Example 2: Importing a Specific Delimited File Using a Fileref

Features:

PROC IMPORT statement options
- DATAFILE=
- DBMS=
- GETNAMES=
- OUT=
- REPLACE

FILENAME statement

PRINT procedure

Details

This example imports the following space-delimited file and creates a temporary SAS data set named Work.States.

```
Region State Capital Bird
South Georgia Atlanta 'Brown Thrasher'
South 'North Carolina' Raleigh Cardinal
North Connecticut Hartford Robin
West Washington Olympia 'American Goldfinch'
Midwest Illinois Springfield Cardinal
```

Program

```
filename stdata 'c:\temp\state_data.txt' lrecl=100;

proc import datafile=stdata
        dbms=dlm
        out=states
        replace;
     delimiter=' ';
     getnames=yes;
run;

proc print data=states;
run;
```

Program Description

Specify a filename.

```
filename stdata 'c:\temp\state_data.txt' lrecl=100;
```

Specify the input file. Specify the input file is a delimited file. Replace the data set if it exists. Identify the output SAS data set.

```
proc import datafile=stdata
        dbms=dlm
        out=states
        replace;
```

Specify a blank value for the DELIMITER statement. Generate variable names from the first row of data with the GETNAMES statement.

```
     delimiter=' ';
     getnames=yes;
run;
```

Print out the data set.

```
proc print data=states;
run;
```

Log

The SAS log displays information about the successful import. For this example, the IMPORT procedure generates a SAS DATA step, as shown in the partial log that follows.

Example Code 36.2 *Importing a Specific Delimited File Using a Fileref*

```
324  filename stdata 'c:\myfiles\state_data.txt' lrecl=100;
325
326  proc import datafile=stdata
327              dbms=dlm
328              out=states
329              replace;
330       delimiter=' ';
331       getnames=yes;
332
333  run;

334   /*********************************************************************

      Create Time=15Apr2014:11:25:38

NOTE: 5 records were read from the infile STDATA.
      The minimum record length was 32.
      The maximum record length was 44.
NOTE: The data set WORK.STATES has 5 observations and 4 variables.
NOTE: DATA statement used (Total process time):
      real time           0.03 seconds
      cpu time            0.03 seconds

5 rows created in WORK.STATES from STDATA.

NOTE: WORK.STATES data set was successfully created.
```

Output

Output 36.2 *Work.States Data Set*

The SAS System

Obs	Region	State	Capital	Bird
1	South	Georgia	Atlanta	Brown Thrasher
2	South	North Carolina	Raleigh	Cardinal
3	North	Connecticut	Hartford	Robin
4	West	Washington	Olympia	American Goldfinch
5	Midwest	Illinois	Springfield	Cardinal

Example 3: Importing a Tab-Delimited File

Features:

PROC IMPORT statement options
- DATAFILE=
- DATAROW=
- DBMS=
- OUT=
- REPLACE

DELIMITER= statement

PRINT procedure

Details

This example imports the following tab-delimited file and creates a temporary SAS data set named Work.Class.

Input Data 36.1 *Input*

```
Name     Gender   Age
Joyce    F        11
Thomas   M        11
Jane     F        12
Louise   F        12
James    M        12
John     M        12
Robert   M        12
Alice    F        13
```

```
Barbara  F        13
Jeffery  M        13
Carol    F        14
Judy     F        14
Alfred   M        14
Henry    M        14
Jenet    F        15
Mary     F        15
Ronald   M        15
William  M        15
Philip   M        16
```

Program

```
proc import datafile='C:\userid\pathname\Class.txt'
            out=class
            dbms=dlm
            replace;

       datarow=5;

     delimiter='09'x;
run;

proc print data=class;
run;
```

Program Description

Specify the input file. The GETNAMES= option defaults to 'yes'. Specify the input file as a delimited file. Replace the data set if it exists. Specify the output data set.

```
proc import datafile='C:\userid\pathname\Class.txt'
            out=class
            dbms=dlm
            replace;
```

The first row read will be row 5 due to the DATAROW= option specification.

```
       datarow=5;
```

Specify the delimiter. On an ASCII platform, the hexadecimal representation of a tab is `'09'x`. On an EBCDIC platform, the hexadecimal representation of a tab is a `'05'x`.

```
     delimiter='09'x;
run;
```

Print out the output data set.

```
proc print data=class;
run;
```

Log

The SAS log displays information about the successful import. For this example, the IMPORT procedure generates a SAS DATA step, as shown in the partial log that follows.

Example Code 36.3 *Importing a Tab-Delimited File*

```
1    proc import datafile='C:\userid\pathname\Class.txt'
2                out=class

Example 4: Importing a Comma-Delimited File with a CSV Extension

Features:

PROC IMPORT statement options
- DATAFILE=
- DBMS=
- GETNAMES=
- OUT=
- REPLACE

PRINT procedure

Details

This example imports the following comma-delimited file and creates a temporary SAS data set named Work.Shoes.

Note: In SAS, the default delimiter for a CSV file is a comma.

```
"Africa","Boot","Addis Ababa","12","$29,761","$191,821","$769"
"Asia","Boot","Bangkok","1","$1,996","$9,576","$80"
"Canada","Boot","Calgary","8","$17,720","$63,280","$472"
"Central America/Caribbean","Boot","Kingston","33","$102,372","$393,376","$4,454"
"Eastern Europe","Boot","Budapest","22","$74,102","$317,515","$3,341"
"Middle East","Boot","Al-Khobar","10","$15,062","$44,658","$765"
"Pacific","Boot","Auckland","12","$20,141","$97,919","$962"
"South America","Boot","Bogota","19","$15,312","$35,805","$1,229"
"United States","Boot","Chicago","16","$82,483","$305,061","$3,735"
"Western Europe","Boot","Copenhagen","2","$1,663","$4,657","$129"
```

Program

```
proc import datafile="C:\temp\test.csv"
        out=shoes
        dbms=csv
        replace;

     getnames=no;
run;

proc print data=work.shoes;
run;
```

Program Description

Specify the input data file. Replace the data set if it exists. Specify the output data set.

```
proc import datafile="C:\temp\test.csv"
        out=shoes
        dbms=csv
        replace;
```

Setting the GETNAMES= option to 'no' causes the variable names in record 1 are not used.

```
     getnames=no;
run;
```

Print the data set.

```
proc print data=work.shoes;
run;
```

Log

The SAS log displays information about the successful import. For this example, the IMPORT procedure generates a SAS DATA step, as shown in the partial log that follows.

Example Code 36.4 *Importing a Comma-Delimited File*

```
457  proc import datafile="C:\myfiles\test.csv"

JAVAINFO Procedure

Overview: JAVAINFO Procedure

What Does the JAVAINFO Procedure Do?

The JAVAINFO procedure conveys diagnostic information to the user about the Java environment that SAS is using. The diagnostic information can be used to confirm that the SAS Java environment has been configured correctly, and can be helpful when reporting problems to SAS technical support. Also, PROC JAVAINFO is often used to verify that the SAS Java environment is working correctly because PROC JAVAINFO uses Java to report its diagnostics.

Syntax: JAVAINFO Procedure

PROC JAVAINFO <*options*>;

Statement	Task
PROC JAVAINFO	Display diagnostic information about the SAS Java environment

PROC JAVAINFO Statement

Displays diagnostic information about the SAS Java environment.

Interaction: When a SAS server is in a locked-down state, the JAVAINFO procedure does not execute. For more information, see "SAS Processing Restrictions for Servers in a Locked-Down State" in *SAS Language Reference: Concepts*.

Syntax

PROC JAVAINFO <*options*>;

Optional Arguments

ALL
lists current information about the SAS Java environment.

CLASSPATHS
lists information about the classpaths that Java is using.

HELP
provides usage assistance in using the JAVAINFO procedure.

JREOPTIONS
lists the Java properties that are set when the JREOPTIONS configuration option is specified.

- When used in PROC JAVAINFO, JREOPTIONS specifies the JREOPTIONS Java properties that are set when Java is started.
- When used in PROC OPTIONS, JREOPTIONS specifies the Java options that are in the configuration file when SAS is started.

Note: SAS.cfg is the configuration file specified during installation, but other configuration files can be specified.

OS
lists information about the operating system that SAS is running under.

version
lists the Java Runtime Environment (JRE) that SAS is using.

38

JSON Procedure

Overview: JSON Procedure

What Does the JSON Procedure Do?

The JSON procedure reads data from a SAS data set and writes it to an external file in JSON[1] representation. You can control the exported data with several options that remove content and affect the format. In addition to exporting data from a SAS data set, PROC JSON provides statements that enable you to write additional data to the external file and control JSON containers.

SAS provides the JSON engine to read a JSON file. For more information, see "LIBNAME Statement: JSON Engine" in *SAS Global Statements: Reference*.

Concepts: JSON Procedure

JSON Output File Containers

Structure of the JSON Output File

The JSON output file consists of a minimum of one container, which is referred to as the top-level container. All of the data, metadata, and additional containers are within the top-level container. The type of top-level container is determined by the statement that immediately follows the PROC JSON statement and the options that are enabled in that statement.

1. Java Script Object Notation (JSON) is a text-based, open standard data format that is designed for human-readable data interchange. JSON is based on a subset of the JavaScript programming language and uses JavaScript syntax for describing data objects.

JSON Containers

JSON output consists of two types of data structure containers:

JSON object container ({ })
: begins with a left brace ({) and ends with a right brace (}). An object container collects key-value pairs that are written as pairs of names and values. A value can be any of the supported JSON data types, an object, or an array. Each name is followed a colon and then the value. The key-value pairs are separated by a comma.

JSON array container ([ ])
: begins with a left bracket ([) and ends with a right bracket (]). An array container collects a list of values that are written as a list of values without names. A value can be any of the supported JSON data types, an object, or an array. Values are separated by a comma.

Creating Object Containers

The following statements create object containers:

- The EXPORT statement with default options enabled implicitly opens an object container as the top-level container. This object container is implicitly opened and automatically closed.

```
proc json out="example.json";
   export sashelp.class (where=(age=11));
...
```

- The WRITE VALUES statement opens an object container as the top-level container when it is the first statement after the PROC JSON statement. This object container is implicitly opened and automatically closed.

```
proc json out="example.json";
   write values "container" "object";
   write values "created" "implicitly";
...
```

- The WRITE OPEN OBJECT statement explicitly opens an object container, which you must explicitly close with the WRITE CLOSE statement.

```
proc json out="example.json"
   write open object;
   write values "container" "object";
   write values "created" "explicitly";
   write close;
...
```

Creating Array Containers

The following statements create array containers:

- The EXPORT statement with the NOSASTAGS option enabled opens an array container as the top-level container when it is the first statement after the PROC JSON statement. This top-level array container is implicitly opened and automatically closed.

```
proc json out="example.json";
   export sashelp.class (where=(age=11)) / nosastags;
...
```

- The WRITE OPEN ARRAY statement explicitly opens an array container, which you must explicitly close with the WRITE CLOSE statement.

```
proc json out="example.json";
   write open array;
   write values "container" "array";
   write values "created" "explictly";
   write close;
...
```

Nesting Containers

The top-level container can include any number of containers. Containers, likewise, can nest containers to an arbitrary depth. When nesting containers, be careful to observe the data structure requirements of the current container.

- Objects require a list of key-value pairs, where the value can itself be an object or array.
- Arrays have no such structural requirement of key-value pairs and are merely a list of values, objects, or arrays.
- The WRITE VALUES statement or statements for an object container must result in an even number of values, and the name portion of the key-value pair must be a string.

In this example, an array is nested within an implicitly opened object:

```
proc json out="example.json";
   write values "level" 1;              /* implicit open of object         */
   write values "container" "object";   /* write data to object            */
   write values "created" "implicitly"; /* write data to object            */
   write values "nest";                 /* required string to start object */
   write open array;                    /* explicit open of array          */
   write values "level" 2;              /* write data to array             */
   write values "container" "array";    /* write data to array             */
   write values "created" "explicitly"; /* write data to array             */
   write close;                         /* close explicit open             */
```

```
run;
```

```
{"level":1,"container":"object","created":"implicitly","nest":["level",2,
"container","array","created","explicitly"]}
```

In this example, the exported data is nested within three array containers.

```
proc json out="example.json";
   write open array;                                /* explicit open of array */
   write values "level" 1;                          /* write data to array    */
   write values "container" "array";                /* write data to array    */
   write values "created" "explicitly";             /* write data to array    */
   write open array;                                /* explicit open of array */
   write values "level" 2;                          /* write data to array    */
   write values "container" "array";                /* write data to array    */
   write values "created" "explicitly";             /* write data to array    */
   export sashelp.class (where=(age=11))/nokeys;    /* export SAS data  */
   write close;                                     /* close explicit open    */
   write close;                                     /* close explicit open    */
run;
```

```
["level",1,"container","array","created","explicitly",["level",2,"container",
"array","created","explicitly","SASJSONExport","1.0 NOKEYS",
"SASTableData+CLASS",[["Joyce","F",11,51.3,50.5],["Thomas","M",11,57.5,85]]]]
```

Missing Values

A missing value in SAS is a type of value for a variable that contains no data for a particular observation or variable. By default, SAS represents a missing numeric value as a single period and a missing character value as a blank space.

JSON also has the concept of missing values referred to as a null value, which is a special value that indicates the absence of information.

PROC JSON writes a JSON null value to the JSON output file when the following is true:

- a SAS data set numeric variable contains a missing value
- the WRITE VALUES statement writes the NULL keyword as a value

By default, SAS writes an empty string ("") to the JSON output file when a SAS data set character variable contains a missing value. However, if you specify the NOTRIMBLANKS option, the entire string of blanks is written to the JSON output file.

Scanning Input Strings

A JSON string is a sequence of zero or more characters that are wrapped in double quotation marks. A JSON string can be any Unicode character except double quotation marks ("), backslash (\), or a control character. A JSON string can contain a backslash as an escape character, which invokes an alternative interpretation on subsequent characters in a character sequence. For example, to allow a JSON string to contain double quotation marks, the " can be escaped by preceding the character with a \.

By default, PROC JSON scans input strings to ensure that they contain only characters that are acceptable as JSON strings. Unacceptable characters in an input string are replaced with the proper escape sequence.

You can specify the NOSCAN option to indicate that the input string is known to contain acceptable characters or has already been scanned. NOSCAN is supported in the PROC JSON statement, the EXPORT statement, and the WRITE VALUES statement.

JSON Output File Encoding

By default, the resulting JSON output file uses the Unicode encoding UTF-8. To override the encoding of a JSON output file, you can use the ENCODING= option in the FILENAME statement. However, you can do so only in the following situations:

- If the current SAS session encoding is UTF-8, you can specify one of the following Unicode encoding forms. Only UTF-8 and the following encoding forms are JSON standards compliant. Other encoding forms might not be recognized by standards-compliant JSON parsers.

  Table 38.1 *Encodings That Are Valid in UTF-8 SAS Session*

Name	Description
utf-16be	Unicode (UTF-16BE)
utf-32be	Unicode (UTF-32BE)
utf-32le	Unicode (UTF-32LE)

- If the current SAS session encoding is not UTF-8, you can override the encoding of a JSON output file only if the current SAS session encoding is compatible with US-ASCII and all strings written to the JSON output file contain only low-range Latin1 characters (that is, code points 0-127).

For example, the following code exports a JSON output file that uses the Unicode UTF-16BE character set encoding. The current SAS session encoding is Wlatin1. The ENCODING= option in the FILENAME statement tells PROC JSON to transcode the data from Wlatin1 to the specified Unicode UTF-16BE form when writing to the external file.

```
filename jsonout "C:\JsonOutput.json" encoding="utf-16be";

proc json out=jsonout;
   export sashelp.class;
quit;
```

Syntax: JSON Procedure

PROC JSON OUT=*fileref* | *"external-file"* <*options*>;

EXPORT <*libref.*>*SAS-data-set* <(*SAS-data-set-options*)> </*options*>;

WRITE VALUES *value(s)* </*options*>;

WRITE OPEN *type*;

WRITE CLOSE;

Statement	Task	Example
PROC JSON	Exports a SAS data set to a JSON file.	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8
EXPORT	Identify the SAS data set to export and control the resulting output	Ex. 1, Ex. 2, Ex. 3, Ex. 5, Ex. 6, Ex. 7, Ex. 8
WRITE VALUES	Write one or more values to the output file	Ex. 4, Ex. 5, Ex. 6, Ex. 8
WRITE OPEN	Open and nest a JSON container in the output file	Ex. 4, Ex. 5, Ex. 6, Ex. 8
WRITE CLOSE	Close a JSON container that is open in the output file	Ex. 4, Ex. 5, Ex. 6, Ex. 8

PROC JSON Statement

Specifies the JSON output file and controls the resulting output.

Examples:

Syntax

PROC JSON OUT=*fileref* | "*external-file*" <*options*>;

Summary of Optional Arguments

FMTCHARACTER | NOFMTCHARACTER
: determines whether to apply a character SAS format to the resulting output if a character SAS format is associated with a SAS data set variable.

FMTDATETIME | NOFMTDATETIME
: determines whether to apply a date, time, or datetime SAS format to the resulting output if a date, time, or datetime SAS format is associated with a SAS data set variable.

FMTNUMERIC | NOFMTNUMERIC
: determines whether to apply a numeric SAS format to the resulting output if a numeric SAS format is associated with a SAS data set variable.

KEYS | NOKEYS
: determines whether exported observations are written as JSON objects or as JSON arrays.

PRETTY | NOPRETTY
: determines how to format the JSON output.

SASTAGS | NOSASTAGS
: determines whether to include or suppress SAS metadata when using the EXPORT statement.

SCAN | NOSCAN
: determines whether PROC JSON scans and encodes input strings to ensure that only characters that are acceptable are exported to the JSON output file.

TRIMBLANKS | NOTRIMBLANKS
: determines whether to remove or retain trailing blanks from the end of character data in the JSON output.

Required Argument

OUT=*fileref* | "*external-file*"
identifies the JSON output file.

fileref
specifies the SAS fileref that is assigned to the JSON output file. To assign a fileref, use the FILENAME statement.

"external-file"
is the physical location of the JSON output file. Include the complete pathname and the filename. Enclose the physical name in single or double quotation marks. The maximum length is 200 characters.

Optional Arguments

FMTCHARACTER | NOFMTCHARACTER
determines whether to apply a character SAS format to the resulting output if a character SAS format is associated with a SAS data set variable.

Alias FMTCHAR | NOFMTCHAR

Default NOFMTCHARACTER

Interaction You can specify FMTCHARACTER | NOFMTCHARACTER in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

Note User-defined formats are also supported.

FMTDATETIME | NOFMTDATETIME
determines whether to apply a date, time, or datetime SAS format to the resulting output if a date, time, or datetime SAS format is associated with a SAS data set variable. Applying a SAS format makes the date and time values in the resulting JSON output more readable.

Alias FMTDT | NOFMTDT

Default FMTDATETIME

Interaction You can specify FMTDATETIME | NOFMTDATETIME in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

Tip User-defined formats are also supported.

FMTNUMERIC | NOFMTNUMERIC
determines whether to apply a numeric SAS format to the resulting output if a numeric SAS format is associated with a SAS data set variable.

Alias FMTNUM | NOFMTNUM

Default NOFMTNUMERIC

Restriction Only the SAS formats BEST*w*., E*w*., and *w.d* write a JSON number to the output file. All other numeric SAS formats result in a JSON string.

Requirement FMTNUMERIC applies numeric SAS formats. For date, time, and datetime SAS formats, use the FMTDATETIME option.

Interactions With NOFMTNUMERIC or when a numeric variable does not have an associated SAS format, numeric values are written to the output file with a maximum of 12 digits.

You can specify FMTNUMERIC | NOFMTNUMERIC in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

Tip User-defined formats are also supported.

KEYS | NOKEYS
determines whether exported observations are written as JSON objects or as JSON arrays.

A JSON object stores SAS variable values from observations as key-value pairs. The SAS variable name is the key. A JSON array stores variable values only.

Default KEYS

Interaction You can specify NOKEYS in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

Tip Use NOKEYS to suppress SAS variable names in observation data when using the EXPORT statement.

See "Example 3: Suppressing SAS Variable Names in Observation Data When Using the EXPORT Statement" on page 1382and "Example 5: Writing Values and Exporting Data in the Same Program" on page 1387.

PRETTY | NOPRETTY
determines how to format the JSON output. PRETTY creates a more human-readable format that uses indention to illustrate the JSON container structure. NOPRETTY writes the output in a single line.

Default NOPRETTY

Restriction You can specify PRETTY | NOPRETTY in the PROC JSON statement only.

SASTAGS | NOSASTAGS
determines whether to include or suppress SAS metadata when using the EXPORT statement. The metadata consists of the SAS export version, exported SAS data set name, and any non-default option specification, such as PRETTY.

When EXPORT is the first statement in the procedure request, the top-level container for the exported data is a JSON object container. The SAS metadata precedes the exported data. When NOSASTAGS is specified, the top-level container is a JSON array container and the SAS metadata is suppressed.

See the following topics for information about what happens when the EXPORT statement is preceded by a WRITE OPEN statement in the PROC JSON request:

- WRITE OPEN ARRAY — "Example 5: Writing Values and Exporting Data in the Same Program" on page 1387.
- WRITE OPEN OBJECT — "Example 8: Exporting Multiple SAS Data Sets to a JSON File" on page 1398.

Default SASTAGS

Interactions NOSASTAGS affects the outermost container for exported data. The top-level JSON container is affected only when the EXPORT statement is the first statement in the procedure request.

You can specify NOSASTAGS in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

Note To modify the format of the exported observations, use the "KEYS | NOKEYS" option.

See "Example 2: Exporting Data to a Top-Level JSON Array Container" on page 1381 and "Example 6: Writing Values and Controlling Containers in Exported Data" on page 1391.

SCAN | NOSCAN

determines whether PROC JSON scans and encodes input strings to ensure that only characters that are acceptable are exported to the JSON output file.

Default SCAN

Interactions NOSCAN indicates that the input string is known to contain acceptable JSON text or has already been scanned. When NOSCAN is in effect, the input string or character value is taken as is, and the output JSON string is enclosed in quotation marks.

You can specify SCAN | NOSCAN in the PROC JSON statement, the EXPORT statement, the WRITE VALUES statement, or all three. If the option is specified in multiple statements, the EXPORT statement specification takes precedence.

See "Scanning Input Strings" on page 1362

TRIMBLANKS | NOTRIMBLANKS

determines whether to remove or retain trailing blanks from the end of character data in the JSON output. Only space characters are removed.

Default TRIMBLANKS

Interaction You can specify TRIMBLANKS | NOTRIMBLANKS in the PROC JSON statement, the EXPORT statement, the WRITE VALUES statement, or all three. If the option is specified in multiple statements, the EXPORT statement specification takes precedence.

EXPORT Statement

Identifies the SAS data set to be exported and controls the resulting output.

Alias: EX

Interaction: If the EXPORT statement is the first statement after the PROC JSON statement, the top-level container is a JSON object. However, if the NOSASTAGS option is specified in either the PROC JSON or the EXPORT statement, the top-level container is a JSON array. PROC JSON automatically closes the implicitly opened top-level container.

Notes: You can export multiple SAS data sets to the JSON output file by submitting multiple EXPORT statements.

The resulting JSON output uses the Unicode encoding form UTF-8. You cannot override the encoding in the output file with the ENCODING= data set option in the EXPORT statement. For information about overriding the encoding, see "JSON Output File Encoding" on page 1362.

Examples:

"Example 1: Exporting a JSON File Using Default Options" on page 1380

"Example 2: Exporting Data to a Top-Level JSON Array Container" on page 1381

"Example 3: Suppressing SAS Variable Names in Observation Data When Using the EXPORT Statement" on page 1382

"Example 5: Writing Values and Exporting Data in the Same Program" on page 1387

"Example 6: Writing Values and Controlling Containers in Exported Data" on page 1391

"Example 7: Applying SAS Formats to the Resulting Output" on page 1395

"Example 8: Exporting Multiple SAS Data Sets to a JSON File" on page 1398

Syntax

EXPORT <*libref.*>*SAS-data-set* <(*SAS-data-set-options*)> </*options*>;

Summary of Optional Arguments

(*SAS-data-set-options*)
specifies SAS data set options that apply to the input SAS data set.

FMTCHARACTER | NOFMTCHARACTER

determines whether to apply a character SAS format to the resulting output if a character SAS format is associated with a SAS data set variable.

FMTDATETIME | NOFMTDATETIME
: determines whether to apply a date, time, or datetime SAS format to the resulting output if a date, time, or datetime SAS format is associated with a SAS data set variable.

FMTNUMERIC | NOFMTNUMERIC
: determines whether to apply a numeric SAS format to the resulting output if a numeric SAS format is associated with a SAS data set variable.

KEYS | NOKEYS
: determines whether exported observations are written as JSON objects or as JSON arrays.

SASTAGS | NOSASTAGS
: determines whether to include or suppress SAS metadata when using the EXPORT statement.

SCAN | NOSCAN
: determines whether PROC JSON scans and encodes input strings to ensure that only characters that are acceptable are exported to the JSON output.

TABLENAME="*name*"
: specifies a name for the exported SAS data set.

TRIMBLANKS | NOTRIMBLANKS
: determines whether to remove or retain trailing blanks from the end of character data in the JSON output.

Required Argument

<libref.>SAS-data-set
: identifies the SAS data set to be exported with either a one- or two-level SAS name (library and member name). If you specify a one-level name, by default, the JSON procedure uses either the User library (if assigned) or the Work library.

Optional Arguments

(*SAS-data-set-options*)
: specifies SAS data set options that apply to the input SAS data set. For example, if the data set that you are exporting has an assigned password, you can use the ALTER=, PW=, READ=, or WRITE= data set options. To export a subset of data that meets a specified condition, you can use the WHERE= option. For information about SAS data set options, see *SAS Data Set Options: Reference*.

FMTCHARACTER | NOFMTCHARACTER
: determines whether to apply a character SAS format to the resulting output if a character SAS format is associated with a SAS data set variable.

Alias FMTCHAR | NOFMTCHAR

Default NOFMTCHARACTER

Interaction You can specify FMTCHARACTER | NOFMTCHARACTER in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

FMTDATETIME | NOFMTDATETIME
determines whether to apply a date, time, or datetime SAS format to the resulting output if a date, time, or datetime SAS format is associated with a SAS data set variable. Applying a SAS format makes the date and time values in the resulting JSON output more readable.

Alias FMTDT | NOFMTDT

Default FMTDATETIME

Interaction You can specify FMTDATETIME | NOFMTDATETIME in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

FMTNUMERIC | NOFMTNUMERIC
determines whether to apply a numeric SAS format to the resulting output if a numeric SAS format is associated with a SAS data set variable.

Alias FMTNUM | NOFMTNUM

Default NOFMTNUMERIC

Restriction Only the SAS formats BEST*w*., E*w*., and *w.d* write a JSON number to the output file. All other numeric SAS formats result in a JSON string.

Requirement FMTNUMERIC applies numeric SAS formats. For date, time, and datetime SAS formats, use the FMTDATETIME option.

Interactions With NOFMTNUMERIC or when a numeric variable does not have an associated SAS format, numeric values are written to the output file with a maximum of 12 digits.

You can specify FMTNUMERIC | NOFMTNUMERIC in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

KEYS | NOKEYS
determines whether exported observations are written as JSON objects or as JSON arrays.

A JSON object stores SAS variable values from observations as key-value pairs. The variable names are the keys. A JSON array stores variable values only.

Default KEYS

Interaction You can specify NOKEYS in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

Tip Use NOKEYS to suppress SAS variable names in observation data when using the EXPORT statement.

See "Example 3: Suppressing SAS Variable Names in Observation Data When Using the EXPORT Statement" on page 1382and "Example 5: Writing Values and Exporting Data in the Same Program" on page 1387.

SASTAGS | NOSASTAGS

determines whether to include or suppress SAS metadata when using the EXPORT statement. The metadata consists of the SAS export version, exported SAS data set name, and any non-default option specification, such as PRETTY.

When EXPORT is the first statement in the procedure request, the top-level container for the exported data is a JSON object container. The SAS metadata precedes the exported data. When NOSASTAGS is specified, the top-level container is a JSON array container and the SAS metadata is suppressed.

See the following topics for information about what happens when the EXPORT statement is preceded by a WRITE OPEN statement in the PROC JSON request:

- WRITE OPEN ARRAY — "Example 5: Writing Values and Exporting Data in the Same Program" on page 1387.
- WRITE OPEN OBJECT — "Example 8: Exporting Multiple SAS Data Sets to a JSON File" on page 1398.

Default SASTAGS

Interactions NOSASTAGS affects the outermost container for exported data. The top-level JSON container is affected only when the EXPORT statement is the first statement in the procedure request.

You can specify SASTAGS | NOSASTAGS in the PROC JSON statement, the EXPORT statement, or both. If the option is specified in both statements, the EXPORT statement specification takes precedence.

Note To modify the format of the exported observations, use the "KEYS | NOKEYS" option.

See "Example 2: Exporting Data to a Top-Level JSON Array Container" on page 1381 and "Example 6: Writing Values and Controlling Containers in Exported Data" on page 1391.

SCAN | NOSCAN

determines whether PROC JSON scans and encodes input strings to ensure that only characters that are acceptable are exported to the JSON output.

Default SCAN

Interactions NOSCAN indicates that the input string is known to contain acceptable JSON text or has already been scanned. When NOSCAN is in effect, the input string or character value is taken as is, and the output JSON string is enclosed in quotation marks.

You can specify SCAN | NOSCAN in the PROC JSON statement, the EXPORT statement, the WRITE VALUES statement, or all three statements. If the option is specified in multiple statements, the EXPORT statement specification takes precedence.

See "Scanning Input Strings" on page 1362

TABLENAME="*name*"
specifies a name for the exported SAS data set. The name is exported as SAS metadata in the JSON output file. Enclose the name in single or double quotation marks.

Default The default is the SAS data set member name.

Requirement The TABLENAME= option requires the SASTAGS option to include the SAS metadata in the JSON output.

TRIMBLANKS | NOTRIMBLANKS
determines whether to remove or retain trailing blanks from the end of character data in the JSON output. Only space characters are removed.

Default TRIMBLANKS

Interaction You can specify TRIMBLANKS | NOTRIMBLANKS in the PROC JSON statement, the EXPORT statement, the WRITE VALUES statement, or all three statements. If the option is specified in multiple statements, the EXPORT statement specification takes precedence.

WRITE VALUES Statement

Writes one or more values to the JSON output file.

Alias: W V

Interaction: If the WRITE VALUES statement is the first statement after the PROC JSON statement, PROC JSON opens a JSON object as the top-level container. PROC JSON automatically closes the implicitly opened top-level container.

Note: Specifying multiple values in one WRITE VALUES statement is equivalent to submitting multiple WRITE VALUES statements with only one value each. Only the order of the values is significant.

Examples: "Example 4: Writing JSON Output without Exporting a SAS Data Set" on page 1384
"Example 5: Writing Values and Exporting Data in the Same Program" on page 1387
"Example 6: Writing Values and Controlling Containers in Exported Data" on page 1391

"Example 8: Exporting Multiple SAS Data Sets to a JSON File" on page 1398

Syntax

WRITE VALUES *value(s)* </*options*>;

Summary of Optional Arguments

SCAN | NOSCAN
: determines whether PROC JSON scans and encodes input strings to ensure that only characters that are acceptable are exported to the JSON output.

TRIMBLANKS | NOTRIMBLANKS
: determines whether to remove or retain trailing blanks from the end of character data in the JSON output.

Required Argument

value(s)
specifies one or more values to write to the JSON output file. Separate values with a blank space. A value can be one of the following:

- a *string*, which can be enclosed in single or double quotation marks. If the string is enclosed in quotation marks, there are no restrictions regarding content or length. However, if the string is not enclosed in quotation marks, the following rules apply:
  - The length of the string cannot exceed 256 bytes.
  - The first character must begin with a letter of the Latin alphabet (A–Z, a–z) or the underscore. Subsequent characters can be letters of the Latin alphabet, numerals, or underscores.
  - The string cannot contain blanks or special characters except for the underscore. A string can contain mixed-case letters.
- a *number* represented in integer, floating point, or exponential format.
- the Boolean value TRUE | T or FALSE | F.
- NULL | N.

For example, the statement `write values "success" true;` causes the following results to be written to the JSON output file:

- **`"success": true`** if the current container is a JSON object
- **`"success", true`** if the current container is a JSON array

Requirement When writing values to a JSON object container, the name portion of the key-value pair must be a string. For example, the statement

`write values "abcd" "1";` is appropriate. However, the statement `write values 1 "abcd";` produces an error.

Optional Arguments

SCAN | NOSCAN

determines whether PROC JSON scans and encodes input strings to ensure that only characters that are acceptable are exported to the JSON output.

Default SCAN

Interactions NOSCAN indicates that the input string is known to contain acceptable JSON text or has already been scanned. When NOSCAN is in effect, the input string or character value is taken as is, and the output JSON string is enclosed in quotation marks.

You can specify SCAN | NOSCAN in the PROC JSON statement, the EXPORT statement, the WRITE VALUES statement, or all three statements. If the option is specified in multiple statements, the EXPORT statement specification takes precedence.

See "Scanning Input Strings" on page 1362

TRIMBLANKS | NOTRIMBLANKS

determines whether to remove or retain trailing blanks from the end of character data in the JSON output. Only space characters are removed.

Default TRIMBLANKS

Interaction You can specify TRIMBLANKS | NOTRIMBLANKS in the PROC JSON statement, the EXPORT statement, the WRITE VALUES statement, or all three statements. If the option is specified in multiple statements, the EXPORT statement specification takes precedence.

WRITE OPEN Statement

Opens and nests a JSON container in the output file.

Alias: W O

Interactions: If the WRITE OPEN statement is the first statement after the PROC JSON statement, the WRITE OPEN statement establishes the top-level container.

Submit the WRITE CLOSE statement for containers that you explicitly open with the WRITE OPEN statement.

Examples: "Example 6: Writing Values and Controlling Containers in Exported Data" on page 1391

"Example 8: Exporting Multiple SAS Data Sets to a JSON File" on page 1398

Syntax

WRITE OPEN *type*;

Required Argument

type
specifies the type of JSON container:

ARRAY
specifies that the JSON container is an array, which collects a list of values. An example statement is `write open array;`.

Alias A

OBJECT
specifies that the JSON container is an object, which collects key-value pairs. An example statement is `write open object;`.

Alias O

WRITE CLOSE Statement

Closes a JSON container that is open in the JSON output file.

Alias: W C

Restriction: The WRITE CLOSE statement cannot be the first statement after the PROC JSON statement.

Interaction: The WRITE CLOSE statement closes the most recently opened container of either type that was explicitly opened with the WRITE OPEN statement. You should submit the WRITE CLOSE statement for containers only if you explicitly opened the container with the WRITE OPEN statement.

Examples: "Example 6: Writing Values and Controlling Containers in Exported Data" on page 1391

"Example 8: Exporting Multiple SAS Data Sets to a JSON File" on page 1398

Syntax

WRITE CLOSE;

Usage: JSON Procedure

Exporting Data

The JSON procedure enables you to export one or more SAS data sets to a JSON output file. In the procedure statements, you specify the name of the JSON output file and the name of the SAS data set to be exported. For example, the following PROC JSON code writes the data in a SAS data set named Sashelp.Class to a JSON output file named Output.json.

```
proc json out="C:\Users\sasabc\JSON\Output.json";
   export sashelp.class;
run;
```

The exported data is written to a JSON object container ({ }) by default. Each observation of the data set is also put into a JSON object container. Options are available to enable you to create both the outer container and the observation containers as arrays. The SASTAGS (or NOSASTAGS) argument controls the outer container. The KEYS (or NOKEYS) argument controls the observation containers. For more information, see “Example 1: Exporting a JSON File Using Default Options” on page 1380, “Example 2: Exporting Data to a Top-Level JSON Array Container” on page 1381, and “Example 3: Suppressing SAS Variable Names in Observation Data When Using the EXPORT Statement” on page 1382.

Writing Values to a JSON Output File

PROC JSON provides the WRITE VALUES statement to explicitly write data to a JSON output file. The WRITE VALUES statement can be used to write one or more values to a JSON object container or a JSON array container. A value can be a string, a number, the Boolean value TRUE or FALSE, or the NULL keyword.

When the WRITE VALUES statement is the first statement specified under the PROC JSON statement, the statement implicitly creates a JSON object container to collect the specified values. In this way, you can use the WRITE VALUES statement in PROC JSON to create your own JSON output file without exporting a SAS data set. SAS variable values are collected in this object container as key and value pairs. For example:

```
proc json out="example.json";
   write values "container" "object";
   write values "created" "implicitly";
run;
```

```
{"container":"object","created":"implicitly"}
```

The WRITE VALUES statement cannot directly add values to a JSON container that contains data from an exported SAS data set. The EXPORT statement implicitly opens and automatically closes a JSON object. You cannot write values to a closed JSON container with the WRITE VALUES statement. To add values to a JSON object that includes exported data, you must precede the WRITE VALUES statement with a WRITE OPEN statement.

The WRITE OPEN statement explicitly opens a JSON container. It also enables you to specify the JSON container type: object or array.

When the WRITE VALUES statement follows a WRITE OPEN OBJECT statement, then the first value in the pair is considered to be a key name. The second value is the key's value. For example:

```
proc json out="example.json"
   write open object;
   write values "container" "object";
   write values "created" "explicitly";
   write close;
run;
```

```
{"container":"object","created":"explicitly"}
```

When the WRITE VALUES statement follows a WRITE OPEN ARRAY statement, then the WRITE VALUES statement creates a comma-separated list of values in the JSON array container.

```
proc json out="example.out";
   write open array;
   write values "container" "array";
   write values "created" "explictly";
   write close;
run;
```

```
["container","array","created","explictly"]
```

Use the WRITE OPEN statement when you want to add information to the JSON file that contains exported SAS data and when you want to nest JSON containers. For more information, see "Example 4: Writing JSON Output without Exporting a SAS Data Set" on page 1384, "Example 5: Writing Values and Exporting Data in the Same Program" on page 1387, "Example 6: Writing Values and Controlling Containers in Exported Data" on page 1391, and "Example 8: Exporting Multiple SAS Data Sets to a JSON File" on page 1398.

Controlling JSON Output with Options

PROC JSON supports several options that control the resulting JSON output. You can specify the options in the PROC JSON, EXPORT, and WRITE VALUES statements.

The following table lists the options and whether they are supported in a statement.

Note: Default option keywords appear in bold.

Table 38.2 Statement Option Availability in the PROC JSON, EXPORT, and WRITE VALUES Statements

Option	Function	PROC JSON Statement	EXPORT Statement	WRITE VALUES Statement
FMTCHARACTER | **NOFMTCHARACTER**	Determines whether to apply an associated character SAS format.	Yes	Yes	No
FMTDATETIME | NOFMTDATETIME	Determines whether to apply an associated date, time, or datetime SAS format.	Yes	Yes	No
FMTNUMERIC | **NOFMTNUMERIC**	Determines whether to apply an associated numeric SAS format (excluding date, time, and datetime SAS formats).	Yes	Yes	No
KEYS | NOKEYS	Determines whether exported observations are written as JSON object or array containers.	Yes	Yes	No
PRETTY | **NOPRETTY**	Determines how to format the JSON output.	Yes	No	No
SASTAGS | NOSASTAGS	Determines whether to include or suppress SAS metadata when using the EXPORT statement. When EXPORT is the first statement in the procedure request, also	Yes	Yes	No

Option	Function	PROC JSON Statement	EXPORT Statement	WRITE VALUES Statement
	determines whether the top-level JSON container is an object container or an array container.			
SAS-data-set-options	Specify actions that apply to the SAS data set.	No	Yes	No
SCAN | NOSCAN	Determines whether PROC JSON scans and encodes input strings.	Yes	Yes	Yes
TABLENAME="*name*"	Specifies a name in the SAS metadata for the exported SAS data set.	No	Yes	No
TRIMBLANKS | NOTRIMBLANKS	Determines whether to remove or retain trailing blanks.	Yes	Yes	Yes

Note: Options specified in the PROC JSON statement apply for the duration of the procedure. Options specified in the EXPORT and WRITE VALUES statement apply only to that statement. If options are specified in more than one statement, the options specified in the EXPORT statement or WRITE VALUES statement take precedence.

For an example, see "Example 2: Exporting Data to a Top-Level JSON Array Container" on page 1381.

PROC JSON Video

For a video that demos how to use PROC JSON, see How to Write JSON Output from SAS. The video shows you how to export a SAS data set to a JSON output file, how to export a subset of data and control the JSON output, and how to write free-form JSON output, control and nest JSON containers, and export multiple SAS data sets.

Examples: JSON Procedure

Example 1: Exporting a JSON File Using Default Options

Features:
PROC JSON statement
PROC JSON PRETTYstatement option
EXPORT statement
WHERE data set option

Details

This PROC JSON example exports a subset of the Sashelp.Class data set to a JSON output file. The PROC JSON PRETTY procedure option is specified to return the output in a format that uses indention to illustrate the default JSON container structure. Otherwise, the default export options are enabled.

Program

Specify the JSON output file and the EXPORT statement. The PROC JSON statement specifies the physical location of the JSON output file with the complete pathname and JSON filename. When the .json extension is omitted, the output is written to a text file.

```
proc json out="C:\Users\sasabc\JSON\DefaultOutput.json" pretty;
   export sashelp.class (where=(age=11));
run;
```

Output: Exporting a JSON File Using Default Options

The top-level container in the output file is a JSON object container ({ }). Each observation in the SAS data set is exported to a JSON object container; variable

values in each object container are key-value pairs. The set of observations is in a JSON array container ([ ]). SAS metadata is included in the top of the top-level container.

Output 38.1 *Content of PROC JSON Output File DefaultOutput.json*

```
{
  "SASJSONExport": "1.0 PRETTY",
  "SASTableData+CLASS": [
    {
      "Name": "Joyce",
      "Sex": "F",
      "Age": 11,
      "Height": 51.3,
      "Weight": 50.5
    },
    {
      "Name": "Thomas",
      "Sex": "M",
      "Age": 11,
      "Height": 57.5,
      "Weight": 85
    }
  ]
}
```

Example 2: Exporting Data to a Top-Level JSON Array Container

Features:

PROC JSON statement options
- PRETTY

EXPORT statement options
- WHERE= data set option
- NOSASTAGS

Details

This example exports a subset of the Sashelp.Class data set to a JSON output file and specifies to write the exported data to a JSON array container.

Program

```
proc json out="C:\Users\sasabc\JSON\NosastagsOutput.json" pretty;
   export sashelp.class (where=(age=11)) / nosastags;
run;
```

Program Description

Specify the JSON output file. The PROC JSON statement specifies the physical location of the JSON output file with the complete pathname and a JSON filename. The PRETTY option creates a more readable format.

```
proc json out="C:\Users\sasabc\JSON\NosastagsOutput.json" pretty;
```

Identify the SAS data set to be exported and control the top-level JSON container. NOSASTAGS in the EXPORT statement suppresses SAS metadata and specifies that the top-level container is an array container. The NOSASTAGS option can be specified on the PROC JSON statement or on the EXPORT statement.

```
   export sashelp.class (where=(age=11)) / nosastags;
run;
```

Output: Exporting Data to a Top-Level JSON Array Container

The top-level container in the output file is an array container ([ ]). There is no SAS metadata. Each observation in the SAS data set is a JSON object ({ }) container. Variable values within the object containers are key-value pairs.

Output 38.2 *Content of PROC JSON Output File NosastagsOutput.json*

```
[
  {
    "Name": "Joyce",
    "Sex": "F",
    "Age": 11,
    "Height": 51.3,
    "Weight": 50.5
  },
  {
    "Name": "Thomas",
    "Sex": "M",
    "Age": 11,
    "Height": 57.5,
    "Weight": 85
  }
]
```

Example 3: Suppressing SAS Variable Names in Observation Data When Using the EXPORT Statement

Features: PROC JSON statement options
PRETTY

EXPORT statement options
WHERE= data set option
NOKEYS

Details

This example exports a subset of the Sashelp.Class data set to a JSON output file and specifies to write the exported data set observations as an array. Array containers store variable values only.

Program

```
proc json out="C:\Users\sasabc\JSON\NokeysOutput.json" pretty;

   export sashelp.class (where=(age=11)) / nokeys;
run;
```

Program Description

Specify the JSON output file. The PROC JSON statement specifies the physical location of the JSON output file with the complete pathname and a JSON filename. The PRETTY option creates a more readable format.

```
proc json out="C:\Users\sasabc\JSON\NokeysOutput.json" pretty;
```

Identify the SAS data set to be exported and control the observation container. NOKEYS in the EXPORT statement writes data set observations as values in an array container instead of to object containers. The NOKEYS option can be specified on the PROC JSON statement or on the EXPORT statement.

```
   export sashelp.class (where=(age=11)) / nokeys;
run;
```

Output: Suppressing SAS Variable Names in Observation Data When Using the EXPORT Statement

The top-level container in the output file is a JSON object container ({ }). SAS metadata is included in the top-level container. Each selected observation in the SAS data set is exported in an array container ([ ]) that is nested in the top-level container. The arrays contain a list of variable values and no variable names.

Output 38.3 *Content of PROC JSON Output File NokeysOutput.json*

```
{
  "SASJSONExport": "1.0 NOKEYS PRETTY",
  "SASTableData+CLASS": [
    [
      "Joyce",
      "F",
      11,
      51.3,
      50.5
    ],
    [
      "Thomas",
      "M",
      11,
      57.5,
      85
    ]
  ]
}
```

Example 4: Writing JSON Output without Exporting a SAS Data Set

Features:

PROC JSON statement options
PRETTY

WRITE OPEN statement

WRITE VALUES statement

WRITE CLOSE statement

Details

This PROC JSON example illustrates how to write JSON output from SAS without exporting data from a SAS data set. This gives you complete control over the content of the JSON output, which enables you to produce arbitrary JSON output.

Program

```
proc json out="C:\Users\sasabc\JSON\WriteOpenOutput.json" pretty;

   write open object;
      write values "Nested object sample";

      write open object;
         write values "Comment" "In a nested object";
```

```
      write close;

   write values "Nested array sample";
   write open array;
      write open array;
         write values "In a nested array";
         write values 1 true null;
         write close;
      write close;

   write values "Finished" "End of samples";

   write close;
run;
```

Program Description

Specify the JSON output file. The PRETTY option creates the output in a more readable format.

```
proc json out="C:\Users\sasabc\JSON\WriteOpenOutput.json" pretty;
```

Open a JSON object container and write a value. The WRITE OPEN OBJECT statement explicitly opens a JSON object container ({ }) as the top-level container. The WRITE VALUES statement writes a string to the object container.

```
   write open object;
      write values "Nested object sample";
```

Nest an object container with values, and then close the nested object container. The WRITE OPEN OBJECT statement explicitly opens a second object container in the top-level container. The WRITE VALUES statement writes two strings in the second-level object container. The WRITE CLOSE statement closes the most recently opened container.

```
      write open object;
         write values "Comment" "In a nested object";
         write close;
```

Write a value to the JSON output file, open an array container, nest an array container with values, and then close the two array containers. The WRITE VALUES statement writes a string in the top-level container. The WRITE OPEN ARRAY statements create an array container in the top-level container, and then nests a second array container in the previously opened array container. The WRITE VALUES statements write a string, a number, the Boolean value TRUE, and the NULL keyword to the second-level array container. Two WRITE CLOSE statements close the array containers.

```
   write values "Nested array sample";
   write open array;
      write open array;
         write values "In a nested array";
         write values 1 true null;
         write close;
      write close;
```

Write a final value. The WRITE VALUES statement writes two strings to the top-level container.

```
    write values "Finished" "End of samples";
```

Close the top-level container. The WRITE CLOSE statement closes the remaining open container, which is the top-level container.

```
    write close;
run;
```

Output: Writing JSON Output without Exporting a SAS Data Set

Because the top-level container was specified as an object container, SAS expects the first WRITE VALUES statement to specify key-value pairs. The first WRITE VALUES statement specifies only one value. Therefore, the string “Nested object sample” is output as the key in a key-value pair. The first nested object is the value of this key-value pair. Because the nested container is also an object container, the nested WRITE VALUES statement is output as a key-value pair. The key in the string is “Comment” and the value is the string “In a nested object”. Because the nested object container is explicitly closed, the specified data is again being written to the top-level container, an object container, which is expected to contain a key-value pair. The string “Nested array sample” is the key in this key-value pair; the first array container is the value. The second, nested array container is an actual array. The nested WRITE VALUES statements define a list of four values in the second-level array container. Because the two array containers are explicitly closed, the final WRITE VALUES statement again is being written to the top-level container, which is expected to contain a key-value pair. The string “Finished” is the key in this key-value pair; the string “End of samples” is the value.

Output 38.4 *Content of PROC JSON Output File WriteOpenOutput.json*

```
{
  "Nested object sample": {
    "Comment": "In a nested object"
  },
  "Nested array sample": [
    [
      "In a nested array",
      1,
      true,
      null
    ]
  ],
  "Finished": "End of samples"
}
```

Example 5: Writing Values and Exporting Data in the Same Program

Features:

PROC JSON statement options
PRETTY
WRITE OPEN ARRAY statement
WRITE VALUES statement
EXPORT statement
WRITE CLOSE statement

Details

This example writes values and performs three exports of the same data to show the behavior of the default export settings, the NOSASTAGS option, and the NOKEYS option. The exported data is inserted into a top-level array container, to show the effect of NOSASTAGS on the exported data.

Program

```
proc json out="C:\Users\sasabc\JSON\WriteAndExport.json" pretty;

   write open array;
      write values "level" 1;
      write values "container" "array";
      write values "created" "explicitly";

      write values "Default Export";
      export sashelp.class (where=(age=11));

    write values "Export with NOSASTAGS Options";
     export sashelp.class (where=(age=11)) / nosastags;

     write values "Export with NOSASTAGS and NOKEYS Option";
      export sashelp.class (where=(age=11)) / nosastags nokeys;

      write close;
   run;
```

Program Description

Specify the JSON output file in the PROC JSON statement. The PRETTY option creates the output in a more readable format.

```
proc json out="C:\Users\sasabc\JSON\WriteAndExport.json" pretty;
```

Open a top-level JSON array container and specify values. The WRITE OPEN ARRAY statement explicitly opens a JSON array container ([ ]) as the top-level container. WRITE VALUES statements specify a string, a numeric value, and additional strings as values for the array.

```
write open array;
   write values "level" 1;
   write values "container" "array";
   write values "created" "explicitly";
```

Specify an EXPORT statement. The EXPORT statement specifies to export a subset of the observations from the SAS data set Sashelp.Class. The WHERE data set option limits the observations that are included in the output file. There are no export options specified. The EXPORT statement implicitly opens and closes the container that holds the exported data. A WRITE VALUES statement that contains a string of descriptive text is specified before the EXPORT statement.

```
   write values "Default Export";
   export sashelp.class (where=(age=11));
```

Specify an EXPORT statement that specifies the NOSASTAGS option. The EXPORT statement specifies to export the same data as the preceding EXPORT statement. NOSASTAGS suppresses the SAS metadata. The EXPORT statement implicitly opens and closes the container that holds the exported data. A WRITE VALUES statement that contains a string of descriptive text is specified before the EXPORT statement.

```
write values "Export with NOSASTAGS Options";
 export sashelp.class (where=(age=11)) / nosastags;
```

Specify an EXPORT statement that specifies the NOSASTAGS and NOKEYS options. The EXPORT statement specifies to export the same data as the preceding EXPORT statements. NOSASTAGS suppresses the SAS metadata. The NOKEYS option specified to export each data set observation to an array container, instead of an object container. The EXPORT statement implicitly opens and closes the container that holds the exported data. A WRITE VALUES statement is specified before the EXPORT statement to print a string containing descriptive text.

```
 write values "Export with NOSASTAGS and NOKEYS Option";
  export sashelp.class (where=(age=11)) / nosastags nokeys;
```

Close the outer JSON array container.

```
   write close;
run;
```

Output: Writing Values and Exporting Data in the Same Program

The default export behavior writes SAS metadata as variable values in the open array container. The exported data is added as an array value in the open array container. The exported observations are comma-separated JSON object containers within the new array. NOSASTAGS suppresses the SAS metadata, as well as the outer array container from the exported observations. The observations are added as comma-separated object containers in the existing array. When the NOKEYS and NOSASTAGS options are specified together, the exported observations are added to the existing array as comma-separated array values.

Example 6: Writing Values and Controlling Containers in Exported Data

Features:

PROC JSON statement options
- NOSASTAGS
- PRETTY

WRITE OPEN statement

WRITE VALUES statement

EXPORT statement

WRITE CLOSE statement

Details

This PROC JSON example illustrates how to write additional values to a JSON output file and control and nest JSON containers. The example exports a subset of the Sashelp.Cars data set to the JSON output file.

Program

```
%let vehicleType=Truck;
%let minCost=26000;

proc json out="C:\Users\sasabc\JSON\WriteOpenArrayOutput.json"
nosastags pretty;

   write open array;
   write values "Vehicles";
   write open array;
   write values "&vehicleType";
   write open array;
   write values "Greater than $&minCost";
   /*********** Asian **********************/
   %let originator=Asia;
   write open object;
   write values "&originator";
   write open array;
   export sashelp.cars(where=((origin = "&originator")  and
                              (type   = "&vehicleType") and
                              (MSRP   > &minCost)           )
                       keep=make model type origin MSRP);
   write close; /* data values */
   write close; /* Asia */
   /*********** European **********************/
```

```
   %let originator=Europe;
   write open object;
   write values "&originator";
   write open array;
   export sashelp.cars(where=((origin = "&originator")  and
                              (type   = "&vehicleType") and
                              (MSRP   > &minCost)           )
                       keep=make model type origin MSRP);
   write close; /* data values */
   write close; /* Europe */
   /*********** American **********************/
   %let originator=USA;
   write open object;
   write values "&originator";
   write open array;
   export sashelp.cars(where=((origin = "&originator")  and
                              (type   = "&vehicleType") and
                              (MSRP   > &minCost)           )
                       keep=make model type origin MSRP);
   write close; /* data values */
   write close; /* USA */
   write close; /* expensive */
   write close; /* vehicleType */
   write close; /* cars */
run;
```

Program Description

Assign macro variables. The %LET statements create macro variables and assign values to be used throughout the code.

```
%let vehicleType=Truck;
%let minCost=26000;
```

Specify the JSON output file and control the resulting output. The PROC JSON statement specifies the physical location of the JSON output file with the complete pathname and filename. The NOSASTAGS option suppresses the SAS metadata and the PRETTY option creates a more readable format.

```
proc json out="C:\Users\sasabc\JSON\WriteOpenArrayOutput.json"
nosastags pretty;
```

Include additional PROC JSON statements. These statements open a series of nested containers for each type of car and write values as labels for the containers. The EXPORT statements specifies the SAS data set to export, selects specific observations, and requests only certain SAS variables.

```
   write open array;
   write values "Vehicles";
   write open array;
   write values "&vehicleType";
   write open array;
   write values "Greater than $&minCost";
   /*********** Asian **********************/
   %let originator=Asia;
```

```
   write open object;
   write values "&originator";
   write open array;
   export sashelp.cars(where=((origin = "&originator")  and
                              (type   = "&vehicleType") and
                              (MSRP   > &minCost)           )
                       keep=make model type origin MSRP);
   write close; /* data values */
   write close; /* Asia */
   /*********** European **********************/
   %let originator=Europe;
   write open object;
   write values "&originator";
   write open array;
   export sashelp.cars(where=((origin = "&originator")  and
                              (type   = "&vehicleType") and
                              (MSRP   > &minCost)           )
                       keep=make model type origin MSRP);
   write close; /* data values */
   write close; /* Europe */
   /*********** American **********************/
   %let originator=USA;
   write open object;
   write values "&originator";
   write open array;
   export sashelp.cars(where=((origin = "&originator")  and
                              (type   = "&vehicleType") and
                              (MSRP   > &minCost)           )
                       keep=make model type origin MSRP);
   write close; /* data values */
   write close; /* USA */
   write close; /* expensive */
   write close; /* vehicleType */
   write close; /* cars */
run;
```

Example 7: Applying SAS Formats to the Resulting Output

Features:

PROC JSON statement options
- PRETTY

EXPORT statement options
- FMTDATETIME
- FMTNUMERIC

DATA step

Details

This PROC JSON example exports a SAS data set named Work.Formats that contains variables with associated SAS formats. The resulting JSON output file applies the SAS formats, which makes the output values more readable.

Program

```
data formats;
   input name $ idnumber $ salary hiredate mmddyy10.;
   format salary dollar7. hiredate date9.;
   datalines;
   Brad 0755 21163 9/24/2012
   Lindzey 0767 34321 9/04/2012
   ;
```

```
proc json out="C:\Users\sasabc\JSON\FormatsOutput.json" pretty;

   export work.formats / fmtnumeric;
run;
```

Program Description

Create a SAS data set with variables that have associated SAS formats. The DATA step creates a SAS data set named Work.Formats with four variables. The FORMAT statement associates the DOLLAR7. SAS numeric format with the variable Salary and the SAS date format DATE9. with the variable HireDate.

```
data formats;
   input name $ idnumber $ salary hiredate mmddyy10.;
   format salary dollar7. hiredate date9.;
   datalines;
   Brad 0755 21163 9/24/2012
   Lindzey 0767 34321 9/04/2012
   ;
```

Specify the JSON output file and control the resulting output file. The PROC JSON statement specifies the physical location of the JSON output file with the complete pathname and filename and includes the PRETTY option to create a more readable format.

```
proc json out="C:\Users\sasabc\JSON\FormatsOutput.json" pretty;
```

Identify the SAS data set to be exported. The EXPORT statement specifies the SAS data set name. The FMTDATETIME option is available by default to apply the date SAS format that is associated with the HireDate variable. The FMTNUMERIC option is specified to apply the numeric SAS format DOLLAR7. that is associated with the Salary variable.

```
   export work.formats / fmtnumeric;
run;
```

Output: Applying SAS Formats to the Resulting Output

Output 38.7 *PROC JSON Output File FormatsOutput.json with FMTDATETIME and FMTNUMERIC*

```
{
  "SASJSONExport": "1.0 PRETTY FMTNUMERIC",
  "SASTableData+FORMATS": [
    {
      "name": "Brad",
      "idnumber": "0755",
      "salary": "$21,163",
      "hiredate": "24SEP2012"
    },
    {
      "name": "Lindzey",
      "idnumber": "0767",
      "salary": "$34,321",
      "hiredate": "04SEP2012"
    }
  ]
}
```

If the EXPORT statement specified the option NOFMTDATETIME and did not specify the option FMTNUMERIC, the resulting JSON output file would include Salary and HireDate values that are less readable.

Output 38.8 *PROC JSON Output File FormatsOutput.json with NOFMTDATETIME and NOFMTNUMERIC*

```
{
  "SASJSONExport": "1.0 PRETTY NOFMTDATETIME",
  "SASTableData+FORMATS": [
    {
      "name": "Brad",
      "idnumber": "0755",
      "salary": 21163,
      "hiredate": 19260
    },
    {
      "name": "Lindzey",
      "idnumber": "0767",
      "salary": 34321,
      "hiredate": 19240
    }
  ]
}
```

Example 8: Exporting Multiple SAS Data Sets to a JSON File

Features:

PROC JSON statement options
- PRETTY
- NOKEYS
- NOSASTAGS

WRITE OPEN statement

WRITE VALUES statement

EXPORT statement options
- WHERE= data set option
- DROP= data set option
- KEYS option

WRITE CLOSE statement

Details

This PROC JSON example exports two SAS data sets to a JSON output file. The SasHelp.Class data set contains student information such as their names, ages, and gender. The MyFiles.Fitness data set contains the student's fitness achievements, such as the number of crunches and push-ups that they can do. The example also illustrates how to control and nest JSON containers and write additional values to the JSON output file.

The resulting JSON output file contains the following content:

- The output begins by opening an object container ({ }) as the top-level container, because the first statement after the PROC JSON statement is WRITE OPEN OBJECT.
- There is no SAS metadata at the beginning of the output file.
- The output is in a more human-readable format that uses indention to illustrate the JSON container structure.
- User-defined strings are written as labels for the containers.
- A series of JSON containers are opened and nested.
- A subset of two SAS data sets is exported. The values for the first SAS data set are exported as nested array containers and consist of a list of values. The values for the second SAS data set are exported as nested object containers and consist of key-value pairs.
- The explicitly opened JSON containers are closed.

Program

```
proc json out='C:\Users\sasabc\\JSON\MultipleDataSets.json' pretty
nokeys;

   write open object; /* top-level object */
     write value "Fitness";
     write open array; /* fitness array */
       write value "Class List";
       write open array; /* class list array */
         export sashelp.class (where=(age eq 11) drop=height weight);

       write close; /* class list array */
     write close;  /* fitness array */

     write value "Results";
     write open array; /* results array */

       export myfiles.fitness (where=(age eq 11) drop=name)/ keys;

     write close; /* results array */
   write close; /* top-level object */
run;
```

Program Description

Specify the JSON output file and control the resulting output. The PROC JSON statement specifies the physical location of the JSON output file with the complete pathname and filename. The PRETTY option creates a more readable format. The NOKEYS option specifies to write the exported observations in array containers.

```
proc json out='C:\Users\sasabc\\JSON\MultipleDataSets.json' pretty
nokeys;
```

Open and nest labeled containers. The statements open a series of nested containers and write values as labels for the containers.

```
   write open object; /* top-level object */
     write value "Fitness";
     write open array; /* fitness array */
       write value "Class List";
       write open array; /* class list array */
```

Identify the first SAS data set to be exported. The EXPORT statement specifies the two-level SAS name. The WHERE= data set option specifies conditions for selecting observations. The DROP= data set option excludes the specified variables from being written to the output file. The selected observations are exported as nested array containers and consist of a list of values.

```
    export sashelp.class (where=(age eq 11) drop=height weight);
```

Close the two array containers. The two WRITE CLOSE statements close the two array containers. Note that when you explicitly open a container, you must explicitly close it.

```
    write close; /* class list array */
  write close;  /* fitness array */
```

Label and open a nested array container. The WRITE VALUE statement nests the user-defined string Results in the top-level container. The WRITE OPEN ARRAY statement opens a nested array container.

```
  write value "Results";
  write open array; /* results array */
```

Identify the second SAS data set to be exported. The EXPORT statement specifies the two-level SAS name. The WHERE= data set option specifies conditions for selecting observations. The DROP= data set option excludes the specified variable from being written to the output file. The KEYS option causes the selected observations to be exported as nested object containers and consist of key-value pairs. Note that for the EXPORT statement, the KEYS option overrides the NOKEYS option that is specified in the PROC JSON statement.

```
    export myfiles.fitness (where=(age eq 11) drop=name)/ keys;
```

Close the two open containers. Two WRITE CLOSE statements explicitly close the array container and the object container for the top-level container.

```
  write close; /* results array */
 write close; /* top-level object */
run;
```

Output: Exporting Multiple SAS Data Sets to a JSON File

Output 38.9 *PROC JSON Output File MultipleDataSets.json*

```
{
  "Fitness": [
    "Class List",
    [
      [
        "Joyce",
        "F",
        11
      ],
      [
        "Thomas",
        "M",
        11
      ]
    ]
  ],
  "Results": [
    {
      "Age": 11,
      "Push-ups": 15,
      "Crunches": 20
    },
    {
      "Age": 11,
      "Push-ups": 22,
      "Crunches": 33
    }
  ]
}
```

39

LUA Procedure

Overview: LUA Procedure

What Does the LUA Procedure Do?

