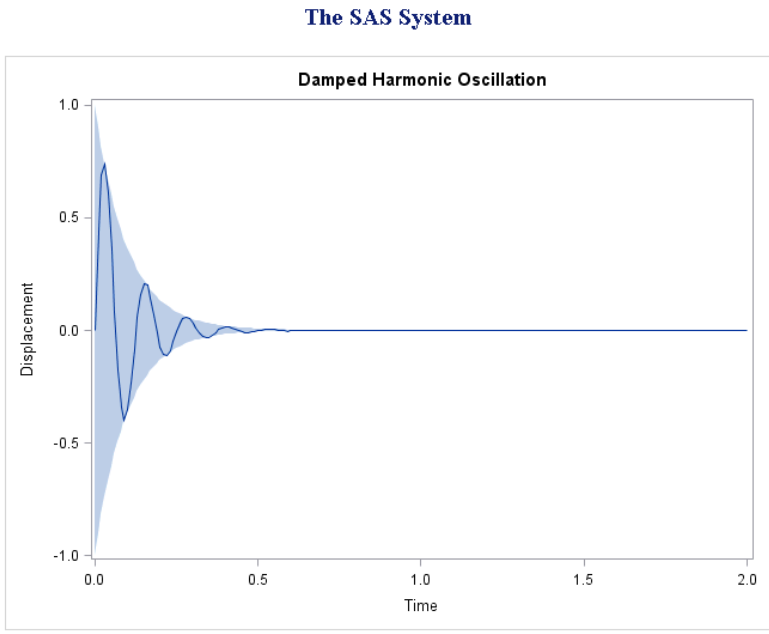
```
      entrytitle "Damped Harmonic Oscillation";
      layout overlay / yaxisopts=(label="Displacement");
         if (exists(X) and exists(AMP) and exists(FREQ))
               bandplot x=X  limitlower=eval(-oscillateBound(X,AMP))
               limitupper=eval(oscillateBound(X,AMP));
               seriesplot x=X y=eval(oscillate(X,AMP,FREQ));
         endif;
       endlayout;
  endgraph;
  end;
  run;
```

Use the SGRENDER procedure to identify the data set that contains the input variables and to assign a statgraph template for the output.

```
proc sgrender data=range template=damping;
     dynamic x="Time" amp=10 freq=50 ;
run;
```

Output: Using GTL with Functions

Output 24.6 *Results from Using GTL with User-Defined Functions*



Example 8: Standardizing Each Row of a Data Set

Features: PROC FCMP functions
- RUN_MACRO
- RUN_SASFILE
- READ_ARRAY
- WRITE_ARRAY

Details

This example shows how to standardize each row of a data set.

Program

```
data numbers;
   drop i j;
   array a[5];
   do j=1 to 5;
   do i=1 to 5;
         a[i] = ranuni(12345) * (i+123.234);
      end;
      output;
      end;
   run;

%macro standardize;
%let dsname=%sysfunc(dequote(&dsname));
%let colname=%sysfunc(dequote(&colname));
proc standard data=&dsname mean=&MEAN std=&STD out=_out;
   var &colname;
run;
data &dsname;
   set_out;
run;
%mend standardize;

proc fcmp outlib=sasuser.ds.functions;
   subroutine standardize(x[*], mean, std);
      outargs x;

      rc=write_array('work._TMP_', x, 'x1');
      dsname='work._TMP_';
         colname='x1';
         rc=run_macro('standardize', dsname, colname, mean, std);
      array x2[1]_temporary_;
         rc=read_array('work._TMP_', x2);
      if dim(x2)=dim(x) then do;
         do i=1 to dim(x);
            x[i]=x2[i];
          end;
         end;
   endsub;
run;

options cmplib=(sasuser.ds);
data numbers2;
   set numbers;
   array a[5];
```

```
   array t[5]_temporary_;
   do i=1 to 5;
      t[i]=a[i];
   end;
   call standardize(t, 0, 1);
   do i=1 to 5;
      a[i]=t[i];
   end;
   output;
run;

proc print data=work.numbers2;
run;
```

Program Description

Create a data set that contains five rows of random numbers.

```
data numbers;
   drop i j;
   array a[5];
   do j=1 to 5;
   do i=1 to 5;
         a[i] = ranuni(12345) * (i+123.234);
      end;
      output;
      end;
   run;
```

Create a macro to standardize a data set with a given value for mean and std.

```
%macro standardize;
%let dsname=%sysfunc(dequote(&dsname));
%let colname=%sysfunc(dequote(&colname));
proc standard data=&dsname mean=&MEAN std=&STD out=_out;
   var &colname;
run;
data &dsname;
   set_out;
run;
%mend standardize;
```

Use the FCMP function to call WRITE_ARRAY, which writes the data to a data set. Call RUN_MACRO to standardize the data in the data set. Call WRITE_ARRAY to write data to a data set. Call READ_ARRAY to read the standardized data back into the array.

```
proc fcmp outlib=sasuser.ds.functions;
   subroutine standardize(x[*], mean, std);
      outargs x;

      rc=write_array('work._TMP_', x, 'x1');
      dsname='work._TMP_';
         colname='x1';
         rc=run_macro('standardize', dsname, colname, mean, std);
      array x2[1]_temporary_;
```

```
         rc=read_array('work._TMP_', x2);
      if dim(x2)=dim(x) then do;
         do i=1 to dim(x);
            x[i]=x2[i];
          end;
         end;
   endsub;
run;
```

Execute the function for each row in the DATA step.

```
options cmplib=(sasuser.ds);
data numbers2;
   set numbers;
   array a[5];
   array t[5]_temporary_;
   do i=1 to 5;
      t[i]=a[i];
   end;
   call standardize(t, 0, 1);
   do i=1 to 5;
      a[i]=t[i];
   end;
   output;
run;
```

Write the output.

```
proc print data=work.numbers2;
run;
```

Output: Standardizing Rows in a Data Set

Output 24.7 *Results from Standardizing Each Row of a Data Set*

The SAS System

FCMP Special Functions and Call Routines

Overview of Special Functions and CALL Routines

The FCMP procedure provides a small set of special use functions. You can call these functions from user-defined FCMP functions but you cannot call these functions directly from the DATA step. To use these functions in a DATA step, you must wrap the special function inside another user-defined FCMP function.

Note: You can call special functions directly in a procedure, but not in the DATA step.

Functions and CALL Routines by Category

Table 25.1 *Categories of FCMP Functions and CALL Routines*

Category	Description
Calling SAS Code from within Functions	Two functions are available that enable you to call SAS code from within functions. The RUN_MACRO function executes a predefined SAS macro. The RUN_SASFILE function executes SAS code from a fileref that you specify.
C Helper	Several helper functions are provided with the package to handle C-language constructs in PROC FCMP. Most C-language constructs must be defined in a package that is created by PROC PROTO before the constructs can be referenced or used by PROC FCMP. The ISNULL function and the SETNULL and STRUCTINDEX CALL routines have been added to extend the SAS language to handle C-language constructs that do not naturally fit into the SAS language.
Arrays	PROC FCMP provides the READ_ARRAY function to read arrays, and the WRITE_ARRAY function to write arrays to a data set. This functionality enables PROC FCMP array data to be processed by SAS programs, macros, and procedures.

Category	Description
Matrix Operations	The FCMP procedure provides you with a number of CALL routines for performing simple matrix operations on declared arrays. These CALL routines are automatically provided by the FCMP procedure. With the exception of ZEROMATRIX, FILLMATRIX, and IDENTITY, the CALL routines listed below do not support matrices or arrays that contain missing values.
Special Purpose	The FCMP procedure provides two special purpose functions: INVCDF and LIMMOMENT. The INVCDF function computes the quantile from any distribution for which you have defined a cumulative distribution function (CDF). The LIMMOMENT function computes the limited moment of any distribution for which you have defined a cumulative distribution function (CDF).

Category	Language Elements	Description
Array	CALL DYNAMIC_ARRAY Routine (p. 946)	Enables an array that is declared within a function to change size in an efficient manner.
	READ_ARRAY Function (p. 969)	Reads data from a SAS data set into a PROC FCMP array variable.
	WRITE_ARRAY Function (p. 982)	Writes data from a PROC FCMP array variable to a data set that can then be used by SAS programs, macros, and procedures.
C Helper	CALL SETNULL Routine (p. 955)	Sets a pointer element of a structure to null.
	CALL STRUCTINDEX Routine (p. 956)	Enables you to access each structure element in an array of structures.
	ISNULL Function (p. 964)	Determines whether a pointer element of a structure is null.
Calling SAS Code from within Functions	RUN_MACRO Function (p. 971)	Executes a predefined SAS macro.
	RUN_SASFILE Function (p. 976)	Executes SAS code in a fileref that you specify.
Compute Implicit Values	SOLVE Function (p. 977)	Computes implicit values of a function using the Gauss-Newton method.
Matrix Operations	CALL ADDMATRIX Routine (p. 942)	Performs an elementwise addition of two matrices or a matrix and a scalar.
	CALL CHOL Routine (p. 943)	Calculates the Cholesky decomposition for a given symmetric matrix.
	CALL DET Routine (p. 945)	Calculates the determinant of a specified matrix that should be square.

Category	Language Elements	Description
	CALL ELEMMULT Routine (p. 948)	Performs an elementwise multiplication of two matrices.
	CALL EXPMATRIX Routine (p. 949)	Returns a matrix etA given the input matrix A and a multiplier t.
	CALL FILLMATRIX Routine (p. 950)	Replaces all of the element values of the input matrix with the specified value.
	CALL IDENTITY Routine (p. 951)	Converts the input matrix to an identity matrix.
	CALL INV Routine (p. 952)	Calculates a matrix that is the inverse of the provided input matrix that should be a square, non-singular matrix.
	CALL MULT Routine (p. 953)	Calculates the multiplicative product of two input matrices.
	CALL POWER Routine (p. 954)	Raises a square matrix to a given scalar value.
	CALL SUBTRACTMATRIX Routine (p. 957)	Performs an element-wide subtraction of two matrices or a matrix and a scalar.
	CALL TRANSPOSE Routine (p. 958)	Returns the transpose of a matrix.
	CALL ZEROMATRIX Routine (p. 959)	Replaces all of the element values of the numeric input matrix with 0.
Special Purpose Functions	INVCDF Function (p. 960)	Computes the quantile from any distribution for which you have defined a cumulative distribution function (CDF).
	LIMMOMENT Function (p. 965)	Computes the limited moment of any distribution for which you have defined a cumulative distribution function (CDF).

Dictionary

CALL ADDMATRIX Routine

Performs an elementwise addition of two matrices or a matrix and a scalar.

Category: Matrix Operations

Requirement: All input and output matrices must have the same dimensions.

Syntax

CALL ADDMATRIX(*X*, *Y*, *Z*);

Required Arguments

X

specifies an input matrix with dimensions *m* x *n* (that is, X[*m*, *n*]) or a scalar.

Y

specifies an input matrix with dimensions *m* x *n* (that is, Y[*m*, *n*]) or a scalar.

Z

specifies an output matrix with dimensions *m* x *n* (that is, Z[*m*, *n*]), such that

$$Z = X + Y$$

Example

The following example uses the ADDMATRIX CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,2] (0.3, -0.78, -0.82, 0.54, 1.74, 1.2);
   array mat2[3,2] (0.2, 0.38, -0.12, 0.98, 2, 5.2);
   array result[3,2];
   call addmatrix(mat1, mat2, result);
   call addmatrix(2, mat1, result);
   put result=;
quit;
```

Output 25.1 *Results from the ADDMATRIX CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=2.3 result[1, 2]=1.22 result[2, 1]=1.18 result[2, 2]=2.54
result[3, 1]=3.74 result[3, 2]=3.2
```

CALL CHOL Routine

Calculates the Cholesky decomposition for a given symmetric matrix.

Category: Matrix Operations

Alias: CHOLESKY_DECOMP

Requirement: Both input and output matrices must be square and have the same dimensions. X must be symmetric positive-definite, and Y a lower triangle matrix.

Syntax

CALL CHOL(*X*, *Y* <, *validate*>);

Required Arguments

X

specifies a symmetric positive-definite input matrix with dimensions *m* x *m* (that is, X[*m*, *m*]).

Y

specifies an output matrix with dimensions *m* x *m* (that is, Y[*m*, *m*]). This variable contains the Cholesky decomposition, such that

$$Z = YY*$$

where Y is a lower triangular matrix with strictly positive diagonal entries and Y* denotes the conjugate transpose of Y.

Note: If X is not symmetric positive-definite, then Y is filled with missing values.

Optional Argument

validate

specifies an optional argument that can increase the processing speed by avoiding error checking. The argument can take the following values:

0 the matrix X checks for symmetry. This is the default if the *validate* argument is omitted.

1 the matrix is assumed to be symmetric.

Example

The following example uses the CHOL CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array xx[3,3] 2 2 3 2 4 2 3 2 6;
   array yy[3,3];
   call chol(xx, yy, 0);
   do i=1 to 3;
      put yy[i, 1] yy[i, 2] yy[i, 3];
   end;
```

```
run;
```

Output 25.2 *Results from PROC FCMP and the CHOL CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

1.4142135624 0 0
1.4142135624 1.4142135624 0
2.1213203436 -0.707106781 1
```

CALL DET Routine

Calculates the determinant of a specified matrix that should be square.

Category: Matrix Operations

Requirement: The input matrix X must be square.

Syntax

CALL DET(*X*, *a*);

Required Arguments

X

specifies an input matrix with dimensions *m* x *n* (that is, X[*m*, *n*]).

a

specifies the returned determinate value, such that

$a = |X|$

Details

The determinant, the product of the eigenvalues, is a single numeric value. If the determinant of a matrix is zero, then that matrix is singular (that is, it does not have an inverse). The method performs an LU decomposition and collects the product of the diagonals (Forsythe, Malcolm, and Moler 1967). For more information, see the *SAS/IML User's Guide*.

Example

The following example uses the DET CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,3] (.03, -0.78, -0.82, 0.54, 1.74,
                    1.2, -1.3, 0.25, 1.49);
   call det(mat1, result);
   put result=;
quit;
```

Output 25.3 *Results from the DET CALL Routine*

```
                                The SAS System                          1

                              The FCMP Procedure

result=-0.052374
```

CALL DYNAMIC_ARRAY Routine

Enables an array that is declared within a function to change size in an efficient manner.

Category: Array

Syntax

CALL DYNAMIC_ARRAY(*array–name*, *new-dimension1–size* <, *new-dimension2–size*, ...>);

Required Arguments

array-name
specifies the name of a temporary array.

new-dimension-size
specifies a new size for the temporary array.

Details

Arrays that are declared in functions and CALL routines can be resized, as well as arrays that are declared with the /NOSYMBOLS option. No other array can be resized.

The DYNAMIC_ARRAY CALL routine attempts to dynamically resize the array to match the dimensions of the target that you provide. This means that the array must be dynamic. That is, the array must be declared either in a function or subroutine, or declared with the /NOSYMBOLS option.

The DYNAMIC_ARRAY CALL routine is passed the array to be resized and a new size for each dimension of the array. In the ALLPERMK routine, a scratch array that is the size of the number of elements being permuted is needed. When the function is created, this value is not known because it is passed in as parameter *n*. A dynamic array enables the routine to allocate the amount of memory that is needed, instead of having to create an array that is large enough to handle all possible cases.

When using dynamic arrays, support is limited to PROC FCMP routines. When an array is resized, the resized array is available only within the routine that resized it. It is not possible to resize a DATA step array or to return a PROC FCMP dynamic array to the DATA step.

Example

The following example creates a temporary array named TEMP. The size of the array area depends on parameters that are passed to the function.

```
proc fcmp;
   function avedev_wacky(data[*]);

   length=dim(data);
   array temp[1] /nosymbols;
   call dynamic_array(temp, length);

   mean=0;
   do i=1 to length;
      mean += data[i];
      if i>1 then temp[i]=data[i-1];
      else temp[i]=0;
   end;
   mean=mean/length;

   avedev=0;
   do i=1 to length;
      avedev += abs((data[i])-temp[i] /2-mean);
   end;
   avedev=avedev/length;

   return(avedev);
endsub;

array data[10];

do i = 1 to 10;

   data[i] = i;
end;
```

```
avedev = avedev_wacky(data);
run;
```

CALL ELEMMULT Routine

Performs an elementwise multiplication of two matrices.

Category: Matrix Operations

Requirement: All input and output matrices must have the same dimensions.

Syntax

CALL ELEMMULT(*X*, *Y*, *Z*);

Required Arguments

X
specifies an input matrix with dimensions *m* x *n* (that is, X[*m*, *n*]).

Y
specifies an input matrix with dimensions *m* x *n* (that is, Y[*m*, *n*]).

Z
specifies an output matrix with dimensions *m* x *n* (that is, Z[*m*, *n*]).

Example

The following example uses the ELEMMULT CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,2] (0.3, -0.78, -0.82, 0.54, 1.74, 1.2);
   array mat2[3,2] (0.2, 0.38, -0.12, 0.98, 2, 5.2);
   array result[3,2];
   call elemmult(mat1, mat2, result);
   call elemmult(2.5, mat1, result);
   put result=;
 quit;
```

Output 25.4 *Results from the ELEMMULT CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=0.75 result[1, 2]=-1.95 result[2, 1]=-2.05 result[2, 2]=1.35
result[3, 1]=4.35 result[3, 2]=3
```

CALL EXPMATRIX Routine

Returns a matrix e^{tA} given the input matrix *A* and a multiplier *t*.

Category: Matrix Operations

Requirement: Both input and output matrices must be square and have the same dimensions. *t* can be any scalar value.

Syntax

CALL EXPMATRIX(*X*, *t*, *Y*);

Required Arguments

X
specifies an input matrix with dimensions *m* x *m* (that is, X[*m*, *m*]).

t
specifies a double scalar value.

Y
specifies an output matrix with dimensions *m* x *m* (that is, Y[*m*, *m*]), such that

$$Y = \varepsilon^{tX}$$

Details

The EXPMATRIX CALL routine uses a Padé approximation algorithm as presented in Golub and van Loan (1989), p. 558. Note that this module does not exponentiate each entry of a matrix. For more information, see the EXPMATRIX documentation in the *SAS/IML User's Guide*.

Example

The following example uses the EXPMATRIX CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,3] (0.3, -0.78, -0.82, 0.54, 1.74,
                    1.2, -1.3, 0.25, 1.49);
   array result[3,3];
   call expmatrix(mat1, 3, result);
   put result=;
quit;
```

Output 25.5 *Results from the EXPMATRIX CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=365.58043585 result[1, 2]=-589.6358476 result[1, 3]=-897.1034008
result[2, 1]=-507.0874798 result[2, 2]=838.64570481 result[2, 3]=1267.3598426
result[3, 1]=-551.588816 result[3, 2]=858.97629382 result[3, 3]=1324.8187125
```

CALL FILLMATRIX Routine

Replaces all of the element values of the input matrix with the specified value.

Category: Matrix Operations

Note: You can use the FILLMATRIX CALL routine with multidimensional numeric arrays.

Syntax

CALL FILLMATRIX(*X*, *Y*);

Required Arguments

X
specifies an input numeric matrix.

Y
specifies the numeric value that fills the matrix.

Example

The following example uses the FILLMATRIX CALL routine.

```
options pageno=1 nodate ls=80 ps=64;

proc fcmp;
   array mat1[3, 2] (0.3, -0.78, -0.82, 0.54, 1.74, 1.2);
   call fillmatrix(mat1, 99);
   put mat1=;
quit;
```

Output 25.6 *Results from the FILLMATRIX CALL Routine*

```
                                The SAS System                                1

                               The FCMP Procedure

mat1[1, 1]=99 mat1[1, 2]=99 mat1[2, 1]=99 mat1[2, 2]=99 mat1[3, 1]=99
mat1[3, 2]=99
```

CALL IDENTITY Routine

Converts the input matrix to an identity matrix.

Category: Matrix Operations

Requirement: The input matrix must be square.

Note: Diagonal element values of the matrix are set to 1, and the rest of the values are set to 0.

Syntax

CALL IDENTITY(*X*);

Required Argument

X
specifies an input matrix with dimensions *m* x *m* (that is, X[*m*, *m*]).

Example

The following example uses the IDENTITY CALL routine:

```
options pageno=1 nodate;
```

```
proc fcmp;
   array mat1[3,3] (0.3, -0.78, -0.82, 0.54, 1.74, 1.2,
                    -1.3, 0.25, 1.49);
   call identity(mat1);
   put mat1=;
quit;
```

Output 25.7 *Results from the IDENTITY CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

mat1[1, 1]=1 mat1[1, 2]=0 mat1[1, 3]=0 mat1[2, 1]=0 mat1[2, 2]=1 mat1[2, 3]=0
mat1[3, 1]=0 mat1[3, 2]=0 mat1[3, 3]=1
```

CALL INV Routine

Calculates a matrix that is the inverse of the provided input matrix that should be a square, non-singular matrix.

Category: Matrix Operations

Requirement: Both the input and output matrices must be square and have the same dimensions.

Syntax

CALL INV(*X*, *Y*);

Required Arguments

X

specifies an input matrix with dimensions *m* x *m* (that is, X[*m*, *m*]).

Y

specifies an output matrix with dimensions *m* x *m* (that is, Y[*m*, *m*]), such that

$$Y[m,m] = X'[m,m]$$

where ′ denotes inverse

$$X \times Y = Y \times X = I$$

and I is the identity matrix.

Example

The following example uses the INV CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,3] (0.3, -0.78, -0.82, 0.54, 1.74,
                    1.2, -1.3, 0.25, 1.49);
   array result[3,3];
   call inv(mat1, result);
   put result=;
quit;
```

Output 25.8 *Results from the INV CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=4.0460407887 result[1, 2]=1.6892917399 result[1, 3]=0.8661767509
result[2, 1]=-4.173108283 result[2, 2]=-1.092427483 result[2, 3]=-1.416802558
result[3, 1]=4.230288655 result[3, 2]=1.6571719011 result[3, 3]=1.6645841716
```

CALL MULT Routine

Calculates the multiplicative product of two input matrices.

Category: Matrix Operations

Requirement: The number of columns for the first input matrix must be the same as the number of rows for the second matrix.

Syntax

CALL MULT(*X*, *Y*, *Z*);

Required Arguments

X
specifies an input matrix with dimensions *m* x *n* (that is, X[*m*, *n*]).

Y
specifies an input matrix with dimensions *n* x *p* (that is, Y[*n*, *p*]).

Z
specifies an output matrix with dimensions *m* x *p* (that is, Z[*m*, *p*]), such that

$$Z[m,p] = X[m,n] \times Y[n,p]$$

Example

The following example uses the MULT CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[2,3] (0.3, -0.78, -0.82, 0.54, 1.74, 1.2);
   array mat2[3,2] (1, 0, 0, 1, 1, 0);
   array result[2,2];
   call mult(mat1, mat2, result);
   put result=;
quit;
```

Output 25.9 *Results from the MULT CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=-0.52 result[1, 2]=-0.78 result[2, 1]=1.74 result[2, 2]=1.74
```

CALL POWER Routine

Raises a square matrix to a given scalar value.

Category: Matrix Operations

Restriction: Large scalar values should be avoided because the POWER CALL routine's internal use of the matrix multiplication routine might cause numerical precision problems.

Requirement: Both input and output matrices must be square and have the same dimensions.

Syntax

CALL POWER(*X*, *a*, *Y*);

Required Arguments

X
specifies an input matrix with dimensions *m* x *m* (that is, X[*m*, *m*]).

a
specifies an integer scalar value (power).

Y
specifies an output matrix with dimensions *m* x *m* (that is, Y[*m*, *m*]), such that

$$Y = X^a$$

Details

If the scalar is not an integer, it is truncated to an integer. If the scalar is less than 0, then it is changed to 0. For more information, see the *SAS/IML User's Guide*.

Example

The following example uses the POWER CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,3] (0.3, -0.78, -0.82, 0.54, 1.74,
                    1.2, -1.3, 0.25, 1.49);
   array result[3,3];
   call power(mat1, 3, result);
   put result=;
quit;
```

Output 25.10 *Results from the POWER CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=2.375432 result[1, 2]=-4.299482 result[1, 3]=-6.339638
result[2, 1]=-3.031224 result[2, 2]=6.272988 result[2, 3]=8.979036
result[3, 1]=-4.33592 result[3, 2]=5.775695 result[3, 3]=9.326529
```

CALL SETNULL Routine

Sets a pointer element of a structure to null.

Category: C Helper

Syntax

CALL SETNULL(*pointer-element*);

Required Argument

pointer-element
is a pointer to a structure.

Example

The following example assumes that the same LINKLIST structure that is described in "Example 1: Generating a Linked List" on page 964 is defined using PROC PROTO. The CALL SETNULL routine can be used to set the NEXT element to null:

```
struct linklist list;
call setnull(list.next);
```

CALL STRUCTINDEX Routine

Enables you to access each structure element in an array of structures.

Category: C Helper

Syntax

CALL STRUCTINDEX(*structure-array*, *index*, *structure-element*);

Required Arguments

structure-array
specifies an array.

index
is a 1–based index as used in most SAS arrays.

structure-element
points to an element in the array.

Example

In the first part of this example, the following structures and function are defined by using PROC PROTO.

```
proc proto package=sasuser.mylib.str2;
struct point{
   short s;
   int i;
   long l;
   double d;
};

struct point_array {
   int            length;
   struct point p[2];
   char           name[32];
};
```

```
run;
```

In the second part of this example, the PROC FCMP code segment shows how to use the STRUCTINDEX CALL routine to retrieve and set each point structure element of an array called P in the POINT_ARRAY structure:

```
options pageno=1 nodate ls=80 ps=64;

proc fcmp libname=sasuser.mylib;
   struct point_array pntarray;
   struct point pnt;

   pntarray.length=2;
   pntarray.name="My funny structure";

   /* Get each element using the STRUCTINDEX CALL routine and set
values. */
do i=1 to 2;
   call structindex(pntarray.p, i, pnt);
   put "Before setting the" i "element: " pnt=;
   pnt.s=1;
   pnt.i=2;
   pnt.l=3;
   pnt.d=4.5;
   put "After setting the" i "element: " pnt=;
end;
run;
```

Output 25.11 *Results of Setting the Point Structure Elements of an Array*

```
                                The SAS System                                1

                              The FCMP Procedure

Before setting the 1 element:  pnt {s=0, i=0, l=0, d=0}
After setting the 1 element:  pnt {s=1, i=2, l=3, d=4.5}
Before setting the 2 element:  pnt {s=0, i=0, l=0, d=0}
After setting the 2 element:  pnt {s=1, i=2, l=3, d=4.5}
```

CALL SUBTRACTMATRIX Routine

Performs an element-wide subtraction of two matrices or a matrix and a scalar.

Category: Matrix Operations

Requirement: All input and output matrices must have the same dimensions.

Syntax

CALL SUBTRACTMATRIX(*X*, *Y*, *Z*);

Required Arguments

X

specifies an input matrix with dimensions *m* x *n* (that is, X[*m*, *n*]) or a scalar.

Y

specifies an input matrix with dimensions *m* x *n* (that is, Y[*m*, *n*]) or a scalar.

Z

specifies an output matrix with dimensions *m* x *n* (that is, Z[*m*, *n*]), such that

$Z = X - Y$

Example

The following example uses the SUBTRACTMATRIX CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,2] (0.3, -0.78, -0.82, 0.54, 1.74, 1.2);
   array mat2[3,2] (0.2, 0.38, -0.12, 0.98, 2, 5.2);
   array result[3,2];
   call subtractmatrix(mat1, mat2, result);
   call subtractmatrix(2, mat1, result);
   put result=;
 quit;
```

Output 25.12 *Results from the SUBTRACTMATRIX CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=1.7 result[1, 2]=2.78 result[2, 1]=2.82 result[2, 2]=1.46
result[3, 1]=0.26 result[3, 2]=0.8
```

CALL TRANSPOSE Routine

Returns the transpose of a matrix.

Category: Matrix Operations

Syntax

CALL TRANSPOSE(*X*, *Y*);

Required Arguments

X
specifies an input matrix with dimensions *m* x *n* (that is, X[*m*, *n*]).

Y
specifies an output matrix with dimensions *n* x *m* (that is, Y[*n*, *m*])

Details

$$Y = X'$$

Note that the number of rows for the input matrix should be equal to the number of columns of the output matrix, and the number of rows for the output matrix should be equal to the number of columns of the input matrix.

Example

The following example uses the TRANSPOSE CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,2] (0.3, -0.78, -0.82, 0.54, 1.74, 1.2);
   array result[2,3];
   call transpose(mat1, result);
   put result=;
quit;
```

Output 25.13 *Results from the TRANSPOSE CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

result[1, 1]=0.3 result[1, 2]=-0.82 result[1, 3]=1.74 result[2, 1]=-0.78
result[2, 2]=0.54 result[2, 3]=1.2
```

CALL ZEROMATRIX Routine

Replaces all of the element values of the numeric input matrix with 0.

Category: Matrix Operations

Note: You can use the ZEROMATRIX CALL routine with multi-dimensional numeric arrays.

Syntax

CALL ZEROMATRIX(*X*);

Required Argument

X
specifies a numeric input matrix.

Example

The following example uses the ZEROMATRIX CALL routine:

```
options pageno=1 nodate;

proc fcmp;
   array mat1[3,2]  (0.3, -0.78, -0.82, 0.54, 1.74, 1.2);
   call zeromatrix(mat1);
   put mat1=;
quit;
```

Output 25.14 *Results from the ZEROMATRIX CALL Routine*

```
                                The SAS System                                1

                              The FCMP Procedure

mat1[1, 1]=0 mat1[1, 2]=0 mat1[2, 1]=0 mat1[2, 2]=0 mat1[3, 1]=0 mat1[3,
2]=0
```

INVCDF Function

Computes the quantile from any distribution for which you have defined a cumulative distribution function (CDF).

Category: Special Purpose Functions

Notes: INVCDF is a special purpose function that is automatically provided by the FCMP procedure for your convenience.

If you specify a probability *p* for a distribution with CDF denoted by *F(x; <parameters>)*, then the INVCDF function returns a quantile *q* that satisfies *F(q;<parameters>) = p*. In other words, $q=F^{-1}(p)$.

Syntax

quantile=**INVCDF**('*CDF-function-name*', *options-array*, *cumulative-probability*, *parameter-1 <, parameter-2, ...>*);

Required Arguments

quantile
specifies the quantile that is returned from the INVCDF function.

'CDF-function-name'
specifies the name of the CDF function. Enclose *CDF-function-name* in quotation marks.

Requirement *CDF-function-name* must be a function defined using the FCMP procedure. It must have a signature as follows:

```
function <CDF-function-name> (x, parameter-1 <, parameter-2, …>);
endsub;
```

Note It is recommended that the CDF be a continuous function. For discrete CDF, the INVCDF function might not be able to compute the quantile.

options-array
specifies an array of options to use with the INVCDF function. *Options-array* is used to control and monitor the process of inverting the CDF. *Options-array* can be a missing value (.), or it can have up to four of the following elements in the following order:

initial-value
specifies the initial guess for the quantile at which the inversion process starts. This is useful when you have an idea of the approximate value for quantile (for example, from the empirical estimate of the CDF).

Default 0.1

desired-accuracy
specifies the desired relative accuracy of the quantile. You can specify any value in the range (0,0.1). If you specify a smaller value, the result is a more accurate estimate of the quantile, but it might take longer to invert the CDF.

Default 1.0e-8

domain-type
specifies the domain for the CDF function. A missing value or a value of 0 indicates a nonnegative support, that is [0,∞). Any other value indicates a support over the entire real line, that is (-∞,∞).

Default 0

return-code
specifies the return status. If *options-array* is of dimension 4 or more, then the fourth element contains the return status. *Return-code* can have one of the following values:

<=0
indicates success. If negative, then the absolute value is the number of times the CDF function was evaluated in order to compute the quantile. A larger absolute value indicates longer convergence time.

1
indicates that the quantile could not be computed.

cumulative-probability
specifies the cumulative probability value for which the quantile is desired.

Range [0,1)

parameter
specifies the parameters of the distribution at which the quantile is desired. You must specify exactly the same number of parameters as required by the specified CDF function, and they should appear exactly in the same order as required by the specified CDF function.

Details

The INVCDF function finds the quantile for the specified cumulative probability from a distribution whose cumulative distribution function is specified by the *CDF-function-name* argument. In other words, it inverts the CDF function such that the following expression is true:

```
cumulative-probability = CDF-function-name(quantile,<parameters>)
```

If ε denotes the desired accuracy of the quantile for cumulative probability *p*, then INVCDF attempts to compute the quantile *q* such that $|p - F(q)| < \varepsilon p$, where *F(x)* denotes the CDF evaluated at *x*.

You can control the inversion process with various options. Here is an example of an options array:

```
array opts[4] initial epsilon support (1.5 1.0e-6 0);
```

These values refer to the preceding line of code:

```
initial(initial-value)=1.5

epsilon(desired-accuracy)=1.0e-6

support(domain-type)=0
```

You can examine the return status of the function by checking opts[4].

Comparisons

You can regard this function as a generic extension of the QUANTILE function, which computes quantiles only from specific distributions. The INVCDF function enables you to compute quantiles from any continuous distribution as long as you can programmatically define that distribution's CDF function. Unlike the QUANTILE function, this function cannot be used directly in a DATA step. It only can be used inside the definition of an FCMP function or subroutine. However, this is not a limitation because you can invoke the FCMP function that uses it from a DATA step. See the following example.

Example: Generating a Random Sample from an Exponential Distribution

The following example demonstrates how you can generate a random sample from any parametric distribution in a DATA step using the INVCDF function. The example uses the exponential distribution for illustration, but it can be extended to any distribution for which you can programmatically define a CDF function. The following statements define an FCMP function EXP_QUANTILE that uses the INVCDF function and the CDF function to compute a quantile from the exponential distribution.

```
proc fcmp library=work.mycdf outlib=work.myquantile.functions;
   function exp_quantile(cdf, theta, rc);
      outargs rc;
      array opts[4] / nosym(0.1 1.0e-8 .);
      q=invcdf("exp_cdf", opts, cdf, theta);
      rc=opts[4];  /* return code */
      return(q);
   endsub;
quit;
```

The preceding code assumes that you have stored the definition of the EXP_CDF function in an FCMP library called Work.Mycdf using a PROC FCMP step as follows:

```
proc fcmp outlib=work.mycdf.functions;
   function exp_cdf(x, theta);
      return(1.0 - exp(-x/Theta));
   endsub;
quit;
```

Now you can invoke the EXP_QUANTILE function from a DATA step to generate a random sample from the exponential distribution with a scale parameter (theta) that has a value of 50. Note that the locations of the EXP_CDF and EXP_QUANTILE functions need to be specified with the appropriate value for the CMPLIB= option before you execute the DATA step:

```
options cmplib=(work.mycdf work.myquantile);

data exp_sample(keep=q);
   n=0;k=0;
   do k=1 to 500;
      if (n=100) then leave;
```

```
      rcode=.;
      q=exp_quantile(rand('UNIFORM'), 50, rcode);
      if (rcode <= 0) then do;
         n=n+1;
         output;
      end;
   end;
run;
```

ISNULL Function

Determines whether a pointer element of a structure is null.

Category: C Helper

Syntax

numeric-variable = **ISNULL** (*pointer-element*);

Required Arguments

numeric-variable
specifies a numeric value.

pointer-element
specifies a variable that contains the address of another variable.

Examples

Example 1: Generating a Linked List

In the following example, the LINKLIST structure and GET_LIST function are defined by using PROC PROTO. The GET_LIST function is an external C routine that generates a linked list with as many elements as requested.

```
struct linklist{
   double value;
   struct linklist * next;
};

struct linklist * get_list(int);
```

Example 2: Using the ISNULL C Helper Function in a Loop

The following code segment shows that the ISNULL C helper function loops over the linked list that is created by GET_LIST and writes out the elements.

```
proc proto package=sasuser.mylib.str2;
```

```
struct linklist{
   double value;
   struct linklist * next;
};

struct linklist * get_list(int);

externc get_list;
   struct linklist * get_list(int len){
      int i;
      struct linklist * list=0;
      list=(struct linklist*)
         malloc(len*sizeof(struct linklist));
      for (i=0;i<len-1;i++){
         list[i].value=i;
         list[i].next=&list[i+1];
      }
      list[i].value=i;
      list[i].next=0;
      return list;
   }
externcend;
run;

options pageno=1 nodate ls=80 ps=64;
proc fcmp libname=sasuser.mylib;
   struct linklist list;
   list=get_list(3);
   put list.value=;

   do while (^isnull(list.next));
      list=list.next;
      put list.value=;
   end;
run;
```

Output 25.15 *Results from Using the ISNULL C Helper Function*

```
                                The SAS System                                1

                              The FCMP Procedure

list.value=0
list.value=1
list.value=2
```

LIMMOMENT Function

Computes the limited moment of any distribution for which you have defined a cumulative distribution function (CDF).

Category: Special Purpose Functions

Notes: LIMMOMENT is a special purpose function that is automatically provided by the FCMP procedure for your convenience.

If you specify order *k* and upper limit *u*, then the LIMMOMENT function computes the limited moment as $E[min(X,u)^k]$, where *E* denotes an expectation taken over the distribution of a random variable X that is defined by the specified CDF function.

Syntax

imom=**LIMMOMENT**('*CDF-function-name*', *options-array*, *order*, *limit*, *parameter-1 <, parameter-2, ...>*);

Required Arguments

imom
specifies the limited moment that is returned from the LIMMOMENT function.

'CDF-function-name'
specifies the name of the CDF function. Enclose *CDF-function-name* in quotation marks.

Requirement *CDF-function-name* must be a function defined using the FCMP procedure. It must have a signature as follows:

```
function <CDF-function-name> (x, parameter-1 <, parameter-2, …>);

endsub;
```

Note It is recommended that the CDF be a continuous function. For discrete CDF, the LIMMOMENT function might not be able to compute the limited moment.

options-array
specifies an array of options to use with the LIMMOMENT function. *Options-array* is used to control and monitor the process of numerical integration used to compute the limited amount. *Options-array* can be a missing value (.), or it can have up to four of the following elements in the following order:

desired-accuracy
specifies the desired accuracy of the numerical integration. You can specify any value in the range (0,0.1). If you specify a smaller value, the result is a more accurate estimate of the moment, but it takes longer to compute the desired-accuracy.

Default 1.0e-8

initial-step-size
specifies the step size that is used initially by the numerical integration process. An increase in the value results in a linear decrease in the number of times the integrand is evaluated. Typically, using the default value of 1 produces good results.

Default 1

maximum-iterations
specifies the maximum number of iterations that are used to refine the integration result in order to achieve the desired accuracy. An increase in this value results in an exponential increase in the number of times the integrand is evaluated.

Default 8

return-code
specifies the return status. If *options-array* is of dimension 4 or more, then the fourth element contains the return status. *Return-code* can have one of the following values:

<=0
indicates success. If negative, then the absolute value is the number of times the integrand function was evaluated in order to compute the limited moment. A larger absolute value indicates longer convergence time.

1
indicates that the limited moment could not be computed.

order
specifies the order of the desired limited moment.

Range [1,10]

limit
specifies the upper limit that is used to compute the desired limited moment.

Requirement The value of *limit* must be greater than 0.

parameter
specifies the parameters of the distribution at which the limited moment is desired. You must specify exactly the same number of parameters as required by the specified CDF function, and they should appear exactly in the same order as required by the specified CDF function.

Details

Let a random variable *X* have a probability distribution with probability density function *f(x;θ)* and cumulative distribution function *F(x;θ)*, where θ denotes the parameters of the distribution. For a specified upper limit *u*, the k^{th}–order limited moment of this distribution is defined as follows:

$$E[(X \wedge u)^k] = \int_0^u x^k f(x)dx + u^k \int_u^\infty f(x)dx = \int_0^u x^k f(x)dx + u^k(1 - F(u))$$

The LIMMOMENT function uses the following alternate expression:

$$E[(X \wedge u)^k] = k \int_0^u x^{k-1}[1 - F(x)]dx$$

Because the expression needs only *F(x)*, you need to specify only the CDF function for the distribution. Limited moments are often used in insurance applications to compute the maximum amount expected to be paid if the policy limit is set at a certain value.

You can control the numerical integration process with various options. Here is an example of an options array:

```
array opts[4] epsilon initial maxiter (1.0e-5 1 6);
```

These values refer to the preceding line of code.

```
epsilon(desired-accuracy)=1.0e-5

initial(initial-step)=1

maxiter(maximum-iterations)=6
```

You can examine the return status of the function by checking opts[4].

Example: Computing a Limited Moment for a Lognormal Distribution

This example demonstrates how you can compute the limited moment for any parametric distribution in a DATA step using the LIMMOMENT function. The example uses the lognormal distribution for illustration, but it can be extended to any distribution for which you can programmatically define a CDF function. The following statements define an FCMP function LOGN_LIMMOMENT that uses the LIMMOMENT function and the CDF function to compute limited moments from the lognormal distribution:

```
proc fcmp library=work.mycdf outlib=work.mylimmom.functions;
        function logn_limmoment(order, limit, mu, sigma, rc);
            outargs rc;
            array opts[4] / nosym (1.0e-8 . . .);

            m=limmoment("logn_cdf", opts, order, limit, mu, sigma);
            rc=opts[4]; /* return code */

            return(m);
        endsub;
    quit;
```

The preceding code assumes that you have stored the definition of the LOGN_CDF function in an FCMP library called Work.Mycdf using a PROC FCMP step as follows:

```
proc fcmp outlib=work.mycdf.functions;
        function logn_cdf(x, Mu, Sigma);
            if (x >= constant('MACEPS')) then do;
                z=(log(x) - Mu)/Sigma;
                return(CDF('NORMAL',z));
            end;
            return (0);
        endsub;
    quit;
```

You can now invoke the LOGN_LIMMOMENT function from a DATA step as shown below. Note that the location of the LOGN_CDF and LOGN_LIMMOMENT functions must be specified with an appropriate value for the CMPLIB= option before you execute the DATA step:

```
options cmplib=(work.mycdf work.mylimmom);

    data _null_;
        do order=1 to 3;
            rcode=.;
            m=logn_limmoment(order, 100, 5, 0.5, rcode);
            if (rcode > 0) then
                put "ERROR: Limited moment could not be computed.";
            else
                put 'Moment of order ' order ' with limit 100 = ' m;
        end;
    run;
```

READ_ARRAY Function

Reads data from a SAS data set into a PROC FCMP array variable.

Category: Array

Syntax

rc = **READ_ARRAY**(*data_set_name*, *array_variable* <, *'column_name_1'*, *'column_name_2'* , ... >);

Required Arguments

rc
is 0 if the function is able to successfully read the data set.

data_set_name
specifies the name of the data set from which the array data is read. *Data_set_name* must be a character literal or variable that contains the member name (libname.memname) of the data set to be read from.

array_variable
specifies the PROC FCMP array variable into which the data is read. *Array_variable* must be a local temporary array variable because the function might need to grow or shrink its size to accommodate the size of the data set.

Optional Argument

column_name
specifies optional names for the specific columns of the data set that are read.

If specified, *column_name* must be a literal string enclosed in quotation marks. *Column_name* cannot be a PROC FCMP variable. If column names are not specified, PROC FCMP reads all of the columns in the data set.

Details

When SAS translates between an array and a data set, the array is indexed as [row,column].

Arrays that are declared in functions and CALL routines can be resized, as well as arrays that are declared with the /NOSYMBOLS option. No other arrays can be resized.

The READ_ARRAY function attempts to dynamically resize the array to match the dimensions of the input data set. This means that the array must be dynamic. That is, the array must be declared either in a function or CALL routine or declared with the /NOSYMBOLS option.

Example

This example creates and reads a SAS data set into an FCMP array variable.

```
options nodate pageno=1;

data account;
   input acct price cost;
   datalines;
1 2 3
4 5 6
;
run;

proc fcmp;
   array x[2,3] / nosymbols;
   rc=read_array('account',x);
   put x=;
run;

proc fcmp;
   array x[2,2] / nosymbols;
   rc=read_array('account', x, 'price', 'acct');
   put x=;
run;
```

Output 25.16 *Results from the READ_ARRAY Function*

```
                                The SAS System                                1

                              The FCMP Procedure

x[1, 1]=1 x[1, 2]=2 x[1, 3]=3 x[2, 1]=4 x[2, 2]=5 x[2, 3]=6
```

```
                                The SAS System                                2

                              The FCMP Procedure

x[1, 1]=2 x[1, 2]=1 x[2, 1]=5 x[2, 2]=4
```

RUN_MACRO Function

Executes a predefined SAS macro.

Category: Calling SAS Code from within Functions

Note: The behavior of this function is similar to executing `%macro_name;` in SAS.

Syntax

rc = **RUN_MACRO** (*'macro_name'* <, *variable_1*, *variable_2, ...*>);

Required Arguments

rc
is 0 if the function is able to submit the macro. The return code indicates only that the macro call was attempted. The macro itself should set the value of a SAS macro variable that corresponds to a PROC FCMP variable to determine whether the macro executed as expected.

macro_name
specifies the name of the macro to be run.

Requirement *Macro_name* must be a string enclosed in quotation marks or a character variable that contains the macro to be executed.

Optional Argument

variable
specifies optional PROC FCMP variables, which are set by macro variables of the same name. These arguments must be PROC FCMP double or character variables.

Before SAS executes the macro, SAS macro variables are defined with the same name and value as the PROC FCMP variables. After SAS executes the macro, the macro variable values are copied back to the corresponding PROC FCMP variables.

Examples

Example 1: Executing a Predefined Macro with PROC FCMP

This example creates a macro called %TESTMACRO, and then uses the macro within PROC FCMP to subtract two numbers.

```
      /* Create a macro called %TESTMACRO. */
%macro testmacro;
   %let p=%sysevalf(&a - &b);
%mend testmacro;

    /* Use %TESTMACRO within a function in PROC FCMP to subtract two
numbers. */
proc fcmp outlib=sasuser.ds.functions;
   function subtract_macro(a, b);
      rc=run_macro('testmacro', a, b, p);
      if rc eq 0 then return(p);
      else return(.);
   endsub;
run;

   /* Make a call from the DATA step. */
option cmplib=(sasuser.ds);

data _null_;
   a=5.3;
   b=0.7;
   p=.;
   p=subtract_macro(a, b);
   put p=;
run;
```

Example Code 25.1 *Results from Executing a Predefined Macro with PROC FCMP*

```
p=4.6
```

Example 2: Comparing Results from the RUN_MACRO and the DOSUBL Functions

This example creates the %TESTMACRO macro, and compares how the DOSUBL function invokes the same %TESTMACRO as RUN_MACRO. In the RUN_MACRO invocation, all variables are passed as arguments so that they can be set. In the DOSUBL invocation, all macro variables are imported to the code to be executed, then exported on completion. The macro variables &a and &b are made available to %TESTMACRO and the macro variable &p is made available to the caller of

DOSUBL. For more information, see "DOSUBL Function" in *SAS Functions and CALL Routines: Reference*.

```
    /* Create a macro called %TESTMACRO. */
%macro testmacro;
   %let p=%sysevalf(&a - &b);
%mend testmacro;

    /* Use %TESTMACRO within a function in PROC FCMP to subtract two
numbers. */
proc fcmp outlib=sasuser.ds.functions;
   function subtract_macro(a, b);
      rc=run_macro('testmacro', a, b, p);
      if rc eq 0 then return(p);
      else return(.);
   endsub;
run;

   /* Make a call from the DATA step. */
option cmplib=(sasuser.ds);

data _null_;
   a=5.3;
   b=0.7;
   p=.;
   p=subtract_macro(a, b);
   put p= '(RUN_MACRO function and a DATA step)';
run;

%global a b p;
%put p=&p;
    /* The value should not yet be known. */
   %let a=5.3;
   %let b=0.7;
data _null_;
   rc=dosubl('%testmacro');
   run;
%put p=&p (DOSUBL function);
```

Example Code 25.2 *Results from the RUN_MACRO and the DOSUBL Functions*

```
p=4.6 (RUN_MACRO function and a DATA step)
p=4.6 (DOSUBL function)
```

Example 3: Executing a DATA Step within a DATA Step

This example shows how to execute a DATA step from within another DATA step. The program consists of the following sections:

- The first section of the program creates a macro called APPEND_DS. This macro can write to a data set or append a data set to another data set.
- The second section of the program calls the macro from function writeDataset in PROC FCMP.

- The third section of the program creates the SALARIES data set and divides the data set into four separate data sets depending on the value of the variable Department.
- The fourth section of the program writes the results to the output window.

```
   /* Create a macro called APPEND_DS. */
%macro append_ds;
   /* Character values that are passed to RUN_MACRO are put
*/
   /* into their corresponding macro variables inside of quotation
*/
   /* marks. The quotation marks are part of the macro variable value.
*/
   /* The DEQUOTE function is called to remove the quotation marks.
*/
   %let dsname=%sysfunc(dequote(&dsname));
   data &dsname;
      %if %sysfunc(exist(&dsname)) %then %do;
         modify &dsname;
      %end;
      Name=&Name;
      WageCategory=&WageCategory;
      WageRate=&WageRate;
      output;
      stop;
   run;
%mend append_ds;

   /* Call the APPEND_DS macro from function writeDataset in PROC
FCMP. */
proc fcmp outlib=sasuser.ds.functions;
   function writeDataset (DsName $, Name $, WageCategory $, WageRate);
      rc=run_macro('append_ds', DsName, Name, WageCategory, WageRate);
      return(rc);
   endsub;
run;

   /* Use the DATA step to separate the salaries data set into four
separate */
   /* departmental data sets (NAD, DDG, PPD, and
STD).                        */
data salaries;
   input Department $ Name $ WageCategory $ WageRate;
   datalines;

RUN_SASFILE Function

Executes SAS code in a fileref that you specify.

Category: Calling SAS Code from within Functions

Syntax

rc = **RUN_SASFILE** (*'fileref_name'* <, *variable-1*, *variable-2*, ...>);

Required Arguments

rc
is 0 if the function is able to submit a request to execute the code that processes the SAS file. The return code indicates only that the call was attempted.

fileref_name
specifies the name of the SAS fileref that points to the SAS code.

Requirement *Fileref_name* must be a string enclosed in quotation marks or a character variable that contains the name of the SAS fileref.

Optional Argument

variable
specifies optional PROC FCMP variables that are set by macro variables of the same name. These arguments must be PROC FCMP double or character variables.

Before SAS executes the code that references the SAS file, the SAS macro variables are defined with the same name and value as the PROC FCMP variables. After execution, these macro variable values are copied back to the corresponding PROC FCMP variables.

Example

The following example is similar to the first example for RUN_MACRO except that RUN_SASFILE uses a SAS file instead of a predefined macro. This example assumes that `test.sas(a, b, c)` is located in the current directory.

```
      /* test.sas(a,b,c) */
data _null_;
   call symput('p', &a * &b);
run;

   /* Set a SAS fileref to point to the data set. */
filename myfileref "test.sas";

   /* Set up a function in PROC FCMP and call it from the DATA step. */
proc fcmp outlib=sasuser.ds.functions;
   function subtract_sasfile(a, b);
   rc=run_sasfile('myfileref', a, b,
p);
   if rc=0 then return(p);
      else return(.);
   endsub;
run;

options cmplib=(sasuser.ds);
data _null_;
   a=5.3;
   b=0.7;
   p=.;
   p=subtract_sasfile(a, b);
   put p=;
run;
```

SOLVE Function

Computes implicit values of a function using the Gauss-Newton method.

Category: Compute Implicit Values

Note: This special purpose function is automatically provided by the FCMP procedure for convenience.

Syntax

answer = **SOLVE**('*function-name*', *options-array*, *expected-value*, *argument-1* <, *argument-2*, ...>);

Required Arguments

answer
specifies the value that is returned from the SOLVE function.

'function-name'
specifies the name of the function. Enclose *function-name* in quotation marks.

options-array
specifies an array of options to use with the SOLVE function. *Options-array* is used to control and monitor the root-finding process. *Options-array* can be a missing value (.), or it can have up to five of the following elements in the following order:

initial-value
specifies the starting value for the implied value. The default for the first call is 0.001. If the same line of code is executed again, then *options-array* uses the previously found implied value.

absolute-criterion
specifies a value for convergence. The absolute value of the difference between the expected value and the predicted value must be less than the value of *absolute-criterion* for convergence.

Default 1.0e–12

relative-criterion
specifies a value for convergence. If the change in the computed implied value is less than the value of *relative-criterion*, then convergence is assumed.

Default 1.0e–6

maximum-iterations
specifies the maximum number of iterations to use to find the solution.

Default 100

solve-status
can be one of the following values:

0 successful.

1 could not decrease the error.

2 could not compute a change vector.

3 maximum number of iterations exceeded.

4 initial objective function is missing.

expected-value
specifies the expected value of the function of interest.

argument
specifies the arguments to pass to the function that is being minimized.

Details

The SOLVE function finds the value of the specified argument that makes the expression of the following form equal to zero.

```
expected-value - function-name
(argument-1, argument-2, ...)
```

You specify the argument of interest with a missing value (.), which appears in place of the argument in the parameter list that is shown above. If the SOLVE function finds the value, then the value that is returned for this function is the implied value.

Here is an example of an options array:

```
array opts[5] initial abconv relconv maxiter (.5 .001 1.0e-6 100);
```

These values refer to the preceding line of code.

- **initial** (initial-value)=.5
- **abconv** (absolute-criterion)=.001
- **relconv** (relative-criterion)=1.0e-6
- **maxiter** (maximum-iterations)=100

The solve status is the fifth element in the array. You can display this value by specifying opts[5] in the output list.

Examples

Example 1: Computing a Square Root Value

The following SOLVE function example computes a value of x that satisfies the equation y=1/sqrt(x). Note that you must first define functions and subroutines before you can use them in the SOLVE function. In this example, the function INVERSESQRT is first defined and then used in the SOLVE function.

```
options pageno=1 nodate ls=80 ps=64;

proc fcmp;
      /* define the function */
   function inversesqrt(x);
      return(1/sqrt(x));
   endsub;

   y=20;
   x=solve("inversesqrt", {.}, y, .);
   put x;
run;
```

Output 25.18 *Results from Computing a Square Root Value*

```
                                The SAS System                                1

                              The FCMP Procedure

0.0025
```

Example 2: Calculating the Garman-Kohlhagen Implied Volatility

In this example, the subroutine GKIMPVOL calculates the Garman-Kohlhagen implied volatility for FX options by using the SOLVE function with the GARKHPRC function.

In this example, note the following:

- The options_array is SOLVOPTS, which requires an initial value.
- The expected value is the price of the FX option.
- The missing argument in the subroutine is the volatility (sigma).

```
proc fcmp;
   function garkhprc(type$, buysell$, amount, E, t, S, rd, rf, sig)
      kind=pricing label='FX option pricing';

   if buysell='Buy' then sign=1.;
   else do;
      if buysell='Sell' then sign=-1.;
      else sign=.;
   end;

   if type='Call' then
      garkhprc=sign*amount*(E+t+S+rd+rf+sig);
   else do;
      if type='Put' then
         garkhprc=sign*amount*(E+t+S+rd+rf+sig);
      else garkhprc=.;
   end;
   return(garkhprc);
   endsub;

   subroutine gkimpvol(n, premium[*], typeflag[*], amt_lc[*],
                       strike[*], matdate[*], valudate, xrate,
                       rd, rf, sigma);
   outargs sigma;

   array solvopts[1] initial (0.20);
   sigma=0;
   do i=1 to n;
      maturity=(matdate[i] - valudate) / 365.25;
      stk_opt=1./strike[i];
      amt_opt=amt_lc[i] * strike[i];
      price=premium[i] * amt_lc[i];
```

```
      if typeflag[i] eq 0 then type="Call";
      if typeflag[i] eq 1 then type="Put";

         /* solve for volatility */
      sigma=sigma + solve("GARKHPRC", solvopts, price,
                          type, "Buy", amt_opt, stk_opt,
                          maturity, xrate, rd, rf, .);
   end;
   sigma=sigma / n;
endsub;
run;
```

Example 3: Calculating the Black-Scholes Implied Volatility

This SOLVE function example defines the function BLKSCH by using the built-in SAS function BLKSHCLPRC. The SOLVE function uses the BLKSCH function to calculate the Black-Scholes implied volatility of an option.

In this example, note the following:

- The options_array is OPTS.
- The missing argument in the function is the volatility (VOLTY).
- PUT statements are used to write the implied volatility (BSVOLTY), the initial value, and the solve status.

```
options pageno=1 nodate ls=80 ps=64;

proc fcmp;
   opt_price=5;
   strike=50;
   today='20jul2010'd;
   exp='21oct2010'd;
   eq_price=50;
   intrate=.05;
   time=exp - today;
   array opts[5] initial abconv relconv maxiter status
                 (.5 .001 1.0e-6 100 -1);
   function blksch(strike, time, eq_price, intrate, volty);
      return(blkshclprc(strike, time/365.25,
                        eq_price, intrate, volty));
   endsub;
   bsvolty=solve("blksch", opts, opt_price, strike,
                           time, eq_price, intrate, .);

   put 'Option Implied Volatility:' bsvolty
       'Initial value: ' opts[1]
       'Solve status: ' opts[5];
run;
```

Output 25.19 *Results of Calculating the Black-Scholes Implied Volatility*

```
                                The SAS System                                1

                              The FCMP Procedure

Option Implied Volatility: 0.4687011859 Initial value:  0.5 Solve status:  0
```

Note: SAS functions and external C functions cannot be used directly in the SOLVE function. They must be enclosed in a PROC FCMP function. In this example, the built-in SAS function BLKSHCLPRC is enclosed in the PROC FCMP function BLKSCH, and then BLKSCH is called in the SOLVE function.

WRITE_ARRAY Function

Writes data from a PROC FCMP array variable to a data set that can then be used by SAS programs, macros, and procedures.

Category: Array

Note: When SAS translates between an array and a data set, the array is indexed as [row, column].

Syntax

rc = **WRITE_ARRAY**(*data_set_name*, *array_variable* <, '*column_name_1*', '*column_name_2*', ...>);

Required Arguments

rc
is 0 if the function is able to successfully write the data set.

data_set_name
specifies the name of the data set to which the array data is written. *Data_set_name* must be a character literal or variable that contains the member name (libname.memname) of the data set to be created.

array_variable
specifies the PROC FCMP array or matrix variable whose contents are written to *data_set_name*.

Optional Argument

column_name
specifies optional names for the columns of the data set that are created.

If specified, *column_name* must be a literal string enclosed in quotation marks. *Column_name* cannot be a PROC FCMP variable. If column names are not specified, the column name is the array name with a numeric suffix.

Examples

Example 1: Using the WRITE_ARRAY Function with a PROC FCMP Array Variable

This example uses the ARRAY statement and the WRITE_ARRAY function with PROC FCMP to write output to a data set.

```
options nodate pageno=1 ls=80 ps=64;

proc fcmp;
   array x[4,5] (11 12 13 14 15 21 22 23 24 25 31 32 33 34 35 41 42 43
44 45);
   rc=write_array('work.numbers', x);
run;

proc print data=work.numbers;
run;
```

Output 25.20 *Results from Using the WRITE_ARRAY Function*

```
                    The SAS System                                    1
               Obs     x1     x2     x3     x4     x5

                 1     11     12     13     14     15
                 2     21     22     23     24     25
                 3     31     32     33     34     35
                 4     41     42     43     44     45
```

Example 2: Using the WRITE_ARRAY Function to Specify Column Names

This example uses the optional *colN* variable to write column names to the data set.

```
options pageno=1 nodate ps=64 ls=80;

proc fcmp;
   array x[2,3] (1 2 3 4 5 6);
   rc=write_array('numbers2', x, 'col1', 'col2', 'col3');
run;

proc print data=numbers2;
run;
```

Output 25.21 *Results from Using the WRITE_ARRAY Function to Specify Column Names*