The Lua programming language is an embeddable scripting language that runs on any platform that has a standard C compiler. This includes all versions of UNIX, Windows, and mobile operating systems, including Android, iOS, and others. Lua uses simple syntax, runs fast computations, and automatically manages memory allocation.

The LUA procedure enables you to run statements from the Lua programming language within SAS code. You can submit Lua statements from an external Lua script, or enter Lua statements directly in SAS code.

Note: Support for the LUA procedure was added in SAS 9.4M3.

PROC LUA enables you to perform these tasks:

- run Lua code within a SAS session
- call most SAS functions within Lua statements
- call PROC FCMP functions within Lua statements
- submit SAS code from Lua
- call CAS actions

  Note: Support for calling CAS actions was added in SAS 9.4M5.

- read VARCHAR data

  Note: Support for VARCHAR data was added in SAS Viya 3.3.

Concepts: LUA Procedure

Specifying the Input Location for Lua Scripts

Using the LUAPATH Fileref

Typically, you store long blocks of Lua code in separate script files. This practice enables you to more easily manage your Lua code. The examples in this chapter use the SUBMIT and ENDSUBMIT statements to identify Lua code. However, any Lua code can be stored in a separate Lua script.

You run the code from the scripts by specifying the following information:

- the location of the Lua script
- the name of the Lua script to execute

You specify the location of your Lua scripts by using the FILENAME statement to define the LUAPATH fileref. To define a single location, enter a SAS statement that is similar to this one:

```
filename LUAPATH "/usr/local/scripts/lua";
```

You can specify more than one location for your Lua scripts. The system searches for the input Lua script from the locations that are listed, in the order in which you specify them. One of these locations must contain the Lua system scripts. To specify more than one location, enclose the list in parentheses and separate values with a comma:

```
filename LUAPATH ("/usr/local/scripts/lua","/user/my_name/my_lua_scripts");
```

Using a single or double quotation mark in your path might cause unexpected results. If there are quotation marks or apostrophes, such as `Mark's dir`, use the LUA_PATH environment variable. For more information, see "Using the LUA_PATH Environment Variable with Special Characters".

Note: If you change the value of LUAPATH during a SAS session, call the LUA procedure and specify the RESTART option. The RESTART option resets the status of Lua in SAS and picks up the last value for LUAPATH.

You specify the name of the Lua script to execute by using the INFILE= option in the PROC LUA statement. For more information, see "Example 2: Specifying Input from an External Lua Script" on page 1427.

Using the LUA_PATH Environment Variable with Special Characters

To specify a special character, such as a single or double quotation mark, in the path to your Lua scripts, use the LUA_PATH environment variable. To set LUA_PATH for multiple paths, use Lua syntax, where each path is separated by a semicolon (;). The Lua syntax also uses a '?' for wildcard matching with LUA or LUC files. For example, you might specify a path that includes a single quotation mark like this:

```
options set=LUA_PATH="/usr/local/lua/?.lua;/usr/local/lua/
lua'files/?.luc";
proc lua infile="script";
run;
```

Running External Lua Files

You can run external scripts that are written in the Lua programming language from the SAS command line. You can run both uncompiled Lua scripts (*.lua files) or precompiled Lua scripts (*.luc files). Support for running external Lua files directly in SAS invocation was added in SAS 9.4M3.

Note: To create a precompiled *.luc file, you must have Lua 5.2 or higher. See your Lua documentation about how to use the Lua compiler.

To run Lua files at invocation, use the -SYSIN option. For example, to run the file abc.lua, submit this command:

```
sas -sysin abc.lua
```

You can also run external Lua scripts (*.lua or *.luc files) by using the %INCLUDE statement in a SAS session. For example, to run the Lua script abc.luc, enter the following line in your SAS program:

```
%include "./tmp/abc.luc";
```

Calling CAS Actions with PROC LUA

Requirements to Connect to the CAS Server

If your system runs a CAS server (most often, as part of SAS Viya), you can call CAS actions from PROC LUA. You need to know the following information to connect to the CAS server:

- the name of the server (host) that is running the CAS server
- the CAS server port
- your user ID, which must have permission to access the CAS server

The following resources must also be in place. These files are typically installed automatically as part of your SAS Viya installation:

- middleclass.lua
- swat.lua
- tkluaswat.so

For more information, see "Requirements" in *Getting Started with SAS Viya for Lua*.

To connect to the CAS server and run Lua code, you must load the appropriate settings and utilities in your SAS program. You must also load the SAS Scripting Wrapper for Analytics Transfer (SWAT) library. For more information, see "Example 13: Connecting to the CAS Server" on page 1453.

Functions That Interact with the CAS Server

Here are the functions that interact with the CAS server. For an example that shows how to connect to the CAS server, see "Example 13: Connecting to the CAS Server" on page 1453.

Note: It is a SAS convention to document function names in all capitals. However, when you call these functions within the LUA procedure, you must use all lower-case letters.

Lua-var:HELP{}
: requests the list of available CAS actions for the CAS session that is associated with the Lua variable. For example, you might specify `s:help{}` if you have assigned your CAS session to the Lua variable s.

CAS.OPEN("*host-name*", *port*, "*user-ID*")
opens a session on the CAS server. You provide the host name and port for the CAS server, and you supply your user ID. Your user ID must have permission to access the CAS server.

Assign the result of CAS.OPEN to a Lua variable that represents the CAS session:

```
s = cas.open("host.mycompany.com", 5570, "myuserid")
```

After you establish the connection, you can refer to the attributes of s, such as s.port or s.hostname.

Lua-var:SHUTDOWN{}
ends the CAS session that is associated with the Lua variable and closes the connection to the CAS server. For example, to close the CAS session represented by the Lua variable s, use this command:

```
s:shutdown{}
```

Support for VARCHAR Data with PROC LUA

Support for reading VARCHAR data was added in SAS Viya 3.3. VARCHAR data is supported on the CAS server only. This means that DATA steps that run entirely on the CAS server and any actions that support VARCHAR data can use VARCHAR values. For other tasks, VARCHAR data is first converted to fixed-length character data.

For more information, see "Determining Where the DATA Step Is Running" in *SAS Cloud Analytic Services: DATA Step Programming* and the documentation for an action, procedure, or function to ensure that VARCHAR data is supported.

Calling Standard SAS Functions within Lua Statements

You can run most standard SAS functions within Lua statements by preceding the function call with a "SAS." prefix. For example, to call the SAS function MAX, precede it with "SAS." as shown here:

```
local max = sas.max(a,b,c)
```

Note: Functions that run only in the DATA step, such as ADDRLONG, do not run in Lua code.

If you do not supply a value for a required argument in a SAS function, then the SAS function converts that argument to a missing value.

Submitting SAS Code within Lua Statements

Functions That Submit SAS Code

Because Lua is a scripting language within SAS, you can submit SAS code and substitute SAS values within Lua statements. You submit SAS code by using the following functions:

Note: It is a SAS convention to document function names in all capitals. However, when you call these functions within the LUA procedure, you must use all lower-case letters.

SAS.SUBMIT(*[[SAS code]]*, {*substitution(s)*})
submits and executes the specified SAS code when the function is issued within Lua statements. Enclose SAS code within [[and]] brackets.

When substitutions are provided, they are assigned first. Any remaining substitutions are supplied by local variables.

If no substitution values are submitted, then local variables from the calling function environment are used. Enclose variables for substitution within @ symbols. For example, to assign the value of a variable called userID to a variable user, issue the following assignment:

```
user = @userID@
```

Here is an example that shows the use of a substitution with the call to SAS.SUBMIT.

```
sas.submit([[
   data @name@;
   x = @x@;
run;
]],{name="foo"})
```

When you submit SAS code, do not include these keywords within SAS comments:

run; %macro
quit; %mend

The presence of these keywords within comments in a SAS code block might trigger warnings or errors in the SAS log and might cause unexpected results. To avoid this situation, modify the keywords by placing blank spaces or escape characters within them. For example, `run ;` or `\%\macro` within a comment would not trigger unexpected behavior.

The return value from SAS.SUBMIT is assigned to the value of the SYSERR automatic macro variable.

SAS.SUBMIT_(*SAS code*, *substitution(s)*)
: submits SAS code and substitution values but does not execute the code. You must issue the SAS.SUBMIT function (no underscore) to run all submitted SAS commands and end preceding calls to SAS.SUBMIT_.

  If no substitution values are submitted, then local variables from the calling function environment are used. Enclose variables for substitution within @ symbols.

For more information, see "Opening a SAS Data Set within Lua Code" on page 1425.

About Lua Variable Substitution within SAS Statements

Variable substitutions are made via a hash table that contains key-value pairs. The key-value pairs are defined by the Lua variable assignments that are made within the submitted Lua statements. To substitute a value, enclose a key within @ symbols, such as @key@. The value of @key@ is replaced with its corresponding value. All substitutions are case sensitive, so @key@ and @Key@ are different key values.

Scope for PROC LUA

Any filerefs, librefs, and local variables that are defined within a call to PROC LUA are defined only for the duration of that procedure call. Similarly, macro variables and macro definitions that are created within a PROC LUA call can be used only within that procedure call. You cannot refer to these objects outside of the LUA procedure.

How PROC LUA Interprets Math.Huge

In Lua, the constant math.huge is a computer representation of infinity. SAS represents this value with the constant value 1.7976931348623E308.

How Lua Interprets Boolean Values

Lua has two data types that are used in the Boolean context. There is a Nil type, which can take the single value of **`nil`**. There is a Boolean type, which can take values **`true`** or **`false`**. In Lua, the values **`nil`** or **`false`** are considered to be false. All other values, including 0, are considered to be true.

In SAS, there are many numeric functions that return a value of 1 if a condition is true and 0 if that condition is false. Examples of these functions include SYMEXIST, SYMLOCAL, SYMGLOBAL, and MISSING. Other SAS functions, such as the ANY* character functions, search a string for given characters and return the position of the first occurrence in the string. These functions return 0 if the characters are not found.

If you call any of these SAS functions in your Lua code, make sure that your Lua code interprets the results as intended.

For example, suppose that the macro variable FOOBAR is not defined. Therefore, it does not exist in a local symbol table. The following code incorrectly states that the variable does exist and is local.

```
/* INCORRECT use of SAS Boolean functions */
proc lua;
   submit;
      if sas.symexist("foobar") then
         if sas.symlocal("foobar") then
            print("In Proc LUA, foobar exists and is LOCAL.")
         else
            print("In Proc LUA, foobar exists but is not LOCAL.")
         end
      else
         print(In Proc LUA, foobar does not exist.")
      end
   endsubmit;
run;
```

The preceding code incorrectly states that FOOBAR exists and is local, because the 0 value that is returned by the SAS functions SYMEXIST and SYMLOCAL are interpreted as true in Lua.

Instead, when you call SAS Boolean functions, explicitly test for the desired return value in your Lua code. The following code correctly tests to see whether the macro variable FOOBAR exists and is local.

```
/* CORRECT use of SAS Boolean functions */
proc lua;
   submit;
      if sas.symexist("foobar") == 1 then
         if sas.symlocal("foobar") == 1 then
            print("In Proc LUA, foobar exists and is LOCAL.")
         else
            print("In Proc LUA, foobar exists but is not LOCAL.")
         end
      else
         print("In Proc LUA, foobar does not exist.")
      end
   endsubmit;
run;
```

The preceding code correctly states that the macro variable FOOBAR does not exist and is not local, because it was never defined. The return value of 0 from the SAS function SYMEXIST is now explicitly compared to the value 1.

Data Set Functions for the LUA Procedure

The following functions have been defined to run in the LUA procedure. These functions interact with SAS or with data sets.

For small data sets, you can read an entire SAS data set into a Lua table. You can then modify or query the Lua table, and you can write changes to a new SAS data set. However, for large data sets, it is more efficient to process the data one observation at a time, as you would with a DATA step. For this reason, you should submit a DATA step within your Lua code for large data sets.

Here are the data set functions that run within the LUA procedure:

Note: It is a SAS convention to document function names in all capitals. However, when you call these functions within the LUA procedure, you must use all lower-case letters.

SAS.ADD_VARS(*data-set-ID*, *variable-definitions*)
adds the specified Lua variables to a new data set. That is, use SAS.ADD_VARS only when you open a data set using SAS.OPEN with mode 'o'.

The format for defining variables is as follows:

```
{ {name="varname", type="N|C",
format="format.", length="value",
label="varlabel", informat="informat."},
{additional variable definition}, ...
}
```

Only the variable name is required. The default variable type is numeric (N) if the Lua variable with the same name is also numeric. The default length of character variables is 200.

You can specify full SAS formats, such as `format="best12.3"`. If you supply a format that includes a period (.), then the system expects that the format is complete and additional format attributes are ignored. If you do not supply a full SAS format, you can use a combination of these variable attributes to provide the format of a variable:

- FORMAT specifies no length nor decimal specification (for example, `format="best"`)
- FORMAT_WIDTH specifies the number of characters or digits (for example, `format_width=12`)
- FORMAT_DEC specifies the number of decimal places (for example, `format_dec=3`)

For more information, see "Example 12: Defining and Adding Variables to a Data Set" on page 1452.

SAS.ATTR(*data-set-ID*, *attribute-name*)
returns the value of *attribute-name* for a data set. For example, `sas.attr(data-set-ID, 'label')` returns the label for the specified data set.

SAS.CLOSE(*data-set-ID*)
closes an open data set. This function exits if the data set ID is not valid.

SAS.EXISTS(*SAS-data-set-name*)
returns the Boolean value **`true`** if the data set exists or **`false`** if the data set does not exist.

Note: This function is different from the standard SAS function EXIST (with no 's' as the end), which returns a 0 or 1 value. In Lua code, 0 and 1 are interpreted as true. As an alternative, test whether the condition `(sas.exist("work.test") > 0)` is true. The SAS.EXISTS function is available only within Lua code blocks.

SAS.NOBS(*data-set-ID*)
returns the number of observations in a data set.

SAS.NVARS(*data-set-ID*)
returns the number of variables in a data set.

SAS.OPEN(*SAS-data-set-name<, mode>*)
opens a SAS data set and returns a data set ID if the data set opens successfully. If the data set does not open, then the function returns **`nil`**. Therefore, use the SAS.EXISTS function before calling the SAS.OPEN function.

In SAS 9.4M5, support was added for specifying data set options, such as KEEP=, DROP=, or WHERE=. For example, you can open the data set Sashelp.Class and keep only the variable Age with the following code:

```
local dsid = sas.open('sashelp.class(keep=age)')
```

Valid data set modes are *I* (for reading), *O* (for creating), and *U* (for updating). If you do not supply a value for data set mode, then the default value of I is used.

SAS.READ_DS(*SAS-data-set-name*)
returns a Lua table that contains the data from the specified SAS data set. If the data set does not exist, the function returns **`nil`**. Therefore, use the SAS.EXISTS function before calling the SAS.READ_DS function.

As a best practice, use the SAS.READ_DS function for small data sets only. For large data sets, iterate over observations with the functions that process individual observations. For more information, see "Functions That Process Observations" on page 1414.

Alias: SAS.LOAD_DS(*SAS-data-set-name*)

SAS.SET_ATTR(*data-set-ID*, *attribute-name*, *value*)
assigns a value to an attribute of a data set.

SAS.WHERE(*data-set-ID*, *where-clause*)
applies a WHERE clause to a data set. If there is a previously existing WHERE clause for the data set, then the specified WHERE clause is added to the previous one. However, if the Boolean value for the optional *replace-where-clause* argument is true, then the specified WHERE clause replaces a previously existing WHERE clause.

The return code from this function is an integer value. Because Lua interprets all integer values as true, explicitly test the return value to see whether it is equal to 0 (false in SAS).

Operations such as `sas.where(dsid, "also <new condition>")`, `sas.where(dsid, "undo")`, and `sas.where(dsid, "clear")` are supported. For more information, see *SAS Component Language: Reference*.

You can submit Lua statements similar to the following to apply a WHERE clause to a data set:

```
sas.submit("data work.air; set sashelp.air; run;")
dsid = sas.open("work.air")
rc, msg = sas.where(dsid,"air=222 or air=999")
print(rc, msg)
rc=sas.close(dsid)
```

SAS.WRITE_DS(*Lua-table*, *SAS-data-set-name*)
creates a SAS data set from a Lua table. You can specify a two-level name for the SAS data set, such as Work.Random. The Lua table must conform to the same structure that is returned by the SAS.READ_DS function.

Processing Data Set Observations

Functions That Process Observations

You can use the following Lua functions to process individual observations within a data set. You must first open the data set in Update mode ('u').

Note: It is a SAS convention to document function names in all capitals. However, when you call these functions within the LUA procedure, you must use all lower-case letters.

SAS.APPEND(*data-set-ID*)
appends a newly created observation to a data set.

SAS.DELOBS(*data-set-ID*)
deletes the current observation in a data set.

SAS.GET_VALUE(*data-set-ID*, *variable-number | variable-name*)
returns the value of the specified variable in the current observation. Identify the variable by its position (number) in the data set or by its name.

SAS.NEXT(*data-set-ID*)
moves to the next observation in a data set for processing. If you have not yet begun processing a data set, the SAS.NEXT function moves to the first observation in that data set. The SAS.NEXT function enables you to work directly with a SAS data set without needing to first read the data into a Lua table. This function is useful for large data sets.

SAS.PUT_VALUE(*data-set-ID*, *variable-name*, *value*)
loads a value into the specified variable in a data set.

Note: The SAS.PUT_VALUE function and syntax replaced the SAS.PUT function and syntax in SAS 9.4M5. Use only the name to identify a variable, not the position in the data set, which was allowed with the SAS.PUT function.

SAS.ROWS(*data-set-ID*)
iterates over the observations in a data set, loads each row into a Lua table for processing, and adds a Lua nil at the end of processing. This function is useful for data sets with relatively few variables.

SAS.UPDATE(*data-set-ID*)
updates an observation with values that were added by calling the SAS.PUT_VALUE function.

SAS.VARS(*data-set-ID*)
iterates over the variables in a data set.

Sequence to Add an Observation

To add a new observation, call the observation-processing functions in the following order:

1. SAS.APPEND.
2. SAS.PUT_VALUE. Repeat this function call until values are set for all desired variables in an observation.
3. SAS.UPDATE.

Out of Scope Warning

If a data set ID (handle) goes out of scope, then the associated SAS data set is automatically closed if it has not been closed already. A warning similar to the following appears in the SAS log:

```
WARNING: Closing SASHELP.CLASS - handle has gone out of scope.
```

A data set ID goes out of scope when the program is no longer able to access it. For example, when a data set ID is defined as a local variable in a user-defined function, the data set ID becomes out of scope at the end of that function definition. As a best practice, close a data set before the data set ID goes out of scope.

System Functions for the LUA Procedure

The following functions control the behavior of SAS code that is submitted from within the LUA procedure. For more information, see "Submitting SAS Code within Lua Statements" on page 1409.

Note: It is a SAS convention to document function names in all capitals. However, when you call these functions within the LUA procedure, you must use all lowercase letters.

SAS.GET_MAX_SYSERR()
: returns the current maximum SYSERR value that can be returned from calls to SAS.SUBMIT without triggering an error in the SAS log.

SAS.IS_QUIET()
: returns **`true`** or **`false`**, depending on the value that was set using the SAS.SET_QUIET function. This Boolean value indicates whether SAS language statements that are submitted to the SAS.SUBMIT function are written to the SAS log.

SAS.SET_MAX_SYSERR(*value*)
: specifies the maximum allowable SYSERR value that can be returned by SAS.SUBMIT calls. If SAS returns a SYSERR value greater than the specified value, an error is printed in the SAS log. The default is zero, and possible values include positive integers.

SAS.SET_QUIET(*value*)
: specifies whether SAS language statements that are submitted to the SAS.SUBMIT function are written to the SAS log.

  Possible argument values are **`true`** or **`false`**. The default value is **`false`**.

About Lua Libraries

Lua Libraries and SAS Extensions to Lua

The Lua programming language contains several libraries that can be used to manipulate tables and strings and to perform common math functions. Most of these functions are available to the LUA procedure. In addition, there are functions that were created for PROC LUA as an extension of the Lua language. These functions enable you to work with tables and strings and to perform calculations on your data. These extension functions are available within PROC LUA, but they are

not part of the Lua programming language and cannot be used outside of PROC LUA.

Restrictions to the Lua IO Library

When SAS is running in lockdown mode (in a locked-down state), access to functions in the Lua IO library is restricted. It is possible for a SAS administrator to disable this restriction. For more information, see LOCKDOWN Statement.

Table Functions for PROC LUA

Here some of the table functions that are available with PROC LUA. You call these functions by preceding them with 'TABLE', such as `table.size(t)`.

Note: It is a SAS convention to document function names in all capitals. However, when you call these functions within the LUA procedure, you must use all lower-case letters.

Here are some of the commonly used table functions from the Lua table library that are available to PROC LUA.

TABLE.CONCAT(*Lua-table*<, "*delimiter*"><, *start-position*<, *end-position*>>)

TABLE.INSERT(*Lua-table*, <*position*, > *value*)

TABLE.REMOVE(*Lua-table*<, *position*>)

TABLE.SORT(*Lua-table*<, *comparison-function*>)

Here are table functions that have been created specifically for PROC LUA. These functions can be called only within PROC LUA.

TABLE.CONTAINS(*Lua-table-name*,*v*)
returns the Boolean value **`true`** if the specified table contains the value *v*. Enclose character values in single or double quotation marks.

For example, suppose you have created table T with a list of names. You can check to see whether a text string is contained in that table and print an appropriate message to the log.

```
local t = {"John", "Paul", "George", "Ringo"}

if (table.contains(t,"Ringo")) then
   print ("The table contains 'Ringo'.")
else
   print ("The table does not contain 'Ringo'.")
end
```

TABLE.SIZE(*Lua-table-name*)
returns the number of elements in the specified table.

TABLE.TOSTRING(*Lua-table-name*)
returns a formatted string representation of the specified table.

For more information, see "Example 3: Loading a SAS Data Set and Viewing the Resulting Lua Table" on page 1428 and "Example 5: Using Table Functions" on page 1434.

Functions That Manipulate Strings

Here are the string functions that are available with PROC LUA. You call these functions by preceding them with 'STRING', such as `string.trim(`*`text-variable`*`)`.

Note: It is a SAS convention to document function names in all capitals. However, when you call these functions within the LUA procedure, you must use all lowercase letters.

These string functions have been created specifically for PROC LUA. These functions can be called only within PROC LUA.

STRING.ENDS_WITH(*string1*, *string2*)
returns a Boolean that indicates whether the end of String1 matches the value of String2. The comparison is case sensitive. Enclose a literal text value in quotation marks.

Note: Support for STRING.ENDS_WITH was added in SAS Viya 3.4.

STRING.RESOLVE(*string*, {token1="*text-value1*"<, token2="*text-value2*"<, ...>>});
returns a string with tokens substituted into it. You provide a string variable with a value that contains substitution tokens in the format @*token-name*@. For each token, you provide a text value to substitute into the returned string value.

For example, suppose you have declared the variable Code:

```
local code="data @results@; set @in@; where @where@; run;"
```

You can provide substitute values for the tokens results, in, and where:

```
string.resolve(code, {results="work.foo", in="bar", where="x > 2"})
```

This call to STRING.RESOLVE returns this string:

```
data work.foo; set bar; where x > 2; run;
```

Note: Support for STRING.RESOLVE was added in SAS Viya 3.4.

STRING.SPLIT(*string*, *delimiter*, *remove-empty-strings*)
separates a string value into a table of substrings by using the specified delimiter value. Enclose the delimiter value in single or double quotation marks or inside double square brackets ([[ ]]). Use the last argument, a Boolean value, to specify whether to remove empty strings from the resulting table. By default, the last argument is TRUE.

Note: Support for STRING.SPLIT was added in SAS Viya 3.4.

STRING.STARTS_WITH(*string1*, *string2*)
returns a Boolean that indicates whether the beginning of String1 matches the value of String2. The comparison is case sensitive. Enclose a literal text value in single or double quotation marks or inside double square brackets ([[ ]]).

Note: Support for STRING.STARTS_WITH was added in SAS Viya 3.4.

STRING.TRIM(*string*)
returns a string with whitespace characters removed from the beginning and end of the original string value. Enclose literal text in single or double quotation marks or inside double square brackets ([[ ]]).

Note: Support for STRING.TRIM was added in SAS Viya 3.4.

For more information, see "Example 6: Using String Functions" on page 1436.

Object Syntax within Lua Statements

For some objects, such as data set IDs, Lua code supports object syntax, where you specify a function preceded by the object that the function is to act upon. For example, the following Lua statements are equivalent:

```
local luavar = sas.get_value(dsid, 'some_var')

local luavar = dsid:get_value('some_var')
```

Make sure that you use a colon (:) when placing the object name before the function that it acts upon.

Similarly, the following code block from "Example 11: Using Iterator Functions for a Large Table" on page 1449 could be written in two ways.

```
-- Iterate over the rows of the data set
local i=0
while sas.next(dsid) do
   i=i+1
   print("OBS=" .. i)
   for vname,var in pairs(vars) do
      print(vname, '=', sas.get_value(dsid, vname) )
   end
end
```

The SAS.NEXT and SAS.GET_VALUE functions can both be represented with object syntax.

```
-- Iterate over the rows of the data set
local i=0
while dsid:next() do
   i=i+1
```

```
      print("OBS=" .. i)
      for vname,var in pairs(vars) do
         print(vname, '=', dsid:get_value(vname) )
      end
   end
```

Calling PROC FCMP Functions within Lua Statements

You can submit functions that are created using the FCMP procedure within Lua code. When you call PROC FCMP functions, you must specify the package in which the function is stored in the SAS OPTIONS statement.

If a PROC FCMP function modifies one of its arguments, that argument is specified in the OUTARGS statement. To retrieve changes to an argument in the OUTARGS statement within Lua code, that argument must be defined as an array.

For more information, see the following information:

- Chapter 24, “FCMP Procedure,” on page 873
- “Example 14: Running PROC FCMP Functions” on page 1458

Using the FULLSTIMER Option with PROC LUA

When you use the FULLSTIMER option with PROC LUA, the run times that FULLSTIMER reports in the log reflect the aggregate of run times for SAS code that is called within the LUA procedure. The run times include the run time of the LUA procedure itself.

For example, consider PROC LUA code that calls the SORT procedure three times. You might see the following output in the SAS log.

Output 39.1 *PROC LUA Output Using FULLSTIMER*

```
proc sort data=one; by i; run;
NOTE: There were 10000 observations read from the data set WORK.ONE.
NOTE: The data set WORK.ONE has 10000 observations and 2 variables.
NOTE: PROCEDURE SORT used (Total process time):
real time           0.03 seconds
user cpu time       0.03 seconds
system cpu time     0.00 seconds
memory              2252.60k
OS Memory           14492.00k
Timestamp           10/20/2015 11:43:40 AM
Step Count                        10  Switch Count  0

proc sort data=two; by i; run;
NOTE: There were 10000000 observations read from the data set WORK.TWO.
NOTE: The data set WORK.TWO has 10000000 observations and 2 variables.
NOTE: PROCEDURE SORT used (Total process time):
real time           8.03 seconds
user cpu time       12.34 seconds
system cpu time     0.70 seconds
memory              71231.17k
OS Memory           83136.00k
Timestamp           10/20/2015 11:43:48 AM
Step Count                        10  Switch Count  0

proc sort data=three; by i; run;
NOTE: There were 100 observations read from the data set WORK.THREE.
NOTE: The data set WORK.THREE has 100 observations and 2 variables.
NOTE: PROCEDURE SORT used (Total process time):
real time           0.01 seconds
user cpu time       0.00 seconds
system cpu time     0.01 seconds
memory              71231.17k
OS Memory           83136.00k
Timestamp           10/20/2015 11:43:48 AM
Step Count                        10  Switch Count  0

NOTE: PROCEDURE LUA used (Total process time):
real time           8.15 seconds
user cpu time       12.37 seconds
system cpu time     0.78 seconds
memory              71231.17k
OS Memory           83136.00k
Timestamp           10/20/2015 11:43:48 AM
Step Count                        10  Switch Count  0
```

In the output, the system CPU time, 0.78 seconds, reflects the aggregate of the calls to PROC SORT and additional CPU time that is used by PROC LUA.

Syntax: LUA Procedure

PROC LUA <INFILE='*filename*'> <RESTART> <TERMINATE>;

<SUBMIT <"*assignment(s);*">;>

... Lua statements ...

<ENDSUBMIT;>

```
run;
```

Statement	Task
PROC LUA	Execute Lua statements within SAS code or specify a file that contains Lua statements to execute
SUBMIT	Identify the beginning of a block of Lua statements
ENDSUBMIT	Identify the end of a block of Lua statements

PROC LUA Statement

Runs Lua statements within a SAS session.

Syntax

PROC LUA <INFILE='*filename*'> <RESTART> <TERMINATE>;

Optional Arguments

INFILE= '*filename*'
identifies a source file that contains Lua statements to run within a SAS session. SAS expects this file to end with a `.lua` file extension, but do not include the extension in the filename that you specify.

Requirements: Enclose the filename in single or double quotation marks.

If you use the INFILE= option, then you must specify the path to the Lua script. Define the path to your Lua scripts by providing a value for the LUAPATH filename before the PROC LUA statement. For more information, see "Example 2: Specifying Input from an External Lua Script" on page 1427.

Example: Specify
`INFILE='open_data'`
to use the code in the open_data.lua Lua script file.

RESTART
resets the state of Lua code submissions for a SAS session. The LUA procedure is a reentrant procedure that maintains the state for Lua code across calls to the LUA procedure. This means that global Lua variable assignments or function definitions remain in memory until you issue the RESTART option, issue the TERMINATE option, or end the SAS session.

You can specify RESTART at the beginning of a new block of Lua code.

Example
```
proc lua restart;
submit;
  <lua statements...>
endsubmit;
run;
```

TERMINATE
stops maintaining the Lua code state in memory and terminates the Lua state when the LUA procedure completes. Subsequent calls to the LUA procedure begin a new instance of the Lua code state.

SUBMIT Statement

Identifies the beginning of a block of Lua code. Enter Lua statements between the SUBMIT and ENDSUBMIT statements.

Requirement: Each SUBMIT statement must have a corresponding ENDSUBMIT statement.

Syntax

SUBMIT <*'assignment(s);'*>;

Optional Argument

assignment(s)
identifies one or more macro variable assignments that are passed to the block of Lua statements. If only one assignment is listed, then the semicolon (;) within the quotation marks is not required. SAS does not expand macro variables within a block of Lua statements. Therefore, macro values must be passed within the list of assignments for the SUBMIT statement.

Example To assign the value of macro variable N to the Lua variable Name, enter the following SUBMIT statement:
```
SUBMIT "name=&n";
```

ENDSUBMIT Statement

Identifies the end of a block of Lua statements. Do not enter any other statement on the same line as the ENDSUBMIT statement.

Syntax

ENDSUBMIT;

Usage: LUA Procedure

Submitting Lua Statements within a SAS Program

You can submit Lua statements within the PROC LUA invocation, between SUBMIT and ENDSUBMIT statements. The following code executes a single Lua print statement.

```
proc lua;
submit;
   print("Hello from Lua")
endsubmit;
run;
```

Any filerefs, librefs, macro variables, and so on, that you define within a SUBMIT and ENDSUBMIT block are available only within that block of code.

For example, the macro variable Mymacrovar is defined within the SUBMIT and ENSUBMIT block in the following call to PROC LUA. However, the variable is not defined in the %PUT statement at the end of the example.

```
proc lua restart;
submit;
   sas.submit([[%let mymacrovar=Hi there;]])
   txt = sas.symget("mymacrovar")
   print(txt)
endsubmit;
run;

%put &mymacrovar;
```

Output 39.2 *Scope for Macro Variable in PROC LUA*

```
%let mymacrovar=Hi there;
Hi there
NOTE: PROCEDURE LUA used (Total process time):
      real time           0.14 seconds
      cpu time            0.07 seconds

WARNING: Apparent symbolic reference MYMACROVAR not resolved.
17
18   %put &mymacrovar;
&mymacrovar
```

Opening a SAS Data Set within Lua Code

Calling the SAS.SUBMIT function enables you to submit a block of SAS code. Enclose the SAS code within [[and]] brackets. The submitted code in this sample first verifies that the SAS data set exists. You can make any changes to the data, via the submitted DATA step, that you would in Base SAS code.

```
/* Test whether a data set exists */
proc lua;
submit;
   if sas.exists("sashelp.air") then
      print("The data set SASHELP.AIR exists.")
   else
      print("The data set SASHELP.AIR does not exist.")
   end
endsubmit;
run;
```

If the data set exists, then you can open the data set and read it into a new data set, WORK.AIR. You can make any changes to the data via the submitted DATA step that you would in a typical DATA step.

Note: Longer blocks of SAS code are typically assigned to a Lua variable.

```
proc lua;
submit;
   sas.submit( [[ data work.air; set sashelp.air; run; ]] )
endsubmit;
run;
```

You can also substitute Lua variable values within the SAS code. The following code shows simple substitutions. For more information, see "Example 9: Submitting SAS Code with Lua Variable Substitutions" on page 1444.

```
proc lua;
submit;
   local dest = 'work.class'
   local source = 'sashelp.class'
```

```
   sas.submit( [[ data @dest@; set @source@; run; ]] )
endsubmit;
run;
```

Examples: LUA Procedure

Example 1: Create a Sample Data Set

This example creates a sample SAS data set, Homes, that contains several variables and 20 observations. This data set is the input for some of the examples that follow.

Here is the code to create a sample data set that can be accessed using PROC LUA.

```
data homes;
  input bad loan mortdue value reason $ job $ yoj derog delinq
        clage ninq clno debtinc;
datalines;

;
```

Example 2: Specifying Input from an External Lua Script

Features: FILENAME statement
PROC LUA statement, INFILE= option

Details

This example specifies an external Lua script and one or more possible paths to that script by using the FILENAME statement and the INFILE= option in the PROC LUA statement.

Program

```
filename LUAPATH ('/usr/local/scripts/lua','/home/user/myname/
my_scripts');

proc lua infile='my_script';
run;
```

Program Description

Specify the directories to search for the input Lua script. The FILENAME statement defines the directories in which Lua scripts are stored and assigns them to the LUAPATH fileref. Enclose a directory path within single or double quotation marks.

```
filename LUAPATH ('/usr/local/scripts/lua','/home/user/myname/
my_scripts');
```

Execute the PROC LUA statement and specify the Lua script name. The INFILE= option provides the name of the Lua script that contains Lua statements. In this example, SAS executes the Lua statements in the my_script.lua file. Do not specify the '.lua' or '.luc' file extension. Check the package.path variable for your system to see whether LUA or LUC files are opened first.

```
proc lua infile='my_script';
run;
```

Example 3: Loading a SAS Data Set and Viewing the Resulting Lua Table

Features: SAS.EXISTS function
SAS.READ_DS function
Observation processing: WHILE and FOR loops

Details

This example uses the Homes data set that you created in Example 1.

In this example, you read the SAS data set Homes and print the data to the SAS log. Treat individual observations as an entry in an array. Each array entry contains associated attributes that are derived from the variables in the original SAS data set. For example, the value of t[2].loan is **4700**.

Program

```
proc lua;
submit;
   if (sas.exists("work.homes")) then
      local t = sas.read_ds("work.homes")
      i=1

      while(t[i] ~= nil) do
         print("Obs #" .. i)
         for k,v in pairs(t[i]) do
             print(k,v)
         end
         print("\n")
         i = i+1
      end

   end
endsubmit;
run;
```

Program Description

Verify that the SAS data set Homes exists and read it into the Lua table T. Each observation in the data set can be accessed as if it were in an array, such as t[i].

```
proc lua;
submit;
   if (sas.exists("work.homes")) then
      local t = sas.read_ds("work.homes")
      i=1
```

Process each observation in the data set. Initialize an iterator, i, and process each observation by using a WHILE loop. Check to see whether the next observation exists and then print each variable-value pair. Use a FOR loop to process each variable name and value, printing both to the SAS log. At the end of each observation, print a newline character and increment i.

```
      while(t[i] ~= nil) do
         print("Obs #" .. i)
         for k,v in pairs(t[i]) do
             print(k,v)
         end
         print("\n")
         i = i+1
      end
```

Submit the PROC LUA call to SAS.

```
   end
endsubmit;
run;
```

Output: Lua Table

```

Example 4: Writing a SAS Data Set from a Lua Table

Features: PROC LUA statement
SUBMIT and ENDSUBMIT statements
SAS.WRITE_DS function
TABLE.TOSTRING function

Details

This example creates a Lua table and then writes that table to a SAS data set. The values in the Lua table are generated by calling the SAS RANNOR and RANUNI random number generator functions. This code also uses Lua conventions for processing arrays.

Program

```
proc lua;
submit;
   local tbl = {}

   for i=1,10 do
       vars = {}
       vars.seed = 1234 * i;
       vars.randnor = sas.rannor( vars.seed )
       vars.randuni = sas.ranuni( vars.seed )
       vars.color = "purple"
       tbl[#tbl+1] = vars
   end

   print("Lua table:", table.tostring(tbl))

   sas.write_ds(tbl, "work.random")
endsubmit;
run;

proc print data=random;run;
```

Program Description

Execute the PROC LUA statement and begin a block of Lua code. Declare a local Lua array called `TBL`.

```
proc lua;
submit;
   local tbl = {}
```

Generate the contents of the Lua table. This example generates the content for the array `TBL`. The variables Seed, Randnor, Randuni, and Color are created and assigned a value over ten iterations of a FOR loop.

```
   for i=1,10 do
       vars = {}
```

```
        vars.seed = 1234 * i;
        vars.randnor = sas.rannor( vars.seed )
        vars.randuni = sas.ranuni( vars.seed )
        vars.color = "purple"
        tbl[#tbl+1] = vars
    end
```

Print the generated Lua table. The resulting Lua table is printed to the SAS log.

```
    print("Lua table:", table.tostring(tbl))
```

Write the Lua table to a SAS data set. This example writes the Lua table to a SAS data set called Random in the Work library. By saving the data set to the Work library, it is accessible only within the same SAS session. You can save the data set permanently by saving it to a library, such as Sasuser.

```
    sas.write_ds(tbl, "work.random")
endsubmit;
run;
```

Print the SAS data set. After you have written the SAS data set, you can access it outside of the LUA procedure. If you save the data set to a library, such as Sasuser, then the data set is accessible in later SAS sessions.

```
proc print data=random;run;
```

Output: SAS Table from a Lua Table

Output 39.4 *Partial Lua Table from the SAS Log*

```
Lua table:    table: 000000002892EAE0=
{
  [1]=table: 00000000289359A0=
  {
    ["color"]="purple"
    ["randuni"]=0.3831937143

Example 5: Using Table Functions

Features:
PROC LUA statement
SUBMIT and ENDSUBMIT statements
TABLE.CONCAT function
TABLE.INSERT function
TABLE.REMOVE function
TABLE.SIZE function
TABLE.SORT function
TABLE.TOSTRING function

Details

This example creates a simple table, prints the number of elements, and prints the table to the SAS log.

Program

```
proc lua;
submit;

  local t={"a", "b", "c", "foo", "bar"}

  print(table.size(t))
  print("Output with function TABLE.TOSTRING")
  print(table.tostring(t))
  print("Output with function TABLE.CONCAT")
  print(table.concat(t, ", "))

  print("Inserting and Removing Values")
  table.insert(t,5,"new")
  print("Table with new value: ", table.concat(t,", "))
  table.remove(t,4)
  print("Table after removing value at position 4: ",
table.concat(t,", "))

  print("Sorting a Table")
  table.sort(t)
  print("Table with sorted values: ",table.concat(t,", "))
  table.sort(t, function(a,b) return a>b end)
```

```
  print("Table sorted in descending order: ",table.concat(t,", "))
endsubmit;
run;
```

Program Description

Execute the PROC LUA statement. The PROC LUA statement enables you to call Lua code within your SAS session.

```
proc lua;
```

Identify the beginning of a block of Lua statements. The SUBMIT statement identifies the beginning of a block of Lua statements.

```
submit;
```

Create a simple table. Assign elements in a table T.

```
  local t={"a", "b", "c", "foo", "bar"}
```

Print information about the table. Print the number of elements in the table and then print the table using the TABLE.TOSTRING function and the TABLE.CONCAT function.

```
  print(table.size(t))
  print("Output with function TABLE.TOSTRING")
  print(table.tostring(t))
  print("Output with function TABLE.CONCAT")
  print(table.concat(t, ", "))
```

Insert and remove items in the table. Print a label, and then insert the value "new" into the table in the fifth position using the TABLE.INSERT function. Print the table to see the added value. Remove the value in the fourth position in the table, "foo", using the TABLE.REMOVE function. Print the resulting table.

```
  print("Inserting and Removing Values")
  table.insert(t,5,"new")
  print("Table with new value: ", table.concat(t,", "))
  table.remove(t,4)
  print("Table after removing value at position 4: ",
table.concat(t,", "))
```

Sort values in the table. Print a label, and then sort the table in ascending order using the TABLE.SORT function. Print the resulting table to see the sorted values. Next, sort the table again and specify a function that sorts the table in descending order. Print the resulting table.

```
  print("Sorting a Table")
  table.sort(t)
  print("Table with sorted values: ",table.concat(t,", "))
  table.sort(t, function(a,b) return a>b end)
  print("Table sorted in descending order: ",table.concat(t,", "))
```

Identify the end of a block of Lua statements with the ENDSUBMIT statement.

```
endsubmit;
run;
```

Output: SAS Log That Shows Table Details

Output 39.6 *Results of TABLE Functions*

```
Output with function TABLE.TOSTRING
table: 00000000289200E0=
{
  [1]="a"
  [2]="b"
  [3]="c"
  [4]="foo"
  [5]="bar"
}
Output with function TABLE.CONCAT
a, b, c, foo, bar
Inserting and Removing Values
Table with new value:     a, b, c, foo, new, bar
Table after removing value at position 4:     a, b, c, new, bar
Sorting a Table
Table with sorted values:     a, b, bar, c, new
Table sorted in descending order:     new, c, bar, b, a
NOTE: PROCEDURE LUA used (Total process time):
      real time           0.03 seconds
      cpu time            0.01 seconds
```

Example 6: Using String Functions

Features:

PROC LUA statement
SUBMIT and ENDSUBMIT statements
STRING.ENDS_WITH function
STRING.RESOLVE function
STRING.SPLIT function
STRING.STARTS_WITH function
STRING.TRIM function

Details

This example uses the STRING functions to manipulate text values.

Program

```
proc lua;
   submit;

   mystring = "@noun@ @verb@ the @object@"

   newstring1 = string.resolve(mystring,
{noun="Pigs",verb="eat",object="pie"})
   newstring2 = string.resolve(mystring, {noun="Cars",verb="guzzle",
                               object="gasoline"})

   print ("Original string: " .. mystring)
   print ("New string 1: " .. newstring1)
   print ("New string 2: " .. newstring2)

   if string.starts_with(newstring2, "Cars") then
      print("Could be about cars: " .. newstring2)
   else
      print("Not about cars: " .. newstring2)
   end

   if string.ends_with(newstring2, "pie") then
      print ("I love pie!" .. newstring2)
   else
      print("Too bad. No pie: " .. newstring2)
   end

   mystring = "     The fox ate the chicken.  "
   trimmedstring = string.trim(mystring)

   print ("Original string between ***s: ***" .. mystring .. "***")
   print ("Trimmed string between ***s:  ***" .. trimmedstring ..
"***")

   t = string.split(mystring," ")

   for element in pairs(t) do
      print("Table index " .. element .. ", Value is: " ..
t[element] .. "\n")
   end

   endsubmit;
run;
```

Program Description

Execute the PROC LUA statement and begin processing Lua statements. The PROC LUA statement enables you to call Lua code within your SAS session. The SUBMIT statement identifies the beginning of a block of Lua statements.

```
proc lua;
```

```
submit;
```

Create a string variable and substitute different values in it. Create a string, Mystring, that contains substitution tokens Noun, Verb, and Object. Use the STRING.RESOLVE function to generate new strings, Newstring1 and Newstring2. Print the original string and the new strings to the SAS log.

```
mystring = "@noun@ @verb@ the @object@"

newstring1 = string.resolve(mystring,
{noun="Pigs",verb="eat",object="pie"})
newstring2 = string.resolve(mystring, {noun="Cars",verb="guzzle",
                            object="gasoline"})

print ("Original string: " .. mystring)
print ("New string 1: " .. newstring1)
print ("New string 2: " .. newstring2)
```

Look for matching at the beginning and end of string variables. Use the STRING.STARTS_WITH function to check whether Newstring2 begins with “Cars” and then print the appropriate message. Next, use the STRING.ENDS_WITH function to check whether Newstring2 ends with “pie” and then print the appropriate message.

```
if string.starts_with(newstring2, "Cars") then
   print("Could be about cars: " .. newstring2)
else
   print("Not about cars: " .. newstring2)
end

if string.ends_with(newstring2, "pie") then
   print ("I love pie!" .. newstring2)
else
   print("Too bad. No pie: " .. newstring2)
end
```

Trim leading and trailing whitespace characters from a string value. Assign a new value to Mystring. Use the STRING.TRIM function to remove leading and trailing whitespace characters. Print the original and trimmed strings for comparison.

```
mystring = "     The fox ate the chicken.  "
trimmedstring = string.trim(mystring)

print ("Original string between ***s: ***" .. mystring .. "***")
print ("Trimmed string between ***s:  ***" .. trimmedstring ..
"***")
```

Create a list of words in a sentence string. Use the STRING.SPLIT function to generate a list of individual words from the string Mystring. By default, blank values are not included in the resulting list. Print the list of words in Mystring.

```
t = string.split(mystring," ")

for element in pairs(t) do
   print("Table index " .. element .. ", Value is: " ..
t[element] .. "\n")
```

```
end
```

End the block of Lua statements and run the LUA procedure. End the block of Lua statements with the ENDSUBMIT statement.

```
    endsubmit;
run;
```

Output: SAS Log That Shows String Function Results

Output 39.7 *Results of STRING Functions*

```
NOTE: Lua initialized.
Original string: @noun@ @verb@ the @object@
New string 1: Pigs eat the pie
New string 2: Cars guzzle the gasoline
Could be about cars: Cars guzzle the gasoline
Too bad. No pie: Cars guzzle the gasoline
Original string between ***s: ***    The fox ate the chicken.    ***
Trimmed string between ***s: ***The fox ate the chicken.***
Table index 1, Value is: The

Table index 2, Value is: fox

Table index 3, Value is: ate

Table index 4, Value is: the

Table index 5, Value is: chicken.

NOTE: PROCEDURE LUA used (Total process time):
      real time           0.20 seconds
      cpu time            0.06 seconds
```

Example 7: Adding an Observation to a Lua Table

Features:

SAS.APPEND function
SAS.CLOSE function
SAS.GET_VALUE function
SAS.PUT_VALUE function
SAS.UPDATE function
Concatenation operator (..)

Details

This example demonstrates how to add an observation using the SAS functions in PROC LUA. First, create a simple data set, and add a record to it using the SAS.APPEND, SAS.PUT_VALUE, and SAS.UPDATE functions. Next, retrieve and print the values from the updated data set.

Program

```
data foo;
  input x y;
  id+1;
  datalines;
1 10
2 20
3 30
;

proc lua;
submit;
   dsid = sas.open("work.foo",'u')

   while(sas.next(dsid) ~= nil) do
      myid = sas.get_value(dsid,"id")
      myx = sas.get_value(dsid,"x")
      myy = sas.get_value(dsid,"y")
      print("ID: " .. myid .. " x: " .. myx .. " y: " .. myy)
   end

   while(sas.next(dsid) ~= nil) do
      myid = sas.get_value(dsid,"id")
      myx = sas.get_value(dsid,"x")
      myy = sas.get_value(dsid,"y")
      print("ID: " .. myid .. " x: " .. myx .. " y: " .. myy)
   end

   sas.append(dsid)
   sas.put_value(dsid,"id",4)
   sas.put_value(dsid,"x",4)
   sas.put_value(dsid,"y",40)
   sas.update(dsid)
   rc=sas.close(dsid)
endsubmit;
run;

proc lua restart;
submit;
   dsid=sas.open("work.foo")
```

```
   while(sas.next(dsid) ~= nil) do
      myid = sas.get_value(dsid,"id")
      myx = sas.get_value(dsid,"x")
      myy = sas.get_value(dsid,"y")
      print("ID: " .. myid .. " x: " .. myx .. " y: " .. myy)
   end

   rc=sas.close(dsid)
endsubmit;
run;
```

Program Description

Create a data set. Use the DATA step to create a small data set called Foo.

```
data foo;
  input x y;
  id+1;
  datalines;
1 10
2 20
3 30
;
```

Invoke PROC LUA and open the Foo data set for updating. Use the SAS.OPEN function to assign the contents of the Foo data set to the Dsid Lua variable. By specifying that you want to open the data set in Update mode (by using the `'u'` argument), you are able to write to the data set. If you do not specify Update mode, the data set opens in Read-Only mode by default.

```
proc lua;
submit;
   dsid = sas.open("work.foo",'u')

   while(sas.next(dsid) ~= nil) do
      myid = sas.get_value(dsid,"id")
      myx = sas.get_value(dsid,"x")
      myy = sas.get_value(dsid,"y")
      print("ID: " .. myid .. " x: " .. myx .. " y: " .. myy)
   end
```

Read the values in Foo and print them to the SAS log. Use the WHILE loop with the SAS.NEXT function to iterate through observations in the data set. For each observation, retrieve the values for Myid, Myx, and Myy from the ID, X, and Y variables, respectively. Print these values to the SAS log.

```
   while(sas.next(dsid) ~= nil) do
      myid = sas.get_value(dsid,"id")
      myx = sas.get_value(dsid,"x")
      myy = sas.get_value(dsid,"y")
      print("ID: " .. myid .. " x: " .. myx .. " y: " .. myy)
   end
```

Append a new observation and assign a value to each variable. Call the SAS.APPEND function to prepare the data set for a new observation. Assign values using the SAS.PUT_VALUE function and finally update the data set with the SAS.UPDATE function. Close the data set.

```
      sas.append(dsid)
      sas.put_value(dsid,"id",4)
      sas.put_value(dsid,"x",4)
      sas.put_value(dsid,"y",40)
      sas.update(dsid)
      rc=sas.close(dsid)
endsubmit;
run;
```

Restart PROC LUA and open the Work.Foo data set. Assign the contents of Work.Foo to the Dsid Lua variable.

```
proc lua restart;
submit;
   dsid=sas.open("work.foo")
```

Retrieve the data from the Work.Foo data set. Use a WHILE loop to process observations in the Work.Foo data set. Retrieve the values using the SAS.GET_VALUE function, and print the values to the SAS log.

```
      while(sas.next(dsid) ~= nil) do
         myid = sas.get_value(dsid,"id")
         myx = sas.get_value(dsid,"x")
         myy = sas.get_value(dsid,"y")
         print("ID: " .. myid .. " x: " .. myx .. " y: " .. myy)
      end
```

Close the Work.Foo data set.

```
      rc=sas.close(dsid)
endsubmit;
run;
```

Output 39.8 *Listing of Original Work.Foo Data Set*

```
ID: 1 x: 1 y: 10
ID: 2 x: 2 y: 20
ID: 3 x: 3 y: 30
NOTE: PROCEDURE LUA used (Total process time):
      real time           0.02 seconds
      cpu time            0.01 seconds
```

Output 39.9 *Listing of Work.Foo Data Set Appended with New Observation*

```
ID: 1 x: 1 y: 10
ID: 2 x: 2 y: 20
ID: 3 x: 3 y: 30
ID: 4 x: 4 y: 40
NOTE: PROCEDURE LUA used (Total process time):
      real time           0.16 seconds
      cpu time            0.06 seconds
```

Example 8: Using SAS Macro Variable Values within Lua Statements

Features:

PROC LUA statement
SUBMIT and ENDSUBMIT statements
Macro variable assignments
Concatenation operator (..)

Details

No macro substitution occurs between the semicolon (;) at the end of the SUBMIT statement and the beginning of the ENDSUBMIT statement, except for those within a SAS.SUBMIT code block. You must specify macro value assignments for Lua commands within the SUBMIT statement. This example shows how to assign macro variable values for use within Lua code.

Separate multiple assignments with a semicolon (;) and place all assignments within a single pair of quotation marks. This example prints the following text to the SAS log: `Hello, George. Have a nice day.`

Program

```
%let g='George';
%let h='Have a nice day.';

proc lua;

submit "name=&g; msg=&h";

   print('Hello, ' .. name .. '. ' .. msg)

endsubmit;
run;
```

Program Description

Define macro variable values. The macro variables G and H are assigned to character values. The use of single quotation marks in the macro variable assignment is required for Lua. Single quotation marks are not normally required for macro variable assignments in SAS.

```
%let g='George';
%let h='Have a nice day.';
```

Execute the PROC LUA statement. The PROC LUA statement enables you to call Lua code within your SAS session.

```
proc lua;
```

Identify the beginning of a block of Lua statements and assign any macro variables. The SUBMIT statement identifies the beginning of a block of Lua statements. This example assigns the values of the macro variables `g` and `h` to the local Lua variables `name` and `msg`, respectively. No macro expansion occurs between the end of the SUBMIT statement and the beginning of the ENDSUBMIT statement. The Lua code refers to the local Lua variables.

```
submit "name=&g; msg=&h";
```

Execute Lua statements. Enter Lua statements between the SUBMIT and ENDSUBMIT statements. Lua statements are not required to end with a semicolon (;). This example prints text values to the SAS log. Concatenate strings using the '..' operator. Each print statement that you use begins on a new line in the log.

```
   print('Hello, ' .. name .. '. ' .. msg)
```

Identify the end of a block of Lua statements with the ENDSUBMIT statement.

```
endsubmit;
run;
```

Example 9: Submitting SAS Code with Lua Variable Substitutions

Features:

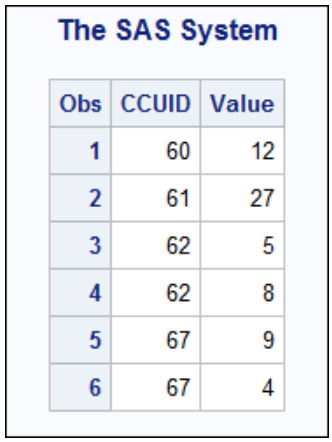
PROC LUA statement
SUBMIT and ENDSUBMIT statements
SAS.SUBMIT function
Variable substitution

Details

This example submits a block of Lua statements. Within the Lua statements, assign a block of SAS code to a local variable. The example then invokes the SAS code with the SAS.SUBMIT function and substitutes variable values.

The example uses the Work.Answer data set as input to the local Lua variable Code.

Figure 39.1 *Work.Answer Data Set*



The SAS System

Obs	CCUID	Value
1	60	12
2	61	27
3	62	5
4	62	8
5	67	9
6	67	4

Program

```
proc lua;
submit;

   local rc
   local code = [[
         data sample; set answer;
         where CCUID = @ccuid@;
         y = @subValue@;
         run;
   ]]
   rc = sas.submit(code, {ccuid="67", subValue=72})
endsubmit;
run;

proc print data=sample;
run;
```

Program Description

Execute the LUA procedure.

```
proc lua;
```

Identify the beginning of the block of Lua statements to execute. Use the SUBMIT statement to identify the Lua statements. Declare a local variable Rc. Semicolons (;) are not required at the end of Lua statements.

```
submit;

   local rc
```

Assign a block of SAS code to a local Lua variable. A block of SAS code, indicated by the [[and]] brackets, is assigned to the local Lua variable Code. The SAS code opens the WORK.ANSWER data set and keeps only records where the value of CCUID matches the value that is specified by @ccuid@. When the SAS code is executed, a value is assigned to the key `@ccuid@`. A new variable Y is assigned to the value that is specified by `@subValue@`. The resulting data set is saved to the WORK.SAMPLE data set.

```
local code = [[
      data sample; set answer;
      where CCUID = @ccuid@;
      y = @subValue@;
      run;
]]
```

Execute the SAS code and assign the result to the Lua variable Rc. The SAS.SUBMIT function tells the system to run SAS code. The code block that was assigned to the Code variable is now executed. The call to the SAS.SUBMIT function includes two variable substitutions. When the SAS code executes, the character value *"67"* is substituted for `@ccuid@`, and the value *72* is substituted for `@subValue@`.

```
rc = sas.submit(code, {ccuid="67", subValue=72})
```

The ENDSUBMIT statement identifies the end of the block of Lua statements. The RUN statement completes the call to PROC LUA.

```
endsubmit;
run;
```

Print the resulting data set, Work.Sample.

```
proc print data=sample;
run;
```

Output: SAS Table Resulting from Substituted Lua Values

Output 39.10 *Generated Work.Sample Table*

The SAS System

Obs	CCUID	Value	y
1	67	9	72
2	67	4	72

Example 10: Using an Iterator Function for a Small Table

Features: SAS.OPEN function
SAS.ROWS function
SAS.CLOSE function

Details

This example traverses a data set and prints the variable names and corresponding values for each observation. Use the SAS.ROWS function when there are relatively few variables.

Program

```
proc lua;
submit;

   local dsid = sas.open("sashelp.class")

   for row in sas.rows(dsid) do
      for n,v in pairs(row) do
         if type(n)=="string" then
            print(n,'=', v)
         end
      end
```

```
   end

   sas.close(dsid)
endsubmit;
run;
```

Program Description

Execute the PROC LUA and SUBMIT statements to begin a block of Lua code.

```
proc lua;
submit;
```

Open the Sashelp.Class SAS data set and load the contents into the Lua variable Dsid. By default, the data set is opened for reading.

```
local dsid = sas.open("sashelp.class")
```

Process the rows of the data set. The outer FOR loop processes each row in the data set. The PAIRS function pulls the variable name and value pairs from each row in the Sashelp.Class data set. The pairs of variable names and values are then printed to the SAS log. Note that in Lua, a double equal sign (==) is used to assess whether two values are equal in the IF condition.

```
for row in sas.rows(dsid) do
   for n,v in pairs(row) do
      if type(n)=="string" then
         print(n,'=', v)
      end
   end
end
```

Close the data set, end the block of Lua code, and complete the call to the LUA procedure.

```
   sas.close(dsid)
endsubmit;
run;
```

Output: ROWS Iterator for a Small Data Set

Output 39.11 *Iterating over a Small Data Set with the ROWS Function (Partial Output)*

```

```

Example 11: Using Iterator Functions for a Large Table

Features:

SAS.OPEN function
SAS.VARS function
SAS.NEXT function
SAS.GET_VALUE function
SAS.CLOSE function

Details

This example uses the SAS.VARS and SAS.NEXT functions to traverse a SAS data set and print its contents.

Program

```
proc lua;
submit;
   local dsid = sas.open("sashelp.company") -- open for input
   local vars = {}
   -- Iterate over the variables in the data set
   for var in sas.vars(dsid) do
      vars[var.name:lower()] = var
   end
   -- Iterate over the rows of the data set
   local i=0
   while (sas.next(dsid) ~= nil) do
      i=i+1
      print("OBS=" .. i)
      for vname,var in pairs(vars) do
         print(vname, '=', sas.get_value(dsid, vname) )
      end
   end
   sas.close(dsid)
endsubmit;
run;
```

Program Description

Execute the PROC LUA and SUBMIT statements to begin a block of Lua code.

```
proc lua;
submit;
```

Open the Sashelp.Company data set.

```
local dsid = sas.open("sashelp.company") -- open for input
```

Declare a local Lua array, VARS, and populate it with the values of the variables in the data set. The brackets ({ }) identify an array in Lua. Use the SAS.VARS function to iterate over all the variables in the data set. The example assigns the value of each variable to the Vars array, where the array key is the variable name in lowercase.

```
local vars = {}
-- Iterate over the variables in the data set
for var in sas.vars(dsid) do
   vars[var.name:lower()] = var
end
```

Iterate over each data set observation and print the values for each variable. The example initializes an iterator variable, I, to 0. The SAS.NEXT iterator function then cycles through the observations in the data set. For each observation, the example prints the variable name and corresponding value for each variable.

```
-- Iterate over the rows of the data set
local i=0
```

```
   while (sas.next(dsid) ~= nil) do
      i=i+1
      print("OBS=" .. i)
      for vname,var in pairs(vars) do
         print(vname, '=', sas.get_value(dsid, vname) )
      end
   end
```

Close the data set and end the call to the LUA procedure.

```
   sas.close(dsid)
endsubmit;
run;
```

Output: Iterators with a Large Data Set

Example 12: Defining and Adding Variables to a Data Set

Features:
PROC LUA statement
SAS.OPEN function with 'o' option
SAS.ADD_VARS function
SAS.CLOSE function

Details

This example defines new variables within Lua code and adds them to a data set. The example uses the SAS.ADD_VARS function to define the variables and add them to the output data set.