```
                              The SAS System                              1

                         Obs     col1     col2     col3

                           1        1        2        3
                           2        4        5        6
```

26

FCmp Function Editor

Introduction to the FCmp Function Editor

SAS language functions and CALL routines that are created with PROC FCMP are stored in SAS data sets that are contained in package declarations. Each package declaration contains one or more functions or CALL routines. The FCmp Function Editor displays all of the functions and CALL routines that are included in a package.

With the FCmp Function Editor, you can view functions in a package declaration as well as create new functions. You can add these new functions to an existing package, or create a new package declaration.

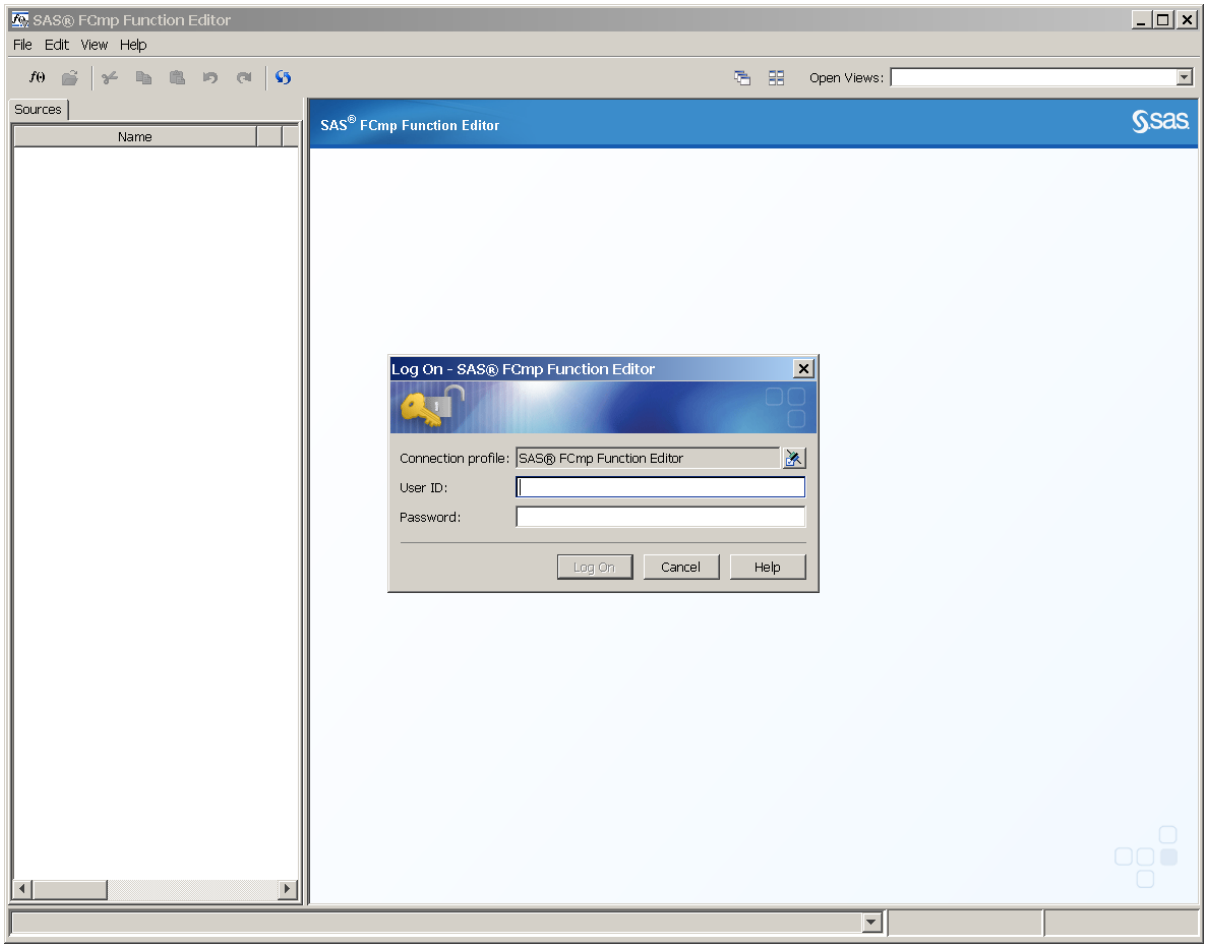
Open the FCmp Function Editor

If you are working in the Windows operating environment and SAS is installed locally on your computer, the sign-on dialog box is bypassed because Windows supports single sign-on functionality.

If you are not working in the Windows operating environment, or if SAS is not installed locally, then you are prompted for your authorization credentials, which are your user ID and password.

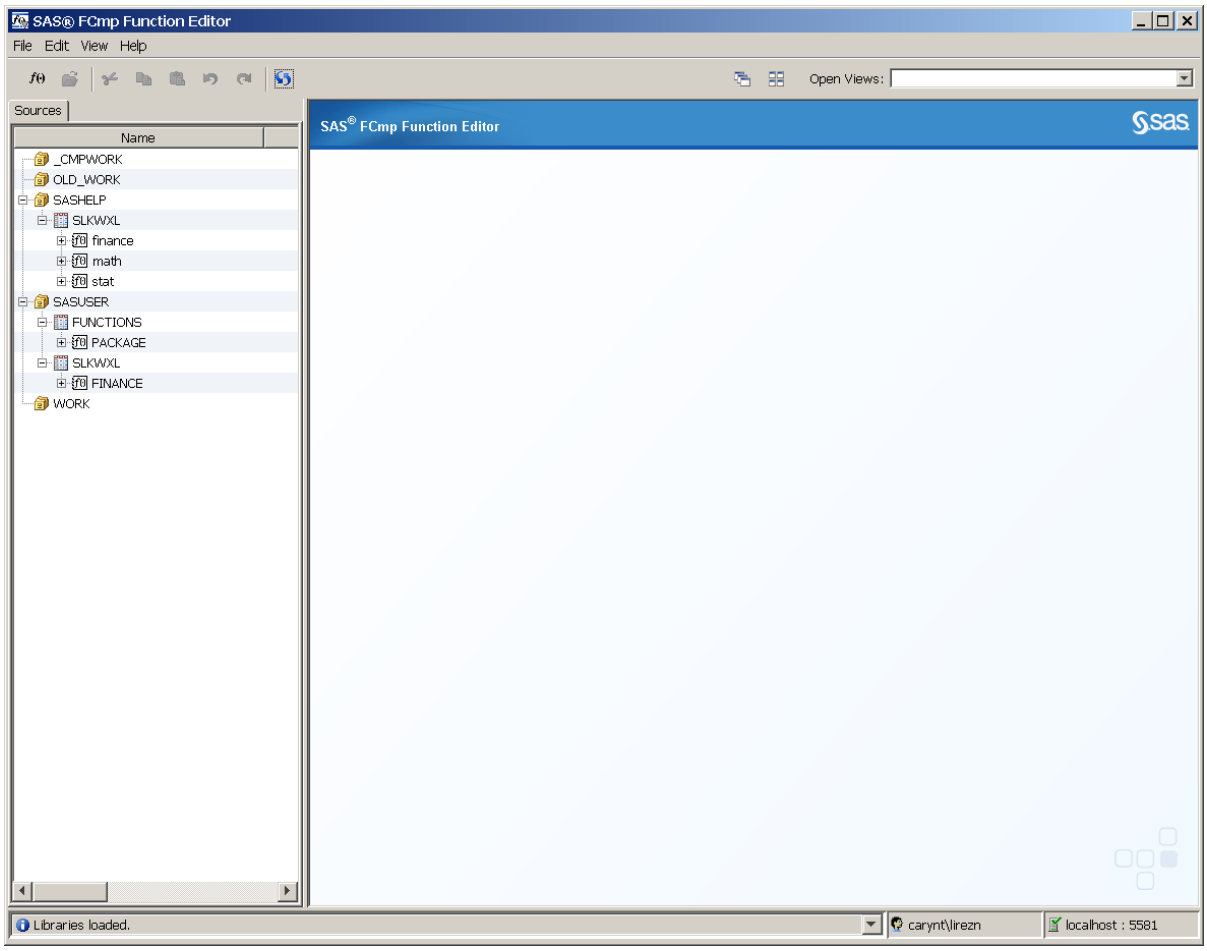
To open the FCmp Function Editor, select **Solutions** ⇨ **Analysis** ⇨ **FCmp Function Editor** from the menu in your SAS session. The following dialog box appears:

Figure 26.1 *Initial Dialog Box for the FCmp Function Editor*



After you enter your user ID and password and click **Log On**, SAS establishes a connection to a port. A window that displays your libraries appears:

Figure 26.2 *The FCmp Function Editor with Libraries Displayed*



In the window above, you can see that the left pane lists the functions that are in the SASHELP and SASUSER libraries. The WORK library is empty. You cannot access the WORK library directly from a spawning SAS session. The FCmp Function Editor remaps the WORK library from the spawning SAS session to the location of OLD_WORK so that you can access the contents of WORK from OLD_WORK.

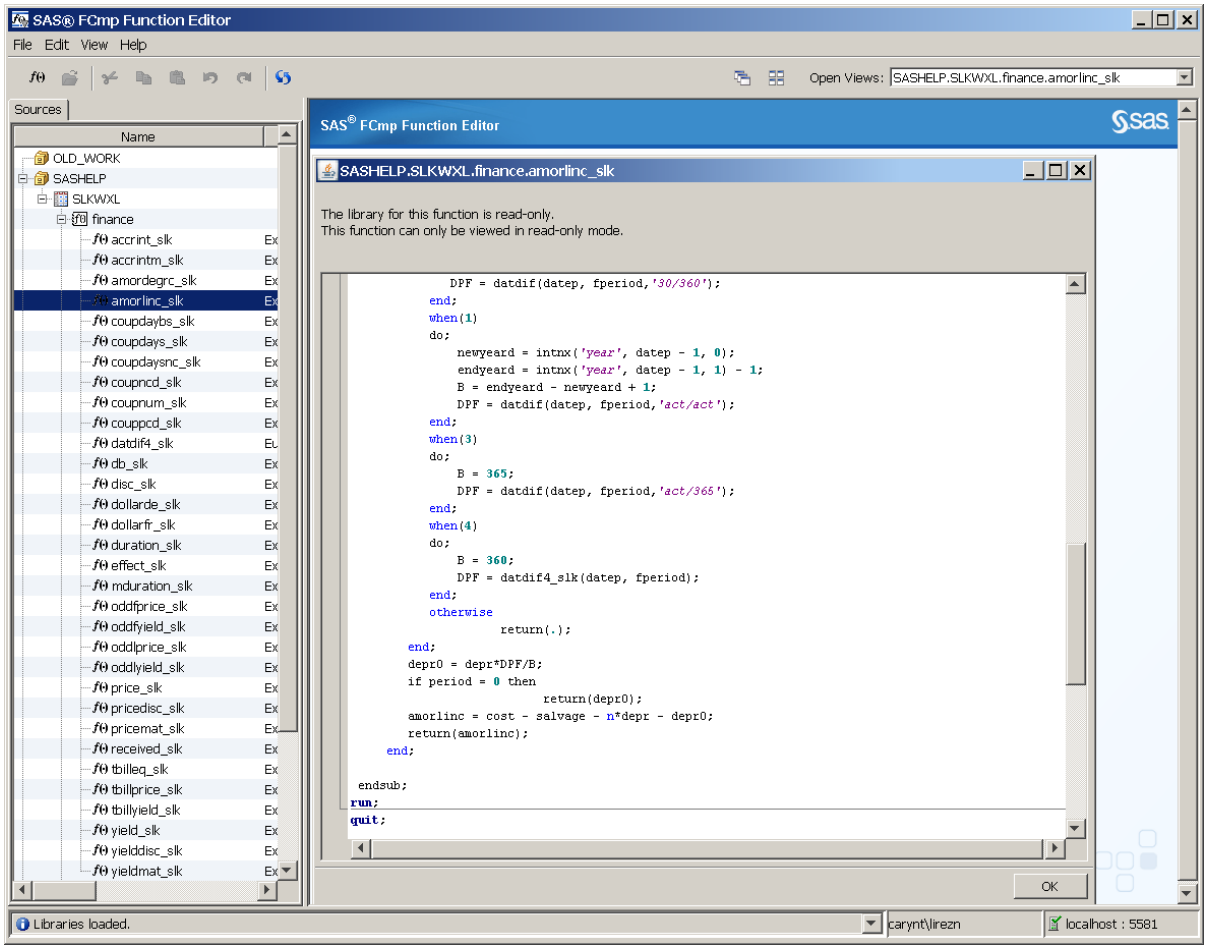
Working with Existing Functions

Open a Function

To open a function, select a library from the left pane, expand the library, and drill down until a list of functions appears. Double-click the name of the function that you want to open.

If you open a function from a read-only library, a window similar to the following appears:

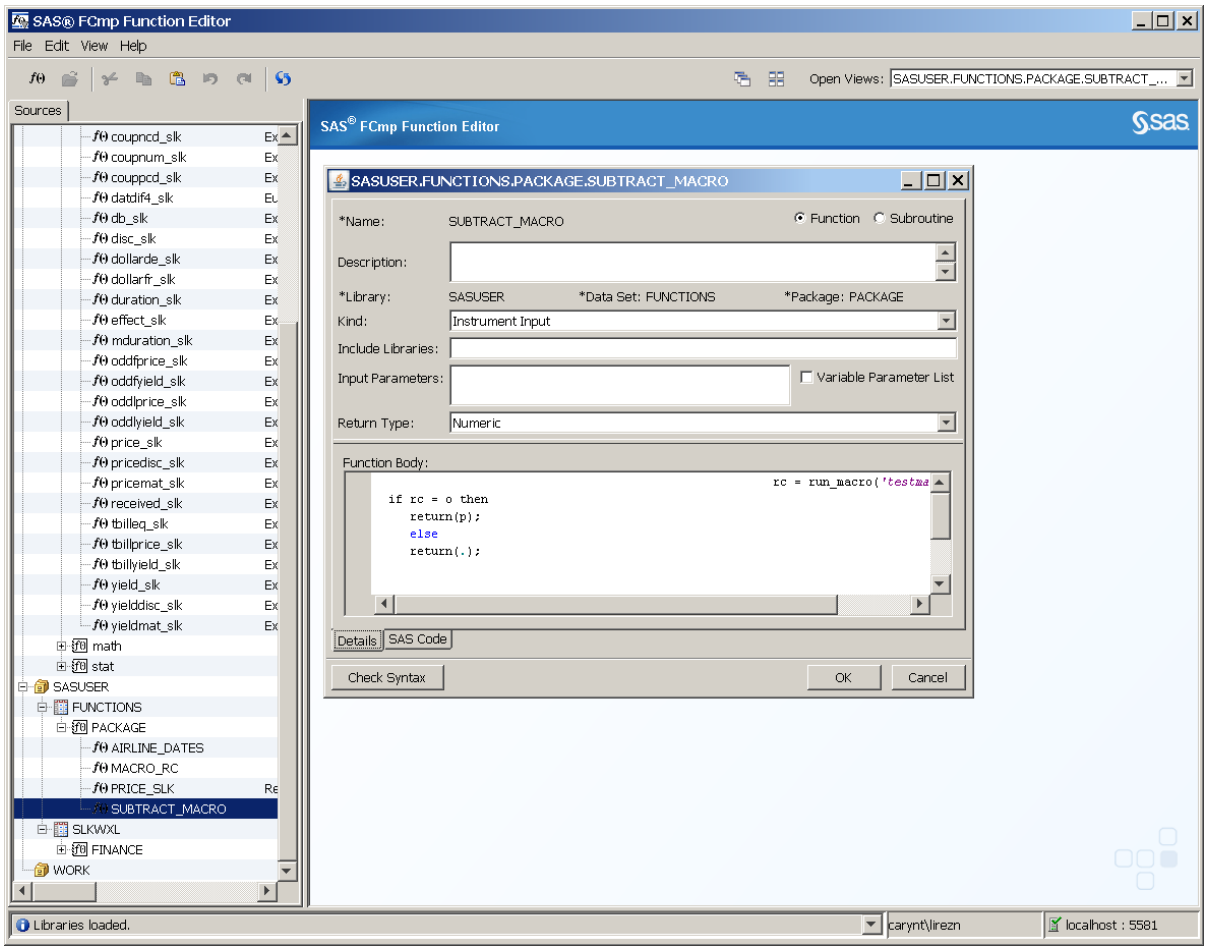
Figure 26.3 *A Function in a Library That Has Read-Only Access*



In the window above, the AMORLINC_SLK function is selected from the read-only SASHELP library. Use the scroll bar to scroll to the top of the function.

If you open a function from a library to which you have Write access, a window similar to the following appears:

Figure 26.4 *A Function in a Library That Has Write Access*



In the window above, SUBTRACT_MACRO is selected from the write-enabled SASUSER library.

You can see that there is a difference in the windows that appear depending on whether the library has Read-Only access or Write access. If the library has Write access, you can enter information in the top section of the window that you are viewing. These fields are the same fields that you use when you create a new function. For a description of the fields, see "Creating a New Function" on page 993.

Opening Multiple Functions

Opening multiple functions results in multiple windows being opened. For example, if you open a second function, a second window appears that shows the code for that function.

The upper right corner of the FCmp Function Editor contains a field called **Open Views**. Click the arrow to list the functions that are open. When you select a function, the window for that function is brought to the foreground.

Two icons that you can use to alter the display of your functions are located to the left of the **Open Views** field:

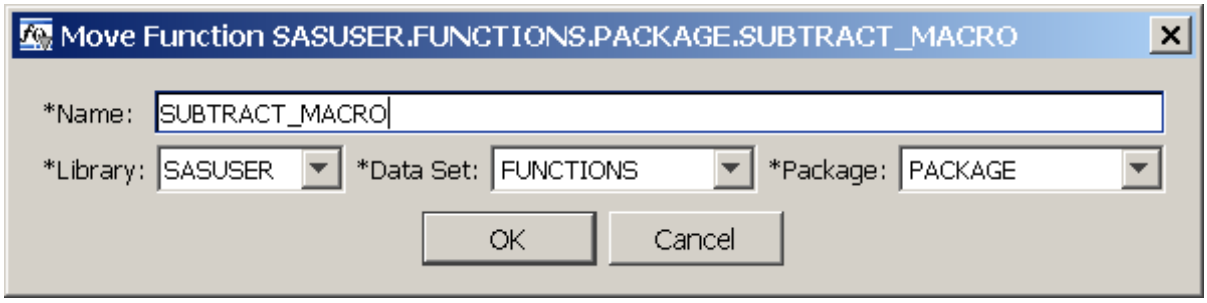
cascades the display of the functions that are open.

arranges the functions to display side by side.

Move a Function

You can move a function to a different library, data set, or package. To move a function, select a function in the left pane. Right-click the function, and select **Move** from the menu. The following dialog box appears:

Figure 26.5 *The Move Function Dialog Box*



In the Move Function dialog box, you can perform the following tasks:

- enter a new name for the function
- select a library into which the function is to be moved
- enter a new data set name
- enter a package name

The descriptions of the fields in the Move Function dialog box are listed below:

Name
specifies the new name for the function.

Library
specifies the library that contains the function that you move. Use the menu in the **Library** field to select a library.

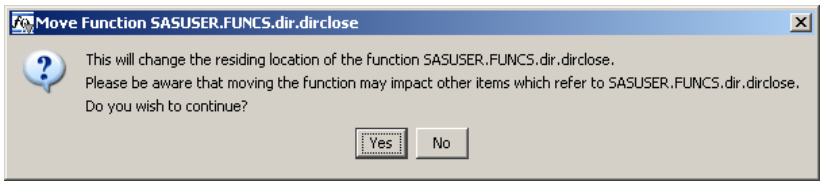
Data Set
specifies the data set that contains the function that you move. Enter the name of the data set, or click the down arrow in the **Data Set** field to select a data set.

If you do not choose a data set, then the value in this field defaults to FUNCTIONS.

Package
specifies the name of the package that contains the new function that you move. Enter the name of the package, or click the down arrow in the **Package** field to select a package. If you do not choose a package, then the value in this field defaults to PACKAGE.

When you click **OK**, the following dialog box appears, cautioning you about the move:

Figure 26.6 *The Move Function Confirmation Dialog Box*



CAUTION
Other functions and macros that reference the function that you want to move is not updated with the new function location. This situation can cause referencing objects such as macros to be out of synchronization.

Click **Yes** or **No**.

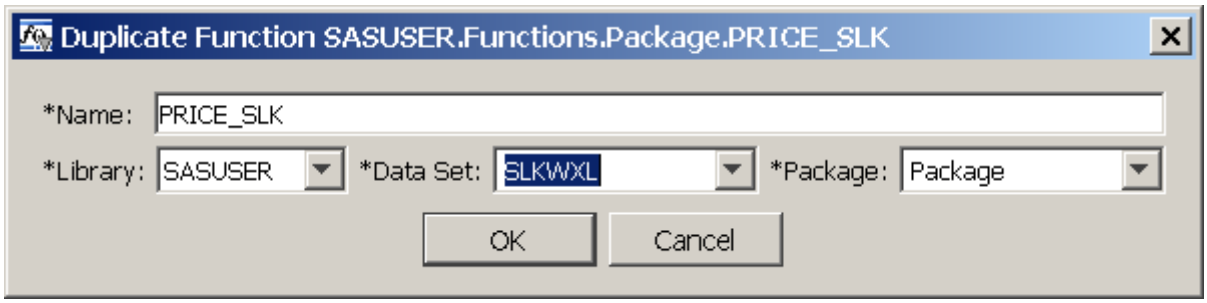
Close a Function

When you right-click the function name in the left pane and select **Close**, the window that displays that function closes. You can also close the function by clicking **OK** in the bottom right corner of the window that displays the function.

Duplicate a Function

You can duplicate (copy) a function that you are viewing to an existing or new package or library to which you have Write access. To duplicate a function, select the function in the left pane. Right-click the function and select **Duplicate** from the menu. The following dialog box appears:

Figure 26.7 *The Duplicate Function Dialog Box*



The fields in this dialog box automatically display the function name, library, data set, and package of the function that you want to duplicate. You can change these fields when you duplicate the function.

For a description of these fields, see "Move a Function" on page 990.

Rename a Function

Use the Rename dialog box to rename a function within a given package. You must have Write access to the library that contains the function. When you rename a function, the new function resides in the same library as the original function.

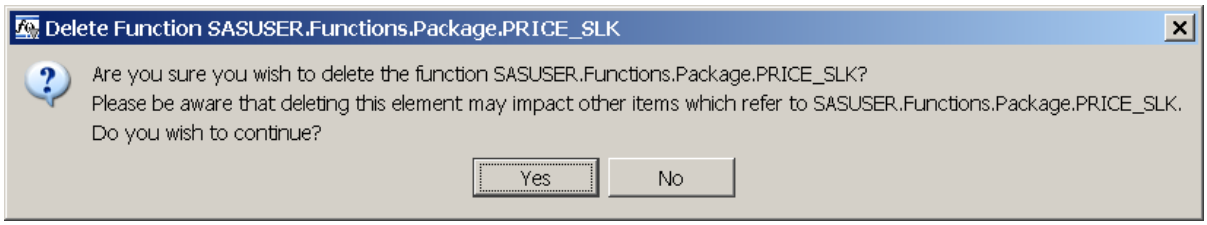
To rename a function, select the function in the left pane. Right-click the function and select **Rename** from the menu. Enter the new name of the function and click **OK**.

CAUTION
Rename enables you to rename a function within a given package. Just as with moving a function, the renaming of a function does not modify dependent macros and other entities.

Delete a Function

You can delete a function from a library to which you have Write access. To delete a function, select the function that you want to delete. Right-click the function and select **Delete** from the menu. The following dialog box appears, cautioning you about the impact that **Delete** has on other items:

Figure 26.8 *Delete Function Confirmation Dialog Box*



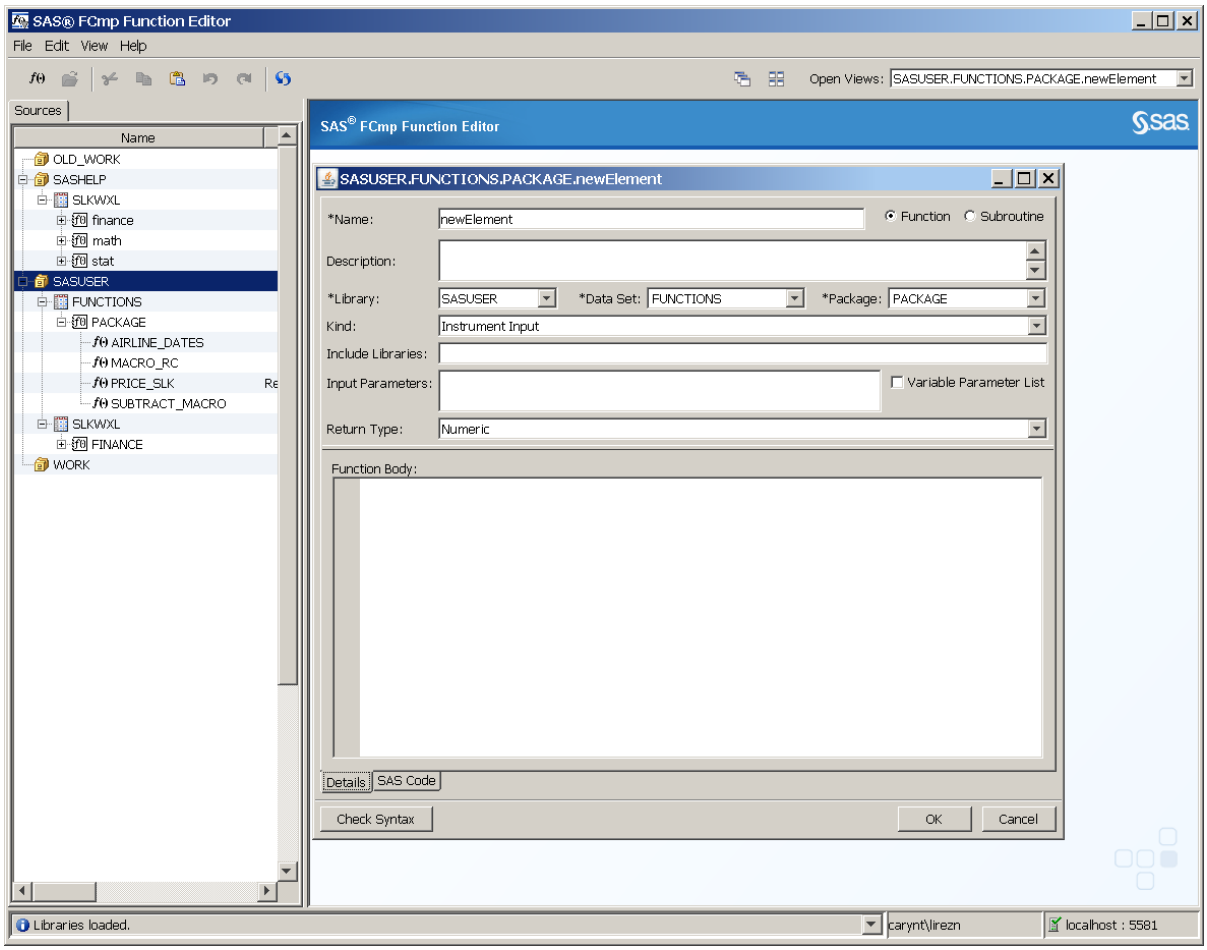
Click **Yes** or **No**.

Creating a New Function

You can create a new function whenever you have a library, data set, or package selected. To create a new function in a library, position your cursor on the library into which the new function is added. Right-click the library and select **New Function**. You can also select **File** ⇨ **New Function** from the menu or click $f(\cdot)$ in the upper left corner below the menu bar.

The following window appears:

Figure 26.9 *The newElement Window*



The upper right corner of the window contains two buttons: **Function** and **Subroutine**. Click one of the buttons depending on whether you want to create a new function or a new subroutine.

The newElement window contains the following fields:

Name
specifies the name of the new function or subroutine.

Description
describes the new function or subroutine.

Library
specifies the library that contains the new function or subroutine. Enter the name of the library, or click the down arrow in the **Library** field to select a library.

Data Set
specifies the data set that contains the new function or subroutine. Enter the name of the data set, or click the down arrow in the **Data Set** field to select a data set. If you do not specify a value, the value in this field defaults to FUNCTIONS.

Package
specifies the name of the package that contains the new function or subroutine. Enter the name of the package, or click the down arrow in the **Package** field to select a package. The **Package** field is a required field. If you do not specify a value, the value in this field defaults to PACKAGE.

Kind
enables you to group functions or subroutines within a given package. Four predefined kind groupings are available and are typically used with SAS Risk Management:

- Project
- Risk Factor Transformation
- Instrument Pricing
- Instrument Input

You can use one of these four groupings, or enter your own kind value in the **Kind** field. The function tree in the left pane groups the functions in a package into their kind grouping, if you specified a value for **Kind**.

Include Libraries
specifies libraries that contain SAS code that you want to include in your function or subroutine.

Input Parameters
specifies the arguments that you use as input to the function or subroutine.

Variable Parameter List
specifies whether the function or subroutine supports a variable number of arguments.

Return Type
specifies whether the function or subroutine returns a character or numeric value.

Function Body
is the area in the window in which you code your function or subroutine.

Three buttons are located at the bottom left of the newElement window:

Details
provides you with an area in which to write descriptive information (name of the new function, list of include libraries, input parameters, and so on) about your function or subroutine. You code your new function or subroutine in the **Function Body** section. The **Details** tab is selected by default.

SAS Code
enables you to view the function or subroutine that you have written. The **SAS Code** selection provides read-only capabilities.

Check Syntax
enables you to check the syntax for the code that you have written. If the syntax is correct, a dialog box appears, stating that the syntax is correct. If the syntax contains an error, a dialog box appears that describes the error. An error message also appears in the lower left bar of the window. Syntax errors are written to the log, which you can access from the **View** ⇨ **Show Log** menu.

When you enter information in the descriptive portion of the **Details** tab, as well as in the **Function Body** section, the information is converted to SAS code that you can see when you select the **SAS Code** button.

Displaying New Libraries in the FCmp Function Editor

You can create a new library in a SAS session while still being logged on to the FCmp Function Editor. However, clicking the refresh button in the FCmp Function Editor does not display the new library. You must log off from the FCmp Function Editor and then log back in to see the new library.

Viewing the Log Window, Function Browser, and Data Explorer

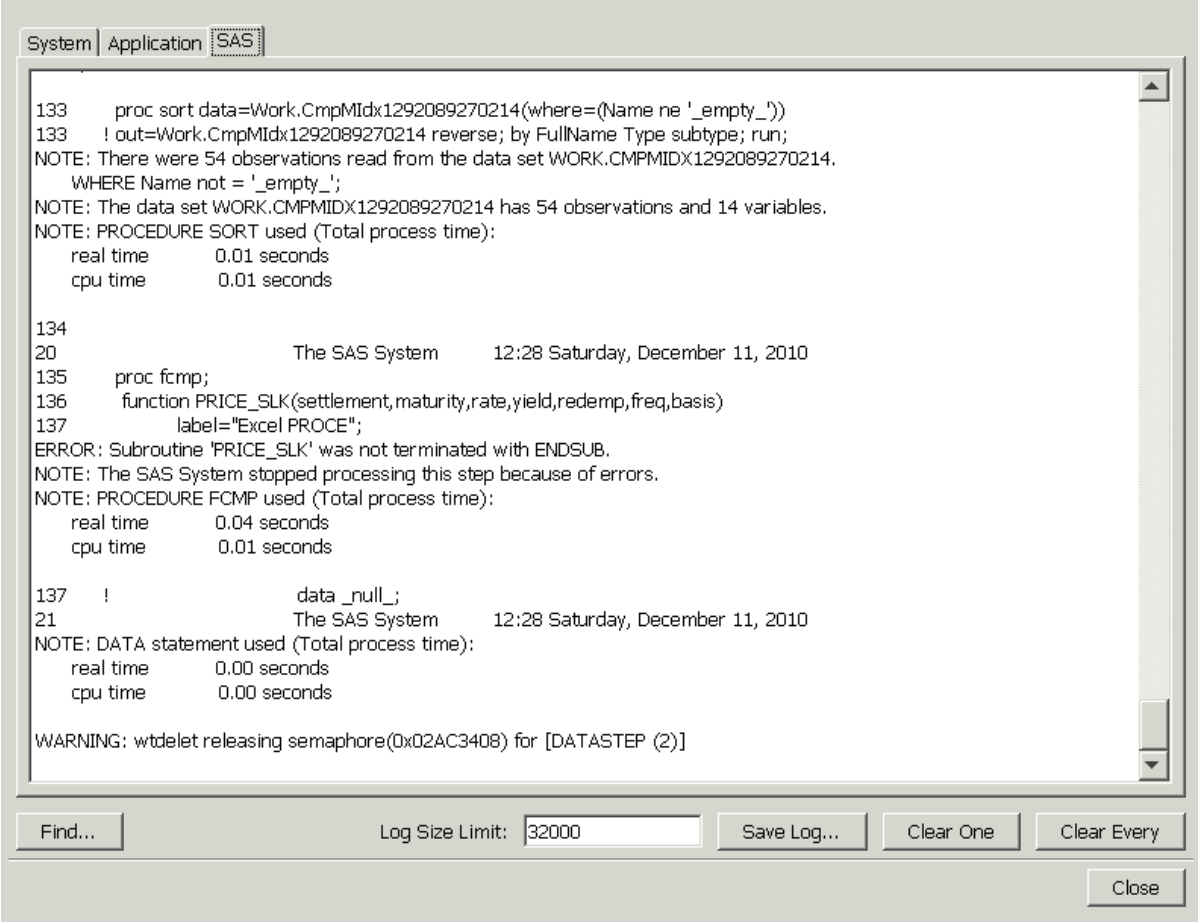
Log Window

To display the Log window, select **View** ⇨ **Show Log** from the menu. When you display the Log window, you can view system, application, and program results by selecting the tabs that are located in the upper left corner of the window.

Click the **SAS** tab to view the contents of the SAS log. The content of the log represents output from the SAS server. In addition, commands that are sent to SAS are also present to add context to the log output.

The following display shows the Log window with a SAS log displayed:

Figure 26.10 The Log Window



Tabs and Buttons in the Log Window

The **System** tab in the Log window shows detailed information in the form of system messages. The window is blank if no messages are logged.

The System window contains two vertical tabs that are located in the upper right section of the window. These tabs provide information about messages that might be of interest:

System.out
displays system output if messages are routed to this location.

System.err
displays error messages if the messages are routed to this location.

The Log window contains three buttons that are located at the bottom right of the window:

Save Log
saves the log output to a file that you choose.

Clear One
clears the results in the active window.

Clear Every
clears the results in all three of the windows.

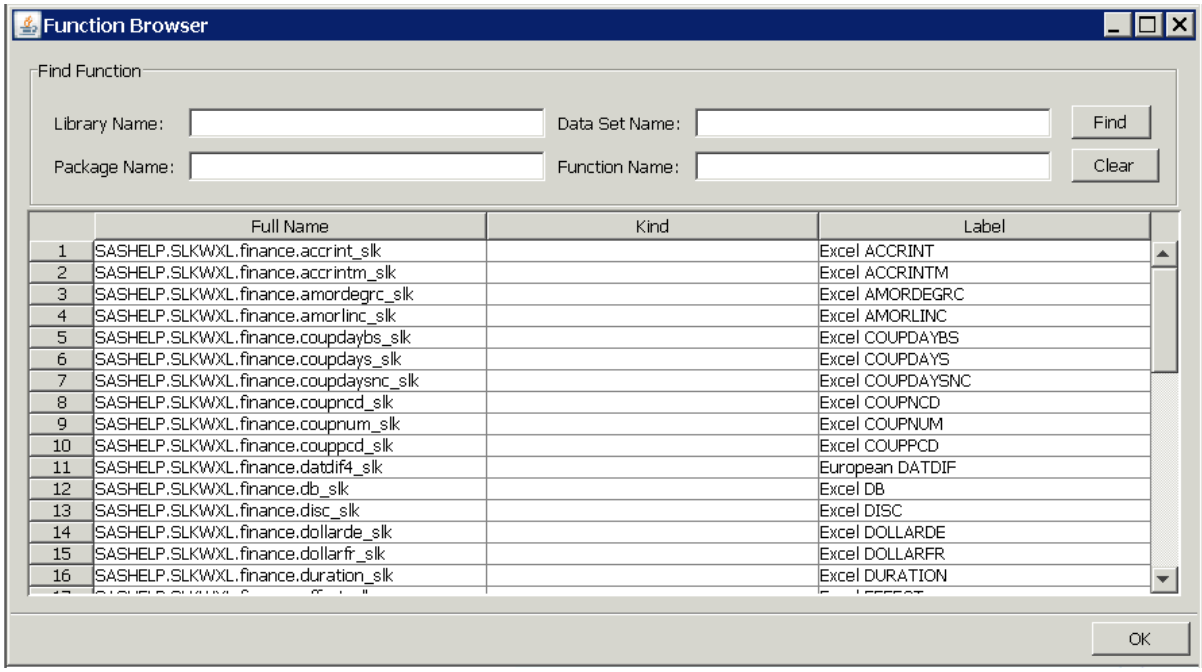
The **Find** button is located at the bottom left of the window. This button opens a dialog box that enables you to search your output. For example, searching for ERROR when the **SAS** tab is selected enables you to quickly find errors in the SAS log.

Function Browser

The Function Browser displays all of the functions that are listed in the left pane of the window. You can filter this list of functions to display a subset of the functions.

To display the Function Browser, select **View** ⇨ **Show Function Browser** from the menu. A window similar to the following appears:

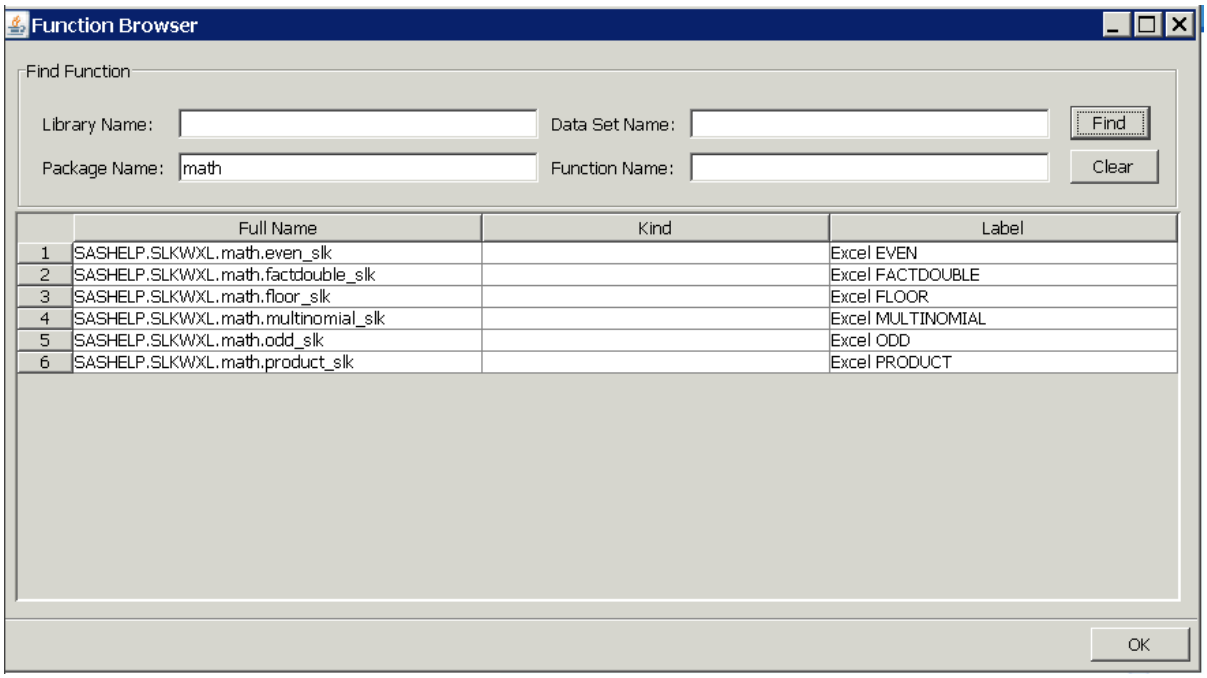
Figure 26.11 *The Function Browser Window*



The partial output that is displayed above shows the functions in the application tree. You can filter the output and create a subset of the functions by entering your criteria in the Function Browser fields that are located above the list of functions. These fields are **Library Name**, **Data Set Name**, **Package Name**, and **Function Name**.

In the following display, the **Package Name** field is used as the filter. When you press the **OK** button that is located in the bottom right corner of the window, or if you press the **Find** button that is located in the upper right corner, the following window appears:

Figure 26.12 *Filtered Output from the Function Browser*



The math functions that are listed are a subset of all of the functions.

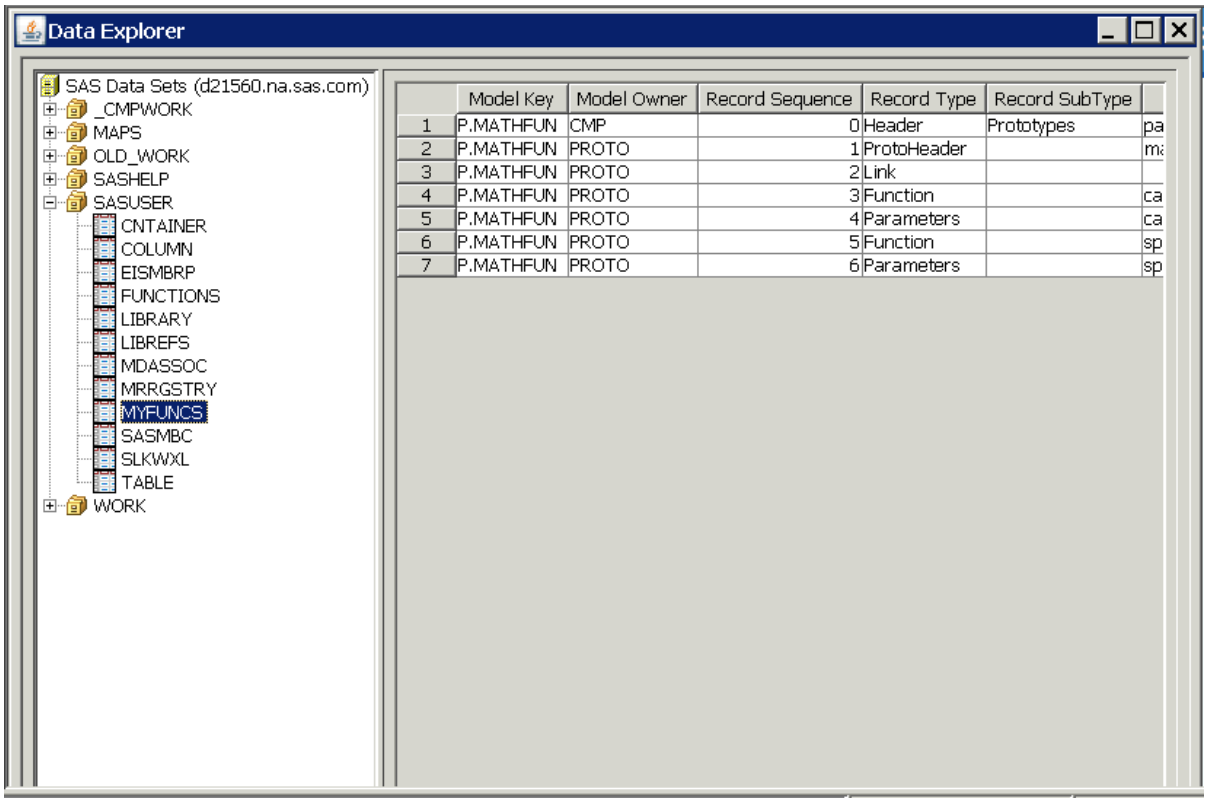
You can enter information in the fields that you choose, depending on your filter criteria. For example, if you enter a value, such as SASHELP, in the **Library Name** field, then all of the functions that are in the SASHELP library appear.

Data Explorer

The Data Explorer enables you to view the data in a data set that you select.

To display the Data Explorer, select **View** ⇨ **Show Data Explorer** from the menu. A window similar to the following appears:

Figure 26.13 The Data Explorer Window



The Data Explorer window displays data set information based on the data set you select from the left pane.

By clicking the column headings, you can move the columns to reposition them in the display. When you click **OK** in the lower right section of the window, the changes that you made are saved.

Using Functions in Your DATA Step Program

For an example of how PROC FCMP and DATA step syntax work together, see "Directory Traversal" on page 905.

27

FEDSQL Procedure

Overview: FEDSQL Procedure

What Does the FEDSQL Procedure Do?

The FEDSQL procedure enables you to submit FedSQL language statements from a Base SAS session. The FEDSQL procedure is supported in both SAS 9.4 and SAS Viya.

The FedSQL language is the SAS implementation of the ANSI SQL:1999 core standard. It provides support for extended data types, such as DECIMAL, INTEGER, and VARCHAR, and other ANSI 1999 core compliance features and proprietary extensions. FedSQL provides data access technology that brings a scalable, threaded, high-performance way to access, manage, and share relational data in multiple data sources. Beginning in April 2019, it also supports some non-relational data sources. When possible, FedSQL queries are optimized with multithreaded algorithms to resolve large-scale operations.

For applications, FedSQL provides a common SQL syntax across all of the data sources that it supports. FedSQL is a vendor-neutral SQL dialect. Applications can submit the same FedSQL queries to all FedSQL data sources instead of having to submit queries in the SQL dialect that is specific to the data source. In addition, a single FedSQL query can target data in several data sources and return a single result set.

Using the FEDSQL procedure, you can submit FedSQL language statements to SAS and third-party data sources that are accessed with SAS and SAS/ACCESS library engines. Or, if you have SAS Cloud Analytic Services (CAS) configured, you can submit FedSQL language statements to the CAS server.

To execute FedSQL statements in a SAS library, specify the PROC FEDSQL statement followed by FedSQL language statements. Qualify table names in your FedSQL language statements with a libref. If you do not specify a libref, the request is executed in the SAS Work library.

To execute FedSQL statements on the CAS server, specify the SESSREF= (or SESSUUID=) connection option with a CAS session name in the procedure statement. Either load tables into your CAS session using other tools and query the tables with PROC FEDSQL, or set an active caslib for your CAS session and query tables from the caslib by name. When you query unloaded tables from the active caslib, FedSQL passes requests that are eligible for implicit pass-through to the data source for processing or dynamically loads the external data into your CAS session for processing.

Note: Do not use a CAS engine libref with PROC FEDSQL. When SESSREF= (or SESSUUID=) is specified, PROC FEDSQL makes a direct connection to the CAS

server. The procedure does not need the CAS engine. PROC FEDSQL silently passes requests to the fedSQL.execDirect action and the action executes your program on the CAS server.

The FedSQL language supports limited functionality in CAS. For an overview of the FedSQL functionality that is available on the CAS server, see "Using FedSQL in SAS Cloud Analytic Services" on page 1021.

For information about the FedSQL language statements that are supported for data accessed with SAS library engines, see *SAS FedSQL Language Reference*.

Concepts: FEDSQL Procedure

Benefits of FedSQL

FedSQL provides the following features that are not provided in the SAS SQL procedure.

- FedSQL conforms to the SQL 1999 ANSI standard. This conformance allows it to process queries in its own language as well as the native languages of other DBMSs that conform to the ANSI 1999 standard.
- FedSQL supports many more data types than previous SAS SQL implementations. Traditional DBMS access through SAS/ACCESS LIBNAME engines translate target DBMS data types to and from two legacy SAS data types, which are SAS numeric and SAS character. When FedSQL connects to a DBMS with a libref, the language matches or translates the target data source's definition to the FedSQL data types, as appropriate, which allows greater precision. When FedSQL connects to a DBMS with a caslib, the language translates the data source's definition to native CAS data types.
- FedSQL handles federated queries, which access data from multiple data sources and returns a single result set. A federated query is the ability to communicate with more than one data source, access that data, and perform operations against that data. FedSQL also has the ability to break apart a single SQL query that is connected to multiple databases and send the parts down to the individual databases.
- FedSQL supports implicit SQL pass-through. That is, FedSQL statements are translated into data source-specific code internally so that they can be passed directly to the data source for processing. There is no need to submit requests in the native SQL of each data source to get the benefits of native processing. FedSQL implicit pass-through improves query response time and enhances security.

- The volume of data being transferred is reduced by performing the query on the data source. The number of rows that are transferred from the data source to FedSQL can be significantly reduced, thereby decreasing the overall query processing time.
- The security benefit is that any part of a query that can be is processed on the data source side. This eliminates the need to have its associated tables, which might contain sensitive information, transmitted over to the FedSQL side for query processing.

Implicit SQL pass-through is available for SAS libraries and for caslibs, although support in CAS is limited. Support for implicit pass-through in CAS is available starting in SAS Viya 3.3. For more information about FedSQL implicit pass-through in CAS, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.

- When connecting to a SAS library, you can use PROC FEDSQL to create data in any of the supported data sources. This enables you to store data in the data source that most closely meets the needs of your application. (FedSQL output tables in CAS are in-memory tables. You can use other CAS functionality to persist data to caslib data sources.)
- When connecting to a SAS library, FedSQL can perform heterogeneous correlated subqueries. A correlated subquery is when the outer query results affect the results of the subquery. FedSQL has the ability to direct a subquery to be performed by the data source and limit the result set that is transferred from the data source. This is done by using a flexible query textualization technique that allows FedSQL to obtain rows that satisfy only the subquery expression. For an example, see "Example 3: Querying Data Using a Correlated Subquery" on page 1033.

  A unique way that FedSQL can perform a heterogeneous operation is to take advantage of an index in a third-party DBMS when performing a join. The row values from one table involved in the join are copied into FedSQL local space. The specific column values are then used to probe the index. Special textualization techniques return qualified values, thereby allowing FedSQL access to the DBMS index to perform the join. For more information, see "Example 4: Creating and Using a DBMS Index to Perform a Join" on page 1034.

For more information about the FedSQL functionality for SAS libraries, see *SAS FedSQL Language Reference*. For information about FedSQL functionality when you target the CAS server, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.

Data Source Support

When submitting FedSQL statements to a SAS library, PROC FEDSQL can read and write data from the following data sources. Unless otherwise noted, availability starts in SAS 9.4 and SAS Viya 3.3. See SAS/ACCESS documentation for supported operating environments.

Table 27.1 *Data Sources for Which FedSQL Supports SAS Library Access*

Data Source	SAS V9	SAS Viya 3.5	Release Notes
Amazon Redshift	*	*	Added in SAS 9.4M5
Aster	*	*	Added in SAS 9.4M1
DB2	*	*	DB2
Greenplum	*	*	
Google BigQuery	*	*	Added in August 2019, on SAS 9.4M6 and SAS Viya 3.4
Hadoop (Hive)	*	*	Added in SAS 9.4M2
HAWQ	*	*	Added in SAS 9.4M3
Impala	*	*	Added in SAS 9.4M3
databases that are compliant with JDBC	*	*	Added in February 2019, on SAS Viya 3.4 and SAS 9.4M6
Microsoft SQL Server	*	*	Added in SAS 9.4M5
MongoDB	*	*	Read-only support available on SAS 9.4M6, starting in April 2019. Write support available starting in November 2019. Read-and-write support available in SAS Viya 3.5.
MySQL	*	*	
Netezza	*	*	
ODBC-compliant databases	*	*	
Oracle	*	*	

Data Source	SAS V9	SAS Viya 3.5	Release Notes
PostgreSQL	*	*	Added in SAS 9.4M2
Salesforce	*	*	Read-only support available on SAS 9.4M6, starting in April 2019. Write support available starting in November 2019. Read-and-write support available in SAS Viya 3.5.
SAP	*	*	Read-only
SAP HANA	*	*	Added in SAS 9.4M1
SAP IQ	*	*	
SAS data sets	*	*	Added in SAS Viya 3.1
SAS Scalable Performance Data (SPD) Engine data sets	*	*	
SAS Scalable Performance Data (SPD) Server tables	*	*	Added in SAS 9.4M4 SPD Server in UNIX and Windows operating environments only SAS Viya access is client only
Snowflake	*	*	Added in August 2019, on SAS 9.4M6 and SAS Viya 3.4
Spark	*		SAS/ACCESS to Spark is available on Linux only in SAS 9.4M7.
Teradata	*	*	Teradata
Vertica	*	*	Added in SAS 9.4M5

Data Source	SAS V9	SAS Viya 3.5	Release Notes
Yellowbrick	*		SAS/ACCESS to Yellowbrick is limited availability for SAS 9.4 only, starting in SAS 9.4M7.

For information about the statements and data types supported for each data source through a SAS library, see *SAS FedSQL Language Reference*.

When you submit FedSQL language statements to CAS, the procedure reads data from files and in-memory tables and creates CAS session tables. You can preload data into your CAS session with PROC CASUTIL. Or you can use a caslib to dynamically load data into your CAS session. A caslib uses a SAS Viya Data Connector (or SAS Viya Data Connector Accelerator) to access data from a corresponding data source for processing in CAS. For information about available SAS Viya Data Connectors, see *SAS Cloud Analytic Services: User's Guide*.

FedSQL has different functionality on the CAS server than it has in a SAS library. For more information, see "Using FedSQL in SAS Cloud Analytic Services" on page 1021.

For information about how to connect to supported data sources with PROC FEDSQL, see "Data Source Connection" on page 1017.

Syntax: FEDSQL Procedure

PROC FEDSQL <*connection-option*><*processing-options*>;

...FedSQL statements

QUIT;

Statement	Task	Example
PROC FEDSQL	Specify that the subsequent input is FedSQL language statements.	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8
QUIT	Stop the execution of the FEDSQL procedure.	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8

PROC FEDSQL Statement

Specifies that the subsequent input is FedSQL language statements.

Requirement: Follow the PROC FEDSQL statement with one or more FedSQL language statements. See *SAS FedSQL Language Reference* for information about FedSQL statements that are supported in a SAS library. See *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services* for information about FedSQL statements that are supported in a CAS session.

Interactions: When creating tables with PROC FEDSQL, note that by default, you cannot overwrite an existing table. You must destroy the table with the DROP TABLE statement first. If you specify the DROP TABLE statement in the same procedure execution as the CREATE TABLE statement, you must specify the FORCE statement option. For more information, see "DROP TABLE Statement" in *SAS FedSQL Language Reference*. In CAS, you can overwrite an existing table by specifying the REPLACE= table option in the CREATE TABLE statement. For more information, see "REPLACE= Table Option" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.

The procedure processes nonexistent values as SAS missing values by default. In a SAS library, you can specify ANSIMODE to request that nonexistent values are processed as ANSI SQL null values.

Note: As of September 2023, Microsoft Azure Active Directory (Azure AD) was renamed to Microsoft Entra ID.

Examples:

"Example 1: Creating a SAS Data Set" on page 1027
"Example 2: Joining Tables from Multiple SAS Libraries" on page 1031
"Example 3: Querying Data Using a Correlated Subquery" on page 1033
"Example 4: Creating and Using a DBMS Index to Perform a Join" on page 1034
"Example 5: Using a DS2 Package in an Expression" on page 1036
"Example 6: Querying Data in CAS" on page 1038
"Example 7: Explicitly Loading and Joining Tables in CAS" on page 1041
"Example 8: Joining Tables from Multiple CAS Libraries" on page 1046

Syntax

PROC FEDSQL <*connection-option*><*processing-options*>;

Summary of Optional Arguments

Connection

LIBS=*libref* | (*libref1libref2 ...librefn*)

restricts the default data source connection to the specified libref(s). All other librefs are ignored.

SESSREF=*session-name*
: specifies to run the FedSQL statements in a CAS session. The CAS session is identified by its session name.

SESSUUID="*session-uuid*"
: specifies to run the FedSQL statements in a CAS session. The CAS session is identified by its universally unique identifier (UUID).

General Processing

_METHOD
: prints a brief text description of the FedSQL query plan.

_POSTOPTPLAN
: prints an XML tree illustrating the FedSQL query plan.

ANSIMODE
: specifies that nonexistent values in CHAR and DOUBLE columns are processed as ANSI SQL null values.

AUTOCOMMIT | NOAUTOCOMMIT
: specifies whether updates are automatically committed (that is, saved to a table) after a default number of rows are updated, and whether rollback is available.

CNTL=(*parameter*)
: specifies optional control parameters for FedSQL query planning and query execution in CAS.

ERRORSTOP | NOERRORSTOP
: specifies whether the procedure stops executing if it encounters an error.

EXEC | NOEXEC
: specifies whether a statement should be executed after its syntax is checked for accuracy.

LABEL | NOLABEL
: specifies whether to use the column label or the column name as the column heading.

MEMSIZE=*n* | *n*M | *n*G
: specifies a limit for the amount of memory that is used for an underlying query (such as a SELECT statement), so that allocated memory is available to support other PROC FEDSQL operations.

NOPRINT
: suppresses the normal display of results.

NUMBER
: specifies to include a column named Row, which is the row (observation) number of the data as the rows are retrieved.

STIMER
: specifies to write a subset of system performance statistics, such as time-elapsed statistics, to the SAS log.

XCODE=ERROR | WARNING | IGNORE
: controls the behavior of the SAS session when an NLS transcoding failure occurs.

Optional Arguments

_METHOD

prints a brief text description of the FedSQL query plan. A FedSQL query is broken into stages. Each stage of execution requires a stand-alone SQL query. This option generates a brief text description of the nodes and stages in the query plan. The information is written to the SAS log.

Notes _METHOD is supported on the CAS server only.

The behavior of this option changed in SAS Viya 3.5. In previous versions of SAS Viya, _METHOD returned the stage query and the number of threads used by a request. Beginning in SAS Viya 3.5, that information and more can be obtained with a new showStages CNTL= option. For more information, see "SHOWSTAGES" on page 1012.

See "FedSQL Query Walk-Through" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*

_POSTOPTPLAN

prints an XML tree illustrating the FedSQL query plan. A FedSQL query is broken into stages. Each stage of execution requires a stand-alone SQL query. This option generates an XML tree that illustrates each stage of the FedSQL query plan and the results from each execution stage. The information is written to the SAS log.

Notes _POSTOPTPLAN is supported on the CAS server only.

The XML tree can be very long. You might want to use the _METHOD option instead.

ANSIMODE

specifies that nonexistent values in CHAR and DOUBLE columns are processed as ANSI SQL null values. By default, PROC FEDSQL processes nonexistent values in CHAR and DOUBLE columns as missing values. This is how SAS processes nonexistent values. The ANSIMODE option specifies to process nonexistent values in CHAR and DOUBLE columns as ANSI SQL null values. It is important to understand the differences, or data can be lost. For information about processing differences, see "How FedSQL Processes Nulls and SAS Missing Values" in *SAS FedSQL Language Reference*. All other data types use ANSI NULL semantics all of the time.

Default SAS mode

Restriction ANSIMODE is supported for SAS libraries only.

AUTOCOMMIT | NOAUTOCOMMIT

specifies whether updates are automatically committed (that is, saved to a table) after a default number of rows are updated, and whether rollback is available.

Default All updates are committed immediately after each request is submitted, and no rollback is possible.

Restriction NOAUTOCOMMIT is supported for SAS libraries only.

Requirement For data sources that do not support transactions, specifying NOAUTOCOMMIT returns an error. The data sources that support transactions include Aster, DB2 for UNIX and PC Hosts, Greenplum, Microsoft SQL Server, MySQL, ODBC databases, and SAP IQ.

CNTL=(*parameter*)
specifies optional control parameters for FedSQL query planning and query execution in CAS. Multiple parameters are allowed inside of the parentheses. Separate each parameter with a space. The following parameters are supported:

DISABLEPASSTHROUGH
disables implicit FedSQL pass-through in CAS. FedSQL attempts to use implicit pass-through for all SQL data sources by default. In order for a FedSQL request to be eligible for implicit pass-through in CAS, all tables must exist in the same caslib and the tables cannot have already been loaded into the CAS session. For other requirements, see "FedSQL Implicit Pass-Through Facility in CAS" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*. This option can save processing time for FedSQL requests that contain functions that are specific to SAS, or whose tables have already been loaded into the CAS session.

DYNAMICCARDINALITY
instructs the FedSQL query planner to perform cardinality estimations before selecting a query plan.

The FedSQL query planner does not perform cardinality estimations before selecting a query plan by default. Cardinality estimation can improve the accuracy of selectivity estimates for join conditions and WHERE clause predicates, which in turn can lead to better join-order decisions and faster query execution times for some queries. However, dynamic cardinality does not help all queries and adds overhead to the query planning process.

Note The DYNAMICCARDINALITY option is available starting in SAS Viya 3.5.

See "Using the Dynamic Cardinality Instruction" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*

OPTIMIZEVARBINARYPRECISION
optimizes VARBINARY precision by using a precision that is appropriate to the actual data, instead of the precision declared for the VARBINARY columns.

The precision is optimized both when reading from a table and when creating a new table from a result set. The greatest benefits from this option are achieved when the declared precision is far larger than the precision of the actual data. Then, this option can improve performance, reduce memory footprint, and create VARBINARY columns in new tables with the needed size rather than propagating the precision from the source table.

Note The OPTIMIZEVARBINARYPRECISION option is available starting in SAS Viya 3.5.

OPTIMIZEVARCHARPRECISION
optimizes VARCHAR precision by using a precision that is appropriate to the actual data, instead of the precision declared for the VARCHAR columns.

The precision is optimized both when reading from a table and when creating a new table from a result set. The greatest benefits from this option are achieved when the declared precision is far larger than the precision of the actual data. Then, this option can improve performance, reduce memory footprint, and create VARCHAR columns in new tables with the needed size rather than propagating the precision from the source table.

Note The OPTIMIZEVARCHARPRECISION option is available starting in SAS Viya 3.5.

PRESERVEJOINORDER
joins tables in the specified order instead of an order chosen by the FedSQL query optimizer.

REQUIREFULLPASSTHROUGH
stops processing the FedSQL request when implicit pass-through of the full query cannot be achieved.

SHOWSTAGES
writes query execution details to the SAS log.

This includes the information returned by the _METHOD option. In addition, showStages prints the stage query, the number of SQL threads used by each stage, and the following execution details:

- Time for each intermediate stage
- Number of output rows from each intermediate stage
- Elapsed time for each stage and for the entire action
- Whether a table was replicated to all workers, or auto-partitioned.

The information is gathered when the query is executed and is written to the client log. Do not specify NOEXEC with showStages. Execution details cannot be printed if the query is not executed.

Note The SHOWSTAGES option is available starting in SAS Viya 3.5.

See "Viewing the FedSQL Query Plan" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*

Notes CNTL= is supported on the CAS server only.

CNTL= is available starting in SAS Viya 3.3.

See "Optimizing FedSQL Performance by Modifying the FedSQL Query Plan" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*

ERRORSTOP | NOERRORSTOP
specifies whether the procedure stops executing if it encounters an error. In a batch or noninteractive session, ERRORSTOP instructs the procedure to stop executing the statements but to continue checking the syntax after it has encountered an error. NOERRORSTOP instructs the procedure to execute the statements and to continue checking the syntax after an error occurs.

Default NOERRORSTOP in an interactive SAS session; ERRORSTOP in a batch or noninteractive session

Tips ERRORSTOP has an effect only when SAS is running in the batch or noninteractive execution mode.

NOERRORSTOP is useful if you want a batch job to continue executing SQL procedure statements after an error is encountered.

EXEC | NOEXEC
specifies whether a statement should be executed after its syntax is checked for accuracy. EXEC specifies to execute the statement. NOEXEC specifies not to execute the statement.

Default EXEC

Tip NOEXEC is useful if you want to check the syntax of your FedSQL statements without executing the statements.

LABEL | NOLABEL
specifies whether to use the column label or the column name as the column heading.

Default LABEL

Interactions If a column does not have a label, the procedure uses the column's name as the column heading.

A column alias overwrites the label or column name as the column heading.

LIBS=*libref* | (*libref1libref2 ...librefn*)
restricts the default data source connection to the specified libref(s). All other librefs are ignored. When you specify a list of librefs, the order of the list defines the library order.

Alias LIBNAMES=

Restriction LIBS= is supported only for SAS libraries.

Interactions If both LIBS= and SESSREF= (or SESSUUID=) are specified in the procedure statement, SESSREF= is applied and the other option is ignored.

If LIBS= is specified multiple times, the last instance on the procedure statement is applied.

Note LIBS= is available starting in SAS 9.4M3

Tips LIBS= is useful when multiple LIBNAME statements are defined in a SAS session, to limit the scope of the FedSQL request to only the LIBNAME statement(s) to which the request applies. It can also avoid duplicate catalog errors when connecting to data sources that support native catalogs, such as Netezza.

If you are curious about how LIBS= affects library assignments, set the MSGLEVEL=i system option before running a PROC FEDSQL request with LIBS=. The option produces Include and Ignore messages for each of the LIBNAME statements that are processed in the procedure request.

See "Data Source Connection" on page 1017

"About the LIBS= Procedure Option" on page 1019

Example The following PROC FEDSQL procedure statement specifies to create a data source connection that uses only librefs MyLib3 and MyLib4:

```
proc fedsql libs=(mylib3 mylib4);
```

MEMSIZE=*n* | *n*M | *n*G

specifies a limit for the amount of memory that is used for an underlying query (such as a SELECT statement), so that allocated memory is available to support other PROC FEDSQL operations. Specify the memory limit in multiples of 1 (bytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). For example, the value 23M specifies 24,117,248 bytes of memory. The value 16G specifies 17,179,869,184 bytes of memory.

Default The procedure optimizes the setting based on the amount of memory on the host.

Note On the CAS server, MEMSIZE= specifies the memory for a single CAS worker.

Tip Generally, specifying a memory limit is not necessary unless FedSQL reports a memory problem error.

NOPRINT

suppresses the normal display of results.

Interaction NOPRINT affects the value of the SQLOBS automatic macro variable, which contains the number of rows that are executed by a statement.

NUMBER

specifies to include a column named Row, which is the row (observation) number of the data as the rows are retrieved.

Default No row numbers.

SESSREF=*session-name*

specifies to run the FedSQL statements in a CAS session. The CAS session is identified by its session name.

Requirements A CAS server must be configured for your system.

The CAS session must have been previously established by using the CAS statement. If the specified CAS session does not exist, the procedure terminates.

Interactions Use SESSREF= or SESSUUID= to connect to the CAS session. If both options are specified, the last option in the procedure statement is applied.

If both SESSREF= and LIBS= are specified on the procedure statement, SESSREF= is applied and the other option is ignored.

Note This option is supported in SAS Viya 3.1 and later and in SAS 9.4M5 and later.

See "Connecting to the CAS Server" on page 1019

"Using FedSQL in SAS Cloud Analytic Services" on page 1021

"Example 7: Explicitly Loading and Joining Tables in CAS" on page 1041

SESSUUID="*session-uuid*"

specifies to run the FedSQL statements in a CAS session. The CAS session is identified by its universally unique identifier (UUID).

Requirements A CAS server must be configured for your system.

The CAS session must have been previously established by using the CAS statement. The CAS statement generates a UUID value. If the specified CAS session does not exist, the procedure terminates.

Interactions Use SESSREF= or SESSUUID= to connect to the CAS session. If both options are specified, the last option in the procedure statement is applied.

If both SESSUUID= and LIBS= are specified in the procedure statement, SESSUUID= is applied and the other option is ignored.

Note This option is supported in SAS Viya 3.1 and later and in SAS 9.4M5 and later.

See "Connecting to the CAS Server" on page 1019

"Using FedSQL in SAS Cloud Analytic Services" on page 1021

Example Here is a PROC FEDSQL procedure statement that specifies SESSUUID=:

```
proc fedsql sessuuid="76904741-fb09-554d-a8de-6cbce2a0e0e5";
```

The UUID value can be enclosed in single or double quotation marks.

STIMER
specifies to write a subset of system performance statistics, such as time-elapsed statistics, to the SAS log. When STIMER is in effect, the procedure writes to the SAS log a list of computer resources used for each step and the entire SAS session.

Default No performance statistics are written to the SAS log.

Interaction If the SAS system option FULLSTIMER is in effect, the complete list of computer resources is written to the SAS log.

XCODE=ERROR | WARNING | IGNORE
controls the behavior of the SAS session when an NLS transcoding failure occurs. Transcoding failures can occur during row input or output operations, or during string assignment. Transcoding is the process of converting character data from one encoding to another encoding.

ERROR
specifies that a run-time error occurs, which causes row processing to halt. An error message is written to the SAS log. This is the default behavior.

WARNING
specifies that the incompatible character is set to a substitution character. A warning message is written to the SAS log.

IGNORE
specifies that the incompatible character is set to a substitution character. No messages are written to the SAS log.

Default ERROR

Note This option was added in SAS 9.4M2.

QUIT Statement

Stops the execution of the FEDSQL procedure.

Interaction: Unlike other SAS procedures, in SAS 9.4, PROC FEDSQL does not recognize step boundaries. The QUIT statement is required to stop the FEDSQL procedure before you can submit a DATA step or another procedure step.

Syntax

QUIT;

Details

When the FEDSQL procedure reaches the QUIT statement, all resources allocated by the procedure are released. You can no longer execute FedSQL language statements without invoking the procedure again. However, the connection to the data source server is not lost, because that connection was made through the LIBNAME statement. As a result, any subsequent invocation of the procedure that uses the same libref executes almost instantaneously because the LIBNAME engine is already connected to the server.

Usage: FEDSQL Procedure

Data Source Connection

PROC FEDSQL can execute requests in SAS libraries (librefs) or on the CAS server. By default, PROC FEDSQL connects to a data source by using available librefs. You can override this default behavior by specifying connection options. The FEDSQL procedure is not affected by the CASNAME= system option.

Understanding the Default Data Source Connection

PROC FEDSQL connects to a data source by using the attributes of currently assigned librefs. Attributes include the physical location of the data, and for some data sources, access information such as network information used to access the data server, and user identification and password.

1 You first submit the LIBNAME statement for a SAS engine and then submit PROC FEDSQL. For information to define a LIBNAME statement, see:

SAS data sets
SAS Global Statements: Reference

Relational DBMS data sources
SAS/ACCESS for Relational Databases: Reference

MongoDB and Salesforce
SAS/ACCESS for Nonrelational Databases: Reference

SPD Engine data sets
SAS Scalable Performance Data Engine: Reference

SPD Server tables
SAS Scalable Performance Data Server: User's Guide

2 In your FedSQL language statements, use a two-part name in the form *libref.table-name* to refer to tables. The libref tells FedSQL where to create or locate a table.

3 Then, submit the FEDSQL procedure.

This example illustrates how PROC FEDSQL accesses a data source by using the attributes of a previously assigned libref. The LIBNAME statement assigns the libref MyFiles, specifies the BASE engine, and then specifies the physical location for the SAS data set. The FedSQL program then creates a SAS data set named MyFiles.Table1 at the location specified in the LIBNAME statement.

```
libname myfiles base 'C:\myfiles';

proc fedsql;
   create table myfiles.table1 (x double);
   insert into myfiles.table1 values (1.0);
   insert into myfiles.table1 values (2.0);
   insert into myfiles.table1 values (3.0);
quit;
```

The procedure builds a data source connection string that includes all the active librefs in the SAS session and sends it to the FedSQL program. You reference a particular library by specifying its libref in a two-part table name in the form *libref.table-name*. If you do not specify a libref, the table is created in the SAS Work library.

PROC FEDSQL uses libref attributes for connection information only (such as physical location). The procedure generally does not use libref attributes that define behavior. For example, if a previously submitted LIBNAME statement for the BASE engine specifies that SAS data sets are to be compressed, the compression attribute is not used by the procedure. There are exceptions. For example, the MAX_BINARY_LEN= and MAX_CHAR_LEN= for Google BigQuery are included in the internal connection string.

You can determine which LIBNAME options are used by the procedure by setting the MSGLEVEL=i system option before submitting a LIBNAME statement. For many data sources, you can specify a DS2 table option to override a LIBNAME option. For example, the COMPRESS= table option can be used to request compression of SAS data sets. The SCANSTRINGCOLUMNS= table option can be used to override the MAX_BINARY_LEN= and MAX_CHAR_LEN= LIBNAME options. Not all LIBNAME statement options have a corresponding table option.

Note: PROC FEDSQL connects immediately, so an error is generated if the LIBNAME statement includes the DEFER=YES option.

z/OS Specifics: The physical location for the libref must be an HFS path specification.

About the LIBS= Procedure Option

When multiple librefs are active in the SAS session, you might want to include the LIBS= option in the PROC FEDSQL statement. LIBS= restricts the data source connection to the specified libref or librefs and the default library. Work is the default library unless a User library is assigned.

You must continue to qualify table names with a libref, even when LIBS= specifies only one library; otherwise, the default library is used.

The following example illustrates the use of the LIBS= option. In the example, the LIBS= option specifies to use only libref MyFiles.

```
libname allfiles base 'C:\sharedfiles';
libname myfiles base 'C:\myfiles';

proc fedsql libs=myfiles;
   create table myfiles.table1 (x double);
   insert into myfiles.table1 values (1.0);
   insert into myfiles.table1 values (2.0);
   insert into myfiles.table1 values (3.0);
quit;
```

For more information, see "LIBS=*libref* | (*libref1 libref2 ...librefn*)" on page 1013.

For information about the FedSQL statements supported in the connections made with LIBS=, see *SAS FedSQL Language Reference*.

Connecting to the CAS Server

You connect to a CAS session on the CAS server by specifying the SESSREF= (or SESSUUID=) procedure option with a CAS session name in the PROC FEDSQL statement. When SESSREF= (or SESSUUID=) is specified, both the default connection mechanism and the LIBS= option are ignored. Instead, the procedure connects to the specified CAS session.

Note: You must have a CAS server configured. You must first submit the CAS statement to establish the CAS session. To interact with data in a CAS session, you need a caslib. You must first define a caslib (or use a pre-defined caslib). You define a caslib and list the caslibs that are available to your CAS session by using the CASLIB statement. For syntax information, see *SAS Cloud Analytic Services: User's Guide*. A caslib uses a SAS Data Connector (or SAS Data Connector Accelerator) to access data. For information about SAS Data Connectors, see *SAS Cloud Analytic Services: User's Guide*.

Use a two-part name in the form *caslib.table-name* to identify tables in your FedSQL statements. The following example illustrates a PROC FEDSQL request to the CAS server.