Program

```
proc lua;
submit;

   local dsid = sas.open("work.sample","o")

   sas.add_vars(dsid, {  {name="var1", type="N", format="BEST12.2"},
                         {name="var2", type="C", length=500,
format="$char80."},
                         {name="var3", type="C", label="Character
Data"}
                      })

   sas.close(dsid)
endsubmit;
run;
```

Program Description

Execute the PROC LUA statement and begin the block of Lua statements. The PROC LUA statement enables you to call Lua code within your SAS session. The SUBMIT statement identifies the beginning of the block of Lua statements.

```
proc lua;
submit;
```

Open the data set and assign its contents to a local Lua variable. Invoke the SAS.OPEN function to open the WORK.SAMPLE data set. Use the 'o' mode to create the data set if it does not already exist.

```
local dsid = sas.open("work.sample","o")
```

Define variables to add to the data set. This example invokes the SAS.ADD_VARS function to add three variables—Var1, Var2, and Var3—to the data set. The type, numeric (N) or character (C), is specified for each variable. Various additional attributes are assigned to the variables. Only the name attribute is required. For more information, see "Data Set Functions for the LUA Procedure" on page 1412.

```
   sas.add_vars(dsid, {  {name="var1", type="N", format="BEST12.2"},
                         {name="var2", type="C", length=500,
format="$char80."},
                         {name="var3", type="C", label="Character
Data"}
                      })
```

Close the data set and end the call to the LUA procedure. This example executes the SAS.CLOSE function to close the data set that is associated with the Lua variable Dsid.

```
   sas.close(dsid)
endsubmit;
run;
```

Output: Adding Variables to a Data Set

Output 39.13 *Partial Output from PROC CONTENTS for Work.Sample*

Alphabetic List of Variables and Attributes					
#	Variable	Type	Len	Format	Label
1	var1	Num	8	BEST12.2	
2	var2	Char	500	$CHAR80.	
3	var3	Char	200		Character Data

Example 13: Connecting to the CAS Server

Features: CAS.OPEN function
CLOSE function
SUBMIT and ENDSUBMIT statements

Details

This example shows how to connect to a CAS server. The host name is **server.mycompany.com**, the port is **5570**.

Note: This example assumes that you have SAS Viya 3.5 installed.

Program

```
proc lua;
submit;

-- Show the content of the swat_enabled variable
print("NOTE: swat_enabled=", swat_enabled)

-- Show path and cpath info at start
print("NOTE: before")
print("NOTE: package.path=\n" .. package.path)
print("NOTE: package.cpath=\n" .. package.cpath)

-- Add required directories to path and cpath
if swat_enabled == false or swat_enabled == nil then
  print("NOTE: changing path and cpath")
package.path = package.path ..
    ';/opt/sas/viya/home/SASFoundation/misc/casluaclnt/lua/?.lua'
package.path = package.path ..
    ';/opt/sas/viya/home/SASFoundation/misc/casluaclnt/lua/deps/?.lua'
package.cpath = package.cpath ..
    ';/opt/sas/viya/home/SASFoundation/misc/casluaclnt/lua/lib/?.so'

swat_enabled = true

-- Show updated path and cpath values
print("NOTE: after")
print("NOTE: package.path=\n" .. package.path)
print("NOTE: package.cpath=\n" .. package.cpath)
end

-- Preload library
cas = require "swat"

-- Connect to the CAS server on your host
s=cas.open("server.mycompany.com",5570)

-- Print the session ID
print("NOTE: s=", s)

-- Run the builtins.serverStatus action
```

```
-- and display session information
result = s:builtins_serverStatus
print("NOTE: server=\n",result['server'])
print("NOTE: nodestatus=\n",result['nodestatus'])

-- Run the addFmtLib action to add a format library
s:addFmtLib{fmtlibname="myformats"}

-- Create a format called demo in the myformats library
s:addFormat{fmtLibName="myformats",
            fmtname="demo",
            ranges={"0-17='demo1'","18-34='demo2'",
                    "35-49='demo3'","50-64='demo4'"
                   }}

-- Format some values with the newly created format
result = s:listFmtValues{fmtname = "demo",
              nvals = {15,23,39,61}}

-- Display the results
print(result)

-- Shutdown the CAS session
s:close{}

endsubmit;
run;
```

Program Description

Start PROC LUA and load utility resources. Use the concatenation operator to append the middleclass.lua location to the package.path value. Similarly, add the location of the tkluaswat.so file to the package.cpath value. A variable called Swat_enabled is created to prevent updating the package.path and package.cpath values if you run this program more than once. For more information about SWAT, see "Requirements" in *Getting Started with SAS Viya for Lua*.

```
proc lua;
submit;

-- Show the content of the swat_enabled variable
print("NOTE: swat_enabled=", swat_enabled)

-- Show path and cpath info at start
print("NOTE: before")
print("NOTE: package.path=\n" .. package.path)
print("NOTE: package.cpath=\n" .. package.cpath)

-- Add required directories to path and cpath
if swat_enabled == false or swat_enabled == nil then
  print("NOTE: changing path and cpath")
package.path = package.path ..
    ';/opt/sas/viya/home/SASFoundation/misc/casluaclnt/lua/?.lua'
```

```
package.path = package.path ..
    ';/opt/sas/viya/home/SASFoundation/misc/casluaclnt/lua/deps/?.lua'
package.cpath = package.cpath ..
    ';/opt/sas/viya/home/SASFoundation/misc/casluaclnt/lua/lib/?.so'

swat_enabled = true

-- Show updated path and cpath values
print("NOTE: after")
print("NOTE: package.path=\n" .. package.path)
print("NOTE: package.cpath=\n" .. package.cpath)
end
```

Load the SWAT library.

```
-- Preload library
cas = require "swat"
```

Connect to the CAS server. Use the CAS.OPEN function to start a CAS session on the CAS server. Assign the CAS session to the Lua variable S. Verify that the connection was successful and print session information. This version of the CAS.OPEN function assumes that you have created an authinfo file. For more information, see "Connect and Start a Session" in *Getting Started with SAS Viya for Lua*.

```
-- Connect to the CAS server on your host
s=cas.open("server.mycompany.com",5570)

-- Print the session ID
print("NOTE: s=", s)

-- Run the builtins.serverStatus action
-- and display session information
result = s:builtins_serverStatus
print("NOTE: server=\n",result['server'])
print("NOTE: nodestatus=\n",result['nodestatus'])
```

Run a CAS action. Run the addFmtLib action to add a new format library. Add a new format definition with the addFormat action. Then apply the format to some values and check the output to see the formatted values.

```
-- Run the addFmtLib action to add a format library
s:addFmtLib{fmtlibname="myformats"}

-- Create a format called demo in the myformats library
s:addFormat{fmtLibName="myformats",
            fmtname="demo",
            ranges={"0-17='demo1'","18-34='demo2'",
                    "35-49='demo3'","50-64='demo4'"
                   }}

-- Format some values with the newly created format
result = s:listFmtValues{fmtname = "demo",
              nvals = {15,23,39,61}}

-- Display the results
```

```
print(result)
```

Shut down the CAS session and disconnect from the CAS server with the CLOSE function. End the Lua code block and submit the call to PROC LUA.

```
-- Shutdown the CAS session
s:close{}

endsubmit;
run;
```

Output 39.14 *Connecting to the CAS Server Output*

```

Example 14: Running PROC FCMP Functions

Features: PROC FCMP statement
PROC LUA statement
FILENAME statement
SUBMIT and ENDSUBMIT statements

Restriction: When you call a function that was created with the FCMP procedure, you can modify only OUTARG arguments that are arrays.

Details

This example calls functions that have been defined using the FCMP procedure, similar to calling standard SAS functions. The function definitions do not need to be included in the same SAS program. PROC FCMP functions can be stored in a function library for use by any program if the CMPLIB system option has been defined within that program. This example defines the SUMX and ADD_SCALAR functions and saves them to the Sasuser.myFuncs data set in the ArrayFuncs package. A *package* is a collection of related routines that are specified by a user. The package name groups related functions in the data set that contains the PROC FCMP functions.

Program

```
proc fcmp outlib=sasuser.myFuncs.ArrayFuncs;
function sumx(x[*]);
  sum = 0;
  do i = 1 to dim(x);
     sum = sum + x[i];
  end;
  return(sum );
endsub;

function add_scalar( scalar, x[*] );
   outargs x;
   do i = 1 to dim(x);
      x[i] = x[i] + scalar;
   end;
   return( dim(x) );
endsub;
run;

options cmplib=sasuser.myFuncs;
```

```
proc lua;
submit;
   array = { 1, 2, 3, 4, 5 }
   sum = sas.sumx(array)
   print(sum)
endsubmit;
run;

proc lua;
submit;
   array = { 1, 2, 3, 4, 5 }
   dim = sas.add_scalar(5, array)
   a1 = array[1]
   a2 = array[2]
   print(a1)
   print(a2)
endsubmit;
run;
```

Program Description

Define functions using the FCMP procedure. The SUMX function sums the values of an array and returns that value. The ADD_SCALAR function adds a scalar value to each member of an array. Because the OUTARGS argument for ADD_SCALAR specifies an array, the call to this function using PROC LUA can change the value of the submitted array. The ADD_SCALAR function returns the number of elements in the array.

```
proc fcmp outlib=sasuser.myFuncs.ArrayFuncs;
function sumx(x[*]);
  sum = 0;
  do i = 1 to dim(x);
     sum = sum + x[i];
  end;
  return(sum );
endsub;

function add_scalar( scalar, x[*] );
   outargs x;
   do i = 1 to dim(x);
      x[i] = x[i] + scalar;
   end;
   return( dim(x) );
endsub;
run;
```

Specify the location of the compiled functions. This example finds the previously defined functions in the Sasuser.myFuncs data set. The call to the FCMP procedure does not need to be included in the same program with the LUA procedure if the functions are stored. Use the OPTIONS statement to specify the function location before calling the function within the LUA procedure.

```
options cmplib=sasuser.myFuncs;
```

Call the SUMX function within the LUA procedure. You call the SUMX function by preceding the call with "SAS.", similar to calling any standard SAS function.

```
proc lua;
submit;
   array = { 1, 2, 3, 4, 5 }
   sum = sas.sumx(array)
   print(sum)
endsubmit;
run;
```

Call the ADD_SCALAR function within the LUA procedure. You call the ADD_SCALAR function by preceding the call with "SAS.", similar to calling any standard SAS function. The calls to SUMX and ADD_SCALAR can come within the same LUA procedure.

```
proc lua;
submit;
   array = { 1, 2, 3, 4, 5 }
   dim = sas.add_scalar(5, array)
   a1 = array[1]
   a2 = array[2]
   print(a1)
   print(a2)
endsubmit;
run;
```

Output: Working with User-Defined Array Functions

Output 39.15 *Calling Functions That Were Created By Using PROC FCMP*

```
388  proc fcmp outlib=sasuser.myFuncs.ArrayFuncs;
389  function sumx(x[*]);
390    sum = 0;
391    do i = 1 to dim(x);
392      sum = sum + x[i];
393    end;
394    return(sum );
395  endsub;
396
397  function add_scalar( scalar, x[*] );
398    outargs x;
399    do i = 1 to dim(x);
400      x[i] = x[i] + scalar;
401    end;
402    return( dim(x) );
403  endsub;
404  run;

MEANS Procedure

Overview: MEANS Procedure

What Does the MEANS Procedure Do?

The MEANS procedure provides data summarization tools to compute descriptive statistics for variables across all observations and within groups of observations. For example, PROC MEANS does the following:

- calculates descriptive statistics based on moments
- estimates quantiles, which includes the median
- calculates confidence limits for the mean
- identifies extreme values
- performs a *t* test

By default, PROC MEANS displays output. You can also use the OUTPUT statement to store the statistics in a SAS data set.

PROC MEANS and PROC SUMMARY are very similar; see Chapter 69, "SUMMARY Procedure," on page 2455 for an explanation of the differences.

What Types of Output Does PROC MEANS Produce?

PROC MEANS Default Output

Output 1.1 shows the default output that PROC MEANS displays. The data set that PROC MEANS analyzes contains the integers 1 through 10. The output reports the number of observations, the mean, the standard deviation, the minimum value, and the maximum value. The statements that produce the output follow:

```
proc means data=OnetoTen;
run;
```

Output 40.1 *The Default Descriptive Statistics*

```
                              The SAS System                                1

                          The MEANS Procedure

                       Analysis Variable : Integer

        N            Mean         Std Dev         Minimum         Maximum
-------------------------------------------------------------------------------
       10       5.5000000       3.0276504       1.0000000      10.0000000
-------------------------------------------------------------------------------
```

PROC MEANS Customized Output

The following output shows the results of a more extensive analysis of two variables, MoneyRaised and HoursVolunteered. The analysis data set contains information about the amount of money raised and the number of hours volunteered by high-school students for a local charity. PROC MEANS uses six combinations of two categorical variables to compute the number of observations, the mean, and the range. The first variable, School, has two values and the other variable, Year, has three values. For an explanation of the program that produces the output, see “Example 11: Identifying an Extreme Value with the Output Statistics” on page 1544.

Output 40.2 Specified Statistics for Class Levels and Identification of Maximum Values

```
                Summary of Volunteer Work by School and Year                1

   7   Kennedy   1992       3        15    Thelma    Jay        52.63        35
   8   Kennedy   1993       3        20    Bill      Amy        42.23        31
   9   Kennedy   1994       3        18    Luther    Che-Min    72.22        33
  10   Monroe    1992       3        16    Tonya     Tonya      55.16        40
  11   Monroe    1993       3        12    Cameron   Myrtle     65.44        26
  12   Monroe    1994       3        28    Willard   L.T.       78.65        33
```

In addition to the report, the program also creates an output data set (located on page 2 of the output) that identifies the students who raised the most money and who volunteered the most time over all the observations and within the combinations of School and Year:

- The first observation in the data set shows the students with the maximum values overall for MoneyRaised and HoursVolunteered.
- Observations 2 through 4 show the students with the maximum values for each year, regardless of school.
- Observations 5 and 6 show the students with the maximum values for each school, regardless of year.

- Observations 7 through 12 show the students with the maximum values for each school-year combination.

PROC MEANS and the ODS OUTPUT Statement

The template for procedures MEANS and SUMMARY causes ODS to apply default formats and format attributes to its output, overriding any formats associated and applied to variables of the input data set, because the option USE_FORMAT_DEFAULTS is specified in the template. This option affects the width and alignment of ODS–formatted output, which can vary from the width and alignment of formats found in the input data set or those specified on a FORMAT or ATTRIB statement. These format defaults affect ODS output and not internal–numeric representation or calculations.

For example, numeric format outputs can be wider and have more characters than expected when the default–format width is greater than the specified width specified in the data set or the statement.

You can prevent default formats being applied to the output data set by creating your output data set using the OUTPUT statement instead of the ODS OUTPUT statement.

If you prefer that format defaults not be applied to ODS output, you can modify the Base.Summary ODS table template with the following code:

```
proc template;
   edit base.summary;
   use_format_defaults=off;
end;
run;
```

Concepts: MEANS Procedure

Using Class Variables

Using TYPES and WAYS Statements

The TYPES statement controls which of the available class variables PROC MEANS uses to subgroup the data. The unique combinations of these active class

variable values that occur together in any single observation of the input data set determine the data subgroups. Each subgroup that PROC MEANS generates for a given type is called a level of that type. Note that for all types, the inactive class variables can still affect the total observation count of the rejection of observations with missing values.

When you use a WAYS statement, PROC MEANS generates types that correspond to every possible unique combination of *n* class variables chosen from the complete set of class variables. For example

```
proc means;
 class a b c d e;
 ways 2 3;
 run;
```

is equivalent to

```
proc means;
 class a b c d e;
 types a*b a*c a*d a*e b*c b*d b*e c*d c*e d*e
       a*b*c a*b*d a*b*e a*c*d a*c*e a*d*e
       b*c*d b*c*e c*d*e;
 run;
```

If you omit the TYPES statement and the WAYS statement, then PROC MEANS uses all class variables to subgroup the data (the NWAY type) for displayed output and computes all types (2^k) for the output data set.

Ordering the Class Values

PROC MEANS determines the order of each class variable in any type by examining the order of that class variable in the corresponding one-way type. You see the effect of this behavior in the options ORDER=DATA or ORDER=FREQ. If you specify the ORDER=DATA option for input data in a DBMS table, PROC MEANS computation might produce different results for separate runs of the same analysis. In addition to determining the order of variable levels in crosstabulation table displays, the ORDER= option can also affect the values of many of the test statistics and measures that PROC MEANS computes. When PROC MEANS subdivides the input data set into subsets, the classification process does not apply the options ORDER=DATA or ORDER=FREQ independently for each subgroup. Instead, one frequency and data order is established for all output based on a non-subdivided view of the entire data set. For example, consider the following statements:

```
data pets;
 input Pet $ Gender $;
 datalines;
dog  m
dog  f
dog  f
dog  f
cat  m
cat  m
cat  f
```

```
;

proc means data=pets order=freq;
   class pet gender;
run;
```

The statements produce this output.

Output 40.3 *Ordering Class Values*

```
                    The SAS System                              1

                 The MEANS Procedure

                                     N
          Pet         Gender       Obs
          ---------------------------
          dog         f              3

                      m              1

          cat         f              1

                      m              2
          ---------------------------
```

In the example, PROC MEANS does not list male cats before female cats. Instead, it determines the order of gender for all types over the entire data set. PROC MEANS found more observations for female pets (f=4, m=3). The default for ORDER is ORDER=INTERNAL.

Computational Resources

PROC MEANS uses the same memory allocation scheme across all operating environments. When class variables are involved, PROC MEANS must keep a copy of each unique value of each class variable in memory. You can estimate the memory requirements to group the class variable by calculating

$$Nc_1(Lc_1 + K) + Nc_2(Lc_2 + K) + ... + Nc_n(Lc_n + K)$$

where

Nc_i
: is the number of unique values for the class variable.

Lc_i
: is the combined unformatted and formatted length of c_i .

K
: is some constant on the order of 32 bytes (64 for 64-bit architectures).

When you use the GROUPINTERNAL option in the CLASS statement, Lc_i is simply the unformatted length of c_i .

Each unique combination of class variables, $c_{1_i}\ c_{2_j}$ for a given type forms a level in that type. See "TYPES Statement" on page 1506. You can estimate the maximum potential space requirements for all levels of a given type, when all combinations actually exist in the data (a complete type), by calculating

$$W * Nc_1 * Nc_2 * \ ... \ * Nc_n$$

where

W
is a constant based on the number of variables analyzed and the number of statistics calculated (unless you request QMETHOD=OS to compute the quantiles).

$Nc_1 ... Nc_n$
are the number of unique levels for the active class variables of the given type.

Clearly, the memory requirements of the levels overwhelm the levels of the class variables. For this reason, PROC MEANS can open one or more utility files and write the levels of one or more types to disk. These types are either the primary types that PROC MEANS built during the input data scan or the derived types.

If PROC MEANS must write partially complete primary types to disk while it processes input data, then one or more merge passes can be required to combine type levels in memory with the levels on disk. In addition, if you use an order other than DATA for any class variable, then PROC MEANS groups the completed types on disk. For this reason, the peak disk space requirements can be more than twice the memory requirements for a given type.

When PROC MEANS uses a temporary work file, you receive the following note in the SAS log:

```
Processing on disk occurred during summarization.
Peak disk usage was approximately nnn
Mbytes.
Adjusting MEMSIZE or REALMEMSIZE may improve performance.
```

In most cases processing ends normally.

When you specify class variables in a CLASS statement, the amount of data-dependent memory that PROC MEANS uses before it writes to a utility file is controlled by the SAS system option REALMEMSIZE=. The value of REALMEMSIZE= indicates the amount of real as opposed to virtual memory that SAS can expect to allocate. PROC MEANS determines how much data-dependent memory to use before writing to utility files by calculating the lesser of these two values:

- the value of REALMEMSIZE=
- 0.8*(M-U), where M is the value of MEMSIZE= and U is the amount of memory that is already in use

REALMEMSIZE also affects the behavior of other memory intensive PROCs such as PROC SORT.

As an alternative, you can use the PROC option SUMSIZE=. Like the PROC option SORTSIZE=, SUMSIZE= sets the memory threshold where disk-based operations begin. For best results, set SUMSIZE= to less than the amount of real memory that

is likely to be available for the task. For efficiency reasons, PROC MEANS can internally round up the value of SUMSIZE=. SUMSIZE= has no effect unless you specify class variables.

Operating Environment Information: The REALMEMSIZE= SAS system option is not available in all operating environments. For details, see the SAS Companion for your operating environment.

If PROC MEANS reports that there is insufficient memory, then increase SUMSIZE= (or REALMEMSIZE=). A SUMSIZE= (or REALMEMSIZE=) value that is greater than MEMSIZE= has no effect. Therefore, you might also need to increase MEMSIZE=. If PROC MEANS reports insufficient disk space, then increase the WORK space allocation. See the SAS documentation for your operating environment for more information about how to adjust your computation resource parameters.

Another way to enhance performance is by carefully applying the TYPES or WAYS statement, limiting the computations to only those combinations of class variables that you are interested in. In particular, significant resource savings can be achieved by not requesting the combination of all class variables.

In-Database Processing for PROC MEANS

When large data sets are stored in an external database, the transfer of the data sets to computers that run SAS can be impacted by performance, security, and resource management issues. SAS in-database processing can greatly reduce data transfer by having the database perform the initial data aggregation.

In-database processing for PROC MEANS supports the following database management systems:

- Amazon Redshift
- Aster
- DB2
- Google BigQuery
- Greenplum
- Hadoop
- HAWQ
- Impala
- Microsoft SQL Server
- Netezza
- Oracle
- PostgreSQL
- SAP HANA
- Snowflake
- Teradata

- Vertica
- Yellowbrick

Under the correct conditions, PROC MEANS generates an SQL query based on the statements that are used and the output statistics that are specified in the PROC step. If class variables are specified, the procedure creates an SQL GROUP BY clause that represents the n-way type. The result set that is created when the aggregation query executes in the database is read by SAS into the internal PROC MEANS data structure, and all subsequent types are derived from the original n-way type to form the final analysis results. When SAS format definitions have been deployed in the database, formatting of class variables occurs in the database. If the SAS format definitions have not been deployed in the database, the in-database aggregation occurs on the raw values, and the relevant formats are applied by SAS as the results' set is merged into the PROC MEANS internal structures. Multi-label formatting is always done by SAS using the initially aggregated result set that is returned by the database. The CLASS, TYPES, WAYS, VAR, BY, FORMAT, and WHERE statements are supported when PROC MEANS is processed inside the database. FREQ, ID, IDMIN, IDMAX, and IDGROUPS are not supported. The following statistics are supported for in-database processing: N, NMISS, MIN, MAX, RANGE, SUM, SUMWGT, MEAN, CSS, USS, VAR, STD, STDERR, PRET, UCLM, LCLM, CLM, and CV.

Weighting for in-database processing is supported only for N, NMISS, MIN, MAX, RANGE, SUM, SUMWGT, and MEAN.

The following statistics are currently not supported for in-database processing: SKEW, KURT, P1, P5, P10, P20, P25/Q1, P30, P40, P50/MEDIAN, P60, P70, P75/Q3, P80, P90, P95, P99, and MODE.

The SQLGENERATION system option or LIBNAME statement option controls whether and how in-database procedures are run inside the database. By default, the in-database procedures are run inside the database when possible. There are many data set options that prevent in-database processing, such as, OBS=, FIRSTOBS=, RENAME=, and DBCONDITION=. For a complete listing, see Data Set-Related Options

In-database processing can greatly reduce the volume of data transferred to the procedure if there are no class variables (one row is returned) or if the selected class variables have a small number of unique values. However, because PROC MEANS loads the result set into its internal structures, the memory requirements for the SAS process are equivalent to what would have been required without in-database processing. The CPU requirements for the SAS process should be significantly reduced if the bulk of the data summarization occurs inside the database. The real time required for summarization should be significantly reduced because many database-process queries are in parallel.

For more information about in-database processing, see *SAS/ACCESS for Relational Databases: Reference*.

Threaded Processing of Input DATA Sets

The THREADS option enables or disables parallel processing of the input data set. Threaded processing achieves a degree of parallelism in the processing operations. This parallelism is intended to reduce the real time to completion for a given operation and therefore limit the cost of additional CPU resources. For more information, see “Support for Parallel Processing in *SAS Language Reference: Concepts*.

The value of the SAS system option CPUCOUNT= affects the performance of the threaded sort. CPUCOUNT= suggests how many system CPUs are available for use by the threaded procedures.

For more information see the “THREADS System Option” and “CPUCOUNT= System Option” in the *SAS System Options: Reference*.

Calculated statistics can vary slightly, depending on the order in which observations are processed. Such variations are due to numerical errors that are introduced by floating–point arithmetic, the results of which should be considered approximate and not exact. The order of observation processing can be affected by nondeterministic effects of multithreaded or parallel processing. The order of processing can also be affected by inconsistent or nondeterministic ordering of observations that are produced by a data source, such as a DBMS that delivers query results through an ACCESS engine. For more information, see “Numerical Accuracy in SAS Software” in *SAS Language Reference: Concepts* and “Threading in Base SAS” in *SAS Language Reference: Concepts*.

CAS Processing for PROC MEANS

When analyzing a data table that resides on a CAS server, a portion of the work that is performed by PROC MEANS is done within CAS. The work that is done in CAS is similar to work performed within a DBMS by in-database processing. If your input data set originates from CAS, some of the PROC MEANS processing can be performed by the CAS server. Running PROC MEANS with CAS actions has several advantages over processing within SAS. These advantages include reduced network traffic, and the potential for faster processing. Faster processing is possible because in-memory tables are manipulated locally on the server instead of being transferred across a relatively slow network connection. CAS is used because it might have more processing resources.

Under the correct conditions, PROC MEANS generates and executes a CAS action based on the statements that are used and the output statistics that are specified in the PROC step. If class variables are specified, the procedure creates a GROUPBY input table parameter that represents the *n*-way type. The result set that is created when the action executes on the CAS server is read by SAS into the internal PROC MEANS data structure. All subsequent types are derived from the original *n*-way type to form the final analysis results.

For intrinsic formats, formatting of class variables occurs in CAS. For user-defined formats, formatting of class variables occurs in CAS if the formats have been defined in or copied to the server. If formats are not available on the CAS server, initial aggregation occurs on the server using raw values, and the relevant formats are applied by SAS as the result set is merged into PROC MEANS internal structure. Multilabel formatting is always done by SAS using the initially aggregated result set that is returned by CAS.

The CLASS, TYPES, WAYS, VAR, BY, FORMAT, and WHERE statements are supported when PROC MEANS is processed inside the CAS server. FREQ, ID, IDMIN, IDMAX, and IDGROUPS are not supported.

The following statistics are supported for processing: N, NMISS, MIN, MAX, RANGE, SUM, SUMWGT, MEAN, CSS, USS, VAR, STD, STDERR, PRET, UCLM, LCLM, CLM, and CV.

Weighting for CAS processing is supported only for N, NMISS, MIN, MAX, RANGE, SUM, SUMWGT, and MEAN.

The following statistics are currently not supported in CAS: SKEW, KURT, P1, P5, P10, P20, P25/Q1, P30, P40, P50/MEDIAN, P60, P70, P75/Q3, P80, P90, P95, P99, and MODE.

By default, when the DATA= input data set references an in-memory table or view in CAS, the MEANS procedure runs on the CAS server when possible. There are many data set options that prevent processing in CAS, such as OBS=, FIRSTOBS=, and RENAME=.

Processing in CAS can reduce the volume of data that is transferred to the procedure if there are no class variables (one row is returned) or if the selected class variables have a small number of unique values. However, because PROC MEANS loads the result set into its internal structure, the memory requirements for the SAS process are equivalent to what would have been required when not processing in CAS. The CPU requirements for the SAS process should be significantly reduced if the bulk of the data summarization occurs inside the CAS server. The real-time processing required for summarization should be significantly reduced because CAS can process the data in parallel. If the results of PROC MEANS are directed back to the CAS server using an OUTPUT statement, processing of intermediate aggregates must still be performed by the MEANS procedure in SAS. If you want all processing to be performed in CAS, you can invoke an appropriate action directly, using PROC CAS or one of the many other CAS clients and languages.

Note: Intermediate results are always processed by the client regardless of the final destination–CAS or the client.

Here is an example of how to run PROC MEANS with CAS. The CAS LIBNAME engine is used to connect a SAS 9.4 session to an existing CAS session through the CAS session name or the CAS session UUID. The resulting libref is then used by SAS to communicate with the specific CAS session.

```
/* Connect to a CAS server */
cas casauto host="cloud.example.com" port=5570;
/* Specify the CAS engine LIBNAME statement and use the CAS engine
libref*/
```

```
libname mycas cas sessref=casauto;
/* Enable INFO messages so that the SAS log reports the use of CAS
actions. */
options msglevel=i;
/*For demonstration purposes, move Grade to CAS and rename it to
GradeBySection.*/
proc casutil;
load data=Grade casout=GradeBySection;
quit;
/*Execute the PROC MEANS procedure*/
/* A SORT step is not needed for BY-processing when running in CAS */
proc means data=cas.GradeBySection min max mean;
   by Section;
   var Score;
   class Status Year;
   title1 'Final Exam Scores for Student Status and Year of
Graduation';
   title2 'Within Each Section';
run;
cas casauto terminate;
```

Syntax: MEANS Procedure

Tip: You can use the ATTRIB, FORMAT, LABEL, and WHERE statements. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73. You can also use any global statement. For a list, see "Global Statements" in *SAS DATA Step Statements: Reference*.

PROC MEANS <*options*> <*statistic-keyword(s)*>;

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...> <NOTSORTED>;

Statement	Task	Example
PROC MEANS	Compute descriptive statistics for variables	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8,

Statement	Task	Example
		Ex. 9, Ex. 10, Ex. 12, Ex. 13
BY	Calculate separate statistics for each BY group	Ex. 3
CLASS	Identify variables whose values define subgroups for the analysis	Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8, Ex. 9, Ex. 10, Ex. 11, Ex. 12
FREQ	Identify a variable whose values represent the frequency of each observation	
ID	Include additional identification variables in the output data set	
OUTPUT	Create an output data set that contains specified statistics and identification variables	Ex. 8, Ex. 9, Ex. 10, Ex. 11, Ex. 12
TYPES	Identify specific combinations of class variables to use to subdivide the data	Ex. 2, Ex. 5, Ex. 12
VAR	Identify the analysis variables and their order in the results	Ex. 1
WAYS	Specify the number of ways to make unique combinations of class variables	Ex. 6
WEIGHT	Identify a variable whose values weight each observation in the statistical calculations	Ex. 6

PROC MEANS Statement

Computes descriptive statistics for variables.

See: Chapter 69, "SUMMARY Procedure," on page 2455

Examples: "Example 1: Computing Specific Descriptive Statistics" on page 1516
"Example 2: Computing Descriptive Statistics with Class Variables" on page 1518
"Example 3: Using the BY Statement with Class Variables" on page 1521
"Example 4: Using a CLASSDATA= Data Set with Class Variables" on page 1523
"Example 5: Using Multilabel Value Formats with Class Variables" on page 1526
"Example 6: Using Preloaded Formats with Class Variables" on page 1531
"Example 7: Computing a Confidence Limit for the Mean" on page 1535
"Example 8: Computing Output Statistics" on page 1537

Syntax

PROC MEANS <*options*> <*statistic-keyword(s)*>;

Summary of Optional Arguments

DATA=*SAS-data-set*
: specifies the input data set.

INCAS=(YES | NO)
: specifies whether to allow in-CAS processing.

NOTHREADS
: overrides the SAS system option THREADS | NOTHREADS.

NOTRAP
: disables floating point exception recovery.

SUMSIZE=*value*
: specifies the amount of memory to use for data summarization with class variables.

THREADS | NOTHREADS
: overrides the SAS system option THREADS | NOTHREADS.

Control the classification levels

CLASSDATA=*SAS-data-set*
: specifies a secondary data set that contains the combinations of class variables to analyze.

COMPLETETYPES
: creates all possible combinations of class variable values.

EXCLUSIVE
: excludes from the analysis all combinations of class variable values that are not in the CLASSDATA= data set.

MISSING
: uses missing values as valid values to create combinations of class variables.

Control the output

FW=*field-width*
: specifies the field width for the statistics.

MAXDEC=*number*
: specifies the number of decimal places for the statistics.

NONOBS
: suppresses reporting the total number of observations for each unique combination of the class variables.

NOPRINT
: suppresses all displayed output.

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
: orders the values of the class variables according to the specified order.

PRINTALLTYPES
: displays the analysis for all requested combinations of class variables.

PRINTIDVARS
: displays the values of the ID variables.

PRINT | NOPRINT
: displays the output.

STACKODSOUTPUT
: produces an ODS output object

Control the output data set

CHARTYPE
: specifies that the _TYPE_ variable contain character values.

DESCENDTYPES
: orders the output data set by descending _TYPE_ value.

IDMIN
: selects ID variables based on minimum values.

NWAY
: limits the output statistics to the observations with the highest _TYPE_ value.

Control the statistical analysis

ALPHA=*value*
: specifies the confidence level for the confidence limits.

EXCLNPWGT
: excludes observations with nonpositive weights from the analysis.

QMARKERS=*number*
: specifies the sample size to use for the P2 quantile estimation method.

QMETHOD=OS | P2
: specifies the quantile estimation method.

QNTLDEF=1 | 2 | 3 | 4 | 5
: specifies the mathematical definition used to compute quantiles.

statistic-keyword(s)
: selects the statistics.

VARDEF=*divisor*
: specifies the variance divisor.

Optional Arguments

ALPHA=*value*
specifies the confidence level to compute the confidence limits for the mean. The percentage for the confidence limits is (1−*value*)×100. An example is (ALPHA=.05 results in a 95% confidence limit).

Default .05

Range between 0 and 1

Interaction To compute confidence limits specify the *statistic-keyword* CLM, LCLM, or UCLM.

See "Confidence Limits" on page 1511

"Example 7: Computing a Confidence Limit for the Mean" on page 1535

CHARTYPE
specifies that the _TYPE_ variable in the output data set is a character representation of the binary value of _TYPE_. The length of the variable equals the number of class variables.

Interaction When you specify more than 32 class variables, _TYPE_ automatically becomes a character variable.

See "Output Data Set" on page 1514

"Example 10: Computing Output Statistics with Missing Class Variable Values" on page 1542

CLASSDATA=*SAS-data-set*
specifies a data set that contains the combinations of values of the class variables that must be present in the output. Any combinations of values of the class variables that occur in the CLASSDATA= data set but not in the input data set appear in the output and have a frequency of zero.

Restriction The CLASSDATA= data set must contain all class variables. Their data type and format must match the corresponding class variables in the input data set.

Interaction If you use the EXCLUSIVE option, then PROC MEANS excludes any observation in the input data set whose combination of class variables is not in the CLASSDATA= data set.

Tip Use the CLASSDATA= data set to filter or to supplement the input data set.

See "Example 4: Using a CLASSDATA= Data Set with Class Variables" on page 1523

COMPLETETYPES
creates all possible combinations of class variables even if the combination does not occur in the input data set.

Interaction The PRELOADFMT option in the CLASS statement ensures that PROC MEANS writes all user-defined format ranges or values for the combinations of class variables to the output, even when a frequency is zero.

Tip Using COMPLETETYPES does not increase the memory requirements.

See "Example 6: Using Preloaded Formats with Class Variables" on page 1531

DATA=*SAS-data-set*
identifies the input SAS data set.

See "Input Data Sets" on page 26

DESCENDTYPES
orders observations in the output data set by descending _TYPE_ value.

Aliases DESCENDING

DESCEND

Interaction Descending has no effect if you specify NWAY.

Tip Use DESCENDTYPES to make the overall total (_TYPE_=0) the last observation in each BY group.

See "Output Data Set" on page 1514

"Example 9: Computing Different Output Statistics for Several Variables" on page 1539

EXCLNPWGT
excludes observations with nonpositive weight values (zero or negative) from the analysis. By default, PROC MEANS treats observations with negative weights like observations with zero weights and counts them in the total number of observations.

Alias EXCLNPWGTS

See "WEIGHT Statement" on page 1509

WEIGHT= option on the VAR statement on page 1507

EXCLUSIVE
excludes from the analysis all combinations of the class variables that are not found in the CLASSDATA= data set.

Requirement If a CLASSDATA= data set is not specified, then this option is ignored.

See "Example 4: Using a CLASSDATA= Data Set with Class Variables" on page 1523

FW=*field-width*
specifies the field width to display the statistics in printed or displayed output. FW= has no effect on statistics that are saved in an output data set.

Default 12

Tip If PROC MEANS truncates column labels in the output, then increase the field width.

See "Example 1: Computing Specific Descriptive Statistics" on page 1516

"Example 4: Using a CLASSDATA= Data Set with Class Variables" on page 1523

"Example 5: Using Multilabel Value Formats with Class Variables" on page 1526

INCAS=(YES | NO)
specifies whether to allow in-CAS processing.

YES
Use in-CAS processing. YES is the default.

NO
Do not use in-CAS processing.

IDMIN
specifies that the output data set contain the minimum value of the ID variables.

Interaction Specify PRINTIDVARS to display the value of the ID variables in the output.

See "ID Statement" on page 1496

MAXDEC=*number*
specifies the maximum number of decimal places to display the statistics in the printed or displayed output. MAXDEC= has no effect on statistics that are saved in an output data set.

Default BEST. width for columnar format, typically about 7.

Range 0-8

See "Example 2: Computing Descriptive Statistics with Class Variables" on page 1518

"Example 4: Using a CLASSDATA= Data Set with Class Variables" on page 1523

MISSING
considers missing values as valid values to create the combinations of class variables. Special missing values that represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a separate value.

Default If you omit MISSING, then PROC MEANS excludes the observations with a missing class variable value from the analysis.

See *SAS Language Reference: Concepts* for a discussion of missing values that have special meaning.

"Example 6: Using Preloaded Formats with Class Variables" on page 1531

NONOBS
suppresses the column that displays the total number of observations for each unique combination of the values of the class variables. This column corresponds to the _FREQ_ variable in the output data set.

See "The N Obs Statistic" on page 1514

"Example 5: Using Multilabel Value Formats with Class Variables" on page 1526

"Example 6: Using Preloaded Formats with Class Variables" on page 1531

NOPRINT
See the `"PRINT | NOPRINT" option.

NOTHREADS
See the "THREADS | NOTHREADS" option.

NOTRAP
disables floating point exception (FPE) recovery during data processing. By default, PROC MEANS traps these errors and sets the statistic to missing.

In operating environments where the overhead of FPE recovery is significant, NOTRAP can improve performance. Note that normal SAS FPE handling is still in effect so that PROC MEANS terminates in the case of math exceptions.

NWAY
specifies that the output data set contain only statistics for the observations with the highest _TYPE_ and _WAY_ values. When you specify class variables, NWAY corresponds to the combination of all class variables.

Interaction If you specify a TYPES statement or a WAYS statement, then PROC MEANS ignores this option.

See "Output Data Set" on page 1514

"Example 10: Computing Output Statistics with Missing Class Variable Values" on page 1542

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
specifies the sort order to create the unique combinations for the values of the class variables in the output, where

DATA
orders values according to their order in the input data set.

Interaction If you use PRELOADFMT in the CLASS statement, then the order for the values of each class variable matches the order that PROC FORMAT uses to store the values of the associated user-defined format. If you use the CLASSDATA= option, then PROC MEANS uses the order of the unique values of each class variable in the CLASSDATA= data set to order the output levels. If you use both options, then PROC MEANS first uses the user-defined formats to order the output. If you omit EXCLUSIVE, then PROC MEANS appends after the user-defined format and the CLASSDATA= values the unique values of the class variables in the input data set based on the order in which they are encountered.

Tip By default, PROC FORMAT stores a format definition in sorted order. Use the NOTSORTED option to store the values or ranges of a user-defined format in the order in which you define them.

FORMATTED
orders values by their ascending formatted values. This order depends on your operating environment.

Aliases FMT

EXTERNAL

FREQ
orders values by descending frequency count so that levels with the most observations are listed first.

Interactions For multiway combinations of the class variables, PROC MEANS determines the order of a class variable combination from the individual class variable frequencies.

Use the ASCENDING option in the CLASS statement to order values by ascending frequency count.

UNFORMATTED
orders values by their unformatted values. This order depends on your operating environment. This sort sequence is particularly useful for displaying dates chronologically.

Specifying ORDER=UNFORMATTED usually, but not always, produces the same results as PROC SORT. For more information about ordering data, see "Controlling the Order of Data Values" on page 27.

Aliases UNFMT

INTERNAL

See "Ordering the Class Values" on page 1468

Default UNFORMATTED

PRINT | NOPRINT
specifies whether PROC MEANS displays the statistical analysis. NOPRINT suppresses all the output.

Default PRINT

Tip Use NOPRINT when you want to create only an OUT= output data set.

See "Example 8: Computing Output Statistics" on page 1537

"Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

PRINTALLTYPES
displays all requested combinations of class variables (all _TYPE_ values) in the printed or displayed output. Normally, PROC MEANS shows only the NWAY type.

Alias PRINTALL

Interaction If you use the NWAY option, the TYPES statement, or the WAYS statement, then PROC MEANS ignores this option.

See "Example 4: Using a CLASSDATA= Data Set with Class Variables" on page 1523

PRINTIDVARS
displays the values of the ID variables in printed or displayed output.

Alias PRINTIDS

Interaction Specify IDMIN to display the minimum value of the ID variables.

See "ID Statement" on page 1496

QMARKERS=*number*
specifies the default number of markers to use for the P^2 quantile estimation method. The number of markers controls the size of fixed memory space.

Default The default value depends on which quantiles you request. For the median (P50), *number* is 7. For the quantiles (P25 and P50), *number* is 25. For the quantiles P1, P5, P10, P75 P90, P95, or P99, *number* is 105. If you request several quantiles, then PROC MEANS uses the largest value of *number*.

Range an odd integer greater than 3

Tip Increase the number of markers above the defaults settings to improve the accuracy of the estimate; reduce the number of markers to conserve memory and computing time.

See "Quantiles" on page 1512

QMETHOD=OS | P2
specifies the method that PROC MEANS uses to process the input data when it computes quantiles. If the number of observations is less than or equal to the

QMARKERS= value and QNTLDEF=5, then both methods produce the same results.

OS
uses order statistics. This method is the same method that PROC UNIVARIATE uses.

Note: This technique can be very memory-intensive.

P2
uses the P^2 method to approximate the quantile.

Default OS

Restriction When QMETHOD=P2, PROC MEANS does not compute MODE or weighted quantiles.

Tip When QMETHOD=P2, reliable estimations of some quantiles (P1,P5,P95,P99) might not be possible for some data sets.

See "Quantiles" on page 1512

QNTLDEF=1 | 2 | 3 | 4 | 5
specifies the mathematical definition that PROC MEANS uses to calculate quantiles when QMETHOD=OS. To use QMETHOD=P2, you must use QNTLDEF=5.

Alias PCTLDEF=

Default 5

See "Quantile and Related Statistics" on page 2706

statistic-keyword(s)
specifies which statistics to compute and the order to display them in the output. The available keywords in the PROC statement are

Descriptive statistic keywords	
CLM	NMISS
CSS	RANGE
CV	SKEWNESS | SKEW
KURTOSIS | KURT	STDDEV | STD
LCLM	STDERR
MAX	SUM
MEAN	SUMWGT

MIN	UCLM
MODE	USS
N	VAR
Quantile statistic keywords	
MEDIAN | P50	Q3 | P75
P1	P90
P5	P95
P10	P99
P20	P30
P40	P60
P70	P80
Q1 | P25	QRANGE
Hypothesis testing keywords	
PROBT | PRT	T

Default N, MEAN, STD, MIN, and MAX

Requirement To compute standard error, confidence limits for the mean, and the Student's *t*-test, you must use the default value of the VARDEF= option, which is DF. To compute skewness or kurtosis, you must use VARDEF=N or VARDEF=DF.

Tip Use CLM or both LCLM and UCLM to compute a two-sided confidence limit for the mean. Use only LCLM or UCLM, to compute a one-sided confidence limit.

See The definitions of the keywords and the formulas for the associated statistics are listed in "Keywords and Formulas" on page 2700.

"Example 1: Computing Specific Descriptive Statistics" on page 1516

"Example 3: Using the BY Statement with Class Variables" on page 1521

STACKODSOUTPUT
produces an ODS output object whose data set resembles the printed output.

The STACKODSOUTPUT option affects output data sets created by ODS OUTPUT statements, not the PROC MEANS OUTPUT statement.

Alias STACKODS

See "Example 13: Using the STACKODSOUTPUT Option to Control Data" on page 1552

SUMSIZE=*value*
specifies the amount of memory that is available for data summarization when you use class variables. *value* might be one of the following:

n
***n*K**
***n*M**
***n*G**
specifies the amount of memory available in bytes, kilobytes, megabytes, or gigabytes, respectively. If *n* is 0, then PROC MEANS use the value of the SAS system option SUMSIZE=.

MAXIMUM
MAX
specifies the maximum amount of memory that is available.

Default The value of the SUMSIZE= system option.

Note Specifying SUMSIZE=0 enables PROC MEANS to use the preferred global REALMEMSIZE option.

Tip For best results, do not make SUMSIZE= larger than the amount of physical memory that is available for the PROC step. If additional space is needed, then PROC MEANS uses utility files.

See The SAS system option SUMSIZE= in *SAS System Options: Reference*.

THREADS | NOTHREADS
enables or disables parallel processing of the input data set. This option overrides the SAS system option THREADS | NOTHREADS unless the system option is restricted. (See Restriction.) For more information, see "Support for Parallel Processing" in the *SAS Language Reference: Concepts*.

Default value of SAS system option THREADS | NOTHREADS.

Restriction Your site administrator can create a restricted options table. A restricted options table specifies SAS system option values that are established at start-up and cannot be overridden. If the THREADS | NOTHREADS system option is listed in the restricted options table, any attempt to set these system options is ignored and a warning message is written to the SAS log.

Interaction PROC MEANS honors the SAS system option THREADS except when a BY statement is specified or the value of the SAS system option CPUCOUNT is less than 2. You can use THREADS in the

PROC MEANS statement to force PROC MEANS to use parallel processing in these situations.

Note If THREADS is specified (either as a SAS system option or in the PROC MEANS statement) and another program has the input data set open for reading, writing, or updating, then PROC MEANS might fail to open the input data set. In this case, PROC MEANS stops processing and writes a message to the SAS log.

VARDEF=*divisor*

specifies the divisor to use in the calculation of the variance and standard deviation. The following table shows the possible values for *divisor* and associated divisors.

Table 40.1 *Possible Values for VARDEF=*

Value	Divisor	Formula for Divisor
DF	Degrees of freedom	$n - 1$
N	Number of observations	n
WDF	Sum of weights minus one	$(\Sigma_i w_i) - 1$
WEIGHT | WGT	Sum of weights	$\Sigma_i w_i$

The procedure computes the variance as $CSS/divisor$, where CSS is the corrected sums of squares and equals $\Sigma (x_i - \overline{x})^2$. When you weight the analysis variables, CSS equals $\Sigma w_i(x_i - \overline{x}_w)^2$, where $\overline{x}_w$ is the weighted mean.

Default DF

Requirement To compute the standard error of the mean, confidence limits for the mean, or the Student's *t*-test, use the default value of VARDEF=.

Tips When you use the WEIGHT statement and VARDEF=DF, the variance is an estimate of σ^2 , where the variance of the *i*th observation is $var(x_i) = \sigma^2/w_i$ and w_i is the weight for the *i*th observation. This method yields an estimate of the variance of an observation with unit weight.

When you use the WEIGHT statement and VARDEF=WGT, the computed variance is asymptotically (for large *n*) an estimate of $\sigma^2/\overline{w}$, where $\overline{w}$ is the average weight. This method yields an asymptotic estimate of the variance of an observation with average weight.

See "Keywords and Formulas" on page 2700

"Weighted Statistics Example" on page 84

BY Statement

Produces separate statistics for each BY group.

See: "BY" on page 74
"Comparison of the BY and CLASS Statements" on page 1495
Example: "Example 3: Using the BY Statement with Class Variables" on page 1521

Syntax

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...> <NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you omit the NOTSORTED option in the BY statement, then the observations in the data set either must be sorted by all the variables that you specify or must be indexed appropriately. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The observations are sorted in another way (for example, chronological order).

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. The procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

Details

Using the BY Statement with the SAS System Option NOBYLINE

If you use the BY statement with the SAS system option NOBYLINE, which suppresses the BY line that normally appears in output that is produced with BY-group processing, then PROC MEANS always starts a new page for each BY group. This behavior ensures that if you create customized BY lines by putting BY-group information in the title and suppressing the default BY lines with NOBYLINE, then the information in the titles matches the report on the pages. See "Creating Titles That Contain BY-Group Information " on page 57. Also see "Suppressing the Default BY Line" on page 57.

CLASS Statement

Specifies the variables whose values define the subgroup combinations for the analysis.

Note: CLASS statements without options use ORDER=INTERNAL, which is the default, or the value specified by the ORDER= option in the PROC MEANS statement. For example, in the following code, variables c and d would use ORDER=INTERNAL. If an ORDER= option had been specified in the PROC MEANS statement, then variables c and d would use the value specified by the ORDER= option in the PROC MEANS statement.

```
class a b / order=data;
 class c d;
```

Tips: You can use multiple CLASS statements.

Some CLASS statement options are also available in the PROC MEANS statement. They affect all CLASS variables. Options that you specify in a CLASS statement apply only to the variables in that CLASS statement.

See: For information about how the CLASS statement groups formatted values, see "Formatted Values" on page 63.

Examples:

"Example 2: Computing Descriptive Statistics with Class Variables" on page 1518

"Example 3: Using the BY Statement with Class Variables" on page 1521

"Example 4: Using a CLASSDATA= Data Set with Class Variables" on page 1523

"Example 5: Using Multilabel Value Formats with Class Variables" on page 1526

"Example 6: Using Preloaded Formats with Class Variables" on page 1531

"Example 7: Computing a Confidence Limit for the Mean" on page 1535

"Example 8: Computing Output Statistics" on page 1537

"Example 9: Computing Different Output Statistics for Several Variables" on page 1539

"Example 10: Computing Output Statistics with Missing Class Variable Values" on page 1542

"Example 11: Identifying an Extreme Value with the Output Statistics" on page 1544

"Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

Syntax

CLASS *variable(s)* </ *options*>;

Required Argument

variable(s)
specifies one or more variables that the procedure uses to group the data. Variables in a CLASS statement are referred to as *class variables*. Class variables are numeric or character. Class variables can have continuous values, but they typically have a few discrete values that define levels of the variable. You do not have to sort the data by class variables.

Interaction Use the TYPES statement or the WAYS statement to control which class variables PROC MEANS uses to group the data.

Tip To reduce the number of class variable levels, use a FORMAT statement to combine variable values. When a format combines several internal values into one formatted value, PROC MEANS outputs the lowest internal value.

See "Using Class Variables " on page 1467

Optional Arguments

ASCENDING
specifies to sort the class variable levels in ascending order.

Alias ASCEND

Interaction PROC MEANS issues a warning message if you specify both ASCENDING and DESCENDING and ignores both options.

See "Example 10: Computing Output Statistics with Missing Class Variable Values" on page 1542

DESCENDING
specifies to sort the class variable levels in descending order.

Alias DESCEND

Interaction PROC MEANS issues a warning message if you specify both ASCENDING and DESCENDING and ignores both options.

EXCLUSIVE
excludes from the analysis all combinations of the class variables that are not found in the preloaded range of user-defined formats.

Requirement You must specify PRELOADFMT to preload the class variable formats.

See "Example 6: Using Preloaded Formats with Class Variables" on page 1531

GROUPINTERNAL

specifies not to apply formats to the class variables when PROC MEANS groups the values to create combinations of class variables.

Interactions If you specify the PRELOADFMT option, then PROC MEANS ignores the GROUPINTERNAL option and uses the formatted values.

If you specify the ORDER=FORMATTED option, then PROC MEANS ignores the GROUPINTERNAL option and uses the formatted values.

Tip This option saves computer resources when the numeric class variables contain discrete values.

See "Computer Resources" on page 1496

MISSING

considers missing values as valid values for the class variable levels. Special missing values that represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a separate value.

Default If you omit MISSING, then PROC MEANS excludes the observations with a missing class variable value from the analysis.

See *SAS Language Reference: Concepts* for a discussion of missing values with special meanings.

"Example 10: Computing Output Statistics with Missing Class Variable Values" on page 1542

MLF

enables PROC MEANS to use the primary and secondary format labels for a given range or overlapping ranges to create subgroup combinations when a multilabel format is assigned to a class variable.

Requirement You must use PROC FORMAT and the MULTILABEL option in the VALUE statement to create a multilabel format.

Interactions If you use the OUTPUT statement with MLF, then the class variable contains a character string that corresponds to the formatted value. Because the formatted value becomes the internal value, the length of this variable is the number of characters in the longest format label.

Using MLF with ORDER=FREQ might not produce the order that you expect for the formatted values. You might not get the expected results when you use MLF with CLASSDATA and EXCLUSIVE because MLF processing requires that each TYPE be

computed independently. Types other than NWAY might contain more levels than expected.

Note When the formatted values overlap, one internal class variable value maps to more than one class variable subgroup combination. Therefore, the sum of the N statistics for all subgroups is greater than the number of observations in the data set (the overall N statistic).

Tip If you omit MLF, then PROC MEANS uses the primary format labels. This action corresponds to using the first external format value to determine the subgroup combinations.

See The MULTILABEL option in the VALUE statement of the FORMAT procedure "Optional Arguments" on page 1100.

"Example 5: Using Multilabel Value Formats with Class Variables" on page 1526

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED

specifies the order to group the levels of the class variables in the output, where

DATA

orders values according to their order in the input data set.

Interaction If you use PRELOADFMT, then the order of the values of each class variable matches the order that PROC FORMAT uses to store the values of the associated user-defined format. If you use the CLASSDATA= option in the PROC statement, then PROC MEANS uses the order of the unique values of each class variable in the CLASSDATA= data set to order the output levels. If you use both options, then PROC MEANS first uses the user-defined formats to order the output. If you omit EXCLUSIVE in the PROC statement, then PROC MEANS appends after the user-defined format and the CLASSDATA= values the unique values of the class variables in the input data set based on the order in which they are encountered.

Tip By default, PROC FORMAT stores a format definition in sorted order. Use the NOTSORTED option to store the values or ranges of a user-defined format in the order in which you define them.

See "Example 10: Computing Output Statistics with Missing Class Variable Values" on page 1542

FORMATTED

orders values by their ascending formatted values. This order depends on your operating environment. If no format has been assigned to a class variable, then the default format, BEST12., is used.

Aliases FMT

EXTERNAL

See "Example 5: Using Multilabel Value Formats with Class Variables" on page 1526

FREQ
orders values by descending frequency count so that levels with the most observations are listed first.

Interactions For multiway combinations of the class variables, PROC MEANS determines the order of a level from the individual class variable frequencies.

Use the ASCENDING option to order values by ascending frequency count.

See "Example 5: Using Multilabel Value Formats with Class Variables" on page 1526

UNFORMATTED
orders values by their unformatted values. This order depends on your operating environment. This sort sequence is particularly useful for displaying dates chronologically.

Specifying ORDER=UNFORMATTED usually, but not always, produces the same results as PROC SORT. For more information about ordering data, see "Controlling the Order of Data Values" on page 27.

Aliases UNFMT

INTERNAL

See "Ordering the Class Values" on page 1468

Default UNFORMATTED

PRELOADFMT
specifies that all formats are preloaded for the class variables.

Requirement PRELOADFMT has no effect unless you specify either COMPLETETYPES, EXCLUSIVE, or ORDER=DATA and you assign formats to the class variables.

Interactions The combination of PRELOADFMT and COMPLETETYPES generates values that might not appear within the input data set. In some cases, for a character class variable, extremely low or high sentinel values are generated. These values might not represent valid characters of the session encoding. These values should not be printed in their raw form but should be printed using the associated format. Use of the OTHER= value in the format definition can prevent the raw sentinel values from printing when using the format.

To limit PROC MEANS output to the combinations of formatted class variable values present in the input data set, use the EXCLUSIVE option in the CLASS statement.

To include all ranges and values of the user-defined formats in the output, even when the frequency is zero, use COMPLETETYPES in the PROC statement.

Note When preloading a character format, there must be at least one representative raw value that produces the label. If a range does not have any raw values, the range is considered unreachable and an error is generated. For example, you cannot preload a multi-label character format with both Other= and Low-High ranges. Other is a special keyword that refers to values or ranges that remain after all labels have been defined. For character formats, missing values are included in the low range so that there are no raw values left to occupy the Other range.

See "Example 6: Using Preloaded Formats with Class Variables" on page 1531

Details

Comparison of the BY and CLASS Statements

Using the BY statement is similar to using the CLASS statement and the NWAY option in that PROC MEANS summarizes each BY group as an independent subset of the input data. Therefore, no overall summarization of the input data is available. However, unlike the CLASS statement, the BY statement requires that the data is pre-sorted or indexed by the variables in the BY statement.

When you use the NWAY option, PROC MEANS might encounter insufficient memory for the summarization of all the class variables. You can move some class variables to the BY statement. For maximum benefit, move class variables to the BY statement that are already sorted or that have the greatest number of unique values.

You can use the CLASS and BY statements together to analyze the data by the levels of class variables within BY groups. See "Example 3: Using the BY Statement with Class Variables" on page 1521.

How PROC MEANS Handles Missing Values for Class Variables

By default, if an observation contains a missing value for any class variable, then PROC MEANS excludes that observation from the analysis. If you specify the MISSING option in the PROC statement, then the procedure considers missing values as valid levels for the combination of class variables.

Specifying the MISSING option in the CLASS statement enables you to control the acceptance of missing values for individual class variables.

Computer Resources

The total of unique class variable values that PROC MEANS allows depends on the amount of computer memory that is available. See "Computational Resources" on page 1469 for more information.

The GROUPINTERNAL option can improve computer performance because the grouping process is based on the internal values of the class variables. If a numeric class variable is not assigned a format and you do not specify GROUPINTERNAL, then PROC MEANS uses the default format, BEST12., to format numeric values as character strings. Then PROC MEANS groups these numeric variables by their character values, which takes additional time and computer memory.

FREQ Statement

Specifies a numeric variable that contains the frequency of each observation.

See: "FREQ" on page 79

Syntax

FREQ *variable*;

Required Argument

variable
specifies a numeric variable whose value represents the frequency of the observation. If you use the FREQ statement, then the procedure assumes that each observation represents *n* observations, where *n* is the value of *variable*. If *n* is not an integer, then SAS truncates it. If *n* is less than 1 or is missing, then the procedure does not use that observation to calculate statistics.

The sum of the frequency variable represents the total number of observations.

Note: The FREQ variable does not affect how PROC MEANS identifies multiple extremes when you use the IDGROUP syntax in the OUTPUT statement.

ID Statement

Includes additional variables in the output data set.

See: Discussion of id-group-specification in "OUTPUT Statement" on page 1497.

Syntax

ID *variable(s)*;

Required Argument

variable(s)
identifies one or more variables from the input data set whose maximum values for groups of observations PROC MEANS includes in the output data set.

Interaction Use IDMIN in the PROC statement to include the minimum value of the ID variables in the output data set.

Tip Use the PRINTIDVARS option in the PROC statement to include the value of the ID variable in the displayed output.

Details

Selecting the Values of the ID Variables

When you specify only one variable in the ID statement, the value of the ID variable for a given observation is the maximum (minimum) value found in the corresponding group of observations in the input data set. When you specify multiple variables in the ID statement, PROC MEANS selects the maximum value by processing the variables in the ID statement in the order in which you list them. PROC MEANS determines which observation to use from all the ID variables by comparing the values of the first ID variable. If more than one observation contains the same maximum (minimum) ID value, then PROC MEANS uses the second and subsequent ID variable values as "tiebreakers." In any case, all ID values are taken from the same observation for any given BY group or classification level within a type.

See "Sorting Orders for Character Variables " on page 2359 for information about how PROC MEANS compares character values to determine the maximum value.

OUTPUT Statement

Writes statistics to a new SAS data set.

Tip: You can use multiple OUTPUT statements to create several OUT= data sets.

Examples:
"Example 8: Computing Output Statistics" on page 1537
"Example 9: Computing Different Output Statistics for Several Variables" on page 1539
"Example 10: Computing Output Statistics with Missing Class Variable Values" on page 1542
"Example 11: Identifying an Extreme Value with the Output Statistics" on page 1544

"Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

Syntax

OUTPUT <OUT=*SAS-data-set*> <*output-statistic-specification(s)*> <*id-group-specification(s)*> <*maximum-id-specification(s)*> <*minimum-id-specification(s)*> </ *options*>;

Optional Arguments

OUT=*SAS-data-set*
names the new output data set. If *SAS-data-set* does not exist, then PROC MEANS creates it. If you omit OUT=, then the data set is named DATA*n*, where *n* is the smallest integer that makes the name unique.

Default DATA*n*

Tip You can use data set options with the OUT= option.

output-statistic-specification(s)
specifies the statistics to store in the OUT= data set and names one or more variables that contain the statistics. The form of the *output-statistic-specification* is

statistic-keyword<(*variable-list*)>=<*name(s)*>

where

statistic-keyword
specifies which statistic to store in the output data set. The available statistic keywords are

Descriptive statistics keyword	
CLM	NMISS
CSS	RANGE
CV	SKEWNESS | SKEW
KURTOSIS | KURT	STDDEV | STD
LCLM	STDERR
MAX	SUM
MEAN	SUMWGT
MIN	UCLM

MODE	USS
N	VAR
Quantile statistics keyword	
MEDIAN | P50	Q3 | P75
P1	P90
P5	P95
P10	P99
P20	P30
P40	P60
P70	P80
Q1 | P25	QRANGE
Hypothesis testing keyword	
PROBT | PRT	T

By default the statistics in the output data set automatically inherit the analysis variable's format, informat, and label. However, statistics computed for N, NMISS, SUMWGT, USS, CSS, VAR, CV, T, PROBT, PRT, SKEWNESS, and KURTOSIS do not inherit the analysis variable's format because this format might be invalid for these statistics (for example, dollar or datetime formats).

Restriction If you omit *variable* and *name(s)*, then PROC MEANS allows the *statistic-keyword* only once in a single OUTPUT statement, unless you also use the AUTONAME option.

See "Example 8: Computing Output Statistics" on page 1537

"Example 9: Computing Different Output Statistics for Several Variables" on page 1539

"Example 11: Identifying an Extreme Value with the Output Statistics" on page 1544

"Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

variable-list
specifies the names of one or more numeric analysis variables whose statistics you want to store in the output data set.

Default all numeric analysis variables

name(s)
specifies one or more names for the variables in the output data set that contain the analysis variable statistics. The first name contains the statistic for the first analysis variable; the second name contains the statistic for the second analysis variable; and so on.

Default the analysis variable name. If you specify AUTONAME, then the default is the combination of the analysis variable name and the *statistic-keyword*. If you use the CLASS statement and an OUTPUT statement without an *output-statistic-specification*, then the output data set contains five observations for each combination of class variables: the value of N, MIN, MAX, MEAN, and STD. If you use the WEIGHT statement or the WEIGHT option in the VAR statement, then the output data set also contains an observation with the sum of weights (SUMWGT) for each combination of class variables.

Interaction If you specify *variable-list*, then PROC MEANS uses the order in which you specify the analysis variables to store the statistics in the output data set variables.

Tip Use the AUTONAME option to have PROC MEANS generate unique names for multiple variables and statistics.

See "Example 8: Computing Output Statistics" on page 1537

id-group-specification
combines the features and extends the ID statement, the IDMIN option in the PROC statement, and the MAXID and MINID options in the OUTPUT statement to create an OUT= data set that identifies multiple extreme values. The form of the *id-group-specification* is

IDGROUP (<MIN | MAX (*variable-list-1*) <...MIN | MAX (*variable-list-n*)>>
<<MISSING>
<OBS> <LAST>> OUT <[*n*]>
(*id-variable-list*)=<*name(s)*>)

MIN
MAX(*variable-list*)
specifies the selection criteria to determine the extreme values of one or more input data set variables specified in *variable-list*. Use MIN to determine the minimum extreme value and MAX to determine the maximum extreme value.

When you specify multiple selection variables, the ordering of observations for the selection of *n* extremes is done the same way that PROC SORT sorts data with multiple BY variables. PROC MEANS concatenates the variable values into a single key. The MAX(*variable-list*) selection criterion is similar to using PROC SORT and the DESCENDING option in the BY statement.

Default If you do not specify MIN or MAX, then PROC MEANS uses the observation number as the selection criterion to output observations.

Restriction If you specify criteria that are contradictory, then PROC MEANS uses only the first selection criterion.

Interaction When multiple observations contain the same extreme values in all the MIN or MAX variables, PROC MEANS uses the observation number to resolve which observation to write to the output. By default, PROC MEANS uses the first observation to resolve any ties. However, if you specify the LAST option, then PROC MEANS uses the last observation to resolve any ties.

LAST

specifies that the OUT= data set contains values from the last observation (or the last *n* observations, if *n* is specified). If you do not specify LAST, then the OUT= data set contains values from the first observation (or the first *n* observations, if *n* is specified). The OUT= data set might contain several observations because in addition to the value of the last (first) observation, the OUT= data set contains values from the last (first) observation of each subgroup level that is defined by combinations of class variable values.

Interaction When you specify MIN or MAX and when multiple observations contain the same extreme values, PROC MEANS uses the observation number to resolve which observation to save to the OUT= data set. If you specify LAST, then PROC MEANS uses the later observations to resolve any ties. If you do not specify LAST, then PROC MEANS uses the earlier observations to resolve any ties.

MISSING

specifies that missing values be used in selection criteria.

Alias MISS

OBS

includes an _OBS_ variable in the OUT= data set that contains the number of the observation in the input data set where the extreme value was found.

Interactions If you use WHERE processing, then the value of _OBS_ might not correspond to the location of the observation in the input data set.

If you use [*n*] to write multiple extreme values to the output, then PROC MEANS creates *n* _OBS_ variables and uses the suffix *n* to create the variable names, where *n* is a sequential integer from 1 to *n*.

[*n*]

specifies the number of extreme values for each variable in *id-variable-list* to include in the OUT= data set. PROC MEANS creates *n* new variables and

uses the suffix _*n* to create the variable names, where *n* is a sequential integer from 1 to *n*.

By default, PROC MEANS determines one extreme value for each level of each requested type. If *n* is greater than one, then *n* extremes are generated for each level of each type. When *n* is greater than one and you request extreme value selection, the time complexity is $O(T * N \log_2 n)$, where T is the number of types requested and N is the number of observations in the input data set. By comparison, to group the entire data set, the time complexity is $O(N \log_2 N)$.

Default 1

Range an integer between 1 and 100

Example For example, to generate two minimum extreme values for each variable, use

```
idgroup(min(x) out[2](x y z)=MinX MinY MinZ);
```

The OUT= data set contains the variables MinX_1, MinX_2, MinY_1, MinY_2, MinZ_1, and MinZ_2.

(id-variable-list)

identifies one or more input data set variables whose values PROC MEANS includes in the OUT= data set. PROC MEANS determines which observations to generate by the selection criteria that you specify (MIN, MAX, and LAST).

Alias IDGRP

Requirement You must specify the MIN | MAX selection criteria first and OUT(*id-variable-list*)= after the suboptions MISSING, OBS, and LAST.

Tips You can use *id-group-specification* to mimic the behavior of the ID statement and a *maximum-id-specification* or *minimum-id-specification* in the OUTPUT statement.

When you want the output data set to contain extreme values along with other ID variables, it is more efficient to include them in the *id-variable-list* than to request separate statistics. For example, the statement `output idgrp(max(x) out(x a b)= );` is more efficient than the statement `output idgrp(max(x) out(a b)= ) max(x)=;`

See "Example 8: Computing Output Statistics" on page 1537

"Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

name(s)

specifies one or more names for variables in the OUT= data set.

Default If you omit *name*, then PROC MEANS uses the names of variables in the *id-variable-list*.

Tip Use the AUTONAME option to automatically resolve naming conflicts.

CAUTION

The IDGROUP syntax enables you to create output variables with the same name. When this action happens, only the first variable appears in the output data set. Use the AUTONAME option to automatically resolve these naming conflicts.

Note: If you specify fewer new variable names than the combination of analysis variables and identification variables, then the remaining output variables use the corresponding names of the ID variables as soon as PROC MEANS exhausts the list of new variable names.

maximum-id-specification(s)

specifies that one or more identification variables be associated with the maximum values of the analysis variables. The form of the *maximum-id-specification* is

MAXID <(*variable-1* <(*id-variable-list-1*)> <...*variable-n* <(*id-variable-list-n*)>>)> = *name(s)*

variable

identifies the numeric analysis variable whose maximum values PROC MEANS determines. PROC MEANS can determine several maximum values for a variable because, in addition to the overall maximum value, subgroup levels, which are defined by combinations of class variables values, also have maximum values.

Tip If you use an ID statement and omit *variable*, then PROC MEANS uses all analysis variables.

id-variable-list

identifies one or more variables whose values identify the observations with the maximum values of the analysis variable.

Default the ID statement variables

name(s)

specifies the names for new variables that contain the values of the identification variable associated with the maximum value of each analysis variable.

Note If multiple observations contain the maximum value within a class level, then PROC MEANS saves the value of the ID variable for only the first of those observations in the output data set.

Tips If you use an ID statement, and omit *variable* and *id-variable*, then PROC MEANS associates all ID statement variables with each analysis variable. Thus, for each analysis variable, the number of variables that are created in the output data set equals the number of variables that you specify in the ID statement.

Use the AUTONAME option to automatically resolve naming conflicts.

See "Example 11: Identifying an Extreme Value with the Output Statistics" on page 1544

CAUTION

The MAXID syntax enables you to create output variables with the same name. When this action happens, only the first variable appears in the output data set. Use the AUTONAME option to automatically resolve these naming conflicts.

Note: If you specify fewer new variable names than the combination of analysis variables and identification variables, then the remaining output variables use the corresponding names of the ID variables as soon as PROC MEANS exhausts the list of new variable names.

minimum-id-specification

See the description of maximum-id-specification. This option behaves in exactly the same way, except that PROC MEANS determines the minimum values instead of the maximum values. The form of the *minid-specification* is

MINID<(*variable-1* <(*id-variable-list-1*)> <...*variable-n* <(*id-variable-list-n*)>>)> = *name(s)*

When MINID is used without an explicit variable list, it is similar to the following more advanced IDGROUP syntax example:

IDGRP(min(x) missing out(id_variable)=idminx) idgrp(min(y) missing out(id_variable)=idminy)

If one or more of the analysis variables has a missing value, the id_variable value corresponds to the observation with the missing value not the observation with the value for the MIN statistic.

option

can be one of the following items:

AUTOLABEL

specifies that PROC MEANS appends the statistic name to the end of the variable label. If an analysis variable has no label, then PROC MEANS creates a label by appending the statistic name to the analysis variable name.

See "Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

AUTONAME

specifies that PROC MEANS creates a unique variable name for an output statistic when you do not assign the variable name in the OUTPUT statement. This action is accomplished by appending to the *statistic-keyword* to the end of the input variable name from which the statistic was derived.

For example, the statement `output min(x)=/autoname;` produces the x_Min variable in the output data set.

AUTONAME activates the SAS internal mechanism to automatically resolve conflicts in the variable names in the output data set. Duplicate variables do not generate errors.

As a result, the statement `output min(x)= min(x)=/autoname;` produces two variables, x_Min and x_Min2, in the output data set.

If the new variable name exceeds 32 characters, then the variable-name portion is truncated.

See "Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

KEEPLEN

specifies that statistics in the output data set inherit the length of the analysis variable that PROC MEANS uses to derive them.

CAUTION

You permanently lose numeric precision when the length of the analysis variable causes PROC MEANS to truncate or round the value of the statistic. However, the precision of the statistic matches that of the input.

LEVELS

includes a variable named _LEVEL_ in the output data set. This variable contains a value from 1 to *n* that indicates a unique combination of the values of class variables (the values of _TYPE_ variable).

See "Output Data Set" on page 1514

"Example 8: Computing Output Statistics" on page 1537

NOINHERIT

specifies that the variables in the output data set that contain statistics do not inherit the attributes (label and format) of the analysis variables that are used to derive them.

Interaction When no option is used (implied INHERIT) then the statistics inherit the attributes, label and format, of the input analysis variable(s). If the INHERIT option is used in the OUTPUT statement, then the statistics inherit the length of the input analysis variable(s), the label and format.

Tip By default, the output data set includes an output variable for each analysis variable and for five observations that contain N, MIN, MAX, MEAN, and STDDEV. Unless you specify NOINHERIT, this variable inherits the format of the analysis variable, which can be invalid for the N statistic (for example, datetime formats).

WAYS
includes a variable named _WAY_ in the output data set. This variable contains a value from 1 to the maximum number of class variables that indicates how many class variables PROC MEANS combines to create the TYPE value.

See "Output Data Set" on page 1514

"WAYS Statement" on page 1509

"Example 8: Computing Output Statistics" on page 1537

TYPES Statement

Identifies which of the possible combinations of class variables to generate.

Requirement: CLASS statement

See: "Output Data Set" on page 1514

Examples: "Example 2: Computing Descriptive Statistics with Class Variables" on page 1518

"Example 5: Using Multilabel Value Formats with Class Variables" on page 1526

"Example 12: Identifying the Top Three Extreme Values with the Output Statistics" on page 1547

Syntax

TYPES *request(s)*;

Required Argument

request(s)
specifies which of the 2^k combinations of class variables PROC MEANS uses to create the types, where k is the number of class variables. A request includes one class variable name, several class variable names separated by asterisks, or ().

To request class variable combinations quickly, use a grouping syntax by placing parentheses around several variables and joining other variables or variable combinations. For example, the following statements illustrate grouping syntax:

Request	Equivalent to
`types A*(B C);`	`types A*B A*C;`
`types (A B)*(C D);`	`types A*C A*D B*C B*D;`

```
types (A B C)*D;          types A*D B*D C*D;
```

Interaction The CLASSDATA= option places constraints on the NWAY type. PROC MEANS generates all other types as if derived from the resulting NWAY type.

Tips Use ( ) to request the overall total (_TYPE_=0).

If you do not need all types in the output data set, then use the TYPES statement to specify particular subtypes rather than applying a WHERE clause to the data set. Doing so saves time and computer memory.

Details

Order of Analyses in the Output

The analyses are written to the output in order of increasing values of the _TYPE_ variable, which is calculated by PROC MEANS. The _TYPE_ variable has a unique value for each combination of class variables; the values are determined by how you specify the CLASS statement, not the TYPES statement. Therefore, if you specify

```
class A B C;
types (A B)*C;
```

then the B*C analysis (_TYPE_=3) is written first, followed by the A*C analysis (_TYPE_=5). However, if you specify

```
class B A C;
types (A B)*C;
```

then the A*C analysis comes first.

The _TYPE_ variable is calculated even if no output data set is requested. For more information about the _TYPE_ variable, see “Output Data Set” on page 1514.

VAR Statement

Identifies the analysis variables and their order in the output.

Default: If you omit the VAR statement, then PROC MEANS analyzes all numeric variables that are not listed in the other statements. When all variables are character variables, PROC MEANS produces a simple count of observations.

Tip: You can use multiple VAR statements.

See: Chapter 69, “SUMMARY Procedure,” on page 2455

Example: “Example 1: Computing Specific Descriptive Statistics” on page 1516

Syntax

VAR *variable(s)* </ WEIGHT=*weight-variable*>;

Required Argument

variable(s)
identifies the analysis variables and specifies their order in the results.

Optional Argument

WEIGHT=*weight-variable*
specifies a numeric variable whose values weight the values of the variables that are specified in the VAR statement. The variable does not have to be an integer. The following table describes how PROC MEANS treats various values of the WEIGHT variable.

Weight Value	PROC MEANS Response
0	Counts the observation in the total number of observations
Less than 0	Converts the value to zero and counts the observation in the total number of observations
Missing	Excludes the observation

To exclude observations that contain negative and zero weights from the analysis, use EXCLNPWGT. Note that most SAS/STAT procedures, such as PROC GLM, exclude negative and zero weights by default.

The weight variable does not change how the procedure determines the range, extreme values, or number of missing values.

Restrictions To compute weighted quantiles, use QMETHOD=OS in the PROC statement.

Skewness and kurtosis are not available with the WEIGHT option.

Note Prior to Version 7 of SAS, the procedure did not exclude the observations with missing weights from the count of observations.

Tips When you use the WEIGHT option, consider which value of the VARDEF= option is appropriate. See the discussion of VARDEF=.

Use the WEIGHT option in multiple VAR statements to specify different weights for the analysis variables.

WAYS Statement

Specifies the number of ways to make unique combinations of class variables.

Tip: Use the TYPES statement to specify additional combinations of class variables.

Example: "Example 6: Using Preloaded Formats with Class Variables" on page 1531

Syntax

WAYS *list*;

Required Argument

list

specifies one or more integers that define the number of class variables to combine to form all the unique combinations of class variables. For example, you can specify 2 for all possible pairs and 3 for all possible triples. The *list* can be specified in the following ways:

- *m*
- *m1 m2 ... mn*
- *m1,m2,...,mn*
- *m* TO *n* <BY *increment*>
- *m1,m2* TO *m3* <BY *increment*>, *m4*

Range: 0 to maximum number of class variables

See: WAYS option

Example: The following code is an example of creating two-way types for the classification variables A, B, and C. This WAYS statement is equivalent to specifying a*b, a*c, and b*c in the TYPES statement.

```
class A B C ; ways 2;
```

WEIGHT Statement

Specifies weights for observations in the statistical calculations.

See: For information about how to calculate weighted statistics and for an example that uses the WEIGHT statement, see "WEIGHT" on page 82.

Syntax

WEIGHT *variable*;

Required Argument

variable
specifies a numeric variable whose values weight the values of the analysis variables. The values of the variable do not have to be integers. The following table describes how PROC MEANS treats various values of the WEIGHT variable.

Weight Value	PROC MEANS Response
0	Counts the observation in the total number of observations
Less than 0	Converts the value to zero and counts the observation in the total number of observations
Missing	Excludes the observation

To exclude observations that contain negative and zero weights from the analysis, use EXCLNPWGT. Note that most SAS/STAT procedures, such as PROC GLM, exclude negative and zero weights by default.

CAUTION
Single extreme weight values can cause inaccurate results. When one (and only one) weight value is many orders of magnitude larger than the other weight values (for example, 49 weight values of 1 and one weight value of 1×10^{14}), certain statistics might not be within acceptable accuracy limits. The affected statistics are based on the second moment (such as standard deviation, corrected sum of squares, variance, and standard error of the mean). Under certain circumstances, no warning is written to the SAS log.

Restrictions To compute weighted quantiles, use QMETHOD=OS in the PROC statement.

Skewness and kurtosis are not available with the WEIGHT statement.

PROC MEANS does not compute MODE when a weight variable is active. Instead, try using the UNIVARIATE procedure when MODE needs to be computed and a weight variable is active.

Interaction If you use the WEIGHT= option in a VAR statement to specify a weight variable, then PROC MEANS uses this variable instead to weight those VAR statement variables.

Note Prior to Version 7 of SAS, the procedure did not exclude the observations with missing weights from the count of observations.

Tip When you use the WEIGHT statement, consider which value of the VARDEF= option is appropriate. See the discussion of VARDEF= and the calculation of weighted statistics in "Keywords and Formulas" on page 2700 for more information.

Usage: MEANS Procedure

Computation of Moment Statistics

PROC MEANS uses single-pass algorithms to compute the moment statistics (such as mean, variance, skewness, and kurtosis). See "Keywords and Formulas" on page 2700 for the statistical formulas.

The computational details for confidence limits, hypothesis test statistics, and quantile statistics follow.

Confidence Limits

With the keywords CLM, LCLM, and UCLM, you can compute confidence limits for the mean. A confidence limit is a range, constructed around the value of a sample statistic, that contains the corresponding true population value with given probability (ALPHA=) in repeated sampling.

A two-sided $100(1-\alpha)$ % confidence interval for the mean has upper and lower limits

$$\overline{x} \pm t_{(1-\alpha/2;n-1)}\frac{s}{\sqrt{n}}$$

where s is $\sqrt{\frac{1}{n-1}\Sigma\,(x_i-\overline{x})^2}$ and $t_{(1-\alpha/2;n-1)}$ is the ($1-\alpha/2$) critical value of the Student's t statistics with $n-1$ degrees of freedom.

A one-sided $100(1-\alpha)$ % confidence interval is computed as

$$\overline{x} + t_{(1-\alpha;n-1)}\frac{s}{\sqrt{n}} \quad \text{(upper)}$$

$$\overline{x} - t_{(1-\alpha;n-1)}\frac{s}{\sqrt{n}} \quad \text{(lower)}$$

If you use the WEIGHT statement or WEIGHT= in a VAR statement and the default value of VARDEF=, which is DF, the $100(1-\alpha)$ % confidence interval for the weighted mean has upper and lower limits

$$\overline{y}_w \pm t_{(1-\alpha/2)} \frac{s_w}{\sqrt{\sum_{i=1}^{n} w_i}}$$

where $\overline{y}_w$ is the weighted mean, s_w is the weighted standard deviation, w_i is the weight for ith observation, and $t_{(1-\alpha/2)}$ is the $(1-\alpha/2)$ critical value for the Student's t distribution with $n-1$ degrees of freedom.

Student's t Test

PROC MEANS calculates the t statistic as

$$t = \frac{\overline{x} - \mu_0}{s/\sqrt{n}}$$

where $\overline{x}$ is the sample mean, n is the number of nonmissing values for a variable, and s is the sample standard deviation. Under the null hypothesis, the population mean equals μ_0 . When the data values are approximately normally distributed, the probability under the null hypothesis of a t statistic as extreme as, or more extreme than, the observed value (the p-value) is obtained from the t distribution with $n-1$ degrees of freedom. For large n , the t statistic is asymptotically equivalent to a z test.

When you use the WEIGHT statement or WEIGHT= in a VAR statement and the default value of VARDEF=, which is DF, the Student's t statistic is calculated as

$$t_w = \frac{\overline{y}_w - \mu_0}{s_w/\sqrt{\sum_{i=1}^{n} w_i}}$$

where $\overline{y}_w$ is the weighted mean, s_w is the weighted standard deviation, and w_i is the weight for ith observation. The t_w statistic is treated as having a Student's t distribution with $n-1$ degrees of freedom. If you specify the EXCLNPWGT option in the PROC statement, then n is the number of nonmissing observations when the value of the WEIGHT variable is positive. By default, n is the number of nonmissing observations for the WEIGHT variable.

Quantiles

The options QMETHOD=, QNTLDEF=, and QMARKERS= determine how PROC MEANS calculates quantiles. QNTLDEF= deals with the mathematical definition of a quantile. See "Quantile and Related Statistics" on page 2706. QMETHOD= deals with the mechanics of how PROC MEANS handles the input data. The two methods are

OS
reads all data into memory and sorts it by unique value.

P2
accumulates all data into a fixed sample size that is used to approximate the quantile.

If data set A has 100 unique values for a numeric variable X and data set B has 1000 unique values for numeric variable X, then QMETHOD=OS for data set B takes 10 times as much memory as it does for data set A. If QMETHOD=P2, then both data sets A and B requires the same memory space to generate quantiles.

The QMETHOD=P2 technique is based on the piecewise-parabolic (P^2) algorithm invented by Jain and Chlamtac (1985). P^2 is a one-pass algorithm to determine quantiles for a large data set. It requires a fixed amount of memory for each variable for each level within the type. However, using simulation studies, reliable estimations of some quantiles (P1, P5, P95, P99) cannot be possible for some data sets such as data sets with heavily tailed or skewed distributions.

If the number of observations is less than the QMARKERS= value, then QMETHOD=P2 produces the same results as QMETHOD=OS when QNTLDEF=5. To compute weighted quantiles, you must use QMETHOD=OS.

Results: MEANS Procedure

Missing Values

PROC MEANS excludes missing values for the analysis variables before calculating statistics. Each analysis variable is treated individually; a missing value for an observation in one variable does not affect the calculations for other variables. The statements handle missing values as follows:

- If a class variable has a missing value for an observation, then PROC MEANS excludes that observation from the analysis unless you use the MISSING option in the PROC statement or CLASS statement.
- If a BY or ID variable value is missing, then PROC MEANS treats it like any other BY or ID variable value. The missing values form a separate BY group.
- If a FREQ variable value is missing or nonpositive, then PROC MEANS excludes the observation from the analysis.
- If a WEIGHT variable value is missing, then PROC MEANS excludes the observation from the analysis.

PROC MEANS tabulates the number of the missing values. Before the number of missing values are tabulated, PROC MEANS excludes observations with frequencies that are nonpositive when you use the FREQ statement and

observations with weights that are missing or nonpositive (when you use the EXCLNPWGT option) when you use the WEIGHT statement. To report this information in the procedure output use the NMISS statistical keyword in the PROC statement.

Column Width for the Output

You control the column width for the displayed statistics with the FW= option in the PROC statement. Unless you assign a format to a numeric class or an ID variable, PROC MEANS uses the value of the FW= option. When you assign a format to a numeric class or an ID variable, PROC MEANS determines the column width directly from the format. If you use the PRELOADFMT option in the CLASS statement, then PROC MEANS determines the column width for a class variable from the assigned format.

The N Obs Statistic

By default when you use a CLASS statement, PROC MEANS displays an additional statistic called N Obs. This statistic reports the total number of observations or the sum of the observations of the FREQ variable that PROC MEANS processes for each class level. PROC MEANS might omit observations from this total because of missing values in one or more class variables or because of the effect of the EXCLUSIVE option when you use it with the PRELOADFMT option or the CLASSDATA= option. Because of this action and the exclusion of observations when the WEIGHT variable contains missing values, there is not always a direct relationship between N Obs, N, and NMISS.

In the output data set, the value of N Obs is stored in the _FREQ_ variable. Use the NONOBS option in the PROC statement to suppress this information in the displayed output.

Output Data Set

PROC MEANS can create one or more output data sets. The procedure does not print the output data set. Use PROC PRINT, PROC REPORT, or another SAS reporting tool to display the output data set.

Note: By default the statistics in the output data set automatically inherit the analysis variable's format and label. However, statistics computed for N, NMISS, SUMWGT, USS, CSS, VAR, CV, T, PROBT, PRT,SKEWNESS, and KURTOSIS do not inherit the analysis variable's format because this format can be invalid for these statistics. Use the NOINHERIT option in the OUTPUT statement to prevent the other statistics from inheriting the format and label attributes.

The output data set can contain these variables:

- the variables specified in the BY statement.
- the variables specified in the ID statement.
- the variables specified in the CLASS statement.
- the variable _TYPE_ that contains information about the class variables. By default _TYPE_ is a numeric variable. If you specify CHARTYPE in the PROC statement, then _TYPE_ is a character variable. When you use more than 32 class variables, _TYPE_ is automatically a character variable.
- the variable _FREQ_ that contains the number of observations that a given output level represents.
- the variables requested in the OUTPUT statement that contain the output statistics and extreme values.
- the variable _STAT_ that contains the names of the default statistics if you omit statistic keywords.
- the variable _LEVEL_ if you specify the LEVEL option.
- the variable _WAY_ if you specify the WAYS option.

The value of _TYPE_ indicates which combination of the class variables PROC MEANS uses to compute the statistics. The character value of _TYPE_ is a series of zeros and ones, where each value of one indicates an active class variable in the type. For example, with three class variables, PROC MEANS represents type 1 as 001, type 5 as 101, and so on.

Usually, the output data set contains one observation per level per type. However, if you omit statistical keywords in the OUTPUT statement, then the output data set contains five observations per level (six if you specify a WEIGHT variable). Therefore, the total number of observations in the output data set is equal to the sum of the levels for all the types that you request multiplied by 1, 5, or 6, whichever is applicable.

If you omit the CLASS statement (_TYPE_= 0), then there is always exactly one level of output per BY group. If you use a CLASS statement, then the number of levels for each type that are requested have an upper bound equal to the number of observations in the input data set. By default, PROC MEANS generates all possible types. In this case the total number of levels for each BY group has an upper bound equal to

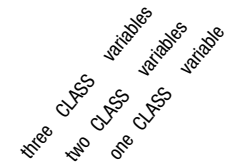
$$m \cdot \left(2^k - 1\right) \cdot n + 1$$

where k is the number of class variables and n is the number of observations for the given BY group in the input data set and m is 1, 5, or 6.

PROC MEANS determines the actual number of levels for a given type from the number of unique combinations of each active class variable. A single level consists of all input observations whose formatted class values match.

The following figure shows the values of _TYPE_ and the number of observations in the data set when you specify one, two, and three class variables.

Figure 40.1 *The Effect of Class Variables on the OUTPUT Data Set*



C	B	A	_WAY_	_TYPE_	Subgroup defined by	Number of observations of this _TYPE_ and _WAY_ in the data set	Total number of observations in the data set
0	0	0	0	0	Total	1	
0	0	1	1	1	A	a	1+a
0	1	0	1	2	B	b	
0	1	1	2	3	A*B	a*b	1+a+b+a*b
1	0	0	1	4	C	c	
1	0	1	2	5	A*C	a*c	
1	1	0	2	6	B*C	b*c	1+a+b+a*b+c
1	1	1	3	7	A *B*C	a*b*c	+a*c+b*c+a*b*c
Character binary equivalent of _TYPE_ (CHARTYPE option)					A , B ,C=CLASS variables	a, b, c,=number of levels of A, B, C, respectively

```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Create the CAKE data set. CAKE contains data from a cake-baking contest: each participant's last name, age, score for presentation, score for taste, cake flavor, and

number of cake layers. The number of cake layers is missing for two observations. The cake flavor is missing for another observation.

```
data cake;
   input LastName $ 1-12 Age 13-14 PresentScore 16-17
         TasteScore 19-20 Flavor $ 23-32 Layers 34 ;
   datalines;
Orlando     27 93 80  Vanilla    1
Ramey       32 84 72  Rum        2
Goldston    46 68 75  Vanilla    1
Roe         38 79 73  Vanilla    2
Larsen      23 77 84  Chocolate  .
Davis       51 86 91  Spice      3
Strickland  19 82 79  Chocolate  1
Nguyen      57 77 84  Vanilla    .
Hildenbrand 33 81 83  Chocolate  1
Byron       62 72 87  Vanilla    2
Sanders     26 56 79  Chocolate  1
Jaeger      43 66 74             1
Davis       28 69 75  Chocolate  2
Conrad      69 85 94  Vanilla    1
Walters     55 67 72  Chocolate  2
Rossburger  28 78 81  Spice      2
Matthew     42 81 92  Chocolate  2
Becker      36 62 83  Spice      2
Anderson    27 87 85  Chocolate  1
Merritt     62 73 84  Chocolate  1
;
```

Specify the statistics and the statistic options. The statistic keywords specify the statistics and their order in the output. FW= uses a field width of eight to display the statistics.

```
proc means data=cake n mean max min range std fw=8;
```

Specify the analysis variables. The VAR statement specifies that PROC MEANS calculate statistics on the PresentScore and TasteScore variables.

```
   var PresentScore TasteScore;
```

Specify the title.

```
   title 'Summary of Presentation and Taste Scores';
run;
```

Example 2: Computing Descriptive Statistics with Class Variables

Features: PROC MEANS statement option
MAXDEC=
CLASS statement
TYPES statement

Data set: GRADE

Details

This example does the following:

- analyzes the data for the two-way combination of class variables and across all observations
- limits the number of decimal places for the displayed statistics

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

data grade;
   input Name $ 1-8 Gender $ 11 Status $13 Year $ 15-16
         Section $ 18 Score 20-21 FinalGrade 23-24;
   datalines;
Abbott    F 2 97 A 90 87
Branford  M 1 98 A 92 97
Crandell  M 2 98 B 81 71
Dennison  M 1 97 A 85 72
Edgar     F 1 98 B 89 80
Faust     M 1 97 B 78 73
Greeley   F 2 97 A 82 91
Hart      F 1 98 B 84 80
Isley     M 2 97 A 88 86
Jasper    M 1 97 B 91 93
;

proc means data=grade maxdec=3;

   var Score;

   class Status Year;

   types () status*year;

   title 'Final Exam Grades for Student Status and Year of Graduation';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Create the GRADE data set. GRADE contains each student's last name, gender, status of either undergraduate (1) or graduate (2), expected year of graduation, class section (A or B), final exam score, and final grade for the course.

```
data grade;
   input Name $ 1-8 Gender $ 11 Status $13 Year $ 15-16
         Section $ 18 Score 20-21 FinalGrade 23-24;
   datalines;
Abbott    F 2 97 A 90 87
Branford  M 1 98 A 92 97
Crandell  M 2 98 B 81 71
Dennison  M 1 97 A 85 72
Edgar     F 1 98 B 89 80
Faust     M 1 97 B 78 73
Greeley   F 2 97 A 82 91
Hart      F 1 98 B 84 80
Isley     M 2 97 A 88 86
Jasper    M 1 97 B 91 93
;
```

Generate the default statistics and specify the analysis options. Because no statistics are specified in the PROC MEANS statement, all default statistics (N, MEAN, STD, MIN, MAX) are generated. MAXDEC= limits the displayed statistics to three decimal places.

```
proc means data=grade maxdec=3;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the Score variable.

```
   var Score;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis into subgroups. Each combination of unique values for Status and Year represents a subgroup.

```
   class Status Year;
```

Specify which subgroups to analyze. The TYPES statement requests that the analysis be performed on all the observations in the GRADE data set as well as the two-way combination of Status and Year, which results in four subgroups (because Status and Year each have two unique values).

```
   types () status*year;
```

Specify the title.

```
   title 'Final Exam Grades for Student Status and Year of Graduation';
run;
```

Output

PROC MEANS displays the default statistics for all the observations (_TYPE_=0) and the four class levels of the Status and Year combination (Status=1, Year=97; Status=1, Year=98; Status=2, Year=97; Status=2, Year=98).

Output 40.4 *Final Exam Grades*

Final Exam Grades for Student Status and Year of Graduation

The MEANS Procedure

Analysis Variable : Score					
N Obs	N	Mean	Std Dev	Minimum	Maximum
10	10	86.000	4.714	78.000	92.000

Analysis Variable : Score							
Status	Year	N Obs	N	Mean	Std Dev	Minimum	Maximum
1	97	3	3	84.667	6.506	78.000	91.000
	98	3	3	88.333	4.041	84.000	92.000
2	97	3	3	86.667	4.163	82.000	90.000
	98	1	1	81.000	.	81.000	81.000

Example 3: Using the BY Statement with Class Variables

Features: PROC MEANS statement option
statistic keywords
BY statement
CLASS statement
SORT procedure

Data set: GRADE

Details

This example does the following:

- separates the analysis for the combination of class variables within BY values
- shows the sort order requirement for the BY statement
- calculates the minimum, maximum, and median

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

proc sort data=Grade out=GradeBySection;
   by section;
run;

proc means data=GradeBySection min max median;

   by Section;

   var Score;

   class Status Year;

   title1 'Final Exam Scores for Student Status and Year of
Graduation';
   title2 ' Within Each Section';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Sort the GRADE data set. PROC SORT sorts the observations by the variable Section. Sorting is required in order to use Section as a BY variable in the PROC MEANS step.

```
proc sort data=Grade out=GradeBySection;
   by section;
run;
```

Specify the analyses. The statistic keywords specify the statistics and their order in the output.

```
proc means data=GradeBySection min max median;
```

Divide the data set into BY groups. The BY statement produces a separate analysis for each value of Section.

```
   by Section;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the Score variable.

```
   var Score;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by the values of Status and Year. Because there is no TYPES statement in this program, analyses are performed for each subgroup, within each BY group.

```
   class Status Year;
```

Specify the titles.

```
   title1 'Final Exam Scores for Student Status and Year of
Graduation';
   title2 ' Within Each Section';
run;
```

Output

Output 40.5 *Final Exam Scores*

Final Exam Scores for Student Status and Year of Graduation
Within Each Section

The MEANS Procedure

Section=A

Analysis Variable : Score					
Status	**Year**	**N Obs**	**Minimum**	**Maximum**	**Median**
1	97	1	85.0000000	85.0000000	85.0000000
	98	1	92.0000000	92.0000000	92.0000000
2	97	3	82.0000000	90.0000000	88.0000000

Section=B

Analysis Variable : Score					
Status	**Year**	**N Obs**	**Minimum**	**Maximum**	**Median**
1	97	2	78.0000000	91.0000000	84.5000000
	98	2	84.0000000	89.0000000	86.5000000
2	98	1	81.0000000	81.0000000	81.0000000

Example 4: Using a CLASSDATA= Data Set with Class Variables

Features: PROC MEANS statement options
- CLASSDATA=
- EXCLUSIVE
- FW=
- MAXDEC=
- PRINTALLTYPES

CLASS statement

Data sets: CAKE
CAKETYPE

Details

This example does the following:

- specifies the field width and decimal places of the displayed statistics
- uses only the values in CLASSDATA= data set as the levels of the combinations of class variables
- calculates the range, median, minimum, and maximum
- displays all combinations of the class variables in the analysis

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

data caketype;
   input Flavor $ 1-10  Layers 12;
   datalines;
Vanilla    1
Vanilla    2
Vanilla    3
Chocolate  1
Chocolate  2
Chocolate  3
;

proc means data=cake range median min max fw=7 maxdec=0
           classdata=caketype exclusive printalltypes;

   var TasteScore;

   class flavor layers;

   title 'Taste Score For Number of Layers and Cake Flavor';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Create the CAKETYPE data set. CAKETYPE contains the cake flavors and number of layers that must occur in the PROC MEANS output.

```
data caketype;
   input Flavor $ 1-10  Layers 12;
   datalines;
Vanilla    1
Vanilla    2
Vanilla    3
Chocolate  1
Chocolate  2
Chocolate  3
;
```

Specify the analyses and the analysis options. The FW= option uses a field width of seven and the MAXDEC= option uses zero decimal places to display the statistics. CLASSDATA= and EXCLUSIVE restrict the class levels to the values that are in the CAKETYPE data set. PRINTALLTYPES displays all combinations of class variables in the output.

```
proc means data=cake range median min max fw=7 maxdec=0
           classdata=caketype exclusive printalltypes;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the TasteScore variable.

```
   var TasteScore;
```

Specify subgroups for analysis. The CLASS statement separates the analysis by the values of Flavor and Layers. Note that these variables, and only these variables, must appear in the CAKETYPE data set.

```
   class flavor layers;
```

Specify the title.

```
   title 'Taste Score For Number of Layers and Cake Flavor';
run;
```

Output

PROC MEANS calculates statistics for the 13 chocolate and vanilla cakes. Because the CLASSDATA= data set contains 3 as the value of Layers, PROC MEANS uses 3 as a class value even though the frequency is zero.

Output 40.6 *Taste Score*

Taste Score For Number of Layers and Cake Flavor

The MEANS Procedure

Analysis Variable : TasteScore				
N Obs	Range	Median	Minimum	Maximum
13	22	80	72	94

Analysis Variable : TasteScore					
Layers	N Obs	Range	Median	Minimum	Maximum
1	8	19	82	75	94
2	5	20	75	72	92
3	0	.	.	.	.

Analysis Variable : TasteScore					
Flavor	N Obs	Range	Median	Minimum	Maximum
Chocolate	8	20	81	72	92
Vanilla	5	21	80	73	94

Analysis Variable : TasteScore						
Flavor	Layers	N Obs	Range	Median	Minimum	Maximum
Chocolate	1	5	6	83	79	85
	2	3	20	75	72	92
	3	0	.	.	.	.
Vanilla	1	3	19	80	75	94
	2	2	14	80	73	87
	3	0	.	.	.	.

Example 5: Using Multilabel Value Formats with Class Variables

Features: PROC MEANS statement options
statistic keywords
FW=
NONOBS

CLASS statement options
MLF
ORDER=
TYPES statement
FORMAT procedure
FORMAT statement

Data set: CAKE

Details

This example does the following:

- computes the statistics for the specified keywords and displays them in order
- specifies the field width of the statistics
- suppresses the column with the total number of observations
- analyzes the data for the one-way combination of cake flavor and the two-way combination of cake flavor and participant's age
- assigns user-defined formats to the class variables
- uses multilabel formats as the levels of class variables
- orders the levels of the cake flavors by the descending frequency count and orders the levels of age by the ascending formatted values

Program

```
options nodate pageno=1 linesize=80 pagesize=64;

proc format;
   value $flvrfmt
                'Chocolate'='Chocolate'
                'Vanilla'='Vanilla'
                'Rum','Spice'='Other Flavor';
   value agefmt (multilabel)
                  15 - 29='below 30 years'
                  30 - 50='between 30 and 50'
                  51 - high='over 50 years'
                  15 - 19='15 to 19'
                  20 - 25='20 to 25'
                  25 - 39='25 to 39'
                  40 - 55='40 to 55'
                  56 - high='56 and above';
run;

proc means data=cake fw=6 n min max median nonobs;

   class flavor/order=data;
   class  age /mlf order=fmt;
```

```
    types flavor flavor*age;
   var TasteScore;
   format age agefmt. flavor $flvrfmt.;
   title 'Taste Score for Cake Flavors and Participant''s Age';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=64;
```

Create the $FLVRFMT. and AGEFMT. formats. PROC FORMAT creates user-defined formats to categorize the cake flavors and ages of the participants. MULTILABEL creates a multilabel format for Age. A multilabel format is one in which multiple labels can be assigned to the same value, in this case because of overlapping ranges. Each value is represented in the output for each range in which it occurs.

```
proc format;
   value $flvrfmt
                'Chocolate'='Chocolate'
                'Vanilla'='Vanilla'
                'Rum','Spice'='Other Flavor';
   value agefmt (multilabel)
                  15 - 29='below 30 years'
                  30 - 50='between 30 and 50'
                  51 - high='over 50 years'
                  15 - 19='15 to 19'
                  20 - 25='20 to 25'
                  25 - 39='25 to 39'
                  40 - 55='40 to 55'
                  56 - high='56 and above';
run;
```

Specify the analyses and the analysis options. FW= uses a field width of six to display the statistics. The statistic keywords specify the statistics and their order in the output. NONOBS suppresses the N Obs column.

```
proc means data=cake fw=6 n min max median nonobs;
```

Specify subgroups for the analysis. The CLASS statements separate the analysis by values of Flavor and Age. ORDER=DATA orders values according to their order in the input data set. ORDER=FMT orders the levels of Age by ascending formatted values. MLF specifies that multilabel value formats be used for Age.

```
   class flavor/order=data;
   class  age /mlf order=fmt;
```

Specify which subgroups to analyze. The TYPES statement requests the analysis for the one-way combination of Flavor and the two-way combination of Flavor and Age.

```
 types flavor flavor*age;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the TasteScore variable.

```
var TasteScore;
```

Format the output. The FORMAT statement assigns user-defined formats to the Age and Flavor variables for this analysis.

```
format age agefmt. flavor $flvrfmt.;
```

Specify the title.

```
title 'Taste Score for Cake Flavors and Participant''s Age';
run;
```

Output

The one-way combination of class variables appears before the two-way combination. A field width of six truncates the statistics to four decimal places. For the two-way combination of Age and Flavor, the total number of observations is greater than the one-way combination of Flavor. This situation arises because of the multilabel format for age, which maps one internal value to more than one formatted value. The order of the levels of Flavor is based on the frequency count for each level. The order of the levels of Age is based on the order of the user-defined formats.

Output 40.7 *Taste Score for Cake Flavors*

Taste Score for Cake Flavors and Participant's Age

The MEANS Procedure

Analysis Variable : TasteScore				
Flavor	N	Minimum	Maximum	Median
Vanilla	6	73.00	94.00	82.00
Other Flavor	4	72.00	91.00	82.00
Chocolate	9	72.00	92.00	83.00

Analysis Variable : TasteScore					
Flavor	Age	N	Minimum	Maximum	Median
Vanilla	25 to 39	2	73.00	80.00	76.50
	40 to 55	1	75.00	75.00	75.00
	56 and above	3	84.00	94.00	87.00
	below 30 years	1	80.00	80.00	80.00
	between 30 and 50	2	73.00	75.00	74.00
	over 50 years	3	84.00	94.00	87.00
Other Flavor	25 to 39	3	72.00	83.00	81.00
	40 to 55	1	91.00	91.00	91.00
	below 30 years	1	81.00	81.00	81.00
	between 30 and 50	2	72.00	83.00	77.50
	over 50 years	1	91.00	91.00	91.00
Chocolate	15 to 19	1	79.00	79.00	79.00
	20 to 25	1	84.00	84.00	84.00
	25 to 39	4	75.00	85.00	81.00
	40 to 55	2	72.00	92.00	82.00
	56 and above	1	84.00	84.00	84.00
	below 30 years	5	75.00	85.00	79.00
	between 30 and 50	2	83.00	92.00	87.50
	over 50 years	2	72.00	84.00	78.00

Example 6: Using Preloaded Formats with Class Variables

Features:

PROC MEANS statement options
- COMPLETETYPES
- FW=
- MISSING
- NONOBS

CLASS statement options
- EXCLUSIVE
- ORDER=
- PRELOADFMT

WAYS statement

FORMAT procedure

FORMAT statement

Data set: CAKE

Details

This example does the following:

- specifies the field width of the statistics
- suppresses the column with the total number of observations
- includes all possible combinations of class variables values in the analysis even if the frequency is zero
- considers missing values as valid class levels
- analyzes the one-way and two-way combinations of class variables
- assigns user-defined formats to the class variables
- uses only the preloaded range of user-defined formats as the levels of class variables
- orders the results by the value of the formatted data

Program

```
options nodate pageno=1 linesize=80 pagesize=64;

proc format;
   value layerfmt 1='single layer'
```

```
                  2-3='multi-layer'
                  .='unknown';
   value $flvrfmt (notsorted)
                  'Vanilla'='Vanilla'
                  'Orange','Lemon'='Citrus'
                  'Spice'='Spice'
                  'Rum','Mint','Almond'='Other Flavor';
run;

proc means data=cake fw=7 completetypes missing nonobs;

   class flavor layers/preloadfmt exclusive order=data;

   ways 1 2;

   var TasteScore;

   format layers layerfmt. flavor $flvrfmt.;

   title 'Taste Score For Number of Layers and Cake Flavors';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=64;
```

Create the LAYERFMT. and $FLVRFMT. formats. PROC FORMAT creates user-defined formats to categorize the number of cake layers and the cake flavors. NOTSORTED keeps $FLVRFMT unsorted to preserve the original order of the format values.

```
proc format;
   value layerfmt 1='single layer'
                  2-3='multi-layer'
                  .='unknown';
   value $flvrfmt (notsorted)
                  'Vanilla'='Vanilla'
                  'Orange','Lemon'='Citrus'
                  'Spice'='Spice'
                  'Rum','Mint','Almond'='Other Flavor';
run;
```

Generate the default statistics and specify the analysis options. FW= uses a field width of seven to display the statistics. COMPLETETYPES includes class levels with a frequency of zero. MISSING considers missing values valid values for all class variables. NONOBS suppresses the N Obs column. Because no specific analyses are requested, all default analyses are performed.

```
proc means data=cake fw=7 completetypes missing nonobs;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Flavor and Layers. PRELOADFMT and EXCLUSIVE restrict the levels

to the preloaded values of the user-defined formats. ORDER=DATA orders the levels of Flavor and Layer by formatted data values.

```
class flavor layers/preloadfmt exclusive order=data;
```

Specify which subgroups to analyze. The WAYS statement requests one-way and two-way combinations of class variables.

```
ways 1 2;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the TasteScore variable.

```
var TasteScore;
```

Format the output. The FORMAT statement assigns user-defined formats to the Flavor and Layers variables for this analysis.

```
format layers layerfmt. flavor $flvrfmt.;
```

Specify the title.

```
    title 'Taste Score For Number of Layers and Cake Flavors';
run;
```

Output

The one-way combination of class variables appears before the two-way combination. PROC MEANS reports only the level values that are listed in the preloaded range of user-defined formats even when the frequency of observations is zero (in this case, citrus). PROC MEANS rejects entire observations based on the exclusion of any single class value in a given observation. Therefore, when the number of layers is unknown, statistics are calculated for only one observation. The other observation is excluded because the flavor chocolate was not included in the preloaded user-defined format for Flavor. The order of the levels is based on the order of the user-defined formats. PROC FORMAT automatically sorted the Layers format and did not sort the Flavor format.

Output 40.8 *Taste Score for Number of Layers*

Taste Score For Number of Layers and Cake Flavors

The MEANS Procedure

Analysis Variable : TasteScore					
Layers	N	Mean	Std Dev	Minimum	Maximum
unknown	1	84.000	.	84.000	84.000

Example 7: Computing a Confidence Limit for the Mean

Features: PROC MEANS statement options
- ALPHA=
- FW=
- MAXDEC=

CLASS statement

Data set: Charity

Details

This example does the following:

- specifies the field width and number of decimal places of the statistics
- computes a two-sided 90% confidence limit for the mean values of MoneyRaised and HoursVolunteered for the three years of data

If this data is representative of a larger population of volunteers, then the confidence limits provide ranges of likely values for the true population means.

Program

```
data charity;
   input School $ 1-7 Year 9-12 Name $ 14-20 MoneyRaised 22-26
         HoursVolunteered 28-29;
   datalines;
Monroe  2016 Allison 31.65 19
Monroe  2016 Barry   23.76 16
Monroe  2016 Candace 21.11  5

     . . . more data lines . . .
Kennedy 2018 Sid     27.45 25
Kennedy 2018 Will    28.88 21
Kennedy 2018 Morty   34.44 25;

proc means data=charity fw=8 maxdec=2 alpha=0.1 clm mean std;

   class Year;

   var MoneyRaised HoursVolunteered;

   title 'Confidence Limits for Fund Raising Statistics';
   title2 '20016-18';
run;
```

Program Description

Create the CHARITY data set. CHARITY contains information about high-school students' volunteer work for a charity. The variables give the name of the high school, the year of the fund-raiser, the first name of each student, the amount of money each student raised, and the number of hours each student volunteered. A DATA step creates this data set.

```
data charity;
   input School $ 1-7 Year 9-12 Name $ 14-20 MoneyRaised 22-26
         HoursVolunteered 28-29;
   datalines;
Monroe  2016 Allison 31.65 19
Monroe  2016 Barry   23.76 16
Monroe  2016 Candace 21.11  5

     . . . more data lines . . .
Kennedy 2018 Sid     27.45 25
Kennedy 2018 Will    28.88 21
Kennedy 2018 Morty   34.44 25;
```

Specify the analyses and the analysis options. FW= uses a field width of eight and MAXDEC= uses two decimal places to display the statistics. ALPHA=0.1 specifies a 90% confidence limit, and the CLM keyword requests two-sided confidence limits. MEAN and STD request the mean and the standard deviation, respectively.

```
proc means data=charity fw=8 maxdec=2 alpha=0.1 clm mean std;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Year.

```
   class Year;
```

Specify the analysis variables. The VAR statement specifies that PROC MEANS calculate statistics on the MoneyRaised and HoursVolunteered variables.

```
   var MoneyRaised HoursVolunteered;
```

Specify the titles.

```
   title 'Confidence Limits for Fund Raising Statistics';
   title2 '20016-18';
run;
```

Output

PROC MEANS displays the lower and upper confidence limits for both variables for each year.

Output 40.9 *Confidence Limits*

Confidence Limits for Fund Raising Statistics
2016-18

The MEANS Procedure

Year	N Obs	Variable	Lower 90% CL for Mean	Upper 90% CL for Mean	Mean	Std Dev
2016	34	MoneyRaised	25.69	32.29	28.99	11.37
		HoursVolunteered	17.68	22.73	20.21	8.71
2017	29	MoneyRaised	24.61	31.61	28.11	11.09
		HoursVolunteered	15.67	20.19	17.93	7.17
2018	46	MoneyRaised	26.73	33.78	30.26	14.23
		HoursVolunteered	19.68	22.63	21.15	5.96

Example 8: Computing Output Statistics

Features:

PROC MEANS statement option
- NOPRINT

CLASS statement

OUTPUT statement options
- statistic keywords
- IDGROUP
- LEVELS
- WAYS

PRINT procedure

Data set: GRADE

Details

This example does the following:

- suppresses the display of PROC MEANS output
- stores the average final grade in a new variable
- stores the name of the student with the best final exam scores in a new variable
- stores the number of class variables that are combined in the _WAY_ variable
- stores the value of the class level in the _LEVEL_ variable
- displays the output data set

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

proc means data=Grade noprint;

   class Status Year;

   var FinalGrade;

   output out=sumstat mean=AverageGrade
          idgroup (max(score) obs out (name)=BestScore)
          / ways levels;
run;

proc print data=sumstat noobs;
   title1 'Average Undergraduate and Graduate Course Grades';
   title2 'For Two Years';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Specify the analysis options. NOPRINT suppresses the display of all PROC MEANS output.

```
proc means data=Grade noprint;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Status and Year.

```
   class Status Year;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the FinalGrade variable.

```
   var FinalGrade;
```

Specify the output data set options. The OUTPUT statement creates the SUMSTAT data set and writes the mean value for the final grade to the new variable AverageGrade. IDGROUP writes the name of the student with the top exam score to the variable BestScore and the observation number that contained the top score. WAYS and LEVELS write information about how the class variables are combined.

```
   output out=sumstat mean=AverageGrade
          idgroup (max(score) obs out (name)=BestScore)
          / ways levels;
run;
```

Print the output data set WORK.SUMSTAT. The NOOBS option suppresses the observation numbers.

```
proc print data=sumstat noobs;
   title1 'Average Undergraduate and Graduate Course Grades';
   title2 'For Two Years';
run;
```

Output

The first observation contains the average course grade and the name of the student with the highest exam score over the two-year period. The next four observations contain values for each class variable value. The remaining four observations contain values for the Year and Status combination. The variables _WAY_, _TYPE_, and _LEVEL_ show how PROC MEANS created the class variable combinations. The variable _OBS_ contains the observation number in the GRADE data set that contained the highest exam score.

Output 40.10 *Average Course Grades*

Average Undergraduate and Graduate Course Grades
For Two Years

Status	Year	_WAY_	_TYPE_	_LEVEL_	_FREQ_	AverageGrade	BestScore	_OBS_
		0	0	1	10	83.0000	Branford	2
	97	1	1	1	6	83.6667	Jasper	10
	98	1	1	2	4	82.0000	Branford	2
1		1	2	1	6	82.5000	Branford	2
2		1	2	2	4	83.7500	Abbott	1
1	97	2	3	1	3	79.3333	Jasper	10
1	98	2	3	2	3	85.6667	Branford	2
2	97	2	3	3	3	88.0000	Abbott	1
2	98	2	3	4	1	71.0000	Crandell	3

Example 9: Computing Different Output Statistics for Several Variables

Features:

PROC MEANS statement options
- DESCEND
- NOPRINT

CLASS statement

OUTPUT statement options

statistic keywords
PRINT procedure
WHERE= data set option

Data set: GRADE

Details

This example does the following:

- suppresses the display of PROC MEANS output
- stores the statistics for the class level and combinations of class variables that are specified by WHERE= in the output data set
- orders observations in the output data set by descending _TYPE_ value
- stores the mean exam scores and mean final grades without assigning new variables names
- stores the median final grade in a new variable
- displays the output data set

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

proc means data=Grade noprint descend;

   class Status Year;

   var Score FinalGrade;

   output out=Sumdata (where=(status='1' or _type_=0))
          mean= median(finalgrade)=MedianGrade;
run;

proc print data=Sumdata;
   title 'Exam and Course Grades for Undergraduates Only';
   title2 'and for All Students';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Specify the analysis options. NOPRINT suppresses the display of all PROC MEANS output. DESCEND orders the observations in the OUT= data set by descending _TYPE_ value.

```
proc means data=Grade noprint descend;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Status and Year.

```
   class Status Year;
```

Specify the analysis variables. The VAR statement specifies that PROC MEANS calculate statistics on the Score and FinalGrade variables.

```
   var Score FinalGrade;
```

Specify the output data set options. The OUTPUT statement writes the mean for Score and FinalGrade to variables of the same name. The median final grade is written to the variable MedianGrade. The WHERE= data set option restricts the observations in SUMDATA. One observation contains overall statistics (_TYPE_=0). The remainder must have a status of 1.

```
   output out=Sumdata (where=(status='1' or _type_=0))
          mean= median(finalgrade)=MedianGrade;
run;
```

Print the output data set WORK.SUMDATA.

```
proc print data=Sumdata;
   title 'Exam and Course Grades for Undergraduates Only';
   title2 'and for All Students';
run;
```

Output

The first three observations contain statistics for the class variable levels with a status of 1. The last observation contains the statistics for all the observations (no subgroup). Score contains the mean test score and FinalGrade contains the mean final grade.

Output 40.11 *Exam and Course Grades*

Exam and Course Grades for Undergraduates Only and for All Students

Obs	Status	Year	_TYPE_	_FREQ_	Score	FinalGrade	MedianGrade
1	1	97	3	3	84.6667	79.3333	73
2	1	98	3	3	88.3333	85.6667	80
3	1		2	6	86.5000	82.5000	80
4			0	10	86.0000	83.0000	83

Example 10: Computing Output Statistics with Missing Class Variable Values

Features:

PROC MEANS statement options
- CHARTYPE
- NOPRINT
- NWAY

CLASS statement options
- ASCENDING
- MISSING
- ORDER=

OUTPUT statement

PRINT procedure

Data set: CAKE

Details

This example does the following:

- suppresses the display of PROC MEANS output
- considers missing values as valid level values for only one class variable
- orders observations in the output data set by the ascending frequency for a single class variable
- stores observations for only the highest _TYPE_ value
- stores _TYPE_ as binary character values
- stores the maximum taste score in a new variable
- displays the output data set

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

proc means data=cake chartype nway noprint;

   class flavor /order=freq ascending;
   class layers /missing;

   var TasteScore;

   output out=cakestat max=HighScore;
run;
```

```
proc print data=cakestat;
   title 'Maximum Taste Score for Flavor and Cake Layers';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Specify the analysis options. NWAY prints observations with the highest _TYPE_ value. NOPRINT suppresses the display of all PROC MEANS output.

```
proc means data=cake chartype nway noprint;
```

Specify subgroups for the analysis. The CLASS statements separate the analysis by Flavor and Layers. ORDER=FREQ and ASCENDING order the levels of Flavor by ascending frequency. MISSING uses missing values of Layers as a valid class level value.

```
   class flavor /order=freq ascending;
   class layers /missing;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the TasteScore variable.

```
   var TasteScore;
```

Specify the output data set options. The OUTPUT statement creates the CAKESTAT data set and generates the maximum value for the taste score to the new variable HighScore.

```
   output out=cakestat max=HighScore;
run;
```

Print the output data set WORK.CAKESTAT.

```
proc print data=cakestat;
   title 'Maximum Taste Score for Flavor and Cake Layers';
run;
```

Output

The CAKESTAT output data set contains only observations for the combination of the two class variables, Flavor and Layers. Therefore, the value of _TYPE_ is 11 for all observations. The observations are ordered by ascending frequency of Flavor. The missing value in Layers is a valid value for this class variable. PROC MEANS excludes the observation with the missing flavor because it is an invalid value for Flavor.

Output 40.12 *Maximum Taste Score*

Maximum Taste Score for Flavor and Cake Layers

Obs	Flavor	Layers	_TYPE_	_FREQ_	HighScore
1	Rum	2	11	1	72
2	Spice	2	11	2	83
3	Spice	3	11	1	91
4	Vanilla	.	11	1	84
5	Vanilla	1	11	3	94
6	Vanilla	2	11	2	87
7	Chocolate	.	11	1	84
8	Chocolate	1	11	5	85
9	Chocolate	2	11	3	92

Example 11: Identifying an Extreme Value with the Output Statistics

Features:
- CLASS statement
- OUTPUT statement options
  - statistic keyword
  - MAXID
- PRINT procedure

Data set: Charity

Details

This example does the following:

- identifies the observations with maximum values for two variables
- creates new variables for the maximum values
- displays the output data set

Program

```
proc means data=Charity n mean range chartype;
   class School Year;
   var MoneyRaised HoursVolunteered;
   output out=Prize maxid(MoneyRaised(name)
          HoursVolunteered(name))= MostCash MostTime
          max= ;

   title 'Summary of Volunteer Work by School and Year';
run;
proc print data=Prize;
   title 'Best Results: Most Money Raised and Most Hours Worked';
run;
```

Program Description

Specify the analyses. The statistic keywords specify the statistics and their order in the output. CHARTYPE writes the _TYPE_ values as binary characters in the output data set

```
proc means data=Charity n mean range chartype;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by School and Year.

```
   class School Year;
```

Specify the analysis variables. The VAR statement specifies that PROC MEANS calculate statistics on the MoneyRaised and HoursVolunteered variables.

```
   var MoneyRaised HoursVolunteered;
```

Specify the output data set options. The OUTPUT statement writes the new variables, MostCash, and MostTime, which contain the names of the students who collected the most money and volunteered the most time, respectively, to the PRIZE data set.

```
   output out=Prize maxid(MoneyRaised(name)
          HoursVolunteered(name))= MostCash MostTime
          max= ;
```

Specify the title.

```
   title 'Summary of Volunteer Work by School and Year';
run;
```

Print the WORK.PRIZE output data set.

```
proc print data=Prize;
   title 'Best Results: Most Money Raised and Most Hours Worked';
run;
```

Output

The first page of output shows the output from PROC MEANS with the statistics for six class levels: one for Monroe High for the years 1992, 1993, and 1994; and one for Kennedy High for the same three years.

Output 40.13 *Summary of Volunteer Work*

Summary of Volunteer Work by School and Year

The MEANS Procedure

School	Year	N Obs	Variable	N	Mean	Range
Kennedy	2007	18	MoneyRaised	18	29.3811111	39.7500000
			HoursVolunteered	18	21.4444444	30.0000000
	2008	17	MoneyRaised	17	28.1564706	23.5600000
			HoursVolunteered	17	19.4117647	20.0000000
	2009	18	MoneyRaised	18	31.5794444	65.4400000
			HoursVolunteered	18	24.2777778	15.0000000
Monroe	2007	16	MoneyRaised	16	28.5450000	48.2700000
			HoursVolunteered	16	18.8125000	38.0000000
	2008	12	MoneyRaised	12	28.0500000	52.4600000
			HoursVolunteered	12	15.8333333	21.0000000
	2009	28	MoneyRaised	28	29.4100000	73.5300000
			HoursVolunteered	28	19.1428571	26.0000000

The output from PROC PRINT shows the maximum MoneyRaised and HoursVolunteered values and the names of the students who are responsible for them. The first observation contains the overall results, the next three contain the results by year, the next two contain the results by school, and the final six contain the results by School and Year.

Output 40.14 *Best Results*

Best Results: Most Money Raised and Most Hours Worked

Obs	School	Year	_TYPE_	_FREQ_	MostCash	MostTime	MoneyRaised	HoursVolunteered
1		.	00	109	Willard	Tonya	78.65	40
2		2007	01	34	Tonya	Tonya	55.16	40
3		2008	01	29	Cameron	Amy	65.44	31
4		2009	01	46	Willard	L.T.	78.65	33
5	Kennedy	.	10	53	Luther	Jay	72.22	35
6	Monroe	.	10	56	Willard	Tonya	78.65	40
7	Kennedy	2007	11	18	Thelma	Jay	52.63	35
8	Kennedy	2008	11	17	Bill	Amy	42.23	31
9	Kennedy	2009	11	18	Luther	Che-Min	72.22	33
10	Monroe	2007	11	16	Tonya	Tonya	55.16	40
11	Monroe	2008	11	12	Cameron	Myrtle	65.44	26
12	Monroe	2009	11	28	Willard	L.T.	78.65	33

Example 12: Identifying the Top Three Extreme Values with the Output Statistics

Features:

PROC MEANS statement option
- NOPRINT

CLASS statement

OUTPUT statement options
- statistic keywords
- AUTOLABEL
- AUTONAME
- IDGROUP

TYPES statement

FORMAT procedure

FORMAT statement

PRINT procedure

RENAME= data set option

Data set: Charity

Details

This example does the following:

- suppresses the display of PROC MEANS output
- analyzes the data for the one-way combination of the class variables and across all observations
- stores the total and average amount of money raised in new variables
- stores in new variables the top three amounts of money raised, the names of the three students who raised the money, the years when it occurred, and the schools the students attended
- automatically resolves conflicts in the variable names when names are assigned to the new variables in the output data set
- appends the statistic name to the label of the variables in the output data set that contain statistics that were computed for the analysis variable
- assigns a format to the analysis variable so that the statistics that are computed from this variable inherit the attribute in the output data set
- renames the _FREQ_ variable in the output data set
- displays the output data set and its contents

Program

```
proc format;
   value yrFmt . = " All";
   value $schFmt ' ' = "All    ";
run;

proc means data=Charity noprint;

   class School Year;

   types () school year;

   var MoneyRaised;

   output out=top3list(rename=(_freq_=NumberStudents))sum= mean=
          idgroup( max(moneyraised) out[3] (moneyraised name
            school year)=)/autolabel autoname;

   label MoneyRaised='Amount Raised';
   format year yrfmt. school $schfmt.
          moneyraised dollar8.2;
  run;

proc print data=top3list;
   title1 'School Fund Raising Report';
   title2 'Top Three Students';
run;
```

```
proc datasets library=work nolist;
   contents data=top3list;
   title1 'Contents of the PROC MEANS Output Data Set';
run;
```

Program Description

Create the YRFMT. and $SCHFMT. formats. PROC FORMAT creates user-defined formats that assign the value of **All** to the missing levels of the class variables.