```
options cashost="cloud.example.com" casport=5570;
cas mysess;

caslib castera desc='Teradata Caslib'
datasource=(srctype='teradata'
username='myname'
password='mypw'
server='testserver',
db='testdb');

proc fedsql sessref=mysess;
  create table newtable as
  select * from castera.employees;
quit;
```

This example establishes a CAS session named MySess on a CAS server on CAS host cloud.example.com. It then uses the CASLIB statement to assign caslib CASTERA. The PROC FEDSQL statement specifies the SESSREF= procedure option with the CAS session name MySess. The FedSQL CREATE TABLE statement identifies table Employees using the CASTERA caslib.

SAS Viya data connectors support automatic (shown here) and explicit loading of data into CAS. For more examples, see "Example 6: Querying Data in CAS" on page 1038, "Example 7: Explicitly Loading and Joining Tables in CAS" on page 1041, and "Example 8: Joining Tables from Multiple CAS Libraries" on page 1046.

The CAS tables that you create with PROC FEDSQL are in-memory tables. That is, the tables are available for the duration of the CAS session and are accessible only to the current session. PROC FEDSQL does not provide a way to persist a table to a data source or to share the table with other CAS sessions. To persist or share a CAS output table, use the CASUTIL procedure.

Note: Although CAS tables are in-memory tables, PROC FEDSQL will not overwrite an existing table of the same name. Specify the REPLACE= table option to overwrite an existing table with a replacement table. Or, use the DROP TABLE statement to remove the initial table before creating the replacement table.

For more information about SAS Cloud Analytic Services, see *SAS Cloud Analytic Services: Fundamentals*. Also see CAS statement, CASLIB statement, and CASUTIL procedure in *SAS Cloud Analytic Services: User's Guide*.

Using FedSQL in a SAS Library

The FedSQL language includes statements for reading and writing data. For information about the FedSQL statements supported in the default connection and with the LIBS= option, see *SAS FedSQL Language Reference*. When using PROC FEDSQL to read and write data in a SAS library, note that not all FedSQL statements are supported for third-party DBMS. For information about statement support, see "FedSQL Statements" in *SAS FedSQL Language Reference*.

Data type support and table option support is also data source-specific. For more information, see "Data Type Reference" in *SAS FedSQL Language Reference* and "FedSQL Statement Table Options by Data Source" in *SAS FedSQL Language Reference*.

Using FedSQL in SAS Cloud Analytic Services

When you specify the SESSREF= (or SESSUUID=) option, PROC FEDSQL submits your FedSQL query on a CAS server. The request is actually executed with the fedSQL.execDirect action.

The CAS server is an alternative environment for processing FedSQL queries. The CAS server is a multiprocessing server. A FedSQL request executing on the CAS server can perform manipulations on multiple table rows concurrently using multiple threads and worker nodes. These multiple resources can reduce the time required to process large tables.

The FedSQL statements available when you target the CAS server are subset of those that are available for a SAS library. The following FedSQL statements are supported in CAS:

- CREATE TABLE, with the AS query expression
- SELECT
- DROP TABLE

The following SELECT statement features are not supported:

- EXCEPT and INTERSECT SET operations (UNION is supported, starting in SAS Viya 3.5)
- correlated subqueries
- IN, ANY, and ALL subqueries
- dictionary queries
- views
- DS2 user-defined functions (also known as DS2 package expressions).

FedSQL output tables in CAS are in-memory tables. The tables are created in the user session. You must use other CAS actions to promote the output tables for global use in CAS or to store data to caslib data sources. For more information about FedSQL functionality on the CAS server, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.

Applying FedSQL Table Options

When you access a data source with PROC FEDSQL, you can apply FedSQL table options in the subsequent FedSQL statements. A table option specifies actions that enable you to perform operations on a table such as assigning buffer page size

or specifying passwords. A FedSQL table option performs much of the same functionality as a Base SAS data set option.

FedSQL table options are used to apply options when you access a data source within PROC FEDSQL. For example, the following code applies a table option to the SAS data set in order to specify the size of a permanent buffer page for the new table:

```
libname myfiles base 'C:\myfiles';

proc fedsql;
   create table myfiles.table1 {options bufsize=16k}(x double) ;
   insert into myfiles.table1 values (1.0);
   insert into myfiles.table1 values (2.0);
   insert into myfiles.table1 values (3.0);
quit;
```

A CAS library supports different table options than a SAS library. For a list of table options that are supported in SAS libraries, see *SAS FedSQL Language Reference*. For a list of table options that are supported in CAS libraries, see *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.

Macro Variables

Using Macro Variables in a Literal String

Note: The information in this section applies to PROC FEDSQL use in SAS libraries.

Macro variables enable you to dynamically modify text in a program through symbolic substitution. When you reference a macro variable in a program, the macro processor replaces the reference with the value of the specified macro variable.

With PROC FEDSQL, you can use a macro variable on a subsequent FedSQL statement. However, if a macro variable occurs within a literal string, you cannot enclose the string in double quotation marks. The macro processor uses double quotation marks to resolve macro variable references. FedSQL considers a string enclosed in double quotation marks to be a delimited (case sensitive) identifier such as a table or column name.

To reference a macro variable in a literal string, use the SAS macro function %TSLIT. %TSLIT overrides the need for double quotation marks around the literal string and puts single quotation marks around the input value. For example, the following statement includes the %TSLIT function to specify the &SYSHOSTNAME macro variable, which returns the host name of the computer on which it is executed:

```
select %tslit(&syshostname);
```

The %TSLIT macro function is stored in the default autocall macro library. For more information, see "Referencing a Macro Variable in a Delimited Identifier" in *SAS FedSQL Language Reference* .

Using Macro Variables Set by the Procedure

PROC FEDSQL sets up macro variables with certain values after it executes each statement. These macro variables can be tested inside a macro to determine whether to continue executing the PROC step. After each statement has executed, the following macro variable is updated with these values:

SQLRC
: contains the following status values that indicate the success of the PROC FEDSQL statement:

  0
  : PROC statement completed successfully with no errors.

  4
  : PROC statement encountered a situation for which it issued a warning. The statement continued to execute.

  8
  : PROC statement encountered an error. The statement stopped execution at this point.

  16
  : PROC statement encountered a run-time error. For example, this error code is used when a subquery (that can return only a single value) evaluates more than one row. These errors can be detected only during run time.

Passwords

SAS software enables you to restrict access to SAS data sets and SPD Engine data sets by assigning SAS passwords to the files. When using PROC FEDSQL with SAS libraries, you can assign or specify a password for a data source using the FedSQL table options ALTER=, PW=, READ=, and WRITE=. For example, the following code applies the FedSQL table option PW= in order to assign READ, WRITE, and ALTER passwords to a SAS data set:

```
libname myfiles base 'C:\myfiles';

proc fedsql;
   create table myfiles.table1 {options pw=luke}(x double) ;
   insert into myfiles.table1 values (1.0);
   insert into myfiles.table1 values (2.0);
   insert into myfiles.table1 values (3.0);
quit;
```

This code shows how to specify a table option to read a data set:

```
select * from myfiles.table1 {options pw=luke};
```

A SAS password does not control access to a SAS file beyond SAS. You should use the operating system-supplied utilities and file system security controls to control access to SAS files outside SAS. For more information about SAS passwords, see *SAS FedSQL Language Reference*.

CAS tables do not support SAS passwords. Therefore, you cannot assign a password for a CAS table. When accessing password-protected data from CAS, passwords are specified in the CAS language element used to access the data. For example, passwords are supported in the CASUTIL procedure, which loads data into CAS, as well as in the CASLIB statement and in the Table.addCaslib action. For more information, see the SAS Data Connector documentation in *SAS Cloud Analytic Services: User's Guide*.

Encryption

SAS software enables you to encrypt the contents of a SAS data set, SPD Engine data set, and SPD Server table. SAS supports SAS proprietary encryption and AES encryption.

When using PROC FEDSQL with SAS libraries, you can encrypt output SAS data sets, SPD Engine data sets, and SPD Server tables with SAS proprietary encryption. This is done by specifying the FedSQL ENCRYPT= table option with the PW= or READ= table option. A data set or table encrypted with SAS proprietary encryption must be decrypted by specifying the PW= or READ= table option with the appropriate password.

AES encryption is performed by specifying the ENCRYPT= table option with the ENCRYPTKEY= table option. A data set or table encrypted with AES encryption is later decrypted by specifying the ENCRYPTKEY= table option with the appropriate key value.

SAS supports two levels of AES encryption: AES and AES2. The new AES2 option provides AES encryption to meet newer and more secure encryption standards. AES2 encryption is initially supported for SAS data sets only. For more information, see "ENCRYPT= Table Option" in *SAS FedSQL Language Reference*.

FedSQL currently does not support the encryption attribute for CAS tables. When accessing SAS and AES encrypted data sets from CAS, passwords and encryption keys are specified in the CAS language element that is used to access the data. For example, passwords and encryption keys are supported in the CASUTIL procedure, which loads data into CAS as well as in the CASLIB statement and in the Table.addCaslib action. For more information, see the SAS Data Connector documentation in *SAS Cloud Analytic Services: User's Guide*.

FedSQL Data Type Support for SAS Data Sets

PROC FEDSQL supports the following data types for reading and writing a SAS data set through a SAS library. For a SAS data set, FedSQL data types are translated to and from predetermined legacy SAS data types, which are SAS numeric and SAS character. For example, when you submit the CONTENTS procedure on a table that is created with the FedSQL language, the DATE data type is reported as a SAS numeric. The following table lists the FedSQL data types and describes how they are translated to and from SAS data types.

Table 27.2 *FedSQL Data Type Translation for SAS Data Sets*

FedSQL Data Type	SAS Data Type	Description
BIGINT	SAS numeric	Because a SAS numeric is a DOUBLE, there is potential for loss of precision. DOUBLE is an approximate numeric data type rather than an exact numeric data type.
BINARY(*n*)	SAS character	Applies the SAS format $*n*.
CHAR(*n*)	SAS character	Applies the SAS format $*n*.
DATE	SAS numeric	Applies the SAS format DATE9. Valid SAS date values are in the range from 1582-01-01 to 9999-12-31. Dates outside the SAS date range are not supported and are treated as invalid dates.
DECIMAL| NUMERIC(*p*,*s*)	SAS numeric	
DOUBLE	SAS numeric	
FLOAT(*p*)	SAS numeric	
INTEGER	SAS numeric	
NCHAR(*n*)	SAS character	Applies the SAS format $*n*.
NVARCHAR(*n*)	SAS character	Applies the SAS format $*n*.
REAL	SAS numeric	
SMALLINT	SAS numeric	

FedSQL Data Type	SAS Data Type	Description
TIME(*p*)	SAS numeric	Applies the SAS format TIME8.
TIMESTAMP(*p*)	SAS numeric	Applies the SAS format DATETIME19.2.
TINYINT	SAS numeric	
VARBINARY(*n*)	SAS character	Applies the SAS format $*n*.
VARCHAR(*n*)	SAS character	Applies the SAS format $*n*.

For information about data type support for DBMS data sources through a SAS library, see "Data Type Reference" in *SAS FedSQL Language Reference*.

FedSQL Data Type Support for CAS Tables

FedSQL supports CAS native data types only in CAS. Beginning with SAS Viya 3.5, FedSQL supports the VARBINARY data type in addition to the CHAR(*n*), DOUBLE, INT32, INT64, and VARCHAR(*n*) data types.

Table 27.3 *FedSQL Data Type Translation for CAS Tables*

FedSQL Data Type	CAS Data Type	Description
BIGINT[1]	INT64	Large signed, exact whole number.
CHAR(*n*)	CHAR	Fixed-length character string, where *n* is the maximum number of characters to store. The maximum number of characters is required to store each value regardless of the actual size of the value. If char(10) is specified and the character string is only five characters long, the value is right-padded with spaces.
DOUBLE	DOUBLE	Signed, approximate, double-precision, floating-point number. Allows numbers of large magnitude and permits computations that require many digits of precision to the right of the decimal point. For the CAS server, this is a 64-bit double-precision, floating-point number.
INTEGER[1]	INT32	Regular signed, exact whole number.

FedSQL Data Type	CAS Data Type	Description
VARBINARY[2]	VARBINARY	Varying-length binary opaque data. This data type is used to store image data, audio, documents, and other unstructured data.
VARCHAR(*n*)	VARCHAR	Varying-length character string, where *n* is the maximum number of characters to store.

1 Support for the integer data types starts in SAS Viya 3.3.

2 Support for the VARBINARY data type starts in SAS Viya 3.5. FedSQL can read and write VARBINARY columns in CAS tables (with CREATE TABLE AS). However, the SELECT statement does not display VARBINARY columns in some clients unless you apply the $HEX. format to the VARBINARY column with the PUT function. In earlier SAS Viya releases, FedSQL does not return an error when reading BINARY and VARBINARY columns. However, the data is incorrectly treated as character data. Attempts to read BINARY data now yield an error.

Date, time, and timestamp values in CAS tables are supported as DOUBLEs, with a SAS format applied. FedSQL applies the DATE9. SAS format to date values, the TIME8. SAS format to time values, and the DATETIME25.6 SAS format to datetime values.

CAS tables use the UTF-8 character set by default.

It is important to understand how FedSQL handles missing values in CAS. See "Handling of Nonexistent Data" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.

Examples: FEDSQL Procedure

Example 1: Creating a SAS Data Set

Features:

PROC FEDSQL statement
FedSQL CREATE TABLE statement
FedSQL INSERT statement
QUIT statement
LIBNAME statement
PROC CONTENTS

Details

This example creates a SAS data set in a Base SAS session by submitting the FEDSQL procedure. The example submits the FedSQL CREATE TABLE and INSERT statements. The CONTENTS procedure then is used to describe the contents of the SAS data set.

Program

```
libname mybase base 'C:\My Documents';

proc fedsql;

create table mybase.sales (prodid double not null,
                           custid double not null,
                           totals double having format comma8.,
                           country char(30));

insert into mybase.sales values (3234, 1, 189400, 'United States');
insert into mybase.sales values (1424, 3, 555789, 'Japan');
insert into mybase.sales values (3421, 4, 781183, 'Japan');
insert into mybase.sales values (3422, 2, 2789654, 'United States');
insert into mybase.sales values (3975, 5, 899453, 'Argentina');

quit;

proc contents data=mybase.sales;
run;
```

Program Description

Assign a library reference to the SAS data set to be created. The LIBNAME statement assigns the libref MyFiles, specifies the BASE engine, and specifies the physical location for the SAS data set.

```
libname mybase base 'C:\My Documents';
```

Execute the PROC FEDSQL statement. The PROC FEDSQL statement sets up an environment to submit FedSQL statements. By default, the PROC FEDSQL statement generates a connection string to the data source from the librefs that are active in the SAS session.

```
proc fedsql;
```

Enter the FedSQL CREATE TABLE statement. The statement specifies to create the SAS data set named MyBase.Sales. Note that the two-level name in the FedSQL CREATE TABLE statement specifies the catalog identifier MyBase, which is the assigned libref. The variable declaration defines a NOT NULL integrity constraint on columns ProdId and CustId, and applies the SAS format COMMAw. on column Totals.

```
create table mybase.sales (prodid double not null,
                           custid double not null,
                           totals double having format comma8.,
                           country char(30));
```

Enter INSERT statements to populate the table with data. Note that the table name is qualified with the catalog identifier in each statement. The data values are submitted in a comma-delimited string, preceded by the keyword VALUES.

```
insert into mybase.sales values (3234, 1, 189400, 'United States');
insert into mybase.sales values (1424, 3, 555789, 'Japan');
insert into mybase.sales values (3421, 4, 781183, 'Japan');
insert into mybase.sales values (3422, 2, 2789654, 'United States');
insert into mybase.sales values (3975, 5, 899453, 'Argentina');
```

Stop the procedure. The QUIT statement stops the procedure.

```
quit;
```

List the contents of the SAS data set. The CONTENTS procedure describes the contents of the SAS data set.

```
proc contents data=mybase.sales;
run;
```

Output: Creating a SAS Data Set

Output 27.1 *PROC CONTENTS Output of MyBase.Sales*

2	_NM0002_	Not Null	CUSTID

Example 2: Joining Tables from Multiple SAS Libraries

Features: PROC FEDSQL statement
CREATE TABLE statement with AS expression
LIBNAME statements

Details

This example creates a new SAS data set from existing tables by using PROC FEDSQL and the CREATE TABLE statement with the AS query expression syntax. The query expression selects rows from three existing tables — SAS data set Sales, SPD Engine data set Products, and Oracle table Customers — to create the new table: Results.

Program

```
libname mybase v9 'C:\base';
libname myspde spde 'C:\spde';
libname myoracle oracle path=ora11g user=xxxxxx password=xxxxxx
schema=xxxxxx;

proc fedsql;
```

```
   create table mybase.results as
      select products.prodid, products.product, customers.name,
         sales.totals, sales.country
      from myspde.products, mybase.sales, myoracle.customers
      where products.prodid = sales.prodid and
         customers.custid = sales.custid;

   select * from mybase.results;

quit;
```

Program Description

Assign three librefs. The first LIBNAME statement assigns the libref MyBase, specifies the V9 engine, and specifies the physical location for the SAS data set to be created. V9 is an alias for the BASE engine. The second LIBNAME statement assigns the libref MySpde, specifies the SPDE engine, and specifies the physical location for the existing SPD Engine data set. The third LIBNAME statement assigns the libref MyOracle, specifies the ORACLE engine, and specifies the connection information to the Oracle database that contains the existing Oracle tables.

```
libname mybase v9 'C:\base';
libname myspde spde 'C:\spde';
libname myoracle oracle path=ora11g user=xxxxxx password=xxxxxx
schema=xxxxxx;
```

Execute the PROC FEDSQL statement. The PROC FEDSQL statement sets up an environment for submitting FedSQL statements.

```
proc fedsql;
```

Create the new table. The CREATE TABLE statement creates a new SAS data set from three existing SAS data sets by using a query expression to select rows from the existing data sets. The SELECT statement retrieves the qualified columns and rows from the existing data sets to create the new SAS data set.

```
   create table mybase.results as
      select products.prodid, products.product, customers.name,
         sales.totals, sales.country
      from myspde.products, mybase.sales, myoracle.customers
      where products.prodid = sales.prodid and
         customers.custid = sales.custid;
```

Retrieve data in the SAS data set. This second SELECT statement displays the contents of the output data set.

```
   select * from mybase.results;
```

Stop the procedure.

```
quit;
```

Output: Joining Tables from Multiple SAS Libraries

Output 27.2 *Contents of Output Data Set MyBase.Results*

PRODID	PRODUCT	NAME	TOTALS	COUNTRY
3234	Rice	Peter Frank	189,400	United States
3422	Oat	Jim Stew art	2789654	United States
1424	Corn	Janet Chien	555,789	Japan
3421	Wheat	Qing Ziao	781,183	Japan
3975	Barley	Humberto Sertu	899,453	Argentina

Example 3: Querying Data Using a Correlated Subquery

Features: PROC FEDSQL statement
FedSQL SELECT statement
LIBNAME statements

Note: This functionality is available in SAS libraries.

Details

This example illustrates querying data using a correlated subquery. In a correlated subquery, the WHERE clause in the subquery refers to values in a table in the outer query. The correlated subquery is evaluated for each row in the outer query. With correlated subqueries, FedSQL executes the subquery and the outer query together. FedSQL can perform heterogeneous correlated subqueries. FedSQL directs the subquery to be performed by the data source, which limits the result set that is transferred from the data source.

Note: Correlated subqueries are not yet supported on the CAS server.

Program

```
libname myspde spde 'C:\spde';
```

```
libname myoracle oracle path=ora11g user=xxxxxx password=xxxxxx
schema=xxxxxx;

proc fedsql;

   select * from myspde.product
      where exists (select * from myoracle.sales
      where product.prodid=sales.prodid);

quit;
```

Program Description

Assign two library references. The first LIBNAME statement assigns the libref MySpde, specifies the SPDE engine, and specifies the physical location for the SPD Engine data set. The second LIBNAME statement assigns the libref MyOracle, specifies the Oracle engine, and specifies the connection information to the Oracle database.

```
libname myspde spde 'C:\spde';
libname myoracle oracle path=ora11g user=xxxxxx password=xxxxxx
schema=xxxxxx;
```

Execute the PROC FEDSQL statement. The PROC FEDSQL statement creates an environment for submitting FedSQL statements.

```
proc fedsql;
```

Submit a correlated query. FedSQL directs the subquery WHERE expression to be evaluated by the Oracle database.

```
   select * from myspde.product
      where exists (select * from myoracle.sales
      where product.prodid=sales.prodid);
```

Stop the procedure. Specify the QUIT statement to complete the procedure request.

```
quit;
```

Example 4: Creating and Using a DBMS Index to Perform a Join

Features:	PROC FEDSQL statement FedSQL language statements LIBNAME statements
Note:	This functionality is available in SAS libraries.

Details

This example illustrates how to create an index for an Oracle table. It then illustrates how to use the index to perform a join of the Oracle table and an SPD Engine data set.

Note: The CREATE INDEX statement is not supported on the CAS server.

Program

```
libname myspde spde 'C:\spde';
libname myoracle oracle path=ora11g user=xxxxxx password=xxxxxx
schema=xxxxxx;

proc fedsql;

   create index prodid on myoracle.sales (prodid);

   select * from myspde.product, myoracle.sales
      where product.prodid=sales.prodid;

quit;
```

Program Description

Assign two library references. The first LIBNAME statement assigns the libref MySpde, specifies the SPDE engine, and specifies the physical location for the SPD Engine data set. The second LIBNAME statement assigns the libref MyOracle, specifies the ORACLE engine, and specifies the connection information to the Oracle database.

```
libname myspde spde 'C:\spde';
libname myoracle oracle path=ora11g user=xxxxxx password=xxxxxx
schema=xxxxxx;
```

Execute the PROC FEDSQL statement. The PROC FEDSQL statement creates an environment for submitting FedSQL statements.

```
proc fedsql;
```

Create an index for the Oracle table. The CREATE INDEX statement creates an index named ProdId in the Oracle table named Sales for the column ProdId.

```
   create index prodid on myoracle.sales (prodid);
```

Retrieve columns and rows. The SELECT statement retrieves data from the SPD Engine data set named Product and the Oracle table named Sales. Even though the index is in the Oracle database, FedSQL can take advantage of the index to perform the join.

```
   select * from myspde.product, myoracle.sales
      where product.prodid=sales.prodid;
```

Stop the procedure. Specify the QUIT statement to complete the procedure request.

```
quit;
```

Example 5: Using a DS2 Package in an Expression

Features: FedSQL SELECT statement
Package method declaration
DS2 PACKAGE statement
DS2 METHOD statement
DS2 DATA statement

Note: This functionality is available in SAS libraries.

Details

The FedSQL language supports the ability to invoke user-defined DS2 package methods as functions in the SELECT statement. This example creates and submits a DS2 package method named Add on a table named Numbers from PROC FEDSQL. The package method and table are created in the Work library.

Note: Package methods that are run from PROC FEDSQL can have only input arguments in the method. For more information, see "Using DS2 Packages in Expressions" in *SAS FedSQL Language Reference*.

Note: User-defined package methods are not supported on the CAS server.

Program

```
proc ds2;
   package adder / overwrite =yes;

   method add( double x, double y ) returns double;
   return x + y;
  end;
endpackage;

data numbers / overwrite = yes;
   dcl double x y;
   method init();
```

```
   dcl int i;
   do i = 1 to 10;
   x = i; y = i * i;
   output;
 end;
end;
enddata;

run;

quit;

proc fedsql;

   select x, y, work.adder.add( x, y ) as z from work.numbers;

quit;
```

Program Description

Invoke the DS2 procedure with the PROC DS2 statement and define a package. This PACKAGE statement specifies to create a package named Adder.

```
proc ds2;
   package adder / overwrite =yes;
```

Define a method. This METHOD statement specifies to create a method named Add. The method Add has two input variables, X and Y, both of type DOUBLE, and it returns an output of type DOUBLE. The output variable contains the sum from adding the value of variable X to variable Y. The END and ENDPACKAGE statements signal the completion of the METHOD and PACKAGE declarations.

```
   method add( double x, double y ) returns double;
   return x + y;
  end;
endpackage;
```

Create a table. This DATA statement specifies to create a table named Numbers. A library is not specified, so the Work library will be used. The table has two columns, X and Y, of type DOUBLE. The system INIT method is called to populate the table with values. A variable, I, is defined to hold input values. A DO statement uses variable I to insert rows containing the values 1 through 10 into column X. Then, it multiplies each instance of I with itself and inserts the result into column Y. The END and ENDDATA statements signal the completion of the DO statement, INIT method, and DATA statement declarations.

```
data numbers / overwrite = yes;
   dcl double x y;
   method init();
   dcl int i;
   do i = 1 to 10;
   x = i; y = i * i;
   output;
 end;
end;
enddata;
```

Submit the DS2 statements. Like in the DATA step, the RUN statement executes DS2 language statements.

```
run;
```

Stop the DS2 procedure. The QUIT statement completes the procedure request.

```
quit;
```

Invoke the FEDSQL procedure. The PROC FEDSQL statement invokes the FEDSQL procedure.

```
proc fedsql;
```

Submit a SELECT statement that invokes the package method on the table. The statement specifies to select columns X and Y, and the result of the package method expression is column Z from table Numbers. The package method is referenced using a three-part name in the form [catalog.][schema.]package.method.

```
select x, y, work.adder.add( x, y ) as z from work.numbers;
```

Stop the FEDSQL procedure. The QUIT statement completes the PROC FEDSQL request.

```
quit;
```

Here is the output from the SELECT statement:

x	y	z
1	1	2
2	4	6
3	9	12
4	16	20
5	25	30
6	36	42
7	49	56
8	64	72
9	81	90
10	100	110

Example 6: Querying Data in CAS

Features:

PROC FEDSQL statement
SESSREF= procedure option
FedSQL language statements
CAS system options
CAS statement
CASLIB statement

Details

This example illustrates the steps necessary to query a database table named Employees from CAS.

Program

```
options cashost="cloud.example.com" casport=5570;

cas mysess;

caslib castera desc='Teradata Caslib'
   datasource=(srctype='teradata',
      dataTransferMode='serial',
      username='myname',
      password='mypw',
      server='testserver',
      db='test');

proc fedsql sessref=mysess;

select Pos, count(Pos) as Count_Pos
    from castera.employees
    group by Pos
    having count(Pos) >= 2;

quit;
```

Program Description

Invoke the CAS server. The CASHOST= and CASPORT= system options specify the name and port number of the CAS server.

```
options cashost="cloud.example.com" casport=5570;
```

Establish a session on the CAS server. The CAS statement specifies to create a session named MySess on the CAS server.

```
cas mysess;
```

Add a caslib for the Teradata database. When submitting a request to the CAS server, you must identify your data source with a caslib instead of a libref. The CASLIB statement specifies to create caslib CasTera. The caslib specifies the SrcType=Teradata, dataTransferMode='serial', and connection details for the Teradata database. A data connect accelerator that loads data in parallel is available for Teradata, but it is not used here. CasTera becomes the active caslib in your CAS session.

```
caslib castera desc='Teradata Caslib'
   datasource=(srctype='teradata',
      dataTransferMode='serial',
      username='myname',
      password='mypw',
      server='testserver',
      db='test');
```

Specify the PROC FEDSQL statement with the SESSREF= procedure option. In the SESSREF= procedure option, specify the name CAS session name MySess. The SESSREF= option establishes the connection to the CAS session and it instructs the procedure to pass FedSQL language statements that follow to the fedSQL.execDirect action.

```
proc fedsql sessref=mysess;
```

Specify FEDSQL statements and identify the data source with caslib CASTERA. The SELECT statement specifies to list all of the job titles in database table Employees that have at least two employees. The table is identified by the two-part name CasTera.Employees. When you identify tables using a two-part name, the execDirect action responds as follows. The FedSQL language supports single-source, full-query implicit SQL pass-through in CAS. If the target tables have not yet been loaded into the CAS session, the tables are evaluated for implicit pass-through. Implicit pass-through passes eligible requests to the data source for processing and loads the result set into CAS. SQL implicit pass-through is possible only for tables that have not yet been loaded into the CAS session. There are other important requirements. For information about these requirements, see "FedSQL Implicit Pass-Through Facility in CAS" in *SAS Viya: FedSQL Programming for SAS Cloud Analytic Services*.. Unloaded tables that are not eligible for pass-through are automatically loaded into the CAS session for processing by the CAS server. Tables already existing in the CAS session are processed by the CAS server.

```
select Pos, count(Pos) as Count_Pos
    from castera.employees
    group by Pos
    having count(Pos) >= 2;
```

Stop the procedure.

```
quit;
```

Output: Result of Database Query from CAS

Output 27.3 *Output of CAS Database Query*

Pos	COUNT_POS
Manager	4.000000
Developer	2.000000
Sales Associate	2.000000

```
1          OPTIONS NONOTES NOSTIMER NOSOURCE NOSYNTAXCHECK
72
73              proc fedsql sessref=mysess;
74              select Pos, count(Pos) as Count_Pos
75                  from castera.employees
76                  groupby Pos
77                  having count(Pos) >=2;
NOTE: The SQL statement was fully offloaded to the underlying data source via
full pass-through
78               quit;
```

Example 7: Explicitly Loading and Joining Tables in CAS

Features:
- PROC FEDSQL statement
- SESSREF= procedure option
- CAS system options
- CAS statement
- CASLIB statement
- CAS LIBNAME statement
- DATA step
- CASUTIL procedure

Details

In some cases, some formatting is required before data can be processed successfully. This example explicitly loads three files that contain comma-delimited data into CAS. The CAS LIBNAME engine and the DATA step are used to format and load the tables. Then, after the tables are in CAS, PROC FEDSQL is used to join them and to create a new CAS table that contains the result set. The input files are named Supplier, Nation, and Customer. The output CAS table is named CASDATA.NewTable. All of the CAS tables are in-memory tables. They disappear at the end of the CAS session, unless you save or promote them using PROC CASUTIL.

The example assigns a caslib and a libref. The libref is mapped to the caslib in the CAS LIBNAME statement. The DATA step executes in the libref. When the SESSREF= option is specified in the PROC FEDSQL procedure statement, FedSQL statements are executed in a caslib.

Note: When formatting your FEDSQL requests, be aware that leading spaces before statements and clauses are important. Do not begin statements and clauses flush with the left margin. If you put a line break in a quoted string, always follow the line break with at least one blank.

Program

```
options cashost="cloud.example.com" casport=5570;

cas mysess;
```

```
caslib casdata path='/r/ge.unx.company.com/vol/vol210/u21/myID/hold';

libname mycas cas host="cloud.example.com" port=5570 sessref=mysess
caslib=casdata;

data mycas.supplier;
  infile "/r/ge.unx.company.com/vol/vol210/u21/myID/hold/supplier.tbl"
delimiter='|';
  length S_SUPPKEY 8. S_NAME VARCHAR(25) S_ADDRESS VARCHAR(40)
S_NATIONKEY 8.
S_PHONE VARCHAR(15) S_ACCTBAL 8. S_COMMENT VARCHAR(101);
  input  S_SUPPKEY S_NAME S_ADDRESS S_NATIONKEY S_PHONE S_ACCTBAL
S_COMMENT;
run;

data mycas.nation;
  infile "/r/ge.unx.company.com/vol/vol210/u21/myID/hold/nation.tbl"
delimiter='|';
  length N_NATIONKEY 8. N_NAME VARCHAR(25) N_REGIONKEY 8. N_COMMENT
VARCHAR(152);
  input  N_NATIONKEY N_NAME N_REGIONKEY N_COMMENT;
run;

data mycas.customer;
  infile "/r/ge.unx.company.com/vol/vol210/u21/myID/hold/customer.tbl"
delimiter='|';
  length C_CUSTKEY 8. C_NAME VARCHAR(25) C_ADDRESS VARCHAR(40)
C_NATIONKEY 8.
 C_PHONE VARCHAR(15) C_ACCTBAL 8. C_MKTSEGMENT VARCHAR(10) C_COMMENT
VARCHAR(117);
  input  C_CUSTKEY C_NAME C_ADDRESS C_NATIONKEY C_PHONE C_ACCTBAL
C_MKTSEGMENT
  C_COMMENT;
run;

proc casutil;
  list tables incaslib="casdata";
run;

proc fedsql sessref=mysess;

  create table newtable {options replace=true} as
  select
    s_name, s_acctbal, n_name, sum_c_acctbal
  from
    supplier,
    nation,
    (select c_nationkey, sum(c_acctbal) as sum_c_acctbal from customer
group by
 c_nationkey) C
   where
    s_nationkey = n_nationkey and
    s_nationkey = c_nationkey
  ;

select * from newtable;

quit;
```

Program Description

Invoke the CAS server. The CASHOST= and CASPORT= system options specify the name and port number of the CAS server.

```
options cashost="cloud.example.com" casport=5570;
```

Establish a session on the CAS server. The CAS statement specifies to create a CAS session named MySess.

```
cas mysess;
```

Assign a caslib that points to your input files. The CASLIB statement assigns the caslib CASDATA to the location specified in the PATH= parameter. The path specification must use an absolute pathname.

```
caslib casdata path='/r/ge.unx.company.com/vol/vol210/u21/myID/hold';
```

Assign a CAS engine libref. The LIBNAME statement specifies the libref MyCas, the CAS engine, connection parameters for the CAS server, and the CASDATA caslib. The LIBNAME statement invokes the CAS engine and maps libref to the caslib.

```
libname mycas cas host="cloud.example.com" port=5570 sessref=mysess
caslib=casdata;
```

Use the DATA step to format and load the first file into CAS. The DATA statement specifies to create a table named MyCas.Supplier. The CAS engine creates the output table as a CAS table. In the SAS session, the table is known as MyCas.Supplier. In CAS session MySess, the table is known as CASDATA.Supplier. The INFILE= statement specifies to read the contents of the file using a | (pipe symbol) as a column delimiter. The LENGTH statement specifies column names and lengths for the output table. (Note that the INFILE specification can be relative to the path that is specified in the CASLIB statement.) The CAS engine creates table Supplier in caslib CASDATA.

```
data mycas.supplier;
  infile "/r/ge.unx.company.com/vol/vol210/u21/myID/hold/supplier.tbl"
delimiter='|';
  length S_SUPPKEY 8. S_NAME VARCHAR(25) S_ADDRESS VARCHAR(40)
S_NATIONKEY 8.
S_PHONE VARCHAR(15) S_ACCTBAL 8. S_COMMENT VARCHAR(101);
  input  S_SUPPKEY S_NAME S_ADDRESS S_NATIONKEY S_PHONE S_ACCTBAL
S_COMMENT;
run;
```

Format and load the second file into CAS. This DATA statement specifies to create a CAS table named MyCas.Nation. The INFILE= statement reads the contents of the file using a pipe symbol as a delimiter. The LENGTH statement specifies column names and lengths for the output table. The CAS engine creates table Nation in caslib CASDATA.

```
data mycas.nation;
  infile "/r/ge.unx.company.com/vol/vol210/u21/myID/hold/nation.tbl"
delimiter='|';
  length N_NATIONKEY 8. N_NAME VARCHAR(25) N_REGIONKEY 8. N_COMMENT
VARCHAR(152);
  input  N_NATIONKEY N_NAME N_REGIONKEY N_COMMENT;
run;
```

Format and load the third file into CAS. The DATA step specifies to create a CAS table named MyCas.Customer. The INFILE= statement reads the contents of the file. The LENGTH statement specifies column names and lengths for the output table. The CAS engine creates table Customer in caslib CASDATA.

```
data mycas.customer;
  infile "/r/ge.unx.company.com/vol/vol210/u21/myID/hold/customer.tbl"
delimiter='|';
  length C_CUSTKEY 8. C_NAME VARCHAR(25) C_ADDRESS VARCHAR(40)
C_NATIONKEY 8.
 C_PHONE VARCHAR(15) C_ACCTBAL 8. C_MKTSEGMENT VARCHAR(10) C_COMMENT
VARCHAR(117);
  input  C_CUSTKEY C_NAME C_ADDRESS C_NATIONKEY C_PHONE C_ACCTBAL
C_MKTSEGMENT
  C_COMMENT;
run;
```

Verify that the files were created in CAS. Submit the CASUTIL procedure to list the tables that are available in caslib CASDATA.

```
proc casutil;
  list tables incaslib="casdata";
run;
```

Specify the PROC FEDSQL statement. In the PROC FEDSQL statement, specify the SESSREF= procedure option with the name MySess to connect to the CAS session and direct the FedSQL statements that follow to the fedSQL.execDirect action. Because of earlier activity in the CAS session, CASDATA is the active caslib.

```
proc fedsql sessref=mysess;
```

Submit the FedSQL statements. The fedSql.execDirect action enables you to identify tables in the active caslib using either a one-part or a two-part name. Because the tables already exist in the session, the one-part form is used here. The CREATE TABLE statement specifies to create a table named NewTable using columns from the Supplier, Nation, and Customer tables. The SELECT statement retrieves the columns S_NAME, S_ACCTBAL, N_NAME from the tables and creates a new column SUM_C_ACCTBAL by issuing a subquery. The tables are joined based on the values in the S_NATIONKEY, N_NATIONKEY, and C_NATIONKEY columns. FedSQL combines the data and returns the results in the new CAS table.

```
  create table newtable {options replace=true} as
  select
    s_name, s_acctbal, n_name, sum_c_acctbal
  from
    supplier,
    nation,
    (select c_nationkey, sum(c_acctbal) as sum_c_acctbal from customer
group by
 c_nationkey) C
   where
    s_nationkey = n_nationkey and
    s_nationkey = c_nationkey
  ;
```

Display the contents of table NewTable. The SELECT statement specifies to display the content of CAS table NewTable. NewTable is an in-memory table. To persist or promote it, you must use PROC CASUTIL.

```
select * from newtable;
```

Stop the procedure.

```
quit;
```

Output: Joining Tables That Were Explicitly Loaded into CAS

Output 27.4 *Output of the CASUTIL Procedure LIST Statement*

The CASUTIL Procedure

Table Information for Caslib CASDATA

Table Name	Number of Rows	Number of Columns	NLS encoding	Created	Last Modified	Promoted Table	Repeated Table	View	Compressed

Example 8: Joining Tables from Multiple CAS Libraries

Features:
PROC FEDSQL statement
SESSREF= procedure option
FedSQL language statements
CAS system options
CAS statement
CASUTIL procedure
CASLIB statements

Details

This example shows how to perform the join in "Example 2: Joining Tables from Multiple SAS Libraries" on page 1031 on the CAS server. A difference is that this example joins a SAS data set and an SPD Engine data set with a Teradata table instead of an Oracle table.

Invoke the CAS server and start a CAS session. These steps are necessary only if a CAS server connection and a CAS session do not already exist.

```
options cashost="cloud.example.com" casport=5570;
cas mysess;
```

Load the SAS data set Customers into your CAS session. PROC CASUTIL loads the data set into default caslib CASUSERHDFS.

```
proc casutil;
  load data="path-to-customers-data-set" outcaslib="casuserhdfs";
quit;
```

Add an SPD Engine caslib. The CASLIB statement specifies to create caslib spdeCasLib. The caslib specifies SrcType=SPDE and it specifies the path to the directory that contains the metadata file for SPD Engine data set Products.

```
caslib spdecaslib Desc="SPD Engine caslib"
datasource=(srctype="spde", username="",
mdfpath="path-to-metafile",
dataTransferMode="serial");
run;
```

Add a Teradata caslib. This step is necessary only if the caslib has not already been assigned in the CAS session.

```
caslib TDcaslib desc='Teradata Caslib'
   datasource=(srctype='teradata'
      username='myname'
```

```
      password='mypw'
      server='testserver',
      db='test')
      notactive;
```

Submit the join request. The PROC FEDSQL statement specifies the SESSREF= procedure option. The SESSREF= option specifies CAS session MySess. Each table name in the CREATE TABLE statement is identified using a two-part table name. A SELECT statement requests to print the contents of table Results.

```
proc fedsql sessref=mysess;
create table results as
      select products.prodid, products.product, customers.name,
         sales.totals, sales.country
      from spdecaslib.products, TDcaslib.sales, casuserhdfs.customers
      where products.prodid = sales.prodid and
         customers.custid = sales.custid;

select * from results;
quit;
```

Output: Joining Tables from Multiple CAS Libraries

Output 27.6 *Contents of CAS Table Results*

PRODID	PRODUCT	NAME	TOTALS	COUNTRY
3421.000000	Wheat	Qing Ziao	781183	Japan

FMTC2ITM Procedure

Overview: FMTC2ITM Procedure

What Does the FMTC2ITM Procedure Do?

The FMTC2ITM procedure converts one or more format catalogs into a single item store that can be made available to CAS. PROC FMTC2ITM enables you to create an item store that has the following contents:

- all of the formats from one catalog
- a subset of the formats from one catalog
- all of the formats from multiple catalogs
- a subset of the formats from each of multiple catalogs.

After you create an item store with PROC FMTC2ITM, you can use the CAS statement with the addFmtLib action to make the item store available to CAS. For more information, see "CAS Statement" in *SAS Cloud Analytic Services: User's Guide* and addFmtLib Action.

Syntax: FMTC2ITM Procedure

PROC FMTC2ITM <*options*>;
<SELECT *member-list*>;

Statement	Task
PROC FMTC2ITM	Converts one or more format catalogs into a single item store.
SELECT	Lists the formats to be placed in the item store.

PROC FMTC2ITM Statement

Converts one or more format catalogs into a single item store.

Note: The item store is written as a new file. If you specify the name of an existing item store with the ITEMSTORE option, it overwrites the contents of the existing item store.

Syntax

PROC FMTC2ITM <*options*>;

Required Arguments

CATALOG= memname | libname.memname(| list)
specifies a catalog that is to be converted to an item store. If you do not specify the CATALOG option, the default catalog is WORK.FORMATS.

You can specify the following values for the CATALOG option:

- A single-level name that SAS interprets as a catalog name in the WORK library.
- A two-level name that SAS interprets as a libname.memname for a catalog.
- A list enclosed in parentheses that SAS interprets as a list of catalog names.

SAS opens each catalog in the list in the listed order and writes the members of the catalogs to the item store. Only the first occurrence of the member is written. For example, if CATALOG A has members X and Y, and CATALOG B has members X and Z as specified in this code example:

```
proc fmtc2itm catalog=(a b) itemstore='itemstoreA'; run;
```

The resulting item store contains members X and Y from CATALOG A, and member Z from CATALOG B.

ITEMSTORE= fileref | 'filename'
specifies the name of the item store. You can specify a fileref, or you can specify a pathname in quotation marks.

Note: You can specify only one item store with each invocation of PROC FMTC2ITM.

ENCODING=*encoding-name*
specifies an encoding for a catalog or for all of the catalogs in a list.

To specify an encoding for one catalog, specify the ENCODING= option after the catalog name as shown in this example code.

```
proc fmtc2itm cat=(abc.fmtlib1/encoding=utf8 abc.fmtlib2);
```

SAS applies the UTF8 encoding to only the Abc.Fmtlib1 catalog. The Abc.Fmtlib2 catalog uses the session encoding.

To specify an encoding for a list of format catalogs, specify the ENCODING= option at the end of a list of catalogs.

```
proc fmtc2itm cat=(abc.fmtlib1 abc.fmtlib2) encoding=utf8;
```

SAS applies the UTF8 encoding to all of the catalogs in the list.

If you do not specify the ENCODING= option for a catalog, then SAS assigns the session encoding option to the catalog.

PROC FMTC2ITM validates all of the character data (all labels and character range values) in a catalog to ensure that they are valid for the specified encoding. SAS issues an error if any of the characters do not transcode successfully.

Optional Arguments

PRINT
displays information about each catalog member that is written.

LOCALE
adds locale-sensitive prefixes to the names of members of an item store.

If you specify the LOCALE option, then the processing of the parenthetical list of member names is different from the usual processing of member names in a list. If any catalog has a locale suffix (of the form _xx or _xx_yy), then the members from the catalog are written to the item store with that suffix as a prefix. For example, if catalog X_EN_US has members ABC, DEF, and GHI, and catalog X_FR_FR also has members ABC, DEF and JKL as specified in this code example

```
proc fmtc2itm catalog=(x_en_us x_fr_fr) itemstore locale; run;
```

The resulting item store contains the members EN_US-ABC, EN_US-DEF, EN_US-GHI, FR_FR-ABC, FR_FR-DEF, and FR_FR-JKL. A subsequent usage of

the item store in CAS allows for ABC or DEF to be loaded properly based on an EN_US or FR_FR locale. If the LOCALE option is not provided, the item store contains the members ABC, DEF, and GHI from X_EN_US, and member JKL from X_FR_FR.

Note: When you specify PROC FMTC2ITM, your SAS session must use the same encoding that was used when the format catalogs were created. For example, if the EN_US locale was used when the catalogs were created, then the session where you specify PROC FMTC2ITM must also use the EN_US locale.

SELECT Statement

Lists the formats to place in the item store.

Tip: If you do not specify the members of the format catalog with a SELECT statement, then all formats in the catalog are written to the item store.

Syntax

SELECT <*member-list*>;

Optional Argument

member-list
Contains the names of the formats to place in the item store.

Details

The SELECT statement enables you to select only the formats from a format library that you want to add to an item store. For example, if you had a format library that contained the formats CHOICE, SINGLE2, TESTFMTA, WHEN, and WHERE, you could specify the WHEN and WHERE formats with the SELECT statement. The WHEN and WHERE formats are then added to the item store, but the CHOICE, SINGLE2, and TESTFMTA, formats are not added.

Example: Migrate Formats to a CAS Session

Features:

PROC FMTC2ITM statement options
- CATALOG
- ITEMSTORE

CAS statement options
- LOADFORMATS
- LISTFORMAT
- SAVEFMTLIB

Details

This example uses the FMTC2ITM procedure to migrate user-defined formats that are stored in one or more SAS format catalogs to a format library in a CAS session.

Program

```
libname orion "path-to-library";

proc format;
   value $codes
      "A" = "Alpha"
      "B" = "Beta"
      "C" = "Charlie"
      "D" = "Delta";
   value response
      1 = "Yes"
      2 = "No"
      3 = "Undecided"
      4 = "No response";
   value MPGrating
      34  - HIGH = "Excellent"
      24  -< 34  = "Good"
      19  -< 24  = "Fair"
      LOW -< 19  = "Poor";
run;

proc format library=orion.mailfmts;
   value $officeCodes
      "CHI" = "Chicago"
```

```
      "NYC" = "New York"
      "ATL" = "Atlanta"
      "CUP" = "Cupertino";
   value $regionCodes
      "E" = "East"
      "W" = "West"
      "N" = "North"
      "S" = "South";
run;

cas casauto;

proc fmtc2itm
   catalog=(work.formats orion.mailfmts)
   itemstore="path-to-item-store-file";
run;

cas casauto addfmtlib fmtlibname="myfmtlib"
   path=path-to-item-store-file
   replacefmtlib;

cas casauto listformat fmtlibname="myfmtlib"
   members;

cas casauto savefmtlib fmtlibname=myfmtlib
   caslib=casuser table=myfmtlib replace;
```

Program Description

Create the Orion library and add the formats.

```
libname orion "path-to-library";

proc format;
   value $codes
      "A" = "Alpha"
      "B" = "Beta"
      "C" = "Charlie"
      "D" = "Delta";
   value response
      1 = "Yes"
      2 = "No"
      3 = "Undecided"
      4 = "No response";
   value MPGrating
      34  - HIGH = "Excellent"
      24  -< 34  = "Good"
      19  -< 24  = "Fair"
      LOW -< 19  = "Poor";
run;

proc format library=orion.mailfmts;
   value $officeCodes
      "CHI" = "Chicago"
      "NYC" = "New York"
      "ATL" = "Atlanta"
      "CUP" = "Cupertino";
```

```
   value $regionCodes
      "E" = "East"
      "W" = "West"
      "N" = "North"
      "S" = "South";
run;
```

Start a CAS session.

```
cas casauto;
```

Create the item store with the formats. The FMTC2ITM procedure writes the formats in format catalogs Work.Formats and Orion.Mailfmts to an item store file. The CATALOG option specifies to search the format catalogs Work.Formats and Orion.Mailfmts. The ITEMSTORE option specifies the path where the item store is to be written. To select a subset of the formats in the specified format catalogs, specify a SELECT statement in the FMTC2ITM procedure step.

```
proc fmtc2itm
   catalog=(work.formats orion.mailfmts)
   itemstore="path-to-item-store-file";
run;
```

Load the Formats The CAS statement ADDFMTLIB option uses the item store file that you created with the FMTC2ITM procedure to add the format library Myfmtlib.

```
cas casauto addfmtlib fmtlibname="myfmtlib"
   path=path-to-item-store-file
   replacefmtlib;
```

List the formats. The CAS statement LISTFORMAT option lists the formats in format library Myfmtlib to the SAS log for verification.

```
cas casauto listformat fmtlibname="myfmtlib"
   members;
```

Save the format library. The CAS statement SAVEFMTLIB option saves the format library to a SASHDAT file. This step is optional.

For format libraries that you use repeatedly, saving to a caslib is a best practice. Use the CAS statement ADDFMTLIB option with parameters CASLIB= and TABLE= when adding a format library from a caslib.

```
cas casauto savefmtlib fmtlibname=myfmtlib
   caslib=casuser table=myfmtlib replace;
```

29

FONTREG Procedure

Overview: FONTREG Procedure

What Does the FONTREG Procedure Do?

The FONTREG procedure enables you to update the SAS registry to include system fonts, which can then be used in SAS output. PROC FONTREG uses FreeType font-

rendering to recognize and incorporate various types of font definitions. Fonts of any type that can be incorporated and used by SAS are known collectively in this documentation as fonts in the FreeType library.

Note: Including a system font in the SAS registry means that SAS knows where to find the font file. The font file is not actually used until the font is called for in a SAS program. Therefore, do not move or delete font files after you have included the fonts in the SAS registry.

For more information, see the following sources:

- "Specifying Fonts in SAS/GRAPH Programs" in *SAS/GRAPH: Reference*
- "GDEVICE Procedure" in *SAS/GRAPH: Reference*
- "FONTSLOC= System Option" in *SAS System Options: Reference* and "SYSPRINTFONT= System Option" in *SAS System Options: Reference*
- gitlab.freedesktop.org/freetype for information about the FreeType project

Concepts: FONTREG Procedure

Supported Font Types and Font Naming Conventions

When a font is added to the SAS registry, the font name is prefixed with a three-character tag, enclosed in angle brackets (< >). This prefix indicates the font type. For example, if you add the TrueType font **Arial** to the SAS registry, then the name in the registry is **<ttf> Arial**. This naming convention enables you to add and distinguish between fonts that have the same name but are of different types.

When you specify a font in a SAS program, use the three-character tag to distinguish between fonts that have the same name:

```
proc report data=sashelp.class nowd
            style(header)=[font_face='<ttf> Palatino Linotype'];
run;
```

Examples of when you can specify a font in a SAS program are in the TEMPLATE procedure or in the STYLE= option in the PROC REPORT.

If you do not include a tag in your font specification, SAS searches the registry for fonts with that name. If more than one font with that name is found, SAS uses the font that has the highest rank in the following table.

Table 29.1 *Supported Font Types*

Rank	Type	Tag	File Extension
1	TrueType	`<ttf>`	`.ttf`
2	Type1	`<at1>`	`.pfa` `.pfb`
3	OpenType	`<cff>`	`.otf`

Note: OpenType font is an extension of TrueType font and is supported by SAS. OpenType contains the family values for serif, sans-serif, monospace, and symbol fonts. OpenType registers .otf font files.

Note: PDF and PostScript do not support double-byte Type1 fonts.

SAS does not support any type of nonscalable fonts that require FreeType font-rendering. Even if they are recognized as valid fonts, they will not be added to the SAS registry.

Font files that are not produced by major vendors can be unreliable, and in some cases SAS might not be able to use them.

The following SAS output methods and device drivers can use FreeType font-rendering:

- SAS/GRAPH GIF, GIFANIM
- SAS/GRAPH JPEG
- SAS/GRAPH PCL
- SAS/GRAPH PNG
- SAS/GRAPH SASEMF
- SAS/GRAPH SASWMF
- SAS/GRAPH TIFFP, TIFFB
- Universal EMF
- Universal PNG
- Universal Printing GIF
- Universal Printing TIFF
- Universal Printing PCL
- Universal Printing PDF
- Universal PS
- Universal SVG

Registering Fonts with PROC FONTREG

PROC FONTREG is used to register fonts in the SAS Registry. For example, if you have a Type1 or OpenType font in your Windows font directory, you can register the font by submitting the following code:

```
proc fontreg mode=add;
fontpath '!SYSTEMROOT\fonts';
run;
```

This code will register all of the other font files in the Windows font directory.

Removing Fonts from the SAS Registry

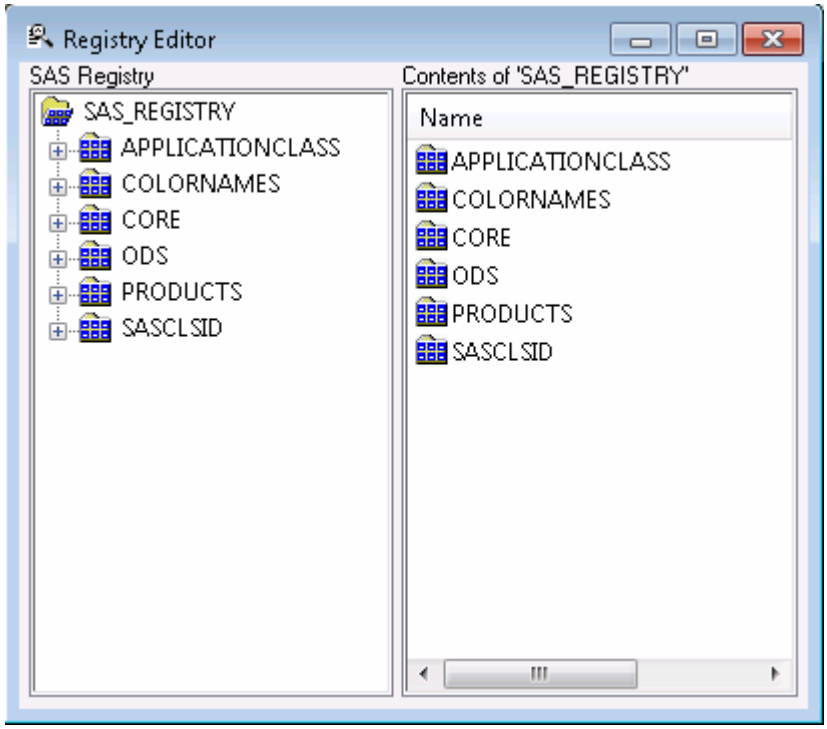
You can remove a font from the SAS registry in the following ways:

- by using the SAS Registry Editor
- by using PROC REGISTRY
- by using the REMOVE statement in PROC FONTREG

To remove a font by using the SAS Registry Editor, select **Solutions** ⇨ **Accessories** ⇨ **Registry Editor**. Alternatively, you can enter `regedit` in the command window or `Command ===>` prompt.

The following display shows the SAS Registry Editor window.

Figure 29.1 *SAS Registry Editor Window*



In the left pane of the Registry Editor window, navigate to the [CORE\PRINTING \FREETYPE\FONTS] key. Select the font that you want to delete, and use one of these methods to delete it:

- Right-click the font name and select **Delete** from the menu.
- Select the **Delete** button  .
- Select **Edit** ⇨ **Delete** ⇨ **Key**.

To delete a font by using PROC REGISTRY, submit a program similar to the following example. This example removes the **<ttf> Arial** font.

```
   /* Write the key name for the font to an external file */
proc registry export='external-filename'
              startat='core\printing\freetype\fonts\<ttf> Arial';
run;

   /* Remove the "<ttf> Arial" font from the SAS registry */
proc registry
uninstall='external-filename' fullstatus;
run;
```

To delete a font by using the REMOVE statement in PROC FONTREG, see "REMOVE Statement" on page 1067.

For more information about PROC REGISTRY, see Chapter 57, "REGISTRY Procedure," on page 2027.

Using a Fileref with PROC FONTREG

You can use a fileref with the FONTPATH, TRUETYPE, TYPE1, and OPENTYPE statements in PROC FONTREG, if you first define a filename. The following examples show how a fileref is used:

```
filename fonts1 'c:\windows\fonts';
proc fontreg mode=all;
   fontpath fonts1;
run;

proc fontreg mode=all;
   truetype fonts1;
run;
```

The ability to use a fileref enables you to directly use the FILENAME statement and its features. For example, you can register available fonts by using a URL. With fileref support, you would use a FILENAME statement and a PROC FONTREG step.

Font Aliases and Locales

The FONTFILE, FONTPATH, TRUETYPE, and OPENTYPE statements support aliases and locales. If the font that is being processed contains a localized name in the same locale as the current SAS session, then an alias of that localized name will be added to the SAS registry to reference the font family.

Syntax: FONTREG Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Interaction: If no statements are specified, then PROC FONTREG searches for TrueType font files in the directory that is indicated in the FONTSLOC= SAS system option.

Note: For z/OS sites that do not use the hierarchical file system (HFS), only the FONTFILE statement is supported. For more information, see "FONTREG Procedure Statement: z/OS" in *SAS Companion for z/OS*.

Tip: If you specify more than one statement, then the statements are executed in the order in which they appear, except for REMOVE statements, which are always executed first. You can use the same statement more than once in a single PROC FONTREG step.

See: "FONTREG Procedure Statement: z/OS" in *SAS Companion for z/OS*

PROC FONTREG <*options*>;

FONTFILE '*file*' <...'*file*'> | '*file-1*, *pfm-file-1*, *afm-file-1*' <...'*file-n*'> ||;

FONTPATH <*fileref*> '*directory*' <...'*directory*'>;

OPENTYPE <*fileref*> '*directory*' <...'*directory*'>

REMOVE '*family-name*' | '*alias*' | *family-type* | _ALL_;

TRUETYPE <*fileref*> '*directory*' <...'*directory*'>;

TYPE1 <*fileref*> '*directory*' <...'*directory*'>;

Statement	Task
PROC FONTREG	Specify how to handle new and existing fonts
FONTFILE	Identify which font files to process
FONTPATH	Search directories to identify valid font files to process
REMOVE	Remove a font family, all fonts of a particular type, or all fonts from the Core\Printing\Freetype\Fonts location of the SAS registry
TRUETYPE	Search directories to identify TrueType font files
TYPE1	Search directories to identify valid Type 1 font files
OPENTYPE	Search directories to identify valid OpenType font files

PROC FONTREG Statement

Enables you to update the SAS registry to include system fonts, which can then be used in SAS output.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Syntax

PROC FONTREG <*options*>;

Summary of Optional Arguments

MODE=ADD | REPLACE | ALL
: specifies how to handle new and existing fonts.

MSGLEVEL=VERBOSE | NORMAL | TERSE | NONE
: specifies the level of detail to include in the SAS log.

NOUPDATE
: specifies that the procedure should run without updating the SAS registry.

USESASHELP
: specifies that the SAS registry in the Sashelp library be updated.

Optional Arguments

MODE=ADD | REPLACE | ALL
specifies how to handle new and existing fonts in the SAS registry:

ADD
specifies to add fonts that do not already exist in the SAS registry. Do not modify existing fonts.

REPLACE
specifies to replace fonts that already exist in the SAS registry. Do not add new fonts.

ALL
specifies to add new fonts that do not already exist in the SAS registry and replace fonts that already exist in the SAS registry.

Default ADD

Example "Example 3: Replacing Existing TrueType Font Files from a Directory" on page 1073

MSGLEVEL=VERBOSE | NORMAL | TERSE | NONE
specifies the level of detail to include in the SAS log.

Here are the levels:

VERBOSE
SAS log messages include which fonts were added, which fonts were not added, and which fonts were not understood. The log also contains a summary that indicates the number of fonts that were added, not added, and not understood.

NORMAL
SAS log messages include which fonts were added, and a summary that indicates the number of fonts that were added, not added, and not understood.

TERSE
SAS log messages include only the summary that indicates the number of fonts that were added, not added, and not understood.

NONE
No messages are written to the SAS log, except for errors (if encountered).

Default TERSE

Example "Example 2: Adding All Font Files from Multiple Directories" on page 1071

NOUPDATE
specifies that the procedure should run without actually updating the SAS registry. This option enables you to test the procedure on the specified fonts before modifying the SAS registry.

USESASHELP
specifies that the SAS registry in the Sashelp library should be updated. You must have Write access to the Sashelp library in order to use this option. If the USESASHELP option is not specified, then the SAS registry in the Sasuser library is updated.

FONTFILE Statement

Specifies one or more font files to be processed.

See: "Example 1: Adding a Single Font File" on page 1070

Syntax

FONTFILE '*file*' <...'*file*'> | '*file-1*, *pfm-file-1*, *afm-file-1*' <...'*file-n*'>;

Required Arguments

file
is the complete pathname to a font file. If the file is recognized as a valid font file, then the file is processed. Each pathname must be enclosed in quotation marks. If you specify more than one pathname, then you must separate the pathnames with a space.

pfm-file
specifies a file specific to Windows that contains font metrics as well as the value of the Windows font name.

afm-file
specifies a file that contains font metrics.

Details

Processing a Type1 Font

When a valid Type1 font is processed by the TYPE1 statement or the FONTPATH statement, SAS attempts to find a corresponding PFM or AFM font metric file in the same directory that contains the font file. The font filename prefix is used with the .PFM and .AFM extensions to generate metric filenames. If these files are opened successfully and are determined to be valid metric files, then they will be associated with the font in the font family when they are added to the SAS registry.

If you specify a Type1 font in the FONTFILE statement, and you do not specify a PFM or AFM file, then SAS does not search for the PFM or AFM files.

Specifying a PFM or AFM File

If the font file contains a Type1 font, then you can also specify its corresponding PFM or AFM file as well. You must specify the full host name (directory and filename) for each file, and all files must be grouped together and enclosed in quotation marks, as in this example:

```
fontfile 'c:\winnt\fonts\alpinerg.pfb,
          c:\winnt\fonts\alpinerg.pfm,
          c:\winnt\fonts\alpinerg.afm';
```

If you specify an AFM file but do not specify a PFM file, then you must use a comma as a placeholder for the missing PFM file, as in this example:

```
fontfile 'c:\winnt\fonts\alpinerg.pfb, ,
c:\winnt\fonts\alpinerg.afm';
```

If you specify a PFM file but do not specify an AFM file, then you do not need a comma as a placeholder for the missing AFM file, as in this example:

```
fontfile 'c:\winnt\fonts\alpinerg.pfb,
c:\winnt\fonts\alpinerg.pfm';
```

When you specify a PFM or AFM file, SAS attempts to open the file and determine whether the file is of the specified type. If it is not, then SAS writes a message to the log and the file is not used.

The PFM file is a file that is specific to Windows, and contains font metrics as well as a value for the Windows Font Name field. If you specify a valid PFM file, then SAS opens the file, retrieves the value in Windows Font Name, and saves it with the font in the SAS registry. SAS uses this field when it creates a file (such as an EMF formatted file) to export into a Windows application.

Not Specifying a PFM or AFM File

You do not need to specify a PFM or AFM file along with a Type1 font file in a FONTFILE statement. In this case, no metric file information is added to the font in the font family in the SAS registry. If an existing font family that contains multiple styles and weights already exists in the SAS registry, and the FONTFILE statement is used to replace one of the fonts in that family, then all of the information for that font will be updated. The replacement also updates the Host Filename, PFM Name, AFM Name, and Windows Font Name.

Note: If you replace a font in a family and the font contains values for the PFM Name or AFM Name, specifying a missing or invalid value for the metric in the FONTFILE statement causes the corresponding metric value to be deleted from the font in the registry.

Note: You cannot use a PFM or AFM file specification if you specify a TrueType font.

FONTPATH Statement

Specifies one or more directories to be searched for valid font files to process.

See: "Example 2: Adding All Font Files from Multiple Directories" on page 1071

Syntax

FONTPATH <*fileref*> '*directory*' <...'*directory*'>;

Required Argument

directory
specifies a directory to search. All files that are recognized as valid font files are processed. Each directory must be enclosed in quotation marks. If you specify more than one directory, then you must separate the directories with a space.

Operating Environment Information: In the Windows operating environment only, you can locate the fonts folder if you do not know where the folder resides.

In addition, you can register system fonts without having to know where the fonts are located. To find this information, submit the following program:

```
proc fontreg;
    fontpath "%sysget(systemroot)\fonts";
run;
```

The %SYSGET macro retrieves the value of the Windowing environment variable SYSTEMROOT, and resolves to the location of your system directory. The fonts subdirectory is located one level below the system directory.

Optional Argument

fileref
specifies a fileref to use with the FONTPATH statement.

REMOVE Statement

Removes a font family, all fonts of a particular type (such as TrueType or Type1), or all fonts from the Core\Printing\Freetype\Fonts location of the SAS registry.

Syntax

REMOVE '*family-name*' | '*alias*' | *family-type* | _ALL_;

Required Arguments

family-name
specifies the family name of the font that you want to remove from the Core\Printing\Freetype\Fonts key in the SAS registry. Enclose *family-name* in quotation marks if the value contains one or more spaces.

alias
specifies an alternative name, usually in a shortened form, for *family-name*. Enclose the alias name in quotation marks if the value contains one or more spaces.

Note The valid values that can be specified as an alias are listed in the Core\Printing\Alias\Fonts\Freetype key in the SAS registry.

family-type
specifies the name of a font type (such as TrueType or Type1) that SAS supports and that you want removed from the SAS registry.

Note: The font type is not removed from the operating system location in which they reside. The registration of the font type from the SAS registry is removed so that SAS does not recognize the fonts.

ALL
specifies that all font families in the Core\Printing\Freetype\Fonts key in the SAS registry will be deleted.

Details

Removing Fonts from the Registry

The REMOVE statement removes a font family, all fonts of a particular type, or all fonts from the **Core\Printing\Freetype\Fonts** location in the SAS registry. If you specify the USESASHELP procedure option, then fonts are removed from the Sashelp portion of the registry. If you do not specify USESASHELP, then fonts are removed from the Sasuser portion of the registry. Removal from the Sasuser portion of the registry is the default.

Note that when you specify the *family-name* argument in the REMOVE statement, SAS removes font families rather than individual fonts within the family. For example, you might register several fonts within the **Arial** family. When you use the `REMOVE Arial;` statement, all fonts in the **Arial** family are removed from the registry. Similarly, when you specify the *family-type* argument and use the `REMOVE Type1;` statement, all Type1 font families are removed from the registry.

The Order in Which Fonts Are Added or Removed

Fonts are removed from the SAS registry before any fonts are added or replaced in the registry using other procedure statements. The REMOVE statement removes a font family from the registry as soon as the statement is processed. Other font statements, such as FONTFILE, FONTPATH, TRUETYPE, and TYPE1, are processed in the order in which they are received. The font information is stored until all of the statements are processed. SAS then updates the registry.

Searching for a Font That Is Specified in the REMOVE Statement

If the name that you specify in a REMOVE statement does not exist, then SAS adds a font tag prefix (for example, <ttf>) to the specified name to determine whether it exists in the SAS registry. For example, if you specify **Arial**, SAS uses the <ttf> prefix tag and first searches for a TrueType font type so that it can be removed from the registry. If the search is not successful, then SAS uses the <at1> prefix tag and searches for a Type1 font type so that it can be removed from the registry.

When SAS Is Unable to Remove a Font Family

If SAS is unable to remove a font family after processing the information in the _ALL_, *family-type*, or *family-name* arguments, then SAS looks in the Core\Printing\Alias\Fonts\Freetype key in the SAS registry to determine whether the specified value is an alias. If the specified value exists as an alias in this key, then SAS deletes the font family that corresponds to the alias and deletes the alias as well. For example, if an alias of Test refers to the **Arial** font family, and you specify the `REMOVE test;` statement with PROC FONTREG, then SAS determines

that Test is an alias for **Arial**. SAS removes the **Arial** font family from the **Core\Printing\Freetype\Fonts** key and the Test alias from the **Core\Printing\Alias\Fonts\Freetype** key in the SAS registry.

If SAS is unable to remove a font family at this point, then SAS writes a message to the log indicating that the specified value in the REMOVE statement is invalid.

TRUETYPE Statement

Specifies one or more directories to be searched for TrueType font files.

See: "Example 3: Replacing Existing TrueType Font Files from a Directory" on page 1073

Syntax

TRUETYPE <*fileref*> '*directory*' <...'*directory*'>;

Required Argument

directory
specifies a directory to search. Only files that are recognized as valid TrueType font files are processed. Each directory must be enclosed in quotation marks. If you specify more than one directory, then you must separate the directories with a space.

Optional Argument

fileref
specifies a fileref to use with the TRUETYPE statement.

TYPE1 Statement

Specifies one or more directories to be searched for valid Type1 font files.

Syntax

TYPE1 <*fileref*> '*directory*' <...'*directory*'>;

Required Argument

directory
specifies a directory to search. Only files that are recognized as valid Type1 font files are processed. Each directory must be enclosed in quotation marks. If you

specify more than one directory, then you must separate the directories with a space.

Optional Argument

fileref
specifies a fileref to use with the TYPE1 statement.

OPENTYPE Statement

Specifies one or more directories to be searched for valid OpenType font files.

Syntax

OPENTYPE <*fileref*> '*directory*' <...'*directory*'>;

Required Argument

directory
specifies a directory to search. Only files that are recognized as valid OpenType font files are processed. Each directory must be enclosed in quotation marks. If you specify more than one directory, then you must separate the directories with a space.

Optional Argument

fileref
specifies a fileref to use with the OPENTYPE statement.

Examples: FONTREG Procedure

Example 1: Adding a Single Font File

Features: FONTFILE statement

Details

This example shows how to add a single font file to the SAS registry. The FONTFILE statement specifies the complete path to a single font file.

Program

```
proc fontreg;
   fontfile '<ttf> Arial';
run;
```

Log

Example Code 29.1 *Adding a Single Font File to the SAS Registry*

```
SUMMARY:
  Files processed: 1
  Unusable files: 0
  Files identified as fonts: 1
  Fonts that were processed: 1
  Fonts replaced in the SAS registry: 0
  Fonts added to the SAS registry: 1
  Fonts that could not be used: 0
  Font Families removed from SAS registry: 0
```

Example 2: Adding All Font Files from Multiple Directories

Features: MSGLEVEL= option
FONTPATH statement

Details

This example shows how to add all valid font files from two different directories and how to write detailed information to the SAS log.

Program

```
proc fontreg msglevel=verbose;

fontpath 'your-font-directory-1' 'your-font-directory-2';
run;
```

Program Description

Write complete details to the SAS log. The MSGLEVEL=VERBOSE option writes complete details about what fonts were added, what fonts were not added, and what font files were not understood.

```
proc fontreg msglevel=verbose;
```

Specify the directories to search for valid fonts. You can specify more than one directory in the FONTPATH statement. Each directory must be enclosed in quotation marks. If you specify more than one directory, then you must separate the directories with a space.

```
fontpath 'your-font-directory-1' 'your-font-directory-2';
run;
```

Log

Example Code 29.2 *Messages from Adding All Font Files from Multiple Directories*

```
1    proc fontreg msglevel=verbose;
2    fontpath 'your-font-directory-1'
3             'your-font-directory-2';
4    run;

ERROR: FreeType base module FT_New_Face -- unknown file format.
ERROR: A problem was encountered with file
"your-font-directory-2\MODERN.FON".

. . .  more log entries . . .

WARNING: The "Sasfont" font in file
         "your-font-directory-2\SAS1252.FON" is non-scalable.     Only scalable
fonts are supported.

. . .  more log entries . . .

NOTE: The font "Albertus Medium" (Style: Regular, Weight: Normal) has been
      added to the SAS Registry at
      [CORE\PRINTING\FREETYPE\FONTS\<ttf>Albertus Medium]. Because it is a
      TRUETYPE font, it can be referenced as "Albertus Medium" or
      "<ttf>Albertus Medium" in SAS. The font resides in file
      "your-font-directory-1\albr55w.ttf".

. . .  more log entries . . .

WARNING: The font "Georgia" (Style: Regular, Weight: Normal) will not be added
because it already exists in the "<ttf>Georgia" font family of the SAS Registry.

. . .  more log entries . . .

SUMMARY:
  Files processed: 138
  Unusable files: 3
  Files identified as fonts: 135
  Fonts that were processed: 135
  Fonts replaced in the SAS registry: 0
  Fonts added to the SAS registry: 91
  Fonts that could not be used: 44
  Font Families removed from SAS registry: 0

NOTE: PROCEDURE FONTREG used (Total process time):
      real time           27.81 seconds
      cpu time            1.18 seconds
```

Example 3: Replacing Existing TrueType Font Files from a Directory

Features: MODE= option
TRUETYPE statement

Details

This example reads all the TrueType fonts in the specified directory and replaces the ones that already exist in the SAS registry.

Program

```
proc fontreg mode=replace;
   truetype 'your-font-directory';
run;
```

Program Description

Replace existing fonts only. The MODE=REPLACE option limits the action of the procedure to replacing fonts that are already defined in the SAS registry. New fonts will not be added.

```
proc fontreg mode=replace;
```

Specify a directory that contains TrueType font files. Files in the directory that are not recognized as being TrueType font files are ignored.