```
proc format;
   value yrFmt . = " All";
   value $schFmt ' ' = "All    ";
run;
```

Generate the default statistics and specify the analysis options. NOPRINT suppresses the display of all PROC MEANS output.

```
proc means data=Charity noprint;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of School and Year.

```
   class School Year;
```

Specify which subgroups to analyze. The TYPES statement requests the analysis across all the observations and for each one-way combination of School and Year.

```
   types () school year;
```

Specify the analysis variable. The VAR statement specifies that PROC MEANS calculate statistics on the MoneyRaised variable.

```
   var MoneyRaised;
```

Specify the output data set options. The OUTPUT statement creates the TOP3LIST data set. RENAME= renames the _FREQ_ variable that contains the frequency count for each class level. SUM= and MEAN= specify that the sum and mean of the analysis variable (MoneyRaised) are written to the output data set. IDGROUP writes 12 variables that contain the top three amounts of money raised and the three corresponding students, schools, and years. AUTOLABEL appends the analysis variable name to the label for the output variables that contain the sum and mean. AUTONAME resolves naming conflicts for these variables.

```
   output out=top3list(rename=(_freq_=NumberStudents))sum= mean=
          idgroup( max(moneyraised) out[3] (moneyraised name
            school year)=)/autolabel autoname;
```

Format the output. The LABEL statement assigns a label to the analysis variable MoneyRaised. The FORMAT statement assigns user-defined formats to the Year and School variables and a SAS dollar format to the MoneyRaised variable.

```
   label MoneyRaised='Amount Raised';
   format year yrfmt. school $schfmt.
          moneyraised dollar8.2;
  run;
```

Print the output data set WORK.TOP3LIST.

```
proc print data=top3list;
   title1 'School Fund Raising Report';
   title2 'Top Three Students';
run;
```

Display information about the TOP3LIST data set. PROC DATASETS displays the contents of the TOP3LIST data set. NOLIST suppresses the directory listing for the WORK data library.

```
proc datasets library=work nolist;
   contents data=top3list;
   title1 'Contents of the PROC MEANS Output Data Set';
run;
```

Output

The output from PROC PRINT shows the top three values of MoneyRaised, the names of the students who raised these amounts, the schools the students attended, and the years when the money was raised. The first observation contains the overall results, the next three contain the results by year, and the final two contain the results by school. The missing class levels for School and Year are replaced with the value ALL. The labels for the variables that contain statistics that were computed from MoneyRaised include the statistic name at the end of the label.

Output 40.15 *School Fund Raising*

Results Viewer - SAS Output

School Fund Raising Report
Top Three Students

MoneyRaised_Sum	MoneyRaised_Mean	MoneyRaised_1	MoneyRaised_2	MoneyRaised_3	Name_1	Name_2	Name_3	School_1

Example 13: Using the STACKODSOUTPUT Option to Control Data

Features: PROC PRINT
PROC CONTENTS

The first example does not use the STACKODSOUTPUT option. The second example uses the STACKODSOUTPUT option.

Program

```
proc means data=sashelp.class;
class sex;
var weight height;
ods output summary=default;
run;

proc print data=default; run;
proc contents data=default; run;
```

Program Description

This code processes the data without using the STACKODSOUTPUT option.

```
proc means data=sashelp.class;
class sex;
var weight height;
ods output summary=default;
run;
```

Prints the data using PROC PRINT. Print the contents of the procedure using PROC CONTENTS.

```
proc print data=default; run;
proc contents data=default; run;
```

OUTPUT

The following outputs show the difference in processing data using the STACKODSOUTPUT option and then not using the option.

This output is generated without the STACKODSOUTPUT option.

Output 40.17 *Output without Using the STACKODSOUTPUT Option*

MIGRATE Procedure

Overview: MIGRATE Procedure

What Does the MIGRATE Procedure Do?

The MIGRATE procedure migrates members in a SAS library to the current SAS version.

The procedure migrates a library from most SAS 6, SAS 7, SAS 8, and SAS®9 operating environments to the current release of SAS. The migration must occur within the same engine family. For example, V6, V7, or V8 can migrate to V9, but V6TAPE must migrate to V9TAPE.

The procedure migrates the following library members:

- data sets with alternate collating sequence, audit trails, compression, created and modified datetimes, deleted observations, encryption (except AES encryption), extended attributes, generations, indexes, integrity constraints, and passwords
- in many cases, views, catalogs, item stores, and multidimensional databases (MDDBs) (see Concepts: MIGRATE Procedure on page 1560)

The procedure does not support stored compiled DATA step programs or stored compiled macros. (Instead, move the source code to the target, where you can compile and store it.) The procedure does not support SAS program files. The procedure does not support Scalable Performance Data (SPD) engine data sets. (See *SAS Scalable Performance Data Engine: Reference*.) The procedure does not support the extended observation count attribute.

Concepts: MIGRATE Procedure

Data Sets

PROC MIGRATE retains alternate collating sequence, compression, created and modified datetimes, deleted observations, encryption, extended attributes, indexes,

integrity constraints, and passwords. See several important restrictions at the beginning of the syntax on page 1563.

The audit trail and generations are also migrated. Indexes and integrity constraints are rebuilt on the member in the target library. See "Migrating a Data Set with Audit Trails, Generations, Indexes, or Integrity Constraints" on page 1567.

Migrated data sets take on the data representation and encoding attributes of the target library. When you migrate a data set to an encoding where the characters are represented by more bytes, truncation might occur if the column length does not accommodate the larger character size. For example, a character might be represented in Wlatin1 encoding as one byte but in UTF-8 as two bytes. The best solution is to expand the column length with the CVP engine and PROC COPY before you migrate. (PROC MIGRATE does not currently support the CVP engine.) The CVPMULTIPLIER=2.5 value is usually sufficient to avoid truncation. If your data contains Asian characters, CVPMULTIPLIER=4 is recommended. For more information, read about the CVPMULTIPLIER= option and avoiding character data truncation in *SAS National Language Support (NLS): Reference Guide*. See also the paper "Multilingual Computing with SAS® 9.4" on support.sas.com.

For SAS data sets that use the ASCII-OEM character set, PROC MIGRATE does not translate non-English characters. This issue is very uncommon. To migrate a SAS data set with ASCII-OEM characters, use the CPORT and CIMPORT procedures with the TRANTAB option. Specify the appropriate TRANTAB values for the source and target data sets.

Views

As with data sets, migrated data views take on the data representation and encoding attributes of the target library. When you migrate a library that contains DATA step views to a different operating environment, and the views were created prior to SAS 9.2, you might need to set the proper encoding. In releases prior to SAS 9.2, DATA step views did not save encoding information. Therefore, if the view has a different encoding than the target session, you must specify the INENCODING= option for the source library's LIBNAME statement. Here is an example:

```
libname Srclib 'source-library-pathname' inencoding="OPEN_ED-1047";
libname Lib1 'target-library-pathname';
proc migrate in=Srclib out=Lib1;
run;
```

In addition, embedded librefs associated with a view are not updated during migration. The following example illustrates the issue. In this example, Lib1.MyView contains a view of the data set Lib1.MyData:

```
data Lib1.MyData;x=1;
run;
proc sql;
   create view Lib1.MyView as select * from Lib1.MyData;
quit;
```

After you migrate Lib1 to Lib2, you have Lib2.MyView and Lib2.MyData. However, because Lib2.MyView was originally created with an embedded libref of Lib1, it still

references the data set Lib1.MyData, not Lib2.MyData. The following example fails with an error message that Lib1 cannot be found:

```
proc print data=Lib2.MyView;
run;
```

PROC MIGRATE supports three types of views: DATA step views, SQL views, and SAS/ACCESS views:

DATA Step Views
: When you create a DATA step view, you can specify the SOURCE= option to store the DATA step code along with the view. PROC MIGRATE supports DATA step views with stored code. The stored code is recompiled the first time the DATA step view is accessed by SAS in the target environment. PROC MIGRATE does not support DATA step views that were created prior to SAS 8 or DATA step views without stored code. For DATA step views without stored code, use the DESCRIBE statement in the source session to recover the DATA step code. Then submit the DATA step code in the target session and recompile it.

PROC SQL Views
: PROC MIGRATE supports PROC SQL views with no known issues.

SAS/ACCESS Views
: PROC MIGRATE supports SAS/ACCESS views that were written with the Oracle, SAP, or DB2 engine. PROC MIGRATE automatically uses the CV2VIEW procedure, which converts SAS/ACCESS views into SQL views. Migrating SAS/ACCESS views to a different operating environment is not supported. For more information about the conversion, see the overview of the CV2VIEW procedure in *SAS/ACCESS for Relational Databases: Reference*.

Catalogs

To migrate catalogs, PROC MIGRATE calls PROC CPORT and PROC CIMPORT. You might notice that CPORT and CIMPORT notes are written to the SAS log during migration. PROC CPORT and CIMPORT restrictions apply. For example, catalogs in sequential libraries are not migrated. Stored compiled macros that are stored in catalogs are not supported. (Instead, move the source code to the target, where you can compile and store it.) Catalog entries might need to be updated after migrating (for example, code that contains hardcoded pathnames).

IMPORTANT PROC MIGRATE is not supported for SAS 6 AIX catalogs. Use PROC CPORT and PROC CIMPORT instead. See "Additional Steps for Unsupported Catalogs or Libraries" on page 1573.

IMPORTANT If cross-environment data access (CEDA) processing is invoked, and if the IN= source library contains catalogs, then you must specify a SAS/CONNECT or SAS/SHARE libref in the IN= option or in the SLIBREF= option. To determine whether to specify the libref in the IN= or SLIBREF= argument, see "Using a SAS/CONNECT or SAS/SHARE Server" on

page 1571. If the catalogs were created in SAS 6 or SAS 8, SLIBREF= must be assigned through a SAS 8 server.

MDDBs

PROC MIGRATE supports MDDBs with no known issues.

Items Stores

PROC MIGRATE supports item stores unless you migrate from a 32-bit to a 64-bit environment. Migrations from 32-bit to 64-bit environments use Remote Library Services (RLS), which does not support item stores. In that case, an error message is not written to the SAS log, but item stores might not work correctly in the target library.

Not Supported

PROC MIGRATE does not support stored compiled DATA step programs or stored compiled macros. (Instead, move the source code to the target, where you can compile and store it.) PROC MIGRATE does not support SAS program files. PROC MIGRATE does not support SPD Engine data sets. (See *SAS Scalable Performance Data Engine: Reference*.) See also restrictions above for each member type.

Syntax: MIGRATE Procedure

Restrictions:

SAS data set options are not supported with PROC MIGRATE.

The CVP engine is not currently supported with PROC MIGRATE. You can use the CVP engine with the COPY procedure (or the COPY statement of the DATASETS procedure) to expand column lengths in the source library before you use PROC MIGRATE.

The source and target libraries must be in different physical locations.

When PROC MIGRATE creates a member in the target library, the member does not retain its permissions from the source library. It has the permissions that are associated with the user ID of the person who ran PROC MIGRATE.

SAS 8.2 source libraries from the following operating environments are not supported: CMS, OS/2, OpenVMS VAX, or 64-bit AIX. See "Additional Steps for Unsupported Catalogs or Libraries" on page 1573.

Catalogs that were created under a Tru64 UNIX source environment are not supported for a Linux for x64 or a Solaris for x64 target environment. To migrate catalogs under those conditions, see "Additional Steps for Unsupported Catalogs or Libraries" on page 1573.

SAS files that were created prior to SAS 6.12 (SAS 6.09E for z/OS) must be converted to SAS 6.12 before they can be migrated to the current release of SAS. Some SAS 6 source environments are not supported; see "Migrating a SAS 6 Library" on page 1568.

This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Interaction: The International Components for Unicode (ICU) version is used to sort data sets with a linguistic collating sequence. If a linguistically sorted data set has a different ICU version number than that of the current SAS session, the following occurs: PROC MIGRATE retains the data set's sort order in the OUT= destination library. However, the data set is no longer marked as sorted, and a message is written to the SAS log. For more information about linguistic sorting, see Chapter 64, "SORT Procedure," on page 2355.

Tips: Assign the OUT= target library to an empty location. If a member already exists in the target library that has the same name and member type as a member in the source library, the member is not migrated. An error message is written to the SAS log, and PROC MIGRATE continues with the next member. Note that members in a sequential library are an exception, because PROC MIGRATE does not read the entire tape to determine existence.

For encoding and transcoding issues, see the *SAS National Language Support (NLS): Reference Guide*.

PROC MIGRATE IN=*libref-1* OUT=*libref-2* <*options*>;

Statement	Task	Example
PROC MIGRATE	Migrate members in a SAS library to the current SAS version	Ex. 1, Ex. 2, Ex. 3

PROC MIGRATE Statement

Migrates a SAS library forward to the current release of SAS.

Syntax

PROC MIGRATE IN=*libref-1* OUT=*libref-2*
<BUFSIZE=KEEPSIZE | *n* | *n*K | *n*M | *n*G>

<MOVE>
<SLIBREF=*libref*>
<KEEPNODUPKEY>;

Required Arguments

IN=*libref-1*
names the source SAS library from which to migrate members.

Restriction Concatenated libraries are not supported. See SAS Note 24539 at https://support.sas.com/kb/24/539.html.

Requirements If you use a server, such as SAS/CONNECT or SAS/SHARE, the server must be SAS 9.1.3 or later.

If cross-environment data access (CEDA) processing is invoked, and if the IN= source library contains catalogs, then you must specify a SAS/CONNECT libref or a SAS/SHARE libref in the IN= option or in the SLIBREF= option. To determine whether to specify the libref in the IN= or the SLIBREF= argument, see "Using a SAS/CONNECT or SAS/SHARE Server" on page 1571.

If CATALOG is the only member type in the library and you are using the SLIBREF= option, then omit the IN= argument.

OUT=*libref-2*
names the target SAS library to contain the migrated members.

Restriction Do not assign the OUT= target library to a server, such as SAS/CONNECT or SAS/SHARE. The REMOTE engine is not supported for the target library. The following example causes an error:

```
libname Lib1 'source-library-pathname';
libname Lib2 server=server id;
proc migrate in=Lib1 out=Lib2;
run;
```

Requirement Assign the OUT= target library to a different physical location than the IN= source library.

Interaction PROC MIGRATE can use the LIBNAME option OUTREP= for DATA, VIEW, ACCESS, MDDB, and DMDB member types. If you specify the OUTREP= option, you might also want to specify the EXTENDOBSCOUNTER= option. These options are appropriate in the LIBNAME statement for the OUT= library. See *SAS DATA Step Statements: Reference*.

Tip Assign the target library to an empty location. If a member already exists in the target library that has the same name and member type as a member in the source library, the member is not migrated. An error message is written to the SAS log, and PROC MIGRATE continues with the next member. Note that members in

a sequential library are an exception, because PROC MIGRATE does not read the entire tape to determine existence.

Optional Arguments

BUFSIZE=KEEPSIZE | *n* | *n*K | *n*M | *n*G

specifies the buffer page size of the members that are written to the target library. For example, a value of `10000` specifies a page size of 10,000 bytes, and a value of `4k` specifies a page size of 4096 bytes. A value of `0` results in the default. Setting the page size can help optimize SAS performance. In SAS 9.4M3, the BUFSIZE default is changed. The new default is the buffer page size of the current session. To continue using the previous behavior, which is to clone the page size of the members from the source library, specify BUFSIZE=KEEPSIZE.

For more details about the BUFSIZE= data set option or system option, see the documentation for your operating environment.

KEEPSIZE
retains (clones) the page size of members from the source library.

n
specifies the number of bytes.

***n*K**
specifies the number of kilobytes.

***n*M**
specifies the number of megabytes.

***n*G**
specifies the number of gigabytes.

Default the buffer page size of the current session

MOVE

deletes the original members from the source library. If a member already exists in the target library, the member is not deleted from the source library and a message is sent to the SAS log. If a catalog already exists in the target library, then no catalogs are deleted from the source library and a message is sent to the log. If a data set has referential integrity constraints, the data set is not deleted from the source library and an error is sent to the log.

Restriction The engine that is associated with the IN= source library must support the deletion of tables. Sequential engines do not support the deletion of tables.

Tip Use the MOVE option only if your system is space-constrained. It is preferable to verify the migration of the member before it is deleted.

SLIBREF=*libref*

specifies a libref that is assigned through a SAS/CONNECT or SAS/SHARE server. If cross-environment data access (CEDA) processing is invoked, and if the IN= source library contains catalogs, then you must specify a SAS/CONNECT or SAS/SHARE libref in the IN= option or in the SLIBREF=

option. To determine whether to specify the libref in the IN= or SLIBREF= argument, see "Using a SAS/CONNECT or SAS/SHARE Server" on page 1571.

Requirements If the catalogs were created in SAS 6 or SAS 8, SLIBREF= must be assigned through a SAS 8 server.

The SLIBREF= server must be running on the same type of operating environment as the source library. For example, if the source session is running under UNIX, then the server must be running under UNIX.

Interactions If CATALOG is the only member type in the library and you are using the SLIBREF= option, then omit the IN= argument.

If you are migrating from a SAS®9 release or later (for example, migrating from SAS 9.1.3 to SAS 9.4), then SLIBREF= is not required. If you have incompatible catalogs, specify the SAS/CONNECT or SAS/SHARE server libref in the IN= argument and omit the SLIBREF= argument. For the IN= argument, the server must be SAS 9.1.3 or later.

KEEPNODUPKEY
specifies to retain the NODUPKEY sort order. See "Migrating a SAS Data Set with NODUPKEY Sort Indicator" on page 1568.

Usage: MIGRATE Procedure

Migrating a Data Set with Audit Trails, Generations, Indexes, or Integrity Constraints

In all cases, the data set migrates first, and then the audit trails, generations, index, or integrity constraints are applied. Errors are handled in the following ways:

- If an error occurs while an index is created for a migrated data set, the data set might migrate without the index, or processing might stop. A message is written to the SAS log. If an index fails to migrate, resolve the error and re-create the index in the target library.

  If an index is missing from the source library, then depending on the environment and system options, SAS might try to repair the data set during migration by re-creating the index. If the data set is incompatible with the session encoding or data representation, re-creating the index produces an error. To resolve the error, re-create the index in the source library using the original operating system or move the index from its original location, and submit the PROC MIGRATE again. The error can occur when a customer has

moved a data set using the operating system and failed to include an index in the move.

- If an error occurs while integrity constraints are applied to a migrated data set, or while an audit trail or generations are migrated, the data set is removed from the target library. A note is written to the SAS log. If the MOVE option is specified, it does not delete the data set from the source library.
- For a data set with referential integrity constraints, the MOVE option does not delete any members in the source library, even when the migration is successful. You must remove referential integrity constraints before the member can be deleted. An error message is written to the SAS log.

Migrating a SAS Data Set with NODUPKEY Sort Indicator

When you migrate a SAS data set that was sorted with the NODUPKEY option, you can either use the default behavior or specify the KEEPNODUPKEY option.

Under the default behavior (without the KEEPNODUPKEY option), the SAS data set retains its sort indicator in the target library. However, the NODUPKEY attribute is removed, and a warning message is written to the SAS log. This is the default behavior because SAS data sets that were sorted with the NODUPKEY option in previous releases might retain observations with duplicate keys. You can re-sort the migrated SAS data set by the key variables in PROC SORT so that observations with duplicate keys are eliminated and the correct attributes are recorded.

If you specify the KEEPNODUPKEY option, you must examine your migrated data to determine whether observations with duplicate keys exist. If so, you must re-sort the SAS data set to have the data and NODUPKEY sort attribute match.

Migrating a SAS 6 Library

For SAS 6 source libraries, the following operating environments are supported. Find your source operating environment in the first column and read across the row for information about the supported target operating environments.

If your catalogs or libraries are not supported, see “Additional Steps for Unsupported Catalogs or Libraries” on page 1573. For important information about the SLIBREF= option, see “Using a SAS/CONNECT or SAS/SHARE Server” on page 1571.

Table 41.1 Supported SAS 6 Libraries

Source Library	Target Library	Instructions for Libraries with Catalogs
SAS 6.12 AIX, HP-UX, or Solaris SPARC	AIX, HP-UX, or Solaris SPARC	PROC MIGRATE does not support catalogs from SAS 6 AIX. For HP-UX or Solaris libraries that contain catalogs, specify the SLIBREF= option.
SAS 6.12 Windows	32-bit Windows	Catalogs are supported. Do not use the SLIBREF= option.
SAS 6.12 Windows	64-bit Windows	For libraries that contain catalogs, specify the SLIBREF= option.
SAS 6.09E z/OS	z/OS	Catalogs are supported. Do not use the SLIBREF= option.

SAS files that were created prior to SAS 6.12 (SAS 6.09E for z/OS) must be converted to SAS 6.12 before they can be migrated to the current release of SAS. See "Additional Steps for Unsupported Catalogs or Libraries" on page 1573.

Migrating Files with Short Extensions on PC Operating Environments

Overview

In SAS 7 and 8, the SHORTFILEEXT option creates a file with a shortened, three-character extension on PC operating environments only. This feature is necessary for operating systems that use a file allocation table (FAT) file system. The FAT file system is also referred to as 8.3 because a file name can include up to eight characters and a file extension can include up to three characters. These files are created on PC environments. They are not usable by SAS on other environments.

Note: SAS 6 files all have three-character extensions but are not affected by this issue. You can distinguish SAS 6 files because their extensions do not contain the number 7.

Below is a table of the short and standard extensions for SAS 7 and 8 files. To determine whether a library contains files with short extensions, look at the file names in the SAS Explorer or use the file management tools of your operating environment.

Table 41.2 *Short and Standard File Extensions for SAS 7 and 8 Files*

Memtype	Short Extension	Standard Extension
ACCESS	sa7	sas7bacs
AUDIT	st7	sas7baud
CATALOG	sc7	sas7bcat
DATA	sd7	sas7bdat
DMDB	s7m	sas7bdmd
FDB	sf7	sas7bfdb
INDEX	si7	sas7bndx
ITEMSTOR	sr7	sas7bitm
MDDB	sm7	sas7bmdb
PROGRAM	ss7	sas7bpgm
PUTILITY	sp7	sas7bput
UTILITY	su7	sas7butl
VIEW	sv7	sas7bvew

SAS®9 Compatibility with Short-Extension Files

Read-Only access is supported for short-extension files from earlier releases. You can migrate your library to the current release of SAS by using PROC MIGRATE. You must specify the SHORTFILEEXT option in the LIBNAME statement for the source library. The files are written to the target library with standard extensions; the files support full access.

For example, a library named MyLib contains two files with short extensions: a SAS data set named MyData.sd7 and a catalog named MyCat.sc7. Use the following code to migrate the library to SAS®9:

```
libname MyLib v8 'source-library-pathname' shortfileext;
libname NewLib v9 'target-library-pathname';

proc migrate in=MyLib out=NewLib;
run;
```

After migration, the target library NewLib contains two files with standard extensions: a SAS data set named MyData.sas7bdat and a catalog named MyCat.sas7bcat.

If your library also contains standard-extension files, then perform an additional migration without the SHORTFILEEXT option in the LIBNAME statement to migrate those files. Make sure that no short-extension files have the same name as a standard-extension file. In the target library, all files have a standard extension. If a short-extension file and a standard-extension file have the same name and same member type in the target library, the second one fails to migrate.

Using a SAS/CONNECT or SAS/SHARE Server

When to Use a SAS/CONNECT or SAS/SHARE Server

Here are two reasons to use a SAS/CONNECT or SAS/SHARE server:

- You can use a server to migrate across computers when you do not have direct access.
- You are required to use a server if the following two conditions are both met:
  - the source library contains catalogs
  - processing would invoke CEDA on the target session

  In general, CEDA is invoked when you migrate to an incompatible operating environment. For more information, see "Cross-Environment Data Access" in *SAS Programmer's Guide: Essentials*.

Here are two ways to determine whether a SAS library contains catalogs:

- Use operating system tools to examine the file system. The file extension for SAS catalogs is `.sas7bcat`.
- Submit a DATASETS procedure with MEMTYPE=CAT. Examine the SAS log for a list of catalogs.

When to Specify the Server in the IN= Option or in the SLIBREF= Option

Specify the SAS/CONNECT or SAS/SHARE server libref in the IN= option when the source library contains catalogs that were created in SAS 9.1.3 or later. See "Example 1: Migrating from a SAS®9 Release by Using SAS/CONNECT" on page 1574.

Specify the SAS/CONNECT or SAS/SHARE server libref in the SLIBREF= option when the source library contains catalogs that were created prior to SAS 9.1.3. See "Example 3: Migrating with Incompatible Catalogs When the SLIBREF= Option Is Required" on page 1577.

For SAS 6 files, use the SLIBREF= option for SAS 6 HP-UX or Solaris libraries that contain catalogs. See "Migrating a SAS 6 Library" on page 1568.

Requirements for the SAS/CONNECT or SAS/SHARE Server

The SAS/CONNECT or SAS/SHARE server must be running on the same type of operating environment as the source library. For example, if the source session is running under UNIX, then the server must be running under UNIX.

If the catalogs were created in SAS 6 or SAS 8, SLIBREF= must be assigned through a SAS 8 server. (Note that this is not the same server that you assign through the IN= argument. If you assign a server through the IN= argument, the IN= server must be SAS 9.1.3 or later.)

If you cannot meet these requirements, use the alternate method described in "Additional Steps for Unsupported Catalogs or Libraries" on page 1573.

Restrictions for the SLIBREF= Option

If CATALOG is the only member type in the library and you are using the SLIBREF= option, then omit the IN= argument.

When you use the SLIBREF= option for a SAS 8.2 library, multilabel formats are not supported. If a catalog contains a multilabel format, the format is not created on the target and an error is printed to the log. See SAS Note 20052, which is available from SAS customer support.

Additional Steps for Unsupported Catalogs or Libraries

When to Use Additional Steps

PROC MIGRATE is not supported for libraries that were created under the following source environments:

- SAS 8.2 libraries from CMS, OS/2, OpenVMS VAX, or 64-bit AIX.
- any unsupported SAS 6 operating environment. For a list of supported SAS 6 operating environments, see "Migrating a SAS 6 Library" on page 1568.

PROC MIGRATE is not supported for migrating catalogs under the following circumstances:

- SAS 6 AIX catalogs to any target library.
- Tru64 UNIX catalogs to either Linux for x64 or Solaris for x64 target library.
- stored compiled macros, which are stored in a catalog.
- incompatible catalogs if SAS/CONNECT or SAS/SHARE software is required, and you do not have access to the software. See "Using a SAS/CONNECT or SAS/SHARE Server" on page 1571.

You can use additional steps for just the catalogs, if unsupported catalogs are the only issue. By using PROC MIGRATE for other members of the library, you can retain those members' attributes.The CPORT and CIMPORT method below has some limitations. For example, when transcoding to a new encoding, truncation can occur. If truncation occurs, you must expand variable lengths. You can either use the CVP engine with PROC CPORT or use the EXTENDVAR= option with PROC CIMPORT.

Process

1. In the source session, create a transport file with PROC CPORT. (See Chapter 16, "CPORT Procedure," on page 537.)
2. Move the transport file to the target environment. Do not use RLS (a feature of SAS/CONNECT and SAS/SHARE software) to move catalogs, or you will encounter errors. You must use binary FTP, the DOWNLOAD procedure, Network File System (NFS), or another method of directly accessing files.
3. In the target session, use CIMPORT to import the transport file. (See Chapter 12, "CIMPORT Procedure," on page 389.)

Process for a Formats Catalog When Encoding Is Not Compatible

Catalog entries do not include encoding in the metadata. SAS assumes that any imported catalog entries have the session encoding or a compatible encoding.

If a catalog entry contains 7-bit ASCII characters only, then the catalog entry can be used in any other ASCII session, including UTF-8. (7-bit ASCII characters include the letters of the English alphabet, digits, and symbols that are frequently used in punctuation or SAS syntax.)

See these examples that change the encoding of a formats catalog:

- "Example: Migrate Catalogs to Avoid CEDA Limitations" in *SAS V9 LIBNAME Engine: Reference*
- "Example: Avoid Truncation in Formats When Migrating Catalogs" in *SAS V9 LIBNAME Engine: Reference*

The CVP engine can help avoid truncation when you re-create a formats catalog in an encoding where the characters are represented by more bytes. Truncation might occur if a format length does not accommodate the larger character size. In the target session, specify the CVPMULT= option in the source LIBNAME statement. Note that the CVP engine cannot increase the values of the START, MIN, MAX, or LABEL variables in the CNTLOUT= data set. In addition, when you use CNTLIN= to import catalogs, you might experience transcoding errors that are not written to the log. For example, a character might not be available in the target encoding, or the code point could be used for a different character in the target encoding. If you continue to experience transcoding problems, re-create the format in the target session. If you do not have access to the SAS program statements that were used to create the original format, you can print the CNTLOUT= data set in the source session and use that information as a guide.

For an overview of potential transcoding errors, see "Transcoding Considerations" in *SAS National Language Support (NLS): Reference Guide*.

Examples: MIGRATE Procedure

Example 1: Migrating from a SAS®9 Release by Using SAS/CONNECT

Features: PROC MIGRATE statement options

IN=
OUT=

Details

In this example, the following is demonstrated:

- A spawner starts a session on the SAS/CONNECT server to access remote SAS data. Here are two reasons to use a SAS/CONNECT or SAS/SHARE server:
  - You can use a server to migrate across machines when you do not have direct access.
  - You are required to use a server if both of the following conditions are met:
    - The source library contains catalogs.
    - Processing would invoke CEDA in the target session.

      In general, CEDA is invoked when you migrate to an incompatible operating environment. For more information about CEDA, see "Cross-Environment Data Access" in *SAS Programmer's Guide: Essentials*.
- The SLIBREF= argument is not used. (To learn whether SLIBREF= is required, see "Using a SAS/CONNECT or SAS/SHARE Server" on page 1571.)
- The IN= argument accesses all of the supported file types in the source library, including incompatible catalogs, by using SAS/CONNECT or SAS/SHARE software. This example uses SAS/CONNECT software. The SAS/CONNECT or SAS/SHARE server that you assign to the IN= argument must be SAS 9.1.3 or later.

Program

```
options comamid=tcp;
%let myserver=host.name.com;
signon myserver.__1234 user=userid password='mypw';

libname source 'source-library-pathname' server=myserver.__1234;
libname target 'target-library-pathname';

proc migrate in=source out=target <options>;
run;
signoff myserver.__1234;
```

Program Description

In the target session, submit the following code to invoke a SAS/CONNECT spawner. The COMAMID= system option specifies TCP/IP as the communications access method. The `myserver` macro variable is assigned to the host name of the

remote SAS/CONNECT server. The SIGNON statement references the `myserver` macro variable followed by the port number that the SAS/CONNECT spawner is listening on. If your port number or service name is defined in the macro variable, then omit it from the SIGNON.

```
options comamid=tcp;
%let myserver=host.name.com;
signon myserver.__1234 user=userid password='mypw';
```

Assign the source and target libraries. Substitute your library paths, and specify the `myserver` macro variable for SERVER= in the source library. Include the port number if it is specified in the SIGNON statement.

```
libname source 'source-library-pathname' server=myserver.__1234;
libname target 'target-library-pathname';
```

Submit PROC MIGRATE, and include any options you want.

```
proc migrate in=source out=target <options>;
run;
signoff myserver.__1234;
```

Log Messages

The following SAS log messages indicate that a data set and a formats catalog are migrated. PROC MIGRATE calls the CPORT and CIMPORT procedures to migrate catalogs. Normally CEDA does not support catalogs, but using a SAS/CONNECT server avoids CEDA restrictions. The server must have the same data representation and encoding as the data.

```
NOTE: Migrating SOURCE.TEST to TARGET.TEST (memtype=DATA).
NOTE: There were 3 observations read from the data set SOURCE.TEST.
NOTE: The data set TARGET.TEST has 3 observations and 2 variables.
NOTE: PROC CPORT begins to transport catalog SOURCE.FORMATS
NOTE: Entry MYFMT.FORMAT has been transported.
NOTE: Entry MYABC.FORMATC has been transported.
```

Example 2: Migrating with Direct Access and No Incompatible Catalogs

Features: PROC MIGRATE statement options
- IN=
- OUT=

Details

In this example, the following is demonstrated:

- The source and target libraries are directly accessible by the target computer. For example, you might use NFS, which is a standard protocol of UNIX operating environments. See the documentation for NFS and for your operating environment.
- A SAS/CONNECT or SAS/SHARE server is not used. To learn whether a server is required, see "Using a SAS/CONNECT or SAS/SHARE Server" on page 1571.
- If CEDA processing is not invoked, then any catalogs in the library are included in the migration. If CEDA is invoked, then catalogs are not migrated.

Program

From a session in the current release of SAS, submit the following.

```
libname Source 'source-library-pathname';
libname Target 'target-library-pathname';

proc migrate in=Source out=Target;
run;
```

Example 3: Migrating with Incompatible Catalogs When the SLIBREF= Option Is Required

Features:

PROC MIGRATE statement options
IN=
OUT=
SLIBREF=

Details

In this example, the following is demonstrated:

- The source and target libraries are on different computers.
- The SLIBREF= argument accesses the catalogs in the source library. (To learn whether SLIBREF= is required, see "Using a SAS/CONNECT or SAS/SHARE Server" on page 1571.) The SLIBREF= argument must be assigned to a

SAS/CONNECT or SAS/SHARE server running in a session of SAS that can access the catalogs. For example, if the source library contains SAS 8.2 catalogs created by 32-bit Solaris, SLIBREF= must be assigned to a SAS 8.2 32-bit Solaris server. If catalogs were created in SAS 6, SLIBREF= must be assigned through a SAS 8.2 server that is compatible with the data representation of the SAS 6 catalogs.

- The IN= argument accesses the rest of the supported file types in the source library. You can assign the source library to the IN= argument in one of the following two ways:
  - directly via a Network File System (NFS)
  - via a SAS/CONNECT or SAS/SHARE server

  This example uses NFS, which is a standard protocol of UNIX operating environments. See the documentation for NFS and for your operating environment.

Program

```
signon v8srv sascmd='my-v8-sas-invocation-command';

rsubmit;
libname Srclib <engine> 'source-library-pathname';
endrsubmit;

libname Source <engine> '/nfs/v8machine-name/source-library-pathname';

libname Srclib <engine> server=v8srv;

libname Target <engine> 'target-library-pathname';

proc migrate in=Source out=Target slibref=Srclib <options>;
run;

proc migrate out=Target slibref=Srclib <options>;
run;
```

Program Description

From a session in the current release of SAS, submit the SIGNON command to invoke a SAS/CONNECT server session. Note that because you are working across computers, you might specify a machine name in the server ID.

```
signon v8srv sascmd='my-v8-sas-invocation-command';
```

Within this remote SAS 8.2 session, assign a libref to the source library that contains the library members to be migrated. Use the RSUBMIT and ENDRSUBMIT commands for SAS/CONNECT.

```
rsubmit;
libname Srclib <engine> 'source-library-pathname';
endrsubmit;
```

In the local (client) session in the current release, assign to the same source library through NFS.

```
libname Source <engine> '/nfs/v8machine-name/source-library-pathname';
```

Assign the same libref to the same source libref as in step 2 (in this example, Srclib). But do not assign the libref to a physical location. Instead, specify the SERVER= option with the server ID (in this example, V8SRV) that you assigned in the SIGNON command in step 1.

```
libname Srclib <engine> server=v8srv;
```

Assign the target library.

```
libname Target <engine> 'target-library-pathname';
```

Use PROC MIGRATE with the SLIBREF= option. For the IN= and OUT= options, specify the usual source and target librefs (in this example, Source and Target, respectively). Set SLIBREF= to the libref that uses the SERVER= option (in this example, Srclib).

```
proc migrate in=Source out=Target slibref=Srclib <options>;
run;
```

Alternatively, if CATALOG is the only member type in the library and you are using the SLIBREF= option, then omit the IN= argument.

```
proc migrate out=Target slibref=Srclib <options>;
run;
```

42

OPTIONS Procedure

Overview: OPTIONS Procedure

What Does the OPTIONS Procedure Do?

The OPTIONS procedure lists the current settings of SAS system options in the SAS log.

SAS system options control how SAS formats output, handles files, processes data sets, interacts with the operating environment, and does other tasks that are not specific to a single SAS program or data set. You use the OPTIONS procedure to obtain information about an option or a group of options. Here is some of the information that the OPTIONS procedure provides:

- the current value of an option and how it was set
- a description of an option
- valid syntax for the option, valid option values, and the range of values
- where you can set the system option
- if the option can be restricted by your site administrator
- if the option has been restricted
- system options that belong to a system option group
- system options that are specific for an operating environment
- if an option value has been modified by the INSERT or APPEND system options
- system options that can be saved by the OPTSAVE procedure or the DMOPTSAVE command (not valid in SAS Viya)

For additional information about SAS system options, see *SAS System Options: Reference*.

Syntax: OPTIONS Procedure

Note: SAS system options are documented in several publications. You can access all system options from "SAS System Options Documented in Other SAS Publications" in *SAS System Options: Reference*.

See: "OPTIONS Procedure: UNIX" in *SAS Companion for UNIX Environments*

"OPTIONS Procedure: Windows" in *SAS Companion for Windows*

"OPTIONS Procedure Statement: z/OS" in *SAS Companion for z/OS*

PROC OPTIONS <*options*>;

Statement	Task	Example
PROC OPTIONS	List the current system option settings to the SAS Log	Ex. 1, Ex. 2, Ex. 3, Ex. 4

PROC OPTIONS Statement

Lists the current settings of SAS system options in the SAS log.

Examples:

Syntax

PROC OPTIONS <*options*>;

Summary of Optional Arguments

LISTGROUPS
: lists the system option groups as well as a description of each group.

Choose the format of the listing

DEFINE
: displays the short description of the option, the option group, and the option type.

EXPAND
: when displaying a character option, replaces an environment variable in the option value with the value of the environment variable. EXPAND is ignored if the option is a Boolean option, such as CENTER or NOCENTER, or if the value of the option is numeric.

HEXVALUE
: displays system option character values as hexadecimal values.

LOGNUMBERFORMAT
: displays numeric system option values using locale-specific punctuation.

LONG
: lists each system option on a separate line with a description.

NOEXPAND
: when displaying a path, displays the path using environment variable(s) and not the value of the environment variable(s). This is the default.

NOLOGNUMBERFORMAT
: displays numeric system option values without using punctuation, such as a comma or a period. This is the default.

SHORT
: specifies to display a compressed listing of options without descriptions.

VALUE
: displays the option's value and scope, as well as how the value was set.

Restrict the number of options displayed

GROUP=*group-name*

GROUP=*(group-name–1 ... group-name-n)*
: displays the options in one or more groups specified by *group-name*.

HOST
: displays only host options.

LISTINSERTAPPEND
: lists the system options whose value can be modified by the INSERT and APPEND system options.

LISTOPTSAVE
: lists the system options that can be saved with PROC OPTSAVE or the DMOPTSAVE command.

LISTRESTRICT
: lists the system options that can be restricted by your site administrator.

NOHOST
: displays only portable options.

OPTION=*option-name*

OPTION=(*option-name-1 ... option-name-n*)
: displays information about one or more system options.

RESTRICT
: displays system options that the site administrator has restricted from being updated.

Optional Arguments

DEFINE
displays the short description of the option, the option group, and the option type. SAS displays information about when the option can be set, whether an option can be restricted, the valid values for the option, and whether the OPTSAVE procedure will save the option.

Restriction Saving and loading system options is not valid in SAS Viya. Information about whether the option can be saved or loaded is displayed only for SAS 9.4.

Interaction This option is ignored when SHORT is specified.

Example "Example 2: Displaying the Setting of a Single Option" on page 1599

EXPAND
when displaying a character option, replaces an environment variable in the option value with the value of the environment variable. EXPAND is ignored if the option is a Boolean option, such as CENTER or NOCENTER, or if the value of the option is numeric.

Restriction Variable expansion is valid only in the Windows and UNIX operating environments.

Tip By default, some option values are displayed with expanded variables. Other options require the EXPAND option in the PROC OPTIONS statement. Use the DEFINE option in the PROC OPTIONS statement to determine whether an option value expands variables by default or if the EXPAND option is required. If the output from PROC OPTIONS DEFINE shows the following information, you must use the EXPAND option to expand variable values:

```
Expansion: Environment variables, within the option value,
```

```
are not expanded
```

See "NOEXPAND" on page 1586 option to view paths that display the environment variable

Example "Example 3: Displaying Expanded Path Environment Variables" on page 1600

GROUP=*group-name*
GROUP=*(group-name-1 ... group-name-n)*
displays the options in one or more groups specified by *group-name*.

Requirement When you specify more than one group, enclose the group names in parenthesis and separate the group names by a space.

See "Display Information about System Option Groups" on page 1591

HEXVALUE
displays system option character values as hexadecimal values.

HOST
displays only host options.

See "NOHOST" on page 1586 option to display only portable options.

LISTINSERTAPPEND
lists the system options whose value can be modified by the INSERT and APPEND system options. The INSERT option specifies a value that is inserted as the first value of a system option value list. The APPEND option specifies a value that is appended as the last value of a system option value list. Use the LISTINERTAPPEND option to display which system options can have values inserted at the beginning or appended at the end of their value lists.

See "INSERT= System Option" in *SAS System Options: Reference*

"APPEND= System Option" in *SAS System Options: Reference*

Example "Example 4: List the Options That Can Be Specified by the INSERT and APPEND Options" on page 1601

LISTGROUPS
lists the system option groups as well as a description of each group.

See "Display Information about System Option Groups" on page 1591

LISTOPTSAVE
lists the system options that can be saved with PROC OPTSAVE or the DMOPTSAVE command.

Restriction This option is not valid in SAS Viya. PROC OPTSAVE and the DMOPTSAVE command are not valid in SAS Viya.

LISTRESTRICT
lists the system options that can be restricted by your site administrator.

See "RESTRICT" on page 1587 option to list options that have been restricted by the site administrator

LONG
lists each system option on a separate line with a description. This is the default. Alternatively, you can create a compressed listing without descriptions.

See "SHORT" on page 1587 option to produce a compressed listing without descriptions

Example "Example 1: Producing the Short Form of the Options Listing" on page 1598

LOGNUMBERFORMAT
displays numeric system option values using locale-specific punctuation.

See "NOLOGNUMBERFORMAT" on page 1586 option to display numeric option values without using commas

Example "Example 2: Displaying the Setting of a Single Option" on page 1599

NOEXPAND
when displaying a path, displays the path using environment variable(s) and not the value of the environment variable(s). This is the default.

See "EXPAND" on page 1584 option to display a path by expanding the value of environment variables

NOHOST
displays only portable options.

Alias PORTABLE or PORT

See "HOST" on page 1585 option to display only host options

NOLOGNUMBERFORMAT
displays numeric system option values without using punctuation, such as a comma or a period. This is the default.

See "LOGNUMBERFORMAT" on page 1586 option to display numeric system options using commas

OPTION=*option-name*
OPTION=(*option-name-1 ... option-name-n*)
displays a short description and the value (if any) of the option specified by *option-name*. DEFINE and VALUE options provide additional information about the option.

option-name
specifies the option to use as input to the procedure.

Requirement If a SAS system option uses an equal sign, such as PAGESIZE=, do not include the equal sign when specifying the option to OPTION=.

Example "Example 2: Displaying the Setting of a Single Option" on page 1599

RESTRICT

displays the system options that have been set by your site administrator in a restricted options configuration file. These options cannot be changed by the user. For each option that is restricted, the RESTRICT option displays the option's value, scope, and how it was set.

If your site administrator has not restricted any options, then the following message appears in the SAS log:

```
Your Site Administrator has not restricted any SAS options.
```

See "LISTRESTRICT" on page 1585 option to list options that can be restricted by the site administrator

SHORT

specifies to display a compressed listing of options without descriptions.

See "LONG" on page 1586 option to create a listing with descriptions of the options.

VALUE

displays the option's value and scope, as well as how the value was set. If the value was set using a configuration file, the SAS log displays the name of the configuration file. If the option was set using the INSERT or APPEND system options, the SAS log displays the value that was inserted or appended.

Interactions This option has no effect when SHORT is specified.

When the option is in the Threaded Kernel (TK) system options group, the value of **How option value set** is displayed as `Internal`

Note SAS options that are passwords, such as EMAILPW and METAPASS, return the value xxxxxxxx and not the actual password.

Example "Example 2: Displaying the Setting of a Single Option" on page 1599

Usage: OPTIONS Procedure

Display a List of System Options

The log that results from running PROC OPTIONS can show the system options for the options that are available for all operating environment and those that are specific to a single operating environment. Options that are available for all operating environments are referred to as portable options. Options that are specific to a single operating environment are referred to as host options.

The following example shows a partial log that displays the settings of portable options.

```
proc options;
run;
```

Example Code 42.1 *The SAS Log Showing a Partial Listing of SAS System Options*

```
Portable Options:

 NOACCESSIBLECHECK Do not detect and log ODS output that is not accessible.
 NOACCESSIBLEGRAPH Do not create accessible ODS graphics by default.
 NOACCESSIBLEPDF   Do not create accessible PDF files by default.
 NOACCESSIBLETABLE Do not create accessible tables for enabled procedures, by default.

 ANIMATION=STOP    Specifies whether to start or stop animation.
 ANIMDURATION=MIN  Specifies the number of seconds that each animation frame displays.
 ANIMLOOP=YES      Specifies the number of iterations that animated images repeat.
 ANIMOVERLAY       Specifies that animation frames are overlaid in order to view all frames.
 APPEND=           Specifies an option=value pair to insert the value at the end of the existing
                   option value.
 APPLETLOC=site-specific-path
                   Specifies the location of Java applets, which is typically a URL.
 ARMAGENT=         Specifies an ARM agent (which is an executable module or keyword, such as
                   LOG4SAS) that contains a specific implementation of the ARM API.
 ARMLOC=ARMLOG.LOG Specifies the location of the ARM log.
 ARMSUBSYS=(ARM_NONE)
                   Specifies the SAS ARM subsystems to enable or disable.
 AUTOCORRECT       Automatically corrects misspelled procedure names and keywords, and global
                   statement names.
```

The log displays both portable and host options when you submit `proc options;`.

To view only host options, use this version of the OPTIONS procedure:

```
proc options host;
run;
```

Example Code 42.2 *The SAS Log Showing a Partial List of Host Options*

```
Host Options:

 ACCESSIBILITY=STANDARD
                   Specifies whether accessibility features are enabled in the Customize Tool
                   dialog box and in some Properties dialog boxes.
 ALIGNSASIOFILES   Aligns SAS files on a page boundary for improved performance.
 ALTLOG=           Specifies the location for a copy of the SAS log when SAS is running in batch
                   mode.
 ALTPRINT=         Specifies the location for a copy of the SAS procedure output when SAS is
                   running in batch mode.
 AUTHPROVIDERDOMAIN=
                   Specifies the authentication provider that is associated with a domain.
 AUTHSERVER=       Specifies the domain server that finds and authenticates secure server logins.
 AWSCONTROL=(SYSTEMMENU MINMAX TITLE)
                   Specifies whether the main SAS window includes a title bar, a system control
                   menu, and minimize and maximize buttons.
 AWSDEF=(0 0 79 80)
                   Specifies the location and dimensions of the main SAS window when SAS
                   initializes.
 AWSMENU           Displays the menu bar in the main SAS window.
```

Display Information about One or More Options

To view the setting of one or more particular options, you can use the OPTION= and DEFINE options in the PROC OPTIONS statement. The following example shows a log that PROC OPTIONS produces for a single SAS system option.

```
proc options option=errorcheck define;
run;
```

Example Code 42.3 *The Setting of a Single SAS System Option*

```
5    proc options option=errorcheck define;
6    run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

 ERRORCHECK=NORMAL
Option Definition Information for SAS Option ERRORCHECK
    Group= ERRORHANDLING
    Group Description: Error messages and error conditions settings
    Description: Specifies whether SAS enters syntax-check mode when errors are found in the
                 LIBNAME, FILENAME,  %INCLUDE, and LOCK statements.
    Type: The option value is of type CHARACTER
          Maximum Number of Characters: 10
          Casing: The option value is retained uppercased
          Quotes: If present during "set", start and end quotes are removed
          Parentheses: The option value does not require enclosure within parentheses. If
          present, the parentheses are retained.
          Expansion: Environment variables, within the option value, are not expanded
          Number of valid values: 2
               Valid value: NORMAL
               Valid value: STRICT
    When Can Set: Startup or anytime during the SAS Session
    Restricted: Your Site Administrator can restrict modification of this option
    Optsave: PROC Optsave or command Dmoptsave will save this option
```

To view the settings for more than one option, enclose the options in parentheses and separate the options with a space:

```
proc options option=(pdfsecurity pdfpassword) define;
run;
```

Example Code 42.4 *The Settings of Two SAS System Options*

```
7    proc options option=(pdfsecurity pdfpassword) define;
8    run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

 PDFSECURITY=NONE
Option Definition Information for SAS Option PDFSECURITY
    Group= PDF
    Group Description: PDF settings
    Group= SECURITY
    Group Description: Security settings
    Description: Specifies the level of encryption to use for PDF documents.
    Type: The option value is of type CHARACTER
          Maximum Number of Characters: 4
          Casing: The option value is retained uppercased
          Quotes: If present during "set", start and end quotes are removed
          Parentheses: The option value does not require enclosure within parentheses. If
          present, the parentheses are retained.
          Expansion: Environment variables, within the option value, are not expanded
          Number of valid values: 3
               Valid value: HIGH
               Valid value: LOW
               Valid value: NONE
    When Can Set: Startup or anytime during the SAS Session
    Restricted: Your Site Administrator can restrict modification of this option
    Optsave: PROC Optsave or command Dmoptsave will save this option
```

```
 PDFPASSWORD=xxxxxxxx
Option Definition Information for SAS Option PDFPASSWORD
    Group= PDF
    Group Description: PDF settings
    Group= SECURITY
    Group Description: Security settings
    Description: Specifies the password to use to open a PDF document and the password used by a
                 PDF document owner.
    Type: The option value is of type CHARACTER
          Maximum Number of Characters: 2048
          Casing: The option value is retained with original casing
          Quotes: If present during "set", start and end quotes are removed
          Parentheses: The option value must be enclosed within parentheses. The parentheses are
          retained.
          Expansion: Environment variables, within the option value, are not expanded
          Number of valid values: 2
               Valid value: OPEN
               Valid value: OWNER
    When Can Set: Startup or anytime during the SAS Session
    Restricted: Your Site Administrator cannot restrict modification of this option
    Optsave: PROC Optsave or command Dmoptsave will not save this option
```

Display Information about System Option Groups

Each SAS system option belongs to one or more groups, which are based on functionality, such as error handling or sorting. You can display a list of system-option groups and the system options that belong to one or more of the groups.

Use the LISTGROUPS option to display a list of system-option groups.

```
proc options listgroups;
run;
```

Example Code 42.5 *List of SAS System Option Groups*

```
26   proc options listgroups;
27   run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

    Option Groups
       GROUP=ADABAS                ADABAS

       GROUP=ANIMATION             Animation

       GROUP=CAS                   CAS Options

       GROUP=CODEGEN               Code generation

       GROUP=COMMUNICATIONS        Networking and encryption

       GROUP=DATACOM               Datacom

       GROUP=DATAQUALITY           Data Quality

       GROUP=DB2                   DB2

       GROUP=EMAIL                 E-mail

       GROUP=ENVDISPLAY            Display
```

```
GROUP=ENVFILES              Files
GROUP=ERRORHANDLING         Error handling
GROUP=EXECMODES             Initialization and operation
GROUP=EXTFILES              External files
GROUP=GRAPHICS              Driver settings
GROUP=HELP                  Help
GROUP=IDMS                  IDMS
GROUP=IMS                   IMS
GROUP=INPUTCONTROL          Data Processing
GROUP=INSTALL               Installation
GROUP=ISPF                  ISPF
GROUP=LANGUAGECONTROL       Language control
GROUP=LISTCONTROL           Procedure output
GROUP=LOGCONTROL            SAS log
GROUP=LOG_LISTCONTROL       SAS log and procedure output
GROUP=MACRO                 SAS macro
GROUP=MEMORY                Memory
GROUP=META                  Metadata
GROUP=ODSPRINT              ODS Printing
GROUP=PDF                   PDF
GROUP=PERFORMANCE           Performance
GROUP=REXX                  REXX
GROUP=SASFILES              SAS Files
GROUP=SECURITY              Security
GROUP=SMF                   SMF
GROUP=SORT                  Procedure options
GROUP=SQL                   SQL
GROUP=SVG                   SVG
GROUP=TK                    TK
```

Use the GROUP= option to display system options that belong to a particular group. You can specify one or more groups.

```
proc options group=(svg graphics);
run;
```

Example Code 42.6 *Sample Output Using the GROUP= Option*

```
5    proc options group=(svg graphics);
6    run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

Group=SVG
 ANIMATION=STOP    Specifies whether to start or stop animation.
 ANIMDURATION=MIN  Specifies the number of seconds that each animation frame displays.
 ANIMLOOP=YES      Specifies the number of iterations that animated images repeat.
 ANIMOVERLAY       Specifies that animation frames are overlaid in order to view all frames.
 SVGAUTOPLAY       Starts animation when the page is loaded in the browser.
 NOSVGCONTROLBUTTONS
                   Does not display the paging control buttons and an index in a multipage SVG
                   document.
 SVGFADEIN=0       Specifies the number of seconds for the fade-in effect for a graph.
 SVGFADEMODE=OVERLAP
                   Specifies whether to use sequential frames or to overlap frames for the
                   fade-in effect of a graph.
 SVGFADEOUT=0      Specifies the number of seconds for a graph to fade out of view.
 SVGHEIGHT=        Specifies the height of the viewport. Specifies the value of the height
                   attribute of the outermost SVG element.
 NOSVGMAGNIFYBUTTON
                   Disables the SVG magnifier tool.
 SVGPRESERVEASPECTRATIO=
                   Specifies whether to force uniform scaling of SVG output. Specifies the
                   preserveAspectRatio attribute on the outermost SVG element.
 SVGTITLE=         Specifies the text in the title bar of the SVG output. Specifies the value of
                   the TITLE element in the SVG file.
 SVGVIEWBOX=       Specifies the coordinates, width, and height that are used to set the viewBox
                   attribute on the outermost SVG element.
 SVGWIDTH=         Specifies the width of the viewport. Specifies the value of the width
                   attribute of the outermost SVG element.
 SVGX=             Specifies the x-axis coordinate of one corner of the rectangular region for
                   an embedded SVG element. Specifies the x attribute in the outermost SVG
                   element.
 SVGY=             Specifies the y-axis coordinate of one corner of the rectangular region for
                   an embedded SVG element. Specifies the y attribute in the outermost SVG
                   element.

Group=GRAPHICS
 DEVICE=           Specifies the device driver to which SAS/GRAPH sends procedure output.
 GSTYLE            Uses ODS styles to generate graphs that are stored as GRSEG catalog entries.
 GWINDOW           Displays SAS/GRAPH output in the GRAPH window.
 MAPS=("!sasroot\path-to-maps")
                   Specifies the location of SAS/GRAPH map data sets.
 MAPSGFK=(          "!sasroot\path-to-maps"  )
                   Specifies the location of GfK maps.
 MAPSSAS=(          "!sasroot\path-to-maps"  )
                   Specifies the location of SAS map data sets.
 FONTALIAS=        Assigns a Windows font to one of the SAS fonts.
```

You can use the following group names as values for the GROUP= option to list the system options in a group:

ANIMATION	GRAPHICS	META
CAS	HELP	ODSPRINT
COMMUNICATIONS	INPUTCONTROL	PDF
DATAQUALITY	INSTALL	PERFORMANCE
EMAIL	LANGUAGECONTROL	SASFILES

ENVDISPLAY	LISTCONTROL	SECURITY
ENVFILES	LOGCONTROL	SORT
ERRORHANDLING	LOG_LISTCONTROL	SQL
EXECMODES	MACRO	SVG
EXTFILES	MEMORY	TK

You can use the following groups to list operating environment–specific values that might be available when you use the GROUP= option with PROC OPTIONS.

ADABAS	IDMS	REXX
CODEGEN	IMS	SMF
DATACOM	ISPF	
DB2	ORACLE	

Operating Environment Information: Refer to the SAS documentation for your operating environment for more information about these host-specific options.

Display Restricted Options

Your site administrator can restrict some system options so that your SAS session conforms to options that are set for your site. Restricted options can be modified only by your site administrator. The OPTIONS procedure provides two options that display information about restricted options. The RESTRICT option lists the system options that your site administrator has restricted. The LISTRESTRICT option lists the options that can be restricted by your site administrator. For a listing of options that cannot be restricted, see "System Options That Cannot Be Restricted" in *SAS System Options: Reference*.

The following SAS logs shows the output when the RESTRICT option is specified and partial output when the LISTRESTRICT option is specified.

Example Code 42.7 *A List of Options That Have Been Restricted by the Site Administrator*

```
1
   proc options restrict;
2    run;
    SAS (r) Proprietary Software Release 9.4  TS1M6

Option Value Information For SAS Option CMPOPT
    Option Value: (NOEXTRAMATH NOMISSCHECK NOPRECISE NOGUARDCHECK
NOGENSYMNAMES NOFUNCDIFFERENCING)
    Option Scope: SAS Session
    How option value set:  Site Administrator Restricted
```

Example Code 42.8 *A Partial Log That Lists Options That Can Be Restricted*

```
13   proc options listrestrict;
14   run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

    Your Site Administrator can restrict the ability to modify the following Portable Options:

     ACCESSIBLECHECK    Detect and log ODS output that is not accessible.
     ACCESSIBLEGRAPH    Create accessible ODS graphics by default.
     ACCESSIBLEPDF      Create accessible PDF files by default.
     ACCESSIBLETABLE    Create accessible tables for enabled procedures, by default.
     ANIMATION          Specifies whether to start or stop animation.
     ANIMDURATION       Specifies the number of seconds that each animation frame displays.
     ANIMLOOP           Specifies the number of iterations that animated images repeat.
     ANIMOVERLAY        Specifies that animation frames are overlaid in order to view all frames.
     APPLETLOC          Specifies the location of Java applets, which is typically a URL.
     ARMAGENT           Specifies an ARM agent (which is an executable module or keyword, such
                        as LOG4SAS) that contains a specific implementation of the ARM API.
     ARMLOC             Specifies the location of the ARM log.
     ARMSUBSYS          Specifies the SAS ARM subsystems to enable or disable.
     AUTOCORRECT        Automatically corrects misspelled procedure names and keywords, and
                        global statement names.
     AUTOSAVELOC        Specifies the location of the Program Editor auto-saved file.
```

Display Options That Can Be Saved

Many system options can be saved by using PROC OPTSAVE or the DMOPTSAVE command. The options can later be restored by using PROC OPTLOAD or the DMOPTLOAD command. You can list the system options that can be saved and later restored by using the LISTOPTSAVE option on PROC OPTIONS.

Note: PROC OPTSAVE does not save these types of system options:

- SAS invocation options
- SAS environment variable options
- SAS system options that include passwords
- SAS system options that are read-only and cannot be set

Note: PROC OPTSAVE and PROC OPTLOAD, as well as the DMOPTSAVE and DMOPTLOAD commands are valid only in SAS 9.4. They are not valid in SAS Viya.

The following SAS log shows a partial list of the options that can be saved by using PROC OPTSAVE or the DMOPTSAVE command:

Example Code 42.9 *A Partial List of System Options That Can Be Saved*

```
11   proc options listoptsave;
     run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

    Core options that can be saved with OPTSAVE

     ACCESSIBLECHECK    Detect and log ODS output that is not accessible.
     ACCESSIBLEGRAPH    Create accessible ODS graphics by default.
     ACCESSIBLEPDF      Create accessible PDF files by default.
     ACCESSIBLETABLE    Create accessible tables for enabled procedures, by default.
     ANIMATION          Specifies whether to start or stop animation.
     ANIMDURATION       Specifies the number of seconds that each animation frame displays.
     ANIMLOOP           Specifies the number of iterations that animated images repeat.
     ANIMOVERLAY        Specifies that animation frames are overlaid in order to view all frames.
     APPLETLOC          Specifies the location of Java applets, which is typically a URL.
     AUTOCORRECT        Automatically corrects misspelled procedure names and keywords, and
                        global statement names.
     AUTOSAVELOC        Specifies the location of the Program Editor auto-saved file.
     AUTOSIGNON         Enables a SAS/CONNECT client to automatically submit the SIGNON command
                        remotely with the RSUBMIT command.
     BINDING            Specifies the binding edge type of duplexed printed output.
     BOMFILE            Writes the byte order mark (BOM) prefix when a Unicode-encoded file is
                        written to an external file.
     BOTTOMMARGIN       Specifies the size of the margin at the bottom of a printed page.
     BUFNO              Specifies the number of buffers for processing SAS data sets.
     BUFSIZE            Specifies the size of a buffer page for output SAS data sets.
```

Results: OPTIONS Procedure

View PROC OPTIONS Output in the SAS Log

SAS writes the options list to the SAS log.

SAS system options of the form *option* | NO*option* are listed as either *option* or NO*option*, depending on the current setting. They are always sorted by the positive form. For example, NOCAPS would be listed under the Cs.

The OPTIONS procedure displays passwords in the SAS log as eight Xs, regardless of the actual password length.

Operating Environment Information: PROC OPTIONS produces additional information that is specific to the environment under which you are running SAS. For more information about this and for descriptions of host-specific options, refer to the SAS documentation for your operating environment.

Examples: OPTIONS Procedure

Example 1: Producing the Short Form of the Options Listing

Features: PROC OPTIONS statement option
SHORT

Details

This example shows how to generate the short form of the listing of SAS system option settings. Compare this short form with the long form that is shown in "Display a List of System Options" on page 1588.

Program

List all options and their settings. SHORT lists the SAS system options and their settings without any descriptions.

```
proc options short;
run;
```

Log

Example Code 42.10 *Partial Listing of the SHORT Option*

```
6    proc options short;
7    run;
    SAS (r) Proprietary Software Release 9.4  TS1M6

Portable Options:

 NOACCESSIBLECHECK NOACCESSIBLEGRAPH NOACCESSIBLEPDF NOACCESSIBLETABLE ANIMATION=STOP
ANIMDURATION=MIN ANIMLOOP=YES ANIMOVERLAY APPEND=

```

Example 2: Displaying the Setting of a Single Option

Features: PROC OPTIONS statement option
- OPTION=
- DEFINE
- LOGNUMBERFORMAT
- VALUE

Details

This example shows how to display the setting of a single SAS system option. The log shows the current setting of the SAS system option MEMBLKSZ. The DEFINE and VALUE options display additional information. The LOGNUMBERFORMAT displays the value using commas.

Program

Specify the MEMBLKSZ SAS system option. OPTION=MEMBLKSZ displays option value information. DEFINE and VALUE display additional information. LOGNUMBERFORMAT specifies to format the value using commas.

```
proc options option=memblksz define value lognumberformat;
```

```
run;
```

Log

Example Code 42.11 *Log Output from Specifying the MEMBLKSZ Option*

```
13   proc options option=memblksz define value lognumberformat;
14   run;

    SAS (r) Proprietary Software Release 9.4 TS1M6

Option Value Information For SAS Option MEMBLKSZ
    Value: 16,777,216
    Scope: Default
    How option value set: Shipped Default

Option Definition Information for SAS Option MEMBLKSZ
    Group= MEMORY
    Group Description: Memory settings
    Description: Specifies the memory block size for Windows memory-based libraries.
    Type: The option value is of type INTMAX
          Range of Values: The minimum is 0 and the maximum is 9223372036854775807
          Valid Syntax(any casing): MIN|MAX|n|nK|nM|nG|nT|hexadecimal
    Numeric Format: Usage of LOGNUMBERFORMAT impacts the value format
    When Can Set: Session startup (command line or config) only
    Restricted: Your Site Administrator can restrict modification of this option
    Optsave: PROC Optsave or command Dmoptsave will not save this option
```

Example 3: Displaying Expanded Path Environment Variables

Features: PROC OPTIONS statement options
- OPTION=
- EXPAND
- NOEXPAND
- HOST

Details

This example shows the value of an environment variable when the path is displayed.

Program

Show the value of the environment variables: The EXPAND option causes the values of environment variables to display in place of the environment variable. The NOEXPAND option causes the environment variable to display. In this example, the environment variable is !sasroot

```
proc options option=msg expand;
run;
proc options option=msg noexpand;
run;
```

Log

Example Code 42.12 *Displaying an Expanded and Nonexpanded Pathname Using the OPTIONS Procedure*

```
6    proc options option=msg expand;
7    run;
    SAS (r) Proprietary Software Release 9.4  TS1M6

 MSG=( 'C:\Program Files\SASHome\SASFoundation\9.4\sasmsg' )
                  The path to the sasmsg directory
NOTE: PROCEDURE OPTIONS used (Total process time):
      real time           0.01 seconds
      cpu time            0.00 seconds

8    proc options option=msg noexpand;
9    run;
    SAS (r) Proprietary Software Release 9.4  TS1M6
0

 MSG=( '!sasroot\sasmsg')
                  The path to the sasmsg directory
```

Example 4: List the Options That Can Be Specified by the INSERT and APPEND Options

Features: PROC OPTIONS statement option
LISTINSERTAPPEND

Details

This example shows how to display the options that can be specified by the INSERT and APPEND system options.

Program

List all options that can be specified by the INSERT and APPEND options in SAS 9.4. The LISTINSERTAPPEND option provides a list and a description of these options.

```
proc options listinsertappend;
run;
```

Log

Example Code 42.13 *Displaying the Options That Can Be Specified by the INSERT and APPEND Options*

```
9    proc options listinsertappend;
10   run;

     SAS (r) Proprietary Software Release 9.4   TS1M6
p

     Core options that can utilize INSERT and APPEND

      AUTOEXEC           Specifies the location of the SAS AUTOEXEC files.
      CMPLIB             Specifies one or more SAS data sets that contain compiler subroutines to
                         include during compilation.
      FMTSEARCH          Specifies the order in which format catalogs are searched.
      MAPS               Specifies the location of SAS/GRAPH map data sets
      MAPSGFK            Specifies the location of GfK maps.
.
      SASAUTOS           Specifies the location of one or more autocall libraries.
      SASHELP            Specifies the location of the Sashelp library.
      SASSCRIPT          Specifies one or more locations of SAS/CONNECT server sign-on script
                         files.

     Host options that can utilize INSERT and APPEND

      HELPLOC            Specifies the location of the text and index files for the facility that
                         is used to view the online SAS Help and Documentation.
      MSG                Specifies the path to the library that contains SAS error messages.
      SET                Defines a SAS environment variable.
```

43

OPTLOAD Procedure

Overview: OPTLOAD Procedure

What Does the OPTLOAD Procedure Do?

The OPTLOAD procedure reads SAS system option settings that are stored in the SAS registry or a SAS data set and puts them into effect.

You can load SAS system option settings from a SAS data set or registry key by using one of these methods:

- the DMOPTLOAD command from a command line in the SAS windowing environment. For example, the command loads system options from the registry: DMOPTLOAD key= “core\options”.
- the PROC OPTLOAD statement.

When an option is restricted by the site administrator, and the option value that is being set by PROC OPTLOAD differs from the option value that was established by the site administrator, SAS issues a warning message to the log.

Syntax: OPTLOAD Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC OPTLOAD <*options*>;

Statement	Task	Example
PROC OPTLOAD	Use SAS system option settings that are stored in the SAS registry or in a SAS data set	Ex. 1

PROC OPTLOAD Statement

Loads saved setting of SAS system options that are stored in the SAS registry or in a SAS data set.

Syntax

PROC OPTLOAD <*options*>;

Summary of Optional Arguments

DATA=*libref.dataset*
: Load SAS system option settings from an existing data set.

KEY="*SAS registry key*"
: Load SAS system option settings from an existing registry key.

Optional Arguments

DATA=*libref.dataset*
specifies the library and data set name from where SAS system option settings are loaded. The SAS variable OPTNAME contains the character value of the SAS system option name, and the SAS variable OPTVALUE contains the character value of the SAS system option setting.

Default: If you omit the DATA= option and the KEY= option, the procedure will use the default SAS library and data set. The default library is where the current user profile resides. Unless you specify a library,

the default library is SASUSER. If SASUSER is being used by another active SAS session, then the temporary WORK library is the default location from which the data set is loaded. The default data set name is MYOPTS.

Requirement The SAS library and data set must exist.

KEY="*SAS registry key*"
specifies the location in the SAS registry of stored SAS system option settings. The registry is retained in SASUSER. If SASUSER is not available, then the temporary WORK library is used. For example, KEY="OPTIONS" loads system options from the OPTIONS registry key.

Requirements "*SAS registry key*" must be an existing SAS registry key.

You must use quotation marks around the "*SAS registry key*" name. Separate the names in a sequence of key names with a backslash (\). For example, KEY="CORE\OPTIONS" loads system options from the CORE\OPTIONS registry key.

Example: Load a Data Set of Saved System Options

Features: PROC OPTLOAD statement option
DATA=

Details

This example saves the current system option settings using the OPTSAVE procedure, modifies the YEARCUTOFF system option, and then loads the original set of system options.

Program

```
libname mysas "c:\mysas";

proc options option=yearcutoff;
run;

proc optsave out=mysas.options;
run;
```

```
options yearcutoff=2000;

proc options option=yearcutoff;
run;

proc optload data=mysas.options;
run;

proc options option=yearcutoff;
run;
```

Program Description

These statements and procedures were submitted one at a time and not run as a SAS program to allow the display of the YEARCUTOFF option.

Assign the libref.

```
libname mysas "c:\mysas";
```

Display the value of the YEARCUTOFF= system option.

```
proc options option=yearcutoff;
run;
```

Save the current system option settings in mysas.options.

```
proc optsave out=mysas.options;
run;
```

Use the OPTIONS statement to set the YEARCUTOFF= system option to the value 2000.

```
options yearcutoff=2000;
```

Display the value of the YEARCUTOFF= system option.

```
proc options option=yearcutoff;
run;
```

Load the saved system option settings.

```
proc optload data=mysas.options;
run;
```

Display the value of the YEARCUTOFF= system option. After loading the saved system option settings, the value of the YEARCUTOFF= option has been restored to the original value.

```
proc options option=yearcutoff;
run;
```

Log

Example Code 43.1 *The SAS Log Shows the YEARCUTOFF= Value After Loading Options Using PROC OPTLOAD*

```
1    libname mysas "c:\mysas";
NOTE: Libref MYSAS was successfully assigned as follows:

OPTSAVE Procedure

Overview: OPTSAVE Procedure

What Does the OPTSAVE Procedure Do?

PROC OPTSAVE saves the current SAS system option settings in the SAS registry or in a SAS data set.

SAS system options can be saved across SAS sessions. You can save the settings of the SAS system options in a SAS data set or registry key by using one of these methods:

- the DMOPTSAVE command from a command line in the SAS windowing environment. Use the command like this: DMOPTSAVE <*save-location*>.
- the PROC OPTSAVE statement.

Syntax: OPTSAVE Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC OPTSAVE <*options* >;

Statement	Task	Example
PROC OPTSAVE	Save the current SAS system option settings to the SAS registry or to a SAS data set	Ex. 1

PROC OPTSAVE Statement

Saves the current SAS system option settings in the SAS registry or in a SAS data set.

Syntax

PROC OPTSAVE <*options* >;

Summary of Optional Arguments

KEY="*SAS registry key*"
: Save SAS system option settings to a registry key.

OUT=*libref.dataset*
: Save SAS system option settings to a SAS data set.

Optional Arguments

KEY="*SAS registry key*"
specifies the location in the SAS registry of stored SAS system option settings. The registry is retained in SASUSER. If SASUSER is not available, then the temporary WORK library is used. For example, KEY="OPTIONS" saves the system options in the OPTIONS registry key.

Restriction "*SAS registry key*" names cannot span multiple lines.

Requirements Separate the names in a sequence of key names with a backslash (\). Individual key names can contain any character except a backslash.

The length of a key name cannot exceed 255 characters (including the backslashes).

You must use quotation marks around the "*SAS registry key*" name.

Tip To specify a subkey, enter multiple key names starting with the root key.

CAUTION **If the key already exists, it will be overwritten.** If the specified key does not already exist in the current SAS registry, then the key is automatically created when option settings are saved in the SAS registry.

OUT=*libref.dataset*
specifies the names of the library and data set where SAS system option settings are saved. The SAS variable OPTNAME contains the character value of the SAS system option name. The SAS variable OPTVALUE contains the character value of the SAS system option setting.

Default If you omit the OUT= and the KEY= options, the procedure will use the default SAS library and data set. The default SAS library is where the current user profile resides. Unless you specify a SAS library, the default library is SASUSER. If SASUSER is in use by another active SAS session, then the temporary WORK library is the default location where the data set is saved. The default data set name is MYOPTS.

CAUTION **If the data set already exists, it will be overwritten.**

Usage: OPTSAVE Procedure

Determine If a Single Option Can Be Saved

You can specify DEFINE in the OPTIONS procedure to determine whether an option can be saved. In the log output, the line beginning with **Optsave:** indicates whether the option can be saved.

```
proc options option=pageno define;
run;
```

Example Code 44.1 *The SAS Log Displaying Output for the Option Procedure DEFINE Option*

```
8    proc options option=pageno define;
9    run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

 PAGENO=1
Option Definition Information for SAS Option PAGENO
    Group= LISTCONTROL
    Group Description: Procedure output and display settings
    Description: Resets the SAS output page number.
    Type: The option value is of type LONG
          Range of Values: The minimum is 1 and the maximum is 2147483647
          Valid Syntax(any casing): MIN|MAX|n|nK|nM|nG|nT|hexadecimal
    Numeric Format: Usage of LOGNUMBERFORMAT impacts the value format
    When Can Set: Startup or anytime during the SAS Session
    Restricted: Your Site Administrator can restrict modification of this option
    Optsave: PROC Optsave or command Dmoptsave will save this option
```

Create a List of Options That Can Be Saved

Some system options cannot be saved. To create a list of options that can be saved, submit this SAS code:

```
proc options listoptsave;
run;
```

Note: PROC OPTSAVE does not save these types of system options:

- SAS invocation options
- SAS environment variable options
- SAS system options that include passwords
- SAS system options that are read-only and cannot be set

Here is a partial listing of options that can be saved:

Example Code 44.2 *A Partial Listing of Options That Can Be Saved*

```
51   proc options listoptsave;
52   run;

    SAS (r) Proprietary Software Release 9.4  TS1M6

    Core options that can be saved with OPTSAVE

     ACCESSIBLECHECK    Detect and log ODS output that is not accessible.
     ACCESSIBLEGRAPH    Create accessible ODS graphics by default.
     ACCESSIBLEPDF      Create accessible PDF files by default.
     ACCESSIBLETABLE    Create accessible tables for enabled procedures, by default.
     ANIMATION          Specifies whether to start or stop animation.
     ANIMDURATION       Specifies the number of seconds that each animation frame
displays.
     ANIMLOOP           Specifies the number of iterations that animated images
repeat.
     ANIMOVERLAY        Specifies that animation frames are overlaid in order to
view all frames.
     APPLETLOC          Specifies the location of Java applets, which is typically a
URL.
     AUTOCORRECT        Automatically corrects misspelled procedure names and
keywords, and
                        global statement names.
     AUTOSAVELOC        Specifies the location of the Program Editor auto-saved file.
     AUTOSIGNON         Enables a SAS/CONNECT client to automatically submit the
SIGNON command
                        remotely with the RSUBMIT command.
     BINDING            Specifies the binding edge type of duplexed printed output.
     BOMFILE            Writes the byte order mark (BOM) prefix when a Unicode-
encoded file is
                        written to an external file.
     BOTTOMMARGIN       Specifies the size of the margin at the bottom of a printed
page.
     BUFNO              Specifies the number of buffers for processing SAS data sets.
     BUFSIZE            Specifies the size of a buffer page for output SAS data sets.
     BYERR              SAS issues an error message and stops processing if the SORT
procedure
                        attempts to sort a _NULL_ data set.
     BYLINE             Prints the BY line above each BY group.
     BYSORTED           Requires observations in one or more data sets to be sorted
in
                        alphabetic or numeric order.
     CAPS               Converts certain types of input, and all data lines, into
uppercase
                        characters.
     CARDIMAGE          Processes SAS source code and data lines as 80-byte records.
     CBUFNO             Specifies the number of extra page buffers to allocate for
each open SAS
                        catalog.
     CENTER             Center SAS procedure output.
```

Example: Saving System Options in a Data Set

Features: PROC OPTSAVE statement option
OUT=

Details

This example saves the current system option settings using the OPTSAVE procedure.

Program

```
libname mysas "c:\mysas";

proc optsave out=mysas.options;
run;
```

Program Description

Create a libref.

```
libname mysas "c:\mysas";
```

Save the current system option settings.

```
proc optsave out=mysas.options;
run;
```

Log

Example Code 44.3 *The SAS Log Shows Processing of PROC OPTSAVE*

```
1    libname mysas "c:\mysas";
NOTE: Libref MYSAS was successfully assigned as follows:
      Engine:        V9
      Physical Name: c:\mysas

2    proc optsave out=mysas.options;
3    run;

NOTE: The data set MYSAS.OPTIONS has 289 observations and 2 variables.
NOTE: PROCEDURE OPTSAVE used (Total process time):
      real time           0.03 seconds
      cpu time            0.03 seconds
```

45

PLOT Procedure

Overview: PLOT Procedure

What Does the PLOT Procedure Do?

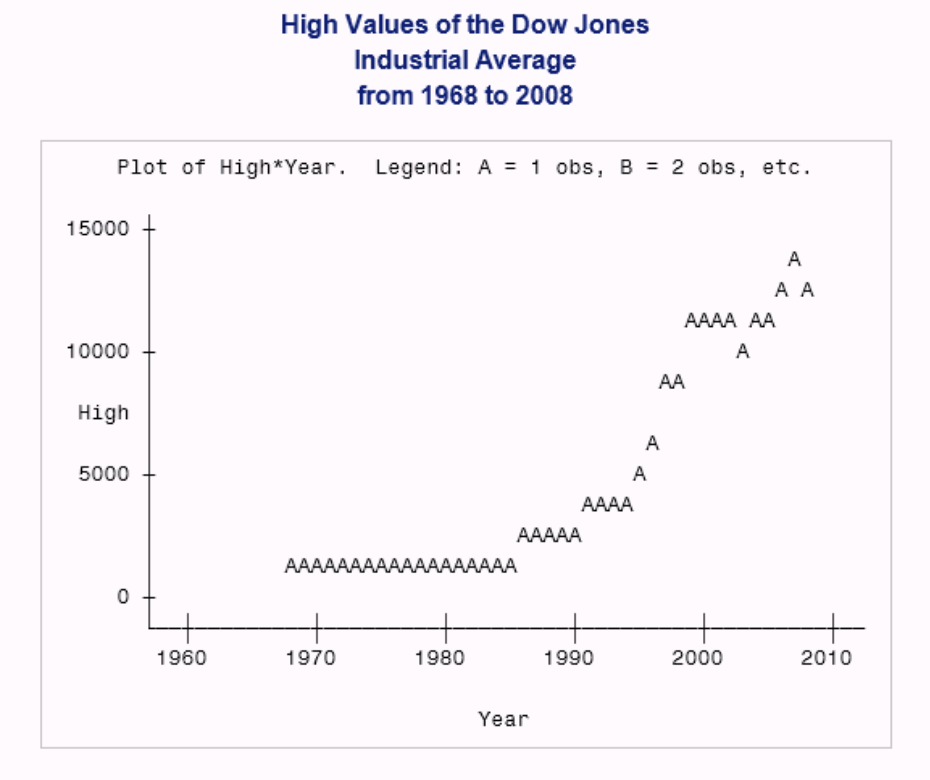
The PLOT procedure plots the values of two variables for each observation in an input SAS data set. The coordinates of each point on the plot correspond to the two variables' values in one or more observations of the input data set.

The following output is a simple plot of the high values of the Dow Jones Industrial Average between 1968 and 2008. PROC PLOT determines the plotting symbol and the scales for the axes. Here are the statements that produce the output:

```
options nodate pageno=1 linesize=64
   pagesize=25;

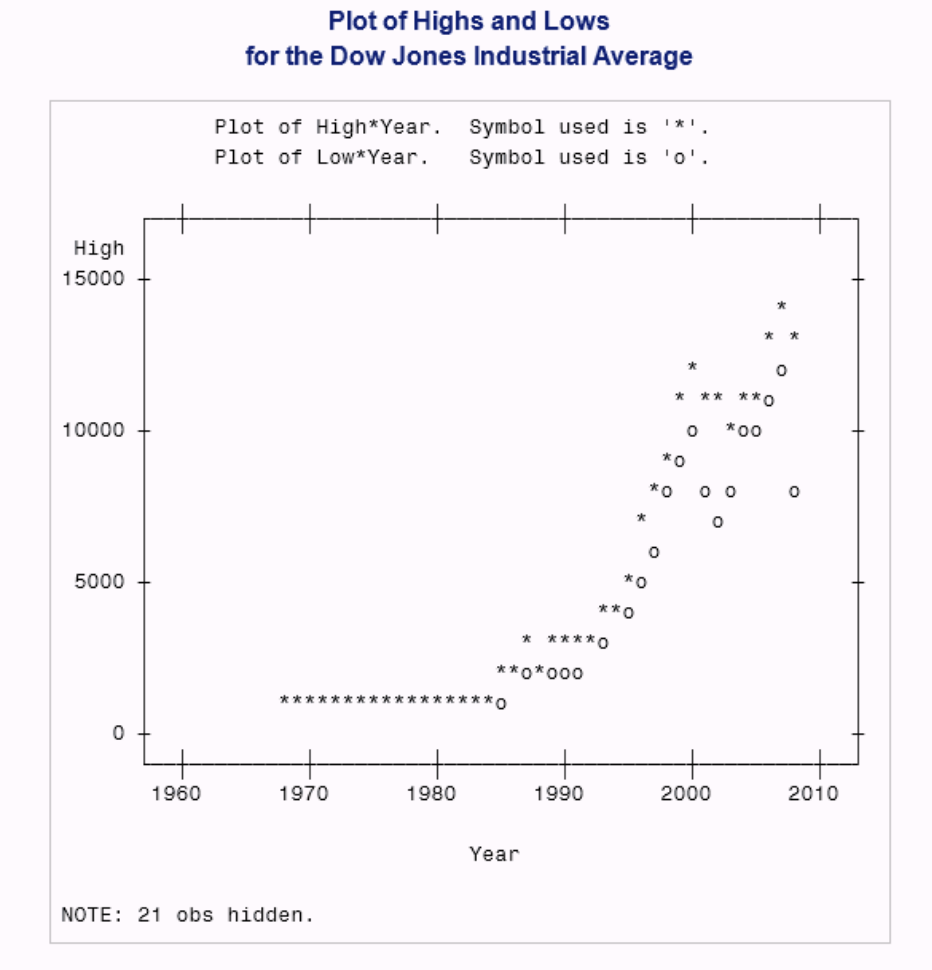
proc plot data=djia;
   plot high*year;
   title 'High Values of the Dow Jones';
   title2 'Industrial Average';
   title3 'from 1968 to 2008';
run;
```

Output 45.1 *A Simple Plot*



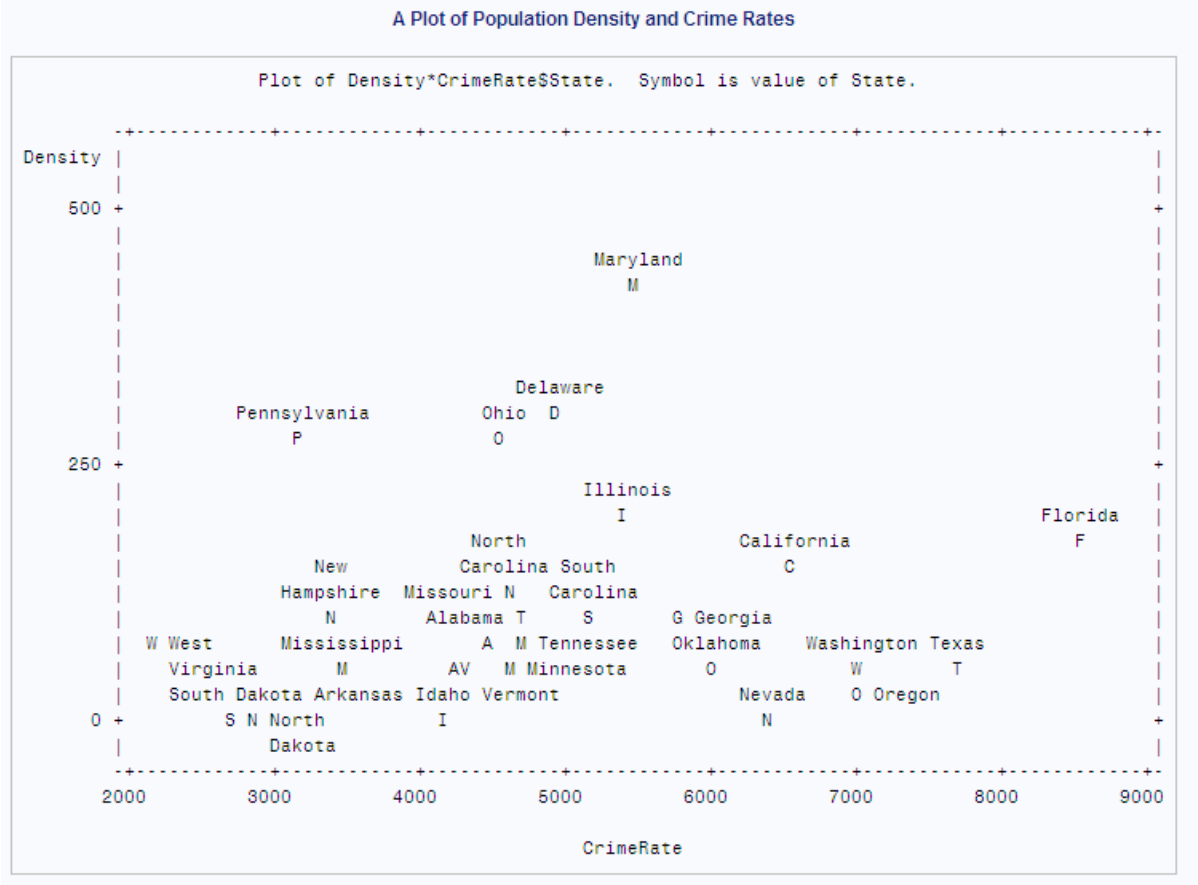
You can also overlay two plots, as shown in the following output. One plot shows the high values of the DJIA data set; the other plot shows the low values. The plot also shows that you can specify plotting symbols and put a box around a plot. The statements that produce the following output are shown in "Example 3: Overlaying Two Plots" on page 1655.

Output 45.2 *Plotting Two Sets of Values at Once*



PROC PLOT can also label points on a plot with the values of a variable, as shown in the following output. The plotted data represents population density and crime rates for selected U.S. states.The SAS code that produces the following output is shown in "Example 11: Adjusting Labels on a Plot with the PLACEMENT= Option" on page 1679.

Output 45.3 *Labeling Points on a Plot*



Concepts: PLOT Procedure

RUN Groups

PROC PLOT is an interactive procedure. It remains active after a RUN statement is executed. Usually, SAS terminates a procedure after executing a RUN statement. When you start the PLOT procedure, you can continue to submit any valid statements without resubmitting the PROC PLOT statement. Thus, you can easily experiment with changing labels, values of tick marks, and so on. Any options submitted in the PROC PLOT statement remain in effect until you submit another PROC PLOT statement.

When you submit a RUN statement, PROC PLOT executes all the statements submitted since the last PROC PLOT or RUN statement. Each group of statements

is called a *RUN group*. With each RUN group, PROC PLOT begins a new page and begins with the first item in the VPERCENT= and HPERCENT= lists, if any.

To terminate the procedure, submit a QUIT statement, a DATA statement, or a PROC statement. Like the RUN statement, each of these statements completes a RUN group. If you do not want to execute the statements in the RUN group, then use the RUN CANCEL statement, which terminates the procedure immediately.

You can use the BY statement interactively. The BY statement remains in effect until you submit another BY statement or terminate the procedure.

See "Example 11: Adjusting Labels on a Plot with the PLACEMENT= Option" on page 1679 for an example of using RUN-group processing with PROC PLOT.

Labels and Plot Points

Pointer Symbols

Pointer symbols associate a point with its label by pointing in the general direction of the label placement. When you use a label variable and do not specify a plotting symbol or if the variable value is null ('00'x), PROC PLOT uses pointer symbols as plotting symbols. PROC PLOT uses four different pointer symbols based on the value of the S= and V= suboptions in the PLACEMENT= option. The table below shows the pointer symbols:

Table 45.1 *Pointer Symbols*

S=	V=	Symbol
LEFT	any	<
RIGHT	any	>
CENTER	>0	∘
CENTER	<=0	v

If you are using pointer symbols and multiple points coincide, then PROC PLOT uses the number of points, 2-9, as the plotting symbol. If the number of points is more than 9, then the procedure uses an asterisk (*).

Note: Because of character set differences among operating environments, the pointer symbol for S=CENTER and V>0 might differ from the one shown here.

Understanding Penalties

PROC PLOT assesses the quality of placements with penalties. If all labels are plotted with zero penalty, then no labels collide and all labels are near their symbols. When it is not possible to place all labels with zero penalty, PROC PLOT tries to minimize the total penalty.

The following table lists the penalty, its default value, the index used to reference the penalty, and the range of values that can be assigned to the penalty. Each penalty is described in more detail in Table 45.85 on page 1624.

Table 45.2 *Penalties Table*

Penalty	Default Penalty	Index	Range
Not placing a blank	1	1	0-500
Bad split, no split character specified	1	2	0-500
Bad split with split character	50	3	0-500
Free horizontal shift, *fhs*	2	4	0-500
Free vertical shift, *fvs*	1	5	0-500
Vertical shift weight, *vsw*	2	6	0-500
Vertical or horizontal shift denominator, *vhsd*	5	7	1-500
Collision state	500	8	0-10,000
(Reserved for future use)		9-14	
Not placing the first character	11	15	0-500
Not placing the second character	10	16	0-500
Not placing the third character	8	17	0-500
Not placing the fourth character	5	18	0-500
Not placing the fifth through 200th character	2	19-214	0-500

The following table contains the index values from the previous table with a description of the corresponding penalty.

Table 45.3 *Index Values for Penalties*

1	A nonblank character in the plot collides with an embedded blank in a label, or there is not a blank or a plot boundary before or after each label fragment.
2	A split occurs on a nonblank or nonpunctuation character when you do not specify a split character.
3	A label is placed with a different number of lines than the L= suboption specifies, when you specify a split character.
4-7	A label is placed far away from the corresponding point. PROC PLOT calculates the penalty according to this (integer arithmetic) formula: $[\mathrm{MAX}(\lvert H\rvert - fhs, 0) + vsw \times \mathrm{MAX}(\lvert V\rvert - (L+fvs+(V > 0))/2, 0)]/vhsd$ Notice that penalties 4 through 7 are actually just components of the formula used to determine the penalty. Changing the penalty for a free horizontal or free vertical shift to a large value such as 500 removes any penalty for a large horizontal or vertical shift. "Example 6: Plotting Date Values on an Axis" on page 1662 illustrates a case in which removing the horizontal shift penalty is useful.
8	A label might collide with its own plotting symbol. If the plotting symbol is blank, then a collision state cannot occur. See "Collision States" on page 1625 for more information.
15-214	A label character does not appear in the plot. By default, the penalty for not printing the first character is greater than the penalty for not printing the second character, and so on. By default, the penalty for not printing the fifth and subsequent characters is the same.

Note: Labels can share characters without penalty.

Changing Penalties

You can change the default penalties with the PENALTIES= option in the PLOT statement. Because PROC PLOT considers penalties when it places labels, changing the default penalties can change the placement of the labels.

For example, if you have labels that all begin with the same two-letters, then you can increase the default penalty for not printing the third, fourth, and fifth characters and decrease the penalty for not printing the first and second characters. See "Using the PENALTIES= Option" on page 1648 for an example of how to use the PENALTIES= option.

Collision States

Collision states are placement states that can cause a label to collide with its own plotting symbol. PROC PLOT usually avoids using collision states because of the large default penalty of 500 that is associated with them. PROC PLOT does not consider the actual length or splitting of any particular label when determining if a placement state is a collision state.

Here are the rules that PROC PLOT uses to determine collision states:

- When S=CENTER, placement states that do not shift the label up or down sufficiently so that all of the label is shifted onto completely different lines from the symbol are collision states.
- When S=RIGHT, placement states that shift the label zero or more positions to the left without first shifting the label up or down onto completely different lines from the symbol are collision states.
- When S=LEFT, placement states that shift the label zero or more positions to the right without first shifting the label up or down onto completely different lines from the symbol are collision states.

Note: A collision state cannot occur if you do not use a plotting symbol.

Reference Lines

PROC PLOT places labels and computes penalties before placing reference lines on a plot. The procedure does not attempt to avoid rows and columns that contain reference lines.

Hidden Label Characters

In addition to the number of hidden observations and hidden plotting symbols, PROC PLOT prints the number of hidden label characters. Label characters can be hidden by plotting symbols or other label characters.

Overlaid Label Plots

When you overlay a label plot and a nonlabel plot, PROC PLOT tries to avoid collisions between the labels and the characters of the nonlabel plot. When a label character collides with a character in a nonlabel plot, PROC PLOT adds the usual penalty to the penalty sum.

When you overlay two or more label plots, all label plots are treated as a single plot in avoiding collisions and computing hidden character counts. Labels of different plots never overprint, even with the OVP system option in effect.

Computational Resources Used for Label Plots

This section uses the following variables to discuss how much time and memory PROC PLOT uses to construct label plots:

n
number of points with labels.

len
constant length of labels.

s
number of label pieces, or fragments.

p
number of placement states specified in the PLACE= option.

Time

For a given plot size, the time that is required to construct the plot is approximately proportional to $n \times len$. The amount of time required to split the labels is approximately proportional to ns^2 . Generally, the more placement states that you specify, the more time that PROC PLOT needs to place the labels. However, increasing the number of horizontal and vertical shifts gives PROC PLOT more flexibility to avoid collisions, often resulting in less time used to place labels.

Memory

PROC PLOT uses 24*p* bytes of memory for the internal placement state list. PROC PLOT uses $n(84 + 5len + 4s(1 + 1.5(s + 1)))$ bytes for the internal list of labels. PROC PLOT builds all plots in memory; each printing position uses one byte of memory.

If you run out of memory, then request fewer plots in each PLOT statement and put a RUN statement after each PLOT statement.

Syntax: PLOT Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Requirement: At least one PLOT statement is required.

Tips: PROC PLOT supports RUN-group processing.

You can use the ATTRIB, FORMAT, LABEL, and WHERE statements with PROC PLOT.

PROC PLOT<*options*>;

BY<DESCENDING>*variable-1*<<DESCENDING>*variable-2*...><NOTSORTED>;

PLOT*plot-request(s)*</ *options*>;

Statement	Task	Example
PROC PLOT	Request the plots be produced	Ex. 10
BY	Produce a separate plot for each BY group	Ex. 8
PLOT	Describe the plots that you want	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8, Ex. 9, Ex. 11, Ex. 12, Ex. 13

PROC PLOT Statement

Requests that the plots be produced.

Tip: You can use data set options with the DATA= option. *SAS Data Set Options: Reference*

Example: "Example 10: Excluding Observations That Have Missing Values" on page 1676

Syntax

PROC PLOT<*options*>;

Summary of Optional Arguments

DATA=<*SAS-data-set*>
specifies the input data set.

ENCRYPTKEY=<*key-value*>
specifies the key value needed for plotting an AES-encrypted data set.

Control the appearance of the plot

FORMCHAR <*(position(s))*>'*formatting-character(s)*'

specifies the characters that construct the borders of the plot.

NOLEGEND
suppresses the legend at the top of the plot.

VTOH=*aspect-ratio*
specifies the aspect ratio of the characters on the output device.

Control the axes

MISSING
includes missing character variable values.

NOMISS
excludes observations with missing values.

UNIFORM
uniformly scales axes across BY groups.

Control the size of the plot

HPERCENT=*percent(s)*
specifies the percentage of the available horizontal space for each plot.

VPERCENT=*percent(s)*
specifies the percentage of the available vertical space for each plot.

Optional Arguments

DATA=<*SAS-data-set*>
specifies the input data set. specifies the input SAS data set.

ENCRYPTKEY=<*key-value*>
specifies the key value needed for plotting an AES-encrypted data set. specifies the key value needed for plotting an AES-encrypted data set. If the input data set was created with ENCRYPT=AES, then you must specify the ENCRYPTKEY= value to plot its data. For example, if a data set named secretPlot is created using the DATA statement

```
data secretPlot(encrypt=AES encryptkey=Ib007)
```

then you must specify the following PROC statement to plot the data in secretPlot:

```
proc plot data=secretPlot(encryptkey=Ib007);
```

See "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference* for more information about the ENCRYPTKEY= data set option.

FORMCHAR <*(position(s))*>'*formatting-character(s)*'
specifies the characters that construct the borders of the plot. defines the characters to use for constructing the borders of the plot.

position(s)
identifies the position of one or more characters in the SAS formatting-character string. A space or a comma separates the positions.

Default Omitting (*position(s)*) is the same as specifying all twenty possible SAS formatting characters, in order.

Range PROC PLOT uses formatting characters 1, 2, 3, 5, 7, 9, and 11. The following table shows the formatting characters that PROC PLOT uses.

Table 45.4 *Character Positions*

Position	Default	Used to Draw
1	|	Vertical separators
2	-	Horizontal separators
3 5 9 11	-	Corners
7	+	Intersection of vertical and horizontal separators

formatting-character(s)
lists the characters to use for the specified positions. PROC PLOT assigns characters in *formatting-character(s)* to *position(s)*, in the order in which they are listed. For example, the following option assigns the asterisk (*) to the third formatting character, the number sign (#) to the seventh character, and does not alter the remaining characters: `formchar(3,7)='*#'`

Interaction The SAS system option FORMCHAR= specifies the default formatting characters. The system option defines the entire string of formatting characters. The FORMCHAR= option in a procedure can redefine selected characters.

Tips You can use any character in *formatting-characters*, including hexadecimal characters. If you use hexadecimal characters, then you must put `x` after the closing quotation mark. For example, the following option assigns the hexadecimal character 2-D to the third formatting character, the hexadecimal character 7C to the seventh character, and does not alter the remaining characters: `formchar(3,7)='2D7C'x`

Specifying all blanks for *formatting-character(s)* produces plots with no borders. For example, the following code specifies all blanks: `formchar (1,2,7)=''`.

HPERCENT=*percent(s)*
specifies the percentage of the available horizontal space for each plot. specifies one or more percentages of the available horizontal space to use for each plot. HPERCENT= enables you to put multiple plots on one page. PROC PLOT tries to fit as many plots as possible on a page. After using each of the *percent(s)*, PROC PLOT cycles back to the beginning of the list. A zero in the list forces PROC PLOT to go to a new page even if it could fit the next plot on the same page.

HPERCENT=33
prints three plots per page horizontally; each plot is one-third of a page wide.

HPERCENT=50 25 25
prints three plots per page; the first is twice as wide as the other two.

HPERCENT=33 0
produces plots that are one-third of a page wide; each plot is on a separate page.

HPERCENT=300
produces plots three pages wide.

At the beginning of every BY group and after each RUN statement, PROC PLOT returns to the beginning of the *percent(s)* and starts printing a new page.

Alias HPCT=

Default 100

Example "Example 4: Producing Multiple Plots per Page" on page 1658

MISSING
includes missing character variable values in the construction of the axes. It has no effect on numeric variables.

Interaction overrides the NOMISS option for character variables.

NOLEGEND
suppresses the legend at the top of each plot. The legend lists the names of the variables being plotted and the plotting symbols used in the plot.

NOMISS
excludes observations for which either variable is missing from the calculation of the axes. Normally, PROC PLOT draws an axis based on all the values of the variable being plotted, including points for which the other variable is missing.

Interactions The HAXIS= option overrides the effect of NOMISS on the horizontal axis. The VAXIS= option overrides the effect on the vertical axis.

NOMISS is overridden by MISSING for character variables.

Example "Example 10: Excluding Observations That Have Missing Values" on page 1676

UNIFORM
uniformly scales axes across BY groups. Uniform scaling enables you to directly compare the plots for different values of the BY variables.

Restriction You cannot use PROC PLOT with the UNIFORM option with an engine that supports concurrent access if another user is updating the data set at the same time.

VPERCENT=*percent(s)*
specifies one or more percentages of the available vertical space to use for each plot. If you use a percentage greater than 100, then PROC PLOT prints sections of the plot on successive pages.

Alias VPCT=

Default 100

See "HPERCENT=*percent(s)*" on page 1629

Example "Example 4: Producing Multiple Plots per Page" on page 1658

VTOH=*aspect-ratio*
specifies the aspect ratio (vertical to horizontal) of the characters on the output device. *aspect-ratio* is a positive real number. If you use the VTOH= option, then PROC PLOT spaces tick marks so that the distance between horizontal tick marks is nearly equal to the distance between vertical tick marks. For example, if characters are twice as high as they are wide, then specify VTOH=2.

Interaction VTOH= has no effect if you use the HSPACE= and VSPACE= options in the PLOT statement.

Note The minimum value allowed is 0.

See "HAXIS=*axis-specification*" on page 1636 for a way to equate axes so that the given distance represents the same data range on both axes.

BY Statement

Produces a separate plot and starts a new page for each BY group.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

See: "BY" on page 74

Example: "Example 8: Plotting BY Groups" on page 1668

Syntax

BY<DESCENDING>*variable-1*<<DESCENDING>*variable-2*...><NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the

BY statement, then you must sort or index the data set by the values of the variables specified in the BY statement. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The data is grouped in another way, such as chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

PLOT Statement

Requests the plots to be produced by PROC PLOT.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Tip: You can use multiple PLOT statements.

Examples:
"Example 1: Specifying a Plotting Symbol" on page 1650
"Example 2: Controlling the Horizontal Axis and Adding a Reference Line" on page 1653
"Example 3: Overlaying Two Plots" on page 1655
"Example 4: Producing Multiple Plots per Page" on page 1658
"Example 5: Plotting Data on a Logarithmic Scale" on page 1660
"Example 6: Plotting Date Values on an Axis" on page 1662
"Example 7: Producing a Contour Plot" on page 1665
"Example 8: Plotting BY Groups" on page 1668
"Example 9: Adding Labels to a Plot" on page 1672
"Example 11: Adjusting Labels on a Plot with the PLACEMENT= Option" on page 1679
"Example 12: Adjusting Labeling on a Plot with a Macro" on page 1684
"Example 13: Changing a Default Penalty" on page 1687

Syntax

PLOT*plot-request(s)*</ *options*>;

Summary of Optional Arguments

BOX
: puts a box around the plot.

OVERLAY
: overlays plots.

Control the axes

HAXIS=*axis-specification*
: specifies the tick-mark values for the horizontal axis.

HEXPAND
: expands the horizontal axis.

HPOS=*axis-length*
: specifies the number of print positions on the horizontal axis.

HREVERSE
: reverses the order of the values on the horizontal axis.

HSPACE=*n*
: specifies the distance between tick marks on the horizontal axis.

HZERO
: assigns a value of zero to the first tick mark on the horizontal axis.

VAXIS=*axis-specification*
: specifies the tick-mark values for the vertical axis.

VEXPAND
: expands the vertical axis.

VPOS=*axis-length*
: specifies the number of print positions on the vertical axis.

VREVERSE
: reverses the order of the values on the vertical axis.

VSPACE=*n*
: specifies the distance between tick marks on the vertical axis.

VZERO
: assigns a value of zero to the first tick mark on the vertical axis.

Label points on a plot

LIST<=*penalty-value*>
: lists the penalty and the placement state of the points.

OUTWARD='*character*'
: forces the labels away from the origin.

PENALTIES<(*index-list*)>=*penalty-list*
: changes default penalties.

PLACEMENT=(*expression(s)*)
: specifies locations for the placement of the labels.

SPLIT='*split-character*'
: specifies a split character for the label.

STATES
: lists all placement states in effect.

Produce a contour plot

CONTOUR<=*number-of-levels*>
: draws a contour plot.

Scontour-level='*character-list*'
: specifies the plotting symbol for one contour level.

Produce a countour plot

SLIST='*character-list-1*' <'*character-list-2 ...*'>
: specifies the plotting symbol for multiple contour levels.

Specify reference lines

HREF=*value-specification*
: draws a line perpendicular to the specified values on the horizontal axis.

HREFCHAR='*character*'
: specifies a character to use to draw the horizontal reference line.

VREF=*value-specification*
: draws a line perpendicular to the specified values on the vertical axis.

VREFCHAR='*character*'
: specifies a character to use to draw the vertical reference line.

Required Argument

plot-request(s)
specifies the variables (vertical and horizontal) to plot and the plotting symbol to use to mark the points on the plot.

Each form of *plot-request(s)* supports a label variable. A label variable is preceded by a dollar sign ($) and specifies a variable whose values label the points on the plot.

```
plot y*x $ label-variable
```

```
plot y*x='*' $ label-variable
```

For more information, see "Labels and Plot Points" on page 1622. In addition, see "Example 9: Adding Labels to a Plot" on page 1672 and all the examples that follow it.

The *plot-request(s)* can be one or more of the following:

vertical*horizontal <$ label-variable>
specifies the variable to plot on the vertical axis and the variable to plot on the horizontal axis.

For example, the following statement requests a plot of Y by X:

```
plot y*x;
```

Y appears on the vertical axis, X on the horizontal axis.

This form of the plot request uses the default method of choosing a plotting symbol to mark plot points. When a point on the plot represents the values of one observation in the data set, PROC PLOT puts the character A at that point. When a point represents the values of two observations, the character B appears. When a point represents values of three observations, the character C appears, and so on, through the alphabet. The character Z is used for the occurrence of 26 or more observations at the same printing position.

vertical*horizontal='character' **<$** ***label-variable>***
specifies the variables to plot on the vertical and horizontal axes and specifies a plotting symbol to mark each point on the plot. A single character is used to represent values from one or more observations.

For example, the following statement requests a plot of Y by X, with each point on the plot represented by a plus sign (+):

```
plot y*x='+';
```

vertical*horizontal=variable **<$** ***label-variable>***
specifies the variables to plot on the vertical and horizontal axes and specifies a variable whose values are to mark each point on the plot. The variable can be either numeric or character. The first (left-most) nonblank character in the formatted value of the variable is used as the plotting symbol (even if more than one value starts with the same letter). When more than one observation maps to the same plotting position, the value from the first observation marks the point. For example, in the following statement GENDER is a character variable with values of `FEMALE` and `MALE`; the values `F` and `M` mark each observation on the plot.

```
plot height*weight=gender;
```

See "Specifying Variable Lists in Plot Requests" on page 1647 and "Specifying Combinations of Variables" on page 1647

Optional Arguments

BOX
draws a border around the entire plot, rather than just on the left side and bottom.

Example "Example 3: Overlaying Two Plots" on page 1655

CONTOUR<=*number-of-levels*>
draws a contour plot using plotting symbols with varying degrees of shading where *number-of-levels* is the number of levels for dividing the range of *variable*. The plot request must be of the form *vertical*horizontal=variable* where *variable* is a numeric variable in the data set. The intensity of shading is determined by the values of this variable.

When you use CONTOUR, PROC PLOT does not plot observations with missing values for *variable*.

Overprinting, if it is enabled by the OVP system option, is used to produce the shading. Otherwise, single characters varying in darkness are used. The CONTOUR option is most effective when the plot is dense.

Default 10

Range 1-10

Example "Example 7: Producing a Contour Plot" on page 1665

HAXIS=*axis-specification*

specifies the tick-mark values for the horizontal axis.

n< ... *n*>

BY *increment*

n TO *n* BY *increment*

- For numeric values, *axis-specification* is either an explicit list of values, a BY increment, or a combination of both:

  The values must be in either ascending or descending order. Use a negative value for *increment* to specify descending order. The specified values are spaced evenly along the horizontal axis even if the values are not uniformly distributed. Numeric values can be specified in the following ways:

Table 45.5 *Specifying Numeric HAXIS= Values*

HAXIS= value	Comments
`10 to 100 by 5`	Values appear in increments of 5, starting at 10 and ending at 100.
`by 5`	Values are incremented by 5. PROC PLOT determines the minimum and maximum values for the tick marks.
`10 100 1000 10000`	Values are not uniformly distributed. This specification produces a logarithmic plot. If PROC PLOT cannot determine the function implied by the axis specification, it uses simple linear interpolation between the points. To determine whether PROC PLOT correctly interpolates a function, you can use the DATA step to generate data that determines the function and see whether it appears linear when plotted. See "Example 5: Plotting Data on a Logarithmic Scale" on page 1660 for an example.
`1 2 10 to 100 by 5`	A combination of the previous specifications.

- *For character variables*, *axis-specification* is a list of unique values that are enclosed in quotation marks:

'value-1' <...*'value-n'*>

For example, the following statement assigns three cities to represent the tick-mark values for the horizontal axis:

```
haxis='Paris' 'London' 'Tokyo'
```

The character strings are case sensitive. If a character variable has an associated format, then *axis-specification* must specify the formatted value. The values can appear in any order.

- *For axis variables that contain date-time values*, *axis-specification* is either an explicit list of values or a starting value and an ending value with an increment specified:

'date-time-value'i<...*'date-time-value'i*>

'date-time-value'i TO <...*'date-time-value'i*><BY *increment*>

'date-time-value'i
any SAS date, time, or datetime value described for the SAS functions INTCK and INTNX. The suffix *i* is one of the following:

D
date

T
time

DT
datetime

increment
one of the valid arguments for the INTCK or INTNX functions. *increment* can be one of the following:

Table 45.6 *INTCK and INTNX Values*

For dates	For datetimes	For times
DAY	DTDAY	HOUR
WEEK	DTWEEK	MINUTE
MONTH	DTMONTH	SECOND
QTR	DTQTR	
YEAR	DTYEAR	

The following example includes the date increment:

```
   haxis='01JAN95'd to '01JAN96'd
   by month

haxis='01JAN95'd to '01JAN96'd
   by qtr
```

Note: You must use a FORMAT statement to print the tick-mark values in an understandable form.

Interaction You can use the HAXIS= and VAXIS= options with the VTOH= option to equate axes. If your data is suitable, then use HAXIS=BY *n* and VAXIS=BY *n* with the same value for *n* and specify a value for the VTOH= option. The number of columns that separate the horizontal tick marks is nearly equal to the number of lines that separate the vertical tick marks times the value of the VTOH= option. In some cases, PROC PLOT cannot simultaneously use all three values and changes one or more of the values.

Examples "Example 2: Controlling the Horizontal Axis and Adding a Reference Line" on page 1653

"Example 5: Plotting Data on a Logarithmic Scale" on page 1660

"Example 6: Plotting Date Values on an Axis" on page 1662

HEXPAND
expands the horizontal axis to minimize the margins at the sides of the plot and to maximize the distance between tick marks, if possible.

HEXPAND causes PROC PLOT to ignore information about the spacing of the data. Plots produced with this option waste less space but can obscure the nature of the relationship between the variables.

HPOS=*axis-length*
specifies the number of print positions on the horizontal axis. The maximum value of *axis-length* that allows a plot to fit on one page is three positions less than the value of the LINESIZE= system option. This maximum ensures that there is enough space for the procedure to print information next to the vertical axis. The exact maximum depends on the number of characters that are in the vertical variable's values. If *axis-length* is too large to fit on a line, then PROC PLOT ignores the option.

HREF=*value-specification*
draws lines on the plot perpendicular to the specified values on the horizontal axis. PROC PLOT includes the values that you specify with the HREF= option on the horizontal axis unless you specify otherwise with the HAXIS= option.

For the syntax for *value-specification*, see "HAXIS=*axis-specification*" on page 1636.

Example "Example 8: Plotting BY Groups" on page 1668

HREFCHAR='*character*'
specifies the character to use to draw the horizontal reference line.

Default vertical bar (|)

See "FORMCHAR <*(position(s))*>'*formatting-character(s)*'" on page 1628 and "HREF=*value-specification*" on page 1638

HREVERSE
reverses the order of the values on the horizontal axis.

HSPACE=*n*
specifies that a tick mark will occur on the horizontal axis at every *n*th print position, where *n* is the value of HSPACE=.

HZERO
assigns a value of zero to the first tick mark on the horizontal axis.

Interaction PROC PLOT ignores HZERO if the horizontal variable has negative values or if the HAXIS= option specifies a range that does not begin with zero.

LIST<=*penalty-value*>
lists the horizontal and vertical axis values, the penalty, and the placement state of all points plotted with a penalty greater than or equal to *penalty-value*. If no plotted points have a penalty greater than or equal to *penalty-value*, then no list is printed.

Tip LIST is equivalent to LIST=0.

See "Understanding Penalties" on page 1623

Example "Example 11: Adjusting Labels on a Plot with the PLACEMENT= Option" on page 1679

OUTWARD='*character*'
tries to force the point labels outward, away from the origin of the plot, by protecting positions next to symbols that match *character* that are in the direction of the origin (0,0). The algorithm tries to avoid putting the labels in the protected positions, so they usually move outward.

Tip This option is useful only when you are labeling points with the values of a variable.

OVERLAY
overlays all plots that are specified in the PLOT statement on one set of axes. The variable names, or variable labels if they exist, from the first plot are used to label the axes. Unless you use the HAXIS= option or the VAXIS= option, PROC PLOT automatically scales the axes in the way that best fits all the variables.

When the SAS system option OVP is in effect and overprinting is allowed, the plots are superimposed. Otherwise, when NOOVP is in effect, PROC PLOT uses the plotting symbol from the first plot to represent points that appear in more than one plot. In such a case, the output includes a message telling you how many observations are hidden.

Example "Example 3: Overlaying Two Plots" on page 1655

PENALTIES<(*index-list*)>=*penalty-list*
changes the default penalties. The *index-list* provides the positions of the penalties in the list of penalties. The *penalty-list* contains the values that you are specifying for the penalties that are indicated in the *index-list*. The *index-list*

and the *penalty-list* can contain one or more integers. In addition, both *index-list* and *penalty-list* accept the form: `value TO value`

See "Understanding Penalties" on page 1623

Example "Example 13: Changing a Default Penalty" on page 1687

PLACEMENT=(*expression(s)*)

controls the placement of labels by specifying possible locations of the labels relative to their coordinates. Each *expression* consists of a list of one or more suboptions (H=, L=, S=, or V=) that are joined by an asterisk (*) or a colon (:). PROC PLOT uses the asterisk and colon to expand each expression into combinations of values for the four possible suboptions. The asterisk creates every possible combination of values in the expression list. A colon creates only pairwise combinations. The colon takes precedence over the asterisk. With the colon, if one list is shorter than the other, then the values in the shorter list are reused as necessary.

Use the following suboptions to control the placement:

H=*integer(s)*

specifies the number of horizontal spaces (columns) to shift the label relative to the starting position. Both positive and negative integers are valid. Positive integers shift the label to the right; negative integers shift it to the left. For example, you can use the H= suboption in the following way:

```
place=(h=0 1 -1 2 -2)
```

You can use the keywords BY ALT in this list. BY ALT produces a series of numbers whose signs alternate between positive and negative and whose absolute values change by one after each pair. For example, the following PLACE= specifications are equivalent:

```
place=(h=0 -1 to -3 by alt)
place=(h=0 -1 1 -2 2 -3 3)
```

If the series includes zero, then the zero appears twice. For example, the following PLACE= options are equivalent:

```
place=(h= 0 to 2 by alt)
place=(h=0 0 1 -1 2 -2)
```

Default H=0

Range −500 to 500

L=*integer(s)*

specifies the number of lines onto which the label can be split.

Default L=1

Range 1-200

S=*start-position(s)*

specifies where to start printing the label. The value for *start-position* can be one or more of the following:

CENTER
the procedure centers the label around the plotting symbol.

RIGHT
the label starts at the plotting symbol location and continues to the right.

LEFT
the label starts to the left of the plotting symbol and ends at the plotting symbol location.

Default CENTER

V=*integer(s)*
specifies the number of vertical spaces (lines) to shift the label relative to the starting position. V= behaves the same as the H= suboption, described earlier.

A new expression begins when a suboption is not preceded by an operator. Parentheses around each expression are optional. They make it easier to recognize individual expressions in the list. However, the entire expression list must be in parentheses, as shown in the following example. The following table shows how this expression is expanded and describes each placement state.