```
   truetype 'your-font-directory';
run;
```

Log

Example Code 29.3 *Replacing Existing TrueType Font Files from a Directory*

```
SUMMARY:
  Files processed: 49
  Unusable files: 3
  Files identified as fonts: 46
  Fonts that were processed: 40
  Fonts replaced in the SAS registry: 40
  Fonts added to the SAS registry: 0
  Fonts that could not be used: 0
  Font Families removed from SAS registry: 0
```

FORMAT Procedure

Overview: FORMAT Procedure

What Does the FORMAT Procedure Do?

The FORMAT procedure enables you to define your own informats and formats for variables. In addition, you can perform these actions:

- print the parts of a catalog that contain informats or formats
- store descriptions of informats or formats in a SAS data set
- use a SAS data set to create informats or formats.

Format Encodings in SAS Viya

SAS Viya supports only UTF-8 encoding.

When you store formats in a library, SAS uses the session encoding in which the formats were created. If the original encoding is not UTF-8, then truncation of characters might occur if you convert the format library to an encoding that requires more bytes to represent the characters.

Note: Moving format libraries between previous versions of SAS and CAS might have some risk. SAS recommends that you use CNTLOUT data sets to reduce this risk.

For more information about using format libraries in SAS Viya, see *Migrating Data to UTF-8 for SAS Viya* and *SAS Viya FAQ for Processing UTF-8 Data*.

What Are Formats and Informats?

Informats determine how raw data values are read and stored. Formats determine how variable values are printed. For simplicity, this section uses the terminology the informat converts and the format prints.

Informats and formats tell SAS the data's type (character or numeric) and form (such as how many bytes it occupies; decimal placement for numbers; how to handle leading, trailing, or embedded blanks and zeros; and so on). SAS provides informats and formats for reading and writing variables. For a thorough description of informats and formats that SAS provides, see *SAS Formats and Informats: Reference*.

With informats, you can do the following:

- Convert a number to a character string (for example, convert 1 to **YES**).
- Convert a character string to a different character string (for example, convert **'YES'** to **'OUI'**).
- Convert a character string to a number (for example, convert **YES** to 1).
- Convert a number to another number (for example, convert 0–9 to 1, 10–100 to 2, and so on).

Note: User-defined informats read-only character data. They can convert character values into real numeric values, but they cannot convert real numbers into characters.

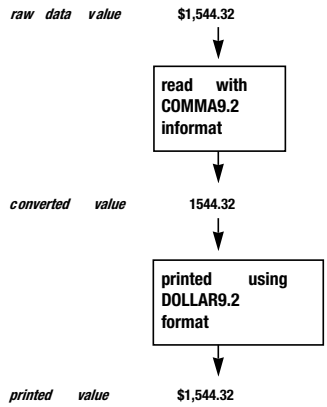
With formats, you can do the following:

- Print numeric values as character values (for example, print 1 as **MALE** and 2 as **FEMALE**).
- Print one character string as a different character string (for example, print **YES** as **OUI**).
- Print numeric values using a template (for example, print 9458763450 as **945-876-3450**).

How Are Formats and Informats Associated with a Variable?

The following figure summarizes what occurs when you associate an informat and format with a variable. The COMMA*w.d* informat and the DOLLAR*w.d* format are provided by SAS.

Figure 30.1 Associating an Informat and a Format with a Variable



In the figure, SAS reads the raw data value that contains the dollar sign and comma. The COMMA9.2 informat ignores the dollar sign and comma and converts the value to 1544.32. The DOLLAR9.2 format prints the value, adding the dollar sign and comma. For more information about associating informats and formats with variables, see "Associating Informats and Formats with Variables " on page 1078.

Concepts: FORMAT Procedure

Associating Informats and Formats with Variables

Methods of Associating Informats and Formats with Variables

The following table summarizes the different methods for associating informats and formats with variables.

Table 30.1 *Associating Informats and Formats with Variables*

Step	Informats	Formats
In a DATA step	Use the ATTRIB or INFORMAT statement to permanently associate an informat with a variable. Use the INPUT function or INPUT statement to associate the informat with the variable only for the duration of the DATA step.	Use the ATTRIB or FORMAT statement to permanently associate a format with a variable. Use the PUT function or PUT statement to associate the format with the variable only for the duration of the DATA step.
In a PROC step	The ATTRIB and INFORMAT statements are valid in Base SAS procedures. However, in Base SAS software, typically you do not assign informats in PROC steps because the data has already been read into SAS variables.	Use the ATTRIB statement or the FORMAT statement to associate formats with variables. If you use either statement in a procedure that produces an output data set, then the format is permanently associated with the variable in the output data set. If you use either statement in a procedure that does not produce an output data set or modify an existing data set, the statement associates the format with the variable only for the duration of the PROC step.

Differences between the FORMAT Statement and PROC FORMAT

Do not confuse the FORMAT statement with the FORMAT procedure. The FORMAT and INFORMAT statements associate an existing format or informat (either standard SAS or user-defined) with one or more variables. PROC FORMAT creates user-defined formats or informats.

Assigning Formats and Informats to a Variable

Assigning your own format or informat to a variable is a two-step process:

1. creating the format or informat with the FORMAT procedure
2. assigning the format or informat with the ATTRIB, FORMAT,or INFORMAT statements, or the INPUT or PUT functions

For complete documentation on the ATTRIB, INFORMAT, and FORMAT statements, see *SAS DATA Step Statements: Reference*. For complete documentation on the

INPUT and PUT functions, see *SAS Functions and CALL Routines: Reference*. For more information and example of using formats in Base SAS procedures, see "Formatted Values" on page 63 .

Storing Informats and Formats

Format Catalogs

PROC FORMAT stores user-defined informats and formats as entries in SAS catalogs.[1] You use the LIBRARY= option in the PROC FORMAT statement to specify the catalog. If you omit the LIBRARY= option, then formats and informats are stored in the Work.Formats catalog. If you specify LIBRARY=*libref* but do not specify a catalog name, then formats and informats are stored in the *libref*.FORMATS catalog. Note that this use of a one-level name differs from the use of a one-level name elsewhere in SAS. With the LIBRARY= option, a one-level name indicates a library; elsewhere in SAS, a one-level name indicates a file in the WORK library.

The name of the catalog entry is the name of the format or informat. The entry types are as follows:

- FORMAT for numeric formats
- FORMATC for character formats
- INFMT for numeric informats
- INFMTC for character informats

Temporary Informats and Formats

Informats and formats are temporary when they are stored in a catalog in the WORK library. If you omit the LIBRARY= option, then PROC FORMAT stores the informats and formats in the temporary catalog Work.Formats. You can retrieve temporary informats and formats only in the same SAS session or job in which they are created. To retrieve a temporary format or informat, simply include the name of the format or informat in the appropriate SAS statement. SAS automatically looks for the format or informat in the Work.Formats catalog.

1. Catalogs are a type of SAS file and reside in a SAS library. If you are unfamiliar with the types of SAS files or the SAS library structure, then see the section on SAS files in *SAS Language Reference: Concepts*.

Permanent Informats and Formats

If you want to use a format or informat that is created in one SAS job or session in a subsequent job or session, then you must permanently store the format or informat in a SAS catalog.

You permanently store informats and formats by using the LIBRARY= option in the PROC FORMAT statement. See the discussion of the LIBRARY= option in the PROC FORMAT Statement on page 1085.

Accessing Permanent Informats and Formats

After you have permanently stored an informat or format, you can use it in later SAS sessions or jobs. If you associate permanent informats or formats with variables in a later SAS session or job, then SAS must be able to access the informats and formats. Thus, you must use a LIBNAME statement to assign a libref to the library that stores the catalog that stores the informats or formats.

SAS uses one of two methods when searching for user-defined formats and informats:

- By default, SAS always searches a library that is referenced by the Library libref for a FORMATS catalog. If you have only one format catalog, then do the following:
  1. Assign the Library libref to a SAS library in the SAS session in which you are running the PROC FORMAT step.
  2. Specify the option `library=library` in the PROC FORMAT statement. PROC FORMAT stores the informats and formats that are defined in that step in the Library.Formats catalog.
  3. In the SAS program that uses your user-defined formats and informats, include a LIBNAME statement to assign the Library libref to the library that contains the permanent format catalog.
- If you have more than one format catalog, or if the format catalog is named something other than Formats, then do the following:
  1. Assign a libref to a SAS library in the SAS session in which you are running the PROC FORMAT step.
  2. Specify the option `library=`*`libref`* or `library=`*`libref.catalog`* in the PROC FORMAT step, where *libref* is the libref that you assigned in step 1.
  3. In the SAS program that uses your user-defined formats and informats, use the FMTSEARCH= option in an OPTIONS statement, and include *libref* or *libref.catalog* in the list of format catalogs.

The syntax for specifying a list of format catalogs to search is

OPTIONS FMTSEARCH=(*catalog-specification-1*<*catalog-specification-2* ... >);

Each *catalog-specification* can be *libref* or *libref.catalog*. If only *libref* is specified, then SAS assumes that the catalog name is Formats.

When searching for a format or informat, SAS always searches in Work.Formats first, and then Library.Formats, unless one of them appears in the FMTSEARCH= list. SAS searches the catalogs in the FMTSEARCH= list in the order in which they are listed until the format or informat is found.

For more information, see "FMTSEARCH= System Option" in *SAS System Options: Reference*. For an example that uses the LIBRARY= and FMTSEARCH= options together, see "Example 17: Writing Ranges for Character Strings" on page 1187.

Missing Informats and Formats

If you reference an informat or format that SAS cannot find, then you receive an error message and processing stops unless the SAS system option NOFMTERR is in effect. When NOFMTERR is in effect, SAS uses the *w.* or $*w.* default format to print values for variables with formats that it cannot find. For example, to use NOFMTERR, use this OPTIONS statement:

```
options nofmterr;
```

For more information, see "FMTERR System Option" in *SAS System Options: Reference*.

If SAS encounters a missing variable to format using a user-defined format and the MISSING= system option defines a character to be printed for missing values, the missing value is determined as follows:

- If the user-defined format or informat has a value-range-set for missing values, the missing value is defined by the user-defined format.
- If the user-defined format does not have a value-range-set defined for missing values, the missing value is defined by the MISSING= system option. The default value for the MISSING= system option is . (period).

Printing Informats and Formats

The output that is provided when you use the FMTLIB option in the PROC FORMAT statement is intended to present a brief view of the informat and format values.

Instead of using the FMTLIB option, you can use the CNTLOUT= option to create an output data set that stores information about informats and formats. You can then use PROC PRINT or PROC REPORT to print the data set. In this case, labels are not truncated.

Note: You can use data set options to keep or drop references to additional variables that were added by using the CNTLOUT= option.

Using Formats in a CAS Session

PROC FORMAT supports creating format libraries in catalogs in a SAS client session and loading format libraries to a SAS Cloud Analytic Services (CAS) session. When you use the SESSREF system option to specify a CAS session, and you also specify the CASFMTLIB option, then PROC FORMAT loads the format libraries to the specified CAS session. Otherwise, PROC FORMAT stores the format libraries where the SAS client session is running. For more information, see "CASFMTLIB='*name*'" on page 1086.

The SAS client session and the CAS session can interact through the session reference that you establish with the SESSREF system option or the SESSREF argument in the CASLIB statement. When you use a SAS language element that can take advantage of processing in CAS, the session reference identifies where that processing should occur. If you do not specify a session reference, then processing occurs in the client session. If the language element is not supported in CAS, then processing occurs in the client session.

For more information about SESSREF, see:

- "SESSREF= System Option" in *SAS Cloud Analytic Services: User's Guide*
- "CASLIB Statement" in *SAS Cloud Analytic Services: User's Guide*

For more information about using formats in a CAS session, see:

- "Example 1: Create a Format Library in a CAS Session" on page 1143
- "Using User-Defined Formats In SAS Cloud Analytic Services" in *SAS Cloud Analytic Services: User-Defined Formats*

A Binary Search Determines the User-Defined Format or Informat for a Value

PROC FORMAT uses a binary search to determine the correct user-defined format or informat to use for a value. In comparison, using IF-THEN/ELSE statements is essentially a sequential search for a value. Because of the search method that the binary search uses, PROC FORMAT can provide a more efficient search for making a large number of comparisons.

Here are some user-defined format values that could be written using PROC FORMAT:

```
1='Yes'
2='No'
3='Possibly'
```

If you use these IF-THEN/ELSE statements, SAS begins searching with the first value in the range, `x=1`, and steps through the values until it finds a matching value.

This type of search can be more efficient if the value that you want is near the beginning of the range of values.

```
if x=1 then label='Yes';
else if x=2 then label='No';
else if x=3 then label='Possibly';
```

If you are searching for the value 3, there will be 3 comparisons before a match is found. If you are searching for the value 1, there will be only one comparison made.

If you use the VALUE statement of PROC FORMAT, SAS begins searching at the middle value in the range. In this example, SAS begins by comparing the value to the middle range value, `2='No'`. It then compares the value to the higher range, value `3="Possibly"`, and then compares the value to the lower range value, `1="Yes"`.

```
value
    1="Yes"
    2="No"
    3="Possibly";
```

A binary search like PROC FORMAT uses is more efficient when the range has a large number of values to search.

Syntax: FORMAT Procedure

Restrictions:

You cannot use a SELECT statement and an EXCLUDE statement within the same PROC FORMAT step.

When the CASFMTLIB option is specified, the SELECT and EXCLUDE statements ignore format libraries in SAS Cloud Analytics Services (CAS) sessions and refer only to catalogs.

Formats that are not enabled for threaded-kernel processing are not written to CAS.

Informats cannot be written to a CAS session. Informats included in your SAS code are ignored.

Formats that use functions-as-labels or formats-as-labels cannot be written to CAS.

Tips:

User–defined format names cannot end in a number. For more information, see "User-Defined Formats" in *SAS Formats and Informats: Reference* and "Names in the SAS Language" in *SAS Language Reference: Concepts*.

You can use appropriate global statements with this procedure. See "Global Statements" on page 25 for a list.

For information about generating a list of user-defined formats that are related to a SAS library, see the documentation for the %UDFSEL macro in *SAS Cloud Analytic Services: User-Defined Formats*.

See:

"Using Formats in a CAS Session" on page 1083

"FORMAT Procedure Statement: z/OS" in *SAS Companion for z/OS*

PROC FORMAT <*options*>;

EXCLUDE *entry(s)*;

INVALUE <$>*name* <(*informat-options*)> <*value-range-set(s)*>;

PICTURE *name* <(*format-options*)>
<*value-range-set-1* <(*picture-1-options*)>
<*value-range-set-2* <(*picture-2-options*)>> ...>;

SELECT *entry(s)*;

VALUE <$>*name* <(*format-options*)> <*value-range-set(s)*>;

Statement	Task	Example
PROC FORMAT	Define formats and informats for variables	Ex. 3, Ex. 13, Ex. 15, Ex. 16
EXCLUDE	Exclude catalog entries from processing by the FMTLIB and CNTLOUT= options	
INVALUE	Create an informat for reading and converting raw data values	Ex. 12
PICTURE	Create a template for printing numbers	Ex. 3, Ex. 5, Ex. 18
SELECT	Select catalog entries for processing by the FMTLIB and CNTLOUT= options	Ex. 15
VALUE	Create a format that specifies character strings to use to print variable values	Ex. 8, Ex. 11, Ex. 17

PROC FORMAT Statement

Creates user-specified formats and informats for variables.

Tips:

User–defined format names cannot end in a number. For more information, see "User-Defined Formats" in *SAS Formats and Informats: Reference* and "Names in the SAS Language" in *SAS Language Reference: Concepts*.

You can use data set options with the CNTLIN= and CNTLOUT= data set options. See "Data Set Options" on page 23 for a list.

Moving catalogs between previous versions of SAS and CAS might have some risk. SAS recommends that you use CNTLOUT data sets to reduce this risk.

Examples:

"Example 3: Creating a Picture Format" on page 1150

"Example 13: Creating a Format from a CNTLIN= Data Set" on page 1173

"Example 15: Printing the Description of Informats and Formats" on page 1183

"Example 16: Retrieving a Permanent Format" on page 1185

Syntax

PROC FORMAT <*options*>;

Summary of Optional Arguments

CASFMTLIB='*name*'
: adds a format library to a CAS session.

CNTLIN=*input-control-SAS-data-set*
: specifies a SAS data set from which PROC FORMAT builds informats or formats.

CNTLOUT=*output-control-SAS-data-set*
: creates a SAS data set that stores information about informats or formats that are contained in the catalog specified in the LIBRARY= option.

FMTLIB
: prints information about informats or formats in the catalog that is specified in the LIBRARY= option.

LIBRARY=*libref<.catalog>*
: specifies a SAS library or catalog that contains the informats or formats that you are creating in the PROC FORMAT step.

LOCALE
: specifies to create a format catalog that corresponds to the current SAS locale.

MAXLABLEN=*number-of-characters*
: specifies the number of characters of the informatted or formatted value that appear in PROC FORMAT output.

MAXSELEN=*number-of-characters*
: specifies the number of characters of the start and end values that appear in the PROC FORMAT output.

NOREPLACE
: prevents a new informat or format from replacing an existing one of the same name.

PAGE
: prints information about each format and informat in the catalog.

Optional Arguments

CASFMTLIB='*name*'
adds a format library to a CAS session.

You can specify the CASFMTLIB option only in an active SAS Cloud Analytic Services (CAS) session. PROC FORMAT connects to the CAS session and loads a format library. If the format library already exists in the CAS session, then SAS updates it. SAS also appends the format library to the search list for any subsequent referencing by procedures that are operating in CAS in that session. That is, if a format library already exists and you create a new library with

CASFMTLIB, then the new library is appended to the search order. The library name should be a one-level name that does not contain any slashes.

Note: A CAS session can have more than one format library. The libraries are available only to that CAS session. For information about using a CAS action to promote a format library to a global scope, see "Promote format library" in *SAS Viya: System Programming Guide*.

You can specify additional CAS sessions with the SESSREF= option. For information about the SESSREF= option and other CAS language elements, see *SAS Cloud Analytic Services: User's Guide*.

SAS formats are available in the local SAS client regardless of whether you add them to a format library in CAS. When the CASFMTLIB option is specified, the EXCLUDE and SELECT statements are applied to the local SAS session format catalogs, not to the CAS session format library. Informats cannot be loaded into a CAS session. If you specify an INVALUE statement with CASFMTLIB, then a note is written to the log and nothing is written to the CAS format library.

Restriction The format library name that you specify with the CASFMTLIB option cannot have a length of more than 63 characters.

Notes The specified value of the CASFMTLIB option must be enclosed in single or double quotation marks.

The library name that you specify is case-sensitive. It has to be a valid SAS name, and cannot contain blank spaces.

Formats defined in the VALUE or PICTURE statements are also written to the format catalog that is specified by the LIBRARY= option. If you do not specify a library, then SAS uses the WORK.FORMATS library.

Tip You can use the CAS action `addFmtLib=fmtsearch` to control the order in which SAS searches for format libraries. For more information, see "Manage User-Defined Formats with CAS Actions" in *SAS Cloud Analytic Services: User's Guide*

See "Using Formats in a CAS Session" on page 1083

CNTLIN=*input-control-SAS-data-set*

specifies a SAS data set from which PROC FORMAT builds informats or formats.

CNTLIN= builds formats and informats without using a VALUE, PICTURE, or INVALUE statement. If you specify a one-level name, then the procedure searches only the default library (either the WORK library or USER library) for the data set, regardless of whether you specify the LIBRARY= option.

Notes When using PROC FORMAT with a CNTLIN data set the START and END columns must have the same length. If the lengths are different, an error might occur.

LIBRARY= can point to either a library or a catalog. If only a libref is specified, a catalog name of FORMATS is assumed.

Tip A common source for an input control data set is the output from the CNTLOUT= option of another PROC FORMAT step.

See "Input Control Data Set" on page 1139

Example "Example 13: Creating a Format from a CNTLIN= Data Set" on page 1173

CNTLOUT=*output-control-SAS-data-set*

creates a SAS data set that stores information about informats or formats that are contained in the catalog specified in the LIBRARY= option. If you are creating an informat or format in the same step that the CNTLOUT= option appears, then the informat or format that you are creating is included in the CNTLOUT= data set.

If you specify a one-level name, then the procedure stores the data set in the default library (either the WORK library or the USER library), regardless of whether you specify the LIBRARY= option.

If you issue CNTLOUT= with an ENCODING option to create an output data set that has a different encoding, Cross Environment Data Access (CEDA) might issue a truncation error, SAS stops processing, and the CNTLOUT= data set is created with 0 observations. SAS writes an error to the log such as the following about the truncation of data:

```
ERROR: Some character data was lost during transcoding in the dataset
       WORK.TEST. Either the data contains characters that are not
       representable in the new encoding or truncation occurred during
       transcoding.
```

Suppose you are using a data set that contains monetary values in Euros. You are using the Wlatin1 session encoding, and you specify UTF-8 encoding for the CNTLOUT= data set. In Wlatin1 the LABEL variable is predetermined to be 5 bytes long and have a value of €1234 (in hexadecimal representation, '803132334'x). When you attempt to store the variable in the CNTLOUT= data set with UTF-8 encoding, the length of that string must be 7 bytes (in hexadecimal representation, 'E282AC3132334'x). The two additional bytes are needed in UTF-8 encoding for the Euro sign. Without the additional two bytes, the string is truncated. You can use the %COPY_TO_NEW_ENCODING macro to prevent this error. For information about the %COPY_TO_NEW_ENCODING macro, see "Avoiding Character Truncation Using the %COPY_TO_NEW_ENCODING Macro" in *SAS National Language Support (NLS): Reference Guide*.

The macro examines the CNTLOUT data set and re-creates it in the new encoding with the necessary lengths. If a width is stored as part of the associated format, the value is not expanded by the CVP engine. The format can cause truncation when the formatted value is displayed.

The DEFAULT value for the format width in the CNTLOUT data set is the default width (in bytes) for the format. The user can specify DEFAULT=, MIN=, and MAX= when they create the format, or the default is computed based on the largest label. If the START, MIN, MAX, or LABEL variable, in characters, is

larger in UTF-8 encoding, then these widths are not expanded by the CVP engine. Use the %COPY_TO_NEW_ENCODING macro instead. For more information about using CNTLOUT= with PROC FORMAT to convert catalogs to UTF-8, see "Converting Format Catalogs to UTF-8 Encoding" in *Moving and Accessing SAS Files*.

Note LIBRARY= can point to either library or a catalog. If only a libref is specified, SAS uses the catalog name FORMATS.

Tip You can use an output control data set as an input control data set in subsequent PROC FORMAT steps.

See "Output Control Data Set" on page 1135

SAS Viya supports only UTF-8 encoding. For information about the encoding of your format catalogs in SAS Viya, see *Migrating Data to UTF-8 for SAS Viya* and *SAS Viya FAQ for Processing UTF-8 Data*.

FMTLIB

prints information about informats or formats in the catalog that is specified in the LIBRARY= option. To get information about specific informats or formats, subset the catalog using the SELECT or EXCLUDE statement.

Note: FMTLIB is not supported for CASFMTLIB.

Interaction The PAGE option invokes FMTLIB.

Tips If your output from FMTLIB is not formatted correctly in the ODS LISTING destination, then try increasing the value of the LINESIZE= system option.

If you use a SELECT or EXCLUDE statement in your code without including a CNTLOUT= option, the FMTLIB option is automatically invoked and the FMTLIB report is generated. If necessary, this report can be suppressed by placing the following ODS EXCLUDE statement immediately before the PROC FORMAT statement:

```
ods exclude FORMAT;
```

Example "Example 15: Printing the Description of Informats and Formats" on page 1183

LIBRARY=*libref<.catalog>*

specifies a SAS library or catalog that contains the informats or formats that you are creating in the PROC FORMAT step. The procedure stores these informats and formats in the catalog that you specify so that you can use them in subsequent SAS sessions or jobs.

Alias LIB=

Default If you omit the LIBRARY= option, then formats and informats are stored in the Work.Formats catalog. If you specify the LIBRARY= option but do not specify a name for *catalog*, then formats and informats are stored in the *libref*.FORMATS catalog.

Note LIBRARY= can point to either a library or a catalog. If only a libref is specified, then SAS uses the catalog name FORMATS.

Tips SAS automatically searches Library.Formats. You might want to define and use the LIBRARY libref for your format catalog.

You can control the order in which SAS searches for format catalogs with the FMTSEARCH= system option. For more information, see "FMTSEARCH= System Option" in *SAS System Options: Reference*.

See "Storing Informats and Formats " on page 1080

Example "Example 3: Creating a Picture Format" on page 1150

LOCALE
specifies to create a format catalog that corresponds to the current SAS locale. The name of the catalog that SAS creates is the SAS library or catalog that is specified in the LIBRARY= option appended with the five-character POSIX locale value for the current SAS locale.

See For a list of POSIX locale values, see "LOCALE= Values for PAPERSIZE and DFLANG, Options" in *SAS National Language Support (NLS): Reference Guide*.

Example If the SAS locale is German_Germany, the POSIX locale value is de_DE. Using the following PROC FORMAT statement, SAS creates the catalog mylib.formats_de_DE to store formats and informats created by this procedure:

```
proc format locale lib=mylib.formats;
```

MAXLABLEN=*number-of-characters*
specifies the number of characters in the informatted or formatted value that you want to appear in the CNTLOUT= data set or in the output of the FMTLIB option. The FMTLIB option prints a maximum of 40 characters for the informatted or formatted value.

MAXSELEN=*number-of-characters*
specifies the number of characters in the start and end values that you want to appear in the CNTLOUT= data set or in the output of the FMTLIB option. The FMTLIB option prints a maximum of 16 characters for start and end values.

NOREPLACE
prevents a new informat or format from replacing an existing one of the same name. If you omit NOREPLACE, then the procedure warns you that the informat or format already exists and replaces it.

Note You can have a format and an informat of the same name.

PAGE
prints information about each format and informat in the catalog.

Interaction The PAGE option activates the FMTLIB option.

Tip In the ODS LISTING destination, the information about each format and informat appears on separate pages in the Output window.

EXCLUDE Statement

Excludes entries from processing by the FMTLIB and CNTLOUT= options.

Restrictions:

Only one EXCLUDE statement can appear in a PROC FORMAT step.

You cannot use a SELECT statement and an EXCLUDE statement within the same PROC FORMAT step.

When the CASFMTLIB option is specified, the EXCLUDE statement ignores format libraries in CAS sessions and refers only to catalogs in the SAS session.

Syntax

EXCLUDE *entry(s)*;

Required Argument

entry(s)
specifies one or more catalog entries to exclude from processing. Catalog entry names are the same as the name of the informat or format that they store. Because informats and formats can have the same name, and because character and numeric informats or formats can have the same name, you must use certain prefixes when specifying informats and formats in the EXCLUDE statement. Follow these rules when specifying entries in the EXCLUDE statement:

- Precede names of entries that contain character formats with a dollar sign ($).
- Precede names of entries that contain character informats with an at sign and a dollar sign (for example, @$*entry-name*).
- Precede names of entries that contain numeric informats with an at sign (@).
- Specify names of entries that contain numeric formats without a prefix.

Details

Shortcuts to Specifying Names

You can use the colon (:) and hyphen (-) wildcard characters to exclude entries. For example, the following EXCLUDE statement excludes all formats or informats that begin with the letter **a**.

```
exclude a:;
```

In addition, the following EXCLUDE statement excludes all formats or informats that occur alphabetically between **apple** and **pear**, inclusive:

```
exclude apple-pear;
```

FMTLIB Output

If you use the EXCLUDE statement without either FMTLIB or CNTLOUT= in the PROC FORMAT statement, then the procedure invokes the FMTLIB option and you receive FMTLIB option output.

INVALUE Statement

Creates an informat for reading and converting raw data values.

See: *SAS Formats and Informats: Reference* for documentation on informats supplied by SAS.

Example: "Example 12: Converting Raw Character Data to Numeric Values" on page 1170

Syntax

INVALUE <$>*name* <(*informat-options*)> <*value-range-set(s)*>;

Summary of Optional Arguments

DEFAULT=*length*
: specifies the default length of the informat.

FUZZ=*fuzz-factor*
: specifies a fuzz factor for matching values to a range.

JUST
: left-justifies all input strings before they are compared to ranges.

MAX=*length*
: specifies a maximum length for the informat.

MIN=*length*
: specifies a minimum length for the informat.

NOTSORTED
: stores values or ranges in the order in which you define them.

REGEXP

REGEXPE
: specifies that the preceding range is to be treated as a Perl regular expression.

UPCASE
: upper cases all input strings before they are compared to ranges.

Control the input template.

value-range-set(s)

specifies the variable template for reading data.

Required Argument

name

names the informat that you are creating.

Restriction
A user-defined informat name cannot be the same as an informat name that is supplied by SAS.

Requirement
The name must be a valid SAS name. A numeric informat name can be up to 31 characters in length; a character informat name can be up to 30 characters in length and cannot end in a number. If you are creating a character informat, then use a dollar sign ($) as the first character. Adding the dollar sign to the name is why a character informat is limited to 30 characters.

Interaction
The maximum length of an informat name is controlled by the VALIDFMTNAME= system option. See *SAS System Options: Reference* for details.

Tips
Refer to the informat later by using the name followed by a period. However, do not use a period after the informat name in the INVALUE statement.

When SAS prints messages that refer to a user-written informat, the name is prefixed by an at sign (@). When the informat is stored, the at sign is prefixed to the name that you specify for the informat. The addition of the at sign to the name is why the name is limited to 31 or 30 characters. You need to use the at sign *only* when you are using the name in an EXCLUDE or SELECT statement; do not prefix the name with an at sign when you are associating the informat with a variable.

Optional Arguments

DEFAULT=*length*

specifies the default length of the informat. The value for DEFAULT= becomes the length of the informat if you do not give a specific length when you associate the informat with a variable.

Defaults
For character informats, the length of the longest label

For numeric informats, 12 if you have numeric data to the left of the equal sign

For quoted strings, the length of the longest string

Note
If you specify an invalid value for DEFAULT=, SAS ignores the value and writes an error to the log.

Tip
As a best practice, if you specify an existing informat in a value-range set, always specify the DEFAULT= option.

FUZZ=*fuzz-factor*
specifies a fuzz factor for matching values to a range. If a number does not match or fall in a range exactly but comes within *fuzz-factor*, then the informat considers it a match. For example, the following INVALUE statement creates the LEVELS. informat, which uses a fuzz factor of .2:

```
invalue levels (fuzz=.2) 1='A'
                         2='B'
                         3='C';
```

FUZZ=.2 means that if a variable value falls within .2 of a value on either end of the range, then the informat uses the corresponding formatted value to store the variable value. So the LEVELS. informat saves the value 2.1 as **B**.

Tips Specify FUZZ=0 to save storage space when you use the INVALUE statement to create numeric informats.

Use a nonzero fuzz factor only with numbers that are very close but not an exact match. Ranges are stored internally in sorted order (unless the NOTSORTED option is used), in order to perform a binary search. When a fuzz-factor is added to the end of one range and subtracted from the beginning of the next range, and the ranges overlap, the results can be unpredictable. A value is placed in the first range that is a match in the binary search. The exclusion operator is insufficient to override this binary search algorithm. As a best practice, when you use the exclusion operator, set FUZZ=0 or the NOTSORTED option.

A best practice is to use FUZZ=0 when you use the < exclusion operator with numeric informats.

JUST
left-justifies all input strings before they are compared to ranges.

MAX=*length*
specifies a maximum length for the informat. When you associate the informat with a variable, you cannot specify a width greater than the MAX= value.

Default 40

Range 1–32767

Note If you specify an invalid value for MAX=, SAS ignores the value and writes an error to the log.

MIN=*length*
specifies a minimum length for the informat. If a CNTLIN= data set contains a value for MIN that rounds to 0 or less, SAS ignores the invalid value and substitutes 1 for it. When you specify the CNTLIN= data set in SAS code, SAS continues processing the code step and does not write an error to the log.

The following example specifies a data set that has a MIN value of -1 and uses CNTLIN= to call the data set on the subsequent PROC FORMAT statement.

```
data temp;
   fmtname='abc';
   start=1;
   label='xyz';
```

```
   min=-1;
run;

proc format cntlin=temp;
run;
```

If you specify an invalid value for MIN in code, SAS does not ignore the invalid value or substitute another value for it. SAS stops processing the code step and writes an error to the log.

The following example specifies `min=-1` for the NEWABC data set, which causes SAS to stop processing and issue an error.

```
proc format;
    value newabc (min=-1) 1='yes';
run;
```

Default 1

Range 1–32767

NOTSORTED

stores values or ranges in the order in which you define them.

If you do not specify NOTSORTED, then values or ranges are stored in sorted order by default, and SAS uses a binary searching algorithm to locate the range that a particular value falls into. If you specify NOTSORTED, then SAS searches each range in the order in which you define them until a match is found.

Use NOTSORTED if one of the following is true:

- You know the likelihood of certain ranges occurring, and you want your informat to search those ranges first to save processing time.
- You want to preserve the order that you define ranges when you print a description of the informat using the FMTLIB option.
- You want to preserve the order that you define ranges when you use the ORDER=DATA option and the PRELOADFMT option to analyze class variables in PROC MEANS, PROC SUMMARY, or PROC TABULATE.

Do not use NOTSORTED if the distribution of values is uniform or unknown, or if the number of values is relatively small. The binary searching algorithm that SAS uses when NOTSORTED is not specified optimizes the performance of the search under these conditions.

SAS automatically sets the NOTSORTED option when you use the CPORT and CIMPORT procedures to transport informats or formats between operating environments with different standard collating sequences. This automatic setting of NOTSORTED can occur when you transport informats or formats between ASCII and EBCDIC operating environments. If this situation is undesirable, then do the following:

- Use the CNTLOUT= option in the PROC FORMAT statement to create an output control data set.
- Use the CPORT procedure to create a transport file for the control data set.
- Use the CIMPORT procedure in the target operating environment to import the transport file.

- In the target operating environment, use PROC FORMAT with the CNTLIN= option to build the formats and informats from the imported control data set.

REGEXP
REGEXPE
specifies that the preceding range is to be treated as a Perl regular expression. If you specify REGEXPE, the regular expression is expected to produce a modified result, as in using the substitute action.

During execution, all regular expressions are compiled and the input data is passed to the first expression to confirm a match. If there is a match, the corresponding label is used. If there is no match, the next range is compared. Ranges are not sorted and are processed in the order in which they were defined in the INVALUE statement or in the order in which they appear in the CNTLIN= data set.

The rules for regular expressions using the REGEXP option are the same as they are for the PRXPARSE function in the DATA step. The rules for the REGEXPE option are the same as they are for the PRXCHANGE function.

Interaction If you are using a CNTLIN= data set, the HLO variable contains P for REGEXP and E for REGEXPE.

See "Example 10: Creating an Informat Using Perl Regular Expressions" on page 1165

UPCASE
converts all raw data values to uppercase before they are compared to the possible ranges. If you use UPCASE, then make sure the values or ranges that you specify are in uppercase.

value-range-set(s)
specifies raw data and values that the raw data becomes. The *value-range-set(s)* can be one or more of the following:

value-or-range-1<, *value-or-range-2* ...>=*informatted-value* | [*existing-informat*]

The informat converts the raw data to the values of *informatted-value* on the right side of the equal sign.

value-or-range
See "Specifying Values or Ranges" on page 1129.

informatted-value
is the value that you want the raw data in *value-or-range* to become. Use one of the following forms for *informatted-value*:

'character-string'
is a character string up to 32,767 characters long. Typically, *character-string* becomes the value of a character variable when you use the informat to convert raw data. Use *character-string* for *informatted-value* only when you are creating a character informat. If you omit the single or double quotation marks around *character-string*, then the INVALUE statement assumes that the quotation marks are there.

For hexadecimal literals, you can use up to 32,767 typed characters, or up to 16,382 represented characters at two hexadecimal characters per represented character.

number
is a number that becomes the informatted value. Typically, *number* becomes the value of a numeric variable when you use the informat to convert raw data. Use *number* for *informatted-value* when you are creating a numeric informat. The maximum for *number* depends on the host operating environment.

ERROR
treats data values in the designated range as invalid data. SAS assigns a missing value to the variable, prints the data line in the SAS log, and issues a warning message.

SAME
prevents the informat from converting the raw data as any other value. For example, the following GROUP informat converts values 01 through 20 and assigns the numbers 1 through 20 as the result. All other values are assigned a missing value.

```
invalue group 01-20= _same_
              other= .;
```

existing-informat
is an informat that is supplied by SAS or an existing user-defined informat. The informat that you are creating uses the existing informat to convert the raw data that match *value-or-range* on the left side of the equal sign. If you use an existing informat, then enclose the informat name in square brackets (for example, [date9.]) or with parentheses and vertical bars (for example, (|date9.|)). Do not enclose the name of the existing informat in single quotation marks.

Tip As a best practice, if you specify an existing informat in a value-range-set, always specify a default value by using the DEFAULT= option.

Examples

Example 1: Create a Character Informat for Raw Data Values

The $GENDER. character informat converts the raw data values **F** and **M** to character values **'1'** and **'2'**:

```
invalue $gender 'F'='1'
                'M'='2';
```

The dollar sign prefix indicates that the informat converts character data.

Example 2: Create Character and Numeric Values or a Range of Values

When you create numeric informats, you can specify character strings or numbers for *value-or-range*. For example, the TRIAL. informat converts any character string that sorts between **A** and **M** to the number 1 and any character string that sorts between **N** and **Z** to the number 2. The informat treats the unquoted range 1–3000 as a numeric range, which includes all numeric values between 1 and 3000:

```
invalue trial 'A'-'M'=1
              'N'-'Z'=2
               1-3000=3;
```

Example 3: Convert Input Strings to Uppercase and Left-justify

The EVALUATION. informat uses the UPCASE and JUST options to uppercase and left-justify all input strings before they are converted to numbers.

```
invalue evaluation (upcase just) 'O'=4
                                 'S'=3
                                 'E'=2
                                 'C'=1
                                 'N'=0;
```

Note: Options in the INVALUE statement must be specified in parentheses.

Example 4: Create an Informat Using _ERROR_ and _SAME_

The CHECK. informat uses _ERROR_ and _SAME_ to convert values of 1 through 4 and 99. All other values are invalid:

```
invalue check 1-4=_same_
               99=.
           other=_error_;
```

If you use a numeric informat to convert character strings that do not correspond to any values or ranges, then you receive an error message.

PICTURE Statement

Creates a template for printing numbers.

Tips:

As a best practice, if you specify an existing format in a value-range-set, always specify a default value by using the DEFAULT= option on page 1123.

If you are using the DATATYPE= option, use the DEFAULT= option to set the default format width to be large enough to format these characters. Without setting the DEFAULT= option, the default width of a format is the width of the largest value to the right of the equation symbol.

The DEFAULT, FUZZ, MAX, MIN, MULTILABEL, NOTSORTED, and ROUND options are valid before the value range specification.

The DATATYPE, DECSEP, DIG3SEP, FILL, LANGUAGE, MULT, NOEDIT, and PREFIX options are valid in parentheses after the user-supplied value label.

The DATATYPE, DECSEP, DIG3SEP, FILL, LANGUAGE, MULT, NOEDIT, PREFIX, and ROUND options are valid only with the PICTURE statement.

See: *SAS Formats and Informats: Reference* and *SAS National Language Support (NLS): Reference Guide* for documentation about formats that are supplied by SAS.

Examples: "Example 3: Creating a Picture Format" on page 1150

"Example 5: Filling a Picture Format" on page 1155

"Example 18: Creating a Format in a non-English Language" on page 1190

Syntax

PICTURE *name* <(*format-options*)>
<*value-range-set-1* <(*picture-1-options*)>
<*value-range-set-2* <(*picture-2-options*)>> ...>;

Summary of Optional Arguments

Control the attributes of each picture in the format

FILL='*character*'
: specifies a character that completes the formatted value.

MULTIPLIER=*n*
: specifies a number to multiply the variable's value by before it is formatted.

NOEDIT
: specifies that numbers are message characters rather than digit selectors.

PREFIX='*prefix*'
: specifies a character prefix to place in front of the formatted value.

Control the attributes of the format

DATATYPE=DATE | TIME | DATETIME | DATETIME_UTIL
: enables the use of directives in the picture as a template to format date, time, or datetime values.

DECSEP='*character*'
: specifies the separator character for the fractional part of a number.

DEFAULT=*length*
: specifies the default length of the picture.

DIG3SEP='*character*'
: specifies the three-digit separator character for a number.

FUZZ=*fuzz-factor*
: specifies a fuzz factor for matching values to a range.

LANGUAGE=

specifies the language that is used for weekdays and months that you can substitute in a date, time, or datetime picture.

MAX=*length*
specifies a maximum length for the format.

MIN=*length*
specifies a minimum length for the format.

MULTILABEL
enables the assignment of labels to multiple *values-or-range* values that might have the same or overlapping values.

NOTSORTED
stores values or ranges in the order in which you define them.

ROUND
rounds the value to the nearest integer before formatting.

Control the template for printing

value-range-set
specifies one or more variable values and a template for printing those values.

Required Argument

name
names the format that you are creating.

Restriction: A user-defined format cannot be the name of a format supplied by SAS.

Requirement: The name must be a valid SAS name. A numeric format name can be up to 32 characters in length; a character format name can be up to 31 characters in length, not ending in a number. If you are creating a character format, you use a dollar sign ($) as the first character, which is why a character informat is limited to 31 characters. For information about SAS names, see "Rules for Words and Names in the SAS Language" in *SAS Language Reference: Concepts*.

Interaction: The maximum length of a format name is controlled by the VALIDFMTNAME= system option. See *SAS System Options: Reference* for details.

Tip: Refer to the format later by using the name followed by a period. However, do not put a period after the format name in the VALUE statement.

Optional Arguments

DATATYPE=DATE | TIME | DATETIME | DATETIME_UTIL
enables the use of directives in the picture as a template to format date, time, or datetime values. Specify either DATE, TIME, DATETIME, or DATETIME_UTIL based on the directive that you use in the picture format. See the definition and list of directives on page 1107 in the description of *picture*.

Interaction DATATYPE=DATETIME results in datetime hours 00:00:00–23:59:59. DATATYPE=DATETIME_UTIL results in datetime hours between 00:00:01–24:00:00.

Tip If you format a numeric missing value, then the resulting label is ERROR. Adding a clause to your program that checks for missing values can eliminate the ERROR label.

DEFAULT=*length*
specifies the default length of the picture. The value for DEFAULT= becomes the length of *picture* if you do not give a specific length when you associate the format with a variable.

Default The length of the longest picture value

Range 1–32767

Tip If you are using the DATATYPE= option, use the DEFAULT= option to set the default format width large enough to format these characters.

DECSEP='*character*'
specifies the separator character for the fractional part of a number.

Default . (a decimal point)

DIG3SEP='*character*'
specifies the three-digit separator character for a number.

Default , (a comma)

FILL='*character*'
specifies a character that completes the formatted value.

If the number of significant digits is less than the length of the format, then the format must complete, or fill, the formatted value:

- The format uses *character* to fill the formatted value if you specify zeros as digit selectors.
- The format uses zeros to fill the formatted value if you specify nonzero-digit selectors. The FILL= option has no effect.

If the picture includes other characters, such as a comma, which appear to the left of the digit selector that maps to the last significant digit placed, then the characters are replaced by the fill character or leading zeros.

Default ' ' (a blank)

Restriction The FILL= option is not valid when you use a function to format a value.

Interaction If you use the FILL= and PREFIX= options in the same picture, then the format places the prefix and then the fill characters.

Example "Example 5: Filling a Picture Format" on page 1155

FUZZ=*fuzz-factor*

specifies a fuzz factor for matching values to a range. If a number does not match or fall in a range exactly but comes within *fuzz-factor*, on either end of the range, then the format considers it a match. For example, the following VALUE statement creates the LEVELS. format, which uses a fuzz factor of .2:

```
value levels (fuzz=.2) 1='A'
                       2='B'
                       3='C';
```

FUZZ=.2 means that if a variable value falls within .2 of a value on either end of the range, then the format uses the corresponding formatted value to print the variable value. The LEVELS format formats the value 2.1 as B.

Default 1E−12 for numeric formats.

Tips Specify FUZZ=0 to save storage space when you use the VALUE statement to create numeric formats.

Use a nonzero fuzz factor only with numbers that are very close but not an exact match. If *fuzz-factor* is added to the end of one range and subtracted from the beginning of the next range, and the ranges overlap, the results can be unpredictable. A value is placed in the first range that is a match in a binary search.

A best practice is to use FUZZ=0 when you use the < exclusion operator with numeric formats.

LANGUAGE=

specifies the language that is used for weekdays and months that you can substitute in a date, time, or datetime picture. If you specify a language that is not supported or is invalid, English is used.

These are the valid values for the LANGUAGE= option:

Afrikaans	English	Macedonian	Spanish
Catalan	Finnish	Norwegian	Swedish
Croatian	French	Polish	Swiss_French
Czech	German	Portuguese	Swiss_German
Danish	Hungarian	Russian	
Dutch	Italian	Slovenian	

Defaults For single-byte character sets, the language that is specified by DFLANG= system option

For double-byte and UTF-8 character sets, the language that is specified by the LOCALE= system option

Tip To use a user-defined format in languages other than those that are supported by the LANGUAGE= option, set the LOCALE= system option to the locale for the language. In PROC FORMAT, do not specify the LANGUAGE= option. The language of a picture format is determined by the locale setting. For a list of locales, see “LOCALE=

Values for PAPERSIZE and DFLANG, Options" in *SAS National Language Support (NLS): Reference Guide*.

See "DFLANG= System Option: UNIX, Windows, and z/OS" in *SAS National Language Support (NLS): Reference Guide*

MAX=*length*

specifies a maximum length for the format. When you associate the format with a variable, you cannot specify a width greater than the MAX= value.

Default 40

Range 1–32767

MIN=*length*

specifies a minimum length for the format.

Default 1

Range 1–32767

MULTILABEL

enables the assignment of labels to multiple *values-or-range* values that might have the same or overlapping values. The label is the formatted value that is determined by the picture definition on the right of the equal sign in a value-range-set. Here is an example of how MULTILABEL is used:

The following PICTURE statements show the two uses of the MULTILABEL option. In each case, number formats are assigned as labels. The first PICTURE statement assigns multiple labels to a single value. Multiple labels can also be assigned to a single range of values. The second PICTURE statement assigns labels to overlapping ranges of values. The MULTILABEL option enables the assignment of multiple labels to the overlapped values.

```
picture abc (multilabel)
    1000='9,999'
    1000='9999';

  picture overlap (multilabel)
    /* without decimals */
    0-999='999'
    1000-9999='9,999'

     /* with decimals */
    0-9='9.999'
    10-99='99.99'
    100-999='999.9';
```

Only multilabel-enabled procedures such as PROC MEANS, PROC SUMMARY, and PROC TABULATE can use multiple labels. All other procedures and the DATA step recognize only the primary label.

The *primary label* for a given entry is the formatted value (based on the picture) that is assigned to the first value or range-of-values (left side of the equal sign) that matches or contains the entry when all values (on the left side of the equal sign) are ordered sequentially. Here is an example:

- In the first PICTURE statement, the primary label for 1000 is 1,000 because the picture 9,999 is the first value that is assigned to 1000. The secondary label for 1000 is 1000, based on the 9999 picture.
- In the second PICTURE statement, the primary label for 5 is 5.000 based on the 9.999 picture that is assigned to the range 0–9 because 0–9 is sequentially the first range of values that contain 5. The secondary label for 5 is 005 because the range 0–999 occurs in sequence after the range 0–9.

Consider carefully when you assign multiple labels to a value.

Unless you use the NOTSORTED option when you assign value-range-sets, SAS stores the value-range-sets in sorted order. This order can produce unexpected results when value-range-sets with the MULTILABEL format are processed. Here is an example:

In the second PICTURE statement, the primary label for 15 is 015, and the secondary label for 15 is 15.00 because the range 0–999 occurs in sequence before the range 10–99. If you want the primary label for 15 to use the 99.99 format, then you might want to change the range 10–99 to 0–99 in the PICTURE statement. The range 0–99 occurs in sequence before the range 0–999 and produces the desired result.

Restriction The maximum number of labels that can be created for a single format or informat is 255.

MULTIPLIER=*n*

specifies a number to multiply the variable's value by before it is formatted. The value of the MULTIPLIER= option depends both on the result of the multiplication and on the digit selectors in the *picture* portion of the *value-range-set*. For example, the following PICTURE statement creates the MILLION. format, which formats the variable value 1600000 as `$1.6M`:

```
picture million low-high='09.9M'
        (prefix='$' mult=.00001);
```

1600000 is first multiplied by .00001, which equals 16. Note that there is a digit selector after the decimal. The value 16 is placed into the picture beginning on the right. The value 16 overlays 09.9, and results in 01.6. Leading zeros are dropped, and the final result is 1.6M.

If the value of low-high is equal to '000M', then the result would be 16M.

Alias MULT=

Default 10^n, where *n* is the number of digits after the first decimal point in the picture. For example, suppose your data contains a value 123.456 and you want to print it using a picture of '999.999'. The format multiplies 123.456 by 10^3 to obtain a value of 123456, which results in a formatted value of 123.456.

Restrictions The MULT= option is not valid when you use a function to format a value.

The MULT= option is ignored when you specify the DATATYPE= option.

Examples "Example 3: Creating a Picture Format" on page 1150

"Example 4: Creating a Picture Format for Large Dollar Amounts" on page 1152

NOEDIT

specifies that numbers are message characters rather than digit selectors. That is, the format prints the numbers as they appear in the picture. For example, the following PICTURE statement creates the MILES. format, which formats any variable value greater than 1000 as **>1000 miles**:

```
picture miles 1-1000='0000'
          1000<-high='>1000 miles'(noedit);
```

Restriction The NOEDIT= option is not valid when you use a function to format a value.

NOTSORTED

stores values or ranges in the order in which you define them. If you do not specify NOTSORTED, then values or ranges are stored in sorted order by default, and SAS uses a binary searching algorithm to locate the range that a particular value falls into. If you specify NOTSORTED, then SAS searches each range in the order in which you define them until a match is found.

Use NOTSORTED if one of the following is true:

- You know the likelihood of certain ranges occurring, and you want your format to search those ranges first to save processing time.
- You want to preserve the order that you define ranges when you print a description of the format using the FMTLIB option.
- You want to preserve the order that you define ranges when you use the ORDER=DATA option and the PRELOADFMT option to analyze class variables in PROC MEANS, PROC SUMMARY, or PROC TABULATE.

Do not use NOTSORTED if the distribution of values is uniform or unknown, or if the number of values is relatively small. The binary searching algorithm that SAS uses when NOTSORTED is not specified optimizes the performance of the search under these conditions.

SAS automatically sets the NOTSORTED option when you use the CPORT and CIMPORT procedures to transport informats or formats between operating environments with different standard collating sequences. This automatic setting of NOTSORTED can occur when you transport informats or formats between ASCII and EBCDIC operating environments. If this situation is undesirable, then do the following:

- Use the CNTLOUT= option in the PROC FORMAT statement to create an output control data set.
- Use the CPORT procedure to create a transport file for the control data set.
- Use the CIMPORT procedure in the target operating environment to import the transport file.

- In the target operating environment, use PROC FORMAT with the CNTLIN= option to build the formats and informats from the imported control data set.

PREFIX='*prefix*'
specifies a character prefix to place in front of the formatted value. The prefix is placed in front of the value's first significant digit. You must use zero-digit selectors or the prefix is not used.

Typical uses for PREFIX= are printing leading currency symbols and minus signs. For example, the PAY format prints the variable value 25500 as **$25,500.00**:

```
picture pay
   low-high='000,009.99' (prefix='$');
```

Default no prefix

Restriction The PREFIX= option is not valid when you use a function to format a value.

Interaction If you use the FILL= and PREFIX= options in the same picture, then the format places the prefix and then the fill characters.

Examples "Example 3: Creating a Picture Format" on page 1150

"Example 5: Filling a Picture Format" on page 1155

CAUTION **If the picture is not wide enough to contain both the value and the prefix, then the format truncates or omits the prefix, which results in inaccurate data.**

ROUND
rounds the value to the nearest integer before formatting. Without the ROUND option, the format multiplies the variable value by the multiplier, truncates the decimal portion (if any), and prints the result according to the template that you define. With the ROUND option, the format multiplies the variable value by the multiplier, rounds that result to the nearest integer, and then formats the value according to the template. Note that if the FUZZ= option is also specified, the rounding takes place after SAS has used the fuzz factor to determine which range the value belongs to.

Tip The ROUND option rounds a value of .5 to the next highest integer.

CAUTION **The picture must be wide enough for an additional digit if rounding a number adds a digit to the number.** For example, the picture for the number .996 could be '99' (prefix '.' mult=100). After rounding the number and multiplying it by 100, the resulting number is 100. When the picture is applied, the result is .00, an inaccurate number. In order to ensure accuracy of numbers when you round numbers, make the picture wide enough to accommodate larger numbers.

value-range-set
specifies one or more variable values and a template for printing those values. *value-range-set* has the following form:

value-or-range-1 <, *value-or-range-2*, ...>='*picture*'

value-or-range
See "Specifying Values or Ranges" on page 1129.

picture
specifies a template for formatting values of numeric variables. The picture is a sequence of characters in single quotation marks. The maximum length for a picture is 40 characters. Pictures are specified with three types of characters: digit selectors, message characters, and directives. You can have a maximum of 16 digit selectors in a picture.

digit selectors
are numeric characters (0 through 9) that define positions for numeric values. A picture format with nonzero-digit selectors prints any leading zeros in variable values; picture digit selectors of 0 do not print leading zeros in variable values. If the picture format contains digit selectors, then a digit selector must be the first character in the picture.

Note This section uses 9s as nonzero-digit selectors.

message characters
are nonnumeric characters that are printed as specified in the picture. The following PICTURE statement contains both digit selectors (99) and message characters (**`illegal day value`**). Because the DAYS. format has nonzero-digit selectors, values are printed with leading zeros. The special range OTHER prints the message characters for any values that do not fall into the specified range (1 through 31).

```
picture days
          01-31='99'
          other='99-illegal day value';
```

Example The values 02 and 67 are printed as

```
                                02
      67-illegal day value
```

directives
are special characters that you can use in the picture to format date, time, or datetime values.

Note: You can use directives only when you specify the DATATYPE= option on page 1100 in the PICTURE statement. Ensure that the value of the DATATYPE= option is appropriate for the type of directive that you want to use. If you use an inappropriate value, the data does not format. For example, for the %a directive, use DATATYPE=DATE.

The DFLANG datetime handler and the National Language (NL) datetime handler are the two methods to control character casing in user format handling. The DFLANG datetime handler is the default method under non–UTF8 and non–DBCS sessions. The NL datetime handler is the default method under UTF8 and DBCS sessions.

Note: The DFLANG datetime handler is used if you specify it for UTF8 and DBCS sessions. Otherwise, the NL datetime handler is used.

Note: The following are handled by the DFLANG datetime handler: a A b B d H I j m M p q S w U y Y.

If you specify the DFLANG datetime handler, then month names are in all uppercase if you specify English (for example, JAN), they are in all lowercase if you specify French (for example, jan), and they are in mixed case if you specify German (for example, Jan).

If you specify the NL datetime handler, then month names are in mixed case if you specify English or German (Jan), and they are in lowercase if you specify French (for example, jan).

The DFLANG datetime handler is used only if a supported language is specified with the DFLANG= system option and all of the specified datetime elements are supported by the DFLANG format handler. Otherwise, the NL datetime handler is used.

The casing of the month names is determined by the DFLANG= system option and the LANGUAGE= argument of the PICTURE statement. Otherwise, the casing is determined by the language elements in the locale data. For example, if the language specified by the LOCALE= option is English, then only the first character is in uppercase because it is defined as mixed–case strings in the locale data. For more information, see "DFLANG= System Option: UNIX, Windows, and z/OS" in *SAS National Language Support (NLS): Reference Guide*.

Note: The DFLANG option supports only 22 languages. Use the DFLANG= option only for compatibility purposes. When you specify the DFLANG= option, support for the datetime directive is limited and some elements such as %I are not supported.

Specify the LANGUAGE= argument if you need to use it in the FORMAT procedure, or you need month names in all uppercase for a locale such as English.

If you mainly use the EUR* datetime formats and you need support for European languages only for compatibility, then you can use the DFLANG= option to specify the language.

Use the LOCALE= system option to set the locale for double-byte and UTF-8 character sets. The %b directive formats month names with only the first letter in uppercase when the locale is set with LOCALE=. For more information, see "LOCALE System Option" in *SAS National Language Support (NLS): Reference Guide*.

If you specify a format element that is supported by only the NL datetime handler, then the NL format handler is used regardless of whether the DFLANG= option is used. %b also produces abbreviated month names in mixed case for English if there is an unsupported directive such as %I.

The permitted directives are as follows:

%a
abbreviated weekday name (for example, Wed).

%A
full weekday name (for example, Wednesday).

%b
abbreviated month name (for example, JAN or Jan).

The default value for the LANGUAGE= argument in UTF-8 sessions is LOCALE. To format month names in all upper–case characters in UTF-8 sessions, specify the locale on the LANGUAGE= argument. For more information, see "LANGUAGE=" on page 1102.

Tip For the English language, use the directive %3B to create an abbreviated month with only an uppercase initial letter (for example, Jan).

%<*n*>B
the full month name (for example, January) if *n* is not included in the directive. *n* specifies the number of characters that appear for the month name. In comparison, the %b directive writes a three-character month abbreviation in uppercase letters for some locales.

Restriction *n* is not supported in DBCS and Unicode SAS sessions.

Example %3B would write Oct for the month of October

%C
long month name with blank padding (January through December) (for example, December).

%d
day of the month.

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0d).

%e
day of the month as a two-character decimal number with leading spaces (" 1"- "31") (for example, " 2").

%F
full weekday name with blank padding.

%G
year as a four-digit decimal number (for example, 2008). If the week that contains January 1 has four or more days in the new year, then it is considered week 1 in the new year. Otherwise, it is the last week of the previous year and the year is considered the previous year.

%H
hour (24-hour clock).

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0H).

Tip When DATETYPE=DATETIME, SAS uses datetime hours 00:00–23:59. When DATETYPE=DATETIME_UTIL, SAS uses datetime hours 00:00:01–24:00:00 and 24:00:00 is

midnight at the end of the day. The hour 00:00:00 is not in the hour range and if used, converts to 24:00:00 of the previous day. When you specify DATETIME, 00:00:00 is midnight of a new day and the value 24:00:00 is midnight of the next day.

Example "Example 7: Change the 24–Hour Clock to 00:00:01–24:00:00" on page 1159

%l
hour (12-hour clock).

Alias %i

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0l).

%j
day of the year as a decimal number (1–366), with leading zero.

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0j).

%m
month (1–12).

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0m).

%M
minute (0–59).

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0M).

%n
number of days in a duration as a decimal number (maximum of 10 digits) (for example, 25).

Restriction This directive is not valid for DBCS and Unicode SAS sessions.

%o
month (1-12) with blank padding (for example, " 2").

%p
equivalent to either a.m. or p.m.

%q
abbreviated quarter of the year string such as 1, 2, 3, or 4.

%Q
quarter of the year string, such as Quarter1, Quarter2, Quarter3, or Quarter4.

%s

fractional seconds as decimal digits (for example, .39555). The number of digits formatted is the number of digits to the right of the decimal point that is specified when you use the format. SAS rounds fractional seconds to accommodate the number of digits specified for fractional seconds.

Restriction This directive is not valid for DBCS and Unicode SAS sessions.

Interaction The %s and %S directives cannot be used together.

Tips The %s directive displays both whole and fractional seconds.

To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0s).

%S

seconds (0–59), allowing for possible leap seconds.

Interaction The %s and %S directives cannot be used together.

Tips The %S directive displays whole seconds. It does not display fractional seconds.

To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0S).

Example 58 and 59.07

%u

weekday as a one-digit decimal number (1–7 (Monday - Sunday)) (for example, Sunday=7).

%U

week number of the year as a decimal number (0–53). Sunday is considered the first day of the week.

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0U).

%V

week number (01–53) with the first Monday as the start day of the first week. Minimum days of the first week is 4.

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0SV).

%w

weekday as a one-digit decimal number (0–6 (Sunday through Saturday)) (for example, Sunday=0).

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0w).

%W
week number (0–53) with the first Monday as the start day of the first week.

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0W).

%y
year without century (0–99) (for example, 93).

Note To add a leading zero before a single-digit number, insert a 0 before the directive (for example, %0y).

%Y
year with century as a four-digit decimal number (1970–2069) (for example, 1994).

%z
UTC time-zone offset.

%Z
time-zone name.

%%
the % character.

Tip Add code to your program to direct how you want missing values to be displayed.

Interaction If you specify LANGUAGE= and PICTURE= in the format definition, the format supports only English and the European languages. To use a user-defined format in languages other than those that are supported by the LANGUAGE= option, use the PICTURE= statement. Do not specify the LANGUAGE= option. The language of a picture format is determined by the locale setting.

Details

Building a Picture Format: Step by Step

This section shows how to write a picture format that eliminates leading zeros. In the SAMPLE data set, the default printing of the variable Amount has leading zeros on numbers between 1 and –1. The PICTURE statement defines two similar formats that eliminate leading zeros on numbers between 1 and –1. The difference between the two formats is that the NOZEROSR. format specifies the ROUND option to round numbers and the NOZEROS. format does not round numbers.

This program creates, sorts, and prints the sample data set:

```
data sample;
   input Amount;
   datalines;
-2.051
```

```
-.05
-.017
  0
.093
.54
.556
6.6
14.63
0.996
-0.999
-45.00
;
run;

proc sort data=sample;
   by amount;
run;

proc print data=sample;
   title 'Default Printing of the Variable Amount';
run;
```

Default Printing of the Variable Amount

Obs	Amount
1	-45.000
2	-2.051
3	-0.999
4	-0.050
5	-0.017
6	0.000
7	0.093
8	0.540
9	0.556
10	0.996
11	6.600
12	14.630

Here is the PROC FORMAT step that creates the NOZEROSR. and NOZEROS. formats. Both formats eliminate leading zeros in the formatted values. The NOZEROSR. format specifies the ROUND option to round numbers. The NOZEROS. format does not perform rounding.

```
libname library 'SAS-library';

proc format;
```

```
  picture nozerosR (round fuzz=0)
    low -  -1      =  '000.00' (prefix='-')
    -1 < - < -.99  =  '0.99'  (prefix='-' mult=100)
    -0.99 <-<  0   =  '99'    (prefix='-.' mult=100)
               0   =  '9.99'
     0 <  -< .99   =  '99'    (prefix='.' mult=100)
     0.99 - < 1    =  '0.99'  (mult=100)
     1  - high     =  '09.99';

  picture nozeros (fuzz=0)
    low -  -1      =  '000.00' (prefix='-')
    -1 < - < -.99  =  '0.99'  (prefix='-.' mult=100)
    -0.99 <-<  0   =  '99'    (prefix='-.' mult=100)
               0   =  '9.99'
     0 <  -< .99   =  '99'    (prefix='.' mult=100)
     0.99 - < 1    =  '0.99'  (prefix='.' mult=100)
     1  - high     =  '09.99';

run;
```

The following table explains how one value from each range is formatted. For an illustration of each step, see Table 30.74 on page 1117.

Table 30.2 *Building a Picture Format*

Step	Rules for Processing the PICTURE Statement	In This Example
1	Determine into which range the value falls and use that picture.	In the second range, the exclusion operator < appears on both sides of the hyphen and excludes −1 and -.99 from the range. The third range excludes 0 and .99. The fourth range excludes 1. Because exclusion operators are used, the FUZZ=0 option is specified.
2	Take the absolute value of the numeric value.	Because the absolute value is used, you need a separate range and picture for the negative numbers in order to prefix the minus sign.
3	Multiply the number by the MULT= value. If you do not specify the MULT= option, then the PICTURE statement uses the default. The default is 10^n, where *n* is the number of digit selectors to the right of the decimal in the picture. (Step 6 discusses digit selectors further.) [1]	Specifying a MULT= value is necessary for numbers between 0 and 1 and numbers between 0 and −1 because no decimal appears in the pictures for those ranges. Because MULT= defaults to 1, truncation of the significant digits results without a MULT= value specified. (Truncation is explained in the next step.) For the three ranges that do not have MULT= values specified, the MULT= value defaults to 100 because the corresponding picture has two digit selectors to the right of the decimal. After the

Step	Rules for Processing the PICTURE Statement	In This Example
		MULT= value is applied, all significant digits are moved to the left of the decimal.
4	If the number is within 10^{-8} of a higher integer, round the number up. This operation is performed before the ROUND option is performed. The ROUND option is in effect. The format rounds the number after the decimal to the next highest integer if the number after the decimal is greater than or equal to .5.	Because the example uses MULT= values that ensured that all of the significant digits were moved to the left of the decimal, no significant digits are lost. The zeros are truncated. 205.1 is rounded to 205. 55.6 is rounded up to 56. 99.6 is rounded up to 100. Rounding is not performed on 5 and 660.
4a	When the ROUND option is not performed, the numbers after the decimal are truncated.	205.1 is truncated to 205. 55.6 is truncated to 55. 99.6 is truncated to 99.
5	Turn the number into a character string. If the number is shorter than the picture, then the length of the character string is equal to the number of digit selectors in the picture. Pad the character string with leading zeros. (The results are equivalent to using the Z*w.* format. Z*w.* is explained in the section on SAS formats in *SAS Formats and Informats: Reference*.	205 becomes the character string 00205. 5 becomes the character string 05. 56 becomes the character string 56. 100 becomes the character string 100. 660 becomes the character string 0660. When the picture is longer than the numbers, the format adds a leading zero to the value. The format does not add leading zeros to the character string 56 and 100 because the corresponding picture has the same number of selectors.
5a		205 becomes the character string 00205. 5 becomes the character string 05. 55 becomes the character string 55. 99 becomes the character string 099. 660 becomes the character string 0660. When the picture is longer than the numbers, the format adds a leading zero to the value. The format does not add leading zeros to the character string 55 because the corresponding picture has the same number of selectors.

Step	Rules for Processing the PICTURE Statement	In This Example
6	Apply the character string to the picture. The format maps only the rightmost *n* characters in the character string, where *n* is the number of digit selectors in the picture. Thus, it is important to make sure that the picture has enough digit selectors to accommodate the characters in the string. After the format takes the right-most *n* characters, it then maps those characters to the picture from left to right. Choosing a zero or nonzero-digit selector is important if the character string contains leading zeros. If one of the leading zeros in the character string maps to a nonzero-digit selector, then it and all subsequent leading zeros and message characters become part of the formatted value. If all of the leading zeros map to zero-digit selectors, then none of the leading zeros or message characters become part of the formatted value. The format replaces the leading zeros in the character string with blanks. [2]	00205 is mapped to 2.05. 05 is mapped to 05. 56 is mapped to 56. 100 is mapped to 1.00. 0660 is mapped to 6.60. The leading zero is dropped from the character strings `00205` and `0660` because the leading zero maps to a zero-digit selector in the picture.
6a		00205 is mapped to 2.05. 05 is mapped to 05. 55 is mapped to 55. 099 is mapped to 99. 0660 is mapped to 6.60. The leading zero is dropped from the character strings `00205`, `099`, and `0660`, because the leading zero maps to a zero-digit selector in the picture.

Step	Rules for Processing the PICTURE Statement	In This Example
		The period (.) message character in the 0.99 picture is dropped because the leading zero maps to a zero-digit selector. Because the period message character is dropped, the format definition for the range 0.99 – < 1 requires a prefix of '.' in the NOZEROS. format to format a decimal number.
7	Prefix any characters that are specified in the PREFIX= option. You need the PREFIX= option because when a picture contains any digit selectors, the picture must begin with a digit selector. Thus, you cannot begin your picture with a decimal point, minus sign, or any other character that is not a digit selector.	The PREFIX= option reclaims the decimal point and the negative sign, as shown with the formatted values `-2.05`, `-.05` and `.56`.
7a		The PREFIX= option reclaims the decimal point and the negative sign, as shown with the formatted values `-2.05`, `-.05`, `.55`, and `.99`.

1 A decimal in a PREFIX= option is not part of the picture.
2 You can use the FILL= option to specify a character other than a blank to become part of the formatted value.

Table 30.3 *Steps to Format Various Values*

Step	Action	-2.051	-.05	.556	.996	6.6
1	Range	low – –1	–0.99 < – < 0	0 < – < .99	0.99 – < 1	1 – high
	Picture	000.00	99	99	0.99	09.99
2	Absolute value	2.051	.05	.556	.996	6.6
3	MULT=	$2.051\times10^{2}=205.1$	.05×100=5	.556×100=55.6	.996×100=99.6	$6.6\times10^{2}=660$
4	Round	205	5	56	100	660
4a	No Rounding	205	5	55	99	660

Step	Action	-2.051	-.05	.556	.996	6.6
5	Character string, rounding	00205	05	56	100	0660
5a	Character string, no rounding	00205	05	55	099	0660
6	Template, rounding	2.05	05	56	1.00	6.60
6a	Template, no rounding	2.05	05	55	99	6.60
7	Prefix, rounding	prefix='–'	prefix='–.'	prefix='.'	none	none
7a	Prefix, no rounding	prefix='–'	prefix='–.'	prefix='.'	prefix='.'	none
	Formatted result, rounding	–2.05	–.05	.56	1.00	6.60
	Formatted results, no rounding	–2.05	–.05	.55	.99	6.60

The following PROC PRINT steps associates the NOZEROSR. format and the NOZEROS. format with the AMOUNT variable in SAMPLE. The first output shows the result of rounding.

```
proc print data=sample;
   format amount nozerosr.;
   title 'Formatting the Variable Amount';
   title2 'with the NOZEROSR. Format Using Rounding';
run;

proc print data=sample;
   format amount nozeros.;
   title 'Formatting the Variable Amount';
   title2 'with the NOZEROS. Format, No Rounding';
run;
```

Formatting the Variable Amount with the NOZEROSR. Format Using Rounding

Obs	Amount
1	-45.00
2	-2.05
3	-1.00
4	-.05
5	-.02
6	00
7	.09
8	.54
9	.56
10	1.00
11	6.60
12	14.63

Formatting the Variable Amount with the NOZEROS. Format, No Rounding

Obs	Amount
1	-45.00
2	-2.05
3	-.99
4	-.05
5	-.01
6	00
7	.09
8	.54
9	.55
10	.99
11	6.60
12	14.63

CAUTION
The picture must be wide enough for the prefix and the numbers. In this example, if the value –45.00 were formatted with NOZEROS., then the result would be 45.00 because it falls into the first range, low – –1, and the picture for that range is not wide enough to accommodate the prefixed minus sign and the number.

CAUTION
The picture must be wide enough for an additional digit if rounding a number adds a digit to the number. For example, the picture for the number .996 could be '99' (prefix '.' mult=100). After rounding the number and multiplying it by 100, the resulting number is 100. When the picture is applied, the result is .00, an inaccurate number. In order to ensure accuracy of numbers when you round numbers, make the picture wide enough to accommodate larger numbers.

Specifying No Picture

This PICTURE statement creates a *picture-name* format that has no picture:

```
picture picture-name;
```

Using this format has the effect of applying the default SAS format to the values.

SELECT Statement

Selects entries for processing by the FMTLIB and CNTLOUT= options.

Restrictions: Only one SELECT statement can appear in a PROC FORMAT step.

You cannot use a SELECT statement and an EXCLUDE statement within the same PROC FORMAT step.

Example: "Example 15: Printing the Description of Informats and Formats" on page 1183

Syntax

SELECT *entry(s)*;

Required Argument

entry(s)
specifies one or more catalog entries for processing. Catalog entry names are the same as the name of the informat or format that they store. Because informats and formats can have the same name, and because character and numeric informats or formats can have the same name, you must use certain prefixes when specifying informats and formats in the SELECT statement. Follow these rules when specifying entries in the SELECT statement:

- Precede names of entries that contain character formats with a dollar sign ($).

- Precede names of entries that contain character informats with an at sign and a dollar sign (for example, @$*entry-name*).
- Precede names of entries that contain numeric informats with an at sign (@).
- Specify names of entries that contain numeric formats without a prefix.

Details

Shortcuts to Specifying Names

You can use the colon (:) and hyphen (-) wildcard characters to select entries. For example, the following SELECT statement selects all formats or informats that begin with the letter **a**.

```
select a:;
```

In addition, the following SELECT statement selects all formats or informats that occur alphabetically between **apple** and **pear**, inclusive:

```
select apple-pear;
```

How the FMTLIB and CNTLOUT= Options Affect Whether a Catalog Is Opened in Read or Update Mode

Using the FMTLIB and CNTLOUT= options in the SELECT statement indicates whether a catalog is opened for Read or Update mode. The following rules apply:

- If you use the SELECT statement and do not specify the FMTLIB option or the CNTLOUT= option, PROC FORMAT assumes that the catalog is opened in Update mode.
- If you use the SELECT statement and specify the FMTLIB option or the CNTLOUT= option, the catalog is opened for Read access.
- If you use the SELECT statement without the FMTLIB option or the CNTLOUT= option, and the SAS program does not have Write access to the catalog, the following error is written to the SAS log:

```
ERROR: User does not have appropriate authorization level
       for file libref.FORMATS.CATALOG.
```

VALUE Statement

Creates a format that specifies character strings to use to print variable values.

See: *SAS Formats and Informats: Reference* for documentation about SAS formats.

Examples: "Example 8: Creating a Format for Character Values" on page 1160

"Example 11: Writing a Format for Dates Using a Standard SAS Format and a Color Background" on page 1167

"Example 17: Writing Ranges for Character Strings" on page 1187

Syntax

VALUE <$>*name* <(*format-options*)> <*value-range-set(s)*>;

Summary of Optional Arguments

DEFAULT=*length*
: specifies the default length of the format.

FUZZ=*fuzz-factor*
: specifies a fuzz factor for matching values to a range.

MAX=*length*
: specifies a maximum length for the format.

MIN=*length*
: specifies a minimum length for the format.

MULTILABEL
: enables the assignment of multiple labels or external values to internal values.

NOTSORTED
: stores values or ranges in the order in which you define them.

value-range-set(s)
: specifies the assignment of a value or a range of values to a formatted value.

Required Argument

name
names the format that you are creating. If you created a function using the FCMP procedure to use as a format, *name* is the function name without parenthesis.

Restrictions
: The name of a user-defined format cannot be the same as the name of a format that is supplied by SAS.

  Format names cannot end in a number. For more information, see "User-Defined Formats" in *SAS Formats and Informats: Reference* and "Names in the SAS Language" in *SAS Language Reference: Concepts*.

Requirement
: The name must be a valid SAS name. A numeric format name can be up to 32 characters in length. A character format name can be up to 31 characters in length. If you are creating a character format, then use a dollar sign ($) as the first character.

Interaction
: The maximum length of a format name is controlled by the VALIDFMTNAME= system option. See *SAS System Options: Reference* for details.

Tip Refer to the format later by using the name followed by a period. However, do not use a period after the format name in the VALUE statement.

See "Using a Function to Format Values" on page 1132

Optional Arguments

DEFAULT=*length*

specifies the default length of the format. The value for DEFAULT= becomes the length of the format if you do not give a specific length when you associate the format with a variable.

Default The length of the longest label that is assigned to the right of the equal sign

Range 1–32767

Tip As a best practice, always specify the DEFAULT= option if you specify a format as a label.

FUZZ=*fuzz-factor*

specifies a fuzz factor for matching values to a range. If a number does not match or fall in a range exactly but comes within *fuzz-factor*, then the format considers it a match. For example, the following VALUE statement creates the LEVELS. format, which uses a fuzz factor of .2:

```
value levels (fuzz=.2) 1='A'
                       2='B'
                       3='C';
```

FUZZ=.2 means that if a variable value falls within .2 of a value on either end of the range, then the format uses the corresponding formatted value to print the variable value. So the LEVELS. format formats the value 2.1 as `B`.

Default 1E−12 for numeric formats and 0 for character formats.

Tips Specify FUZZ=0 to save storage space when you use the VALUE statement to create numeric formats.

Use a nonzero fuzz factor only with numbers that are very close but not an exact match. Ranges are stored internally in sorted order (unless the NOTSORTED option is used), in order to perform a binary search. When a fuzz-factor is added to the end of one range and subtracted from the beginning of the next range, and the ranges overlap, the results can be unpredictable. A value is placed in the first range that is a match in the binary search. The exclusion operator is insufficient to override this binary search algorithm. As a best practice, when you use the exclusion operator, set FUZZ=0 or the NOTSORTED option

A best practice is to use FUZZ=0 when you use the < exclusion operator with numeric formats.

MAX=*length*
specifies a maximum length for the format. When you associate the format with a variable, you cannot specify a width greater than the MAX= value.

Default 40

Range 1–32767

MIN=*length*
specifies a minimum length for the format.

Default 1

Range 1–32767

MULTILABEL
enables the assignment of multiple labels or external values to internal values. The following VALUE statements show the two uses of the MULTILABEL option. The first VALUE statement assigns multiple labels to a single internal value. Multiple labels can also be assigned to a single range of internal values. The second VALUE statement assigns labels to overlapping ranges of internal values. The MULTILABEL option allows the assignment of multiple labels to the overlapped internal values.

```
value one (multilabel)
    1='ONE'
    1='UNO'
    1='UN';

  value agefmt (multilabel)
    15-29='below 30 years'
    30-50='between 30 and 50'
    51-high='over 50 years'
    15-19='15 to 19'
    20-25='20 to 25'
    25-39='25 to 39'
    40-55='40 to 55'
    56-high='56 and above';
```

Only multilabel-enabled procedures such as PROC MEANS, PROC SUMMARY, and PROC TABULATE can use multiple labels. All other procedures and the DATA step recognize only the primary label.

The primary label for a given entry is the external value that is assigned to the first internal value or range of internal values that matches or contains the entry when all internal values are ordered sequentially. Here is an example:

- In the first VALUE statement, the primary label for 1 is ONE because ONE is the first external value that is assigned to 1. The secondary labels for 1 are UNO and UN.
- In the second VALUE statement, the primary label for 33 is **`25 to 39`** because the range 25–39 is sequentially the first range of internal values that contains 33. The secondary label for 33 is **`between 30 and 50`** because the range 30–50 occurs in sequence after the range 25–39.

Restriction The maximum number of labels that can be created for a single format is 255.

NOTSORTED
stores values or ranges in the order in which you define them. If you do not specify NOTSORTED, then values or ranges are stored in sorted order by default, and SAS uses a binary searching algorithm to locate the range that a particular value falls into. If you specify NOTSORTED, then SAS searches each range in the order in which you define them until a match is found.

Use NOTSORTED if one of the following is true:

- You know the likelihood of certain ranges occurring, and you want your format to search those ranges first to save processing time.
- You want to preserve the order that you define ranges when you print a description of the format using the FMTLIB option.
- You want to preserve the order that you define ranges when you use the ORDER=DATA option and the PRELOADFMT option to analyze class variables in PROC MEANS, PROC SUMMARY, or PROC TABULATE.

Do not use NOTSORTED if the distribution of values is uniform or unknown, or if the number of values is relatively small. The binary searching algorithm that SAS uses when NOTSORTED is not specified optimizes the performance of the search under these conditions.

SAS automatically sets the NOTSORTED option when you use the CPORT and CIMPORT procedures to transport formats between operating environments with different standard collating sequences. This automatic setting of NOTSORTED can occur when you transport formats between ASCII and EBCDIC operating environments. If this situation is undesirable, then do the following:

- Use the CNTLOUT= option in the PROC FORMAT statement to create an output control data set.
- Use the CPORT procedure to create a transport file for the control data set.
- Use the CIMPORT procedure in the target operating environment to import the transport file.
- In the target operating environment, use PROC FORMAT with the CNTLIN= option to build the formats from the imported control data set.

value-range-set(s)
specifies the assignment of a value or a range of values to a formatted value. The *value-range-set(s)* have the following form:

value-or-range-1 <, *value-or-range-2*, ...>=*formatted-value* | [*existing-format*] | [*functionname*]

The variable values on the left side of the equal sign prints as the character string on the right side of the equal sign. The maximum length of each *value-or-range* to the left of the equal sign is 32,767 characters.

value-or-range
For details about how to specify *value-or-range*, see "Specifying Values or Ranges" on page 1129.

formatted-value

specifies a character string that becomes the printed value of the variable value that appears on the left side of the equal sign. Formatted values are always character strings, regardless of whether you are creating a character or numeric format.

Formatted values can be up to 32,767 characters. For hexadecimal literals, you can use up to 32,767 typed characters, or up to 16,382 represented characters at 2 hexadecimal characters per represented character. Some procedures, however, use only the first 8 or 16 characters of a formatted value.

Requirements You must enclose a formatted value in single or double quotation marks. The following example shows a formatted value that is enclosed in double quotation marks:

```
value $ score
   'M'="Male"
   'F'="Female";
```

If a formatted value contains a single quotation mark, then enclose the value in double quotation marks:

```
value sect
   1="Smith's class"
   2="Leung's class";
```

Tip Formatting numeric variables does not preclude the use of those variables in arithmetic operations. SAS uses stored values for arithmetic operations.

existing-format

specifies a format that is supplied by SAS or an existing user-defined format. The format that you are creating uses the existing format to convert the raw data that is a match for *value-or-range* on the left side of the equal sign.

Using an existing format can be thought of as nesting formats. A nested level of one means that if you are creating the format A with the format B as a formatted value, then the procedure has to use only one existing format to create A.

Requirement If you use an existing format, then enclose the format name in square brackets (for example, [date9.]) or with parentheses and vertical bars (for example, (|date9.|)). Do not enclose the name of the existing format in single quotation marks.

Tips Avoid nesting formats more than one level. The resource requirements can increase dramatically with each additional level.

As a best practice, if you specify an existing format in *value-range-set*, always specify a default value by using the DEFAULT= option on page 1123.

functionname
specifies a function that is supplied by SAS or an existing user-defined function.

Tips As a best practice, you should define the default length.

If you create a function using the FCMP procedure to use as a format, *name* is the function name without parenthesis.

See "Using a Function to Format Values"

Examples

Example 1: Create a Format to Print Postal Codes for Selected States

The $STATE. character format prints the postal code for selected states:

```
value $state 'Delaware'='DE'
             'Florida'='FL'
             'Ohio'='OH';
```

The variable value **Delaware** prints as **DE**, the variable value **Florida** prints as **FL**, and the variable value **Ohio** prints as **OH**. Note that the $STATE. format begins with a dollar sign.

Note: Range specifications are case sensitive. In the $STATE. format above, the value **OHIO** would not match any of the specified ranges. If you are not certain what case the data values are in, then one solution is to use the UPCASE function on the data values and specify all uppercase characters for the ranges.

Example 2: Write Numeric Values as Character Values

The numeric format ANSWER. writes the values 1 and 2 as yes and no:

```
value answer 1='yes'
             2='no';
```

Example 3: Specifying No Ranges

This VALUE statement creates a *format-name* format that has no ranges:

```
value format-name;
```

Using this format has the effect of applying the default SAS format to the values.

Example 4: Create a Format Using Existing SAS Formats as Labels

This program creates the MYfmt. format to format dates based on the year.

Note: If the format-as-label or function-as-label is within square brackets, then it is referred to as nested. A format specification in square brackets is followed by at least a period, for example, `[year.]`. A function specification in square brackets is followed by parentheses, for example, `[year()]`. SAS uses the nested format to format the values in the range. For example, see `low-'31DEC2011'd=[year4.]` in the following example. For another example that uses nested formats, see "Example 5: Create a Format for Missing and Nonmissing Values Using an Existing SAS Format as a Label" on page 1128.

```
data test;
  do Date='01jan2006'd to '31dec2013'd;
    do j=1 to rannor(0)*100;
       output;
    end;
  end;
run;
proc format;
   value MYfmt
        /* Format dates prior to 31DEC2011 using only a year. */
        low-'31DEC2011'd=[year4.]

        /* Format 2012 dates using the month and year. */
        '01jan2012'd-'31DEC12'd=[monyy7.]

        /* Format dates 01JAN2013 and beyond using the day, month, and
year. */
        '01JAN2013'd-high=[date9.]

        /* Catch missing values. */
        other='n/a';
run;

proc freq data=test;
      table date /missing;
      format date myfmt.;
run;
```

Example 5: Create a Format for Missing and Nonmissing Values Using an Existing SAS Format as a Label

This program formats missing numeric values with the label N/A, and formats nonmissing values with the existing SAS format 12.1.

```
proc format;
      value myfmt .='N/A' other=[12.1];
run;
```

Usage: FORMAT Procedure

Specifying Values or Ranges

As the syntax of the INVALUE, PICTURE, and VALUE statements indicates, you must specify values as *value-range-sets*. On the left side of the equal sign, you specify the values that you want to convert to other values. On the right side of the equal sign, you specify the values that you want the values on the left side to become. This section discusses the different forms that you can use for *value-or-range*, which represents the values on the left side of the equal sign. For details about how to specify values for the right side of the equal sign, see the "Required Arguments" section for the appropriate statement.

The INVALUE, PICTURE, and VALUE statements accept numeric values on the left side of the equal sign. In character informats, numeric ranges are treated as character strings. INVALUE and VALUE also accept character strings on the left side of the equal sign.

As the syntax shows, you can have multiple occurrences of *value-or-range* in each *value-range-set*, using a comma to separate the occurrences. Each occurrence of *value-or-range* is either one of the following:

value
a single value, such as 12 or **'CA'**. For character formats and informats, enclose the character values in single quotation marks.

You can use the keyword OTHER= as a single value. OTHER= matches all values that do not match any other value or range. OTHER= includes missing values for both numeric and character user-defined formats. You cannot nest a user-defined format by using the format as the value of OTHER=, unless the format is a function that formats values.

If you specify a format that is too narrow to represent a value, then SAS tries to fit the longer label into the available space. SAS truncates character values on the right, and it sometimes reverts numeric values to the BEST*w.d* format. If you do not specify an adequate width for a format, then SAS prints asterisks in the output. In this example, the specified value is two characters, DK. The width of DK is not adequate for the five-character 99999 value, and SAS prints two asterisks in the output.

```
proc format;
   value fmtzip 99999="DK";

data testzip;
   zip=27609;
   output;
```

```
   zip=99999;
   output;
run;

proc print data=testzip;
   format Zip fmtzip.;
run;
```

The result of `zip=99999;` is that `**` appears in the first observation of the column labeled “Zip” in the output table.

One way to prevent this problem from occurring is to assign a width when you apply the format, as in this example.

```
proc format;
   value fmtzip 99999="DK";

data testzip;
   zip=27609;
   output;
   zip=99999;
   output;
run;

proc print data=testzip;
   format Zip fmtzip5.;
run;
```

The result of `format Zip fmtzip5.;` is that adequate space is specified for `27609` to appear correctly in the first observation of the column labeled “Zip” in the output table.

You can also prevent the problem by specifying the DEFAULT or MIN options when you create the format, as in this example.

```
proc format;
   value fmtzip (default=5) 99999="DK";

data testzip;
   zip=27609;
   output;
   zip=99999;
   output;
run;

proc print data=testzip;
   format Zip fmtzip5.;
run;
```

The result of including `(default=5)` in the value specification is that adequate space is specified for `27609` to appear correctly in the first observation of the column labeled “Zip” in the output table.

Adding blank spaces at the end of a specified value increases the width of the value. For example, the specified value DK is not wide enough for 99999. Adding three blank spaces to the value when you specify DK provides five spaces for the 99999 value.

Note: If you add blank spaces to a specified value, be sure to add enough blank spaces to accommodate the longest value that the format might handle.

For more information about how SAS formats widths, see "Syntax " in *SAS Formats and Informats: Reference*.

For more information about format values, see "Using a Function to Format Values" on page 1132. For examples, see "Example 8: Creating a Format for Character Values" on page 1160 and "Example 20: Creating a Function to Use as a Format" on page 1198.

range
a list of values (for example, 12–68 or **'A'-'Z'**). For ranges with character strings, be sure to enclose each string in single quotation marks. For example, if you want a range that includes character strings from A to Z, then specify the range as **'A'-'Z'**, with single quotation marks around the **A** and around the **Z**.

If you specify **'A-Z'**, then the procedure interprets it as a three-character string with **A** as the first character, a hyphen (-) as the second character, and a **Z** as the third character.

In numeric user-defined informats, the procedure interprets an unquoted numeric range on the left side of a *value-range-set* as a numeric range. In a character user-defined informat, the procedure interprets an unquoted numeric range on the left side of a **value-range-set** as a character string. For example, in a character informat, the range **12–86** is interpreted as **'12'–'86'**.

You can use LOW or HIGH as one value in a range, and you can use the range LOW-HIGH to encompass all values. For example, the following are valid ranges:

```
low-'ZZ'
35-high
low-high
other
```

In numeric ranges, LOW includes the lowest numeric value, excluding missing values. HIGH includes the largest value in the range. In character ranges, LOW includes missing values. OTHER includes missing values for both numeric and character formats.

You can use the less than (<) symbol to exclude values from ranges. If you are excluding the first value in a range, then put the < exclusion operator after the value. If you are excluding the last value in a range, then put the < exclusion operator before the value. For example, the following range does not include 0:

```
0<-100
```

Likewise, the following range does not include 100:

```
0-<100
```

> **TIP** When you use the < exclusion operator to place values in ranges, use the option FUZZ=0 in the VALUE statement for numeric formats. This is not necessary for character formats because FUZZ=0 is the default.

If a value at the high end of one range also appears at the low end of another range, and you do not use the < exclusion operator, then PROC FORMAT assigns the value to the first range. For example, in the following ranges, the value **AJ** is part of the first range:

```
'AA'-'AJ'=1 'AJ'-'AZ'=2
```

In this example, to include the value **AJ** in the second range, use the < exclusion operator on the first range:

```
'AA'-<'AJ'=1 'AJ'-'AZ'=2
```

If you overlap values in ranges, then PROC FORMAT returns an error message unless, for the VALUE statement, the MULTILABEL option is specified. For example, the following ranges will cause an error: `'AA'-'AK'=1 'AJ'-'AZ'=2`.

Each *value-or-range* can be up to 32,767 characters. If *value-or-range* has more than 32,767 characters, then the procedure truncates the value after it processes the first 32,767 characters.

Note: You do not have to account for every value on the left side of the equal sign. Those values are converted using the default informat or format. For example, the following VALUE statement creates the TEMP. format, which prints all occurrences of 98.6 as **NORMAL**:

```
value temp 98.6='NORMAL';
```

If the value were 96.9, then the printed result would be **96.9**.

Using a Function to Format Values

SAS provides a way to format a value by first performing a function on a value. By using a function to format values, you can create customized formats. For example, SAS provides four formats to format dates by quarters, YYQ*w*., YYQ*xw*., YYQR*w*., and YYQR*xw*. None of these formats satisfy your requirement to use Q1, Q2, Q3, or Q4. You can create a function using the FCMP procedure that creates the Q1, Q2, Q3, and Q4 values based on a date and a SAS format, and then use that function in the FORMAT procedure to create a format.

Here are the steps to create and use a function to format values:

1. Use the FCMP procedure to create the function.
2. Use the OPTIONS statement to make the function available to SAS by specifying the location of the function in the CMPLIB= system option.

3 Use the FORMAT procedure to create a new format.

4 Use the new format in your SAS program.

Here is an example:

```
/* Create a function that creates the value Qx from a formatted value.
*/

proc fcmp outlib=work.functions.smd;

   function qfmt(date) $;
      length qnum $4;
      qnum=put(date,yyq4.);
      if substr(qnum,3,1)='Q'
         then return(substr(qnum,3,2));
      else return(qnum);
   endsub;
run;

/* Make the function available to SAS. */

options cmplib=(work.functions);

/* Create a format using the function created by the FCMP procedure. */

proc format;
   value qfmt
         other=[qfmt()]; run;

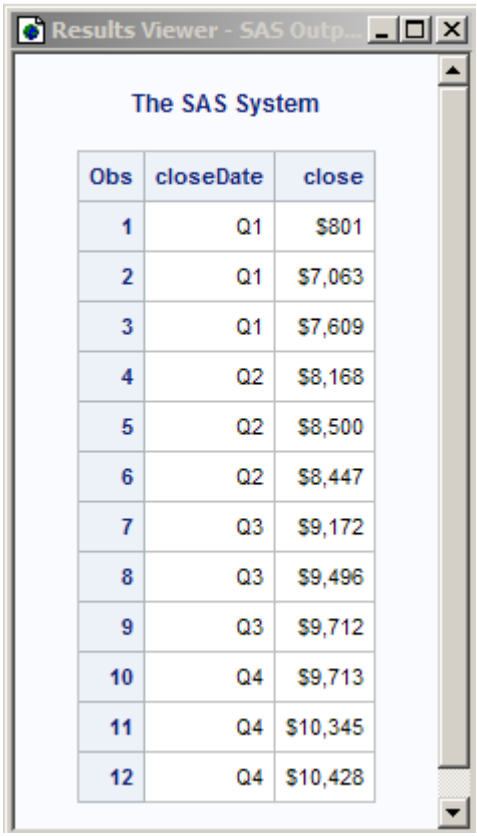
/* Use the format in a SAS program.  */

data djia2013;
      input closeDate date7. close;
      datalines;
01jan13 800.86
02feb13 7062.93
02mar13 7608.92
01apr13 8168.12
01may13 8500.33
01jun13 8447.00
01jul13 9171.61
03aug13 9496.28
01sep13 9712.28
01oct13 9712.73
02nov13 10344.84
02dec13 10428.05
run;

proc print data=djia2013;
format closedate qfmt. close dollar9.;
run;
```

Here is the output:

Output 30.1 *Dow Jones Closings by Quarter*



Obs	closeDate	close
1	Q1	$801
2	Q1	$7,063
3	Q1	$7,609
4	Q2	$8,168
5	Q2	$8,500
6	Q2	$8,447
7	Q3	$9,172
8	Q3	$9,496
9	Q3	$9,712
10	Q4	$9,713
11	Q4	$10,345
12	Q4	$10,428

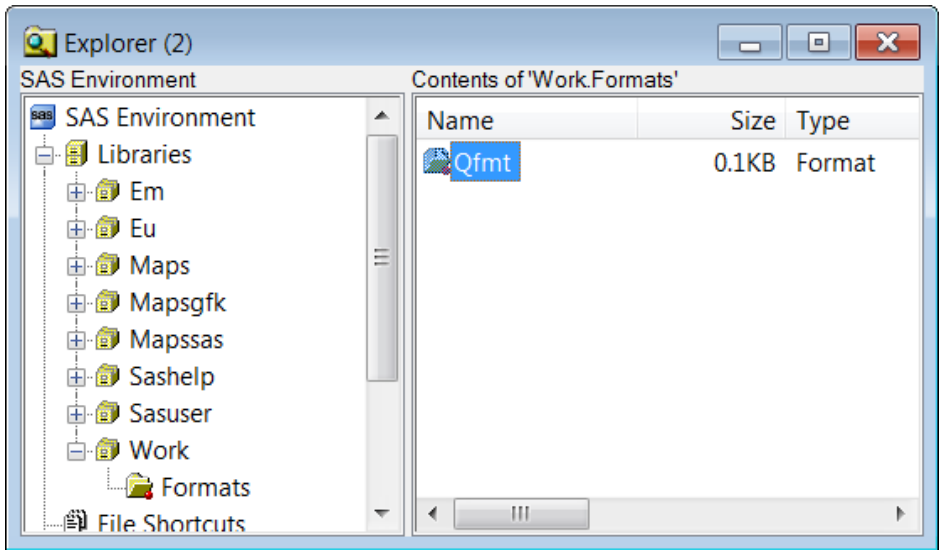
You can use the function format as the value to OTHER=.

Viewing a Format Definition Using SAS Explorer

After you create a format, you can view the definition for the format using SAS Explorer.

1 Select **View** ⇨ **Explorer**.

2 Open the format folder. To view the default format folder, expand **Libraries** ⇨ **Work** and select **Formats**.



3 To view the format description, do one of the following actions on the format name in the contents pane:

- double-click the format name
- right-click the format name and select **View**

The format description appears in the Results Viewer window.

The SAS System

FORMAT NAME: QFMT LENGTH: 6 NUMBER OF VALUES: 1 MIN LENGTH: 1 MAX LENGTH: 40 DEFAULT LENGTH: 6 FUZZ: STD		
START	END	LABEL (VER. V7|V8 11OCT2012:13:08:36)
OTHER	**OTHER**	[QFMT()]

Results: FORMAT Procedure

Output Control Data Set

The output control data set contains information that describes informats or formats. Output control data sets have a number of uses. For example, an output control data set can be edited with a DATA step to programmatically change value ranges or can be subset with a DATA step to create new formats and informats. In addition, you can move formats and informats from one operating environment to another by creating an output control data set, using the CPORT procedure to

create a transfer file of the data set. Then, use the CIMPORT and FORMAT procedures in the target operating environment to create the formats and informats there.

You create an output control data set with the CNTLOUT= option in the PROC FORMAT statement. You use output control data sets, or a set of observations from an output control data set, as an input control data set in a subsequent PROC FORMAT step using the CNTLIN= option.

Output control data sets contain an observation for every value or range in each of the informats or formats in the LIBRARY= catalog. The data set consists of variables that give either global information about each format and informat created in the PROC FORMAT step or specific information about each range and value.

The variables in the output control data set are as follows:

DATATYPE
enables the use of directives in a picture as a template to format date, time, or datetime values.

DECP
specifies the separator character for the fractional part of a number.

DEFAULT
specifies a numeric variable that indicates the default length for format or informat.

DIG3SEP
specifies the three-digit separator character for a number.

END
specifies a character variable that gives the range's ending value.

EEXCL
specifies a character variable that indicates whether the range's ending value is excluded. Valid values are as follows:

Y
specifies that the range's ending value is excluded.

N
specifies that the range's ending value is not excluded.

FILL
for picture formats, specifies a numeric variable whose value is the value of the FILL= option.

FMTNAME
specifies a character variable whose value is the format or informat name.

FUZZ
specifies a numeric variable whose value is the value of the FUZZ= option.

HLO
specifies a character variable that contains range information about the format or informat. The following valid values can appear in any combination:

F
specifies a standard SAS format or informat that is used with a value.

H
specifies that a range's ending value is HIGH.

I
specifies a numeric informat range.

J
specifies justification for an informat.

L
specifies that a range's starting value is LOW.

M
specifies that the MULTILABEL option is in effect.

N
specifies that the format or informat has no ranges, including no OTHER= range.

O
specifies that the range is OTHER.

R
specifies that the ROUND option is in effect.

S
specifies that the NOTSORTED option is in effect.

U
specifies that the UPCASE option for an informat be used.

LABEL
specifies a character variable whose value is associated with a format or an informat.

LANGUAGE
specifies the language that is used for weekdays and months that you can substitute in a date, time, or datetime picture. If you specify a language that is not supported or is invalid, English is used.

LENGTH
specifies a numeric variable whose value is the value of the LENGTH= option.

MAX
specifies a numeric variable whose value is the value of the MAX= option.

MIN
specifies a numeric variable whose value is the value of the MIN= option.

MULT
specifies a numeric variable whose value is the value of the MULT= option.

NOEDIT
for picture formats, specifies a numeric variable whose value indicates whether the NOEDIT option is in effect. Valid values are as follows:

1
specifies that the NOEDIT option is in effect.

0
specifies that the NOEDIT option is not in effect.

PREFIX
for picture formats, specifies a character variable whose value is the value of the PREFIX= option.

SEXCL
specifies a character variable that indicates whether the range's starting value is excluded. Valid values are as follows:

Y
specifies that the range's starting value is excluded.

N
specifies that the range's starting value is not excluded.

START
specifies a character variable that gives the range's starting value.

TYPE
specifies a character variable that indicates the type of format. Possible values are as follows:

C
specifies a character format.

I
specifies a numeric informat.

J
specifies a character informat.

N
specifies a numeric format (excluding pictures).

P
specifies a picture format.

This table specifies TYPE values for creating formats and informats using PROC FORMAT and the CNTLIN option. For example, in Scenario 1 if START=Numeric and LABEL=Numeric, then TYPE=I and you can use the INPUT function to create a numeric column. See "Example 13: Creating a Format from a CNTLIN= Data Set" for an example of creating a format using PROC FORMAT and the CNTLIN option.

Table 30.4 *TYPE Values*

Scenarios	Format/Informat	START	LABEL	TYPE
1	Format	Numeric	Character	N
2	Format	Character	Character	C
3	Informat	Character	Numeric	I
4	Informat	Character	Character	J

The following output shows an output control data set that contains information about all the informats and formats created in the FORMAT procedure examples.

Output 30.2 *Output Control Data Set for PROC FORMAT Examples*

You can use the SELECT or EXCLUDE statement to control which formats and informats are represented in the output control data set. For details, see "SELECT Statement" on page 1120 and "EXCLUDE Statement" on page 1091.

Input Control Data Set

You specify an input control data set with the CNTLIN= option in the PROC FORMAT statement. The FORMAT procedure uses the data in the input control data set to construct informats and formats. Thus, you can create informats and formats without writing INVALUE, PICTURE, or VALUE statements.

The input control data set must have these characteristics:

- For both numeric and character formats, the data set must contain the variables FMTNAME, START, and LABEL, which are described in "Output Control Data Set" on page 1135. The remaining variables are not always required.
- If you are creating a character format or informat, then you must either begin the format or informat name with a dollar sign ($) or specify a TYPE variable with the value `C`.
- If you are creating a PICTURE statement format, then you must specify a TYPE variable with the value `P`.
- If you are creating a format with ranges of input values, then you must specify the END variable. If range values are to be noninclusive, then the variables SEXCL and EEXCL must each have a value of `Y`. Inclusion is the default.
- If you are creating a format with the CNTLIN= option, the value of LOW or OTHER for the START variable and the value of HIGH for the END variable are interpreted as their corresponding keywords of LOW, OTHER, or HIGH. This interpretation occurs whether you specify the values in uppercase or lowercase. If you want the explicit values of LOW, OTHER, or HIGH to be used, then specify the HLO variable with the values as described below.

If you specify `START='LOW'`, and the HLO variable does not contain 'L', then the literal value of LOW is used. If you specify `START='OTHER'`, and the HLO variable does not contain 'O', then the literal value of OTHER is used. If you specify `END='HIGH'`, and the HLO variable does not contain 'H', then the literal value of HIGH is used.

You can create more than one format from an input control data set if the observations for each format are grouped together.

You can use a VALUE, INVALUE, or PICTURE statement in the same PROC FORMAT step with the CNTLIN= option. If the VALUE, INVALUE, or PICTURE statement is creating the same informat or format that the CNTLIN= option is creating, then the VALUE, INVALUE, or PICTURE statement creates the informat or format and the CNTLIN= data set is not used. However, you can create an informat or format with VALUE, INVALUE, or PICTURE and create a different informat or format with CNTLIN= in the same PROC FORMAT step.

For an example featuring an input control data set, see "Example 13: Creating a Format from a CNTLIN= Data Set" on page 1173.

Procedure Output

The FORMAT procedure prints output only when you specify the FMTLIB option or the PAGE option in the PROC FORMAT statement. The printed output is a table for each format or informat entry in the catalog that is specified in the LIBRARY= option. The output also contains global information and the specifics of each value or range that is defined for the format or informat. You can use the SELECT or EXCLUDE statement to control which formats and informats are represented in the FMTLIB output. For details, see "SELECT Statement" on page 1120 and "EXCLUDE Statement" on page 1091. For an example, see "Example 15: Printing the Description of Informats and Formats" on page 1183.

The FMTLIB output shown in the following output contains a description of the $CITY. format, which is created in "Example 8: Creating a Format for Character Values" on page 1160, and the EVALUATION. informat, which is created in "Example 12: Converting Raw Character Data to Numeric Values" on page 1170.

Output 30.3 *Output from PROC FORMAT with the FMTLIB Option*

FORMAT NAME: $CITY LENGTH: 14 NUMBER OF VALUES: 6
MIN LENGTH: 1 MAX LENGTH: 40 DEFAULT LENGTH: 14 FUZZ: 0

START	END	LABEL (VER. V7|V8 12OCT2012:11:33:26)
BR1	BR1	Birmingham UK
BR2	BR2	Plymouth UK
BR3	BR3	York UK
US1	US1	Denver USA
US2	US2	Miami USA
OTHER	**OTHER**	INCORRECT CODE

INFORMAT NAME: @EVALUATION LENGTH: 1
MIN LENGTH: 1 MAX LENGTH: 40 DEFAULT LENGTH: 1 FUZZ: 0

START	END	INVALUE(VER. 9.4 12OCT2012:11:34:18)
C	C	1
E	E	2

INFORMAT NAME: @EVALUATION LENGTH: 1
MIN LENGTH: 1 MAX LENGTH: 40 DEFAULT LENGTH: 1 FUZZ: 0

START	END	INVALUE (CONT'D)
N	N	0
O	O	4
S	S	3

The fields are described below in the order in which they appear in the output, from left to right:

INFORMAT NAME or **FORMAT NAME**
the name of the informat or format. Informat names begin with an at-sign (@).

LENGTH
the length of the informat or format. PROC FORMAT determines the length in the following ways:

- For character informats, the value for LENGTH is the length of the longest raw data value on the left side of the equal sign.
- For numeric informats, the following is true:
  - LENGTH is 12 if all values on the left side of the equal sign are numeric.

- LENGTH is the same as the longest raw data value on the left side of the equal sign.

- For formats, the value for LENGTH is the length of the longest value on the right side of the equal sign.

In the output for $CITY., the LENGTH is 14 because the longest picture is 14 characters.

In the output for @EVALUATION., the length is 1 because 1 is the longest raw data value on the left side of the equal sign.

NUMBER OF VALUES
the number of values or ranges associated with the informat or format. NOZEROS. has 4 ranges, and EVAL. has 5.

MIN LENGTH
the minimum length of the informat or format. The value for MIN LENGTH is 1 unless you specify a different minimum length with the MIN= option.

MAX LENGTH
the maximum length of the informat or format. The value for MAX LENGTH is 40 unless you specify a different maximum length with the MAX= option.

DEFAULT LENGTH
the length of the longest value in the INVALUE or LABEL field, or the value of the DEFAULT= option.

FUZZ
the fuzz factor. For informats, FUZZ always is 0. For formats, the value for this field is STD if you do not use the FUZZ= option. STD signifies the default fuzz value.

START
the beginning value of a range. FMTLIB prints only the first 16 characters of a value in the START and END columns.

END
the ending value of a range. The exclusion sign (<) appears after the values in START and END, if the value is excluded from the range.

INVALUE
appears only for informats and contains the values that have informats. The SAS version specifies the version in which the informat is compatible. The date indicates the date in which the informat was created.

Note: If SAS displays version numbers V7 | V8, then the informat is compatible with those versions. If it is not compatible with earlier releases, the release that created the informat is shown. Version V9 supports long informat names (more than eight characters), and V7 | V8 do not.

LABEL
LABEL appears only for formats and contains either the formatted value or picture. The SAS version specifies the version in which the format is compatible. The date indicates the date in which the format was created.

Note: If SAS displays version numbers V7 | V8, then the format is compatible with those versions. If it is not compatible with earlier releases, the release that created the format is shown. Version V9 supports long format names (more than eight characters), and V7 | V8 do not.

For picture formats, such as NOZEROS., the LABEL section contains the PREFIX=, FILL=, and MULT= values. To note these values, FMTLIB prints the letters **P**, **F**, and **M** to represent each option, followed by the value. For example, in the LABEL section, **P-.** indicates that the prefix value is a hyphen followed by a period.

FMTLIB prints only 40 characters in the LABEL column.

Examples: FORMAT Procedure

Example 1: Create a Format Library in a CAS Session

Features: PROC FORMAT statement option
CASFMTLIB
CAS statement

Details

This example uses the CASFMTLIB option to create a format library in a CAS session. It associates the format library with a table in the WORK directory and assigns a CAS engine libref.

Program

```
cas casauto sessopts=(caslib="casuser");
caslib _all_ assign;

libname proclib cas;
proc format casfmtlib='myformats';
     value hospx
```

```
      1='New_York            '
      2='Massachusetts_General'
      3='Los_Angeles'
      4='Mary_Fletcher';
run;

data clinicalTrial;
  input hospital treatment $ @@;
  severity=rannor(1323)*5 + 10;
  format hospital hospx.;
  cards;
3 B  3 B  3 C   3 C
1 A  1 A  1 A   1 B
1 B  1 B  1 C   1 C
1 C  1 D  1 D   1 D
2 A  2 A  2 A   2 B
2 B  2 B  2 C   2 C
2 C  2 D  2 D   2 D
3 A  3 A  3 A   3 B
3 C  3 D  3 D   3 D
4 A  4 A  4 A   4 B
4 B  4 B  4 C   4 C
4 C  4 D  4 D   4 D
;

data proclib.clinicalTrial;
       set work.clinicalTrial;
run;

proc regselect data=proclib.clinicalTrial;   class treatment hospital;
   model severity=treatment hospital;
run;
```

Program Description

Create a format library in a CAS session. Assign a library with the LIBNAME statement. PROC FORMAT creates a format named *hospx*. The CASFMTLIB option specifies the name of the format library *myformats* in the CAS session.

```
cas casauto sessopts=(caslib="casuser");
caslib _all_ assign;

libname proclib cas;
proc format casfmtlib='myformats';
     value hospx
       1='New_York            '
       2='Massachusetts_General'
       3='Los_Angeles'
       4='Mary_Fletcher';
run;
```

Associate the HOSPX format with a column or variable.

```
data clinicalTrial;
  input hospital treatment $ @@;
  severity=rannor(1323)*5 + 10;
```

```
  format hospital hospx.;
  cards;
3 B  3 B  3 C   3 C
1 A  1 A  1 A   1 B
1 B  1 B  1 C   1 C
1 C  1 D  1 D   1 D
2 A  2 A  2 A   2 B
2 B  2 B  2 C   2 C
2 C  2 D  2 D   2 D
3 A  3 A  3 A   3 B
3 C  3 D  3 D   3 D
4 A  4 A  4 A   4 B
4 B  4 B  4 C   4 C
4 C  4 D  4 D   4 D
;
```

Send actions to the CAS session. The LIBNAME statement assigns a CAS engine libref that is used to identify the table in the REGSELECT procedure step.

```
data proclib.clinicalTrial;
        set work.clinicalTrial;
run;

proc regselect data=proclib.clinicalTrial;   class treatment hospital;
   model severity=treatment hospital;
run;
```

Example 2: Create the Example Data Set

Details

Several examples in this section use the PROCLIB.STAFF data set. In addition, many of the informats and formats that are created in these examples are stored in Library.Formats. The output data set shown in "Output Control Data Set" on page 1135 contains a description of these informats and the formats.

The variables are about a small subset of employees who work for a corporation that has sites in the U.S. and Britain. The data contain the name, identification number, salary (in British pounds), location, and date of hire for each employee.

Program

```
libname proclib 'SAS-library';

data proclib.staff;
   infile datalines dlm='#';
   input Name & $16. IdNumber $ Salary
         Site $ HireDate date8.;
   format hiredate date8.;
   datalines;
Capalleti, Jimmy#  2355# 21163# BR1# 30JAN13
Chen, Len#         5889# 20976# BR1# 18JUN06

;
```

Example 3: Creating a Picture Format

Features:
- PROC FORMAT statement options
  - LIBRARY=
- PICTURE statement options
  - MULT=
  - PREFIX=
- LIBRARY libref
- LOW and HIGH keywords

Data set: PROCIB.STAFF from Example 1

Details

This example uses a PICTURE statement to create a format that prints the values for the variable Salary in the data set PROCLIB.STAFF in U.S. dollars.

Program

```
libname proclib 'SAS-library-1';
libname library 'SAS-library-2';

options nodate pageno=1 linesize=80 pagesize=40;

   proc format library=library;

      picture uscurrency low-high='000,000' (mult=1.61 prefix='$');
   run;
```

```
proc print data=proclib.staff noobs label;

   label salary='Salary in U.S. Dollars';
   format salary uscurrency.;

   title 'PROCLIB.STAFF with a Format for the Variable Salary';
run;
```

Program Description

Assign two SAS library references (PROCLIB and LIBRARY). Assigning a library reference LIBRARY is useful in this case because if you use PROC FORMAT, then SAS automatically searches for informats and formats in any library that is referenced with the LIBRARY libref.

```
libname proclib 'SAS-library-1';
libname library 'SAS-library-2';
```

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Specify that user-defined formats will be stored in the catalog Library.Formats. The LIBRARY= option specifies a SAS catalog that will contain the formats or informats that you create with PROC FORMAT. When you create the library named LIBRARY, SAS automatically creates a catalog named FORMATS inside LIBRARY.

```
proc format library=library;
```

Define the USCURRENCY. picture format. The PICTURE statement creates a template for printing numbers. LOW-HIGH ensures that all values are included in the range. The MULT= statement option specifies that each value is multiplied by 1.61. The PREFIX= statement adds a US dollar sign to any number that you format. The picture contains six digit selectors, five for the salary and one for the dollar sign prefix.

```
   picture uscurrency low-high='000,000' (mult=1.61 prefix='$');
run;
```

Print the PROCLIB.STAFF data set. The NOOBS option suppresses the printing of observation numbers. The LABEL option uses variable labels instead of variable names for column headings.

```
proc print data=proclib.staff noobs label;
```

Specify a label and format for the Salary variable. The LABEL statement substitutes the specific label for the variable in the report. In this case, “Salary in US Dollars” is substituted for the variable Salary for this print job only. The FORMAT statement associates the USCurrency. format with the variable name Salary for the duration of this procedure step.

```
label salary='Salary in U.S. Dollars';
format salary uscurrency.;
```

Specify the title.

```
   title 'PROCLIB.STAFF with a Format for the Variable Salary';
run;
```

Output

Output 30.4 *PROCLIB.STAFF with a Format for the Variable Salary*

PROCLIB.STAFF with a Format for the Variable Salary

Name	IdNumber	Salary in U.S. Dollars	Site	HireDate
Capalleti, Jimmy	2355	$34,072	BR1	30JAN09
Chen, Len	5889	$33,771	BR1	18JUN06

Orfali, Philip	0740	$80,648	US2	16FEB03
Patel, Mary	2398	$56,643	BR3	02FEB90
Smith, Robert	5162	$64,561	BR5	15APR06
Sorrell, Joseph	4421	$62,403	US1	19JUN11
Zook, Carla	7385	$37,010	BR3	18DEC10

Example 4: Creating a Picture Format for Large Dollar Amounts

Features: PICTURE statement option
MULT

Format: BIGMONEY.

Details

This example uses the MULT option of the PICTURE statement to format dollars that displays M, B, or T to indicate millions, billions, and trillions of dollars,

respectively. The example uses exponential notation as well as decimal notation in the format definition.

> **TIP** This example uses dollar values without cents and rounding is not necessary. If your dollar values include cents, you can use the ROUND option in the PICTURE statement to round values to the nearest dollar value. For more information, see "ROUND" on page 1106.

Program

```
proc format;
   picture bigmoney (fuzz=0)
      1E06-<1000000000='0000 M' (prefix='$' mult=.000001)
      1E09-<1000000000000='0000 B' (prefix='$' mult=1E-09)
      1E12-<1000000000000000='0000 T' (prefix='$' mult=1E-012);
run;

data mult;
   do i=5 to 12;
      x=16**i;
      put x=comma20. x= bigmoney.;
   end;
run;
```

Program Description

Create the BIGMONEY format. The BIGMONEY. format defines three value-range sets to format millions, billions, and trillions of dollars. 1E06 is one million, 1E09 is one billion, and 1E12 is one trillion. The < exclusion operator indicates not to include the number that follows in the range. A best practice is to use the FUZZ=0 option when you use the exclusion operator to ensure accurate numbers. For a million dollars, the range is 1,000,000 to 999,999,999. The label that is specified on the right side of the equal sign uses 4 zeros as digit selectors. The zero-digit selector specifies not to print leading zeros. The first digit selector is necessary to print the $ prefix symbol when the value is three digits. The value .000001 for the MULT= option is another way to write 1E-06, which is one millionth. Multiplying a value by the millionth, billionth, and trillionth multipliers return the number of millions, billions, and trillions of dollars.

```
proc format;
   picture bigmoney (fuzz=0)
      1E06-<1000000000='0000 M' (prefix='$' mult=.000001)
      1E09-<1000000000000='0000 B' (prefix='$' mult=1E-09)
      1E12-<1000000000000000='0000 T' (prefix='$' mult=1E-012);
run;
```

Generate large numbers to format as dollars.

```
data mult;
   do i=5 to 12;
```

```
      x=16**i;
      put x=comma20. x= bigmoney.;
   end;
run;
```

LOG

Example Code 30.3 *Formatted Millions, Billions, and Trillions Dollar Amounts*

```
x=1,048,576 x=$1 M
x=16,777,216 x=$16 M
x=268,435,456 x=$268 M
x=4,294,967,296 x=$4 B
x=68,719,476,736 x=$68 B
x=1,099,511,627,776 x=$1 T
x=17,592,186,044,416 x=$17 T
x=281,474,976,710,656 x=$281 T
```

Program

```
proc format;
   picture bigmoney (fuzz=0)
      1E06-<1000000000='0000.99 M' (prefix='$' mult=.0001)
      1E09-<1000000000000='0000.99 B' (prefix='$' mult=1E-07)
      1E12-<1000000000000000='0000.99 T' (prefix='$' mult=1E-010);
run;

data mult;
   do i=5 to 12;
      x=16**i;
      put x=comma20. x= bigmoney.;
   end;
run;
```

Program Description

In this program, the BIGMONEY. format is modified to display a more accurate number by adding decimal values.

Modify the BIGMONEY format. To display a more accurate number, the picture value and the MULT= value are modified. To display two decimal values, .99 is added to the picture. To calculate two decimal values, the value in the MULT= option is reduced from one millionth to one ten-thousandth. When 16^5 is multiplied by .0001, the results is 104.8576. The decimal values are truncated and the 104 is placed in the picture beginning on the right. The resulting formatted value is 1.04 M.

```
proc format;
   picture bigmoney (fuzz=0)
      1E06-<1000000000='0000.99 M' (prefix='$' mult=.0001)
      1E09-<1000000000000='0000.99 B' (prefix='$' mult=1E-07)
```

```
      1E12-<1000000000000000='0000.99 T' (prefix='$' mult=1E-010);
run;
```

Generate large numbers to format as dollars.

```
data mult;
   do i=5 to 12;
      x=16**i;
      put x=comma20. x= bigmoney.;
   end;
run;
```

LOG

Example Code 30.4 *More Precisely Formatted Large Dollar Amounts*

```
x=1,048,576 x=$1.04 M
x=16,777,216 x=$16.77 M
x=268,435,456 x=$268.43 M
x=4,294,967,296 x=$4.29 B
x=68,719,476,736 x=$68.71 B
x=1,099,511,627,776 x=$1.09 T
x=17,592,186,044,416 x=$17.59 T
x=281,474,976,710,656 x=$281.47 T
```

Example 5: Filling a Picture Format

Features: PICTURE statement options
FILL=
PREFIX=

Details

This example does the following tasks:

- prefixes the formatted value with a specified character
- fills the leading blanks with a specified character
- shows the interaction between the FILL= and PREFIX= options

Program

```
data pay;
   input Name $ MonthlySalary;
```

```
   datalines;
Liu   1259.45
Lars  1289.33
Kim   1439.02
Wendy 1675.21
Alex  1623.73
;

proc format;
   picture salary low-high='00,000,000.00' (fill='*' prefix='$');
run;

proc print data=pay noobs;
   format monthlysalary salary.;

   title 'Printing Salaries for a Check';
run;
```

Program Description

Create the PAY data set. The PAY data set contains the monthly salary for each employee.

```
data pay;
   input Name $ MonthlySalary;
   datalines;
Liu   1259.45
Lars  1289.33
Kim   1439.02
Wendy 1675.21
Alex  1623.73
;
```

Define the SALARY. picture format and specify how the picture will be filled. When FILL= and PREFIX= PICTURE statement options appear in the same picture, the format places the prefix and then the fill characters. The SALARY. format fills the picture with the fill character because the picture has zeros as digit selectors. The left-most comma in the picture is replaced by the fill character.

```
proc format;
   picture salary low-high='00,000,000.00' (fill='*' prefix='$');
run;
```

Print the PAY data set. The NOOBS option suppresses the printing of observation numbers. The FORMAT statement temporarily associates the SALARY. format with the variable MonthlySalary.

```
proc print data=pay noobs;
   format monthlysalary salary.;
```

Specify the title.

```
   title 'Printing Salaries for a Check';
run;
```

Output

Output 30.5 *Printing Salaries for a Check*

Printing Salaries for a Check

Name	Monthly Salary
Liu	****$1,259.45
Lars	****$1,289.33
Kim	****$1,439.02
Wendy	****$1,675.21
Alex	****$1,623.73

Example 6: Create a Date or Time Format with Directives

Features: PICTURE statement option
DATATYPE=TIME
directives

Details

This example uses directives to format date, time, and datetime values. It also uses directives on more than one value-range pair.

Program

```
proc format;
   picture mytime  (round)
      low-<86400='%H hours, %M minutes'          (datatype=time)    1
      86400-high='%n days, %H hours, %M minutes' (datatype=time) ; 2
      /*  86400=number of seconds in one day */
run;

data test;
   input xtime;
   newtime=put(xtime,mytime.);
datalines;
```

```
12345
46987
86400
99999
172800
1012345
3333333
;

run;

proc print data=test;
run;
```

Program Description

Use directives with the keywords LOW, HIGH, and LOW–HIGH. The directives format the date, time, and datetime values.

```
proc format;
   picture mytime  (round)
      low-<86400='%H hours, %M minutes'          (datatype=time)    1
      86400-high='%n days, %H hours, %M minutes' (datatype=time) ; 2
      /*  86400=number of seconds in one day */
run;
```

1 The %H and %M directives specify that the hours and minutes are identified in the output. The DATATYPE option enables the use of directives in the picture.

2 The %n, %H, %M directives specify that the days, hours, and minutes are identified in the output.

Create the data set.

```
data test;
   input xtime;
   newtime=put(xtime,mytime.);
datalines;
12345
46987
86400
99999
172800
1012345
3333333
;

run;
```

Print the contents of the data set.

```
proc print data=test;
run;
```

Output 30.6 *The Test data set with formatted values*

The SAS System

Obs	xtime	newtime
1	12345	3 hours, 25 minutes
2	46987	13 hours, 3 minutes
3	86400	1 days, 0 hours, 0 minutes
4	99999	1 days, 3 hours, 46 minutes
5	172800	2 days, 0 hours, 0 minutes
6	1012345	11 days, 17 hours, 12 minutes
7	3333333	38 days, 13 hours, 55 minutes

Example 7: Change the 24–Hour Clock to 00:00:01–24:00:00

Features: PICTURE statement option
DATATYPE=DATETIME_UTIL

Details

At times, you might need to express midnight as 24:00, or you need to use a datetime hour range 00:00:01–24:00:00. The hour value range for DATATYPE=DATETIME is 00:00:00–23:59:59. This example uses the option DATATYPE=DATETIME_UTIL to express hours in the range 00:00:01–24:00:00, and shows a date change if you use 00:00:00.

Program

```
proc format;
  picture  hours (default=19)
          other='%Y-%0m-%0d %0H:%0M:%0S' (datatype=datetime_util);
run;

data _null_;
  x = '01jul2015:00:00:01'dt; put x=hours.;
  x = '01jul2015:00:00:00'dt; put x=hours.;
run;
```

Program Description

Use the DATATYPE=DATETIME_UTIL option to use the hour range 00:00:01–24:00:00.

```
proc format;
  picture  hours (default=19)
          other='%Y-%0m-%0d %0H:%0M:%0S' (datatype=datetime_util);
run;
```

Compare Date Values. The first datetime value is in the range 00:00:01 and shows the day as July 1. The second datetime value is not in the range 00:00:01–24:00:00 and shows results as midnight of the previous day.

```
data _null_;
  x = '01jul2015:00:00:01'dt; put x=hours.;
  x = '01jul2015:00:00:00'dt; put x=hours.;
run;
```

Log

Example Code 30.5 *Using Hour Range 00:00:01–24:00:00*

```
x=2015-07-01 00:01:00
x=2015-06-30 24:00:00
```

Example 8: Creating a Format for Character Values

Features: VALUE statement option
OTHER

Data set: PROCLIB.STAFF

Format: USCURRENCY. from Example 2

Details

This example uses a VALUE statement to create a character format that prints a value of a character variable as a different character string.

Program

```
libname proclib 'SAS-library-1';
```

```
libname library 'SAS-library-2';

   proc format library=library;

      value  $city 'BR1'='Birmingham UK'
                   'BR2'='Plymouth UK'
                   'BR3'='York UK'
                   'US1'='Denver USA'
                   'US2'='Miami USA'
                   other='INCORRECT CODE';
   run;

proc print data=proclib.staff noobs label;

   label salary='Salary in U.S. Dollars';

   format salary uscurrency. site $city.;

   title 'PROCLIB.STAFF with a Format for the Variables';
   title2 'Salary and Site';
run;
```

Program Description

Assign two SAS library references (PROCLIB and LIBRARY). Assigning a library reference LIBRARY is useful in this case because if you use PROC FORMAT, then SAS automatically searches for informats and formats in any library that is referenced with the LIBRARY libref.

```
libname proclib 'SAS-library-1';
libname library 'SAS-library-2';
```

Create the catalog named Library.Formats, where the user-defined formats will be stored. The LIBRARY= option specifies a permanent storage location for the formats that you create. It also creates a catalog named FORMAT in the specified library. If you do not use LIBRARY=, then SAS temporarily stores formats and informats that you create in a catalog named Work.Formats.

```
   proc format library=library;
```

Define the $CITY. format. The special codes BR1, BR2, and so on, are converted to the names of the corresponding cities. The keyword OTHER specifies that values in the data set that do not match any of the listed city code values are converted to the value INCORRECT CODE.

```
      value  $city 'BR1'='Birmingham UK'
                   'BR2'='Plymouth UK'
                   'BR3'='York UK'
                   'US1'='Denver USA'
                   'US2'='Miami USA'
                   other='INCORRECT CODE';
   run;
```

Print the PROCLIB.STAFF data set. The NOOBS option suppresses the printing of observation numbers. The LABEL option uses variable labels instead of variable names for column headings.

```
proc print data=proclib.staff noobs label;
```

Specify a label for the Salary variable. The LABEL statement substitutes the label "Salary in U.S. Dollars" for the name SALARY.

```
label salary='Salary in U.S. Dollars';
```

Specify formats for Salary and Site. The FORMAT statement temporarily associates the USCURRENCY. format with the variable SALARY and also temporarily associates the format $CITY. with the variable SITE.

```
format salary uscurrency. site $city.;
```

Specify the titles.

```
title 'PROCLIB.STAFF with a Format for the Variables';
title2 'Salary and Site';
run;
```

Output

Output 30.7 *PROCLIB.STAFF with Formatted Variables for Salary and Site*

PROCLIB.STAFF with a Format for the Variables Salary and Site

Name	IdNumber	Salary in U.S. Dollars	Site	HireDate
Capalleti, Jimmy	2355	$34,072	Birmingham UK	30JAN09
Chen, Len	5889	$33,771	Birmingham UK	18JUN06
Davis, Brad	3878	$31,509	Plymouth UK	20MAR04
Leung, Brenda	4409	$55,256	Plymouth UK	18SEP94
Martinez, Maria	3985	$78,980	Miami USA	10JAN93
Orfali, Philip	0740	$80,648	Miami USA	16FEB03
Patel, Mary	2398	$56,643	York UK	02FEB90
Smith, Robert	5162	$64,561	INCORRECT CODE	15APR06
Sorrell, Joseph	4421	$62,403	Denver USA	19JUN11
Zook, Carla	7385	$37,010	York UK	18DEC10

Example 9: Creating a Format for Missing and Nonmissing Variable Values

Features: VALUE statement

VALUE statement option
OTHER

Data set: EDUCATION

Details

The EDUCATION data set reports dropout rates and math scores for several states, and indicates a region for each state.

In this example, you use the VALUE statement to create the text value n/a for all math score missing values. All nonmissing math score values are formatted using the 5.1 format.

The example then prints the dropout rate and math scores for each state, by region.

Program

```
options obs=20;

proc format;
   value myfmt .='n/a' other=[5.1];
run;

proc sort data=education;
   by region;
run;

proc print data=education;
   by region;
   var state dropOutRate mathScore;
   format mathScore myfmt.;
run;
```

Program Description

Set the number of observations to print.

```
options obs=20;
```

Create a format for the Mathscore variable values. Use the VALUE statement to create the format MYFMT. for the Mathscore variable. When the program encounters a missing Mathscore value, the value is formatted as n/a. All other values for Mathscore are formatted using the 5.1 format.

```
proc format;
   value myfmt .='n/a' other=[5.1];
run;
```

Sort and print the data. Use PROC SORT to sort the data set by region. To print the data by region, specify the region variable in the PROC PRINT BY statement. To report the state, dropout rate, and math scores, use the VAR statement and specify the state, dropOutRate, and mathScore variables. Finally, use the FORMAT statement to tell SAS to format the mathScore variable using the MYFMT. format.

```
proc sort data=education;
   by region;
run;

proc print data=education;
   by region;
   var state dropOutRate mathScore;
   format mathScore myfmt.;
run;
```

Output

Output 30.8 *Dropout Rates and Math Scores for Each State in a Region*

The SAS System

Region=MW

Obs	State	DropoutRate	Math Score
1	Illinois	21.5	260.0
2	Indiana	13.8	267.0
3	Iowa	13.6	278.0
4	Kansas	17.9	n/a

Region=NE

Obs	State	DropoutRate	Math Score
5	Connecticut	16.8	270.0
6	Delaware	28.5	261.0
7	Maine	22.5	n/a
8	Maryland	26.0	260.0

Region=SE

Obs	State	DropoutRate	Math Score
9	Alabama	22.3	252.0
10	Arkansas	11.5	256.0
11	Florida	38.5	255.0
12	Georgia	27.9	258.0
13	Kentucky	32.7	256.0
14	Louisiana	43.1	246.0

Region=W

Obs	State	DropoutRate	Math Score
15	Alaska	35.8	n/a
16	Arizona	31.2	259.0
17	California	32.7	256.0
18	Colorado	24.7	267.0
19	Hawaii	18.3	251.0
20	Idaho	21.8	272.0

Example 10: Creating an Informat Using Perl Regular Expressions

Features: INVALUE statement options
REGEXP
REGEXPE

Details

This example uses two Perl regular expressions to create an informat. The informat using the first expression verifies that the input is an integer and reads the integer. The second informat uses a regular expression that invokes substitution to read a number different from the input value.

Program

```
proc format;
```

```
   invalue isnum (default=5) '/[0-9]/' (regexp) = _same_ other=_error_;
   invalue x1to2x(default=5) 's/1/2/' (regexpe) = _same_ other=_same_;
run;

data _null_;
   input x:isnum. y:x1to2x.;
   put x= y=;
   datalines;
1 121
2 145
a 232
run;
```

Program Description

Create new informats. If the input is a decimal integer, the ISNUM. format reads the number. Otherwise, SAS writes an error to the log. The X1TO2X. informat substitutes all 1s in the input value with a 2.

```
proc format;
   invalue isnum (default=5) '/[0-9]/' (regexp) = _same_ other=_error_;
   invalue x1to2x(default=5) 's/1/2/' (regexpe) = _same_ other=_same_;
run;
```

Read the data. The first two lines of data are valid. The first input value 121 is formatted as 222 because a 1 is substituted with a 2. The input value of 145 is formatted as 245 using the same substitution rule. The third line produces an error because the value for `x` is a character.

```
data _null_;
   input x:isnum. y:x1to2x.;
   put x= y=;
   datalines;
1 121
2 145
a 232
run;
```

LOG

```
1    proc format;
2         invalue isnum (default=5) '/[0-9]/' (regexp) = _same_ other=_error_;
NOTE: Informat ISNUM has been output.
3         invalue x1to2x(default=5) 's/1/2/' (regexpe) = _same_ other=_same_;
NOTE: Informat X1TO2X has been output.
4         run;

NOTE: PROCEDURE FORMAT used (Total process time):
      real time           0.32 seconds
      cpu time            0.07 seconds

5
6    data _null_;
7        input x:isnum. y:x1to2x.;
8        put x= y=;
9        datalines;

x=1 y=222
x=2 y=245
NOTE: Invalid data for x in line 12 1-1.
x=. y=232
RULE:      ----+----1----+----2----+----3----+----4----+----5----+----6----+----7----
+----8----+--
12          a 232

```

Example 11: Writing a Format for Dates Using a Standard SAS Format and a Color Background

Features: VALUE statement option
HIGH
PROC PRINT statement
VAR statement STYLE option

Data set: PROCLIB.STAFF

Format: USCURRENCY. from Example 3

Format: $CITY. from Example 7

Details

This example uses an existing format that is supplied by SAS as a formatted value and color codes values based on dates.

Tasks include the following:

- creating a numeric format

- nesting formats
- writing a format using a standard SAS format
- formatting dates using a color scheme

Program

```
libname proclib 'SAS-library-1';
libname library 'SAS-library-2';

proc format library=library;

   value benefit
      low-'31DEC2008'd=[worddate20.]
      '01JAN2009'd-high='  ** Not Eligible **';

   value color
      low-'31DEC2008'd='light green'
      '01JAN2009'd-high='light red';
run;

proc print data=proclib.staff noobs label;
   var name idnumber salary site;
   var hiredate /style=[background=color.];

   label salary='Salary in U.S. Dollars';

   format salary uscurrency. site $city. hiredate benefit.;

   title 'PROCLIB.STAFF with a Format for the Variables';
   title2 'Salary, Site, and HireDate';
run;
```

Program Description

This program defines a format called BENEFIT., which differentiates between employees hired on or before 31DEC2008. The purpose of this program is to indicate any employees who are eligible to receive a benefit, based on a hire date on or before December 31, 2008. All other employees with a later hire date are listed as ineligible for the benefit.

Assign two SAS library references (PROCLIB and LIBRARY). Assigning a library reference LIBRARY is useful in this case because if you use PROC FORMAT, then SAS automatically searches for informats and formats in any library that is referenced with the LIBRARY libref.

```
libname proclib 'SAS-library-1';
libname library 'SAS-library-2';
```

Store the BENEFIT. format in the catalog Library.Formats. The LIBRARY= option specifies the permanent storage location LIBRARY for the formats that you create. If you do not use LIBRARY=, then SAS temporarily stores formats and informats that you create in the catalog Work.Formats.

```
proc format library=library;
```

Define the first range in the BENEFIT. format. This first range differentiates between the employees who were hired on or before 31DEC2008 and those who were hired after that date. The keyword LOW and the SAS date constant '31DEC2008'd create the first range, which includes all date values that occur on or before December 31, 2008. For values that fall into this range, SAS applies the WORDDATE*w*. format. For more information about SAS date constants, see "Dates, Times, and Intervals" in *SAS Language Reference: Concepts*. For more information about the WORDDATE formats, see "WORDDATEw." in *SAS Formats and Informats: Reference*.

```
      value benefit
         low-'31DEC2008'd=[worddate20.]
         '01JAN2009'd-high='  ** Not Eligible **';
```

Define the colors for the ranges. Using the same date ranges, employees who are eligible for a benefit based on the dates are color coded in light green. Employees who are not eligible for a benefit are color coded in a light red.

```
      value color
         low-'31DEC2008'd='light green'
         '01JAN2009'd-high='light red';
   run;
```

Print the data set PROCLIB.STAFF. The NOOBS option suppresses the printing of observation numbers. The LABEL option uses variable labels instead of variable names for column headings. The VAR statement names the variables to be printed. The second VAR statement uses the STYLE= option to name the color. format as the background color for the Hiredate variable.

```
   proc print data=proclib.staff noobs label;
      var name idnumber salary site;
      var hiredate /style=[background=color.];
```

Specify a label for the Salary variable. The LABEL statement substitutes the label "Salary in U.S. Dollars" for the name SALARY.

```
      label salary='Salary in U.S. Dollars';
```

Specify formats for Salary, Site, and Hiredate. The FORMAT statement associates the USCURRENCY. format (created in "Example 3: Creating a Picture Format" on page 1150) with SALARY, the $CITY. format (created in "Example 8: Creating a Format for Character Values" on page 1160) with SITE, and the BENEFIT. format with HIREDATE.

```
      format salary uscurrency. site $city. hiredate benefit.;
```

Specify the titles.

```
      title 'PROCLIB.STAFF with a Format for the Variables';
      title2 'Salary, Site, and HireDate';
   run;
```

Output

Output 30.9 *PROCLIB.STAFF with a Format for the Variables Salary, Site, and HireDate*

PROCLIB.STAFF with a Format for the Variables Salary, Site, and HireDate

Name	IdNumber	Salary in U.S. Dollars	Site	HireDate
Capalleti, Jimmy	2355	$34,072	Birmingham UK	** Not Eligible **
Chen, Len	5889	$33,771	Birmingham UK	June 18, 2006
Davis, Brad	3878	$31,509	Plymouth UK	March 20, 2004

Zook, Carla	7385	$37,010	York UK	** Not Eligible **

Example 12: Converting Raw Character Data to Numeric Values

Features: INVALUE statement

Details

This example uses an INVALUE statement to create a numeric informat that converts numeric and character raw data to numeric data.

Program

```
libname proclib 'SAS-library-1';
libname library 'SAS-library-2';

proc format library=library;

   invalue evaluation 'O'=4
```

```
                        'S'=3
                        'E'=2
                        'C'=1
                        'N'=0;
run;

data proclib.points;
   input EmployeeId $ (Q1-Q4) (evaluation.,+1);
   TotalPoints=sum(of q1-q4);
   datalines;
2355 S O O S
5889 2 2 2 2
3878 C E E E
4409 0 1 1 1
3985 3 3 3 2
0740 S E E S
2398 E E C C
5162 C C C E
4421 3 2 2 2
7385 C C C N
;

proc print data=proclib.points noobs;

   title 'The PROCLIB.POINTS Data Set';
run;
```

Program Description

This program converts quarterly employee evaluation grades, which are alphabetic, into numeric values so that reports can be generated that sum the grades up as points.

Set up two SAS library references, one named PROCLIB and the other named LIBRARY.

```
libname proclib 'SAS-library-1';
libname library 'SAS-library-2';
```

Store the EVALUATION. informat in the catalog Library.Formats.

```
proc format library=library;
```

Create the numeric informat EVALUATION.. The INVALUE statement converts the specified values. The letters O (Outstanding), S (Superior), E (Excellent), C (Commendable), and N (None) correspond to the numbers 4, 3, 2, 1, and 0, respectively.

```
   invalue evaluation 'O'=4
                      'S'=3
                      'E'=2
                      'C'=1
                      'N'=0;
run;
```

Create the PROCLIB.POINTS data set. The instream data, which immediately follows the DATALINES statement, contains a unique identification number

(EmployeeId) and bonus evaluations for each employee for each quarter of the year (Q1–Q4). Some of the bonus evaluation values that are listed in the data lines are numbers; others are character values. Where character values are listed in the data lines, the EVALUATION. informat converts the value O to 4, the value S to 3, and so on. The raw data values 0 through 4 are read as themselves because they are not referenced in the definition of the informat. Converting the letter values to numbers makes it possible to calculate the total number of bonus points for each employee for the year. TotalPoints is the total number of bonus points.

```
data proclib.points;
   input EmployeeId $ (Q1-Q4) (evaluation.,+1);
   TotalPoints=sum(of q1-q4);
   datalines;
2355 S O O S
5889 2 2 2 2
3878 C E E E
4409 0 1 1 1
3985 3 3 3 2
0740 S E E S
2398 E E C C
5162 C C C E
4421 3 2 2 2
7385 C C C N
;
```

Print the PROCLIB.POINTS data set. The NOOBS option suppresses the printing of observation numbers.

```
proc print data=proclib.points noobs;
```

Specify the title.

```
   title 'The PROCLIB.POINTS Data Set';
run;
```

Output

Output 30.10 *The PROCLIB.POINT Data Set*

The PROCLIB.POINTS Data Set

EmployeeId	Q1	Q2	Q3	Q4	TotalPoints
2355	3	4	4	3	14
5889	2	2	2	2	8
3878	1	2	2	2	7
4409	0	1	1	1	3
3985	3	3	3	2	11
0740	3	2	2	3	10
2398	2	2	1	1	6
5162	1	1	1	2	5
4421	3	2	2	2	9
7385	1	1	1	0	3

Example 13: Creating a Format from a CNTLIN= Data Set

Features: PROC FORMAT statement option
CNTLIN=
Input control data set

Details

This example shows how to create a format from a SAS data set.

Here are the tasks:

- create a format from an input control data set
- create an input control data set from an existing SAS data set

Program To Create a Temporary Data Set

```
data scale;
   input begin: $char2. end: $char2. amount: $char2.;
   datalines;
0   3    0%
4   6    3%
7   8    6%
9   10   8%
11  16   10%
;

data ctrl;
   length label $ 11;

   set scale(rename=(begin=start amount=label)) end=last;

   retain fmtname 'PercentageFormat' type 'n';

   output;

   if last then do;
      hlo='O';
      label='***ERROR***';
      output;
   end;
run;

proc print data=ctrl noobs;

   title 'The CTRL Data Set';
run;
```

Program Description

Create a temporary data set named scale. The first two variables in the data lines, called BEGIN and END, will be used to specify a range in the format. The third variable in the data lines, called AMOUNT, contains a percentage that will be used as the formatted value in the format. Note that all three variables are character variables as required for PROC FORMAT input control data sets.

```
data scale;
   input begin: $char2. end: $char2. amount: $char2.;
   datalines;
0   3    0%
4   6    3%
7   8    6%
9   10   8%
11  16   10%
;
```

Create the input control data set CTRL and set the length of the LABEL variable. The LENGTH statement ensures that the LABEL variable is long enough to accommodate the label ***ERROR***.

```
data ctrl;
   length label $ 11;
```

Rename variables and create an end-of-file flag. The data set CTRL is derived from WORK.SCALE. RENAME= renames BEGIN and AMOUNT as START and LABEL, respectively. The END= option creates the variable LAST, whose value is set to 1 when the last observation is processed.

```
   set scale(rename=(begin=start amount=label)) end=last;
```

Create the variables Fmtname and Type with fixed values. The RETAIN statement is more efficient than an assignment statement in this case. RETAIN retains the value of Fmtname and Type in the program data vector and eliminates the need for the value to be written on every iteration of the DATA step. Fmtname specifies the name PercentageFormat, which is the format that the input control data set creates. The Type variable specifies that the input control data set will create a numeric format.

```
   retain fmtname 'PercentageFormat' type 'n';
```

Write the observation to the output data set.

```
   output;
```

Create an "other" category. Because the only valid values for this application are 0–16, any other value (such as missing) should be indicated as an error to the user. The IF statement executes only after the DATA step has processed the last observation from the input data set. When IF executes, HLO receives a value of O to indicate that the range is OTHER, and LABEL receives a value of ***ERROR***. The OUTPUT statement writes these values as the last observation in the data set. HLO has missing values for all other observations.

```
   if last then do;
      hlo='O';
      label='***ERROR***';
      output;
   end;
run;
```

Print the control data set, CTRL. The NOOBS option suppresses the printing of observation numbers.

```
proc print data=ctrl noobs;
```

Specify the title.