```
place=((v=1)
    (s=right left : h=2 -2)
    (v=-1)
    (h=0 1 to 2 by alt * v=1 -1)
    (l=1 to 3 * v=1 to 2 by alt *
     h=0 1 to 2 by alt))
```

Each combination of values is a *placement state*. The procedure uses the placement states in the order in which they appear in the placement states list, so specify your most preferred placements first. For each label, the procedure tries all states, then it uses the first state that places the label with minimum penalty. When all labels are initially placed, the procedure cycles through the plot multiple times, systematically refining the placements. The refinement step tries to both minimize the penalties and to use placements nearer to the beginning of the states list. However, PROC PLOT uses a heuristic approach for placements, so the procedure does not always find the best set of placements.

Table 45.7 *Expanding an Expression List into Placement States*

Expression	Placement State	Meaning
(V=1)	S=CENTER L=1 H=0 V=1	Center the label, relative to the point, on the line above the point. Use one line for the label.
(S=RIGHT LEFT : H=2 −2)	S=RIGHT L=1 H=2 V=0	Begin the label in the second column to the right of the point. Use one line for the label.

Expression	Placement State	Meaning
	S=LEFT L=1 H=−2 V=0	End the label in the second column to the left of the point. Use one line for the label.
(V=−1)	S=CENTER L=1 H=0 V=− 1	Center the label, relative to the point, on the line below the point. Use one line for the label.
(H=0 1 to 2 BY ALT * V=1 −1)	S=CENTER L=1 H=0 V=1	Center the label, relative to the point, on the line above the point.
	S=CENTER L=1 H=0 V=−1	Center the label, relative to the point, on the line below the point.
	S=CENTER L=1 H=1 V=1	From center, shift the label one column to the right on the line above the point.
	S=CENTER L=1 H=1 V=−1	From center, shift the label one column to the right on the line below the point.
	S=CENTER L=1 H=−1 V=1	From center, shift the label one column to the left on the line above the point.
	S=CENTER L=1 H=− 1 V=−1	From center, shift the label one column to the left on the line below the point.
	S=CENTER L=1 H=2 V=1 S=CENTER L=1 H=2 V=−1	From center, shift the labels two columns to the right, first on the line above the point, then on the line below.
	S=CENTER L=1 H=−2 V=1 S=CENTER L=1 H=−2 V=−1	From center, shift the labels two columns to the left, first on the line above the point, then on the line below.
(L=1 to 3 * V=1 to 2 BY ALT * H=0 1 to 2 BY ALT)	S=CENTER L=1 H=0 V=1	Center the label, relative to the point, on the line above

Expression	Placement State	Meaning
		the point. Use one line for the label.
	S=CENTER L=1 H=1 V=1 S=CENTER L=1 H=−1 V=1 S=CENTER L=1 H=2 V=1 S=CENTER L=1 H=−2 V=1	From center, shift the label one or two columns to the right or left on the line above the point. Use one line for the label.
	S=CENTER L=1 H=0 V=−1	Center the label, relative to the point, on the line below the point. Use one line for the label.
	S=CENTER L=1 H=1 V=−1 S=CENTER L=1 H=−1 V=−1 S=CENTER L=1 H=2 V=−1 S=CENTER L=1 H=−2 V=−1	From center, shift the label one or two columns to the right and the left on the line below the point.
	.	Use the same horizontal shifts on the line two lines above the point and on the line two lines below the point.
	S=CENTER L=1 H=− 2 V=−2	
	S=CENTER L=2 H=0 V=1	Repeat the whole process splitting the label across two lines. Then repeat it splitting the label across three lines.
	S=CENTER L=3 H=− 2 V=−2	

Alias PLACE=

Default There are two defaults for the PLACE= option. If you are using a blank as the plotting symbol, then the default placement state is PLACE=(S=CENTER : V=0 : H=0 : L=1), which centers the label. If you are using anything other than a blank, then the default is PLACE=((S=RIGHT LEFT : H=2 −2) (V=1 −1 * H=0 1 -1 2 -2)). The default for labels placed with symbols includes multiple positions around the plotting symbol so the procedure has flexibility when placing labels on a crowded plot.

Tip Use the STATES option to print a list of placement states.

See "Labels and Plot Points" on page 1622

Examples "Example 11: Adjusting Labels on a Plot with the PLACEMENT= Option" on page 1679

"Example 12: Adjusting Labeling on a Plot with a Macro" on page 1684

Scontour-level='character-list'
specifies the plotting symbol to use for a single contour level. When PROC PLOT produces contour plots, it automatically chooses the symbols to use for each level of intensity. You can use the S= option to override these symbols and specify your own. You can include up to three characters in *character-list*. If overprinting is not allowed, then PROC PLOT uses only the first character.

For example, to specify three levels of shading for the Z variable, use the following statement:

```
plot y*x=z /
    contour=3 s1='A' s2='+' s3='X0A';
```

You can also specify the plotting symbols as hexadecimal constants:

```
plot y*x=z /
    contour=3 s1='7A'x  s2='7F'x s3='A6'x;
```

This feature was designed especially for printers where the hexadecimal constants can represent gray scale fill characters.

Range 1 to the highest contour level (determined by the CONTOUR option).

See "SLIST='*character-list-1*' <'*character-list-2* ...'>" on page 1644 and "CONTOUR<=*number-of-levels*>" on page 1635

SLIST='*character-list-1*' <'*character-list-2* ...'>
specifies plotting symbols for multiple contour levels. Each *character-list* specifies the plotting symbol for one contour level: the first *character-list* for the first level, the second *character-list* for the second level, and so on. The following example shows how to assign 5 different plotting symbols to 5 contour levels:

```
plot y*x=z /
     contour=5  slist='.' ':' '!' '=' '+O';
```

If you omit a plotting symbol for each contour level, then PROC PLOT uses the default symbols:

```
slist='.' ',' '-' '=' '+' 'O' 'X'       'W' '*' '#'
```

Restriction If you use the SLIST= option, then it must be listed last in the PLOT statement.

See "*Scontour-level='character-list'*" on page 1644 and "CONTOUR<=*number-of-levels*>" on page 1635

SPLIT='*split-character*'
when labeling plot points, specifies where to split the label when the label spans two or more lines. The label is split onto the number of lines that is specified in the L= suboption to the PLACEMENT= option. If you specify a split

character, then the procedure always splits the label on each occurrence of that character, even if it cannot find a suitable placement. If you specify L=2 or more but do not specify a split character, then the procedure tries to split the label on blanks or punctuation but will split words if necessary.

PROC PLOT shifts split labels as a block, not as individual fragments (a *fragment* is the part of the split label that is contained on one line). For example, to force `This is a label` to split after the `a`, change it to `This is a*label` and specify `SPLIT='*'`.

See "Labels and Plot Points" on page 1622

STATES
lists all the placement states in effect. STATES prints the placement states in the order in which you specify them in the PLACE= option.

VAXIS=*axis-specification*
specifies tick mark values for the vertical axis. VAXIS= follows the same rules as the HAXIS= option.

Examples "Example 7: Producing a Contour Plot" on page 1665

"Example 12: Adjusting Labeling on a Plot with a Macro" on page 1684

VEXPAND
expands the vertical axis to minimize the margins above and below the plot and to maximize the space between vertical tick marks, if possible.

See "HEXPAND" on page 1638

VPOS=*axis-length*
specifies the number of print positions on the vertical axis. The maximum value for *axis-length* that allows a plot to fit on one page is eight lines less than the value of the SAS system option PAGESIZE= because you must allow room for the procedure to print information under the horizontal axis. The exact maximum depends on the titles that are used, whether plots are overlaid, and whether CONTOUR is specified. If the value of *axis-length* specifies a plot that cannot fit on one page, then the plot spans multiple pages.

See "HPOS=*axis-length*" on page 1638

VREF=*value-specification*
draws lines on the plot perpendicular to the specified values on the vertical axis. PROC PLOT includes the values that you specify with the VREF= option on the vertical axis unless you specify otherwise with the VAXIS= option. For the syntax for *value-specification*, see "HAXIS=*axis-specification*" on page 1636.

Example "Example 2: Controlling the Horizontal Axis and Adding a Reference Line" on page 1653

VREFCHAR='*character*'
specifies the character to use to draw the vertical reference lines.

Default horizontal bar (-)

See "FORMCHAR <*(position(s))*>*'formatting-character(s)'*" on page 1628, "HREFCHAR=*'character'*" on page 1638, and "VREF=*value-specification*" on page 1645

VREVERSE
reverses the order of the values on the vertical axis.

VSPACE=*n*
specifies that a tick mark will occur on the vertical axis at every *n*th print position, where *n* is the value of VSPACE=.

VZERO
assigns a value of zero to the first tick mark on the vertical axis.

Interaction PROC PLOT ignores the VZERO option if the vertical variable has negative values or if the VAXIS= option specifies a range that does not begin with zero.

Usage: PLOT Procedure

Generating Data with Program Statements

When you generate data to be plotted, a good rule is to generate fewer observations than the number of positions on the horizontal axis. PROC PLOT then uses the increment of the horizontal variable as the interval between tick marks.

Because PROC PLOT prints one character for each observation, using SAS program statements to generate the data set for PROC PLOT can enhance the effectiveness of continuous plots. For example, suppose that you want to generate data in order to plot the following equation, for *x* ranging from 0 to 100:

$$y = 2.54 + 3.83x$$

You can submit these statements:

```
options linesize=80;
 data generate;
    do x=0 to 100 by 2;
       y=2.54+3.83*x;
       output;
    end;
 run;
 proc plot data=generate;
    plot y*x;
 run;
```

If the plot is printed with a LINESIZE= value of 80, then about 75 positions are available on the horizontal axis for the X values. Thus, 2 is a good increment: 51 observations are generated, which is fewer than the 75 available positions on the horizontal axis.

However, if the plot is printed with a LINESIZE= value of 132, then an increment of 2 produces a plot in which the plotting symbols have space between them. For a smoother line, a better increment is 1, because 101 observations are generated.

Specifying Variable Lists in Plot Requests

You can use SAS variable lists in plot requests. For example, the following are valid plot requests:

Table 45.8 *Plot Requests*

Plot Request	What is Plotted
`(a - - d)`	`a*b a*c a*d b*c b*d c*d`
`(x1 - x4)`	`x1*x2 x1*x3 x1*x4 x2*x3 x2*x4 x3*x4`
`(_numeric_)`	All combinations of numeric variables
`y*(x1 - x4)`	`y*x1 y*x2 y*x4 y*x4`

If both the vertical and horizontal specifications request more than one variable and if a variable appears in both lists, then it will not be plotted against itself. For example, the following statement does not plot B*B and C*C:

```
plot (a b c)*(b c d);
```

Specifying Combinations of Variables

The operator in request is either an asterisk (*) or a colon (:). An asterisk combines the variables in the lists to produce all possible combinations of *x* and *y* variables. For example, the following plot requests are equivalent:

```
plot (y1-y2) * (x1-x2);

plot y1*x1 y1*x2 y2*x1 y2*x2;
```

A colon combines the variables pairwise. Thus, the first variables of each list combine to request a plot, as do the second, third, and so on. For example, the following plot requests are equivalent:

```
plot (y1-y2) : (x1-x2);

plot y1*x1 y2*x2;
```

Using the PENALTIES= Option

In the following example, the PENALTIES= option increases the default penalty for not printing the third, fourth, and fifth label characters to 11, 10, and 8, and it decreases the penalties for not printing the first and second characters to 2:

```
penalties(15 to 20)=2 2 11 10 8 2
```

This example extends the penalty list. The 20th penalty of 2 is the penalty for not printing the sixth through 200th character. When the last index *i* is greater than 18, the last penalty is used for the (*i* − 14th character and beyond.

You can also extend the penalty list by just specifying the starting index. For example, the following PENALTIES= option is equivalent to the one above:

```
penalties(15)=2 2 11 10 8 2
```

Results: PLOT Procedure

Scale of the Axes

Normally, PROC PLOT looks at the minimum difference between each pair of the five lowest ordered values of each variable (the *delta*) and ensures that there is no more than one of these intervals per print position on the final scaled axis, if possible. If there is not enough room for this interval arrangement, and if PROC PLOT guesses that the data was artificially generated, then it puts a fixed number of deltas in each print position. Otherwise, PROC PLOT ignores the value.

Printed Output

Each plot uses one full page unless the plot's size is changed by the VPOS= and HPOS= options in the PLOT statement, the VPERCENT= or HPERCENT= options in the PROC PLOT statement, or the PAGESIZE= and LINESIZE= system options.

Titles, legends, and variable labels are printed at the top of each page. Each axis is labeled with the variable's name or, if it exists, the variable's label.

Normally, PROC PLOT begins a new plot on a new page. However, the VPERCENT= and HPERCENT= options enable you to print more than one plot on a page. VPERCENT= and HPERCENT= are described earlier in "PROC PLOT Statement" on page 1627 .

PROC PLOT always begins a new page after a RUN statement and at the beginning of a BY group.

ODS Table Names

The PLOT procedure assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. For more information, see "ODS Table Names Produced by Base SAS Procedures" in *SAS Output Delivery System: Procedures Guide*.

Table 45.9 *ODS Tables Produced by the PLOT Procedure*

Table Name	Description	Conditions When Table Is Generated
Plot	A single plot	When you do not specify the OVERLAY option.
Overlaid	Two or more plots on a single set of axes	When you specify the OVERLAY option.

Portability of ODS Output with PROC PLOT

Under certain circumstances, using PROC PLOT with the Output Delivery System produces files that are not portable. If the SAS system option FORMCHAR= in your SAS session uses nonstandard line-drawing characters, then the output might include strange characters instead of lines in operating environments in which the SAS Monospace font is not installed. To avoid this problem, specify the following OPTIONS statement before executing PROC PLOT:

```
options formchar="|----|+|---+=|-/\<>*";
```

Missing Values

If values of either of the plotting variables are missing, then PROC PLOT does not include the observation in the plot. However, in a plot of Y*X, values of X with corresponding missing values of Y are included in scaling the X axis, unless the NOMISS option is specified in the PROC PLOT statement.

Hidden Observations

By default, PROC PLOT uses different plotting symbols (A, B, C, and so on) to represent observations whose values coincide on a plot. However, if you specify your own plotting symbol or if you use the OVERLAY option, then you might not be able to recognize coinciding values.

If you specify a plotting symbol, then PROC PLOT uses the same symbol regardless of the number of observations whose values coincide. If you use the OVERLAY option and overprinting is not in effect, then PROC PLOT uses the symbol from the first plot request. In both cases, the output includes a message telling you how many observations are hidden.

Examples: PLOT Procedure

Example 1: Specifying a Plotting Symbol

Features: PROC PLOT statement option
FORMCHAR
PLOT statement

Data set: DJIA

Details

This example expands on Output 45.237 on page 1619 by specifying a different plotting symbol.

Program

```
options formchar="|----|+|---+=|-/\<>*";

data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;

proc plot data=djia;
      plot high*year='*'
      / vspace=5 vaxis=by 1000;

   title 'High Values of the Dow Jones Industrial Average';
   title2 'from 1968 to 2008';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the DJIA data set. DJIA contains the high and low closing marks for the Dow Jones Industrial Average from 1968 to 2008 . The DATA step creates this data set.

```
data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;
```

Create the plot. The plot request plots the values of High on the vertical axis and the values of Year on the horizontal axis. It also specifies an asterisk as the plotting symbol. The VAXIS= option and the VSPACE= option. The VAXIS=by 1000 option specifies tick mark values for the vertical axis in increments of 1,000. The VSPACE= option specifies the amount of print space between tick marks on the vertical axis.

```
proc plot data=djia;
      plot high*year='*'
      / vspace=5 vaxis=by 1000;
```

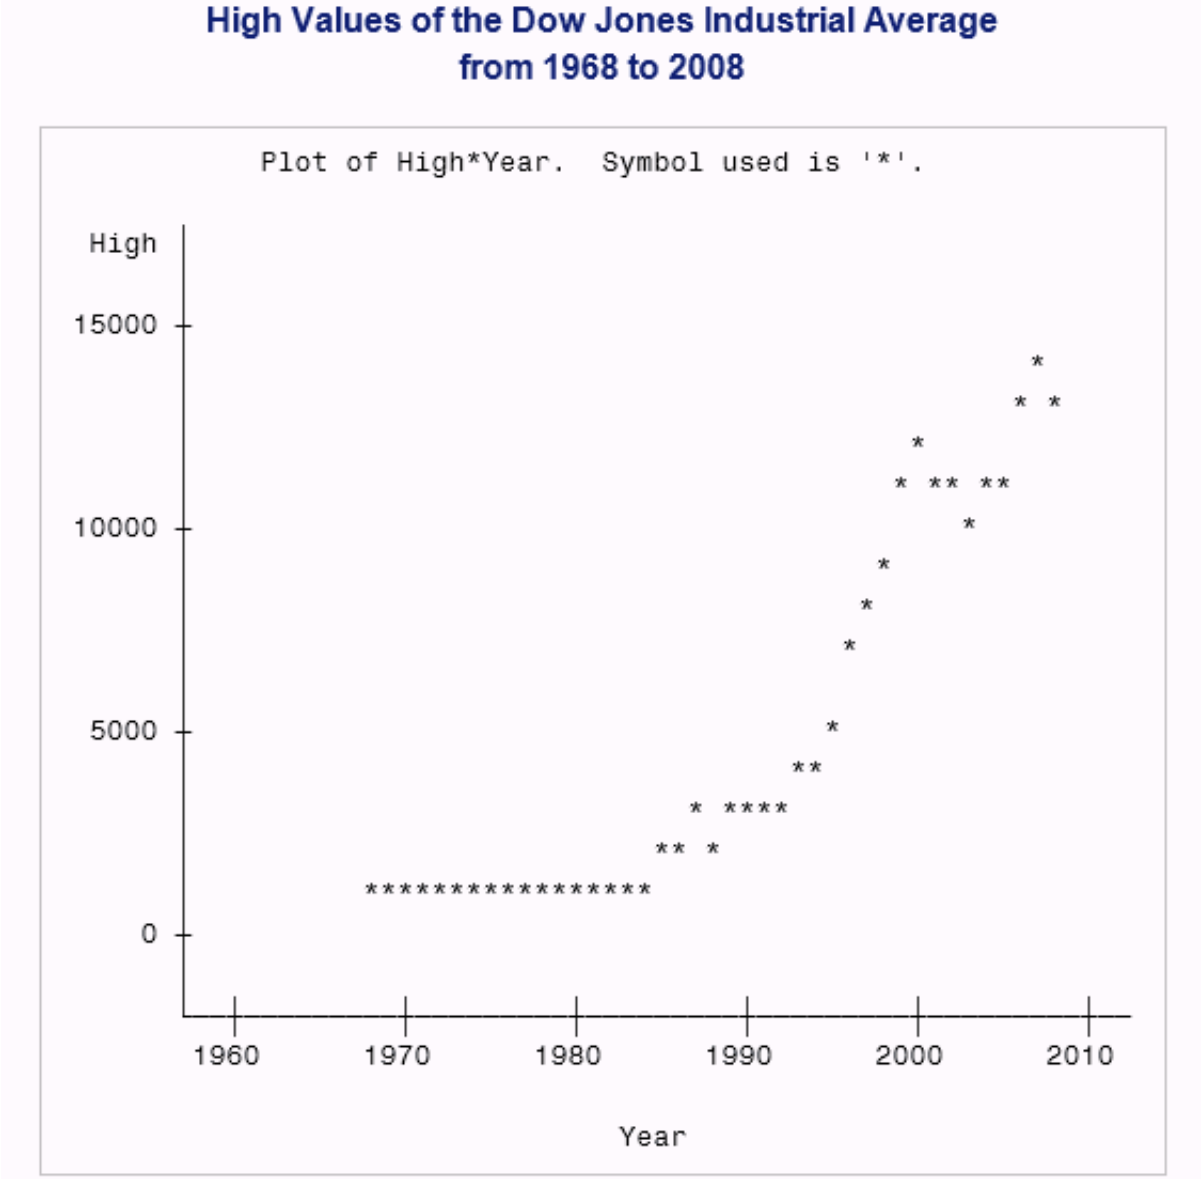
Specify the titles.

```
   title 'High Values of the Dow Jones Industrial Average';
   title2 'from 1968 to 2008';
run;
```

Output

PROC PLOT determines the tick marks and the scale of both axes.

Output 45.4 *Plot with Asterisk as the Plotting Symbol*



Example 2: Controlling the Horizontal Axis and Adding a Reference Line

Features:
PROC PLOT statement option
FORMCHAR
PLOT statement
PLOT statement options
HAXIS=
VREF=

Data set: DJIA

Details

This example specifies values for the horizontal axis and draws a reference line from the vertical axis.

Program

```
options formchar="|----|+|---+=|-/\<>*";

data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;

proc plot data=djia;
   plot high*year='*'

     / haxis=1965 to 2020 by 10 vref=3000;

title 'High Values of Dow Jones Industrial Average';
title2 'from 1968 to 2008';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the DJIA data set. DJIA contains the high and low closing marks for the Dow Jones Industrial Average from 1968 to 2008. The DATA step creates this data set.

```
data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;
```

Create the plot. The plot request plots the values of High on the vertical axis and the values of Year on the horizontal axis. It also specifies an asterisk as the plotting symbol.

```
proc plot data=djia;
   plot high*year='*'
```

Customize the horizontal axis and draw a reference line. HAXIS= specifies that the horizontal axis will show the values 1968 to 2008 in ten-year increments. VREF= draws a reference line that extends from the value 3000 on the vertical axis.

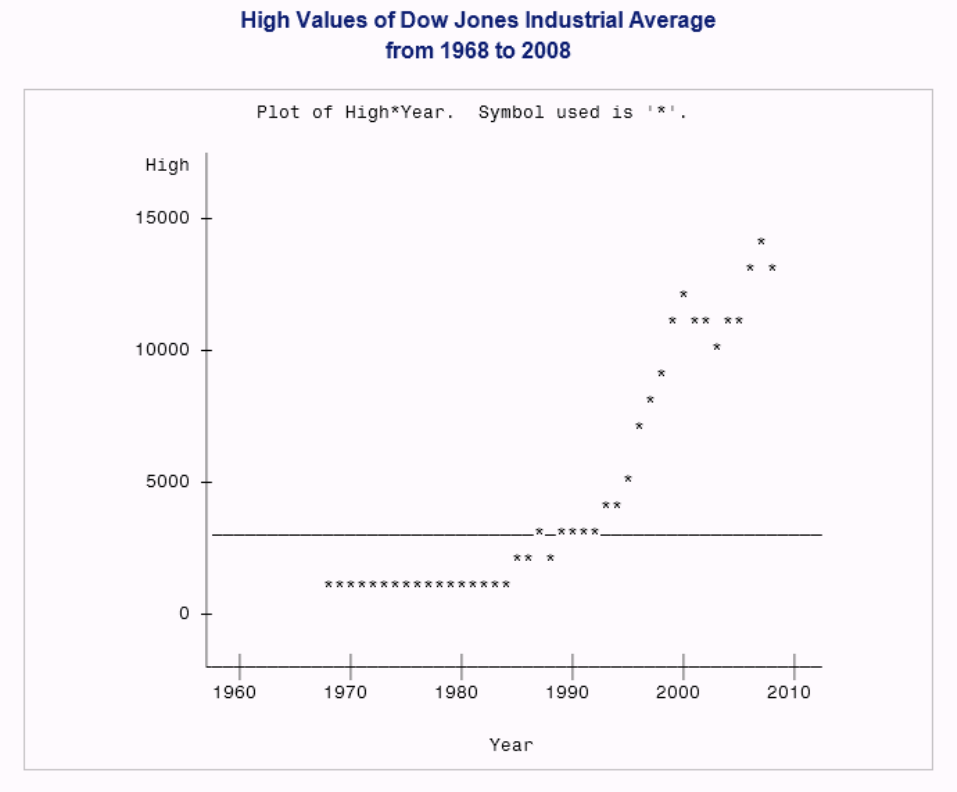
```
      / haxis=1965 to 2020 by 10 vref=3000;
```

Specify the titles.

```
title 'High Values of Dow Jones Industrial Average';
title2 'from 1968 to 2008';
run;
```

Output

Output 45.5 *Plot with Reference Line*



Example 3: Overlaying Two Plots

Features:

PROC PLOT statement option
- FORMCHAR

PLOT statement

PLOT statement options
- BOX
- HAXIS
- OVERLAY
- VAXIS

Data set: DJIA

Details

This example overlays two plots and puts a box around the plot.

Program

```
options formchar="|";

data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;

proc plot data=djia formchar="|----|+|---+=|-/\<>*";
   plot high*year='*'
        low*year='o' / overlay box
        haxis=by 10
        vaxis=by 5000;

   title 'Plot of Highs and Lows';
   title2 'for the Dow Jones Industrial Average';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|";
```

Create the DJIA data set. DJIA contains the high and low closing marks for the Dow Jones Industrial Average from 1968 to 2008. The DATA step creates this data set.

```
data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;
```

Create the plot. Create the plot using the PROC statement. Set the FORMCHAR option. Setting the FORMCHAR option to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available. The first plot request plots High on the vertical axis, plots Year on the horizontal axis, and specifies an asterisk as a plotting symbol. The second plot request plots Low on the vertical axis, plots Year on the horizontal axis,

and specifies an 'o' as a plotting symbol. OVERLAY superimposes the second plot onto the first. BOX draws a box around the plot. OVERLAY and BOX apply to both plot requests. HAXIS= specifies that the horizontal axis will show the values 1968 to 2008 in ten-year increments. VAXIS= specifies that the vertical axis will show the values in increments of 5,000.

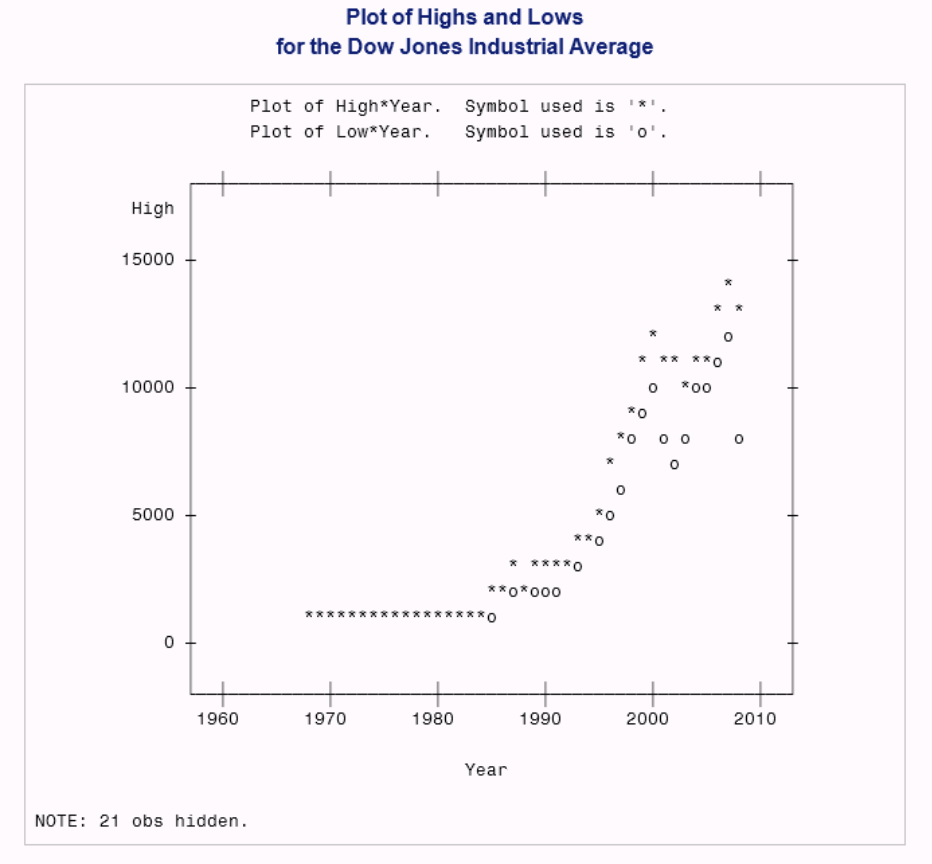
```
proc plot data=djia formchar="|----|+|---+=|-/\<>*";
   plot high*year='*'
        low*year='o' / overlay box
        haxis=by 10
        vaxis=by 5000;
```

Specify the titles.

```
   title 'Plot of Highs and Lows';
   title2 'for the Dow Jones Industrial Average';
run;
```

Output

Output 45.6 *Two Plots Overlaid Using Different Plotting Symbols*



Example 4: Producing Multiple Plots per Page

Features: PROC PLOT statement options
- FORMCHAR
- HPERCENT=
- VPERCENT=

PLOT statement

Data set: DJIA

Details

This example places three plots on one page of output.

Program

```
options formchar="|----|+|---+=|-/\<>*" pagesize=40 linesize=120;

data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;

proc plot data=djia vpercent=50 hpercent=50;

   plot high*year='*';

   plot low*year='o';

   plot high*year='*' low*year='o' / overlay box;

   title 'Plots of the Dow Jones Industrial Average';
   title2 'from 1968 to 2008';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available. The PAGESIZE= option sets the number of lines of output to 40, and the LINESIZE= option sets the line size in the output window to 120 characters.

```
options formchar="|----|+|---+=|-/\<>*" pagesize=40 linesize=120;
```

Create the DJIA data set. DJIA contains the high and low closing marks for the Dow Jones Industrial Average from 1968 to 2008. The DATA step creates this data set.

```
data djia;
      input Year HighDate date7. High LowDate date7. Low;
      format highdate lowdate date7.;
      datalines;
1968 03DEC68   985.21 21MAR68   825.13
1969 14MAY69   968.85 17DEC69   769.93
...more data lines...
2006 27DEC06 12510.57 20JAN06 10667.39
2007 09OCT07 14164.53 05MAR07 12050.41
2008 02MAY08 13058.20 10OCT08  8451.19
;
```

Specify the plot sizes. VPERCENT= specifies that 50% of the vertical space on the page of output is used for each plot. HPERCENT= specifies that 50% of the horizontal space is used for each plot.

```
proc plot data=djia vpercent=50 hpercent=50;
```

Create the first plot. This plot request plots the values of High on the vertical axis and the values of Year on the horizontal axis. It also specifies an asterisk as the plotting symbol.

```
   plot high*year='*';
```

Create the second plot. This plot request plots the values of Low on the vertical axis and the values of Year on the horizontal axis. It also specifies an asterisk as the plotting symbol.

```
   plot low*year='o';
```

Create the third plot. The first plot request plots High on the vertical axis, plots Year on the horizontal axis, and specifies an asterisk as a plotting symbol. The second plot request plots Low on the vertical axis, plots Year on the horizontal axis, and specifies an 'o' as a plotting symbol. OVERLAY superimposes the second plot onto the first. BOX draws a box around the plot. OVERLAY and BOX apply to both plot requests.

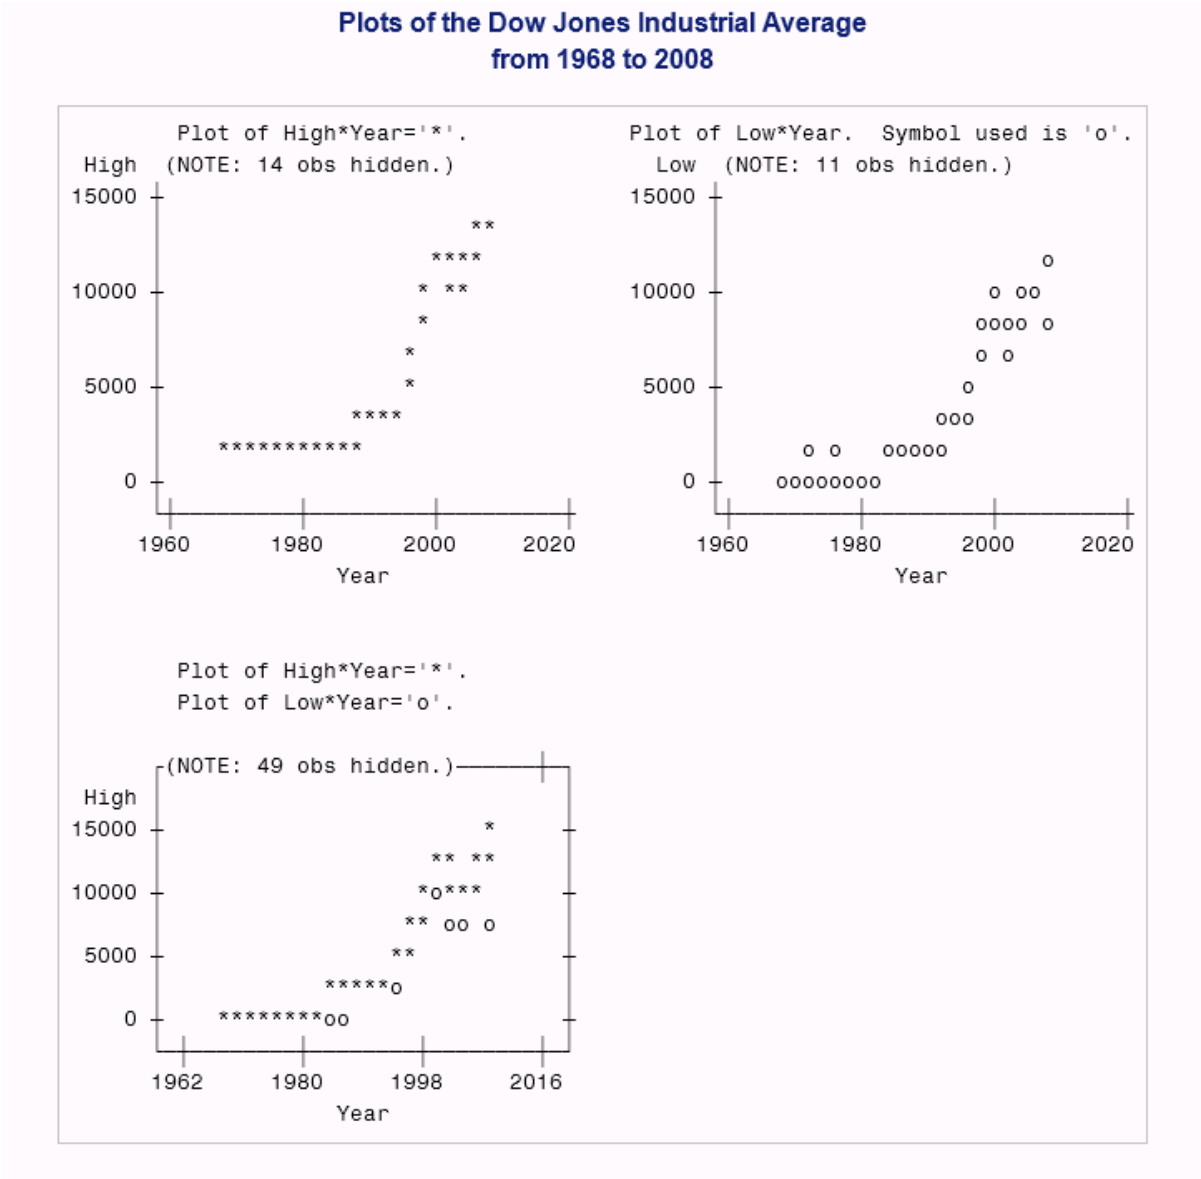
```
   plot high*year='*' low*year='o' / overlay box;
```

Specify the titles.

```
   title 'Plots of the Dow Jones Industrial Average';
   title2 'from 1968 to 2008';
run;
```

Output

Output 45.7 *Three Plots on One Page*



Example 5: Plotting Data on a Logarithmic Scale

Features:
- PROC PLOT statement option
  - PLOT statement
- PLOT statement options
  - HAXIS=
  - VSPACE=
- DATA step

Data set: EQUA

Details

This example uses a DATA step to generate the data set EQUA. The DATA step creates the data by using an iterative DO statement. The PROC PLOT step shows two plots of the same data: one plot without a horizontal axis specification and one plot with a logarithmic scale specified for the horizontal axis.

Program

```
data equa;
   do Y=1 to 3 by .1;
      X=10**y;
      output;
   end;
run;

proc plot data=equa hpercent=50;

    plot y*x / vspace=1;
    plot y*x / haxis=10 100 1000 vspace=1;

    title 'Two Plots with Different';
    title2 'Horizontal Axis Specifications';
run;
```

Program Description

Create the EQUA data set. EQUA creates values of X and Y by incrementing the variable Y from 1 to 3 by increments of .1. Each value of X is calculated as 10^{Y}.

```
data equa;
   do Y=1 to 3 by .1;
      X=10**y;
      output;
   end;
run;
```

Specify the plot sizes. HPERCENT= makes room for two plots side-by-side by specifying that 50% of the horizontal space is used for each plot.

```
proc plot data=equa hpercent=50;
```

Create the plots. The PLOT statement requests plot Y on the vertical axis and X on the horizontal axis. HAXIS= specifies a logarithmic scale for the horizontal axis for the second plot. The VSPACE= option specifies the amount of print space between the tick marks.

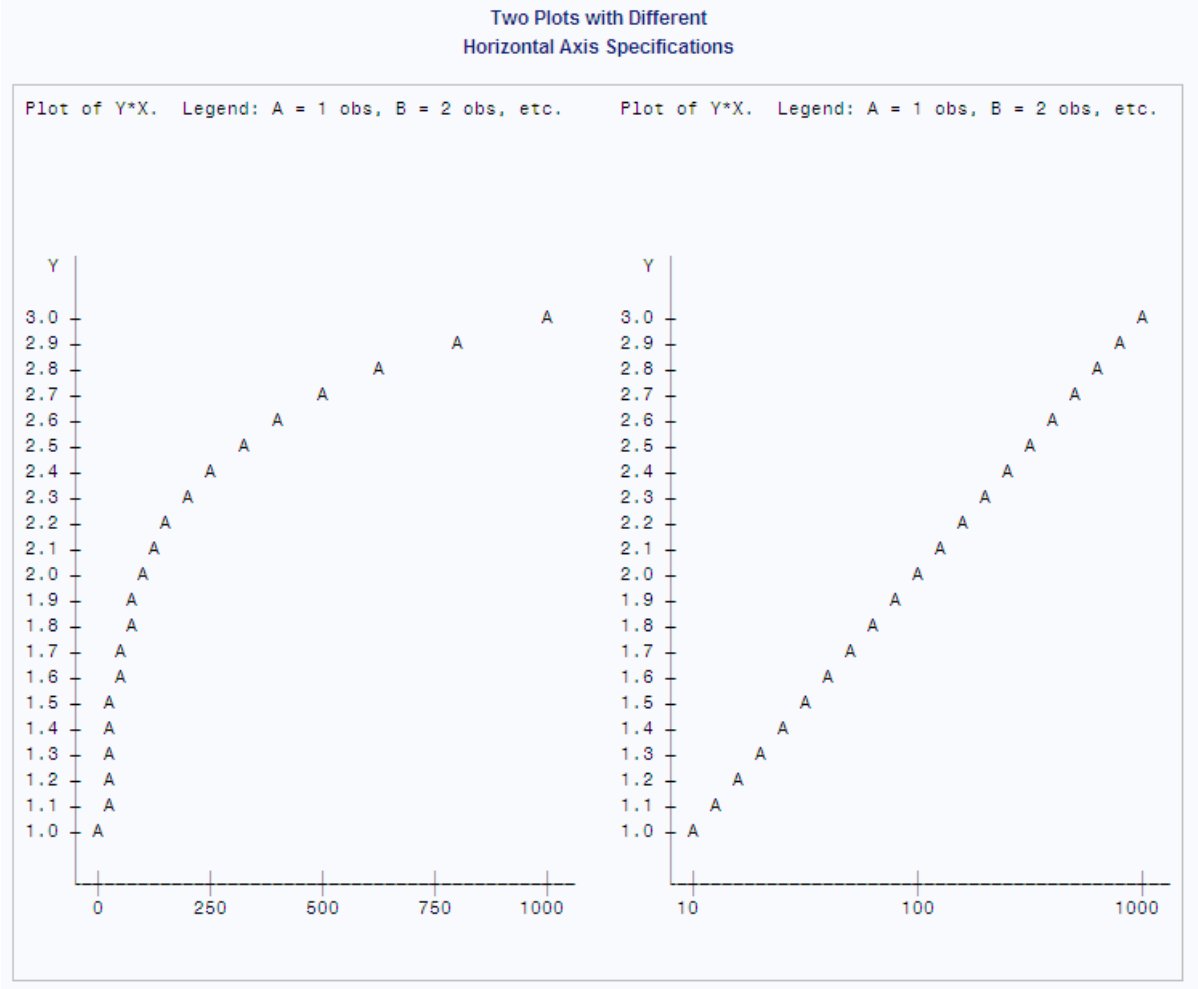
```
    plot y*x / vspace=1;
    plot y*x / haxis=10 100 1000 vspace=1;
```

Specify the titles.

```
    title 'Two Plots with Different';
    title2 'Horizontal Axis Specifications';
run;
```

Output

Output 45.8 *Two Plots with Different Horizontal Axis Specifications*



Example 6: Plotting Date Values on an Axis

Features:

PROC PLOT statement options
FORMCHAR

PLOT statement

PLOT statement options
HAXIS=

DATA step

Data set: EMERGENCY_CALLS

Details

This example uses a DATA step to create the data set EMERGENCY_CALLS and shows how you can specify date values on an axis.

Program

```
options formchar="|----|+|---+=|-/\<>*";

data emergency_calls;
   input Date : date7. Calls @@;
   label calls='Number of Calls';
   datalines;
1APR94 134   11APR94 384  13FEB94 488
2MAR94 289   21MAR94 201  14MAR94 460
3JUN94 184   13JUN94 152  30APR94 356
4JAN94 179   14JAN94 128  16JUN94 480
5APR94 360   15APR94 350  24JUL94 388
6MAY94 245   15DEC94 150  17NOV94 328

11NOV94 294  26APR94 412   2DEC94 511
27MAY94 294  22DEC94 413  28JUN94 309
;

proc plot data=emergency_calls;
   plot calls*date / haxis='1JAN94'd to '1JAN95'd by month vaxis=by
100 vspace=5;

   format date mmyyd5.;

   title 'Calls to City Emergency Services Number';
   title2 'Sample of Days for 1994';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the EMERGENCY_CALLS data set. EMERGENCY_CALLS contains the number of telephone calls to an emergency help line for each date.

```
data emergency_calls;
   input Date : date7. Calls @@;
   label calls='Number of Calls';
   datalines;
1APR94 134   11APR94 384  13FEB94 488
2MAR94 289   21MAR94 201  14MAR94 460

;
```

Create the plot. The plot request plots Calls on the vertical axis and Date on the horizontal axis. HAXIS= uses a monthly time for the horizontal axis. The notation **'1JAN94'd** is a date constant. The value **'1JAN95'd** ensures that the axis will have enough room for observations from December.

```
proc plot data=emergency_calls;
   plot calls*date / haxis='1JAN94'd to '1JAN95'd by month vaxis=by
100 vspace=5;
```

Format the DATE values. The FORMAT statement assigns the MMYYD5. format to Date, which uses 2-digit month and 2-digit year values separated by a hyphen.

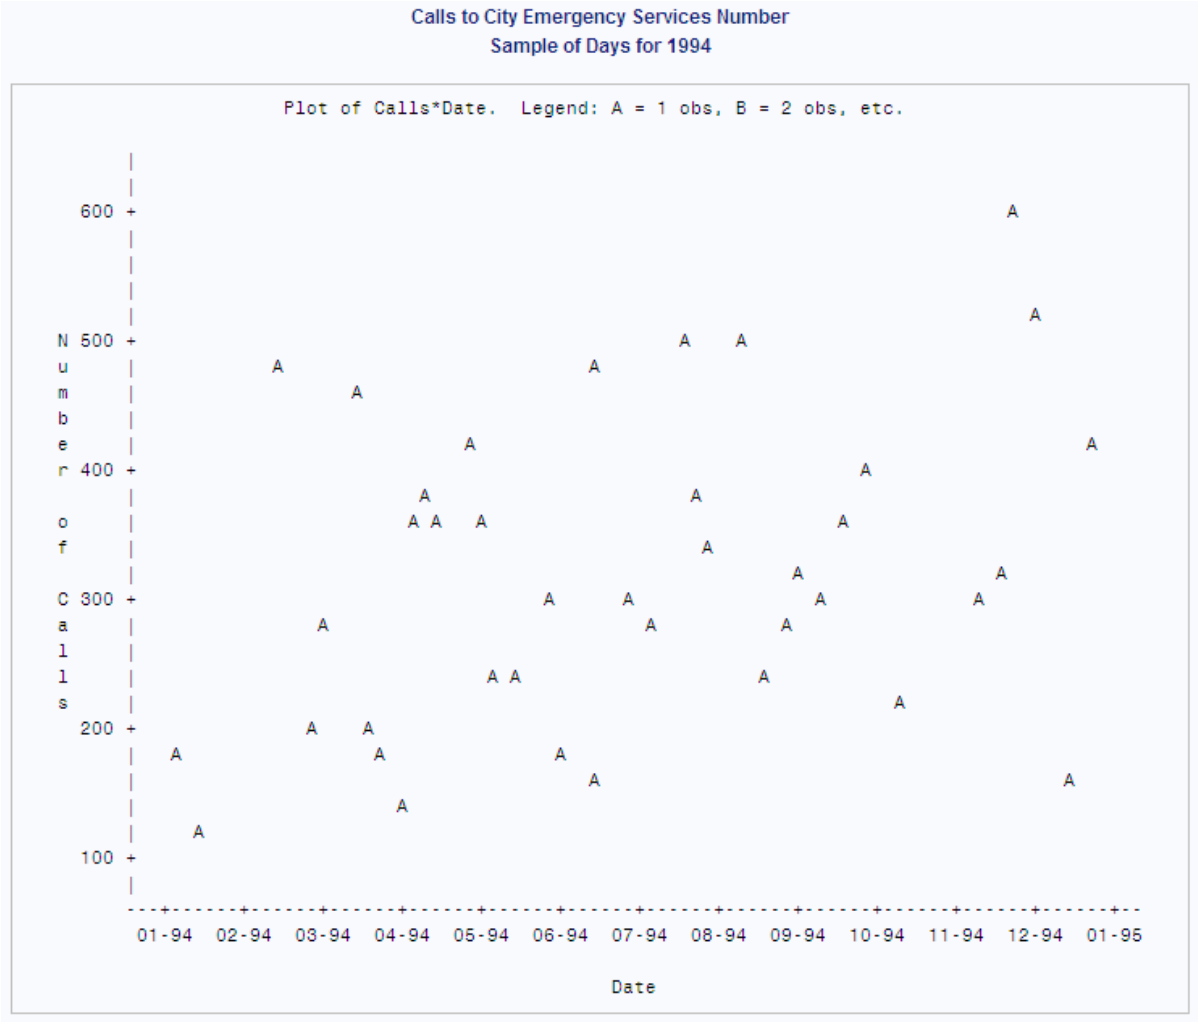
```
   format date mmyyd5.;
```

Specify the titles.

```
   title 'Calls to City Emergency Services Number';
   title2 'Sample of Days for 1994';
run;
```

Output

Output 45.9 *Plot with Date Values along the Horizontal Axis*



Example 7: Producing a Contour Plot

Features:
- PROC PLOT statement option FORMCHAR
- PLOT statement
- PLOT statement option CONTOUR=
- DATA step
- PROC PRINT
- OBS= data set option
- NOOBS system option

Data set: CONTOURS

Details

This example uses a DATA step to create the data set CONTOURS. It shows how to represent the values of three variables with a two-dimensional plot by setting one of the variables as the CONTOUR variable. The variables X and Y appear on the axes, and Z is the contour variable. Program statements are used to generate the observations for the plot, and the following equation describes the contour surface:

$$z = 46.2 + .09x - .0005x^2 + .1y - .0005y^2 + .0004xy$$

Program

```
options formchar="|----|+|---+=|-/\<>*";

data contours;
   format Z 5.1;
   do X=0 to 400 by 5;
      do Y=0 to 350 by 10;
         z=46.2+.09*x-.0005*x**2+.1*y-.0005*y**2+.0004*x*y;
         output;
      end;
   end;
run;

proc print data=contours(obs=5) noobs;
   title 'CONTOURS Data Set';
   title2 'First 5 Observations Only';
run;

proc plot data=contours;
plot y*x=z / contour=10;

    title 'A Contour Plot';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the CONTOURS data set. The CONTOURS data set contains observations with values of X that range from 0 to 400 by 5 and with values of Y that range from 0 to 350 by 10.

```
data contours;
   format Z 5.1;
```

```
   do X=0 to 400 by 5;
      do Y=0 to 350 by 10;
         z=46.2+.09*x-.0005*x**2+.1*y-.0005*y**2+.0004*x*y;
         output;
      end;
   end;
run;
```

Print the CONTOURS data set. The OBS= data set option limits the printing to only the first 5 observations. NOOBS suppresses printing of the observation numbers.

```
proc print data=contours(obs=5) noobs;
   title 'CONTOURS Data Set';
   title2 'First 5 Observations Only';
run;
```

Create the plot. The PLOT statement plots Y on the vertical axis, plots X on the horizontal axis, and specifies Z as the contour variable. CONTOUR=10 specifies that the plot will divide the values of Z into ten increments, and each increment will have a different plotting symbol.

```
proc plot data=contours;
plot y*x=z / contour=10;
```

Specify the title.

```
    title 'A Contour Plot';
run;
```

Output

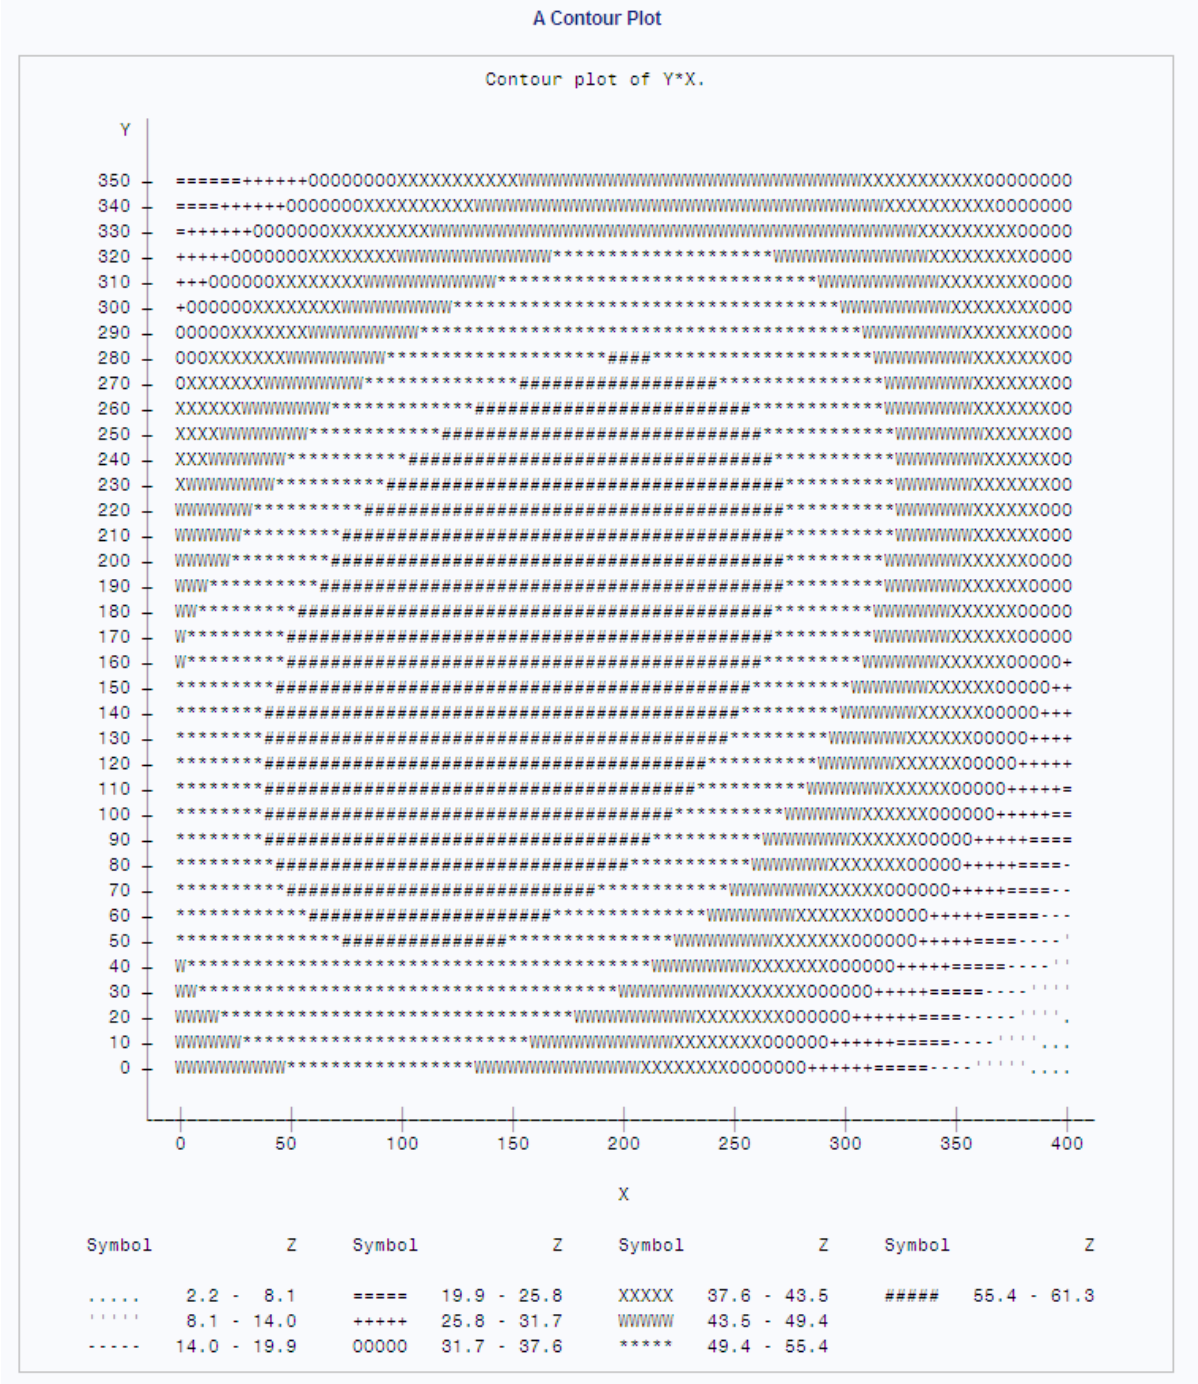
The shadings associated with the values of Z appear at the bottom of the plot. The plotting symbol # shows where high values of Z occur.

Output 45.10 *CONTOURS Data Set, First Five Observations*

CONTOURS Data Set
First 5 Observations Only

Z	X	Y
46.2	0	0
47.2	0	10
48.0	0	20
48.8	0	30
49.4	0	40

Output 45.11 *Contour Plot of Y*X*



Example 8: Plotting BY Groups

- VSPACE=

PROC SORT

DATA step

Data set: EDUCATION

Details

This example uses the data set "EDUCATION" on page 2785 to show BY-group processing in PROC PLOT.

Program

```
options formchar=|----|+|---+=|-/\<>*";

data education;
   input State $14. +1 Code $ DropoutRate Expenditures MathScore
         Region $;
   label dropout='Dropout Percentage - 1989'
          expend='Expenditure Per Pupil - 1989'
            math='8th Grade Math Exam - 1990';
   datalines;
Alabama        AL 22.3 3197 252 SE
Alaska         AK 35.8 7716 .   W
...more data lines...
New York       NY 35.0 .    261 NE
North Carolina NC 31.2 3874 250 SE
North Dakota   ND 12.1 3952 281 MW
Ohio           OH 24.4 4649 264 MW
;

proc sort data=education;
   by region;
run;

proc plot data=education;
   by region;

    plot expenditures*dropoutrate='*' / href=28.6
         vaxis=by 500 vspace=5
         haxis=by 5 hspace=12;

    title 'Plot of Dropout Rate and Expenditure Per Pupil';
 run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar=|----|+|---+=|-/\<>*";
```

Create the EDUCATION data set. "EDUCATION" on page 2785 contains educational data (Source: U.S. Department of Education) about some U.S. states. DropoutRate is the percentage of high school dropouts. Expenditures is the dollar amount the state spends on each pupil. MathScore is the score of eighth-grade students on a standardized math test. Not all states participated in the math test.

```
data education;
   input State $14. +1 Code $ DropoutRate Expenditures MathScore
         Region $;
   label dropout='Dropout Percentage - 1989'
          expend='Expenditure Per Pupil - 1989'
            math='8th Grade Math Exam - 1990';
   datalines;
Alabama        AL 22.3 3197 252 SE
Alaska         AK 35.8 7716 .   W
...more data lines...
New York       NY 35.0 .    261 NE
North Carolina NC 31.2 3874 250 SE
North Dakota   ND 12.1 3952 281 MW
Ohio           OH 24.4 4649 264 MW
;
```

Sort the EDUCATION data set. PROC SORT sorts EDUCATION by Region so that Region can be used as the BY variable in PROC PLOT.

```
proc sort data=education;
   by region;
run;
```

Create a separate plot for each BY group. The BY statement creates a separate plot for each value of Region.

```
proc plot data=education;
   by region;
```

Create the plot with a reference line. The PLOT statement plots Expenditures on the vertical axis, plots DropoutRate on the horizontal axis, and specifies an asterisk as the plotting symbol. HREF= draws a reference line that extends from 28.6 on the horizontal axis. The reference line represents the national average. VAXIS and HAXIS are used to set the tick marks along the vertical and horizontal axes. The VSPACE= option specifies the amount of print space between the vertical tick marks.

```
   plot expenditures*dropoutrate='*' / href=28.6
        vaxis=by 500 vspace=5
        haxis=by 5 hspace=12;
```

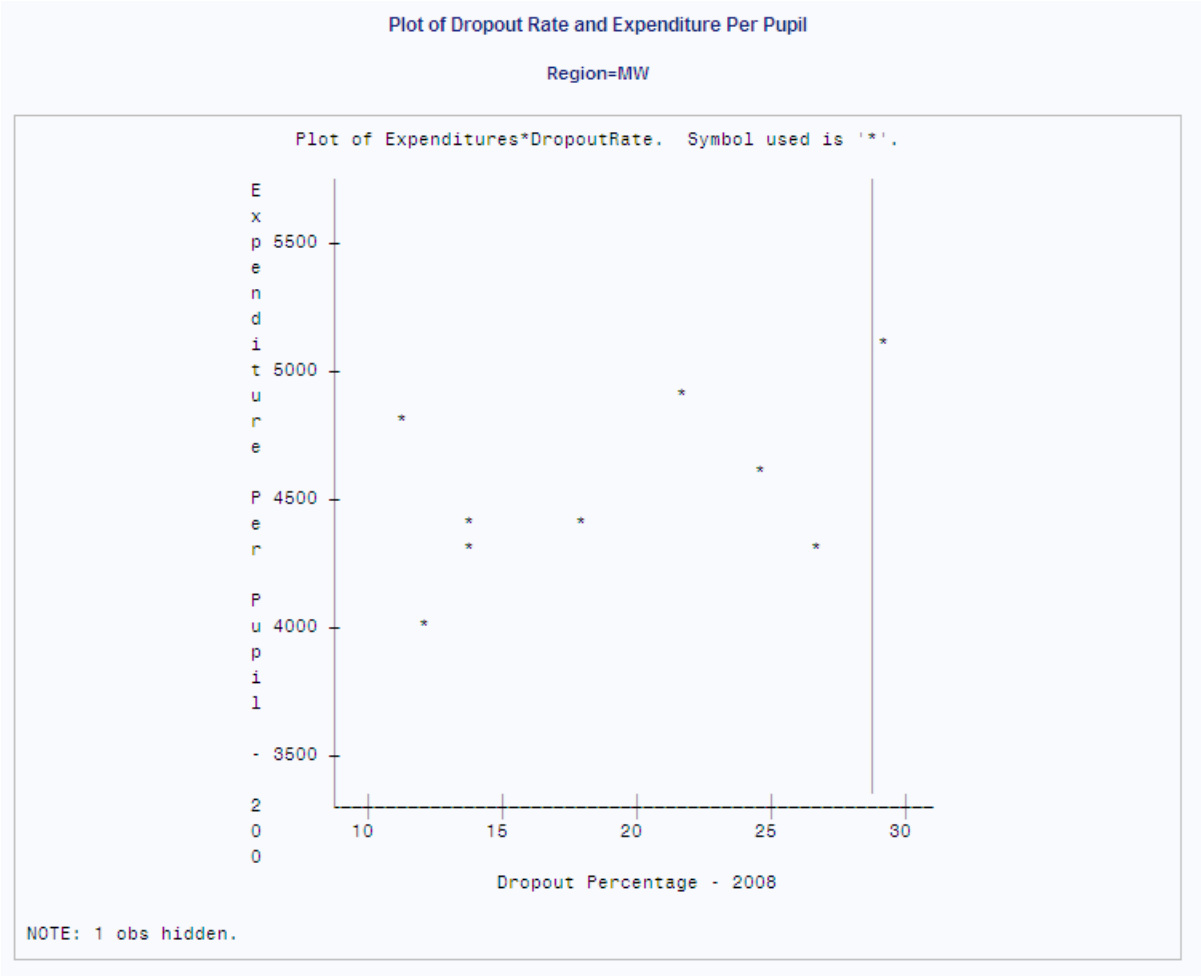
Specify the title.

```
   title 'Plot of Dropout Rate and Expenditure Per Pupil';
run;
```

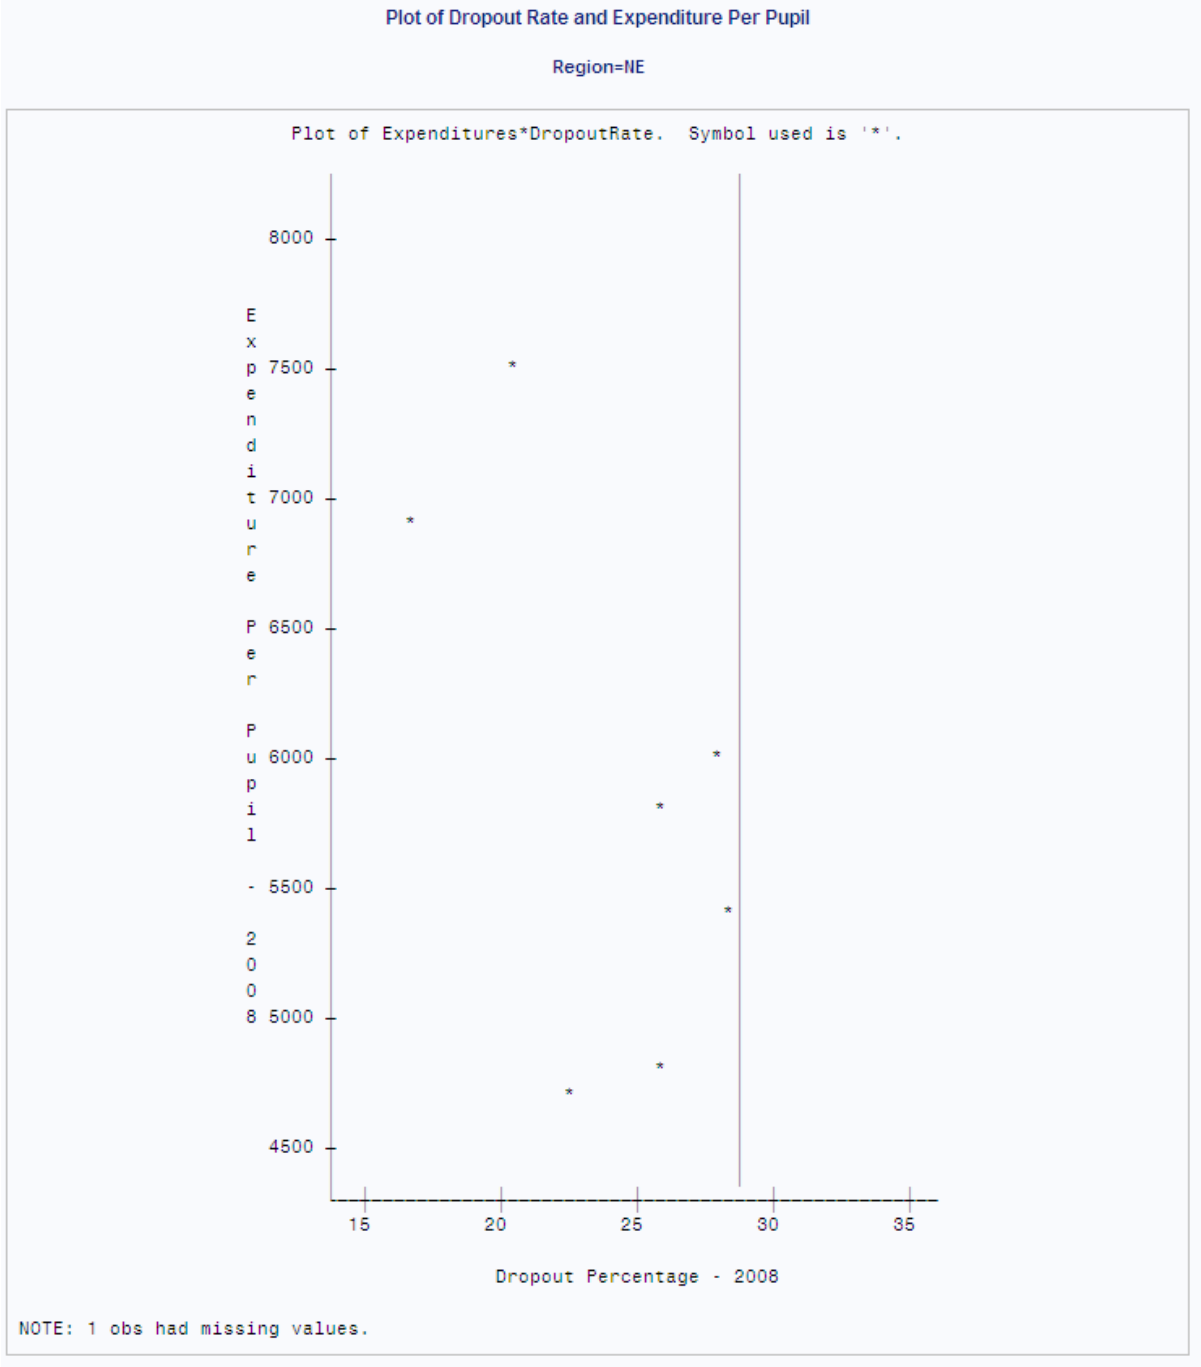
Output

PROC PLOT produces a plot for each BY group. Only the plots for Midwest and Northeast are shown.

Output 45.12 *Plot for Each BY Group, Midwest Region*



Output 45.13 *Plot for Each BY Group, Northeast Region*



Example 9: Adding Labels to a Plot

Features: PROC PLOT statement option
FORMCHAR

BY statement

PLOT statement

PROC SORT

Data set: EDUCATION

Details

This example shows how to use variables in a data set to label the points on a plot. The example adds labels to the output from the example "Example 8: Plotting BY Groups" on page 1668 . PROC SORT is used first to sort the data set by Region so that Region can be used as the BY variable in the first PLOT statement.

Program

```
options formchar="|----|+|---+=|-/\<>*";

proc sort data=education;
   by region;
run;

proc plot data=education;
   by region;

   plot expenditures*dropoutrate='*' $ state / href=28.6
        vaxis=by 500 vspace=5
        haxis=by 5 hspace=12;

   title 'Plot of Dropout Rate and Expenditure Per Pupil';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Sort the EDUCATION data set. PROC SORT sorts EDUCATION by Region so that Region can be used as the BY variable in PROC PLOT.

```
proc sort data=education;
   by region;
run;
```

Create a separate plot for each BY group. The BY statement creates a separate plot for each value of Region.