```
   title 'The CTRL Data Set';
run;
```

Output

Output 30.11 *The CTRL Data Set*

The CTRL Data Set

label	start	end	fmtname	type	hlo
0%	0	3	PercentageFormat	n	
3%	4	6	PercentageFormat	n	
6%	7	8	PercentageFormat	n	
8%	9	10	PercentageFormat	n	
10%	11	16	PercentageFormat	n	
ERROR	11	16	PercentageFormat	n	O

Program To Create the Format

```
proc format library=work cntlin=ctrl;
run;

proc format library=library;
   invalue evaluation 'O'=4
                      'S'=3
                      'E'=2
                      'C'=1
                      'N'=0;
run;

data points;
   input EmployeeId $ (Q1-Q4) (evaluation.,+1);
   TotalPoints=q1+q2+q3+q4;
   datalines;
2355 S O O S
5889 2 . 2 2
3878 C E E E
4409 0 1 1 1
3985 3 3 3 2
0740 S E E S
2398 E E   C
5162 C C C E
4421 3 2 2 2
7385 C C C N
;

proc report data=work.points nowd headskip split='#';
   column employeeid totalpoints totalpoints=Pctage;
   define employeeid / right;
   define totalpoints / 'Total#Points' right;
   define pctage / format=PercentageFormat12. 'Percentage' left;
```

```
   title 'The Percentage of Salary for Calculating Bonus';
run;
```

Program Description

Store the created format in the catalog Work.Formats and specify the source for the format. The CNTLIN= option specifies that the data set CTRL is the source for the format PercentageFormat.

```
proc format library=work cntlin=ctrl;
run;
```

Create the numeric informat EVALUATION.. The INVALUE statement converts the specified values. The letters O (Outstanding), S (Superior), E (Excellent), C (Commendable), and N (None) correspond to the numbers 4, 3, 2, 1, and 0, respectively.

```
proc format library=library;
   invalue evaluation 'O'=4
                      'S'=3
                      'E'=2
                      'C'=1
                      'N'=0;
run;
```

Create the WORK.POINTS data set. The instream data, which immediately follows the DATALINES statement, contains a unique identification number (EmployeeId) and bonus evaluations for each employee for each quarter of the year (Q1–Q4). Some of the bonus evaluation values that are listed in the data lines are numbers; others are character values. Where character values are listed in the data lines, the Evaluation. informat converts the value O to 4, the value S to 3, and so on. The raw data values 0 through 4 are read as themselves because they are not referenced in the definition of the informat. Converting the letter values to numbers makes it possible to calculate the total number of bonus points for each employee for the year. TotalPoints is the total number of bonus points. The addition operator is used instead of the SUM function so that any missing value will result in a missing value for TotalPoints.

```
data points;
   input EmployeeId $ (Q1-Q4) (evaluation.,+1);
   TotalPoints=q1+q2+q3+q4;
   datalines;
2355 S O O S
5889 2 . 2 2
3878 C E E E
4409 0 1 1 1
3985 3 3 3 2
0740 S E E S
2398 E E   C
5162 C C C E
4421 3 2 2 2
7385 C C C N
;
```

Generate a report for WORK.POINTS and associate the PERCENTAGEFORMAT. format with the TotalPoints variable. The DEFINE statement performs the association. The column that contains the formatted values of TotalPoints is using the alias Pctage. Using an alias enables you to print a variable twice, once with a format and once with the default format. For more information about the REPORT procedure, see Chapter 58, "REPORT Procedure," on page 2047.

```
proc report data=work.points nowd headskip split='#';
   column employeeid totalpoints totalpoints=Pctage;
   define employeeid / right;
   define totalpoints / 'Total#Points' right;
   define pctage / format=PercentageFormat12. 'Percentage' left;
   title 'The Percentage of Salary for Calculating Bonus';
run;
```

Output

Output 30.12 *The Percentage of Salary for Calculating Bonus*

The Percentage of Salary for Calculating Bonus

EmployeeId	Total Points	Percentage
2355	14	10%
5889	.	***ERROR***
3878	7	6%
4409	3	0%
3985	11	10%
0740	10	8%
2398	.	***ERROR***
5162	5	3%
4421	9	8%
7385	3	0%

Example 14: Creating an Informat from a CNTLIN= Data Set

Features: PROC FORMAT statement option
CNTLIN=
Input control data set

Details

This example shows how to create an informat from a CNTLIN= data set.

Here are the tasks:

- create an informat from an input control data set
- create an input control data set from an existing SAS data set

Program

```
proc format;
     invalue mytest
       'abc'=1
       'xyz'=2
       other=3;
     invalue $chrtest
       'abc'='xyz'
       other='else';
     run;

data _null_;
     input value:mytest. @@;
     put value=;

     put value=;
     datalines;
abc xyz ghi 4
     run;

proc print data=temp noobs;
title 'The CTRL Data Set';
run;
```

Program Description

Create informats with an INVALUE statement. Create a numeric informat and a character informat.

```
proc format;
     invalue mytest
       'abc'=1
```

```
        'xyz'=2
        other=3;
      invalue $chrtest
        'abc'='xyz'
        other='else';
      run;
```

Use the numeric informat with instream data. The code should produce 1, 2, 3, and 3 again as the results of VALUE.

```
data _null_;
     input value:mytest. @@;
     put value=;
     datalines;
abc xyz ghi 4
     run;
```

Use the character informat with instream data. The code should produce xyz, else, else, and else as the results of VALUE.

```
data _null_;
     input value:$chrtest. @@;
     put value=;
     datalines;
abc xyz ghi 4
     run;
```

Create the equivalent of the MYTEST numeric informat using a CNTLIN= data set, and use the informat name of NEWTEST. Specify that the FMTNAME variable has the value NEWTEST. Specify the value 'i' or 'I' for the TYPE variable to indicate that it is a numeric informat. Specify a value of O for other, or a blank value, for the HLO variable.

```
data temp;
     length start $8 type $1 hlo $1;
     fmtname='newtest'; type='i';
     start='abc'; label=1; hlo=' '; output;
     start='xyz'; label=2; hlo=' '; output;
     start=' ';   label=3; hlo='O'; output;
     run;
```

Use the character informat with instream data. The code should produce xyz, else, else, and else as the results of VALUE.

```
proc format cntlin=temp; run;
```

Create a CNTLIN= data set for the character informat. The informat is the equivalent to the $CHRTEST informat that was created above. Specify the name $NEWCHR for it. The value of TYPE should be 'j' or 'J' to indicate that it is a character informat.

```
data temp;
     length start label $8 type $1 hlo $1;
     fmtname='$newchr'; type='j';
     start='abc'; label='xyz'; hlo=' '; output;
     start=' ';   label='else'; hlo='O'; output;
     run;
```

Read in the CNTLIN= data set to create the character informat. This example uses *temp* as the value for CNTLIN. If you are saving the code example, specify a more descriptive name.

```
proc format cntlin=temp; run;
```

Create two DATA steps that are the same as the previously created versions. Use the informat names NEWTEST and $NEWCHR for these versions.

```
data _null_;
     input value:newtest. @@;
     put value=;
     datalines;
abc xyz ghi 4
     run;

data _null_;
     input value:$newchr. @@;
     put value=;
     datalines;
abc xyz ghi 4
     run;
```

Show that the FMTNAME value can start with an @ to indicate that it is an informat, and that the type variable is not necessary. Numeric and character informats can be created in the same CNTLIN= data set. The label variable must be a character because character formats are being defined. Numeric values are saved as character strings that contain numeric values.

```
data temp;
     length start label $8 hlo $1;
     fmtname='@new2test';
     start='abc'; label='1'; hlo=' '; output;
     start='xyz'; label='2'; hlo=' '; output;
     start=' ';   label='3'; hlo='O'; output;
     fmtname='@$new2chr';
     start='abc'; label='xyz'; hlo=' '; output;
     start=' ';   label='else'; hlo='O'; output;
     run;

proc format cntlin=temp; run;

data _null_;
     input value:new2test. @@;
     put value=;
     datalines;
abc xyz ghi 4
     run;

data _null_;
     input value:$new2chr. @@;
     put value=;
     datalines;
abc xyz ghi 4
     run;
```

Print the contents of the CNTLIN= data set. Label the table “The CTRL Data Set.”

```
proc print data=temp noobs;
title 'The CTRL Data Set';
run;
```

Output 30.13 *Contents of the CRTL Data Set*

The CTRL Data Set

start	label	hlo	fmtname
abc	1		@new2test
xyz	2		@new2test
	3	O	@new2test
abc	xyz		@$new2chr
	else	O	@$new2chr

Example 15: Printing the Description of Informats and Formats

Features: PROC FORMAT statement option
FMTLIB
SELECT statement

Format: BENEFIT. from Example 4

Informat: EVALUATION. from Example 6

Details

This example illustrates how to print a description of an informat and a format. The description shows the values that are read in and written.

Program

```
libname library 'SAS-library';

proc format library=library fmtlib;

   select @evaluation benefit;

   title 'FMTLIB Output for the BENEFIT. Format and the';
   title2 'EVALUATION. Informat';
run;
```

Program Description

Set up a SAS library reference named LIBRARY.

```
libname library 'SAS-library';
```

Print a description of EVALUATION. and BENEFIT. The FMTLIB option prints information about the formats and informats in the catalog that the LIBRARY= option specifies. LIBRARY=LIBRARY points to the Library.Formats catalog.

```
proc format library=library fmtlib;
```

Select an informat and a format. The SELECT statement selects EVALUATION. and BENEFIT., which were created in previous examples. The at sign (@) in front of EVALUATION. indicates that EVALUATION. is an informat.

```
   select @evaluation benefit;
```

Specify the titles.

```
   title 'FMTLIB Output for the BENEFIT. Format and the';
   title2 'EVALUATION. Informat';
run;
```

Output

Output 30.14 *FMTLIB Output for the BENEFIT Format and the EVALUATION Informat*

FMTLIB Output for the BENEFIT. Format and the EVALUATION. Informat

Example 16: Retrieving a Permanent Format

Features: PROC FORMAT statement option
LIBRARY=
FMTSEARCH= system option

Data set: SAMPLE

This example uses the LIBRARY= option and the FMTSEARCH= system option to store and retrieve a format stored in a catalog other than Work.Formats or Library.Formats.

Program

```
libname proclib 'SAS-library';

proc format library=proclib;

picture nozeros (fuzz=0)
           low -  -1  = '000.00'(prefix='-')
       -1 < - < -.99  = '0.99' (prefix='-.' mult=100)
       -0.99 < - < 0  = '99'    (prefix='-.' mult=100)
                   0  = '0.99'
        0 < - < .99   = '99'    (prefix='.'  mult=100)
           0.99 - <1  = '0.99'  (prefix='.'  mult=100)
            1  - high = '00.99';
run;

options  fmtsearch=(proclib);

data sample;
  input Amount;
   datalines;
-2.051
-.05
-.017
  0
.093
.54
.556
6.6
14.63
0.996
-0.999
-45.00
;
run;

proc print data=sample;
   format amount nozeros.;

   title1 'Retrieving the NOZEROS. Format from PROCLIB.FORMATS';
```

```
   title2 'The SAMPLE Data Set';
run;
```

Program Description

Set up a SAS library reference named PROCLIB.

```
libname proclib 'SAS-library';
```

Store the NOZEROS. format in the PROCLIB.FORMATS catalog.

```
proc format library=proclib;
```

Create the NOZEROS. format. The PICTURE statement defines the picture format NOZEROS. See "Details" on page 1112.

```
picture nozeros (fuzz=0)
           low -  -1  = '000.00'(prefix='-')
       -1 < - < -.99  = '0.99' (prefix='-.' mult=100)
       -0.99 < - < 0  = '99'    (prefix='-.' mult=100)
                   0  = '0.99'
        0 < - < .99   = '99'    (prefix='.'  mult=100)
           0.99 - <1  = '0.99'  (prefix='.'  mult=100)
            1  - high = '00.99';
run;
```

Add the PROCLIB.FORMATS catalog to the search path that SAS uses to find user-defined formats. The FMTSEARCH= system option defines the search path. The FMTSEARCH= system option requires only a libref. FMTSEARCH= assumes that the catalog name is FORMATS if no catalog name appears. Without the FMTSEARCH= option, SAS would not find the NOZEROS. format. For more information, see "FMTSEARCH= System Option" in *SAS System Options: Reference*.

```
options  fmtsearch=(proclib);
```

Create the sample data set.

```
data sample;
  input Amount;
   datalines;
-2.051
-.05
-.017
  0
.093
.54
.556
6.6
14.63
0.996
-0.999
-45.00
;
run;
```

Print the SAMPLE data set. The FORMAT statement associates the NOZEROS. format with the Amount variable.

```
proc print data=sample;
   format amount nozeros.;
```

Specify the titles.

```
   title1 'Retrieving the NOZEROS. Format from PROCLIB.FORMATS';
   title2 'The SAMPLE Data Set';
run;
```

Output

Output 30.15 *Retrieving the NOZEROS. Format from PROCLIB.FORMATS*

Retrieving the NOZEROS. Format from PROCLIB.FORMATS
The SAMPLE Data Set

Obs	Amount
1	-2.05
2	-.05
3	-.01
4	.00
5	.09
6	.54
7	.55
8	6.60
9	14.63
10	.99
11	-.99
12	45.00

Example 17: Writing Ranges for Character Strings

Features: VALUE statement

Data set: PROCLIB.STAFF

This example creates a format and shows how to use ranges with character strings.

Program

```
libname proclib'SAS-library';

data train;
   set proclib.staff(keep=name idnumber);
run;

proc print data=train noobs;

   title 'The TRAIN Data Set without a Format';
run;
```

Program Description

```
libname proclib'SAS-library';
```

Create the TRAIN data set from the PROCLIB.STAFF data set. PROCLIB.STAFF was created in "Example 2: Create the Example Data Set" on page 1149.

```
data train;
   set proclib.staff(keep=name idnumber);
run;
```

Print the data set TRAIN without a format. The NOOBS option suppresses the printing of observation numbers.

```
proc print data=train noobs;
```

Specify the title.

```
   title 'The TRAIN Data Set without a Format';
run;
```

Output

Output 30.16 *The TRAIN Data Set without a Format*

The TRAIN Data Set without a Format

Name	IdNumber
Capalleti, Jimmy	2355
Chen, Len	5889
Davis, Brad	3878
Leung, Brenda	4409
Martinez, Maria	3985
Orfali, Philip	0740
Patel, Mary	2398
Smith, Robert	5162
Sorrell, Joseph	4421
Zook, Carla	7385

Store the format in Work.Formats. Because the LIBRARY= option does not appear, the format is stored in Work.Formats and is available only for the current SAS session.

```
proc format;
```

Create the $SKILLTEST. format. The $SKILLTEST. format prints each employee's identification number and the skills test that they have been assigned. Employees must take either TEST A, TEST B, or TEST C, depending on their last name. The exclusion operator (<) excludes the last value in the range. Thus, the first range includes employees whose last name begins with any letter from A through D, and the second range includes employees whose last name begins with any letter from E through M. The tilde (~) in the last range is necessary to include an entire string that begins with the letter Z.

```
   value $skilltest  'a'-<'e','A'-<'E'='Test A'
                     'e'-<'m','E'-<'M'='Test B'
                     'm'-'z~','M'-'Z~'='Test C';
run;
```

Generate a report of the TRAIN data set. The FORMAT= option in the DEFINE statement associates the $SKILLTEST. format with the Name variable. The column that contains the formatted values of Name is using the alias Test. Using an alias enables you to print a variable twice, once with a format and once with the default format. For more information, see Chapter 58, "REPORT Procedure," on page 2047.

```
proc report data=train nowd headskip;
   column name name=test idnumber;
   define test / display format=$skilltest. 'Test';
```

```
   define idnumber / center;
   title 'Test Assignment for Each Employee';
run;
```

Output

Output 30.17 *Test Assignment for Each Employee*

Test Assignment for Each Employee

Name	Test	IdNumber
Capalleti, Jimmy	Test A	2355
Chen, Len	Test A	5889
Davis, Brad	Test A	3878
Leung, Brenda	Test B	4409
Martinez, Maria	Test C	3985
Orfali, Philip	Test C	0740
Patel, Mary	Test C	2398
Smith, Robert	Test C	5162
Sorrell, Joseph	Test C	4421
Zook, Carla	Test C	7385

Example 18: Creating a Format in a non-English Language

Features: PICTURE statement options
DATATYPE=
LANGUAGE=
LOCALE= system option

Details

This example does the following tasks:

- Creates picture formats using directives for formatting date and datetime values by using the DATATYPE= statement option.

- Uses the LOCALE= system option to specify the locale for German.
- Prints date and datetime values to the SAS log in German using the picture formats.
- Prints a datetime value in French to the log by using the picture format that specifies LANGUAGE=French.

Program

```
proc format;
   picture mdy(default=8) other='%0d%0m%Y' (datatype=date);
   picture langtsda (default=50) other='%A, %d %B, %Y' (datatype=date);
   picture langtsdt (default=50) other='%A, %d,%B, %Y %H %M %S'
                                 (datatype=datetime);
   picture langtsfr (default=50) other='%A, %d %B, %Y %H %M %S'
                                 (datatype=datetime language=french);
   picture alltest (default=100)
           other='%a %A %b %B %d %H %I %j %m %M %p %S %w %U %y %%'
           (datatype=datetime);
run;

option locale = de_DE;

data _null_ ;
   a= 18903;
   b = 1633239000;
   put a= mdy.;
   put a= langtsda.;
   put b= langtsdt.;
   put b= langtsfr.;
   put b= alltest.;
run ;
```

Program Description

Create formats using the PICTURE statement. Each PICTURE statement specifies the date or datetime values to format using directives. %A prints a full weekday name. %B prints a full month name. %d prints the day of the month. %Y prints the year. %H prints the hour (24–hour clock). %M prints the minute. %S prints the seconds. The first three formats print the date or datetime in the language specified by the current value of the LOCALE= system option. The format LANGTSFT. prints the datetime in French. For the remaining directives, see the PICTURE statement on page 1098.

```
proc format;
   picture mdy(default=8) other='%0d%0m%Y' (datatype=date);
   picture langtsda (default=50) other='%A, %d %B, %Y' (datatype=date);
   picture langtsdt (default=50) other='%A, %d,%B, %Y %H %M %S'
                                 (datatype=datetime);
   picture langtsfr (default=50) other='%A, %d %B, %Y %H %M %S'
                                 (datatype=datetime language=french);
   picture alltest (default=100)
```

```
            other='%a %A %b %B %d %H %I %j %m %M %p %S %w %U %y %%'
            (datatype=datetime);
run;
```

Set the LOCALE= system option. de_DE is the locale value for Germany.

```
option locale = de_DE;
```

Print date and datetime values in German and French. The DATA step prints to the SAS log the date and datetime information for 3 October, 2011, 05:30:00 AM. All values are written in German except for the value of `b` when it is formatted using the LANGTSFR. format. The LANGSTSFR. format prints the datetime value in French.

```
data _null_ ;
   a= 18903;
   b = 1633239000;
   put a= mdy.;
   put a= langtsda.;
   put b= langtsdt.;
   put b= langtsfr.;
   put b= alltest.;
run ;
```

The SAS Log Displaying Picture Format Output in German and French

```
1    proc format;
2       picture mdy(default=8) other='%0d%0m%Y' (datatype=date);
NOTE: Format MDY has been output.
3       picture langtsda (default=50) other='%A, %d %B, %Y' (datatype=date);
NOTE: Format LANGTSDA has been output.
4       picture langtsdt (default=50) other='%A, %d,%B, %Y %H %M %S'
5                                     (datatype=datetime);
NOTE: Format LANGTSDT has been output.
6       picture langtsfr (default=50) other='%A, %d %B, %Y %H %M %S'
7                                     (datatype=datetime language=french);
NOTE: Format LANGTSFR has been output.
8       picture alltest (default=100)
9               other='%a %A %b %B %d %H %I %j %m %M %p %S %w %U %y %%'
10              (datatype=datetime);
NOTE: Format ALLTEST has been output.
11   run;

NOTE: PROCEDURE FORMAT used (Total process time):
      real time           0.03 seconds
      cpu time            0.03 seconds

12
13   option locale = de_DE;
14
15   data _null_ ;
16      a= 18903;
17      b = 1633239000;
18      put a= mdy.;
19      put a= langtsda.;
20      put b= langtsdt.;
21      put b= langtsfr.;
22      put b= alltest.;
23   run ;

a=03102011
a=Montag, 3 Oktober, 2011
b=Montag, 3,Oktober, 2011 5 30 0
b=Lundi, 3 octobre, 2011 5 30 0
b=Mo  Montag Okt Oktober 3 5 5 276 10 30 AM 0 2 40 11 %
```

Example 19: Creating a Locale-Specific Format Catalog

Features: PROC FORMAT LOCALE option
FMTSEARCH= system option

Details

This example demonstrates how to create a format in two languages, English and Romanian, and how to access the English and Romanian format catalogs to print a data set in the two languages. The example works best if the SAS session encoding is a latin 2 encoding that supports the Romanian locale.

Program

```
/*no locale information*/
proc format lib=work.formats;
value age low - 5 = 'baby'
6 - 12 = 'child'
13 - 15 = 'teen'
16 - 30 = 'youth'
31 - 50 = 'midlife'
51 - high = 'older';
run;

options locale=ro_RO;

proc format lib = work.formats locale;
value age low - 5 = 'Copil'
6 - 12 = 'Copil'
13 - 15 = 'Adolescent'
16 - 30 = 'Tineretului'
31 - 50 = 'Asta vrei'
51 - high = 'Mai vechi';
run;

options fmtsearch=(work/locale);

/* Set the locale back to English(US) */
options locale=en_US;

data datatst;
input age sex $;
attrib age format= age.;
cards;
5 M
6 F
12 M
13 F
15 M
16 F
30 M
35 F
51 M
100 F
;
```

```
run;
/* Use the English format catalog*/
title "Locale is English, Use the Original Format Catalog";
proc print data=datatst; run;

/* Use the Romanian format catalog*/
options locale=ro_RO;
title 'Locale is ro_RO, Use the Romanian Format Catalog';
proc print data=datatst;run;
```

Program Description

Create the AGE. format in English.

```
/*no locale information*/
proc format lib=work.formats;
value age low - 5 = 'baby'
6 - 12 = 'child'
13 - 15 = 'teen'
16 - 30 = 'youth'
31 - 50 = 'midlife'
51 - high = 'older';
run;
```

Change the locale and create the AGE. format in a locale-specific format catalog. Using the LOCALE= system option, the locale is change to the Romanian locale. In the PROC FORMAT statement, the LOCALE option specifies to create a format catalog that corresponds to the current locale, which is for the Romanian language.

```
options locale=ro_RO;

proc format lib = work.formats locale;
value age low - 5 = 'Copil'
6 - 12 = 'Copil'
13 - 15 = 'Adolescent'
16 - 30 = 'Tineretului'
31 - 50 = 'Asta vrei'
51 - high = 'Mai vechi';
run;
```

Add the locale-specific format catalogs to the format search path. The FMTSEARCH= system option specifies the format catalog to search. Because you can create more than one locale-specific catalog, when /LOCALE is added to a libref in the search list, SAS searches for a catalog that is associated with the current locale.

```
options fmtsearch=(work/locale);
```

Create a data set and print it using the English format catalog. The LOCALE= system option sets the locale to English.

```
/* Set the locale back to English(US) */
options locale=en_US;

data datatst;
input age sex $;
```

```
attrib age format= age.;
cards;
5 M
6 F
12 M
13 F
15 M
16 F
30 M
35 F
51 M
100 F
;
run;
/* Use the English format catalog*/
title "Locale is English, Use the Original Format Catalog";
proc print data=datatst; run;
```

Print the data set Using the Romanian format catalog. Using the LOCALE= system option, the locale is set to the Romanian locale.

```
/* Use the Romanian format catalog*/
options locale=ro_RO;
title 'Locale is ro_RO, Use the Romanian Format Catalog';
proc print data=datatst;run;
```

Here is the data set printed using the English and Romanian format catalogs:

Output 30.18 *A Data Set Printed Using an English and Romanian Format Catalog*

Locale is English, Use the Original Format Catalog

Obs	age	sex
1	baby	M
2	child	F
3	child	M
4	teen	F
5	teen	M
6	youth	F
7	youth	M
8	midlife	F
9	older	M
10	older	F

Locale is ro_RO, Use the Romanian Format Catalog

Obs	age	sex
1	Copil	M
2	Copil	F
3	Copil	M
4	Adolescent	F
5	Adolescent	M
6	Tineretului	F
7	Tineretului	M
8	Asta vrei	F
9	Mai vechi	M
10	Mai vechi	F

Example 20: Creating a Function to Use as a Format

Features:

PROC FCMP statement
CMPLIB= system option
PROC FORMAT statement
Function as a format feature

Details

This example creates a function that converts temperatures from Celsius to Fahrenheit and Fahrenheit to Celsius. The program uses the function as a function in one DATA step and then as a format in another DATA step.

Program

```
proc fcmp outlib=library.functions.smd;
   function ctof(c) $;
      return(cats(((9*c)/5)+32,'F'));
   endsub;

   function ftoc(f) $;
      return(cats((f-32)*5/9,'C'));
   endsub;

run;

options cmplib=(library.functions);

data _null_;
   f=ctof(100);
   put f=;
run;

proc format;
   value ctof (default=10) other=[ctof()];
   value ftoc (default=10) other=[ftoc()];
 run;

data _null_;
   c=100;
   put c=ctof.;
   f=212;
   put f=ftoc.;
run;
```

Program Description

Create the functions that change temperature from Celsius to Fahrenheit and Fahrenheit to Celsius. The FCMP procedure creates the CTOF function to convert Celsius temperatures to Fahrenheit and the FTOC to convert Fahrenheit temperatures to Celsius.

```
proc fcmp outlib=library.functions.smd;
   function ctof(c) $;
      return(cats(((9*c)/5)+32,'F'));
   endsub;

   function ftoc(f) $;
      return(cats((f-32)*5/9,'C'));
   endsub;

run;
```

Access the function library. The CMPLIB system option enables the functions to be included during program compilation.

```
options cmplib=(library.functions);
```

Use the function as a function in a SAS program.

```
data _null_;
   f=ctof(100);
   put f=;
run;
```

Create user-defined formats using the functions. The name of the format is the name of the function. When you use a function as a format, you can nest the format as shown by the OTHER keyword.

```
proc format;
   value ctof (default=10) other=[ctof()];
   value ftoc (default=10) other=[ftoc()];
 run;
```

Use the function as a format. This DATA step formats temperatures using a named PUT statement, where you assign a format to a variable in the PUT statement.

```
data _null_;
   c=100;
   put c=ctof.;
   f=212;
   put f=ftoc.;
run;
```

Output: Log

Example Code 30.6 *The SAS Log After Creating a Function to Use as a Format*

```
323  proc fcmp outlib=library.functions.smd;
324     function ctof(c) $;
325        return(cats(((9*c)/5)+32,'F'));
326     endsub;
327
328     function ftoc(f) $;
329        return(cats((f-32)*5/9,'C'));
330     endsub;
331
332  run;

NOTE: Function ftoc saved to library.functions.smd.
NOTE: Function ctof saved to library.functions.smd.

351  run;

c=212F
f=100C
```

Example 21: Using a Format to Create a Drill-down Table

Features: VALUE statement
PROC PRINT FORMAT statement

Details

This example creates an HTML table that has population information about five U.S. states. The name of the state is a link to the state's website. The link is created using a user-defined format to format the state name. This example does the following:

- creates the data set that contains the state population information
- creates a user-defined format using the VALUE statement, where the value is an HTML link (<a>) element
- defines the name of the HTML file and the titles for the HTML file
- prints the HTML table using the user-defined format

Program

```
data mydata;
   format population comma12.0;
   label st='State';
   label population='Population';
   input st $ 1-2 population;
   year=2000;
   datalines;
VA  7078515
NC  8049313
SC  4012012
GA  8186453
FL 15982378
;
run;

proc format;
value $COMPND
'VA'='<a href=http://www.va.gov>VA</a>'
'NC'='<a href=http://www.nc.gov>NC</a>'
'SC'='<a href=http://www.sc.gov>SC</a>'
'GA'='<a href=http://www.ga.gov>GA</a>'
```

```
'FL'='<a href=http://www.fl.gov>FL</a>';
run;

ods html file="c:\mySAS\html\Drilldown.htm"
 (title="An ODS HTML Drill-down Table Using a User-defined Format in
the PRINT
 Procedure");

title h=.25in "Year 2000 U.S. Census Population";
title2 color=gray "An ODS HTML Drill-down Table Using a User-defined
Format in
the PRINT Procedure";
footnote color=gray "(Click the underlined text to drill down.)";

options nodate;
proc print data=mydata label noobs;
 var st population;
 format st $compnd. ;
run;

ods html close;
ods html;
```

Program Description

Create the data set. The mydata DATA step creates a data set that contains information about five U.S. state populations based on the census taken in the year 2000. The variables that are created assign data for the year of the census, the state abbreviations, and the state population.

```
data mydata;
   format population comma12.0;
   label st='State';
   label population='Population';
   input st $ 1-2 population;
   year=2000;
   datalines;
VA  7078515
NC  8049313
SC  4012012
GA  8186453
FL 15982378
;
run;
```

Create the $COMPND. format. The $COMPND. format formats each state as a link to the state's respective website.

```
proc format;
value $COMPND
'VA'='<a href=http://www.va.gov>VA</a>'
'NC'='<a href=http://www.nc.gov>NC</a>'
'SC'='<a href=http://www.sc.gov>SC</a>'
'GA'='<a href=http://www.ga.gov>GA</a>'
'FL'='<a href=http://www.fl.gov>FL</a>';
run;
```

Set up the table filename and table titles. The ODS HTML FILE= option names the directory and filename where SAS saves the HTML output.

```
ods html file="c:\mySAS\html\Drilldown.htm"
 (title="An ODS HTML Drill-down Table Using a User-defined Format in
the PRINT
 Procedure");

title h=.25in "Year 2000 U.S. Census Population";
title2 color=gray "An ODS HTML Drill-down Table Using a User-defined
Format in
the PRINT Procedure";
footnote color=gray "(Click the underlined text to drill down.)";
```

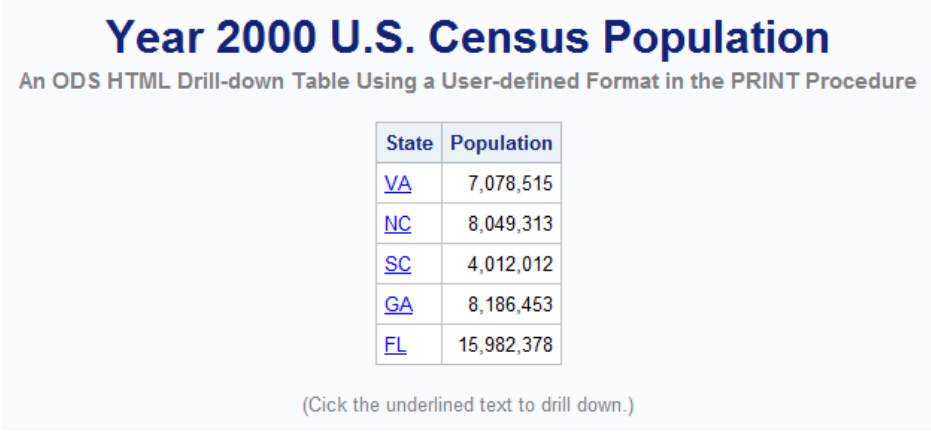
Print the table and close and reopen the HTML destination. The PRINT procedure uses the format $COMPND. to format the state name. The formatted name is a link to the state's respective website. The ODS HTML statements close and reopen the HTML destination so that future output does not overwrite the HTML file that you just created.

```
options nodate;
proc print data=mydata label noobs;
 var st population;
 format st $compnd. ;
run;

ods html close;
ods html;
```

Output

Output 30.19 *Using a Format to Create Drill-down Text in an HTML Table*



Year 2000 U.S. Census Population

An ODS HTML Drill-down Table Using a User-defined Format in the PRINT Procedure

State	Population
VA	7,078,515
NC	8,049,313
SC	4,012,012
GA	8,186,453
FL	15,982,378

(Cick the underlined text to drill down.)

31

FSLIST Procedure

Overview: FSLIST Procedure

What Does the FSLIST Procedure Do?

The FSLIST procedure enables you to browse, within a SAS session, external files that are not SAS data sets. Because the files are displayed in an interactive window, the procedure provides a highly convenient mechanism for examining file contents. In addition, you can copy text from the FSLIST window into any window that uses the SAS Text Editor.

Syntax: FSLIST Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC FSLIST FILEREF=*file-specification* | UNIT=*nn* <*options*>;

PROC FSLIST DDNAME=*file-specification* | UNIT=*nn* <*options*>;

PROC FSLIST DD=*file-specification* | UNIT=*nn* <*options*>;

Statement	Task
PROC FSLIST	Initiate the FSLIST procedure and specify the external file to browse

PROC FSLIST Statement

Enables you to browse external files that are not SAS data sets within a SAS session.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Syntax

PROC FSLIST FILEREF=*file-specification* | UNIT=*nn* <*options*>;

PROC FSLIST DDNAME=*file-specification* | UNIT=*nn* <*options*>;

PROC FSLIST DD=*file-specification* | UNIT=*nn* <*options*>;

Summary of Optional Arguments

CAPS

NOCAPS
: controls how search strings for the FIND command are treated.

CC

FORTCC

NOCC
: indicates whether carriage-control characters are used to format the display.

HSCROLL=*n* | HALF | PAGE
: indicates the default horizontal scroll amount for the LEFT and RIGHT commands.

NOBORDER
: suppresses the sides and bottom of the FSLIST window's border.

NUM

NONUM
: controls the display of line sequence numbers.

OVP

NOOVP
indicates whether the carriage-control code for overprinting is in effect.

Required Arguments

FILEREF | DDNAME | DD=*file-specification*
specifies the external file to browse. *File-specification* can be one of the following:

'external-file'
is the complete operating environment file specification (called the fully qualified pathname under some operating environments) for the external file. You must enclose the name in quotation marks.

fileref
is a fileref that has been previously assigned to the external file. You can use the FILENAME statement to associate a fileref with an actual filename. For more information, see "FILENAME Statement" in *SAS Global Statements: Reference*.

UNIT=*nn*
defines the FORTRAN-style logical unit number of the external file to browse. This option is useful when the file to browse has a fileref of the form FT*nn*F001, where *nn* is the logical unit number that is specified in the UNIT= argument. For example, you can specify the following: `proc fslist unit=20;` instead of `proc fslist fileref=ft20f001;`

Optional Arguments

CAPS | NOCAPS
controls how search strings for the FIND command are treated:

CAPS
converts search strings into uppercase unless they are enclosed in quotation marks. For example, with this option in effect, the command `find nc`locates occurrences of **NC**, but not **nc**. To locate lowercase characters, enclose the search string in quotation marks: `find 'nc'`

NOCAPS
does not perform a translation. The FIND command locates only those text strings that exactly match the search string.

The default is NOCAPS. You can use the CAPS command in the FSLIST window to change the behavior of the procedure while you are browsing a file.

CC | FORTCC | NOCC
indicates whether carriage-control characters are used to format the display. You can specify one of the following values for this option:

CC
uses the native carriage-control characters of the operating environment.

FORTCC
uses FORTRAN-style carriage control. The first column of each line in the external file is not displayed. The character in this column is interpreted as a

carriage-control code. The FSLIST procedure recognizes the following carriage-control characters:

+
skip zero lines and print (overprint).

blank
skip one line and print (single space).

0
skip two lines and print (double space).

-
skip three lines and print (triple space).

1
go to new page and print.

NOCC
treats carriage-control characters as regular text.

If the FSLIST procedure can determine from the file's attributes that the file contains carriage-control information, then that carriage-control information is used to format the displayed text. In this case, the CC option is the default. Otherwise, the entire contents of the file are treated as text. In this case, the NOCC option is the default.

Note: Under some operating environments, FORTRAN-style carriage control is the native carriage control. For these environments, the FORTCC and CC options produce the same behavior.

HSCROLL=*n* | HALF | PAGE
indicates the default horizontal scroll amount for the LEFT and RIGHT commands. The following values are valid:

n
sets the default scroll amount to *n* columns.

HALF
sets the default scroll amount to half the window width.

PAGE
sets the default scroll amount to the full window width.

The default is HSCROLL=HALF. You can use the HSCROLL command in the FSLIST window to change the default scroll amount.

NOBORDER
suppresses the sides and bottom of the FSLIST window's border. When this option is used, text can appear in the columns and row that are normally occupied by the border.

NUM | NONUM
controls the display of line sequence numbers in files that have a record length of 80 and contain sequence numbers in columns 73 through 80. NUM displays the line sequence numbers. NONUM suppresses them.

Default NONUM

OVP | NOOVP
indicates whether the carriage-control code for overprinting is in effect:

OVP
causes the procedure to honor the overprint code and print the current line over the previous line when the code is encountered.

NOOVP
causes the procedure to ignore the overprint code and print each line from the file on a separate line of the display.

Usage: FSLIST Procedure

FSLIST Command

Initiates an FSLIST session from any SAS window. The command enables you to use either a fileref or a filename to specify the file to browse. It also enables you to specify how carriage-control information is interpreted.

Syntax

FSLIST <* | ? | *file-specification <carriage-control-option <overprinting-option>>*>

Without Arguments

If you do not specify any of these three arguments, then a selection window appears that enables you to select an external filename.

Optional Arguments

*
opens a dialog box in which you can specify the name of the file to browse, along with various FSLIST procedure options. In the dialog box, you can specify either a physical filename, a fileref, or a directory name. If you specify a directory name, then a selection list of the files in the directory appears, from which you can choose the desired file.

?

opens a selection window from which you can choose the external file to browse. The selection list in the window includes all external files that are identified in the current SAS session (all files with defined filerefs).

To select a file, position the cursor on the corresponding fileref and press Enter.

Notes Only filerefs that are defined within the current SAS session appear in the selection list. Under some operating environments, it is possible to allocate filerefs outside of SAS. Such filerefs do not appear in the selection list that is displayed by the FSLIST command.

The selection window is not opened if no filerefs have been defined in the current SAS session. Instead, an error message is written, instructing you to enter a filename with the FSLIST command.

file-specification

identifies the external file to browse. *File-specification* can be one of the following:

'external-file'

the complete operating environment file specification (called the fully qualified pathname under some operating environments) for the external file. You must enclose the name in quotation marks.

If the specified file is not found, then a selection window appears that shows all available filerefs.

fileref

a fileref that is currently assigned to an external file. If you specify a fileref that is not currently defined, then a selection window appears that shows all available filerefs. An error message in the selection window indicates that the specified fileref is not defined.

If you specify *file-specification* with the FSLIST command, then you can also use the following carriage control or overprinting options. These options are not valid with the ? argument, or when no argument is used:

CC
FORTCC
NOCC

indicates whether carriage-control characters are used to format the display.

If the FSLIST procedure can determine from the file's attributes that the file contains carriage-control information, then that carriage-control information is used to format the displayed text. In this case, the CC option is the default. Otherwise, the entire contents of the file are treated as text. In this case, the NOCC option is the default.

You can specify one of the following values for this option:

CC

uses the native carriage-control characters of the operating environment.

FORTCC
uses FORTRAN-style carriage control. See the discussion of the PROC FSLIST statement's FORTCC option for details.

NOCC
treats carriage-control characters as regular text.

OVP | NOOVP
indicates whether the carriage-control code for overprinting is honored. OVP causes the overprint code to be honored. NOOVP causes it to be ignored. The OVP option is ignored if NOCC is in effect.

Default NOOVP

Using the FSLIST Window

Overview of the FSLIST Window

The FSLIST window displays files for browsing only. You cannot edit files in the FSLIST window. However, you can copy text from the FSLIST window into a paste buffer in the following ways, depending on your operating environment:

- Use a mouse to select text, and select **Copy** from the **Edit** menu.
- Use the global MARK and STORE commands.

Depending on your operating environment, the text that you copy can then be pasted into any SAS window that uses the SAS text editor, including the FSLETTER window in SAS/FSP software, or into any other application that allows pasting of text.

You can use commands in the command window or command line to control the FSLIST window.

FSLIST Window Commands

Global Commands

In the FSLIST window, you can use any of the global commands that are described in the *SAS/FSP Procedures Guide*.

Scrolling Commands

n
scrolls the window so that line *n* of text is at the top of the window. Type the desired line number in the command window or on the command line and press Enter. If *n* is greater than the number of lines in the file, then the last few lines of the file are displayed at the top of the window.

BACKWARD <*n*|HALF | PAGE | MAX>
scrolls vertically toward the first line of the file. The following scroll amounts can be specified:

n
scrolls upward by the specified number of lines.

HALF
scrolls upward by half the number of lines in the window.

PAGE
scrolls upward by the number of lines in the window.

MAX
scrolls upward until the first line of the file is displayed.

If the scroll amount is not explicitly specified, then the window is scrolled by the amount that was specified in the most recent VSCROLL command. The default VSCROLL amount is PAGE.

BOTTOM
scrolls downward until the last line of the file is displayed.

FORWARD <*n*|HALF | PAGE | MAX>
scrolls vertically toward the end of the file. The following scroll amounts can be specified:

n
scrolls downward by the specified number of lines.

HALF
scrolls downward by half the number of lines in the window.

PAGE
scrolls downward by the number of lines in the window.

MAX
scrolls downward until the first line of the file is displayed.

If the scroll amount is not explicitly specified, then the window is scrolled by the amount that was specified in the most recent VSCROLL command. The default VSCROLL amount is PAGE. Regardless of the scroll amount, this command does not scroll beyond the last line of the file.

HSCROLL <*n*|HALF | PAGE>
sets the default horizontal scrolling amount for the LEFT and RIGHT commands. The following scroll amounts can be specified:

n
sets the default scroll amount to the specified number of columns.

HALF
sets the default scroll amount to half the number of columns in the window.

PAGE
sets the default scroll amount to the number of columns in the window.

The default HSCROLL amount is HALF.

LEFT <*n*|HALF | PAGE | MAX>
scrolls horizontally toward the left margin of the text. This command is ignored unless the file width is greater than the window width. The following scroll amounts can be specified:

n
scrolls left by the specified number of columns.

HALF
scrolls left by half the number of columns in the window.

PAGE
scrolls left by the number of columns in the window.

MAX
scrolls left until the left margin of the text is displayed at the left edge of the window.

If the scroll amount is not explicitly specified, then the window is scrolled by the amount that was specified in the most recent HSCROLL command. The default HSCROLL amount is HALF. Regardless of the scroll amount, this command does not scroll beyond the left margin of the text.

RIGHT <*n*|HALF | PAGE | MAX>
scrolls horizontally toward the right margin of the text. This command is ignored unless the file width is greater than the window width. The following scroll amounts can be specified:

n
scrolls right by the specified number of columns.

HALF
scrolls right by half the number of columns in the window.

PAGE
scrolls right by the number of columns in the window.

MAX
scrolls right until the right margin of the text is displayed at the left edge of the window.

If the scroll amount is not explicitly specified, then the window is scrolled by the amount that was specified in the most recent HSCROLL command. The default HSCROLL amount is HALF. Regardless of the scroll amount, this command does not scroll beyond the right margin of the text.

TOP
scrolls upward until the first line of text from the file is displayed.

VSCROLL <*n* | HALF | PAGE>
sets the default vertical scrolling amount for the FORWARD and BACKWARD commands. The following scroll amounts can be specified:

n
sets the default scroll amount to the specified number of lines.

HALF
sets the default scroll amount to half the number of lines in the window.

PAGE
sets the default scroll amount to the number of lines in the window.

The default VSCROLL amount is PAGE.

Searching Commands

BFIND <*search-string* <PREFIX | SUFFIX | WORD>>
locates the previous occurrence of the specified string in the file, starting at the current cursor position and proceeding backward toward the beginning of the file. The *search-string* value must be enclosed in quotation marks if it contains embedded blanks.

If a FIND command has previously been issued, then you can use the BFIND command without arguments to repeat the search in the opposite direction.

The CAPS option in the PROC FSLIST statement and the CAPS ON command cause search strings to be converted to uppercase for the purposes of the search, unless the strings are enclosed in quotation marks. See the discussion of the FIND command for details.

By default, the BFIND command locates any occurrence of the specified string, even where the string is embedded in other strings. You can use any one of the following options to alter the command's behavior:

PREFIX
causes the search string to match the text string only when the text string occurs at the beginning of a word.

SUFFIX
causes the search string to match the text string only when the text string occurs at the end of a word.

WORD
causes the search string to match the text string only when the text string is a distinct word.

You can use the RFIND command to repeat the most recent BFIND command.

CAPS <ON | OFF>
controls how the FIND, BFIND, and RFIND commands locate matches for a search string. By default, the FIND, BFIND, and RFIND commands locate only those text strings that exactly match the search string as it was entered. When you issue the CAPS command, the FIND, BFIND, and RFIND commands convert search strings into uppercase for the purposes of searching (displayed text is not affected), unless the strings are enclosed in quotation marks. Strings in quotation marks are not affected.

For example, after you issue a CAPS ON command, both of the following commands locate occurrences of **`NC`** but not occurrences of **`nc`**: `find NC`, `find`

`nc`. If you omit the ON or OFF argument, then the CAPS command acts as a toggle, turning the attribute on if it was off or off if it was on.

FIND *search-string* <NEXT | FIRST | LAST | PREV | ALL> <PREFIX | SUFFIX | WORD>

locates an occurrence of the specified *search-string* in the file. The *search-string* must be enclosed in quotation marks if it contains embedded blanks.

The text in the *search-string* must match the text in the file in terms of both characters and case. For example, the following command locates occurrences of **`raleigh`**: `find raleigh`. The following command locates occurrences of **`Raleigh`**: `find Raleigh`.

When the CAPS option is used with the PROC FSLIST statement or when a CAPS ON command is issued in the window, the search string is converted to uppercase for the purposes of the search, unless the string is enclosed in quotation marks. In that case, the command `find raleigh` will locate only the text **`RALEIGH`** in the file. You must instead use the command `find 'Raleigh'` to locate the text **`Raleigh`**.

You can modify the behavior of the FIND command by adding any one of the following options:

ALL
: reports the total number of occurrences of the string in the file in the window's message line and moves the cursor to the first occurrence.

FIRST
: moves the cursor to the first occurrence of the string in the file.

LAST
: moves the cursor to the last occurrence of the string in the file.

NEXT
: moves the cursor to the next occurrence of the string in the file.

PREV
: moves the cursor to the previous occurrence of the string in the file.

The default option is NEXT.

By default, the FIND command locates any occurrence of the specified string, even where the string is embedded in other strings. You can use any one of the following options to alter the command's behavior:

PREFIX
: causes the search string to match the text string only when the text string occurs at the beginning of a word.

SUFFIX
: causes the search string to match the text string only when the text string occurs at the end of a word.

WORD
: causes the search string to match the text string only when the text string is a distinct word.

After you issue a FIND command, you can use the RFIND command to repeat the search for the next occurrence of the string, or you can use the BFIND command to repeat the search for the previous occurrence.

RFIND
repeats the most recent FIND command, starting at the current cursor position and proceeding forward toward the end of the file.

Display Commands

COLUMN <ON | OFF>
displays a column ruler below the message line in the FSLIST window. The ruler is helpful when you need to determine the column in which a particular character is located. If you omit the ON or OFF specification, then the COLUMN command acts as a toggle, turning the ruler on if it was off and off if it was on.

HEX <ON | OFF>
controls the special hexadecimal display format of the FSLIST window. When the hexadecimal format is turned on, each line of characters from the file occupies three lines of the display. The first is the line displayed as characters. The next two lines of the display show the hexadecimal value of the operating environment's character codes for the characters in the line of text. The hexadecimal values are displayed vertically, with the most significant byte on top. If you omit the ON or OFF specification, then the HEX command acts as a toggle, turning the hexadecimal format on if it was off and off if it was on.

NUMS <ON | OFF>
controls whether line numbers are shown at the left side of the window. By default, line numbers are not displayed. If line numbers are turned on, then they remain at the left side of the display when text in the window is scrolled right and left. If you omit the ON or OFF argument, then the NUMS command acts as a toggle, turning line numbering on if it was off or off if it was on.

Other Commands

BROWSE *fileref* | '*actual-filename*' <CC | FORTCC | NOCC <OVP | NOOVP>>
closes the current file and displays the specified file in the FSVIEW window. You can specify either a fileref previously associated with a file or an actual filename enclosed in quotation marks. The BROWSE command also accepts the same carriage-control options as the FSLIST command. See "Optional Arguments" on page 1209 for details.

END
closes the FSLIST window and ends the FSLIST session.

HELP <*command*>
opens a Help window that provides information about the FSLIST procedure and about the commands available in the FSLIST window. To get information about a specific FSLIST window command, follow the HELP command with the name of the desired command.

KEYS
opens the KEYS window for browsing and editing function key definitions for the FSLIST window. The default key definitions for the FSLIST window are stored in the FSLIST.KEYS entry in the Sashelp.Fsp catalog.

If you change any key definitions in the KEYS window, then a new FSLIST.KEYS entry is created in your personal PROFILE catalog (Sasuser.Profile, or Work.Profile if the Sasuser library is not allocated).

When the FSLIST procedure is initiated, it looks for function key definitions first in the FSLIST.KEYS entry in your personal PROFILE catalog. If that entry does not exist, then the default entry in the Sashelp.Fsp catalog is used.

32

GROOVY Procedure

Overview: GROOVY Procedure

What Does the GROOVY Procedure Do?

Groovy is a dynamic language that runs on the Java Virtual Machine (JVM). PROC GROOVY enables SAS code to execute Groovy code on the JVM.

PROC GROOVY can run Groovy statements that are written as part of your SAS code, and it can run statements that are in files that you specify with PROC GROOVY commands. It can parse Groovy statements into Groovy Class objects,

and it can run these objects or make them available to other PROC GROOVY statements or Java DATA Step Objects. You can also use PROC GROOVY to update your CLASSPATH environment variable with additional CLASSPATH strings or filerefs to JAR files.

Special Considerations

Groovy code that is submitted with PROC GROOVY runs as the process owner, and has the same access to resources (file system, network, and so on) as any process owner. Groovy code access to resources can cause problems when SAS code is running inside multiuser servers like the Stored Process Server. To give administrators some control over this functionality, PROC GROOVY runs only if the NOXCMD option is turned off. All SAS servers are shipped with the NOXCMD option turned on.

The use of a percent character (%) in the first byte of the text that is written by Java to the SAS log is reserved by SAS. If you need to write a percent character in the first byte of a Java text line, then you must immediately follow it with another percent character (%%).

PROC GROOVY does not support the THREADS | NOTHREADS SAS system option. However, Groovy code that you submit with PROC GROOVY can use threaded processing in the JVM.

Syntax: GROOVY Procedure

Restrictions: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC GROOVY does not run if the NOXCMD option is turned on.

Interaction: When a SAS server is in a locked-down state, PROC GROOVY will not execute. For more information, see "SAS Processing Restrictions for Servers in a Locked-Down State" in *SAS Language Reference: Concepts*.

PROC GROOVY <*classpath options*>;

ADD *classpath options*;

EVALUATE <(LOAD | PARSEONLY | NORUN)>
"*Groovy statement string*" <*argument(s)*>;

EXECUTE <(LOAD | PARSEONLY | NORUN)>
Groovy filename | *fileref* <*argument(s)*>;

SUBMIT <(LOAD | PARSEONLY | NORUN)> <*argument(s)*>;
Groovy statement(s)

ENDSUBMIT;

CLEAR;

QUIT;

Statement	Task	Example
PROC GROOVY	Enable SAS code to run Groovy code on the JVM	Ex. 1
ADD	Append the given classpath to the current CLASSPATH environment variable	
EVALUATE	Parse the Groovy statement in the quoted string and call the Run method on the Script	
EXECUTE	Read the contents of the file that is specified as either a quoted string path or as a fileref and call the Run method on the Script	
SUBMIT	Parse the Groovy statements between the SUBMIT and ENDSUBMIT commands and call the Run method on the Script	
ENDSUBMIT	End the Groovy statements that begin with the SUBMIT command	
CLEAR	Empty the binding and unload the Groovy classloader	

PROC GROOVY Statement

Enables SAS code to run Groovy code on the JVM.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Syntax

PROC GROOVY <*classpath options*>;

Optional Argument

classpath options
can be one of the following:

CLASSPATH=
specifies a quoted CLASSPATH string or a fileref to a specific JAR file that is to be added to the current classpath. This path is searched after the paths that are in the user's CLASSPATH environment variable.

Alias PATH=

SASJAR=<*version*=> | <*range*=>
specifies a quoted string that identifies a JAR in the Versioned JAR Repository (VJR) that should be added to the current classpath. The VERSION and RANGE values are optional. RANGE takes precedence over VERSION, as in the following example:

```
ADD SASJAR="sas.core";
ADD SASJAR="sas.core" version="903000.9.0.20100810190000_v930";
ADD SASJAR="sas.core" range="[0,909000]";
```

Note: SAS JAR files do not have a source compatibility guarantee across versions of SAS. Future versions of this JAR can change without notice. To ensure continued functionality, contact SAS Technical Support.

Details

PROC GROOVY uses the current user's CLASSPATH environment variable as the base for building its classpath. You can use the CLASSPATH and SASJAR options to add paths to the current classpath.

When a class is loaded, the paths are searched in the following order:

1. CLASSPATH environment variable when process started
2. paths added with the ADD CLASSPATH and ADD SASJAR statements in the order in which they were executed

ADD Statement

Appends the given classpath to the current CLASSPATH environment variable.

Syntax

ADD *classpath options*;

Required Argument

classpath options
can be one of the following:

CLASSPATH=
specifies a quoted CLASSPATH string or a fileref to a specific JAR file that is to be added to the current classpath. This path is searched after the paths that are in the user's CLASSPATH environment variable.

Alias PATH=

SASJAR=<*version*=> | <*range*=>
specifies a quoted string that identifies a JAR file in the Versioned JAR Repository (VJR) that should be added to the current classpath. The VERSION and RANGE values are optional. RANGE takes precedence over VERSION, as in the following example:

```
ADD SASJAR="sas.core";
ADD SASJAR="sas.core" version="903000.9.0.20100810190000_v930";
ADD SASJAR="sas.core" range="[0,909000]";
```

Note: SAS JAR files do not have a source compatibility guarantee across versions of SAS. Future versions of this JAR file can change without notice. To ensure continued functionality, contact SAS Technical Support.

Details

The ADD statement appends the given classpath to the current CLASSPATH environment variable.

You must specify at least one CLASSPATH or one SASJAR. You can specify multiple CLASSPATHs or SASJARs.

EVALUATE Statement

Parses the Groovy statement that is provided in the quoted string into a groovy.lang.Script object and calls the Run method on the Script.

Syntax

EVALUATE <(LOAD | PARSEONLY | NORUN)>
"*Groovy statement string*" <*argument(s)*>;

Required Argument

Groovy statement string
specifies a Groovy statement string that is to be parsed by the EVALUATE statement.

Optional Arguments

LOAD | PARSEONLY | NORUN
parses the Groovy statement into a groovy.lang.Script object, but does not run it. The arguments are aliases for each other.

argument(s)
specifies arguments that are passed to the code that is being evaluated.

Details

The EVALUATE statement parses the Groovy statement that is provided in the quoted string into a groovy.lang.Script object and calls the Run method on the Script. If one of the LOAD, PARSEONLY, or NORUN options is present, then this statement parses the Groovy statement into a Class object but does not run it. Any classes that are defined by the Groovy code are then available for use by PROC GROOVY statements or by Java DATA Step Objects.

EVAL is an alias for the EVALUATE statement.

EXECUTE Statement

Reads the contents of the file that is specified as either a quoted string path or as a fileref.

Syntax

EXECUTE <(LOAD | PARSEONLY | NORUN)>
Groovy filename | fileref <*argument(s)*>;

Required Arguments

Groovy filename
specifies the name of the Groovy file that is to be parsed by the EXECUTE statement.

fileref
specifies the name of a fileref that is to be parsed by the EXECUTE statement.

Optional Arguments

LOAD | PARSEONLY | NORUN
parses the Groovy statement in the specified Groovy file or fileref into a groovy.lang.Script object, but does not run it. The arguments are aliases for each other.

argument(s)
specifies arguments that are passed to the code that is being executed.

Details

The EXECUTE statement reads the contents of the file that is specified as either a quoted string path or as a fileref. The contents are then parsed into a groovy.lang.Script object, and the Run method is called on the Script. If one of the LOAD, PARSEONLY, or NORUN options is present, then this statement parses the file contents into a Class object but does not run it. Any classes that are defined by the Groovy code are then available for use by PROC GROOVY statements or by Java DATA Step Objects.

EXEC is an alias for the EXECUTE statement.

Note: If you used an EXEC PARSEONLY statement to compile a file into a Class, then you must submit a CLASS statement so that changes to that file are honored by future EXEC PARSEONLY commands. If you do not submit the CLEAR statement, then any changes that you made to the file after you issued the EXEC PARSEONLY statement are not included by subsequent submissions of the EXEC PARSEONLY statement. You can use the GroovyScriptEngine Class if you need to use reloadable scripts.

SUBMIT Statement

Parses the Groovy statements that are between the SUBMIT and ENDSUBMIT commands into a groovy.lang.Script object and calls the Run method on the Script.

Syntax

SUBMIT <(LOAD | PARSEONLY | NORUN)> <*argument(s)*>;
Groovy statement(s)

ENDSUBMIT;

Required Argument

Groovy statement(s)
specifies Groovy statements that are to be parsed by the SUBMIT statement into a groovy.lang.Script object.

Optional Arguments

LOAD | PARSEONLY | NORUN
parses the Groovy statements into a groovy.lang.Script object, but does not run it. The arguments are aliases for each other.

argument(s)
specifies arguments that are passed to the code that is being submitted.

Details

The SUBMIT statement parses the Groovy statements that are between the SUBMIT and ENDSUBMIT commands into a groovy.lang.Script object and calls the Run method on the Script. If one of the LOAD, PARSEONLY, or NORUN options is present, then this statement parses the Groovy statements into a Class object but does not run it. Any classes that are defined by the Groovy code are then available for use by PROC GROOVY statements or by Java DATA Step Objects.

Note:

- The ENDSUBMIT statement must be on a line by itself and preceded by only blank space.
- Macro substitution is disabled between the SUBMIT and ENDSUBMIT commands.
- PROC GROOVY with multi-line submit commands cannot be used inside a macro.

ENDSUBMIT Statement

Ends the Groovy statements that begin with the SUBMIT command.

Syntax

ENDSUBMIT;

Details

Ends the Groovy statements that begin with the SUBMIT statement.

Note: The ENDSUBMIT statement must be on a line by itself and preceded by only blank space.

CLEAR Statement

Empties the binding and unloads the Groovy classloader.

Syntax

CLEAR;

Details

The CLEAR statement empties the binding and unloads the Groovy classloader. When this statement is executed, any variables that are saved in the binding are rendered unavailable. Any classes that are loaded into the Groovy classloader are also rendered unavailable.

RESET is an alias for the CLEAR statement.

Note: Neither the CLEAR statement nor the RESET statement resets the System.Properties collection or the CLASSPATH.

Usage: GROOVY Procedure

Special Variables

PROC GROOVY has four special variables: BINDING, ARGS, EXPORTS, and SHELL. It makes these variables available to any Groovy code that it is running.

BINDING

The BINDING special variable is used to share the state of objects between executions of PROC GROOVY. It is populated by any variables that are created without scope or that are explicitly stored in the binding. BINDING also holds all of the other special variables that are discussed in this section. The binding can be cleared with the CLEAR statement.

Note: The BINDING special variable is available to any Groovy code that PROC GROOVY is running.

```
proc groovy;
  eval "a = 42";
  eval "binding.b = 84";
```

```
  eval "binding.setProperty( 'c', 168 )";
quit;
proc groovy;
  eval "println ""----> ${binding.getProperty('a')}""";
  eval "println ""----> ${b}""";
  eval "println ""----> ${binding.c}""";
quit;
```

ARGS

Arguments are passed to Groovy code in the ARGS special variable in the binding.

Note: The ARGS special variable is available to any Groovy code that PROC GROOVY is running.

```
proc groovy;
  eval "args.each{ println ""----> ev ${it}"" }" "arg1" "arg2" "arg3";

  exec "args.groovy" "arg1" "arg2" "arg3";

  submit "arg1" "arg2" "arg3";
    args.each{
      println "----> su ${it}"
    }
  endsubmit;
quit;
```

EXPORTS

The EXPORTS special variable contains a map in the binding. Adding a key or value pair to this map will create a SAS macro variable when PROC GROOVY ends. Groovy is case sensitive, but macros are not. If two keys exist in the map that differ only by their case, then the one that is exported into a SAS macro is not determined. You can also replace the EXPORTS variable in the binding with any object that inherits from java.util.Map. If you replace the variable, all of the key or value pairs in that object will be exported.

Note: The EXPORTS special variable is available to any Groovy code that PROC GROOVY is running.

```
proc groovy;
  eval "exports.fname = ""first name""";
  eval "binding.exports.lname = ""last name""";
  eval "exports.put('state', 'NC')";
quit;

data _NULL_;
  put "----> &fname &lname: &state";
```

```
run;

proc groovy;
  submit;
    exports = [fname:"first name", lname: "last name", state: "NC"]
  endsubmit;
quit;

data _NULL_;
  put "----> &fname &lname: &state";
run;
```

SHELL

The SHELL special variable in the binding is set to the groovy.lang.GroovyShell that was used to compile the current script. You must submit a CLEAR statement before changes that were made to the execution.groovy file in this example are reflected in subsequent runs of the code.

Note: The SHELL special variable is available to any Groovy code that PROC GROOVY is running.

```
proc groovy;
  eval "shell.run(
              new File(""execution.groovy""),
              [] as String[] )";
quit;
```

Note: If you need Groovy scripts that will be reloaded automatically when they are modified, then create a new instance of the GroovyScriptEngine class.

Examples: GROOVY Procedure

Example 1: Define Classes

Features:

PROC GROOVY statement option
    CLASSPATH

SUBMIT statement option
    PARSEONLY

SUBMIT Statement

ENDSUBMIT Statement

The following three examples show how to use PROC GROOVY to define a class.

Program

Groovy code is run by default. If your script does not have any executable code, then an error is returned. The following example defines a class, but it does not have any executable code, and an error is returned.

```
proc groovy classpath=cp;
  submit;
    class Speaker {
      def say( word ) {
        println "----> \"${word}\""
      }
    }
  endsubmit;
quit;
```

Program

The following example shows how to define a class that can be run by including a `main` method.

```
proc groovy classpath=cp;
  submit;
    class Speaker {
      def Speaker() {
        println "----> ctor"
      }
      def main( args ) {
        println "----> main"
      }
    }
  endsubmit;
quit;
```

Program

The following example shows how to use the PARSEONLY option to avoid a run call. You can then use the new class in another execution of PROC GROOVY.

```
proc groovy classpath=cp;
  submit parseonly;
    class Speaker {
      def say( word ) {
        println "----> \"${word}\""
      }
```

```
    }
  endsubmit;
quit;

proc groovy classpath=cp;
  eval "s = new Speaker(); s.say( ""Hi"" )";
quit;
```

Example 2: Pass a Macro Variable to PROC GROOVY

Features: SUBMIT Statement
ENDSUBMIT Statement

The following example shows how to define a macro variable and pass it to PROC GROOVY.

```
%let _inzip = C:/path/example.zip;
proc groovy;
   submit "&_inzip.";
      def zipFile = new java.util.zip.ZipFile(new File(args[0]))
         zipFile.entries().each {
            println zipFile.getInputStream(it).text
         }

   endsubmit;
quit;
```

33

HADOOP Procedure

Overview: HADOOP Procedure

What Does the HADOOP Procedure Do?

The HADOOP procedure enables SAS to interact with Hadoop data by running Apache Hadoop code. Apache Hadoop is an open-source framework, written in

Java, that provides distributed data storage and processing of large amounts of data.

PROC HADOOP interfaces with the Hadoop JobTracker. This is the service within Hadoop that controls tasks to specific nodes in the cluster. PROC HADOOP enables you to submit the following:

- Hadoop Distributed File System (HDFS) commands
- MapReduce programs
- Pig language code

The HADOOP procedure is supported in SAS 9.4 and in SAS Viya.

Syntax: HADOOP Procedure

Restrictions: This procedure is not supported in the z/OS operating environment.

This procedure is not supported on the CAS server.

When SAS is in a locked-down state, PROC HADOOP is not available. Your server administrator can re-enable this procedure so that it is accessible in the lockdown state. When the FILENAME Hadoop access method is re-enabled by using the LOCKDOWN ENABLE_AMS= statement, PROC HADOOP is automatically re-enabled. For more information, see "SAS Processing Restrictions for Servers in a Locked-Down State" in *SAS Programmer's Guide: Essentials*.

Requirement: Java Runtime Environment (JRE) 1.6 and higher

Interactions: Beginning with SAS 9.4M3, to connect to the Hadoop cluster, the Hadoop cluster configuration files must be accessible to the SAS client machine. You can copy the configuration files to a physical location that is accessible to the SAS client machine and then set the SAS environment variable SAS_HADOOP_CONFIG_PATH to the location. Or, you can create a single configuration file by merging the properties from the multiple Hadoop cluster configuration files and then identify the configuration file with the PROC HADOOP statement CFG= argument. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

To submit HDFS commands, MapReduce programs, and Pig language code using the Java API, the Hadoop distribution JAR files must be copied to a physical location that is accessible to the SAS client machine. The SAS environment variable SAS_HADOOP_JAR_PATH must be set to the location of the Hadoop JAR files. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

To submit HDFS commands through WebHDFS, the SAS environment variable SAS_HADOOP_RESTFUL must be set to 1. In addition, the Hadoop configuration file hdfs-site.xml must include the properties for the WebHDFS location. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

Beginning with SAS 9.4M3, to submit MapReduce programs and Pig language code through the Apache Oozie RESTful API, the SAS environment variable

SAS_HADOOP_RESTFUL must be set to 1. You must also set the SAS environment variable SAS_HADOOP_CONFIG_PATH to the location where the hdfs-site.xml and core-site.xml configuration files exist. The hdfs-site.xml must include the property for the WebHDFS location. You also need to specify Oozie specific properties in a configuration file and identify the configuration file with the PROC HADOOP statement CFG= argument. The Oozie specific properties include oozie_http_port, fs.default.name, and mapred.job.tracker. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*. PROC HADOOP does not support running an Oozie job (MAPREDUCE or PIG) on a server that has Kerberos enabled.

Note: For a list of Hadoop distributions that are supported in SAS 9.4, see SAS 9.4 Supported Hadoop Distributions. For a list of Hadoop distributions that are supported in SAS Viya, see *SAS Viya: Deployment Guide*. For information about configuration, see SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS.

PROC HADOOP <*hadoop-server-options*>;

HDFS <*hadoop-server-options*> <*hdfs-command-options*>;

MAPREDUCE <*hadoop-server-options*> <*mapreduce-options*>;

PIG <*hadoop-server-options*> <*pig-code-options*>;

PROPERTIES <*configuration-properties*>;

Statement	Task	Example
PROC HADOOP	Control access to the Hadoop server	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5
HDFS	Submit Hadoop Distributed File System (HDFS) commands	Ex. 1, Ex. 2
MAPREDUCE	Submit MapReduce programs into a Hadoop cluster	Ex. 3
PIG	Submit Pig language code into a Hadoop cluster	Ex. 4
PROPERTIES	Submit configuration properties	Ex. 5

PROC HADOOP Statement

Controls access to the Hadoop server.

Examples:
"Example 1: Submitting HDFS Commands" on page 1250
"Example 2: Submitting HDFS Commands with Wildcard Characters" on page 1251
"Example 3: Submitting a MapReduce Program" on page 1253
"Example 4: Submitting Pig Language Code" on page 1255
"Example 5: Submitting Configuration Properties" on page 1256

Syntax

PROC HADOOP <*hadoop-server-options*>;

Summary of Optional Arguments

AUTHDOMAIN='*authentication-domain*'
: specifies the name of an authentication domain metadata object in order to connect to the Hadoop server.

CFG=*fileref* | '*external-file*'
: identifies the Hadoop configuration file to use in order to connect to the Hadoop server.

MAXWAIT=*wait-interval*
: specifies the HTTP status response time when using WebHDFS.

PASSWORD='*password*'
: is the password for the user ID on the Hadoop server.

USERNAME='*ID*'
: is an authorized user ID on the Hadoop server.

VERBOSE
: enables additional messages that are displayed on the SAS log.

Hadoop Server Options

These options control access to the Hadoop server and can be specified in all HADOOP procedure statements.

AUTHDOMAIN='*authentication-domain*'
specifies the name of an authentication domain metadata object in order to connect to the Hadoop server. The authentication domain references credentials (user ID and password) without your explicitly specifying the credentials.

An administrator creates authentication domain definitions while creating a user definition with the User Manager in SAS Management Console. The authentication domain is associated with one or more login metadata objects that provide access to the Hadoop server. The metadata objects are resolved by SAS calling the SAS Metadata Server and returning the authentication credentials.

Restriction
: This option is not valid in SAS Viya.

Requirements
: Enclose the *authentication-domain* name in single or double quotation marks.

: The authentication domain and the associated login definition must be stored in a metadata repository, and the metadata server must be running to resolve the metadata object specification.

Interaction If you specify AUTHDOMAIN=, do not specify USERNAME= and PASSWORD=.

See For more information about creating and using authentication domains, see the discussion about credential management in the *SAS Intelligence Platform: Security Administration Guide*.

CFG=*fileref* | '*external-file*'
identifies the Hadoop configuration file to use in order to connect to the Hadoop server. The configuration file contains entries for Hadoop system information, including file system properties such as fs.defaultFS. The configuration file can be a copy of the Hadoop core-site.xml file. However, if your Hadoop cluster is running with HDFS failover enabled, you need to create a file that combines the properties of the Hadoop core-site.xml and hdfs-site.xml. The configuration file must specify the name and JobTracker addresses for the specific server.

fileref
specifies the SAS fileref that is assigned to the Hadoop configuration file. To assign a fileref, use the FILENAME statement.

'***external-file***'
is the physical location of the XML document. Include the complete pathname and the filename. The maximum length is 200 characters.

Requirement Enclose the physical name in single or double quotation marks.

Alias OPTIONS=

Requirement The file must be an XML document.

Interaction The CFG= option is required for a configuration file that is specific to Apache Oozie. You must also set the SAS environment variable SAS_HADOOP_CONFIG_PATH. For more information, see *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*. For other uses, specify the location of configuration files by setting the SAS_HADOOP_CONFIG_PATH environment variable only. The environment variable is used by several SAS components.

Note For more information about Hadoop configuration, see SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS.

MAXWAIT=*wait-interval*
specifies the HTTP status response time when using WebHDFS.

Default 40000 milliseconds

Requirement The environment variable SAS_HADOOP_RESTFUL must be set to 1.

Tip If you receive a time-out message in the log, use MAXWAIT= to increase the wait period.

PASSWORD='*password*'
is the password for the user ID on the Hadoop server. The user ID and password are added to the set of options that are identified by CFG=.

Alias PASS=

Interaction To specify PASSWORD=, you must also specify USERNAME=.

USERNAME='*ID*'
is an authorized user ID on the Hadoop server. The user ID and password are added to the set of options that are identified by CFG=.

Alias USER=

VERBOSE
enables additional messages that are displayed on the SAS log. VERBOSE is a good error diagnostic tool. If you receive an error message when you invoke SAS, you can use this option to see whether you have an error in your system option specifications.

HDFS Statement

Submits Hadoop Distributed File System (HDFS) commands.

Restrictions: The HDFS statement supports only one operation per invocation.

The CAT, CHMOD, and LS commands are available only when submitting HDFS commands through webHDFS.

The RECURSE option and use of wildcards are permitted only when submitting HDFS commands through webHDFS.

Requirements: To submit HDFS commands through WebHDFS, the SAS environment variable SAS_HADOOP_RESTFUL must be set to 1. In addition, the Hadoop configuration file must include the properties for the WebHDFS location. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

To submit HDFS commands using the Java API, the Hadoop distribution JAR files must be copied to a physical location that is accessible to the SAS client machine. The SAS environment variable SAS_HADOOP_JAR_PATH must be set to the location of the Hadoop JAR files. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

Note: For more information about Hadoop configuration, see SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS.

Examples: "Example 1: Submitting HDFS Commands" on page 1250

"Example 2: Submitting HDFS Commands with Wildcard Characters" on page 1251

Syntax

HDFS <*hadoop-server-options*> <*hdfs-command-options*>;

Summary of Optional Arguments

CAT='*HDFS-file*' <ONLY=*n*> <OUT='*output-location*'> <RECURSE> <SHOW_FILENAME>
: displays the contents of the specified file or files.

CHMOD='*HDFS-file*' PERMISSION=<'>*value*<'> <RECURSE>
: changes file access permissions for one or more HDFS files.

COPYFROMLOCAL='*local-file*' OUT='*output-location*' <DELETESOURCE> <OVERWRITE> <RECURSE>
: copies the specified local file to an HDFS output location.

COPYTOLOCAL='*HDFS-file*' OUT='*output-location*' <DELETESOURCE> <KEEPCRC> <OVERWRITE> <RECURSE>
: copies the specified HDFS file to a local output location.

DELETE='*HDFS-file*' <NOWARN>
: deletes the specified HDFS file.

LS='*HDFS-pathname*' <OUT=*output-location*><RECURSE>
: lists the files in the specified HDFS pathname.

MKDIR='*HDFS-pathname*'
: creates the specified HDFS pathname. Specify the complete HDFS pathname.

RENAME='*HDFS-file*' OUT='*output-location*'
: renames the specified HDFS file.

HDFS Command Options

These options support commands that interact with the HDFS. Include only one operation per HDFS statement.

CAT='*HDFS-file*' <ONLY=*n*> <OUT='*output-location*'> <RECURSE> <SHOW_FILENAME>
: displays the contents of the specified file or files.

'HDFS-file'
: specifies a pathname or a pathname and a filename. You can use wildcard characters to substitute for any other character or characters in the pathname or the filename. Use * to match one or more characters, or ? to match a single character.

ONLY=*n*
: displays only the specified number of lines from the beginning of the file. For example, `only=10` displays the first ten lines of a file. This option is helpful to determine the contents of a file.

OUT='*output-location*'
: specifies the output location for the contents, which can be an external file for your machine or a fileref that is assigned with the FILENAME statement. By default, the output location is the SAS log.

RECURSE
: specifies to display the contents for all files in the specified pathname and all files that are in subdirectories. RECURSE has no effect if the specified HDFS file is not a directory.

SHOW_FILENAME
includes the name of the file in the output. For example, `hdfs cat='/tmp/*.txt' show_filename only=10 recurse;` displays in the SAS log the name of the file and the first ten lines of all .txt files that are found in the /tmp directory and all of its subdirectories.

Note The CAT= option is supported beginning with SAS 9.4M3.

CHMOD='*HDFS-file*' PERMISSION=<'>*value*<'> <RECURSE>
changes file access permissions for one or more HDFS files.

'HDFS-file'
specifies a pathname or a pathname and a filename. You can use a wildcard character to substitute for any character or characters in the pathname or filename. Use * to match any number of characters, or ? to match a single character.

PERMISSION=*value*
specifies a value that represents three levels of permissions, which are owner, group, and user. All three permission levels are required. You can specify the permissions in read, write, and execute (rwx) symbolic notation or octal notation.

- For the rwx symbolic notation, use nine characters. The first set of three characters represents what the owner can do, the second set represents what a group can do, and the third set represents what a user can do. For each set of three characters, the first position must be r or - (for read), the second position must be w or - (for write), and the third position must be x or - (for execute). For example, `permission=rwxr-xr-x` specifies that the owner has Read, Write, and Execute permission, group members have Read and Execute permission, and users have Read and Execute permission.
- For octal notation, use three digits. Each digit represents the permissions for owner, group, and user. Each digit must be from 0 to 7. The octal notation represents the same numeric value as the rwx symbolic notation. That is, 4 is r, 2 is w, 1 is x, and 0 is -. For example, `permission=755;` specifies that the owner has Read, Write, and Execute permission, group members have Read and Execute permission, and users have Read and Execute permission.

RECURSE
specifies to change the access permissions to all files and directories in the specified pathname and all files and directories that are in subdirectories. RECURSE has no effect if the specified HDFS file is not a directory. For example, `hdfs chmod='/tmp' permission=755 recurse;` changes the permissions to the specified directory and all files and subdirectories within the directory.

Note The CHMOD= option is supported beginning with SAS 9.4M3.

COPYFROMLOCAL='*local-file*' OUT='*output-location*' <DELETESOURCE> <OVERWRITE> <RECURSE>
copies the specified local file to an HDFS output location.

'local-file'
specifies the complete pathname and the filename. Beginning with SAS 9.4M3, you can use a wildcard character to substitute for any other character or characters in the pathname or the filename. Use * to match any number of characters, or ? to match a single character.

OUT='*output-location*'
specifies the output location for the copied file, which is a complete HDFS pathname and the filename.

DELETESOURCE
deletes the input source file after a copy command.

OVERWRITE
specifies to overwrite an existing output location.

RECURSE
specifies to copy all the files in the specified pathname and all files that are in subdirectories. RECURSE has no effect if the specified file is not a directory.

Note The RECURSE option is supported beginning with SAS 9.4M3.

COPYTOLOCAL='*HDFS-file*' OUT='*output-location*' <DELETESOURCE> <KEEPCRC> <OVERWRITE> <RECURSE>
copies the specified HDFS file to a local output location.

'HDFS-file'
specifies the complete pathname and the filename. Beginning with SAS 9.4M3, you can use a wildcard character to substitute for any other character or characters in the pathname or the filename. Use * to match any number of characters, or ? to match a single character.

OUT='*output-location*'
specifies the output location for the copied file, which is an external file for your machine.

DELETESOURCE
deletes the input source file after a copy command.

KEEPCRC
saves the Cyclic Redundancy Check (CRC) file after the copy command to a local output location. The CRC file is saved to the same location that is specified in the OUT= option. The CRC file is used to ensure the correctness of the file being copied. By default, the CRC file is deleted.

OVERWRITE
specifies to overwrite an existing output location.

RECURSE
specifies to copy all the files in the specified pathname and all files that are in subdirectories. RECURSE has no effect if the specified HDFS file is not a directory.

Note The RECURSE option is available beginning with SAS 9.4M3.

DELETE='*HDFS-file*' <NOWARN>
deletes the specified HDFS file.

HDFS-file
specifies a pathname or a pathname and a filename. If you include the filename, then only that file is deleted. If you do not include a filename, then all the files in the specified pathname and all the files that are in subdirectories are deleted. Beginning with SAS 9.4M3, you can use a wildcard character to substitute for any other character or characters in the pathname or the filename. Use * to match any number of characters, or ? to match a single character.

NOWARN
suppresses the warning message when there is an attempt to delete a file that does not exist.

LS='*HDFS-pathname*' <OUT=*output-location*><RECURSE>
lists the files in the specified HDFS pathname. The output for each file consists of its permissions, User ID, User ID group, file size, creation date, creation time, and the filename.

HDFS-pathname
specifies a pathname. You can use a wildcard character to substitute for any character or characters in the pathname. Use * to match any number of characters, or ? to match a single character.

OUT=*output-location*
specifies the output location for the list of files, which can be an external file for your machine or a fileref that is assigned with the FILENAME statement. By default, the output location is the SAS log.

RECURSE
specifies to list the files in the specified pathname and all files that are in subdirectories. RECURSE has no effect if the specified file is not a directory.

Default The default output location is the SAS log.

Note The LS= option is supported beginning with SAS 9.4M3.

MKDIR='*HDFS-pathname*'
creates the specified HDFS pathname. Specify the complete HDFS pathname.

RENAME='*HDFS-file*' OUT='*output-location*'
renames the specified HDFS file.

'*HDFS-file*'
specifies the pathname and the filename to rename.

OUT='*output-location*'
specifies the new HDFS pathname and filename.

MAPREDUCE Statement

Submits MapReduce programs into a Hadoop cluster.

Requirement: To submit MapReduce programs to a Hadoop server, the Hadoop configuration file must include the properties to run MapReduce (MR1) or MapReduce 2 (MR2) and YARN.

Interactions: To submit MapReduce programs using the Java API, the Hadoop distribution JAR files must be copied to a physical location that is accessible to the SAS client machine. The SAS environment variable SAS_HADOOP_JAR_PATH must be set to the location of the Hadoop JAR files. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

Beginning with SAS 9.4M3, to submit MapReduce programs through the Apache Oozie RESTful API, the SAS environment variable SAS_HADOOP_RESTFUL must be set to 1. You must also set the SAS environment variable SAS_HADOOP_CONFIG_PATH to the location where the hdfs-site.xml and core-site.xml configuration files exist. The hdfs-site.xml file must include the property for the WebHDFS location. You also need to specify Oozie specific properties in a configuration file and identify the configuration file with the PROC HADOOP statement CFG= argument. The Oozie specific properties include oozie_http_port, fs.default.name, and mapred.job.tracker. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

Note: For more information about Hadoop configuration, see SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS.

Example: "Example 3: Submitting a MapReduce Program" on page 1253

Syntax

MAPREDUCE<*hadoop-server-options*> <*mapreduce-options*>;

Summary of Optional Arguments

COMBINE='*class-name*'
: specifies the name of the combiner class in dot notation.

DELETERESULTS
: specifies to delete the output directory, if it exists, before starting the MapReduce job.

GROUPCOMPARE='*class-name*'
: specifies the name of the grouping comparator (GroupComparator) class in dot notation.

INPUT='*HDFS-pathname*'
: specifies the HDFS pathname to the MapReduce input file.

INPUTFORMAT='*class-name*'
: specifies the name of the input format class in dot notation.

JAR='*external-file(s)*'
: specifies the locations of the JAR files that contain the MapReduce program and named classes.

MAP='*class-name*'
: specifies the name of the map class in dot notation.

OUTPUT='*HDFS-pathname*'
: when connecting to the Hadoop server, specifies a new HDFS pathname for the MapReduce output.

OUTPUTFORMAT='*class-name*'
: specifies the name of the output format class in dot notation.

OUTPUTKEY='*class-name*'
: specifies the name of the output key class in dot notation.

OUTPUTVALUE='*class-name*'
: is the name of the output value class in dot notation.

PARTITIONER='*class-name*'
: specifies the name of the partitioner class in dot notation.

REDUCE='*class-name*'
: specifies the name of the reducer class in dot notation.

REDUCETASKS=*integer*
: specifies the number of reduce tasks.

REPLACE
: when connecting to Hadoop through the Oozie RESTful API, specifies to delete any existing workflow and JAR file(s) in the Oozie application before copying new files to the working directory.

SORTCOMPARE='*class-name*'
: specifies the name of the sort comparator class in dot notation.

WORKINGDIR='*HDFS-pathname*'
: specifies the name of the HDFS working directory pathname.

MapReduce Options

COMBINE='*class-name*'
specifies the name of the combiner class in dot notation.

DELETERESULTS
specifies to delete the output directory, if it exists, before starting the MapReduce job.

Note This option is supported beginning with SAS 9.4M3.

GROUPCOMPARE='*class-name*'
specifies the name of the grouping comparator (GroupComparator) class in dot notation.

INPUT='*HDFS-pathname*'
specifies the HDFS pathname to the MapReduce input file.

INPUTFORMAT='*class-name*'
specifies the name of the input format class in dot notation.

JAR='*external-file(s)*'
specifies the locations of the JAR files that contain the MapReduce program and named classes. Include the complete pathname and the filename.

Requirement Enclose each location in single or double quotation marks.

MAP='*class-name*'
specifies the name of the map class in dot notation. A map class contains elements that are formed by the combination of a key value and a mapped value.

OUTPUT='*HDFS-pathname*'
when connecting to the Hadoop server, specifies a new HDFS pathname for the MapReduce output.

Requirements You must specify the MapReduce output location.

Enclose the physical name in single or double quotation marks.

OUTPUTFORMAT='*class-name*'
specifies the name of the output format class in dot notation.

OUTPUTKEY='*class-name*'
specifies the name of the output key class in dot notation.

OUTPUTVALUE='*class-name*'
is the name of the output value class in dot notation.

PARTITIONER='*class-name*'
specifies the name of the partitioner class in dot notation. A partitioner class controls the partitioning of the keys of the intermediate map outputs.

REDUCE='*class-name*'
specifies the name of the reducer class in dot notation. The reduce class reduces a set of intermediate values that share a key to a smaller set of values.

REDUCETASKS=*integer*
specifies the number of reduce tasks.

REPLACE
when connecting to Hadoop through the Oozie RESTful API, specifies to delete any existing workflow and JAR file(s) in the Oozie application before copying new files to the working directory.

Note The REPLACE option is supported beginning with SAS 9.4M3.

SORTCOMPARE='*class-name*'
specifies the name of the sort comparator class in dot notation.

WORKINGDIR='*HDFS-pathname*'
specifies the name of the HDFS working directory pathname.

Requirements Beginning with SAS 9.4M3, when connecting to Hadoop through the Oozie RESTful API, this argument is required and specifies the HDFS pathname for the Oozie workflow application directory.

Enclose the *HDFS-pathname* name in single or double quotation marks.

PIG Statement

Submits Pig language code into a Hadoop cluster.

Interactions: To submit Pig language code using the Java API, the Hadoop distribution JAR files must be copied to a physical location that is accessible to the SAS client machine. The SAS environment variable SAS_HADOOP_JAR_PATH must be set to the location of the Hadoop JAR files. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

Beginning with SAS 9.4M3, to submit Pig language code through the Apache Oozie RESTful API, the SAS environment variable SAS_HADOOP_RESTFUL must be set to 1. You must also set the SAS environment variable SAS_HADOOP_CONFIG_PATH to the location where the hdfs-site.xml and core-site.xml configuration files exist. The hdfs-site.xml file must include the property for the WebHDFS location. You also need to specify Oozie specific properties in a configuration file and identify the configuration file with the PROC HADOOP statement CFG= argument. The Oozie specific properties include oozie_http_port, fs.default.name, and mapred.job.tracker. For more information, see the *SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS*.

Note: For more information about Hadoop configuration, see SAS Hadoop Configuration Guide for Base SAS and SAS/ACCESS.

Example: "Example 4: Submitting Pig Language Code" on page 1255

Syntax

PIG <*hadoop-server-options*> <*pig-code-options*>;

Summary of Optional Arguments

CODE=*fileref* | '*external-file*'
: specifies the source that contains the Pig language code to execute.

DELETERESULTS
: when connecting to the Hadoop server through the Oozie RESTful API, specifies to delete the existing output location before starting the Oozie job.

OUTPUT='*HDFS-pathname*'
: when connecting to the Hadoop server through the Oozie RESTful API, specifies the existing output location to delete before starting the Oozie job.

PARAMETERS=*fileref* | '*external-file*'
: specifies the source that contains parameters to be passed as arguments when the Pig code executes.

REGISTERJAR='*external-file(s)*'
specifies the locations of the JAR files that contain the Pig scripts to execute.

REPLACE
when connecting to Hadoop through the Oozie RESTful API, specifies to delete any existing workflow and JAR file(s) in the Oozie application before copying new files to the working directory.

WORKINGDIR='*HDFS-pathname*'
when connecting to Hadoop through the Oozie RESTful API, specifies the HDFS pathname for the Oozie workflow application directory.

Pig Code Options

CODE=*fileref* | '*external-file*'
specifies the source that contains the Pig language code to execute.

fileref
is a SAS fileref that is assigned to the source file. To assign a fileref, use the FILENAME statement.

'external-file'
is the physical location of the source file. Specify the complete pathname and the filename.

Requirement Enclose the physical name in single or double quotation marks.

DELETERESULTS
when connecting to the Hadoop server through the Oozie RESTful API, specifies to delete the existing output location before starting the Oozie job.

Interaction Use the DELETERESULTS option with the OUTPUT= option.

Note The DELETERESULTS option is supported beginning with SAS 9.4M3.

OUTPUT='*HDFS-pathname*'
when connecting to the Hadoop server through the Oozie RESTful API, specifies the existing output location to delete before starting the Oozie job.

Requirement Enclose the physical name in single or double quotation marks.

Interaction Use the OUTPUT= option with the DELETERESULTS option.

Note The OUTPUT= option is supported beginning with SAS 9.4M3.

PARAMETERS=*fileref* | '*external-file*'
specifies the source that contains parameters to be passed as arguments when the Pig code executes.

fileref
is a SAS fileref that is assigned to the source file. To assign a fileref, use the FILENAME statement.

'external-file'
is the physical location of the source file. Specify the complete pathname and the filename.

Requirement Enclose the physical name in single or double quotation marks.

REGISTERJAR='*external-file(s)*'
specifies the locations of the JAR files that contain the Pig scripts to execute. Specify the complete pathname and the filename.

Requirement Enclose each location in single or double quotation marks.

REPLACE
when connecting to Hadoop through the Oozie RESTful API, specifies to delete any existing workflow and JAR file(s) in the Oozie application before copying new files to the working directory.

Note The REPLACE option is supported beginning with SAS 9.4M3.

WORKINGDIR='*HDFS-pathname*'
when connecting to Hadoop through the Oozie RESTful API, specifies the HDFS pathname for the Oozie workflow application directory.

Requirements When connecting to Hadoop through the Oozie RESTFUL API, this argument is required.

Enclose the *HDFS-pathname* name in single or double quotation marks.

Note The WORKINGDIR= option is supported beginning with SAS 9.4M3.

PROPERTIES Statement

Submits configuration properties to the Hadoop server.

Alias: PROP

Example: "Example 5: Submitting Configuration Properties" on page 1256

Syntax

PROPERTIES '*configuration-property-1*' <'*configuration-property-2*'> ...;

Required Argument

configuration-property
specifies any property that can be specified in a Hadoop configuration file.

Requirement Enclose each property in single or double quotation marks, and enclose each value in single or double quotation marks. For example, `prop 'mapred.job.tracker'='xxx.us.company.com:8021' 'fs.default.name'='hdfs://xxx.us.company.com:8020';`

Usage: HADOOP Procedure

Submitting Hadoop Distributed File System Commands

The Hadoop Distributed File System (HDFS) is a distributed, scalable, and portable file system for the Hadoop framework. HDFS is designed to hold large amounts of data that is distributed across a network and to provide access to the data by many clients.

The PROC HADOOP HDFS statement submits HDFS commands to the Hadoop server. HDFS commands are like the Hadoop shell commands that interact with HDFS and manipulate files. For the list of HDFS commands, see "HDFS Statement" on page 1238.

Submitting MapReduce Programs

MapReduce is a parallel processing framework that enables developers to write programs to process vast amounts of data. There are two types of key functions in the MapReduce framework:

- map function that separates the data to be processed into independent chunks
- reduce function that performs analysis on that data

The PROC HADOOP MAPREDUCE statement submits a MapReduce program into a Hadoop cluster. For more information, see "MAPREDUCE Statement" on page 1242.

Submitting Pig Language Code

The Apache Pig language is a high-level programming language that creates MapReduce programs that are used with Hadoop.

The PROC HADOOP PIG statement submits Pig language code into a Hadoop cluster. For more information, see "PIG Statement" on page 1246.

Submitting Configuration Properties

Rather than specifying a Hadoop configuration file, you can submit configuration properties with the PROC HADOOP PROPERTIES statement. For more information, see "PROPERTIES Statement" on page 1248.

Examples: HADOOP Procedure

Example 1: Submitting HDFS Commands

Features:

SAS_HADOOP_CONFIG_PATH environment variable
SAS_HADOOP_JAR_PATH environment variable
PROC HADOOP statement
HDFS statement
OPTIONS statement
SET system option

Details

This PROC HADOOP example submits HDFS commands to a Hadoop server. The statements create a directory, delete a directory, and copy a file from HDFS to a local output location.

Program

```
options set=SAS_HADOOP_CONFIG_PATH="\\sashq\root\u\abcdef\cdh45p1";
options set=SAS_HADOOP_JAR_PATH="\\sashq\root\u\abcdef\cdh45";

proc hadoop username='sasabc' password='sasabc' verbose;

   hdfs mkdir='/user/sasabc/new_directory';

   hdfs delete='/user/sasabc/temp2_directory';
```

```
   hdfs copytolocal='/user/sasabc/testdata.txt'
        out='C:\Users\sasabc\Hadoop\testdata.txt' overwrite;
run;
```

Program Description

Define the SAS_HADOOP_CONFIG_PATH environment variable and the SAS_HADOOP_JAR_PATH environment variable. The OPTIONS statements include the SET system option to define the environment variables. The environment variables set the location of the Hadoop cluster configuration files and the Hadoop JAR files so that the required files are available to the SAS session.

```
options set=SAS_HADOOP_CONFIG_PATH="\\sashq\root\u\abcdef\cdh45p1";
options set=SAS_HADOOP_JAR_PATH="\\sashq\root\u\abcdef\cdh45";
```

Execute the PROC HADOOP statement. The PROC HADOOP statement controls access to the Hadoop server by identifying the user ID and password on the Hadoop server. The statement specifies the VERBOSE option, which enables additional messages to be written to the SAS log.

```
proc hadoop username='sasabc' password='sasabc' verbose;
```

Create an HDFS pathname. The first HDFS statement specifies the MKDIR= option to create an HDFS pathname.

```
   hdfs mkdir='/user/sasabc/new_directory';
```

Delete an HDFS file. The second HDFS statement specifies the DELETE= option to delete an HDFS file.

```
   hdfs delete='/user/sasabc/temp2_directory';
```

Copy an HDFS file. The third HDFS statement specifies the COPYTOLOCAL= option to specify the HDFS file to copy, the OUT= option to specify the output location on the local machine, and the OVERWRITE option to specify that if the output location exists, write over it.

```
   hdfs copytolocal='/user/sasabc/testdata.txt'
        out='C:\Users\sasabc\Hadoop\testdata.txt' overwrite;
run;
```

Example 2: Submitting HDFS Commands with Wildcard Characters

Features:

SAS_HADOOP_CONFIG_PATH environment variable
SAS_HADOOP_JAR_PATH environment variable
SAS_HADOOP_RESTFUL environment variable
PROC HADOOP statement
HDFS statement
Wildcard characters

OPTIONS statement
SET system option

Details

This PROC HADOOP example submits HDFS commands to a Hadoop server. The statements display the contents of the specified files, change the permissions for one HDFS file, and list the files in a specified HDFS pathname.

Program

```
options set=SAS_HADOOP_CONFIG_PATH="\\sashq\root\u\abcdef\cdh45p1";
options set=SAS_HADOOP_JAR_PATH="\\sashq\root\u\abcdef\cdh45";
options set=SAS_HADOOP_RESTFUL 1;

proc hadoop username='sasabc' password='sasabc' verbose;

   hdfs cat='/user/sasabc/*';

   hdfs chmod='/user/sasabc/' permission=rwxr-xr-x;

   hdfs ls='/user/sasabc/*';
run;
```

Program Description

Define the SAS_HADOOP_CONFIG_PATH environment variable, the SAS_HADOOP_JAR_PATH environment variable, and the SAS_HADOOP_RESTFUL environment variable. The OPTIONS statements include the SET system option to define the environment variables. The first two environment variables set the location of the Hadoop cluster configuration files and the Hadoop JAR files so that the required files are available to the SAS session. The SAS_HADOOP_RESTFUL environment variable specifies to connect to the Hadoop server by using the WebHDFS REST API.

```
options set=SAS_HADOOP_CONFIG_PATH="\\sashq\root\u\abcdef\cdh45p1";
options set=SAS_HADOOP_JAR_PATH="\\sashq\root\u\abcdef\cdh45";
options set=SAS_HADOOP_RESTFUL 1;
```

Execute the PROC HADOOP statement. The PROC HADOOP statement controls access to the Hadoop server by identifying the user ID and password on the Hadoop server. The statement specifies the VERBOSE option, which enables additional messages to be written to the SAS log.

```
proc hadoop username='sasabc' password='sasabc' verbose;
```

Display the contents of HDFS files. The first HDFS statement specifies the CAT= option to display the contents of HDFS files. The wildcard character * specifies to

match one or more characters. All files that are contained in the directory /user/sasabc/ are displayed in the SAS log.

```
hdfs cat='/user/sasabc/*';
```

Change the file access permissions. The second HDFS statement specifies the CHMOD= option to change the file access permissions for the specified HDFS pathname. The file access permissions provide the owner with Read, Write, and Execute permission, group members with Read and Execute permission, and users with Read and Execute permission.

```
hdfs chmod='/user/sasabc/' permission=rwxr-xr-x;
```

List the files in an HDFS pathname. The third HDFS statement specifies the LS= option to list the files in the specified HDFS pathname to the SAS log. The wildcard character * specifies to match one or more characters. All files that are contained in the directory /user/sasabc/ are displayed in the SAS log. The output for each file consists of its permissions, User ID, User ID group, file size, creation date, creation time, and the filename.

```
   hdfs ls='/user/sasabc/*';
run;
```

Example 3: Submitting a MapReduce Program

Features:

SAS_HADOOP_CONFIG_PATH environment variable

SAS_HADOOP_JAR_PATH environment variable

PROC HADOOP statement

MAPREDUCE statement

FILENAME statement

Details

This PROC HADOOP example submits a MapReduce program to a Hadoop server. This code runs the MapReduce job by using the Java API. To run the job by using the Apache Oozie RESTful API would require additional setup.

The example uses the Hadoop MapReduce application WordCount that reads a text input file, breaks each line into words, counts the words, and then writes the word counts to the output text file.

Program

```
options set=SAS_HADOOP_CONFIG_PATH="pathname";
options set=SAS_HADOOP_JAR_PATH="pathname";
```

```
proc hadoop username='sasabc' password='sasabc' verbose;
   mapreduce input='/user/sasabc/architectdoc.txt'
      output='/user/sasabc/outputtest'
      jar='pathname/WordCount.jar'
      outputkey='org.apache.hadoop.io.Text'
      outputvalue='org.apache.hadoop.io.IntWritable'
      reduce='org.apache.hadoop.examples.WordCount$IntSumReducer'
      combine='org.apache.hadoop.examples.WordCount$IntSumReducer'
      map='org.apache.hadoop.examples.WordCount$TokenizerMapper';
run;
```

Program Description

Define the SAS_HADOOP_CONFIG_PATH environment variable and the SAS_HADOOP_JAR_PATH environment variable. The OPTIONS statements include the SET system option to define the environment variables. The environment variables set the location of the Hadoop cluster configuration files and the Hadoop JAR files so that the required files are available to the SAS session.

```
options set=SAS_HADOOP_CONFIG_PATH="pathname";
options set=SAS_HADOOP_JAR_PATH="pathname";
```

Execute the PROC HADOOP statement. The PROC HADOOP statement controls access to the Hadoop server by identifying the user ID and password on the Hadoop server. The statement specifies the VERBOSE option, which enables additional messages to be written to the SAS log.

```
proc hadoop username='sasabc' password='sasabc' verbose;
```

Submit a MapReduce program. The MAPREDUCE statement includes several options. INPUT= specifies the HDFS pathname and the filename of the input Hadoop file named ArchitectDoc.txt.

```
   mapreduce input='/user/sasabc/architectdoc.txt'
```

Create an HDFS pathname. OUTPUT= creates the HDFS pathname for the program output location named OutputTest.

```
      output='/user/sasabc/outputtest'
```

Specify the JAR file. JAR= specifies the location of the JAR file that contains the MapReduce program named WordCount.jar.

```
      jar='pathname/WordCount.jar'
```

Specify an output key class. OUTPUTKEY= specifies the name of the output key class org.apache.hadoop.io.Text.

```
      outputkey='org.apache.hadoop.io.Text'
```

Specify an output value class. OUTPUTVALUE= specifies the name of the output value class org.apache.hadoop.io.IntWritable.

```
      outputvalue='org.apache.hadoop.io.IntWritable'
```

Specify a reducer class. REDUCE= specifies the name of the reducer class org.apache.hadoop.examples.WordCount$IntSumReducer.

```
        reduce='org.apache.hadoop.examples.WordCount$IntSumReducer'
```

Specify a combiner class. COMBINE= specifies the name of the combiner class org.apache.hadoop.examples.WordCount$IntSumReducer.

```
        combine='org.apache.hadoop.examples.WordCount$IntSumReducer'
```

Specify a map class. MAP= specifies the name of the map class org.apache.hadoop.examples.WordCount$TokenizerMapper.

```
        map='org.apache.hadoop.examples.WordCount$TokenizerMapper';
run;
```

Example 4: Submitting Pig Language Code

Features:

SAS_HADOOP_CONFIG_PATH environment variable

SAS_HADOOP_JAR_PATH environment variable

PROC HADOOP statement

PIG statement

FILENAME statement

Details

This PROC HADOOP example submits Pig language code into a Hadoop cluster. This code runs the Pig job by using the Java API. To run the job by using the Apache Oozie RESTful API would require additional setup.

Here is the Pig language code, which is stored in a text file named sample_pig.txt.

```
A = LOAD '/user/sasabc/class.txt' USING PigStorage(' ')
AS (name,grade,age,height,weight);
B = FOREACH A GENERATE name, grade, some.custom.class.promotionDecision(grade) as promote;
store B into '/user/sasabc/pigout' USING PigStorage(',');
```

The Pig code references a data file named class.txt. The Pig code also calls a user-defined Java function named some.custom.class.promotionDecision() to manipulate the data. The user has created that function and made it available in a JAR file.

Program

```
options set=SAS_HADOOP_CONFIG_PATH="pathname";
options set=SAS_HADOOP_JAR_PATH="pathname";
```

```
filename mycode 'pathname/sample_pig.txt';

proc hadoop username='sasabc' password='sasabc' verbose;

   pig code=mycode registerjar='pathname/gradeAnalysis.jar';
run;
```

Program Description

Define the SAS_HADOOP_CONFIG_PATH environment variable and the SAS_HADOOP_JAR_PATH environment variable. The OPTIONS statements include the SET system option to define the environment variables. The environment variables set the location of the Hadoop cluster configuration files and the Hadoop JAR files so that the required files are available to the SAS session.

```
options set=SAS_HADOOP_CONFIG_PATH="pathname";
options set=SAS_HADOOP_JAR_PATH="pathname";
```

Assign a file reference to the Pig language code. The FILENAME statement assigns the file reference MYCODE to the physical location of the file that contains the Pig language code that is named Sample_Pig.txt, which is shown above.

```
filename mycode 'pathname/sample_pig.txt';
```

Execute the PROC HADOOP statement. The PROC HADOOP statement controls access to the Hadoop server by identifying the user ID and password on the Hadoop server with the USERNAME= and PASSWORD= options. The statement specifies the VERBOSE option, which enables additional messages to be written to the SAS log.

```
proc hadoop username='sasabc' password='sasabc' verbose;
```

Execute the PIG statement. The CODE= option specifies the SAS fileref MYCODE, which is assigned to the physical location of the file that contains the Pig language code. The REGISTERJAR= option specifies the JAR file gradeAnalysis.jar, which the user has created, to provide user-defined functions.

```
   pig code=mycode registerjar='pathname/gradeAnalysis.jar';
run;
```

Example 5: Submitting Configuration Properties

Features: PROC HADOOP statement
PROPERTIES statement
MAPREDUCE statement

Details

This PROC HADOOP example submits a MapReduce program to a Hadoop server. Rather than specifying a Hadoop configuration file in the PROC HADOOP statement, the configuration properties are submitted in the PROPERTIES statement.

Program

```
proc hadoop username='sasabc' password='sasabc' verbose;

   prop 'mapred.job.tracker'='xxx.us.company.com:8021'
      'fs.default.name'='hdfs://xxx.us.company.com:8020';

   mapreduce jar="&mapreducejar."
      input="&inputfile."
      output="&outdatadir."
      deleteresults;
run;
```

Program Description

Execute the PROC HADOOP statement. The PROC HADOOP statement controls access to the Hadoop server by identifying the user ID and password on the Hadoop server. The statement specifies the VERBOSE option, which enables additional messages to be written to the SAS log.

```
proc hadoop username='sasabc' password='sasabc' verbose;
```

Submit configuration properties. The PROPERTIES statement submits properties to specify the name and JobTracker addresses in order to connect to the Hadoop server.

```
   prop 'mapred.job.tracker'='xxx.us.company.com:8021'
      'fs.default.name'='hdfs://xxx.us.company.com:8020';
```

Submit a MapReduce program. The MAPREDUCE statement includes several options.

```
   mapreduce jar="&mapreducejar."
      input="&inputfile."
      output="&outdatadir."
      deleteresults;
run;
```

34

HDMD Procedure

Overview: HDMD Procedure

What Does the HDMD Procedure Do?

Use PROC HDMD to generate XML-based metadata that describes the contents of files that are stored in HDFS. This metadata enables SAS/ACCESS Interface to Hadoop, SAS/ACCESS Interface to Spark, and SAS high-performance procedures to

read Hadoop data directly without an intermediate metadata repository such as Hive.

File Readers

You can use PROC HDMD to describe tabular HDFS files for these formats:

- fixed-record length (binary) data
- delimited text
- XML-encoded text

PROC HDMD can also associate a custom MapReduce reader (one that is based in Java) with a file. The custom reader is able to produce delimited text or fixed length binary records that can be described using the PROC HDMD syntax. You can use custom MapReduce readers only with SAS high-performance procedures for Hadoop. SAS/ACCESS Interface to Hadoop does not currently use custom readers.

Concepts: HDMD Procedure

Accessing Data Independently from Hive

When you specify the HDFS_METADIR= connection option, SAS/ACCESS does not connect to Hive. It instead accesses data through HDFS. SAS can create and use XML-based metadata descriptions of HDFS files and tables. You can create XML-based metadata with PROC HDMD. The filetype for an XML-based metadata description that PROC HDMD produces is SASHDMD (for example, product_table.sashdmd). Another name for this metadata is a *SASHDMD descriptor*.

Similar to HiveQL data definition language (DDL), SASHDMD descriptors describe the columns in an HDFS file or table, and it contains the file or table location. If it describes one file, a SASHDMD descriptor contains a complete HDFS file path.

```
/corp/files/product_codes.dat
```

When it describes a table, the SASHDMD descriptor contains an HDFS directory:

```
/corp/tables/purchases/franchise_201
```

Similar to Hive, it is expected that the directory contains identically structured files. These files have identical column layout:

```
/corp/tables/purchases/franchise_201/income_2012-01-02.dat
```

```
/corp/tables/purchases/franchise_201/income_2012-01-03.dat
```

/corp/tables/purchases/franchise_201/income_2012-01-04.dat

In this example, PROC HDMD creates a SASHDMD descriptor for this income table data. The income table has four comma-separated columns, a product code, the quantity purchased, the price, and the total purchase amount including tax.

```
libname hdplib hadoop server=mysrv1
   user=myusr1 pass=mypwd1
   hdfs_metadir="/corp/metadata"
   hdfs_datadir="/corp/tables/purchases/franchise_201";

proc hdmd hdplib.meta_income
   file_format=delimited encoding=utf8 sep=','
   data_file='file01.ebcd'
;

column product_code int;
column quantity_purchased int;
column price real;
column total_purchase_amount real;
run;
```

Working with Hive 3.0

Overview

Apache Hive 3.0 provides better support for transactional data. Changes to improve transaction support for Hive *managed tables* also mean that PROC HDMD users must perform extra steps to create and use metadata descriptions (.HDMD files) for existing Hive tables.

Managed and External Tables

Hive has two types of tables: *managed* and *external*. By default, a table that you create in Hive is always a *managed table*, which means that Hive manages its life cycle. To create an *external table*, you specify the EXTERNAL keyword in the CREATE TABLE query and include the LOCATION.

The difference between the two tables is what Hive deletes when you drop the table.

- *managed:* table metadata from the Hive MetaStore and physical data from the Hadoop file system
- *external:* only table metadata; table data from the Hadoop file system is retained

Managed Tables and Transactional Support

By default in Apache 3.0, all new tables are created with *transactional support*. Apache 3.0 also introduces a new restriction that Hive managed tables must be transactional. However, you can override this by setting the hive.strict.managed.tables Hive property to FALSE.

Therefore, in Apache Hive 3.0, by default a new table is both *managed* and *transactional*.

This example shows how to create the CLASS managed, transactional table.

```
0: jdbc:hive2:> create table class (name varchar(8), sex varchar(1),
   age double, weight double);
INFO  : OK
No rows affected (0.045 seconds)
0: jdbc:hive2:> describe formatted class;
INFO  : OK
```

```
+----------------------+----------------------------------------------------+--------------------+
|       col_name       |                     data_type                      |       comment      |
+----------------------+----------------------------------------------------+--------------------+
| # col_name           | data_type                                          |                    |
| name                 | varchar(8)                                         |                    |
| sex                  | varchar(1)                                         |                    |
| age                  | double                                             |                    |
| height               | double                                             |                    |
| weight               | double                                             |                    |
|                      | NULL                                               | NULL               |
| # Detailed Table     |                                                    |                    |
| # Information        | NULL                                               | NULL               |
| Database:            | default                                            | NULL               |

Transactional, Managed, and PROC HDMD

When a text file is created with transactional support, the on-disk structure of the file is different from a non-transactional table. When PROC HDMD creates metadata about a Hive transactional table, it stores metadata in the .HDMD file such that the table cannot be directly read by downstream operations. For example, attempting to run PROC PRINT using an HDMD table reference to a transactional table fails and generates this error message:

```
ERROR:  Cannot read the HDMD-defined data file NLSCARS in CUSTOM
        format.  The table is managed by Hive and is either a Hive
        transactional table or represented in a "non-native" HDMD format.
```

To resolve this issue, you must create the table as *non-transactional*. Because of the restriction that managed tables must be *transactional*, the table must also be created as *external*.

Here is an example using the Beeline client. Note that DESCRIBE FORMATTED does not show transactional in the table parameters.

```
0: jdbc:hive2:> create external table class
   (name varchar(8), sex varchar(1), age double, weight double)
      location '/tmp' tblproperties ("transactional"="false");
INFO  : OK
No rows affected (0.267 seconds)
0: jdbc:hive2://server18.corp.com:2181,srv> describe formatted class;
INFO  : OK
```

```

Creating External, Non-Transactional Tables with SAS

To use PROC HDMD to describe a Hive source table, you must create the table as both managed and non-transactional. You can create it readily with PROC SQL using explicit SQL.

Here is an example that uses a LIBNAME statement.

```
options sastrace=',,,d' sastraceloc=saslog nostsuffix
   sql_ip_trace=(note,source) msglevel=i;
options set=SAS_HADOOP_JAR_PATH=
   "/u/corpadmin/viya/hadoopjars/hdp30/prod";
options set=SAS_HADOOP_CONFIG_PATH=
   "/u/corpadmin/viya/hadoopcfg/hdp30d1/test";
options set=SAS_HADOOP_JAR_PATH=
   "\\newwinsrc\u\corpadmin\viya\hadoopjars\hdp30\prod";
options set=SAS_HADOOP_CONFIG_PATH=
   "\\newwinsrc\u\corpadmin\viya\hadoopcfg\hdp30d1\test";

libname x hadoop user=abc pwd=abc;
libname nohive hadoop hdfs_tempdir='/tmp/'
   hdfs_datadir='/tmp' hdfs_metadir='/tmp' server=server18;

proc delete data=x.class;run;

proc sql;
connect using x;
execute (create external table if not exists default.class
   (name varchar(8), sex varchar(1), age double, weight double)
      location '/tmp/class' tblproperties ("transactional"="false")
   ) by x;
quit;

proc delete data=nohive.classhdmd;run;
proc hdmd from=x.class nohive.classhdmd;run;
proc print data=nohive.classhdmd;run;
```

Summary

When you know how to use PROC HDMD to create a metadata description of a Hive table, you can use PROC PRINT and other SAS tools to reference the table. The example shows how to specify the EXTERNAL and LOCATION keywords along with the table properties set to FALSE to create the source Hive table.

Syntax: HDMD Procedure

Restriction: This procedure is not supported on the CAS server.

Requirements: To be able to work with Hive 3.0 data, you must first set external table properties. For details, see "Working with Hive 3.0" on page 1261.

At least one COLUMN statement is required in a PROC HDMD procedure step.

Supports: Hadoop, Spark

See: "LIBNAME Statement for the Hadoop Engine" in *SAS/ACCESS for Relational Databases: Reference*

PROC HDMD <*hadoop-metadata-options*;>

COLUMN <*column-specifications*>;

Statement	Task	Example
PROC HDMD	Generate and use metadata descriptions of HDFS files and tables.	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8, Ex. 9
COLUMN	Specifies the columns of HDFS files and tables with which to work.	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8, Ex. 9

PROC HDMD Statement

Generates the XML metadata for tables or files that are not registered in Hive.

Syntax

PROC HDMD
<BYTE_ORDER=LITTLEENDIAN | BIGENDIAN>
<DATA_FILE='*input-filename*'>
<ENCODING=*encoding*>
<FILE_FORMAT=*file-format*>
<FILE_TYPE='*custom-input-file-type*'>
<FROM=*Hive-table*>

<HEADER_LINES=*n*>
<INPUT_CLASS='*java.class*'>
<MANAGED>
<NAME=*libref.filename* <hadoop | spark>>
<RECORD_LENGTH=*record-length*>
<ROW_TAG='*row-tag*'>
<SEP='*character-separator*'>
<TEXT_QUALIFIER='*character-qualifier*'>;

COLUMN *column-specifications*;

run;

Optional Hadoop Metadata Options

These options control how metadata is generated.

BYTE_ORDER=< LITTLEENDIAN | BIGENDIAN >
specifies how numeric data is stored. If LITTLEENDIAN, it is stored with the least significant byte first, such as a PC. If BIGENDIAN,, it is stored with the most significant byte first.

Type optional

Default client

Applies to BINARY

DATA_FILE='*input-filename*'
specifies the path to the input data file relative to the HDFS_DATADIR= option in the Hadoop engine LIB statement.

Type required

Default none

Applies to BINARY, DELIMITED, XML

ENCODING=*encoding*
specifies the encoding for text for the input data file or folder.

Type optional

Default UTF8 (if you do not specify a value)

Applies to BINARY

FILE_FORMAT=*file-format*
specifies the format of the input data that is passed to the SAS Embedded Process for Hadoop.

file-format can be one of the following values:

BINARY
specifies a file with fixed length records where numeric data is stored in machine-specific binary form.

DELIMITED
specifies a file that contains only text-based data where fields are separated by a specific delimiter. Delimited records can vary in length.

See "SEP='*character-separator*'" on page 1270

XML
specifies a text-based data file in XML format.

Type required

Alias FILE_FMT=

Default none

Applies to BINARY, DELIMITED, XML

FILE_TYPE='*custom-input-file-type*'
specifies the file type that is used in the MapReduce framework to load the data into the SAS Embedded Process. The file type maps to a SAS provided MapReduce input format classes name. The input format classes that is provided by SAS for a particular file type creates specific input readers. For example, the DELIMITED file type is mapped to the MapReduce input format class, com.sas.access.hadoop.ep.delimited.DelimitedInputFormat.

Type optional

Default none

Applies to BINARY, DELIMITED, XML

Requirement To use a custom-sequence file type, you must specify INPUT_CLASS= and also FILE_TYPE=CUSTOM_SEQUENCE.

Interaction If you specify an input class, FILE_TYPE= defaults to CUSTOM.

FROM=*Hive-table*
specifies the name of a Hive table that you want to use for in-database scoring. SAS creates the metadata file *Hive-table*.sashdmd in the target's metadata directory.

Example
```
proc hdmd hdfs.&modelnm. from=hive.&modelnm.; run;
```

HEADER_LINES=*n*
specifies the number of lines that are skipped when parsing delimited files.

Type optional

Default none

Applies to DELIMITED

INPUT_CLASS='*java.class*'
specifies the fully qualified class name that implements the Java custom MapReduce reader to use.

Type optional

Default none

Applies to BINARY, DELIMITED, XML

Requirement The class must be in the class path of the Hadoop server.

Interaction The DBCREATE_EXTERNAL_TABLE= LIBNAME option ignores this option.

MANAGED
specifies that the file is deleted when its metadata is deleted (for example, by using PROC DELETE).

Type optional

Default By default, data files are not managed—namely, they are not deleted when the metadata is deleted..

Applies to BINARY, DELIMITED, XML

Interaction The DBCREATE_EXTERNAL_TABLE= LIBNAME option ignores this option.

NAME=*libref.filename* <hadoop | spark>
specifies the name of the metadata file to create. The HDFS_METADIR= connection option specifies where metadata is located.

Type required

Default none

Applies to BINARY, DELIMITED, XML

Requirement The *libref* must be a valid Hadoop or Spark engine libref for which HDFS_METADIR= and HDFS_DATADIR= options have been specified.

Data source Hadoop, Spark

RECORD_LENGTH=*record-length*
specifies the record length of the BINARY file.

Type required

Default none

Applies to BINARY

ROW_TAG='*row-tag*'
specifies the XML tag that identifies records in the input XML.

Type required

Default none

Applies to XML

Restriction This option is case sensitive.

SEP='*character-separator*'
specifies the character to separate the columns for the records in the delimited input file. Here is how you can specify values.

- SEP=^A
- SEP=','
- SEP=TAB
- SEP=^Z
- SEP='09'x
- SEP=32

Type required

Default ^A (if you do not specify a value)

Range You can specify only a single character between the Unicode range of U+0001 to U+007F.

Applies to DELIMITED

Restriction The value of this option cannot be the same character as for TEXT_QUALIFIER= and cannot be a newline ('0a'x).

TEXT_QUALIFIER='*character-qualifier*'
specifies the text qualifier for the input data file or folder. Here is how you can specify values.

Type optional

Default none

Range You can specify only a single character between the Unicode range of U+0001 to U+007F.

Applies to DELIMITED

Restriction The value of this option cannot be the same character as for SEP= and cannot be a newline ('0a'x).

Requirement You must specify either a double quotation mark enclosed in single quotation marks(' " ') or a single quotation mark enclosed in double quotation marks (" ' ").

COLUMN Statement

Provides specifications for one or more columns.

Requirement: One or more of these statements is required.

Syntax

COLUMN <*column-options*> <*data-type*> <*name*>;

Column Specifications

column-options
specifies one or more column options.

BYTES=*byte-length*
for BINARY files, specifies the number of bytes that the data occupies in the record.

Type required

Default none

Applies to BINARY

CTYPE=*ctype*
for BINARY files, specifies the actual binary type of data that to be stored in the record. Here are the valid binary data types:

- CHAR
- DOUBLE
- FLOAT
- INT8
- INT16
- INT32
- INT64
- UINT8
- UINT16
- UINT32
- UINT64

Type optional

Default none

Applies to BINARY

ENCODING=*encoding*
for BINARY files, specifies the encoding for the character data if it differs from the overall file encoding.

Type optional

Default none

Applies to BINARY

FORMAT=*format-specification*
specifies the format that is associated with the column.

Type optional

Default none

Applies to BINARY, DELIMITED, XML

See *SAS Formats and Informats: Reference*

INFORMAT=*informat-specification*
specifies the informat to use to read the input data.

Type optional

Default none

Applies to BINARY, DELIMITED, XML

See *SAS Formats and Informats: Reference*

OFFSET=*bytes*
specifies the offset of the column data in the record.

Type required

Default none

Applies to BINARY

TAG='*tag*'
specifies the XML element that encloses the column data.

Type required

Default none

Applies to XML

data-type
specifies a valid data type:

- BIGINT

- CHAR(*n*)
- DATE
- DOUBLE
- INT
- REAL
- SMALLINT
- TIME[(prec)]
- TIMESTAMP[(prec)]
- TINYINT
- VARCHAR(*n*)

Type required

Default none

Applies to BINARY, DELIMITED, XML

Interaction The Hadoop engine converts all numeric types to DOUBLE.

name
specifies a name for the column.

Type required (when specified)

Default none

Applies to BINARY, DELIMITED

Examples: HDMD Procedure

Example 1: Create Hadoop Metadata from a Delimited File

You can use the HDMD procedure to create metadata in a Hadoop file or directory of files. This example starts with a comma-delimited file with three columns.

```
Name,Age,Weight
```

```
John,32,180
Jane,27,112
Tim,54,210
```

By assigning a data type for each column that is retrieved, here is how you can create the metadata.

```
libname hdplib hadoop server=mysrv1_cluster1
user=myusr1 pass=mypwd1
/* connection options */
config='/user/configs/hadoop_cluster1.xml'
hdfs_tempdir='/corp/tempdir'
hdfs_metadir='/corp/metadata'
hdfs_datadir='/corp/tables/purchases';

proc hdmd hdplib.people
   file_format=delimited sep=',' encoding=utf8
   data_file='people.csv' header_lines=1;
column name char(8);
column age int;
column weight int;
run;
```

Example 2: Define Metadata for a Delimited File

This example uses the Hadoop LIBNAME statement to define metadata for a delimited file. The file contains this data:

```
12.34 23f45 "This shows quotes" 4.5 2013-05-05
unquoted 11:12:13 09:05:12.2345 "2013-03-04
12:13:12.12345678" 3 10240 1298378438743
```

A blank character and a double quotation mark are used to parse the file.

```
libname hdplib hadoop server=mysrv1_cluster1
user=myusr1 pass=mypwd1
/* connection options */
config='/user/configs/hadoop_cluster1.xml'
hdfs_tempdir='/corp/tempdir'
hdfs_metadir='/corp/metadata'
hdfs_datadir='/corp/tables/purchases';

proc hdmd hdp.foo file_format=delimited
encoding=utf8 sep='20'x text_qualifier='"'
data_dir='franchise_201';
column col1 double file_format=dollar6.2;
column col2 int informat=hex5.;
column 'col3 has a blank'n char(20) file_format=$revers20.;
column col4 real;
column col5 date;
column col5 varchar(42);
column col6 time;
```

```
column col7 time(4);
column col8 timestamp(8);
column col9 tinyint;
column col10 smallint;
column col11 bigint;
run;
```

Example 3: Define Metadata for a Delimited File with Column Headings

This example starts with a comma-delimited file with two columns.

```
ID,Full Name
1,"Doe, John"
2,"Smith, Sally"
```

Here is the syntax for the HDMD procedure.

```
proc hdmd hdplib.text_qualifer_example
   file_format=delimited sep=',' text_qualifier='"'
   header_lines=1 input_dir="text_qualifier.csv";

column id double;
column fullname char(32);
run;
```

Here is the resulting PROC PRINT output.

```
proc print data=hdplib.text_qualifer_example;run;
```

```
The SAS System

Obs    id    fullname
1      1     Doe, John
2      2     Smith, Sally
```

Example 4: Extract Columns from Binary Data

In this example, two columns are extracted from a binary file.

```
proc hdmd hdp.foo file_format=binary
record_length=80
data_file='foo.bin';
column size double ctype=double bytes=8;
column id bigint ctype=int64 offset=8;
column name char(42) ctype=char offset=16 bytes=42;
run;
```

Example 5: Extract Columns from MVS Binary Data

This example is similar to the previous one. However, because the data was extracted from MVS, it contains DOUBLE data types and EBCDIC characters.

```
proc hdmd hdp.foo file_format=binary
record_length=80 encoding=ebcdic037
data_file='foo.bin';
column size double ctype=double bytes=8 informat=s370frb8.;
column name char(42) ctype=char offset=8 bytes=42 encoding=ebcdic037;
run;
```

Example 6: Extract Columns from a Binary File with Chinese Encoding

In this example, two columns are extracted from the beginning of a binary 80 ASCII file. The character column is encoded in Chinese.

```
proc hdmd hdp.foo file_format=binary
record_length=80 encoding=utf8
data_file='foo.bin';
column size double ctype=double bytes=8;
column name char(42) ctype=char offset=8 bytes=42 encoding='euc-cn';
run;
```

Example 7: Extract Columns from XML Data

In this example, two columns are extracted from an XML file that contains these XML tags:

```
<row><Size>42.5</Size><Name>Julius Caesar</Name></row>
```

Here is the syntax for the HDMD procedure.

```
proc hdmd hdp.foo file_format=xml
row_tag='row'data_file='foo.xml';
column size double tag='Size';
column name char(42) tag='Name';
run;
```

Example 8: Use the DESCRIBE Option

This example uses the HDMD procedure to describe the syntax and output.

```
proc hdmd libname.data
   file_format=delimited sep=','
   input_dir="mydata.csv"
;

column I   double;
column J   double;
column W   double;
run;

proc hdmd libname.data describe;
run;
```

Here is the resulting log file.

```
1103  proc hdmd libname.data
1104  describe;
1105  run;
```

Here is the resulting output.

```
PROC HDMD HDPLIB.REAL2
    FILE_FORMAT=DELIMITED ENCODING=UTF8 SEP=',' BYTE_ORDER=LITTLEENDIAN
    FILE_TYPE=DELIMITED
    DATA_DIR='/user/data/csv/data/mydasta.csv'
    META_DIR='/user/data/csv/meta';
COLUMN /* 1 */ I DOUBLE OFFSET=0 BYTES=8 CTYPE=DOUBLE;
COLUMN /* 2 */ J DOUBLE OFFSET=0 BYTES=8 CTYPE=DOUBLE;
COLUMN /* 3 */ W DOUBLE OFFSET=0 BYTES=8 CTYPE=DOUBLE;
```

Example 9: Define a Custom Reader and Use a Data File

Before PROC HDMD runs, this example starts by defining the SAS_HADOOP_JAR_PATH environment variable within SAS by entering this OPTION SET statement. The variable points to folders with all Hadoop JAR files.

```
option set=SAS_HADOOP_JAR_PATH="/users/SAS/JARS:/users/SAS/JARS/
cdh420";
```

It then defines a LIBNAME statement to point to Hadoop.

```
libname hdplib hadoop
   user=myusr1 pw=mypwd1 server="mysrv1"
   HDFS_TEMPDIR="/user/hdmddemo/temp"
   HDFS_DATADIR="/user/hdmddemo/data"
   HDFS_METADIR="/user/hdmddemo/meta"
   DBCREATE_TABLE_EXTERNAL=NO
   CONFIG="/user/mycfg1.xml";
```

Last, it creates the HDMD file.

```
proc hdmd hdplib.peopleseq
   file_format=delimited sep=tab
   file_type=custom_sequence
   input_class=

'com.abc.hadoop.ep.inputformat.sequence.PeopleCustomSequenceInputFormat
'
   data_file='people.seq';

column name varchar(20);
column sex varchar(1);
column age int;
column height double;
column weight double;
run;
```

35

HTTP Procedure

Overview: HTTP Procedure

What Does the HTTP Procedure Do?

The HTTP procedure issues Hypertext Transfer Protocol (HTTP) requests. The procedure is supported in both SAS 9.4 and SAS Viya.

PROC HTTP allows an open-ended set of methods. In addition to standard HTTP methods, PROC HTTP accepts any method that conforms to the HTTP/1.1 standard and that is recognized by the target web server. PROC HTTP also implements HTTP/1.1 features such as persistent connections, cookie caching, EXPECT_100_CONTINUE support, and it provides authentication type specification.

For web servers that support it, PROC HTTP uses connection caching and cookie caching by default. You can toggle the behavior of both types of caching and clear the caches within the procedure by specifying procedure arguments. Or you can turn cookie caching off by using a macro variable.

The authentication specification feature enables you to specify one or multiple authentication types for a request.

Beginning with the November 2019 release of SAS 9.4M6 and SAS Viya 3.5, you can easily post form data as well as perform HTTP multipart requests. A new QUERY= procedure option simplifies the process of submitting query parameters for the URL= argument. For more information, see "Using the FORM and QUERY Options with PROC HTTP" on page 1298 and "Using the MULTI Option" on page 1299.

The procedure includes a DEBUG statement, response status macro variables, and the ability to specify a time-out period for requests. Beginning with SAS 9.4M6 and SAS Viya 3.5, a new statement, SSLPARMS, enables you to override global SAS system options for encryption with local options for a specific PROC HTTP request.

Syntax: HTTP Procedure

Restrictions: This procedure is not supported on the CAS server.

When SAS is in a locked-down state, the HTTP procedure is not available. Your server administrator can re-enable this procedure so that it is accessible in the lockdown state. When the FILENAME, URL access method is re-enabled by using the LOCKDOWN ENABLE_AMS= statement, the HTTP procedure is automatically

re-enabled. For more information, see "SAS Processing Restrictions for Servers in a Locked-Down State" in *SAS Programmer's Guide: Essentials*

Tip: PROC HTTP sets up macro variables with certain values after it executes each statement. These macro variables can be used inside a macro to test for HTTP errors. For more information, see "PROC HTTP Response Status Macro Variables" on page 1301.

PROC HTTP URL="*URL-to-target*" <*options*>;

DEBUG *options*;

HEADERS "*HeaderName*"="*HeaderValue*"
<"*HeaderName-n*"="*HeaderValue-n*">;

SSLPARMS *encryption-options*;

Statement	Task	Example
PROC HTTP	Issue HTTP requests	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 9, Ex. 10, Ex. 11, Ex. 12
DEBUG	Display debugging messages	Ex. 13
HEADERS	Specify request headers for the HTTP request	Ex. 8
SSLPARMS	Set encryption options for the PROC HTTP request	Ex. 14

PROC HTTP Statement

Invokes a web service that issues requests.

Examples:

"Example 13: Use the DEBUG Statement with the LEVEL= Option" on page 1316
"Example 14: Specify Local Options for Two-Way Encryption in Windows" on page 1319

Syntax

PROC HTTP URL="*URL-to-target*</redirect/*n*>"
<METHOD=<">*http-method*<">>
<*authentication-type-options*>
<*caching-options*>
<*header-options*>
<*proxy-server-connection-options*>
<*web-server-authentication-options*>
<EXPECT_100_CONTINUE>
<FOLLOWLOC | NOFOLLOWLOC>
<HTTP_TOKENAUTH>
<IN=<*fileref* | FORM (*arguments*) | MULTI <options> (*parts*) | "*string*">>
<MAXREDIRECTS=*n*>
<OUT=*fileref*>
<QUERY=("*parm1*"="*value1*" "*parm2*="*value2*" ...)>
;

Summary of Optional Arguments

EXPECT_100_CONTINUE
: enables a client to determine whether the target server is willing to accept the request.

FOLLOWLOC
: enables write methods to automatically follow URL redirections.

HTTP_TOKENAUTH
: generates a one-time password from the metadata server that can be used to access the SAS Content Server.

IN=*fileref* | FORM (*arguments*) | MULTI <*options* > | "*string*"
: specifies the input data.

MAXREDIRECTS=*n*
: specifies the maximum number of redirects that are allowed.

METHOD=<">*http-method*<">
: specifies an HTTP method.

NOFOLLOWLOC
: prevents the GET method from following URL redirections.

OUT=*fileref-to-response-data*
: specifies a fileref where output is written.

QUERY=(<NOENCODE>*"parm1"="value1" "parm2"="value2"*)
: provides an alternate method for submitting query parameters for the URL= argument.

TIMEOUT=*integer*
: specifies the number of seconds of inactivity to wait before canceling an HTTP request.

Authenticate to Web Server

WEBAUTHDOMAIN="*web-credentials-from-metadata*"
: specifies the web authentication domain.

WEBPASSWORD="*basic-authentication-password*"
: specifies a password for basic authentication.

WEBUSERNAME="*basic-authentication-name*"
: specifies a user name for basic authentication.

Connect to Proxy Server

PROXYHOST="*proxy-host-name*"
: specifies the Internet host name of an HTTP proxy server.

PROXYPASSWORD="*proxy-passwd*"
: specifies an HTTP proxy server password.

PROXYPORT=*proxy-port-number*
: specifies an HTTP proxy server port.

PROXYUSERNAME="*proxy-user-name*"

Disable Shared Connection and Cookie Caching

CLEAR_CACHE
: specifies to clear both the shared connection and cookie caches before the HTTP request is executed.

CLEAR_CONN_CACHE
: specifies to clear the shared connection cache before the HTTP request is executed.

CLEAR_COOKIES
: specifies to clear the shared cookie cache before the HTTP request is executed.

NO_CONN_CACHE
: disables connection caching for this procedure execution.

NO_COOKIES
: specifies cached cookies will not be used for this procedure execution.

Specify Authentication Type

AUTH_ANY
: specifies that any type of authentication can be used to authenticate to the connected server.

AUTH_BASIC
: specifies to use user identity authentication to authenticate to the connected server.

AUTH_NEGOTIATE
: specifies to use NTLM, Kerberos. or some other type of HTTP authentication to authenticate to the connected server.

AUTH_NONE
: specifies not to use basic authentication, NTLM authentication, or to negotiate authentication, even when authentication with one of these methods is possible.

AUTH_NTLM
: specifies to use NTLM authentication to authenticate to the connected server.

OAUTH_BEARER=*token*
: sends an OAuth access token along with the HTTP call.

PROXY_AUTH_BASIC
: specifies to perform user identity authentication through a proxy server.

PROXY_AUTH_NEGOTIATE
: specifies to perform NTLM, Kerberos, or some other type of HTTP authentication through a proxy server.

PROXY_AUTH_NTLM
: specifies to perform NTLM authentication through a proxy server.

Specify HTTP Headers

CT="*content-type*"
: specifies the HTTP content-type to be set in the request headers.

HEADERIN=*fileref-to-request-header-file*
: specifies a fileref to a text file that contains one line per request header in the format *key:value*.

HEADEROUT_OVERWRITE
: causes the response header to record only the last header block sent by the web server when a redirect occurs.

HEADEROUT=*fileref-to-response-header-file*
: specifies a fileref to a text file to which the response headers are written in the format *key:value*.

Required Argument

URL="*URL-to-target*"
specifies a fully qualified URL path that identifies the endpoint for the HTTP request.

Note The URL that is passed to PROC HTTP is assumed to be URL encoded. To ensure correct encoding, use an appropriate connection class for the target web server. For example, use the AWSV4Signer class for Amazon Web Services. Or, encode reserved characters as described in RFC3986.

Tip Beginning with SAS 9.4M3, you do not have to specify the protocol. If you set just the path (for example, `"httpbin.org"`), the actual URL used is `http://httpbin.org`.

Optional Arguments

AUTH_ANY
When a user name and password are supplied, they are used to authenticate the connected server. Otherwise, any other form of authentication that is available

is used. Specifying AUTH_ANY is equivalent to specifying AUTH_NEGOTIATE, AUTH_NTLM, and AUTH_BASIC on the procedure statement.

Default This is the default authentication type if an authentication type is not specified.

Note This option is supported beginning with SAS 9.4M3.

Tip Since there is a chance of more than one trip to the HTTP server, specify EXPECT_100_CONTINUE to prevent data from being uploaded multiple times.

AUTH_BASIC
specifies to use user identity authentication to authenticate the connected server. The user name and password are supplied with the WEBUSERNAME and WEBPASSWORD arguments.

Note This option is supported beginning with SAS 9.4M3.

AUTH_NTLM
specifies to use NTLM authentication to authenticate to the connected server. As long as your current user identity has permissions, authentication is established.

Restriction NTLM is currently available only on Windows clients.

Note This option is supported beginning with SAS 9.4M3.

Example “Example 10: A Request That Specifies an Authentication Type” on page 1310

AUTH_NEGOTIATE
specifies to use NTLM, Kerberos. or some other type of HTTP authentication to authenticate to the connected server. As long as your current user identity has permissions, authentication is established.

Note This option is supported beginning with SAS 9.4M3.

Example “Example 10: A Request That Specifies an Authentication Type” on page 1310

AUTH_NONE
specifies not to use basic authentication, NTLM authentication, or to negotiate authentication, even when authentication with one of these methods is possible. The OAUTH_BEARER= procedure option can be used with NO_AUTH.

Note This option is supported beginning with SAS 9.4M3.

CLEAR_CACHE
specifies to clear both the shared connection and cookie caches before the HTTP request is executed.

Note This option is supported beginning with SAS 9.4M3.

CLEAR_CONN_CACHE
specifies to clear the shared connection cache before the HTTP request is executed.

Note This option is supported beginning with SAS 9.4M3.

CLEAR_COOKIES
specifies to clear the shared cookie cache before the HTTP request is executed.

Note This option is supported beginning with SAS 9.4M3.

CT="*content-type*"
used in conjunction with the HEADERIN= argument, specifies the HTTP content-type to be set in the request headers. The content-type describes the data contained in the body fully enough that the receiving user agent can present the data to the user.

Examples of content-type specifications are:

```
CT="Text/HTML; charset=ISO-8859-4"

CT="Text/plain; charset=us-ascii"

CT="Application/x-www-form-urlencoded"
```

Note Beginning with SAS 9.4M3, this option is supported for compatibility with previous versions of SAS software. Use the "HEADERS Statement" on page 1294 instead of CT= .

EXPECT_100_CONTINUE
enables a client that is sending a request message with a request body to determine whether the target server is willing to accept the request, based on the request headers. Use EXPECT_100_CONTINUE when you are sending large amounts of data and want to make sure that no unnecessary transfers of the data occur. For more information, see http://www.w3.org/Protocols/rfc2616/rfc2616-sec8.html#sec8.2.3.

Valid in HTTP requests that specify the IN= argument, most commonly with PUT.

Interaction This option is used in conjunction with the HEADEROUT= argument.

Note This option is supported beginning with SAS 9.4M3.

Example "Example 11: A PUT That Specifies EXPECT_100_CONTINUE" on page 1311

FOLLOWLOC
enables write methods to automatically follow URL redirections. By default, PROC HTTP methods that write data, like POST and PUT, terminate processing when they are redirected to an alternate location. When FOLLOWLOC is specified, PROC HTTP initially returns a 300-level response, then submits the POST or PUT again to the redirected location.

FOLLOWLOC is the default behavior for the GET method.

Note This option is supported beginning with SAS 9.4M5.

See "NOFOLLOWLOC" on page 1289

HEADERIN=*fileref-to-request-header-file*
specifies a fileref to a text file that contains one line per request header in the format *key:value*.

z/OS Specifics: In the z/OS operating environment, HEADERIN= files must be created with a variable record length.

Note Beginning with SAS 9.4M3, this option is supported for compatibility with previous versions of SAS software. Use the "HEADERS Statement" on page 1294 instead of HEADERIN=

CAUTION **Do not specify both the HEADERS statement and the HEADERIN= argument.** The behavior that results from specifying both options together is not defined.

HEADEROUT=*fileref-to-response-header-file*
specifies a fileref to a text file to which the response headers are written in the format *key:value*.

Examples "Example 6: A POST That Captures the Response Headers" on page 1306

"Example 11: A PUT That Specifies EXPECT_100_CONTINUE" on page 1311

HEADEROUT_OVERWRITE
used in conjunction with the HEADEROUT= argument, causes the response header to record only the last header block sent by the web server when a redirect occurs.

Example "Example 7: A GET That Specifies HEADEROUT_OVERWRITE" on page 1307

HTTP_TOKENAUTH
generates a one-time password from the metadata server that can be used to access the SAS Content Server.

IN=*fileref* | FORM (*arguments*) | MULTI <*options* > | *"string"*
specifies the input data. There are multiple ways to submit input data:

fileref
specifies a fileref. The fileref is a pointer to data that exists in another location. A fileref is assigned with the FILENAME statement.

Example "Example 2: A Simple POST Request" on page 1303

FORM (*"name1"="value1" "name2"="value2" ...*)
sends input data as a standard HTML form.

The data is input as name=value pairs. The FORM option URL-encodes and delimits the pairs with an & (ampersand) as is standard for form submissions. If a name=value pair should not be URL-encoded, you can specify a NOENCODE flag before the name=value pair.

Note The FORM option is available beginning with the November 2019 release of SAS 9.4M6 and SAS Viya 3.5.

See "Using the FORM and QUERY Options with PROC HTTP" on page 1298

MULTI <FORM | "*type*" > (*parts*)
specifies the upload is performed as a multipart request.

You can specify form data or generic data as input. These options do not include support for nested multipart uploads. See https://www.w3.org/Protocols/rfc1341/7_2_Multipart.html for more information about the multipart content-type.

When the FORM option is used, the upload is performed using the specialized multipart type known as multipart/form-data. More information can be found at https://tools.ietf.org/html/rfc7578#section-4.

Note The MULTI option is available beginning with the November 2019 release of SAS 9.4M6 and SAS Viya 3.5.

See "Using the MULTI Option" on page 1299

"*string*"
specifies input data in a quoted string.

Note This method of submission is available beginning with SAS 9.4M3.

Example "Example 4: Specifying Input Data as a String" on page 1304

Requirement The IN= option is required when the POST and PUT methods are used.

MAXREDIRECTS=*n*
specifies the maximum number of redirects that are allowed. PROC HTTP automatically follows redirects coming from a 300-level response code, as long as the NOFOLLOWLOC option is not specified. This option enables you to limit the number of redirects that are performed.

Default 5

Note The MAXREDIRECTS= option is available beginning with the November 2019 release of SAS 9.4M6 and SAS Viya 3.5.

METHOD=<">*http-method*<">
specifies an HTTP method. Standard methods include HEAD, TRACE, GET, POST, PUT, and DELETE. Beginning with SAS 9.4M3, the method is open-ended. Any method that conforms to the HTTP/1.1 standard and is recognizable by the target web server is acceptable. For information, see the HTTP/1.1 specification at www.w3.org.

Default Beginning with SAS 9.4M3, if you omit the METHOD argument and do not specify the IN argument, the default method is GET. If you omit METHOD and do specify the IN argument — and in SAS releases prior to SAS 9.4M3 — the default method is POST.

Restriction Software releases prior to SAS 9.4M3 support only the standard methods.

Requirement Quotation marks continue to be required around *http-method* in SAS versions before the November 2019 release of SAS 9.4M6 and SAS Viya versions before SAS Viya 3.5.

Examples "Example 1: A Simple GET Request" on page 1302

"Example 2: A Simple POST Request" on page 1303

"Example 9: A Nonstandard Method" on page 1310

NO_CONN_CACHE
disables connection caching for this HTTP request. The connection will be made with the specified connection parameters.

Notes This option is supported beginning with SAS 9.4M3.

When you enable NO_CONN_CACHE, you forgo all benefits of cached connections, including cached authentication. Each call that uses authentication must re-authenticate, which can take time.

NO_COOKIES
specifies that cached cookies will not be used for this HTTP request. This option does not prevent cookies from being sent manually with the "Cookie" header.

Note This option is supported beginning with SAS 9.4M3.

NOFOLLOWLOC
prevents the GET method from following URL redirections.

NOFOLLOWLOC is the default behavior for HTTP methods that write data.

Note This option is supported beginning with SAS 9.4M5.

See "FOLLOWLOC" on page 1286

OAUTH_BEARER=*token*
sends an OAuth access token along with the HTTP call. Valid token values are a string, a fileref, or the constant SAS_SERVICES. String values must be quoted. For all token types, the argument sends an authorization header in the form: `Authorization: Bearer Value`.

In addition to adding a header, OAUTH_BEARER= disables other types of HTTP authentication. Any HTTP-Authenticate headers that come back will be ignored.

Notes This option is supported beginning with SAS 9.4M5 and SAS Viya 3.3.

The SAS_SERVICES constant is supported only in SAS Viya.

OUT=*fileref-to-response-data*
specifies a fileref that indicates where output is written.

Example "Example 2: A Simple POST Request" on page 1303

PROXY_AUTH_BASIC
specifies to perform user identity authentication through a proxy server. The user name and password are supplied with the PROXYUSERNAME and PROXYPASSWORD arguments.

Note This option is supported beginning with SAS 9.4M3.

PROXY_AUTH_NTLM
specifies to perform NTLM authentication through a proxy server. As long as your current user identity has permissions, authentication is established.

Restriction NTLM is currently available only on Windows clients.

Note This option is supported beginning with SAS 9.4M3.

PROXY_AUTH_NEGOTIATE
specifies to perform NTLM, Kerberos, or some other type of HTTP authentication through a proxy server. As long as your current user identity has permissions, authentication is established.

Note This option is supported beginning with SAS 9.4M3.

PROXYHOST="*proxy-host-name*"
specifies the Internet host name of an HTTP proxy server. Beginning with SAS 9.4M3, you can specify both the host name and the port number in the PROXYHOST argument in the form:

```
host-name:port-number
```

When this syntax is used, there is no need to specify the PROXYPORT argument.

Earlier SAS versions require you to specify both the PROXYHOST and PROXYPORT arguments. For the earlier releases, specify PROXYHOST= as:

```
host-name
```

Example "Example 3: Specify a Proxy In the HTTP Request" on page 1303

PROXYPASSWORD="*proxy-passwd*"
specifies an HTTP proxy server password.

Tips The password is required only if your proxy server requires credentials.

Encodings that are produced by PROC PWENCODE are supported.

PROXYPORT=*proxy-port-number*
specifies an HTTP proxy server port. Beginning with SAS 9.4M3, PROXYPORT is an optional argument. You are not required to specify PROXYPORT if you specified both the HTTP proxy server host name and port number in the PROXYHOST argument.

Note Earlier SAS releases require that the HTTP proxy server host name and port number are specified separately in the PROXYHOST and PROXYPORT arguments. See "Example 3: Specify a Proxy In the HTTP Request" on page 1303.

PROXYUSERNAME="*proxy-user-name*"
specifies an HTTP proxy server user name.

Tip The user name is required only if your proxy server requires credentials.

QUERY=(<NOENCODE>"*parm1*"="*value1*" "*parm2*"="*value2*")
provides an alternate method for submitting query parameters for the URL= argument.

Typically, query strings are placed on the URL in the URL= option. This can be cumbersome when a value must be URL-encoded and arguments need to be separated with an & (ampersand). You must encode the values in advance. SAS interprets values preceded by an & as a macro. The QUERY= option enables you to specify query arguments as name=value pairs in a list, which is automatically URL-encoded and added to the query string on the URL.

When QUERY= is specified, if the input URL already has an existing query string, the entire generated replacement string uses an & instead of a ?.

The keyword NOENCODE can be specified before a name=value pair to indicate the pair should not be URL-encoded. NOENCODE applies only to the pair that it precedes. Other characters that normally are encoded are still encoded, like spaces.

Note The QUERY= option is available beginning with the November 2019 release of SAS 9.4M6 and SAS Viya 3.5.

See "Using the FORM and QUERY Options with PROC HTTP" on page 1298

TIMEOUT=*integer*
specifies the number of seconds of inactivity to wait before canceling an HTTP request. Use this option to prevent hangs if there is a chance that the server will not respond. The default value, 0 (zero), means no time-out period.

WEBAUTHDOMAIN="*web-credentials-from-metadata*"
specifies the web authentication domain. If specified, a user name and password are retrieved from metadata for the specified authentication domain.

Restriction This option applies to SAS 9 only.

WEBPASSWORD="*basic-authentication-password*"
specifies a password for basic authentication.

Alias PASSWORD

Tip Encodings that are produced by PROC PWENCODE are supported.

WEBUSERNAME="*basic-authentication-name*"
specifies a user name for basic authentication.

Alias USERNAME

DEBUG Statement

Writes debugging information to the SAS log.

Supports: All HTTP methods

Notes: This statement is supported beginning with SAS 9.4M5 and SAS Viya 3.3.

The OUTPUT_TEXT, REQUEST_BODY, RESPONSE_BODY, REQUEST_HEADERS, RESPONSE_HEADERS, NO_REQUEST_BODY, NO_RESPONSE_BODY, NO_REQUEST_HEADERS, and NO_RESPONSE_HEADERS options are new in SAS 9.4M6. SAS 9.4M6 enhancements are currently not supported in SAS Viya.

Example: "Example 13: Use the DEBUG Statement with the LEVEL= Option" on page 1316

Syntax

DEBUG *options*;

Optional Arguments

Level= 0 | 1 | 2 | 3

0 no debugging. This is the same as specifying PROC HTTP without the DEBUG statement.

1 displays request and response headers in the log. Setting a debug level of 1 equates to setting the REQUEST_HEADERS and RESPONSE_HEADERS options in the DEBUG statement.

2 displays request data as well as level 1 messages in the log. Setting a debug level of 2 equates to setting the REQUEST_HEADERS, RESPONSE_HEADERS, and REQUEST_BODY options in the DEBUG statement.

3 displays response data as well as level 2 messages in the log. Setting a debug level of 3 equates to setting the REQUEST_HEADERS, RESPONSE_HEADERS, REQUEST_BODY, and RESPONSE_BODY options in the DEBUG statement.

CAUTION

Use level 3 with care in SAS 9.4M5 and SAS Viya. The system may become unstable when the response is binary data.

NO_REQUEST_BODY

suppresses the request body from the information displayed when a debug level of 2 or greater is specified.

NO_REQUEST_HEADERS
suppresses the request header from the information displayed when a debug level of 1 or greater is specified.

NO_RESPONSE_BODY
suppresses the response body from the information displayed when a debug level of 3 is specified.

NO_RESPONSE_HEADERS
suppresses the response header from the information displayed when a debug level of 1 or greater is specified.

OUTPUT_TEXT
displays the request body and response body as if they are text.

REQUEST_BODY
displays the request body in the log.

REQUEST_HEADERS
displays the request header in the log.

RESPONSE_BODY
displays the response body in the log.

RESPONSE_HEADERS
displays the response header in the log.

Details

You must specify at least one option in the DEBUG statement for debugging information to be written to the log.

In SAS 9.4M5 and in SAS Viya, you control the amount of information that is printed with the LEVEL= option. A value of 1 or greater in the LEVEL= option is required to display debugging information. All DEBUG statement output in these software versions is written as text.

Beginning with SAS 9.4M6:

- the HTTP request body and response body are written as binary by default. You can set the OUTPUT_TEXT option to print the information as text.
- you have a choice of options, in addition to LEVEL=, which can be specified alone or in combination. For example, you can specify RESPONSE_HEADERS to display debugging information for response headers only, or RESPONSE_HEADERS and RESPONSE_BODY to display response information only. Or, you can specify LEVEL=3 to display all debugging information, and also to specify NO_RESPONSE_BODY to omit the response body. The options that control individual components can be used to limit or expand the information displayed for a particular LEVEL= value.

HEADERS Statement

Specifies request headers for the HTTP request.

Supports: All HTTP methods

Notes: This statement is supported beginning with SAS 9.4M3.

Use the HEADERS statement instead of the PROC HTTP CT= and HEADERIN= arguments.

Example: "Example 8: A GET That Uses the HEADERS Statement" on page 1309

Syntax

HEADERS *"HeaderName"="HeaderValue"* <*"HeaderName-n"="HeaderValue-n"*>;

Required Argument

"HeaderName"="HeaderValue"

is a name and value pair that represents a header name and its value. The HeaderName can be a standard header name or a custom header name. For information about header field definitions, see the HTTP/1.1 specification at www.w3.org.

Note: Do not specify a colon (:) in the header name. The name=value pairs are automatically translated into the following form:

```
HeaderName : HeaderValue
```

Details

The HEADERS statement enables you to specify header values easily within the procedure request, instead of having to provide a fully formatted input file via a fileref. Use the HEADERS statement to specify the content-type and character set of the document that you are uploading when the values are different from the default values for the method.

Table 35.1 *Default Content-Type for the POST and PUT Methods*

HTTP Method	Default Content-Type
POST	application/x-www-form-urlencoded

HTTP Method	Default Content-Type
PUT	application/octet-stream

SSLPARMS Statement

Sets encryption options for the PROC HTTP request.

Supports: All HTTP methods

Note: Support for this statement starts in SAS 9.4M6 and SAS Viya 3.5.

See: "Using Hypertext Transfer Protocol Secure (HTTPS) " on page 1296

Example: "Example 14: Specify Local Options for Two-Way Encryption in Windows" on page 1319

Syntax

SSLPARMS *encryption-options*;

Required Argument

encryption-options
specifies SAS system options for encryption that enable a secure client-server connection with the target server. For a listing of available system options, see "SAS System Options for Encryption" in *Encryption in SAS*.

Note: Only system options for encryption that begin with "SSL" are supported.

The SAS system options for encryption can be specified in either of the following ways:

```
"SystemOption"="OptionValue"
SystemOption="OptionValue"
```

Note SAS system options for encryption are host-specific.

Details

Use the SSLPARMS statement to apply a SAS system option for encryption locally instead of globally.

Usage: HTTP Procedure

Using Hypertext Transfer Protocol Secure (HTTPS)

HTTP Security: TLS and Data Encryption

Transport Layer Security (TLS) and its predecessor, Secure Sockets Layer (SSL), enables web browsers and web servers to communicate over a secured connection by encrypting data. Both browsers and servers encrypt data before the data is transmitted. The receiving browser or server then decrypts the data before it is processed.

Note: All discussion of TLS is also applicable to the predecessor protocol, SSL.

Using HTTPS with PROC HTTP

For both SAS 9.4 (beginning with SAS 9.4M3) and the full SAS Viya deployment, secure communication over HTTP (HTTPS) is provided globally by default. HTTPS is controlled by a Trusted Root CA bundle. A default Trusted Root CA bundle is laid down at installation and pointed to by the SSLCALISTLOC= system option. The SSLCALISTLOC= system option sets secure communications globally for the SAS system. Do not change the value of the SSLCALISTLOC= system option unless you are instructed to do so by SAS Technical Support. "SSLCALISTLOC=" in *Encryption in SAS*.

Some UNIX installations require the Server Name Indicator (SNI) to be set so that they can serve up the proper certificate. Beginning with SAS 9.4M5, the SNI is also set by default. Earlier SAS 9.4 releases and SAS Viya require you to set the SNI with environment variables. For information about setting environment variables for a SAS 9.4 installation, see *Encryption in SAS*. For information about setting environment variables for SAS Viya, see *Encryption in SAS Viya: Data in Motion*.

Beginning with SAS 9.4M6 and SAS Viya 3.5, PROC HTTP enables you to override the global communication security settings with local communication security settings with the SSLPARMS statement. In the SSLPARMS statement, specify SAS system options for encryption. The options that are set in the SSLPARMS

statement apply only to the PROC HTTP request in which they are specified. For more information, see "SSLPARMS Statement" on page 1295 and "Example 14: Specify Local Options for Two-Way Encryption in Windows" on page 1319.

Using Authentication Other Than Basic

Beginning with SAS 9.4M3, PROC HTTP enables you to specify the authentication type. The ability to specify the authentication type is useful when you know which authentication type is required for a request to succeed in advance. Specifying the correct type, rather than requiring the procedure to negotiate it, optimizes procedure execution. For example, if you know that the server supports only Kerberos authentication, it is a good idea to specify the AUTH_NEGOTIATE argument. If you know that the server supports only NTLM authentication, then specify AUTH_NTLM.

If you do not specify the authentication type, the default type (which is the type of authentication that is available in SAS releases prior to the third maintenance release), is AUTH_ANY. AUTH_ANY is equivalent to specifying AUTH_NTLM, AUTH_NEGOTIATE, and AUTH_BASIC together in the request. AUTH_NTLM authentication is attempted first (for Windows only), then AUTH_NEGOTIATE, and so on, although the server ultimately determines which authentication type is used. If the server that you are connecting to supports the NTLM authentication protocol or the Kerberos authentication protocol, it usually is not necessary to specify a user name and password. As long as your current user identity has permissions, authentication is established.

EXPECT_100_CONTINUE support is provided to optimize requests that must make more than one trip to the server. This option prevents the data from being uploaded multiple times.

Note: When using authentication, do not enable NO_CONN_CACHE. When NO_CONN_CACHE is enabled, each call that uses authentication must re-authenticate, which can take time.

HTTP_TOKENAUTH enables you to access SAS Content Servers from PROC HTTP without having to supply a user name and password.

WEBAUTHDOMAIN is also used in lieu of a user name and password. However, you must set up a metadata entry that stores the user name and password for the specified web authentication domain.

Wire Logging

Wire logging logs packets of information as they appear on the network. This information is normally referred to as a dump. Wire dumps enable you to see what information is being sent to the server and what information the server is sending

back. Because you can see the raw data, wire dumps can be useful in debugging your programs.

Beginning with SAS 9.4M3, logger APP.TK.HTTPC is used to log HTTP-specific messages. The wire dumps that the logger generates can be enabled by setting logger APP.TK.HTTPC to the DEBUG level or higher. In earlier versions of SAS 9.4, logger HTTP is used to log HTTP-specific messages. Set logger HTTP to the DEBUG level or higher. At the DEBUG level, the first 64 bytes of incoming and outgoing data is logged. At the TRACE level, all of the data is written to the log. Note that at the TRACE level, performance can be greatly diminished.

For more information, see “SAS Logging” in *SAS Logging: Configuration and Programming Reference*.

Using Encodings with PROC HTTP

Responses are not encoded to session encodings. You must supply the request with the encoding that you want to use, and set the content type.

Beginning with the November 2019 release of SAS 9.4M6 and SAS Viya 3.5, you can send post URL-encoded data with the FORM parameter in the IN= argument. The QUERY= procedure option enables you to submit URL-encoded query parameters.

Using the FORM and QUERY Options with PROC HTTP

Beginning with the November 2019 release of SAS 9.4M6 and SAS Viya 3.5, uploading standard URL encoded form data has been made more convenient. The FORM option enables you to submit a single-part form with PROC HTTP. For example, in order to post values to this form in previous SAS releases, you had to prepare your PROC HTTP request as follows:

```
%let firstname=Mickey;
%let lastname=Mouse;

data _null_;
      firstname = urlencode("&firstname");
      lastname = urlencode("&lastname");
      call symputx("firstname",firstname,'G');
      call symputx("lastname",lastname,'G');
run;

proc http url="http://httpbin.org/post"
in="firstname=&firstname.%nrstr(&lastname)=&lastname";
run;
```

The URLENCODE function and the SYMPUTX call routine were necessary to encode the data before submitting the PROC HTTP request.

With the new FORM option, the same request can now be submitted as follows:

```
%let firstname=Mickey;
%let lastname=Mouse;
proc http url="http://httpbin.org/post"
in = form ("firstname"="&firstname"
           "lastname"="&lastname");
run;
```

The QUERY= option makes adding query parameters to a URL easier. You can still add query parameters to a URL manually as shown below. However, when you modify the URL manually you are responsible for URL encoding any special characters and making sure that the & (ampersand) appears correctly and is not mistaken for a macro variable.

```
url="http://httpbin.org/GET?firstname=&firstname
%nrstr(&lastname)=&lastname";
```

With the new QUERY= procedure option, the above request can now be submitted as follows:

```
%let firstname=Mickey;
%let lastname=Mouse;
proc http url="http://httpbin.org/get"
query = ("firstname"="&firstname"
           "lastname"="&lastname");
run;
```

Both options URL-encode the input data by default unless you specify the NOENCODE option before a name=value pair.

Using the MULTI Option

A multipart upload enables you to upload multiple entities in a single request. The PROC HTTP MULTI option provides support for sending multipart form data as well as generic multipart uploads. The multipart feature is useful for uploading files to an HTTP server. For example, you might use it to upload a JSON file that contains the metadata about a file followed by the binary code of the file.

Note: The new functionality does not include support for nested multipart uploads.

Here is an example of a multipart form post:

```
filename input1 "input1.txt";
filename input2 "input2.txt";
filename resp "multi_resp.json";

proc http
url="httpbin.org/post"
in = MULTI FORM ( "Name1" = "Raw Input 1" ,
                  "Name2" = input1 header="Foo: Bar" header="Foo2: Bar2" ,
                  "Name3" = input2 FILENAME="Different Filename"
                    header="Content-Type: text/plain")
```

```
out=resp
;
run;
```

This HTTP request sends a three-part form.

In a multipart form post:

- the MULTI keyword is specified in the IN= statement. The keyword must follow the equal sign.
- the FORM keyword indicates that this upload is of type multipart/form-data.
- the parts of the form are submitted within parenthesis
- Each part of the form includes the following components:
  - a unique identifier that indicates the beginning of the part. In this example, that is "Name*n*".
  - one or more optional HTTP headers. The HTTP headers must be specified before the input data. For a form, it is a good idea to specify a content-type header to indicate the type of content that will follow. The Content-Disposition header is derived from Name= and FILENAME= values. If the input is a fileref, and a FILENAME value is not specified, the FILENAME= value is derived from the fileref.
  - input data, supplied as a string or a fileref.

Here is an example of a generic multipart request:

```
proc http
   url="httpbin.org/post"
   method=POST
   in = MULTI "related" ( input1 header="content-type: text/plain",
         "some text data with no header");
run;
```

In a generic multipart request:

- The quoted value after the MULTI keyword is used to derive the Content-Disposition header. For this request, a header of Content-Type: multipart/related is sent.
- The input data for each part can come from a fileref or be specified in a quoted string.
- Headers are optional on each part. When a header is specified, the specification must contain a full header in proper form.
- Parts are separated by commas.

The preceding example uploads two entities.

Using HEADERS= to Send Chunked Data

To force chunked data to be sent, specify a header as follows:

```
proc http url="httpbin.org/post"
 in="hello";
 headers "Transfer-Encoding"="chunked";
 debug level=3;
run;
```

PROC HTTP Response Status Macro Variables

Beginning with SAS 9.4M5, PROC HTTP sets up macro variables with certain values after it executes each statement. These macro variables can be used inside a macro to test for HTTP errors. An HTTP error is an error that is encountered after a successful host connection has been made and the HTTP request has been successfully parsed by the HTTP procedure. The macro variables do not store values for host connection errors or for PROC HTTP syntax errors. The macro variables are reset on each invocation of PROC HTTP.

SYS_PROCHTTP_STATUS_CODE
: stores the status code of the HTTP request.

SYS_PROCHTTP_STATUS_PHRASE
: stores the descriptive phrase that is associated with the status code.

Consider this example:

```
HTTP/1.1 200 OK
```

The SYS_PROCHTTP_STATUS_CODE macro variable stores the value 200. The SYS_PROCHTTP_STATUS_PHRASE macro variable stores OK, which indicates that this HTTP request was successful.

For more information, see "Example 12: Create A Program That Captures Status Response Values" on page 1312.

Macro Variables for Setting Global Values

Beginning with SAS 9.4M3, PROC HTTP produces two automatic macro variables to enable you to set or change default PROC HTTP settings.

PROCHTTP_PROXY=*proxy-server-name-and-port-number*;
: sets a default proxy server for PROC HTTP requests. Once set, the specified proxy server establishes a proxy for all PROC HTTP requests in the SAS session, unless you specify the PROXYHOST= argument in the PROC HTTP request. The value that is specified in the procedure argument overrides the value that is specified in the macro variable. Specify the PROXYHOST= argument with a value that is different from the macro variable to use a different proxy server for a request. Specify PROXYHOST= without a value to disable proxy use for a request. For more information, see "Example 5: Specify A Proxy In a Macro Variable" on page 1305.

PROCHTTP_NOCOOKIES= blank | *integer*;
provides global control of cookie caching for PROC HTTP requests. Omitting the macro variable or specifying the macro variable without a value enables cookie caching (cookie caching is on by default). To globally disable cookie caching, specify a nonzero value in the macro variable. Cookie caching can be disabled for a specific PROC HTTP request by specifying the NO_COOKIES procedure option in the PROC HTTP request along with the CLEAR_COOKIES or CLEAR_CACHE arguments.

The macro variables are set with the %LET statement. In the event that you disable cookie caching, you can delete the macro variable from the symbol table with the %SYMDEL statement.

Examples: HTTP Procedure

Example 1: A Simple GET Request

Features: METHOD= argument
URL= Argument
OUT= Argument

Details

This example makes a GET request to a server on the local network. GET is the simplest and most common request that you can make with PROC HTTP. Beginning with SAS 9.4M3, GET is the default METHOD value when the IN argument is omitted for a PROC HTTP request, making the argument optional. A GET request must specify METHOD=GET in earlier releases of SAS software.

Program

```
filename resp TEMP;

proc http
   url="http://httpbin.org/get"
   out=resp;
run;
```

Example 2: A Simple POST Request

Features: METHOD= Argument
IN= Argument
OUT= Argument

Details

This example makes a simple POST request to a server on the local network. The file to upload is identified by a fileref in the IN argument. When the IN argument is specified, the default METHOD= value in all SAS releases is POST. The response and the output headers are written to filerefs.

Program

```
filename resp TEMP;
filename headout TEMP;
filename input TEMP;

data _null_;
   file input;
   put "this is some sample text";
run;

proc http
   url="http://httpbin.org/post"
   in=input
   out=resp
   headerout=headout;
run;
```

Example 3: Specify a Proxy In the HTTP Request

Features: PROXYHOST= Argument
PROXYPORT= Argument

Note: The PROXYHOST and PROXYPORT arguments are the only way to specify a proxy server in software releases before SAS 9.4M3.

Details

This example makes the same request as in “Example 2: A Simple POST Request” on page 1303, except the call is sent to an external server and therefore requires the use of a proxy server. This example uses the PROXYHOST argument to specify the name of the external server and the PROXYPORT argument to specify the port number.

Program

```
filename out "u:\prochttp\Testware\ProxyTest_out.txt";
filename input TEMP;

data _null_;
   file input;
   put "this is some sample text";
run;

proc http
   url="http://httpbin.org/post"
   method=post
   in=input
   out=out
   proxyhost="proxyhost.company.com"
   proxyport=889;
run;
```

Example 4: Specifying Input Data as a String

Features: IN= *"string"*

Note: The ability to specify input text as a string is supported beginning with SAS 9.4M3.

Details

The PROC HTTP IN= argument accepts a quoted input string or a fileref to submit input data. Specifying input in a string makes it easier to send text posts and form-based posts. This example submits the form that can be found at http://httpbin.org/forms/post. The response is written to a response file.

Program

```
filename resp TEMP;

proc http
   method=post
   url="http://httpbin.org/post"
   in='custname=Sas+User&custtel=919-555-5555&custemail=sas.user%40
   sas.com&size=medium&topping=cheese&delivery=12%3A00&comments=Dont
+Drop+It'
   out=resp;
run;

data _null_;
   infile resp;
   input;
   put _infile_;
run;
```

This is the content of the Resp file:

```
{
  "args": {},
  "data": "",
  "files": {},
  "form": {
    "comments": "Dont Drop It",
    "custemail": "sas.user@sas.com",
    "custname": "Sas User",
    "custtel": "919-555-5555",
    "delivery": "12:00",
    "size": "medium",
    "topping": "cheese"
  },
  "headers": {
    "Accept": "*/*",
    "Content-Length": "133",
    "Content-Type": "application/x-www-form-urlencoded",
    "Host": "httpbin.org",
    "User-Agent": "SAS/9",
  },
  "json": null,
  "origin": "149.173.1.80, 104.129.194.85",
  "url": "http://httpbin.org/post"
}
```

Example 5: Specify A Proxy In a Macro Variable

Features: PROCHTTP_PROXY= Macro Variable
IN="*string*"

Note: The PROCHTTP_PROXY= macro variable and the ability to specify input text as a string are supported beginning with SAS 9.4M3.

Details

This example makes the same request as in "Example 3: Specify a Proxy In the HTTP Request" on page 1303, except the proxy server is specified in a macro variable and the input text is specified as a string in the IN argument. The PROCHTTP_PROXY macro variable specifies the proxy server's Internet host name and port number as one value. Because the proxy is set in the macro variable, it is available to all subsequent HTTP requests that are made in the SAS session. In this request, parameters to the POST are read from a string that is specified in the IN argument.

Program

```
%let PROCHTTP_PROXY=proxyhost.company.com:889;

filename out "u:\prochttp\Testware\ProxyTest_out.txt";
filename input TEMP;

proc http
   url="http://httpbin.org/post"
   method=post
   in="text to write out"
   out=out;
run;
```

Example 6: A POST That Captures the Response Headers

Features: IN="*string*"
HEADEROUT= Argument

Details

This example makes the same POST request as in "Example 5: Specify A Proxy In a Macro Variable" on page 1305 but captures the response headers in a file called headerOut.txt.

Program

```
%let PROCHTTP_PROXY=proxyhost.company.com:889;

filename out "u:\prochttp\Testware\ProxyTest_out.txt";
filename hdrout "u:\prochttp\Testware\headerOut.txt";

 proc http
   url="http://httpbin.org/post"
   method=post
   in="text to write out"
   out=out
   headerout=hdrout;
run;
```

Example 7: A GET That Specifies HEADEROUT_OVERWRITE

Features: HEADEROUT argument
HEADEROUT_OVERWRITE argument

Note: The HEADEROUT_OVERWRITE argument is supported beginning with SAS 9.4M3.

Details

This example shows the effects of the HEADEROUT_OVERWRITE argument. The GET requests redirect twice before reaching their destination. HEADEROUT_OVERWRITE causes only the last output header to be recorded.

Example of Normal HEADEROUT Output after a Redirect

```
filename hdrs "u:\prochttp\Testware\GetHdr_out.txt";
filename out "u:\prochttp\Testware\GetTest_out.txt";

proc http
   url="http://httpbin.org/redirect/2"
   method=GET
   headerout=hdrs
   out=out;
run;
```

This is the content of GetHdr_out.txt:

```
HTTP/1.1 302 FOUND
Server: nginx
Date: Mon, 20 Apr 2015 14:19:52 GMT
Content-Type: text/html; charset=utf-8
Content-Length: 247
Connection: keep-alive
Location: /relative-redirect/1
Access-Control-Allow-Origin: *
Access-Control-Allow-Credentials: true

HTTP/1.1 302 FOUND
Server: nginx
Date: Mon, 20 Apr 2015 14:19:53 GMT
Content-Type: text/html; charset=utf-8
Content-Length: 0
Connection: keep-alive
Location: /get
Access-Control-Allow-Origin: *
Access-Control-Allow-Credentials: true

HTTP/1.1 200 OK
Server: nginx
Date: Mon, 20 Apr 2015 14:19:53 GMT
Content-Type: application/json
Content-Length: 195
Connection: keep-alive
Access-Control-Allow-Origin: *
Access-Control-Allow-Credentials: true
```

Example of HEADEROUT Request with HEADEROUT_OVERWRITE

```
filename hdrs "u:\prochttp\Testware\GetHdr2_out.txt";
filename out "u:\prochttp\Testware\GetTest2_out.txt";

proc http
 url="http://httpbin.org/redirect/2"
method=GET
headerout=hdrs
out=out
HEADEROUT_OVERWRITE;
run;
```

This is the content of GetHdr2_out.txt:

```
HTTP/1.1 200 OK
Server: nginx
Date: Mon, 20 Apr 2015 14:22:48 GMT
Content-Type: application/json
Content-Length: 195
Connection: keep-alive
Access-Control-Allow-Origin: *
Access-Control-Allow-Credentials: true
```

Example 8: A GET That Uses the HEADERS Statement

Features: HEADERS Statement
GET Method

Note: The HEADERS statement is supported beginning with SAS 9.4M3.

Details

The following is an example of a GET method request that specifies the HEADERS statement. As of SAS 9.4M3, GET is also the default method when the IN argument is not specified.

Program

```
filename resp TEMP;

proc http
   url="http://httpbin.org/headers"
   out=resp;
 headers
   "Accept"="application/json";
run;

data _null_;
   infile resp;
   input;
   put _infile_;
run;
```

The output looks like this:

```
  "headers": {
    "Accept": "*/*,application/json",
    "Host": "httpbin.org",
    "User-Agent": "SAS/9",
  }
}
```

Example 9: A Nonstandard Method

Features: METHOD Argument

Note: Nonstandard methods are supported in SAS 9.4M3 and later releases.

Details

This example submits the MKCOL WEBDAV http method. Output is written to a temporary file named Resp. There are no input and output requirements for nonstandard methods. As long as the target server returns data and you have specified a valid OUT, data will be written to your OUT fileref. Here, output is written to Resp.

Program

```
filename resp TEMP;

proc http
   url="http://hostname/directory/"
   method=MKCOL
   out=resp;
run;
```

Example 10: A Request That Specifies an Authentication Type

Features: AUTH_NEGOTIATE Argument

AUTH_NTLM Argument

Note: The ability to specify an authentication type is supported beginning with SAS 9.4M3.

Details

This example specifies an authentication type for a PROC HTTP request. Two authentication types are specified, indicating that only Negotiate or NTLM authentication are allowed.

Program

```
proc http
   url="http://securesite.com"
   AUTH_NEGOTIATE
   AUTH_NTLM;
run;
```

Example 11: A PUT That Specifies EXPECT_100_CONTINUE

Features: EXPECT_100_CONTINUE Argument
HEADEROUT= Argument

Note: The EXPECT_100_CONTINUE argument is supported beginning with SAS 9.4M3.

Details

This example specifies the EXPECT_100_CONTINUE header.

Program

```
filename resp TEMP;
filename hdrs TEMP;

proc http
   url="http://httpbin.org/put"
   method=PUT
   in='Some Put Data'
   out=resp
   headerout=hdrs
   EXPECT_100_CONTINUE;
```

```
run;

data _null_;
   infile hdrs;
   input;
   put _infile_;
run;

data _null_;
   infile resp;
   input;
   put _infile_;
run;
```

The output in the HDRS looks like this:

```
HTTP/1.1 100 Continue

HTTP/1.1 200 OK
Server: myserver/18.0
Date: Mon, 24 Nov 2014 20:18:29 GMT
Content-Type: application/json
Content-Length: 652
Access-Control-Allow-Origin: *
Access-Control-Allow-Credentials: true
X-Cache: MISS from transproxy
Via: 1.1 vegur, 1.1 transproxy (squid)
Connection: keep-alive
```

The output in the Resp file looks like this:

```
{
  "args": {},
  "data": "Some Put Data",
  "files": {},
  "form": {},
  "headers": {
    "Accept": "*/*",
    "Content-Length": "13",
    "Content-Type": "application/octet-stream",
    "Host": "httpbin.org",
    "User-Agent": "SAS/9",
    "Xxpect": "100-continue",
  },
  "json": null,
  "origin": "149.173.1.80, 104.129.194.85",
  "url": "http://httpbin.org/put"
}
```

Example 12: Create A Program That Captures Status Response Values

Features: SYS_PROCHTTP_STATUS_CODE macro variable
SYS_PROCHTTP_STATUS_PHRASE macro variable

Details

This example creates a simple macro program that tests the value set in the SYS_PROCHTTP_STATUS_CODE macro variable. The program specifies to print an error message when the result code does not match a specified value for the SYS_PROCHTTP_STATUS_CODE macro variable. The program also specifies to print the actual values returned by the SYS_PROCHTTP_STATUS_CODE and SYS_PROCHTTP_STATUS_PHRASE macro variables in any error messages.

The macro program is then invoked after various PROC HTTP requests to illustrate the results that you can expect under various circumstances. The macro program is invoked with a value of 200 in each execution. A value of 200 indicates successful completion of the HTTP request.

Program

The following code creates the macro program.

```
%macro prochttp_check_return(code);
%if %symexist(SYS_PROCHTTP_STATUS_CODE) ne 1 %then %do;
  %put ERROR: Expected &code., but a response was not received from
 the HTTP Procedure;
  %abort;
  %end;
%else %do;
  %if &SYS_PROCHTTP_STATUS_CODE. ne &code. %then %do;
   %put ERROR: Expected &code., but received &SYS_PROCHTTP_STATUS_CODE.
 &SYS_PROCHTTP_STATUS_PHRASE.;
   %abort;%end;
%end;
%mend;
```

Result for a Successful HTTP Request

Here is an example of a successful PROC HTTP request. The macro program specifies to print an error message and the return code and status values for any HTTP request that does not return the code value 200.

```
proc http url="httpbin.org/get";
run;
%prochttp_check_return(200);
```

Here is the log for the request. The request returned 200. For PROC HTTP requests whose return code matches the code value specified in the macro program, the values of the macro variables are ignored. There is no error message; therefore, no need to print the value of the status reporting macro variables.

```
173  proc http url="httpbin.org/get";
174  run;

NOTE: PROCEDURE HTTP used (Total process time):
      real time           3.40 seconds
      cpu time            0.03 seconds

NOTE: 200 OK

175
176  %prochttp_check_return(200);
177
178
```

Result for Failed Host Connection

The following is an example of a PROC HTTP request that cannot establish a host connection:

```
proc http url="foo.bar";
run;
%prochttp_check_return(200);
```

When a server connection cannot be made, the procedure returns an error message. However, the error message does not include a return code or a status phrase.

```
179  proc http url="foo.bar";
180  run;

ERROR: Host name resolution failed
NOTE: PROCEDURE HTTP used (Total process time):
      real time           2.28 seconds
      cpu time            0.00 seconds

NOTE: The SAS System stopped processing this step because of errors.
181
182  %prochttp_check_return(200);
ERROR: Expected 200, but a response was not received from the HTTP Procedure
ERROR: Execution terminated by an %ABORT statement.
183
```

Result for a Valid HTTP Error

The following is an example of a PROC HTTP request that connects but specifies an invalid secondary path:

```
proc http url="httpbin.org/get2";
run;
%prochttp_check_return(200);
```

When a server connection is made, but the HTTP request fails, the error message prints the actual return code and its corresponding status phrase.

```
184  proc http url="httpbin.org/get2";
185  run;

NOTE: PROCEDURE HTTP used (Total process time):
      real time           0.04 seconds
      cpu time            0.00 seconds

NOTE: 404 Not Found

186
187  %prochttp_check_return(200);
ERROR: Expected 200, but received 404 Not Found
ERROR: Execution terminated by an %ABORT statement.
188
```

Results for a Parsing Error

The following is an example of a PROC HTTP request that specifies an invalid argument:

```
proc http url="httpbin.org/get" foo;
run;
%prochttp_check_return(200);
```

When a server connection is made, but the PROC HTTP request cannot be parsed, the macro returns an error message. The message does not include a return code or status phrase.

```
189  proc http url="httpbin.org/get" foo;
                                     ---
                                     22
                                     202
ERROR 22-322: Syntax error, expecting one of the following: ;, AUTH_ANY, AUTH_BASIC,
              AUTH_NEGOTIATE, AUTH_NONE, AUTH_NTLM, CLEAR_CACHE, CLEAR_CONN_CACHE,
              CLEAR_COOKIES, CT, EXPECT_100_CONTINUE, FOLLOWLOC, HEADERIN, HEADEROUT,
              HEADEROUT_OVERWRITE, HTTP_TOKENAUTH, IN, METHOD, NOFOLLOW, NOFOLLOWLOC,
              NO_CONN_CACHE, NO_COOKIES, OAUTH_BEARER, OUT, PASSWORD, PROXYHOST,
              PROXYPASSWORD, PROXYPORT, PROXYUSERNAME, PROXY_AUTH_BASIC,
PROXY_AUTH_NEGOTIATE,
              PROXY_AUTH_NONE, PROXY_AUTH_NTLM, TIMEOUT, URL, USERNAME, VERBOSE,
              WEBAUTHDOMAIN, WEBPASSWORD, WEBUSERNAME.
ERROR 202-322: The option or parameter is not recognized and will be ignored.
190  run;
191
192  %prochttp_check_return(200);
ERROR: Expected 200, but a response was not received from the HTTP Procedure
NOTE: PROCEDURE HTTP used (Total process time):
      real time           0.07 seconds
      cpu time            0.07 seconds

ERROR: Execution terminated by an %ABORT statement.
NOTE: The SAS System stopped processing this step because of errors.
```

Example 13: Use the DEBUG Statement with the LEVEL= Option

Features: DEBUG statement
LEVEL= statement option
Statement output

Details

This example shows the information returned by the DEBUG statement Level= option.

Debug Level 1

A debug level of 1 displays the HTTP request and response headers.

```
proc http
   in = "*************testing prochttp****************"
   method=POST
   url="http://httpbin.org/post";
   debug level = 1;
run;
```

The following information is displayed in the log:

```
> POST /post HTTP/1.1
> User-Agent: SAS/9
> Host: httpbin.org
> Accept: */*
> Connection: Keep-Alive
> Content-Length: 45
> Content-Type: application/x-www-form-urlencoded
>
< HTTP/1.1 200 OK
< Connection: keep-alive
< Server: myserver/19.9.0
< Date: Tue, 07 Aug 2018 19:12:34 GMT
< Content-Type: application/json
< Content-Length: 418
< Access-Control-Allow-Origin: *
< Access-Control-Allow-Credentials: true
< Via: 1.1 vegur
<
```

Debug Level 2

A debug level of 2 displays the HTTP request and response headers and the HTTP request body.

```
proc http
   in = "**************testing prochttp****************"
   method=POST
   url="http://httpbin.org/post";
   debug level = 2;
run;
```

Beginning with SAS 9.4M6, the following information is displayed in the log. The request body is written as binary by default. Use the OUTPUT_TEXT DEBUG statement option if you want to write the information as text.

```
> POST /post HTTP/1.1
> User-Agent: SAS/9
> Host: httpbin.org
> Accept: */*
> Connection: Keep-Alive
> Content-Length: 45
> Content-Type: application/x-www-form-urlencoded
>
> 000000000A9FC4C0: 2A 2A 2A 2A 2A 2A 2A 2A 2A 2A 2A 2A 74 65 73

< Content-Type: application/json
< Content-Length: 418
< Access-Control-Allow-Origin: *
< Access-Control-Allow-Credentials: true
< Via: 1.1 vegur
<
```

Debug Level 3

A debug level of 3 displays the request header, response header, request body, and response body.

```
proc http
   in = "**************testing prochttp*****************"
   method=POST
   url="http://httpbin.org/post";
   debug level = 3;
run;
```

Beginning with SAS 9.4M6, the following information is displayed in the log. The request and response body are written as binary by default.

```
> POST /post HTTP/1.1
> User-Agent: SAS/9
> Host: httpbin.org
> Accept: */*
> Connection: Keep-Alive
> Content-Length: 45
> Content-Type: application/x-www-form-urlencoded
>

```

Example 14: Specify Local Options for Two-Way Encryption in Windows

Features: SSLPARMS statement
SSLCERTISS= system option
SSLCERTSERIAL= system option

Details

The following is an example of a PROC HTTP request that specifies local encryption options to send a client certificate for two-way TLS authentication on Windows. The name of the Certificate Authority (CA) that issued the client certificate is named Glenn's CA.

The system options used are host dependent. For more information about the system options in a SAS 9.4 installation, see *Encryption in SAS*. For more information about system options in SAS Viya, see *Encryption in SAS Viya: Data in Motion*.

This request specifies the Windows system options SSLCERTISS and SSLCERTSERIAL.

```
proc http
  method=GET
  url="https://internal.site.com/";
  sslparms
    sslcertiss="Glenn's CA"
    sslcertserial="0a1dcfa3000000000015"
  ;
run;
```

Example 15: Specify Local Options for Two-Way Encryption in UNIX

Features:

SSLPARMS statement

SSLCERTLOC= system option

SSLPVTKEYLOC= system option

SSLPVTKEYPASS= system option

SSLPKCS12LOC= system option

SSLPKCS12PASS= system option

Details

The following is an example of a PROC HTTP request that specifies local encryption options to send a client certificate for two-way TLS authentication on UNIX. On UNIX, the encryption options that you use depend on whether the certificate is in PEM or DER format. This example shows how to specify the location of PEM and DER certificates for user John Doe.

Note: The paths to the certificates are relative to the location where the web server is running. Therefore, the certificates must be accessible on disk.

For more information about the system options, see *Encryption in SAS*.

SSLPARMS Arguments for a PEM Certificate

The SSLCERTLOC= and SSLPVTKEYLOC= system options specify the location of a PEM certificate. SSLPVTKEYPASS= is specified only if needed.

```
proc http
  method=GET
  url="https://internal.site.com/";
  sslparms
    sslcertloc="/users/johndoe/certificates/server.pem"
    sslpvtkeyloc="/users/johndoe/certificates/serverkey.pem"
    sslpvtkeypass="password"
  ;
run;
```

SSLPARMS Arguments for a DER Certificate

The SSLPKCS12LOC= and SSLPKCS12PASS= system options specify the location of a DER certificate.

Example Code 35.1 *System Options for a DER-Encoded Certificate*

```
proc http
  method=GET
  url=https://internal.site.com/;
  sslparms
    sslpkcs12loc="/users/server/certificates/server.p12"
    sslpkcs12pass="password"
  ;
run;
```

36

IMPORT Procedure

Overview: IMPORT Procedure

What Does the IMPORT Procedure Do?

The IMPORT procedure reads data from an external data source and writes it to a SAS data set. In Base SAS 9.4, you can import JMP files and delimited files.

In delimited files, a delimiter (such as a blank, comma, or tab) separates columns of data values. If you license SAS/ACCESS Interface to PC Files, additional external data sources can include Microsoft Access database files, Microsoft Excel files, and Lotus spreadsheets. For more information, see *SAS/ACCESS Interface to PC Files: Reference*.

Starting in SAS 9.4, you can import data from JMP 7 or later files, and JMP variables can be up to 255 characters long. You can also import value labels to a SAS format catalog. Extended attributes are now used automatically, and the META= statement is no longer supported. For more information, see "JMP Files" in *SAS/ACCESS Interface to PC Files: Reference*.

When you run the IMPORT procedure, it reads the input file and writes the data to the specified SAS data set. By default, IMPORT procedure expects the variable names to appear in the first row. The procedure scans the first 20 rows to count the variables, and it attempts to determine the correct informat and format for each variable. You can use the IMPORT procedure's statements to do the following:

- indicate how many rows SAS scans for variables to determine the type and length (GUESSINGROWS=)
- indicate at which row SAS begins to read the data (DATAROW=)
- modify whether SAS extracts the variable names (GETNAMES=).

You can also use these same statements to change the default values.

When the IMPORT procedure reads a delimited file, it generates a DATA step to import the data. You control the results with options and statements that are specific to the input data source. The IMPORT procedure generates the specified output SAS data set and writes information about the import to the SAS log. The log displays the DATA step code that is generated by the IMPORT procedure.

If you need to revise your code after the procedure runs, issue the RECALL command (or press F4) to recall the generated DATA step. At this point, you can add or remove options from the INFILE statement and customize the INFORMAT, FORMAT, and INPUT statements to your data.

If you use this method and modify an informat, also modify the format for that same variable. The informat and format for a given variable also must be of the same type (either character or numeric). In addition, if the type is character, the assigned format should be as long as the variable to avoid truncation when the data is displayed. For example, if a character variable is 400 characters long but has a format of `$char50`, then only the first 50 characters are shown when the data is displayed.

To recall your PROC IMPORT code, issue a second RECALL command (or press F4 again).

Note: By default, the IMPORT procedure reads delimited files as varying record-length files. If your external file has a fixed-length format, use a SAS DATA step with an INFILE statement that includes the RECFM=F and LRECL= options. For more information, see the INFILE statement, RECFM= option in *SAS DATA Step Statements: Reference*.

The **Import Wizard** or the **External File Interface** (EFI) can also be used to import data. They can guide you through the steps to import an external data source. You can use the Import Wizard to generate IMPORT procedure statements, which you can save to a file for subsequent use.

To open the Import Wizard or EFI from the SAS windowing environment, select **File** ⇨ **Import Data**. For more information about the Import Wizard or EFI, see the Base SAS online Help and documentation. For more detail and an example, see "Using SAS Import and Export Wizards" in *SAS/ACCESS Interface to PC Files: Reference*.

Note: EFI does not recognize non-ASCII characters when SAS Registry contains "UseDateStyle"="Yes".

CAUTION
Sequential access is not allowed when you use EFI.

TIP **Sharing Delimited Files Across Hosts:** When a delimited file is read into SAS using the IMPORT procedure, each row must end with a host-specific, end-of-line delimiter. If you share delimited files that were created on one host with another host, the default end-of-line delimiters will not match. When this occurs, you must specify the new host's end-of-line delimiter for your files.

- Microsoft Windows: The default newline delimiter is Carriage Return/Linefeed (CRLF). To read a file that is native to UNIX or Linux, use a FILENAME statement with the TERMSTR=LF option. For more information, see the FILENAME statement in*SAS DATA Step Statements: Reference*.
- UNIX or Linux: The default end-of-row delimiter is Linefeed (LF). To read a file that is native to Windows, use a FILENAME statement with the TERMSTR=CRLF option. For more information, see the FILENAME statement in *SAS DATA Step Statements: Reference*.

Beginning with SAS 9.4M3, PROC IMPORT uses the NLNUM informat instead of the COMMA informat. When you import a file that contains values such as 14,000.01 that have commas, the COMMA informat removes the commas and other non-numeric characters from the numerical values. Removing these characters can cause interpretation errors in the values. NLNUM prevents these errors by using the specified value of the LOCALE system option to interpret numerical values that have commas.

For example, to enter the numerical equivalent of fourteen thousand and one hundredth, a person specifying LOCALE=English_UnitedStates would enter 14,000.01. A person specifying LOCALE=French_France would enter 14.000,01. NLNUM interprets either input value correctly and writes the correct value based on the specified locale. If you read in 14.000,01 with NLNUM and LOCALE=French_France, store it in a data set, and then write it with NLNUM and LOCALE=English_UnitedStates, it is displayed as 14,000.01.

If you want to import a character value such as AAFFGG_ 06JAN2016:10:04:26 into a SAS data set, SAS might try to read it as a date. You can use the Registry Editor window to ensure that SAS imports such values as character values.

1 Type REGEDIT in the SAS command line to open the Registry Editor.

2 Click on **Products** ⇨ **Base** ⇨ **EFI**.

3 Change the value of AllChars to Yes.

For more information, see:

- "COMMAw.d" in *SAS Formats and Informats: Reference*
- "NLNUMw.d Informat" in *SAS National Language Support (NLS): Reference Guide*
- "Overview of Locale Concepts for NLS" in *SAS National Language Support (NLS): Reference Guide*

Format Catalog Encodings in SAS Viya

SAS Viya supports only the UTF-8 encoding.

For more information about the encodings of format catalogs, see *Migrating Data to UTF-8 for SAS Viya* and *SAS Viya FAQ for Processing UTF-8 Data*.

TIP

- Use the XLSX engine to read UTF−8 data. For more information, see "LIBNAME Statement: XLSX Engine" in *SAS/ACCESS Interface to PC Files: Reference*.
- Do not use the `DBMS=xls` option to import spreadsheets that contain UTF-8 data.
- Use Microsoft Excel to convert your .xls spreadsheets to .xlsx spreadsheets before you import them with the `DBMS=xlsx` option.

Support for the VARCHAR Data Type

PROC IMPORT supports the VARCHAR data type in CAS. VARCHAR stores a character variable that can have a varying length. The length that you specify for the variable represents the maximum number of characters that you want to store.

The VARCHAR data type is similar to the CHAR data type. CHAR variables have a length that is measured in terms of bytes. VARCHAR variables have a length that is measured in terms of characters rather than bytes. For information about using

VARCHAR, see “Data Types Supported in the CAS DATA Step” in *SAS Cloud Analytic Services: User’s Guide*.

In the following example, the CAS engine is used with the LENGTH statement to create a VARCHAR variable and a CHAR variable. The VARCHAR variable, X, has a length of 30 and the CHAR variable, Y, also has a length of 30.

```
libname mycas cas;
data mycas.string;
   length x varchar(30);
   length y $30;
   x = 'abc'; y = 'def';
run;
proc contents data=mycas.string; run;
```

Here is the output that the code produces.

The CONTENTS Procedure

Data Set Name	MYCAS.STRING	Observations	1
Member Type	DATA	Variables	2
Engine	CAS	Indexes	0
Created	09/11/2016 13:48:30	Observation Length	48
Last Modified	09/11/2016 13:48:30	Deleted Observations	0
Protection		Compressed	NO
Data Set Type		Sorted	NO
Label			
Data Representation	SOLARIS_X86_64, LINUX_X86_64, ALPHA_TRU64, LINUX_IA64		
Encoding	utf-8 Unicode (UTF-8)		

Engine/Host Dependent Information	
Data Limit	100MB

Alphabetic List of Variables and Attributes

#	Variable	Type	Len
1	x	Varchar	30
2	y	Char	30

External File Interface (EFI) Macro Variables

External File Interface (EFI) macro variables can be used to control how PROC IMPORT reads and interprets character values.

EFI_ALLCHARS=YES | NO

Default NO

Notes The value of EFI_ALLCHARS applies to all PROC IMPORT steps that follow.

The AllChars SAS Registry option has the same effect as the EFI_ALLCHARS macro variable.

Example %let EFI_ALLCHARS=YES;

specifies whether all columns default to a CHAR data type to avoid misinterpretation of a SAS datetime. Beginning in SAS 9.4TS1M4, you can specify the EFI macro variable, EFI_ALLCHARS, which causes PROC IMPORT to define all of the variables as character. Here is an example of how to use EFI_ALLCHARS with PROC IMPORT:

```
%let EFI_ALLCHARS=YES;
proc import datafile='c:\temp\class.csv' out=class dbms=csv replace;
run;
%let EFI_ALLCHARS=NO;
```

Reset the value of EFI_ALLCHARS after the PROC IMPORT step. Otherwise, all PROC IMPORT steps that follow EFI_ALLCHARS=YES define all variables as character.

EFI_MISSING_NUMERICS=YES | NO

Default NO

Note The MissingNumerics SAS Registry option has the same effect as the EFI_MISSING_NUMERICS macro variable.

Example %let EFI_MISSING_NUMERICS=YES;

specifies whether a single period is numeric or character. When MissingNumerics is set to No, the single period is interpreted as a character.

EFI_NOQUOTED_DELIMITER=YES | NO

Default NO

Note The QuotedDelimiter SAS Registry option has the same effect as the EFI_NOQUOTED_DELIMITER macro variable.

Example %let EFI_NOQUOTED_DELIMITER=YES;

specifies whether single quotation marks within a variable value are read as delimiters inside open quotation marks or as part of the variable value. If your variables contain delimiters, or to read in a single quotation mark as part of the variable value, set EFI_NOQUOTED_DELIMITER to Yes.

EFI_QUOTED_NUMERICS=YES | NO

Default NO

Note The QuotedNumerics SAS Registry option has the same effect as the EFI_QUOTED_NUMERICS macro variable.

Example %let EFI_QUOTED_NUMERICS=YES;

specifies whether to read numbers that are enclosed in quotation marks as character or numeric values. When PROC IMPORT reads an external file, values that are enclosed in quotation marks are automatically created as character values. Setting EFI_QUOTED_NUMERICS to Yes enables you to read quoted numbers as numeric. For example, "10MAY14" is a character value, but with

EFI_QUOTED_NUMERICS set to Yes, it becomes 10MAY14, which is a date value.

Syntax: IMPORT Procedure

Restrictions: The IMPORT procedure is available for the following operating environments:

- Microsoft Windows
- UNIX or Linux

A pathname for a file can have a maximum length of 201 characters.

Interaction: All data with the percent sign (%) is considered character data to avoid misinterpretation. Percentage data is considered character data because of the danger of misinterpretation.

Supports: PROC IMPORT supports the CSV, TAB, DLM, and JMP file types in CAS.

Note: You can use PROC IMPORT to import an external file to a SAS data set or to a CAS table.

Tips: Beginning with SAS 9.4M5, PROC IMPORT supports the VARCHAR data type for CAS tables. For more information, see "Support for the VARCHAR Data Type" on page 1326.

Use the XLSX engine to read UTF–8 data. For more information, see "LIBNAME Statement: XLSX Engine" in *SAS/ACCESS Interface to PC Files: Reference*.

Do not use the `DBMS=xls` option to import spreadsheets that contain UTF-8 data.

Use Microsoft Excel to convert your .xls spreadsheets to .xlsx spreadsheets before you import them with `DBMS=xlsx`.

See: "ANYDTDTMw." in *SAS Formats and Informats: Reference*

PROC IMPORT

DATAFILE="*filename*" | TABLE="*tablename*"

statements for importing from JMP files

DBENCODING=*12-char SAS encoding-value*;

FMTLIB=<*libref*.>*format-catalog*;

META=*libref.member-data-set*;

Statement	Task	Example
PROC IMPORT	Import an external data file to a SAS data set	Ex. 1, Ex. 2, Ex. 3, Ex. 4
DATAROW	Start reading data from a specific row in the delimited text file	Ex. 3
DBENCODING	Indicate the encoding character set to use for the JMP file	
DELIMITER	Specify the delimiter that separates columns of data in the input file	Ex. 1, Ex. 3, Ex. 4
FMTLIB	Save value labels to the specified SAS format catalog	
GETNAMES	Generate SAS variable names from the data values in the first row in the input file	Ex. 1, Ex. 2
GUESSINGROWS	Specify the number of rows of the input file to scan to determine the appropriate data type and length for the variables	
META	Save JMP metadata information to the specified SAS data set	

PROC IMPORT Statement

Imports an external data file to a SAS data set.

Restriction: A pathname for a file can have a maximum length of 201 characters.

Tips: Beginning with SAS Viya 3.5, PROC IMPORT supports all access types that are available in the FILENAME statement.

Beginning with SAS 9.4M5, PROC IMPORT supports the VARCHAR data type for CAS tables. For more information, see "Support for the VARCHAR Data Type" on page 1326.

Use the XLSX engine to read UTF–8 data. For more information, see "LIBNAME Statement: XLSX Engine" in *SAS/ACCESS Interface to PC Files: Reference*.

Do not use the `DBMS=xls` option to import spreadsheets that contain UTF-8 data.

Use Microsoft Excel to convert your .xls spreadsheets to .xlsx spreadsheets before you import them with `DBMS=xlsx`.

Syntax

PROC IMPORT

DATAFILE="*filename* " | TABLE="*tablename* "

OUT=<*libref .>SAS data set* <(*SAS data set options*)>
<DBMS=*identifier*> <REPLACE>;

Summary of Optional Arguments

DBMS=*identifier*
: specifies the type of data to import.

REPLACE
: overwrites an existing SAS data set.

SAS data set options
: specifies SAS data set options.

Required Arguments

DATAFILE="*filename*" | "*fileref*"
specifies the complete path and filename or fileref for the input PC file, spreadsheet, or delimited external file. A fileref is a SAS name that is associated with the physical location of the output file. To assign a fileref, use the FILENAME statement. For more information about the FILENAME statement, see *SAS Global Statements: Reference*. For more information about PC file formats, see *SAS/ACCESS Interface to PC Files: Reference*

If you specify a fileref or if the complete path and filename does not include special characters such as the backslash in a path, lowercase characters, or spaces, then you can omit the quotation marks.

Alias
: FILE=

Restrictions
: The IMPORT procedure does not support device types or access methods for the FILENAME statement except for DISK. For example, the IMPORT procedure does not support the TEMP device type, which creates a temporary external file.

  The IMPORT procedure can import data only if SAS supports the data type. SAS supports numeric and character types of data but not (for example) binary objects. If the data that you want to import is a type that SAS does not support, the IMPORT procedure might not be able to import it correctly. In many cases, the procedure attempts to convert the data to the best of its ability. However, conversion is not possible for some types.

Interactions
: By default, the IMPORT procedure reads delimited files as varying record-length files. If your external file has a fixed-length format, use a SAS DATA step with an INFILE statement that includes the RECFM=F and LRECL= options. For more information, see the INFILE statement.

  When you use a *fileref* to specify a delimited file to import, the logical record length (LRECL) defaults to 256, unless you specify

the LRECL= option in the FILENAME statement. The maximum LRECL that the IMPORT procedure supports is 32767.

For delimited files, the first 20 rows are scanned to determine the variable attributes. You can increase the number of rows that are scanned by using the GUESSINGROWS= statement. All values are read in as character strings. If a Date and Time format or a numeric informat can be applied to the data value, the type is declared as numeric. Otherwise, the type remains character.

Examples "Example 1: Importing a Delimited File" on page 1339

"Example 2: Importing a Specific Delimited File Using a Fileref" on page 1342

"Example 3: Importing a Tab-Delimited File" on page 1345

"Example 4: Importing a Comma-Delimited File with a CSV Extension" on page 1349

OUT=<*libref.*>*SAS data set*

identifies the output SAS data set with either a one or two-level SAS name (library and member name). If the specified SAS data set does not exist, the IMPORT procedure creates it. If you specify a one-level name, by default the IMPORT procedure uses either the USER library (if assigned) or the WORK library (if USER is not assigned).

In the first maintenance release of SAS 9.4, a SAS data set name can contain a single quotation mark when the VALIDMEMNAME=EXTEND system option is also specified. Using VALIDMEMNAME= expands the rules for the names of certain SAS members, such as a SAS data set name. For more information, see "Rules for SAS Data Set Names, View Names, and Item Store Names" in *SAS Language Reference: Concepts*.

Examples "Example 1: Importing a Delimited File" on page 1339

"Example 2: Importing a Specific Delimited File Using a Fileref" on page 1342

"Example 3: Importing a Tab-Delimited File" on page 1345

"Example 4: Importing a Comma-Delimited File with a CSV Extension" on page 1349

TABLE="*tablename*"

specifies the name of the input DBMS table. If the name does not include special characters (such as question marks), lowercase characters, or spaces, you can omit the quotation marks. Note that the DBMS table name might be case sensitive.

Requirements You must have a license for SAS/ACCESS Interface to PC Files to import from a DBMS table.

When you import a DBMS table, you must specify the DBMS= option.

Optional Arguments

DBMS=*identifier*

specifies the type of data to import. You can import delimited files or JMP files (DBMS=JMP) in Base SAS. The JMP file format must be Version 7 or later, and JMP variable names can be up to 255 characters long. SAS supports importing JMP files that have more than 32,767 variables.

To import a tab-delimited file, specify TAB as the identifier. To import any other delimited file that does not end in .CSV, specify DLM as the identifier. For a comma-separated file with a .CSV extension, DBMS= is optional. The IMPORT procedure recognizes .CSV as an extension for a comma-separated file.

The DBMS argument is required if you are importing a file that does not have an extension, and the data is delimited by tabs. It is also required if you are importing a TXT file that has data that is delimited with a comma.

The following values are valid for the DBMS identifier.

Table 36.1 *DBMS Identifiers Supported in Base SAS*

Identifier	Output Data Source	Extension
CSV	Delimited file (comma-separated values)	.csv
DLM	Delimited file (default delimiter is a blank)	.dat or .txt
JMP	JMP files, Version 7 or later format	.jmp
TAB	Delimited file (tab-delimited values)	.txt

See Table 23.66 on page 855 for more information about identifiers for this option.

"LIBNAME Statement: Options for Excel and Access Engines" in *SAS/ACCESS Interface to PC Files: Reference* for a list of additional DBMS values when using SAS/ACCESS Interface to PC Files.

"DELIMITER Statement" on page 1335

Examples "Example 1: Importing a Delimited File" on page 1339

"Example 2: Importing a Specific Delimited File Using a Fileref" on page 1342

"Example 3: Importing a Tab-Delimited File" on page 1345

"Example 4: Importing a Comma-Delimited File with a CSV Extension" on page 1349

REPLACE

overwrites an existing SAS data set. If you omit REPLACE, the IMPORT procedure does not overwrite an existing data set.

CAUTION

Using the IMPORT procedure with the REPLACE option to write to an existing SAS generation data set causes the most recent (base) generation data set or group of generation data sets to be deleted.

If you write to an existing generation data set using the IMPORT procedure with the REPLACE option and you do one of the following:

- specify the GENMAX= data set option to increase or decrease the number of generations, then all existing generations are deleted and replaced with a single new base generation data set
- omit the GENMAX= data set option, then all existing generations are deleted and replaced with a single new data set by the same name, but it is not a generation data set

Instead, use a SAS DATA step with the REPLACE= data set option to replace a permanent SAS data set and to maintain the generation group for that SAS data set. For more information, see "Understanding Generation Data Sets" in *SAS Language Reference: Concepts*.

Examples "Example 1: Importing a Delimited File" on page 1339

"Example 2: Importing a Specific Delimited File Using a Fileref" on page 1342

"Example 3: Importing a Tab-Delimited File" on page 1345

"Example 4: Importing a Comma-Delimited File with a CSV Extension" on page 1349

SAS data set options

specifies SAS data set options. For example, to assign a password to the resulting SAS data set, you can use the ALTER=, PW=, READ=, or WRITE= data set option. To import only data that meets a specified condition, you can use the WHERE= data set option.

Restriction You cannot specify data set options when importing delimited, comma-separated, or tab-delimited external files.

See *SAS Data Set Options: Reference*

DATAROW Statement

Starts reading data from the specified row number in the delimited text file.

Default: When GETNAMES=NO: 1, when GETNAMES=YES: 2

Restriction: When GETNAMES=NO, DATAROW must be equal to or greater than 1. When GETNAMES=YES, DATAROW must be equal to or greater than 2.

Interaction: The DATAROW statement is valid only for delimited and XLSX files.

See: "GETNAMES Statement" on page 1337

Example: "Example 3: Importing a Tab-Delimited File" on page 1345

Syntax

DATAROW=*n*;

Required Argument

n
specifies the row number in the input file for the IMPORT procedure to start reading data.

DBENCODING Statement

Indicates the encoding character set to use for the JMP file.

Interaction: The DBENCODING statement is valid only when DBMS=JMP.

Syntax

DBENCODING=*12-char SAS encoding-value*;

Required Argument

12-char SAS encoding-value
indicates the encoding to use with JMP files. Encoding maps each character in a character set to a unique numeric representation, which results in a table of code points. A single character can have different numeric representations in different encodings. This value can be up to 12 characters long.

DELIMITER Statement

Specifies the delimiter that separates columns of data in the input file.

Defaults: Comma for .CSV files
Blank space for all other file types

Interaction: If you specify DBMS=DLM, you must also specify the DELIMITER= statement.

See: Table 36.77 on page 1333 for a list of DBMS identifiers supported in Base SAS.
"DBMS=*identifier*" on page 1333

Example: "Example 1: Importing a Delimited File" on page 1339

Syntax

DELIMITER=*char'' | 'nnx*;

Required Argument

***char* | *'nn'*x**

specifies the delimiter that separates columns of data in the input file. You can specify the delimiter as a single character or as a hexadecimal value. For example, if columns of data are separated by an ampersand, specify DELIMITER='&'.

Note: If you omit DELIMITER=, the IMPORT procedure assumes that the delimiter is a space.

The DELIMITER statement is required when you import a file that meets any of these criteria:

- a file that does not have a file extension
- a file that has a .TXT extension and contains data that is delimited by anything other than tabs
- a file that has a .TXT, .CSV, or .JMP extension and contains data that is delimited by blank spaces

This example shows how to use the DBMS argument and the DELIMITER statement to specify a comma delimiter for a file that has a .TXT extension.

```
proc import datafile="C:\temp\test.txt"
   out=test
   dbms=dlm
   replace;
   delimiter=',';
run;
```

FMTLIB Statement

Saves value labels to the specified SAS format catalog.

Interaction: The FMTLIB statement is valid only when DBMS=JMP.

Syntax

FMTLIB=<*libref.>format-catalog*;

Required Argument

<libref.>format-catalog
specifies the format catalog where the value labels are saved.

GETNAMES Statement

Specifies whether the IMPORT procedure generates SAS variable names from the data values in the first row in the input file.

Default: YES

Restrictions: Valid only with the IMPORT procedure.

If VALIDVARNAME=ANY is used, GETNAMES= might not prefix an underscore to the data value.

Interaction: The GETNAMES statement is valid only for delimited files.

Examples: "Example 1: Importing a Delimited File" on page 1339
"Example 2: Importing a Specific Delimited File Using a Fileref" on page 1342
"Example 4: Importing a Comma-Delimited File with a CSV Extension" on page 1349

Syntax

GETNAMES=YES | NO;

Required Argument

YES | NO

YES specifies that the IMPORT procedure generate SAS variable names from the data values in the first row of the imported delimited file.

NO specifies that the IMPORT procedure generate SAS variable names as VAR1, VAR2, and so on.

Note: If a data value in the first row in the input file is read and it contains special characters that are not valid in a SAS name, such as a blank, then SAS converts the character to an underscore. For example, the variable name `Occupancy Code` would become the SAS variable name `Occupancy_Code`. Because SAS variable names cannot begin with a number, GETNAMES= prefixes an underscore to a variable name rather than replace the value's first character. For example, `2014.CHANGES` becomes `_2014_CHANGES`.

GUESSINGROWS Statement

Specifies the number of rows of the file to scan to determine the appropriate data type and length for the variables.

Default: 20

Restriction: This value should be greater than the value specified for DATAROW.

Interaction: The GUESSINGROWS statement is valid only for delimited files.

Syntax

GUESSINGROWS=*n* | MAX;

Required Arguments

n
indicates the number of rows the IMPORT procedure scans in the input file to determine the appropriate data type and length of variables. The range is 1 to 2147483647 (or MAX). The scan data process scans from row 1 to the number that is specified by the GUESSINGROWS option.

Note: You can change the default row value in the SAS Registry. From the SAS command line, enter `regedit`. When the **Registry Editor** opens, select **Products** ⇨ **BASE** ⇨ **EFI** ⇨ **GuessingRows**.

MAX
can be specified instead of 2147483647. Specifying the maximum value could adversely affect performance.

META Statement

Saves JMP metadata information to the specified SAS data set. (Deprecated)

Interaction: The META statement is valid only when DBMS=JMP.

Syntax

META=*libref.member-data-set*;

Required Argument

libref.member-data-set
specifies the SAS data set that contains the metadata information is to be written.

The META statement is no longer supported for importing a JMP file and is ignored. Instead, extended attributes are automatically used. When importing a JMP file with extended attributes, the attributes are automatically attached to the new SAS data set.

The META statement can remain in programs, yet it generates a NOTE in the log saying that META has been replaced by extended attributes and is ignored.

Examples: IMPORT Procedure

Example 1: Importing a Delimited File

Features:

PROC IMPORT statement options
- DATAFILE=
- DBMS=
- GETNAMES=
- OUT=
- REPLACE

DELIMITER= statement

OPTIONS statement

PRINT procedure

Details

This example imports the following delimited external file and creates a temporary SAS data set named WORK.MYDATA:

```
Region&State&Month&Expenses&Revenue
Southern&GA&JAN2001&2000&8000
Southern&GA&FEB2001&1200&6000
Southern&FL&FEB2001&8500&11000
Northern&NY&FEB2001&3000&4000
Northern&NY&MAR2001&6000&5000
Southern&FL&MAR2001&9800&13500
```

```
Northern&MA&MAR2001&1500&1000
;
```

Program

```
options nodate ps=60 ls=80;

proc import datafile="C:\My Documents\myfiles\delimiter.txt"
            dbms=dlm
            out=mydata
            replace;

     delimiter='&';

     getnames=yes;

run;

proc print data=mydata;
run;
```

Program Description

Set your system options. The NODATE option suppresses the display of the date and time in the output. The LINESIZE= option specifies the output line length, and the PAGESIZE= option specifies the number of lines on an output page.

```
options nodate ps=60 ls=80;
```

Specify the input file. Specify that the input file is a delimited file. Replace the data set if it exists. Identify the output SAS data set.

```
proc import datafile="C:\My Documents\myfiles\delimiter.txt"
            dbms=dlm
            out=mydata
            replace;
```

Specify delimiter as an & (ampersand).

```
     delimiter='&';
```

Generate variable names from first row of data.

```
     getnames=yes;

run;
```

Print out the output data set.

```
proc print data=mydata;
run;
```

Log

The SAS log displays information about the successful import. For this example, the IMPORT procedure generates a SAS DATA step, as shown in the partial log that follows.

Example Code 36.1 *External File Imported to Create a SAS Data Set*

```
1    options nodate ps=60 ls=80; proc import datafile="C:\My
1  ! Documents\myfiles\delimiter.txt" dbms=dlm out=mydata replace; delimiter='&'
1  !  delimiter='&'; getnames=yes;run;