```
proc plot data=education;
   by region;
```

Create the plot with a reference line and a label for each data point. The plot request plots Expenditures on the vertical axis, plots DropoutRate on the horizontal axis, and specifies an asterisk as the plotting symbol. The label variable specification (**$ state**) in the PLOT statement labels each point on the plot with the name of the corresponding state. HREF= draws a reference line that extends from 28.6 on the horizontal axis. The reference line represents the national average. VAXIS and HAXIS are used to set the tick marks along the vertical and horizontal axes. The HSPACE=12 option specifies that there are 12 print spaces between the horizontal tick marks.

```
plot expenditures*dropoutrate='*' $ state / href=28.6
     vaxis=by 500 vspace=5
     haxis=by 5 hspace=12;
```

Specify the title.

```
   title 'Plot of Dropout Rate and Expenditure Per Pupil';
run;
```

Output

PROC PLOT produces a plot for each BY group. Only the plots for `Midwest` and `Northeast` are shown.

Output 45.14 Plot with Labels, Midwest Region

Plot of Dropout Rate and Expenditure Per Pupil

Region=MW

```
                     Plot of Expenditures*DropoutRate$State.  Symbol used is '*'.

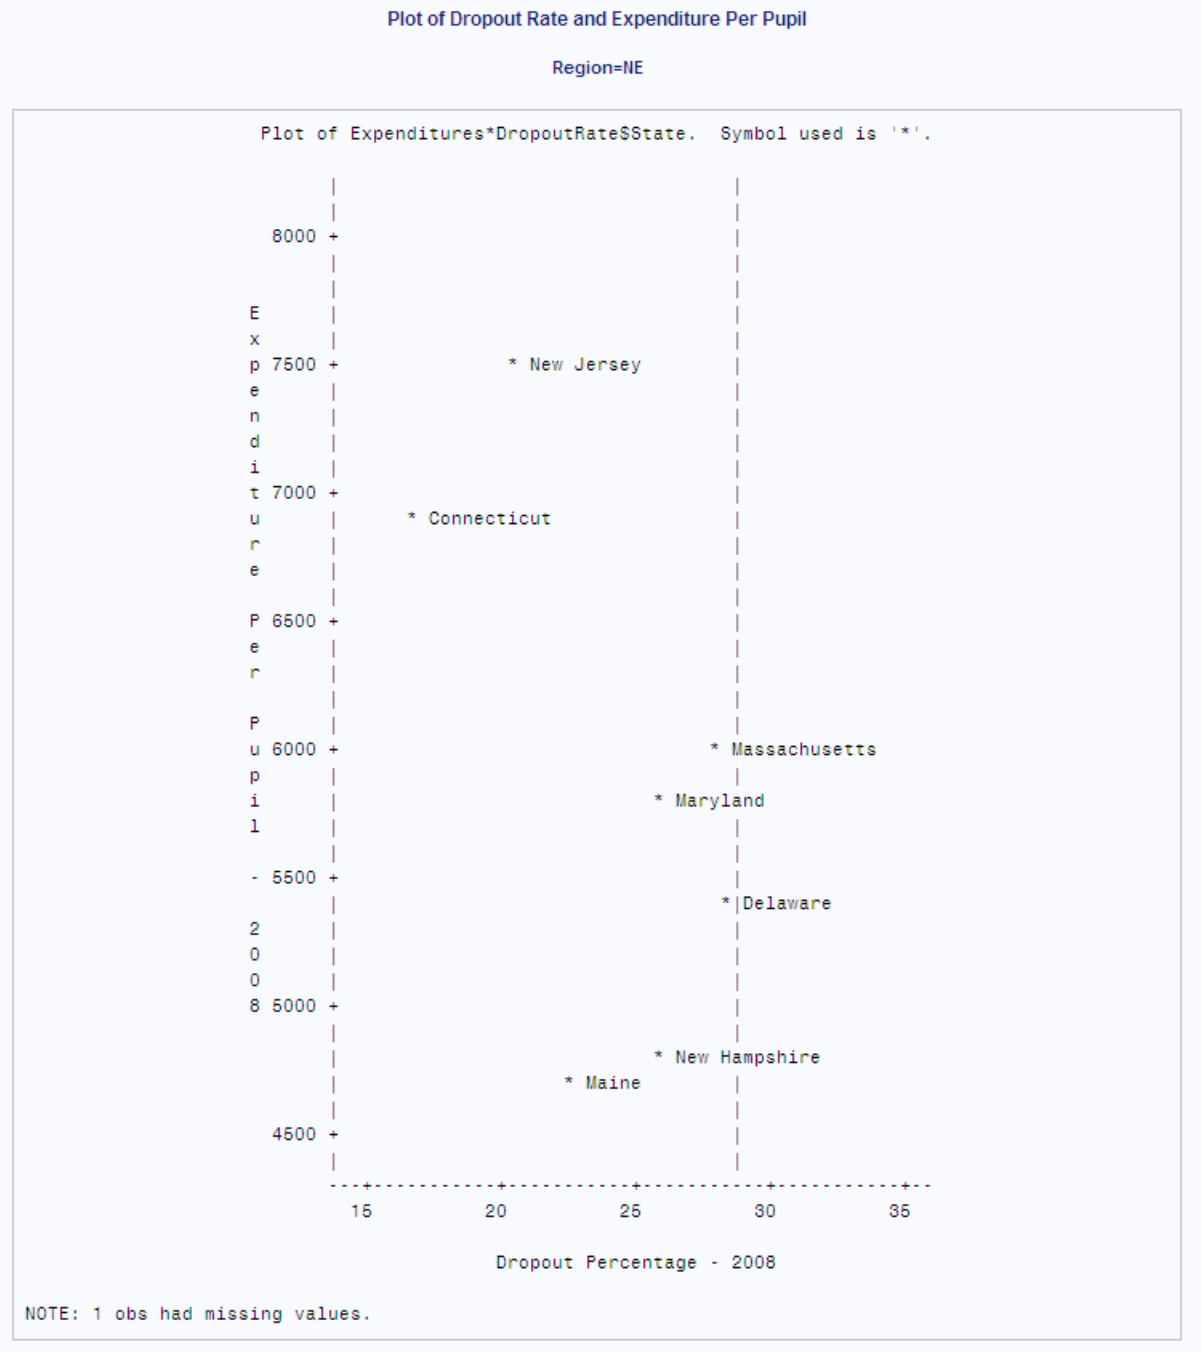
                    l      |                                               |
                           |                                               |
                    - 3500 +                                               |
                           |                                               |
                    2      ---+-----------+-----------+-----------+-----------+--
                    0        10          15          20          25          30
                    0
                                          Dropout Percentage - 2008

NOTE: 1 obs hidden.
```

Output 45.15 *Plot with Labels, Northeast Region*



Example 10: Excluding Observations That Have Missing Values

Features: PROC PLOT statement options
FORMCHAR
NOMISS

BY statement

PLOT statement

PLOT statement options

HAXIS=
HREF=
HSPACE=
VAXIS=
VSPACE=

PROC SORT

WHERE statement

Data set: EDUCATION

Details

This example shows how missing values affect the calculation of the axes. The example uses the "EDUCATION" on page 2785 data set.

Program

```
options formchar="|----|+|---+=|-/\<>*";

proc sort data=education;
   by region;
run;

proc plot data=education nomiss;

    by region;

    plot expenditures*dropoutrate='*' $ state / href=28.6
         vaxis=by 500 vspace=5
         haxis=by 5 hspace=12;

    title 'Plot of Dropout Rate and Expenditure Per Pupil';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Sort the EDUCATION data set. PROC SORT sorts EDUCATION by Region so that Region can be used as the BY variable in PROC PLOT.

```
proc sort data=education;
```

```
   by region;
run;
```

Exclude data points with missing values. NOMISS excludes observations that have a missing value for either of the axis variables.

```
proc plot data=education nomiss;
```

Create a separate plot for each BY group. The BY statement creates a separate plot for each value of Region.

```
     by region;
```

Create the plot with a reference line and a label for each data point. The plot request plots Expenditures on the vertical axis, plots DropoutRate on the horizontal axis, and specifies an asterisk as the plotting symbol. The label variable specification (**$ state**) in the PLOT statement labels each point on the plot with the name of the corresponding state. HREF= draws a reference line extending from 28.6 on the horizontal axis. The reference line represents the national average. VAXIS and HAXIS are used to set the tick marks along the vertical and horizontal axes. The VSPACE=5 option specifies that there are 5 spaces between tick marks on the vertical axis and HSPACE=12 specifies that there are 12 spaces between the horizontal tick marks.

```
     plot expenditures*dropoutrate='*' $ state / href=28.6
          vaxis=by 500 vspace=5
          haxis=by 5 hspace=12;
```

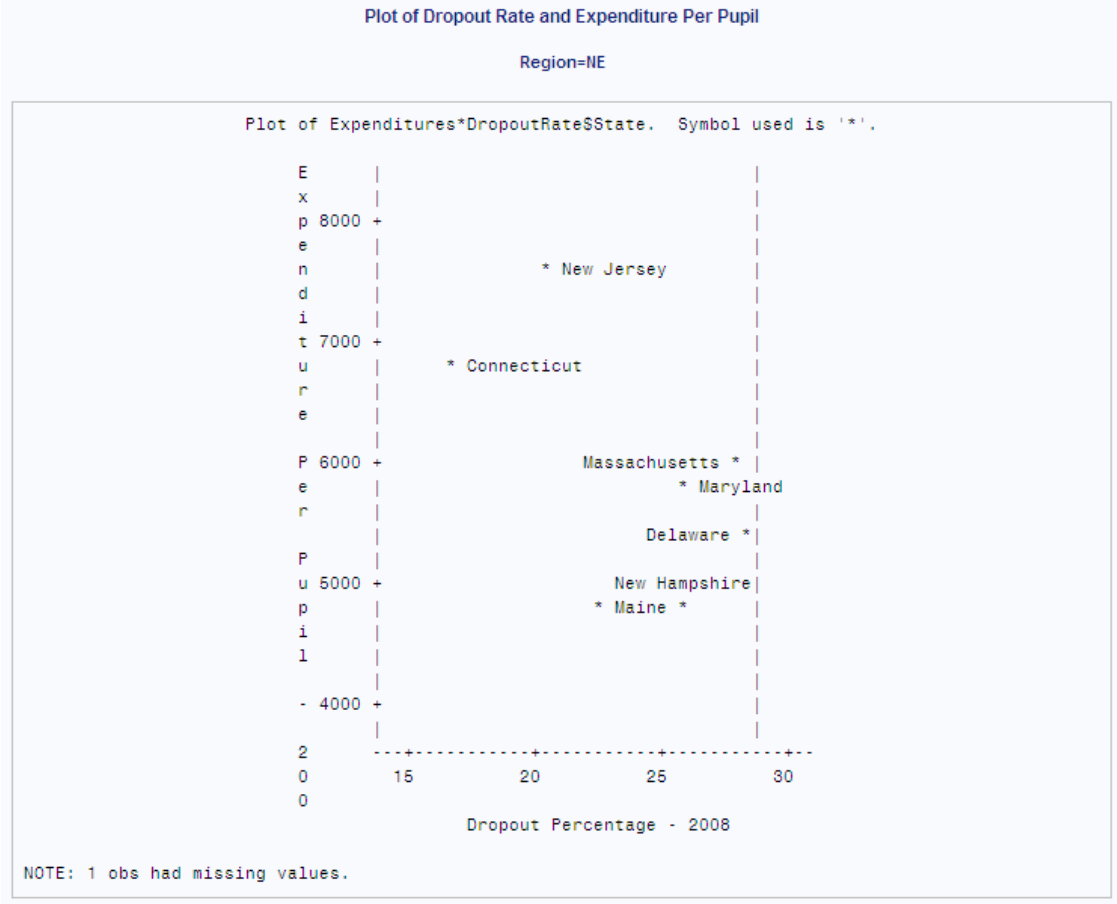
Specify the title.

```
     title 'Plot of Dropout Rate and Expenditure Per Pupil';
run;
```

Output

PROC PLOT produces a plot for each BY group. Only the plot for the **Northeast** is shown. Because **New York** has a missing value for Expenditures, the observation is excluded and PROC PLOT does not use the value 35 for DropoutRate to calculate the horizontal axis. Compare the horizontal axis in this output with the horizontal axis in the plot for **Northeast** in “Example 9: Adding Labels to a Plot” on page 1672.

Output 45.16 *Plot with Missing Values Excluded*



Example 11: Adjusting Labels on a Plot with the PLACEMENT= Option

Features:

- HAXIS=
- HSPACE=
- VAXIS=
- VSPACE=

DATA step

RUN-group processing

Data set: CENSUS

Details

This example illustrates the default placement of labels and how to adjust the placement of labels on a crowded plot. The labels are values of variables in the data set "CENSUS" on page 2748.[1]

This example also shows RUN group processing in PROC PLOT.

Program

```
options formchar="|----|+|---+=|-/\<>*";

data census;
   input Density CrimeRate State $ 14-27 PostalCode $ 29-30;
   datalines;
263.3 4575.3 Ohio           OH
62.1 7017.1  Washington     WA

...more data lines...

111.6 4665.6 Tennessee      TN
120.4 4649.9 North Carolina NC
;

proc plot data=census;
   plot density*crimerate=state $ state /

   box
   list=1
   haxis=by 1000
   vaxis=by 250
   vspace=10
   hspace=10;

    plot density*crimerate=state $ state /
              box
              list=1
              haxis=by 1000
              vaxis=by 250
              vspace=10

           placement=((v=2 1 : l=2 1)
                 ((l=2 2 1 : v=0 1 0) * (s=right left : h=2 -2))
                 (s=center right left * l=2 1 * v=0 1 -1 2 *
                  h=0 1 to 5 by alt));

   title 'A Plot of Population Density and Crime Rates';
run;
```

1. Source: U.S. Bureau of the Census and the 1987 Uniform Crime Reports, FBI.

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the CENSUS data set. CENSUS contains the variables CrimeRate and Density for selected states. CrimeRate is the number of crimes per 100,000 people. Density is the population density per square mile in the 1980 census. A DATA step, "CENSUS" on page 2748 creates this data set.

```
data census;
   input Density CrimeRate State $ 14-27 PostalCode $ 29-30;
   datalines;
263.3 4575.3 Ohio           OH
62.1 7017.1  Washington     WA

...more data lines...

111.6 4665.6 Tennessee      TN
120.4 4649.9 North Carolina NC
;
```

Create the plot with a label for each data point. The plot request plots Density on the vertical axis, CrimeRate on the horizontal axis, and uses the first letter of the value of State as the plotting symbol. This makes it easier to match the symbol with its label. The label variable specification (`$ state`) in the PLOT statement labels each point with the corresponding state name.

```
proc plot data=census;
   plot density*crimerate=state $ state /
```

Specify plot options. BOX draws a box around the plot. LIST= lists the labels that have penalties greater than or equal to 1. HAXIS= and VAXIS= specify increments only. PROC PLOT uses the data to determine the range for the axes. The VSPACE=10 option specifies that there are 10 spaces between tick marks on the vertical axis and HSPACE=10 specifies that there are 10 spaces between the horizontal tick marks.

```
      box
      list=1
      haxis=by 1000
      vaxis=by 250
      vspace=10
      hspace=10;
```

Request a second plot. Because PROC PLOT is interactive, the procedure is still running at this point in the program. It is not necessary to restart the procedure to submit another plot request. LIST=1 produces no output because there are no penalties of 1 or greater.

```
      plot density*crimerate=state $ state /
                box
                list=1
                haxis=by 1000
```

```
      vaxis=by 250
      vspace=10
```

Specify placement options. PLACEMENT= gives PROC PLOT more placement states to use to place the labels. PLACEMENT= contains three expressions. The first expression specifies the preferred positions for the label. The first expression resolves to placement states centered above the plotting symbol, with the label on one or two lines. The second and third expressions resolve to placement states that enable PROC PLOT to place the label in multiple positions around the plotting symbol.

```
      placement=((v=2 1 : l=2 1)
            ((l=2 2 1 : v=0 1 0) * (s=right left : h=2 -2))
            (s=center right left * l=2 1 * v=0 1 -1 2 *
             h=0 1 to 5 by alt));
```

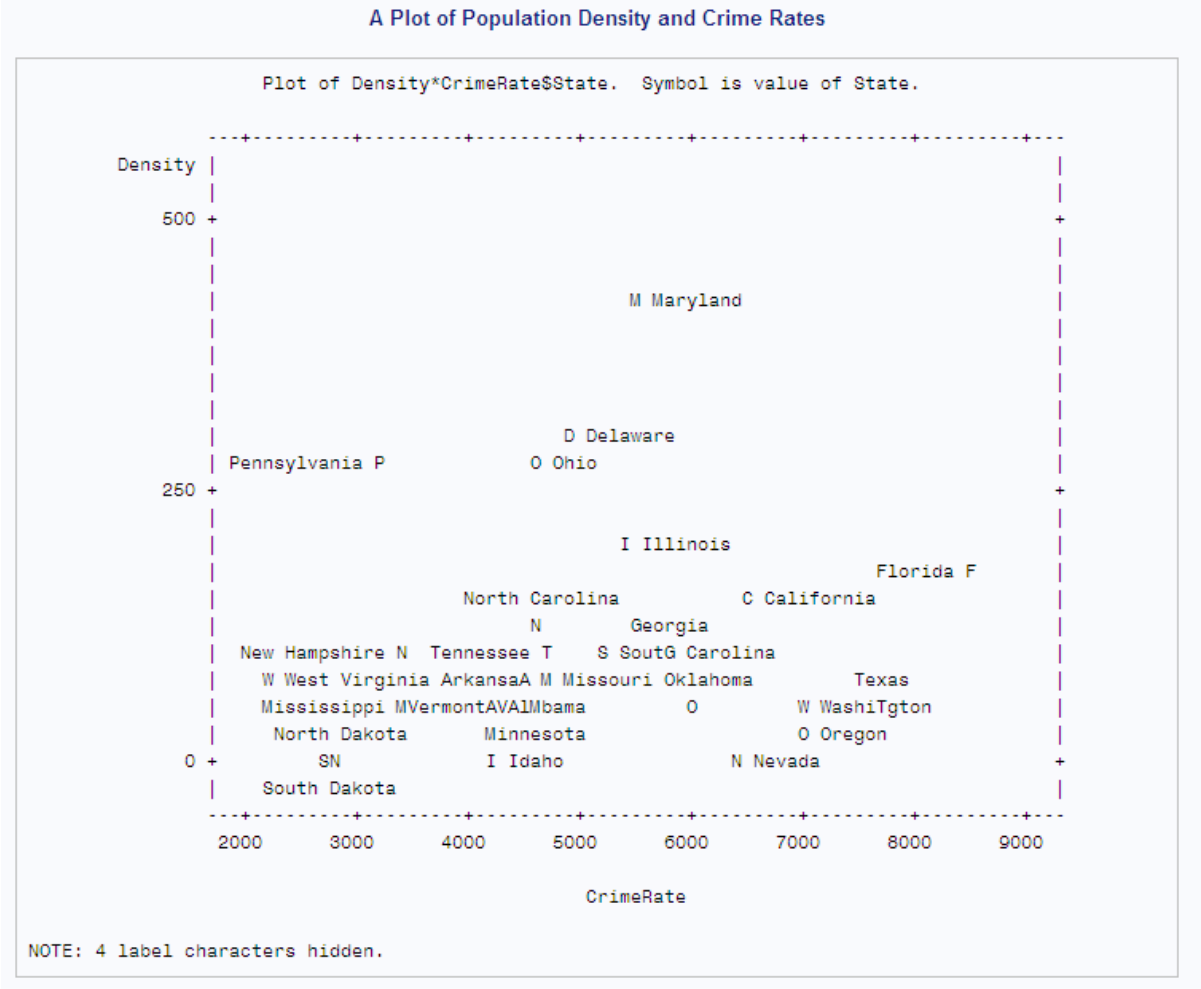
Specify the title.

```
   title 'A Plot of Population Density and Crime Rates';
run;
```

Output

The labels **Tennessee**, **South Carolina**, **Arkansas**, **Minnesota**, and **South Dakota** have penalties. The default placement states do not provide enough possibilities for PROC PLOT to avoid penalties given the proximity of the points. Four label characters are hidden.

Output 45.17 *Plot with Penalties*

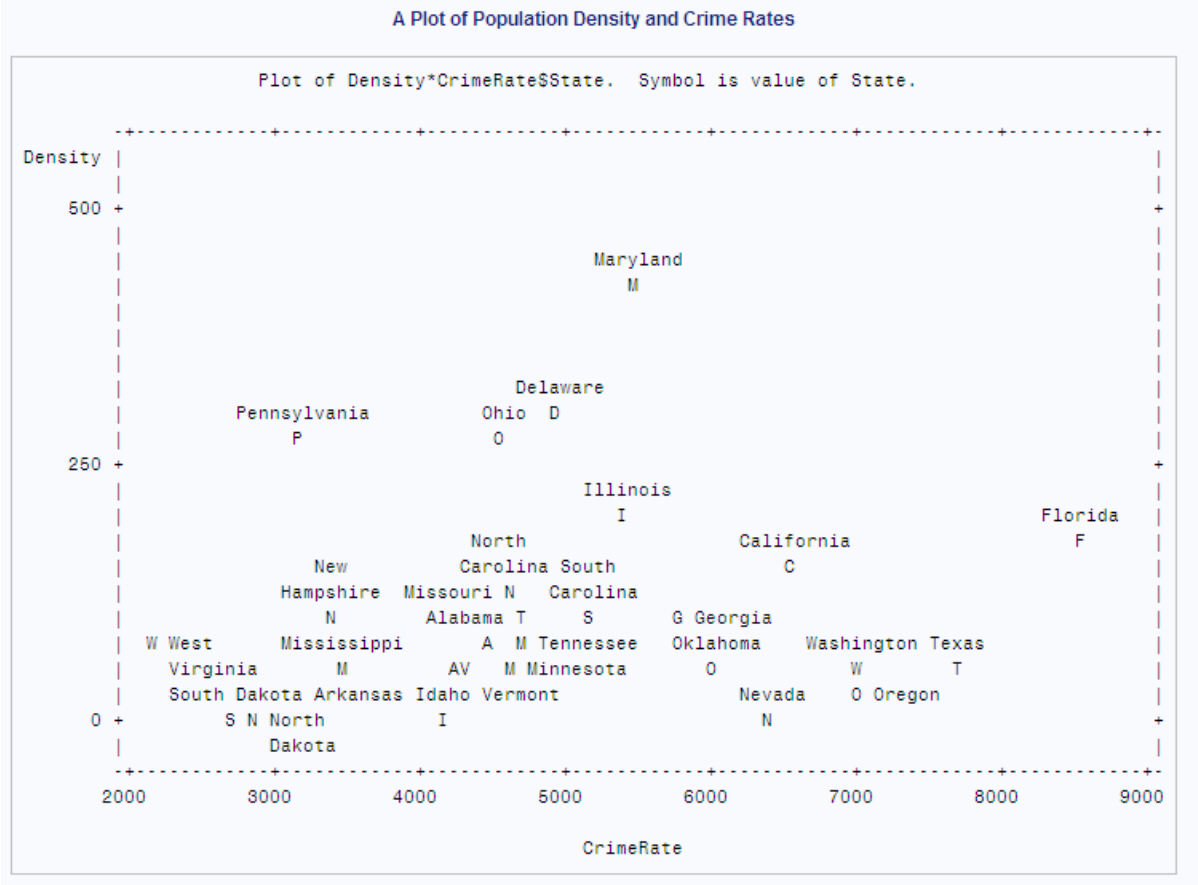


List of Point Locations, Penalties, and Placement States

Label	Vertical Axis	Horizontal Axis	Penalty	Starting Position	Lines	Vertical Shift	Horizontal Shift
South Carolina	103.40	5161.9	2	Right	1	0	2
Alabama	76.60	4451.4	9	Center	1	-1	2
Arkansas	43.90	4245.2	2	Center	1	1	-1
Vermont	55.20	4271.2	2	Left	1	0	-2
Washington	62.10	7017.1	2	Right	1	0	2

No collisions occur in the plot.

Output 45.18 *Plot with Labels Placed to Avoid Collisions*



Example 12: Adjusting Labeling on a Plot with a Macro

Features:

PROC PLOT statement option
- FORMCHAR

PLOT statement

PLOT statement option
- BOX=
- LIST=
- HAXIS=
- VAXIS=
- VSPACE=

%IF statement

%MACRO statement

Data set: CENSUS

Details

This example illustrates the default placement of labels and uses a macro to adjust the placement of labels. The labels are values of a variable in the data set "CENSUS" on page 2748.

Program

```
options formchar="|----|+|---+=|-/\<>*";

%macro place(n);
   %if &n > 13 %then %let n = 13;
       placement=(
   %if &n <= 0 %then (s=center); %else (h=2 -2 : s=right left);
   %if &n = 1 %then (v=1 * h=0 -1 to -2 by alt);
   %else %if &n = 2 %then (v=1 -1 * h=0 -1 to -5 by alt);
   %else %if &n > 2 %then (v=1 to 2 by alt * h=0 -1 to -10 by alt);
   %if &n > 3 %then
       (s=center right left * v=0 1 to %eval(&n - 2) by alt *
       h=0 -1 to %eval(-3 * (&n - 2)) by alt *
       l=1 to %eval(2 + (10 * &n - 35) / 30)); )
   %if &n > 4 %then penalty(7)=%eval((3 * &n) / 2);
%mend;

proc plot data=census;
   plot density*crimerate=state $ state /

           box
           list=1
           haxis=by 1000
           vaxis=by 250
           vspace=12
           %place(4);

   title 'A Plot of Population Density and Crime Rates';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Use conditional logic to determine placement. The %PLACE macro provides an alternative to using the PLACEMENT= option. The higher the value of n , the more freedom PROC PLOT has to place labels.

```
%macro place(n);
```

```
   %if &n > 13 %then %let n = 13;
       placement=(
   %if &n <= 0 %then (s=center); %else (h=2 -2 : s=right left);
   %if &n = 1 %then (v=1 * h=0 -1 to -2 by alt);
   %else %if &n = 2 %then (v=1 -1 * h=0 -1 to -5 by alt);
   %else %if &n > 2 %then (v=1 to 2 by alt * h=0 -1 to -10 by alt);
   %if &n > 3 %then
       (s=center right left * v=0 1 to %eval(&n - 2) by alt *
       h=0 -1 to %eval(-3 * (&n - 2)) by alt *
       l=1 to %eval(2 + (10 * &n - 35) / 30)); )
   %if &n > 4 %then penalty(7)=%eval((3 * &n) / 2);
%mend;
```

Create the plot. The plot request plots Density on the vertical axis, CrimeRate on the horizontal axis, and uses the first letter of the value of State as the plotting symbol. The label variable specification ($ state) in the PLOT statement t labels each point with the corresponding state name.

```
proc plot data=census;
   plot density*crimerate=state $ state /
```

Specify plot options. BOX draws a box around the plot. LIST= lists the labels that have penalties greater than or equal to 1. HAXIS= and VAXIS= specify increments only. PROC PLOT uses the data to determine the range for the axes. The VSPACE=12 option specifies that there are 12 spaces between tick marks on the vertical axis. The PLACE macro determines the placement of the labels.

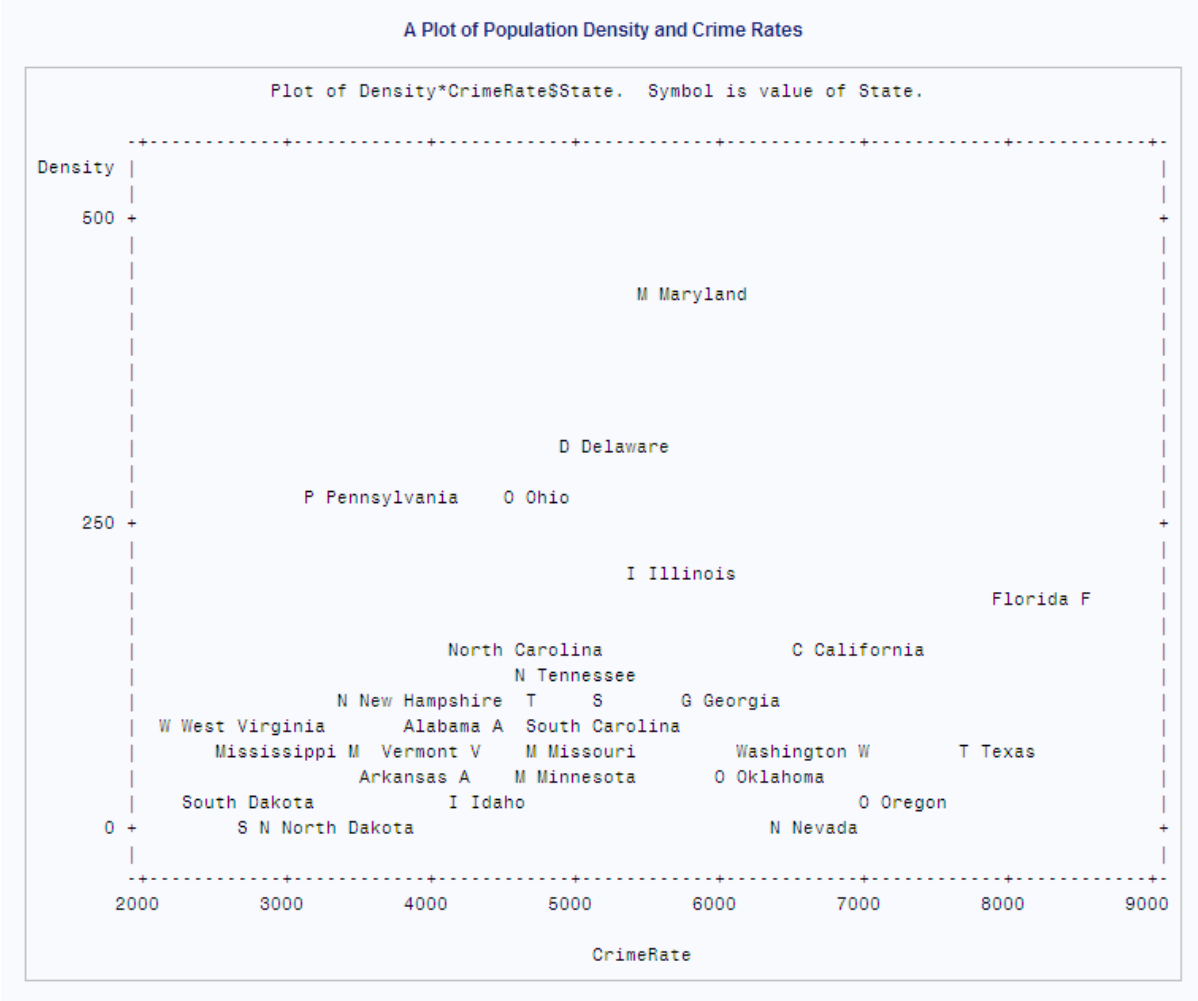
```
            box
            list=1
            haxis=by 1000
            vaxis=by 250
            vspace=12
            %place(4);
```

Specify the title.

```
   title 'A Plot of Population Density and Crime Rates';
run;
```

Output

Output 45.19 *Plot with Labels Placed Using a Macro*



Example 13: Changing a Default Penalty

Features:
- PROC PLOT statement option
  - FORMCHAR
- PLOT statement
- PLOT statement option
  - HAXIS=
  - LIST=
  - PENALTIES=
  - PLACEMENT=
  - VAXIS=
  - VSPACE=

Data set: CENSUS

Details

This example demonstrates how changing a default penalty affects the placement of labels. The goal is to produce a plot that has labels that do not detract from how the points are scattered.

Program

```
options formchar="|----|+|---+=|-/\<>*";

   proc plot data=census;
      plot density*crimerate=state $ state /

           placement=(h=100 to 10 by alt * s=left right)

           penalties(4)=500  list=0

           haxis=0 to 13000 by 1000
           vaxis=by 100
           vspace=5;

   title 'A Plot of Population Density and Crime Rates';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";

   proc plot data=census;
      plot density*crimerate=state $ state /
```

Specify the placement. PLACEMENT= specifies that the preferred placement states are 100 columns to the left and the right of the point, on the same line with the point.

```
           placement=(h=100 to 10 by alt * s=left right)
```

Change the default penalty. PENALTIES(4)= changes the default penalty for a free horizontal shift to 500, which removes all penalties for a horizontal shift. LIST= shows how far PROC PLOT shifted the labels away from their respective points.

```
           penalties(4)=500  list=0
```

Customize the axes. HAXIS= creates a horizontal axis long enough to leave space for the labels on the sides of the plot. VAXIS= specifies that the values on the vertical axis be in increments of 100. The VSPACE=5 option specifies that there are 5 spaces between tick marks on the vertical axis.

```
         haxis=0 to 13000 by 1000
         vaxis=by 100
         vspace=5;
```

Specify the title.

```
   title 'A Plot of Population Density and Crime Rates';
run;
```

Output

Output 45.20 *Plot with Default Penalties Adjusted*

A Plot of Population Density and Crime Rates

```
                              Plot of Density*CrimeRate$State.  Symbol is value of State.

PMENU Procedure

Overview: PMENU Procedure

What Does the PMENU Procedure Do?

The PMENU procedure defines menus that can be used in DATA step windows, macro windows, both SAS/AF and SAS/FSP windows, or in any SAS application that enables you to specify customized menus.

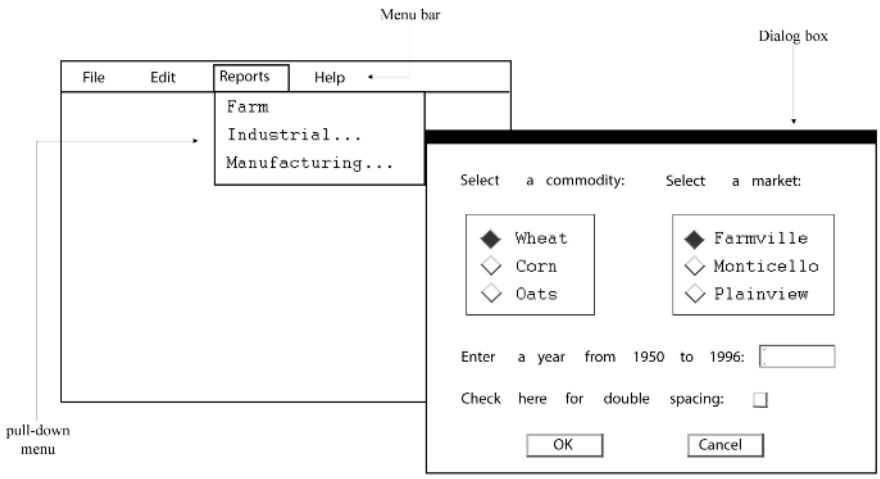
Menus can replace the command line as a way to execute commands. To activate menus, issue the PMENU command from any command line. Menus must be activated in order for them to appear.

The PMENU procedure produces no immediately visible output. It simply builds a catalog entry of type PMENU that can be used later in an application.

SAS Menus

When menus are activated, each active window has a menu bar, which lists items that you can select. Depending on which item you select, SAS either processes a command, displays a menu or a submenu, or requests that you complete information in a dialog box. The dialog box is simply a box of questions or choices that require answers before an action can be performed. The following figure illustrates features that you can create with PROC PMENU.

Figure 46.1 *Menu Bar, Menu, and Dialog Box*



Note: A menu bar in some operating environments might appear as a pop-up menu or might appear at the bottom of the window.

Concepts: PMENU Procedure

Procedure Execution

Initiating the Procedure

You can define multiple menus by separating their definitions with RUN statements. A group of statements that ends with a RUN statement is called a RUN group. You must completely define a PMENU catalog entry before submitting a RUN statement. You do not have to restart the procedure after a RUN statement.

You must include an initial MENU statement that defines the menu bar, and you must include all ITEM statements and any SELECTION, MENU, SUBMENU, and DIALOG statements as well as statements that are associated with the DIALOG statement within the same RUN group. For example, the following statements define two separate PMENU catalog entries. Both are stored in the same catalog, but each PMENU catalog entry is independent of the other. In the example, both PMENU catalog entries create menu bars that simply list windowing environment commands the user can select and execute:

```
libname proclib 'SAS-data-library';

proc pmenu catalog=proclib.mycat;
   menu menu1;
   item end;
   item bye;
run;

   menu menu2;
   item end;
   item pgm;
   item log;
   item output;
run;
```

When you submit these statements, you receive a message that says that the PMENU entries have been created. To display one of these menu bars, you must associate the PMENU catalog entry with a window and then activate the window

with the menus turned on, as described in "Steps for Building and Using PMENU Catalog Entries" on page 1694.

Ending the Procedure

Submit a QUIT, DATA, or new PROC statement to execute any statements that have not executed and end the PMENU procedure. Submit a RUN CANCEL statement to cancel any statements that have not executed and end the PMENU procedure.

Steps for Building and Using PMENU Catalog Entries

In most cases, building and using PMENU entries requires the following steps:

1. Use PROC PMENU to define the menu bars, menus, and other features that you want. Store the output of PROC PMENU in a SAS catalog. For more information, see "Associating a Menu with a Window" on page 1732.
2. Define a window using SAS/AF and SAS/FSP software, or the WINDOW or %WINDOW statement in Base SAS software.
3. Associate the PMENU catalog entry created in step 1 with a window by using one of the following:
   - the MENU= option in the WINDOW statement in Base SAS software. For more information, see "Associating a Menu with a Window" on page 1732.
   - the MENU= option in the %WINDOW statement in the macro facility.
   - the **Command Menu** field in the GATTR window in PROGRAM entries in SAS/AF software.
   - the Keys, Pmenu, and **Commands** window in a FRAME entry in SAS/AF software. See "Example 5: Associating Menus with a FRAME Application" on page 1735.
   - the PMENU function in SAS/AF and SAS/FSP software.
   - the SETPMENU command in SAS/FSP software. See "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713.
4. Activate the window that you created. Make sure that the menus are turned on.

Templates for Coding PROC PMENU Steps

The following coding templates summarize how to use the statements in the PMENU procedure. Refer to descriptions of the statements for more information:

- Build a simple menu bar. All items on the menu bar are windowing environment commands:

```
proc pmenu;
   menu menu-bar;
   item command;
   ...more-ITEM-statements...
run;
```

- Create a menu bar with an item that produces a menu:

```
proc pmenu;
    menu menu-bar;
    item 'menu-item' menu=pull-down-menu;
    ...more-ITEM-statements...
    menu pull-down-menu;
    ...ITEM-statements-for-pull-down-menu...
run;
```

- Create a menu bar with an item that submits a command other than the one that appears on the menu bar:

```
proc pmenu;
   menu menu-bar;
   item 'menu-item' selection=selection;
   ...more-ITEM-statements...
   selection selection 'command-string';
run;
```

- Create a menu bar with an item that opens a dialog box, which displays information and requests text input:

```
proc pmenu;
   menu menu-bar;
   item 'menu-item' menu=pull-down-menu;
   ...more-ITEM-statements...
   menu pull-down-menu;
      item 'menu-item' dialog=dialog-box;
      dialog dialog-box 'command @1';
         text #line @column 'text';
         text #line @column LEN=field-length;
run;
```

- Create a menu bar with an item that opens a dialog box, which permits one choice from a list of possible values:

```
proc pmenu;
   menu menu-bar;
   item 'menu-item' menu=pull-down-menu;
   ...more-ITEM-statements...
   menu pull-down-menu;
```

```
      item 'menu-item' dialog=dialog-box;
      dialog dialog-box 'command %1';
         text #line @column 'text';
         radiobox default=button-number;
         rbutton #line @column
                 'text-for-selection';
         ...more-RBUTTON-statements...
run;
```

- Create a menu bar with an item that opens a dialog box, which permits several independent choices:

```
proc pmenu;
   menu menu-bar;
   item 'menu-item' menu=pull-down-menu;
   ...more-ITEM-statements...
   menu pull-down-menu;
      item 'menu-item' dialog=dialog-box;
      dialog dialog-box 'command &1';
         text #line @column 'text';
         checkbox #line @column 'text';
         ...more-CHECKBOX-statements...
run;
```

Syntax: PMENU Procedure

Restriction: You must use at least one MENU statement followed by at least one ITEM statement.

Tips: Supports RUN group processing

You can also use any global statement. For a list, see "Global Statements" on page 25 and "Dictionary of SAS Global Statements" in *SAS Global Statements: Reference*.

See: "PMENU Procedure: Windows" in *SAS Companion for Windows*

"PMENU Procedure: UNIX" in *SAS Companion for UNIX Environments*

"PMENU Procedure Statement: z/OS" in *SAS Companion for z/OS*

PROC PMENU <CATALOG=<*libref.*>*catalog*>
<DESC *'entry-description'*>;

MENU *menu-bar*;

ITEM *command* <*options*> <*action-options*>;

ITEM *'menu-item'* <*options*> <*action-options*>;

DIALOG *dialog-box 'command-string field-number-specification'*;

CHECKBOX <ON> #*line* @*column 'text-for-selection'*
<COLOR=*color*> <SUBSTITUTE=*'text-for-substitution'*>;

RADIOBOX DEFAULT=*button-number*;

RBUTTON <NONE> #*line* @*column'text-for-selection'*
<COLOR=*color*> <SUBSTITUTE=*'text-for-substitution'*>;

TEXT #*line* @*column field-description*
<ATTR=*attribute*> <COLOR=*color*>;

MENU *pull-down-menu*;

SELECTION *selection* '*command-string*';

SEPARATOR;

SUBMENU *submenu-name SAS-file*;

Statement	Task	Example
PROC PMENU	Define customized menus	Ex. 1
CHECKBOX	Define choices a user can make in a dialog box	
DIALOG	Describe a dialog box that is associated with an item in a menu	Ex. 2, Ex. 3, Ex. 4
ITEM	Identify an item to be listed in a menu bar or in a menu	Ex. 1, Ex. 3, Ex. 5
MENU	Name the catalog entry or define a menu	Ex. 1, Ex. 5
RADIOBOX	List and define mutually exclusive choices within a dialog box	Ex. 3
RBUTTON	List and define mutually exclusive choices within a dialog box	Ex. 3
SELECTION	Define a command that is submitted when an item is selected	Ex. 1, Ex. 4
SEPARATOR	Draw a line between items in a menu	
SUBMENU	Define a common submenu associated with an item	Ex. 1
TEXT	Specify text and the input fields for a dialog box	Ex. 2

PROC PMENU Statement

Invokes the PMENU procedure and specifies where to store all PMENU catalog entries that are created in the PROC PMENU step.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Example: "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713

Syntax

PROC PMENU <CATALOG=<*libref*.>*catalog*>
<DESC *'entry-description'*>;

Optional Arguments

CATALOG=<*libref*.>*catalog*
specifies the catalog in which you want to store PMENU entries.

Default If you omit *libref*, then the PMENU entries are stored in a catalog in the SASUSER library. If you omit CATALOG=, then the entries are stored in the SASUSER.PROFILE catalog.

Example "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713

DESC *'entry-description'*
provides a description for the PMENU catalog entries created in the step.

Default Menu description

Note These descriptions are displayed when you use the CATALOG window in the windowing environment or the CONTENTS statement in the CATALOG procedure.

CHECKBOX Statement

Defines choices that a user can make within a dialog box.

Restriction: Must be used after a DIALOG statement.

Syntax

CHECKBOX <ON> #*line* @*column* '*text-for-selection*'
<COLOR=*color*> <SUBSTITUTE='*text-for-substitution*'>;

Required Arguments

column
specifies the column in the dialog box where the check box and text are placed.

line
specifies the line in the dialog box where the check box and text are placed.

text-for-selection
defines the text that describes this check box. This text appears in the window and, if the SUBSTITUTE= option is not used, is also inserted into the command in the preceding DIALOG statement when the user selects the check box.

Optional Arguments

COLOR=*color*
defines the color of the check box and the text that describes it.

ON
indicates that by default this check box is active. If you use this option, then you must specify it immediately after the CHECKBOX keyword.

SUBSTITUTE='*text-for-substitution*'
specifies the text that is to be inserted into the command in the DIALOG statement.

Details

Check Boxes in a Dialog Box

Each CHECKBOX statement defines a single item that the user can select independent of other selections. That is, if you define five choices with five CHECKBOX statements, then the user can select any combination of these choices. When the user selects choices, the text-for-selection values that are associated with the selections are inserted into the command string of the previous DIALOG statement at field locations prefixed by an ampersand (&).

DIALOG Statement

Describes a dialog box that is associated with an item on a menu.

Restriction: Must be followed by at least one TEXT statement.

Examples:
"Example 2: Collecting User Input in a Dialog Box" on page 1716
"Example 3: Creating a Dialog Box to Search Multiple Variables" on page 1719
"Example 4: Creating Menus for a DATA Step Window Application" on page 1727

Syntax

DIALOG *dialog-box* '*command-string field-number-specification*';

Required Arguments

command-string

is the command or partial command that is executed when the item is selected. The limit of the *command-string* that results after the substitutions are made is the command-line limit for your operating environment. Typically, the command-line limit is approximately 80 characters.

The limit for '*command-string field-number-specification*' is 200 characters.

Note: If you are using PROC PMENU to submit any command that is valid only in the PROGRAM EDITOR window (such as the INCLUDE command), then you must have the windowing environment running, and you must return control to the PROGRAM EDITOR window.

dialog-box

is the same name specified for the DIALOG= option in a previous ITEM statement.

field-number-specification

can be one or more of the following:

@1...@*n* %1...%*n* &1...&*n*

You can embed the field numbers, for example, @1, %1, or &1, in the command string and mix different types of field numbers within a command string. The numeric portion of the field number corresponds to the relative position of TEXT, RADIOBOX, and CHECKBOX statements, not to any actual number in these statements.

@1...@*n*

are optional TEXT statement numbers that can add information to the command before it is submitted. Numbers preceded by an at sign (@) correspond to TEXT statements that use the LEN= option to define input fields.

%1...%*n*

are optional RADIOBOX statement numbers that can add information to the command before it is submitted. Numbers preceded by a percent sign (%) correspond to RADIOBOX statements following the DIALOG statement.

Note Keep in mind that the numbers correspond to RADIOBOX statements, not to RBUTTON statements.

&1...&*n*

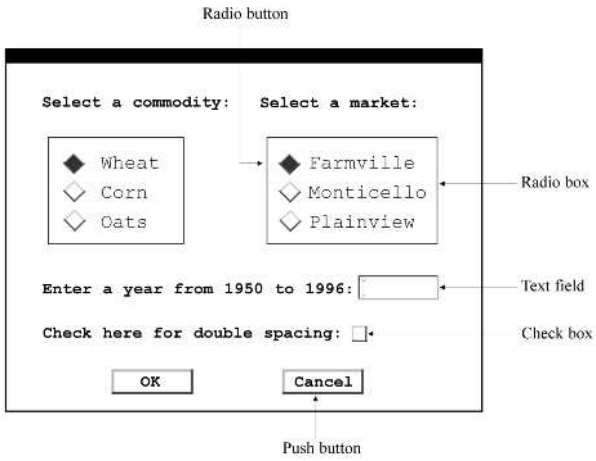
are optional CHECKBOX statement numbers that can add information to the command before it is submitted. Numbers preceded by an ampersand (&) correspond to CHECKBOX statements following the DIALOG statement.

Note To specify a literal @ (at sign), % (percent sign), or & (ampersand) in the *command-string*, use a double character: @@ (at signs), %% (percent signs), or && (ampersands).

Details

- You cannot control the placement of the dialog box. The dialog box is not scrollable. The size and placement of the dialog box are determined by your windowing environment.
- To use the DIALOG statement, specify an ITEM statement with the DIALOG= option in the ITEM statement.
- The ITEM statement creates an entry in a menu bar or in a menu, and the DIALOG= option specifies which DIALOG statement describes the dialog box.
- You can use CHECKBOX, RADIOBOX, and RBUTTON statements to define the contents of the dialog box.
- The following figure shows a typical dialog box. A dialog box can request information in three ways:
  - Fill in a field. Fields that accept text from a user are called text fields.
  - Choose from a list of mutually exclusive choices. A group of selections of this type is called a radio button, and each individual selection is called a radio button.
  - Indicate whether you want to select other independent choices. For example, you could choose to use various options by selecting any or all of the listed selections. A selection of this type is called a check box.

Figure 46.2 *A Typical Dialog Box*



Dialog boxes have two or more buttons, such as OK and Cancel, automatically built into the box. A button causes an action to occur.

Note: The actual names of the buttons vary in different windowing environments.

ITEM Statement

Identifies an item to be listed in a menu bar or in a menu.

Examples:
"Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713
"Example 3: Creating a Dialog Box to Search Multiple Variables" on page 1719
"Example 5: Associating Menus with a FRAME Application" on page 1735

Syntax

ITEM *command* <*options*> <*action-options*>;
ITEM '*menu-item*' <*options*> <*action-options*>;

Summary of Optional Arguments

ACCELERATE=*name-of-key*
: defines a key sequence that can be used instead of selecting an item.

action-option
: specifies the action for the item.

GRAY
: indicates that the item is not an active choice in this window.

HELP='*help-text*'
: specifies text that is displayed when the user displays the menu item.

ID=*integer*
: specifies a value that is used as an identifier for an item in a menu.

MNEMONIC=*character*
: defines a single character that can select the item.

STATE=CHECK | RADIO
: places a check box or a radio button next to an item.

Required Arguments

command
: a single word that is a valid SAS command for the window in which the menu appears. Commands that are more than one word, such as WHERE CLEAR, must be enclosed in single quotation marks. The *command* appears in uppercase letters on the menu bar.

  If you want to control the case of a SAS command on the menu, then enclose the command in single quotation marks. The case that you use then appears on the menu.

'menu-item'
a word or text string, enclosed in quotation marks, that describes the action that occurs when the user selects this item. A menu item should not begin with a percent sign (%).

Optional Arguments

ACCELERATE=*name-of-key*
defines a key sequence that can be used instead of selecting an item. When the user presses the key sequence, it has the same effect as selecting the item from the menu bar or menu.

Restrictions The functionality of this option is limited to only a few characters. For details, see the SAS documentation for your operating environment.

This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

action-option
is one of the following:

DIALOG=*dialog-box*
specifies the name of an associated DIALOG statement, which displays a dialog box when the user selects this item.

Example "Example 3: Creating a Dialog Box to Search Multiple Variables" on page 1719

MENU=*pull-down-menu*
specifies the name of an associated MENU statement, which displays a menu when the user selects this item.

See "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713

SELECTION=*selection*
specifies the name of an associated SELECTION statement, which submits a command when the user selects this item.

See "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713

SUBMENU=*submenu*
associates the item with a common submenu.

specifies the name of an associated SUBMENU statement, which displays a pmenu entry when the user selects this item.

See "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713

If no DIALOG=, MENU=, SELECTION=, or SUBMENU= option is specified, then the *command* or *menu-item* text string is submitted as a command-line command when the user selects the item.

GRAY
indicates that the item is not an active choice in this window. This option is useful when you want to define standard lists of items for many windows, but not all items are valid in all windows. When this option is set and the user selects the item, no action occurs.

HELP='*help-text*'
specifies text that is displayed when the user displays the menu item. For example, if you use a mouse to pull down a menu, then position the mouse pointer over the item and the text is displayed.

Restriction This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

Tip The place where the text is displayed is operating environment-specific.

ID=*integer*
specifies a value that is used as an identifier for an item in a menu. This identifier is used within a SAS/AF application to selectively activate or deactivate items in a menu or to set the state of an item as a check box or a radio button.

Restrictions Integers from 0 to 3000 are reserved for operating environment and SAS use.

This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

Note The minimum value allowed is 3001.

Tips ID= is useful with the WINFO function in SAS Component Language.

You can use the same ID for more than one item.

See "STATE=CHECK | RADIO" on page 1705

MNEMONIC=*character*
underlines the first occurrence of *character* in the text string that appears on the menu. The *character* must be in the text string.

The *character* is typically used in combination with another key, such as Alt. When you use the key sequence, it has the same effect as putting your cursor on the item. But it *does not* invoke the action that the item controls.

Restriction This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

STATE=CHECK | RADIO
provides the ability to place a check box or a radio button next to an item that has been selected.

Restriction This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

Tip STATE= is used with the ID= option and the WINFO function in SAS Component Language.

Details

Defining Items on the Menu Bar

You must use ITEM statements to name all the items that appear in a menu bar. You also use the ITEM statement to name the items that appear in any menus. The items that you specify in the ITEM statement can be commands that are issued when the user selects the item, or they can be descriptions of other actions that are performed by associated DIALOG, MENU, SELECTION, or SUBMENU statements.

All ITEM statements for a menu must be placed immediately after the MENU statement and before any DIALOG, SELECTION, SUBMENU, or other MENU statements. In some operating environments, you can insert SEPARATOR statements between ITEM statements to produce lines separating groups of items in a menu. For more information, see "SEPARATOR Statement" on page 1710.

Note: If you specify a menu bar that is too long for the window, then it might be truncated or wrapped to multiple lines.

MENU Statement

Names the catalog entry that stores the menus or defines a menu.

Examples: "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713
"Example 5: Associating Menus with a FRAME Application" on page 1735

Syntax

MENU *menu-bar*;

MENU *pull-down-menu*;

Required Arguments

One of the following arguments is required:

menu-bar
names the catalog entry that stores the menus.

pull-down-menu
names the menu that appears when the user selects an item in the menu bar. The value of *pull-down-menu* must match the *pull-down-menu* name that is specified in the MENU= option in a previous ITEM statement.

Details

Defining Menus

When used to define a menu, the MENU statement must follow an ITEM statement that specifies the MENU= option. Both the ITEM statement and the MENU statement for the menu must be in the same RUN group as the MENU statement that defines the menu bar for the PMENU catalog entry.

For both menu bars and menus, follow the MENU statement with ITEM statements that define each of the items that appear on the menu. Group all ITEM statements for a menu together. For example, the following PROC PMENU step creates one catalog entry, WINDOWS, which produces a menu bar with two items, **Primary windows** and **Other windows**. When you select one of these items, a menu is displayed.

```
libname proclib 'SAS-data-library';

proc pmenu cat=proclib.mycat;

      /* create catalog entry */
   menu windows;
   item 'Primary windows' menu=prime;
   item 'Other windows' menu=other;

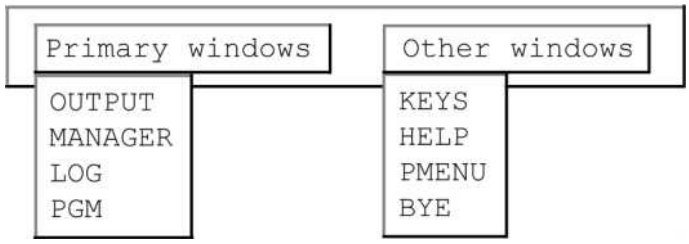
      /* create first menu */
   menu prime;
   item output;
   item manager;
   item log;
   item pgm;

      /* create second menu */
   menu other;
   item keys;
   item help;
   item pmenu;
   item bye;

   /* end of run group */
run;
```

The following figure shows the resulting menu selections.

Figure 46.3 *Menu*



RADIOBOX Statement

Defines a box that contains mutually exclusive choices within a dialog box.

Restrictions: Must be used after a DIALOG statement.

Must be followed by one or more RBUTTON statements.

Example: "Example 3: Creating a Dialog Box to Search Multiple Variables" on page 1719

Syntax

RADIOBOX DEFAULT=*button-number*;

Required Argument

DEFAULT=*button-number*
indicates which radio button is the default.

Default 1

Details

The RADIOBOX statement indicates the beginning of a list of selections. Immediately after the RADIOBOX statement, you must list an RBUTTON statement for each of the selections the user can make. When the user makes a choice, the text value that is associated with the selection is inserted into the command string of the previous DIALOG statement at field locations prefixed by a percent sign (%).

RBUTTON Statement

Lists mutually exclusive choices within a dialog box.

Restriction: Must be used after a RADIOBOX statement.

Example: "Example 3: Creating a Dialog Box to Search Multiple Variables" on page 1719

Syntax

RBUTTON <NONE> #*line* @*column*'*text-for-selection*'
<COLOR=*color*> <SUBSTITUTE='*text-for-substitution*'>;

Required Arguments

column
specifies the column in the dialog box where the radio button and text are placed.

line
specifies the line in the dialog box where the radio button and text are placed.

text-for-selection
defines the text that appears in the dialog box and, if the SUBSTITUTE= option is not used, defines the text that is inserted into the command in the preceding DIALOG statement.

Note: Be careful not to overlap columns and lines when placing text and radio buttons. If you overlap text and buttons, Then you will get an error message. Also, specify space between other text and a radio button.

Optional Arguments

COLOR=*color*
defines the color of the radio button and the text that describes the button.

Restriction This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

NONE
defines a button that indicates none of the other choices. Defining this button enables the user to ignore any of the other choices. No characters, including blanks, are inserted into the DIALOG statement.

Restriction If you use this option, then it must appear immediately after the RBUTTON keyword.

SUBSTITUTE='*text-for-substitution*'
specifies the text that is to be inserted into the command in the DIALOG statement.

See "Example 3: Creating a Dialog Box to Search Multiple Variables" on page 1719

SELECTION Statement

Defines a command that is submitted when an item is selected.

Restriction: Must be used after an ITEM statement

Examples: "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713
"Example 4: Creating Menus for a DATA Step Window Application" on page 1727

Syntax

SELECTION *selection* '*command-string*';

Required Arguments

selection
is the same name specified for the SELECTION= option in a previous ITEM statement.

command-string
is a text string, enclosed in quotation marks, that is submitted as a command-line command when the user selects this item. There is a limit of 200 characters for *command-string*. However, the command-line limit of approximately 80 characters cannot be exceeded. The command-line limit differs slightly for various operating environments.

Note: SAS uses only the first eight characters of an item that is specified with a SELECTION statement. When a user selects an item from a menu list, the first eight characters of each item name in the list must be unique so that SAS can select the correct item in the list. If the first eight characters are not unique, SAS selects the last item in the list.

Details

You define the name of the item in the ITEM statement and specify the SELECTION= option to associate the item with a subsequent SELECTION

statement. The SELECTION statement then defines the actual command that is submitted when the user chooses the item in the menu bar or menu.

You are likely to use the SELECTION statement to define a command string. You create a simple alias by using the ITEM statement, which invokes a longer command string that is defined in the SELECTION statement. For example, you could include an item in the menu bar that invokes a WINDOW statement to enable data entry. The actual commands that are processed when the user selects this item are the commands to include and submit the application.

Note: If you are using PROC PMENU to issue any command that is valid only in the PROGRAM EDITOR window (such as the INCLUDE command), then you must have the windowing environment running. Also, you must return control to the PROGRAM EDITOR window.

SEPARATOR Statement

Draws a line between items on a menu.

Restrictions: Must be used after an ITEM statement.

Not available in all operating environments.

Syntax

SEPARATOR;

SUBMENU Statement

Specifies the SAS file that contains a common submenu associated with an item.

Example: "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713

Syntax

SUBMENU *submenu-name SAS-file*;

Required Arguments

submenu-name
specifies a name for the submenu statement. To associate a submenu with a menu item, *submenu-name* must match the submenu name specified in the SUBMENU= action-option in the ITEM statement.

SAS-file
specifies the name of the SAS file that contains the common submenu.

TEXT Statement

Specifies text and the input fields for a dialog box.

Restriction: Can be used only after a DIALOG statement.

Example: "Example 2: Collecting User Input in a Dialog Box" on page 1716

Syntax

TEXT #*line* @*column field-description*
<ATTR=*attribute*> <COLOR=*color*>;

Required Arguments

column
specifies the starting column for the text or input field.

field-description
defines how the TEXT statement is used. The *field-description* can be one of the following:

LEN=***field-length***
is the length of an input field in which the user can enter information. If the LEN= argument is used, then the information entered in the field is inserted into the command string of the previous DIALOG statement at field locations that are prefixed by an at sign (@).

See "Example 2: Collecting User Input in a Dialog Box" on page 1716

'text'
is the text string that appears inside the dialog box at the location defined by *line* and *column*.

line
specifies the line number for the text or input field.

Optional Arguments

ATTR=*attribute*
defines the attribute for the text or input field. These are valid attribute values:

- BLINK
- HIGHLIGH
- REV_VIDE
- UNDERLIN

Restrictions This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

Your hardware might not support all of these attributes.

COLOR=*color*
defines the color for the text or input field characters. Here are the color values that you can use:

BLACK	BROWN
GRAY	MAGENTA
PINK	WHITE
BLUE	CYAN
GREEN	ORANGE
RED	YELLOW

Restrictions This option is not available in all operating environments. If you include this option and it is not available in your operating environment, then the option is ignored.

Your hardware might not support all of these colors.

Examples: PMENU Procedure

Example 1: Building a Menu Bar for an FSEDIT Application

Features:

PROC PMENU statement option
CATALOG=

ITEM statement options
MENU=
SELECTION=
SUBMENU=

MENU statement

SELECTION statement

SUBMENU statement

Details

This example creates a menu bar that can be used in an FSEDIT application to replace the default menu bar. The selections available on these menus do not enable end users to delete or duplicate observations.

Note:

- The windows in the PROC PMENU examples were produced in the UNIX environment and might appear slightly different from the same windows in other operating environments.
- You should know the operating environment-specific system options that can affect how menus are displayed and merged with existing SAS menus. For details, see the SAS documentation for your operating environment.

Program

```
libname proclib
```

```
'SAS-data-library';

proc pmenu catalog=proclib.menucat;

   menu project;

      item 'File' menu=f;
      item 'Edit' submenu=editmnu;
      item 'Scroll' menu=s;
      item 'Help' menu=h;

      menu f;
         item 'Goback' selection=g;
         item 'Save';
         selection g 'end';

      submenu editmnu sashelp.core.edit;

      menu s;
         item 'Next Obs' selection=n;
         item 'Prev Obs' selection=p;
         item 'Top';
         item 'Bottom';
         selection n 'forward';
         selection p 'backward';

      menu h;
         item 'Keys';
         item 'About this application' selection=hlp;
         selection hlp 'sethelp user.menucat.staffhlp.help;help';
quit;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store menu definitions.

```
libname proclib
'SAS-data-library';
```

Specify the catalog for storing menu definitions. Menu definitions will be stored in the PROCLIB.MENUCAT catalog.

```
proc pmenu catalog=proclib.menucat;
```

Specify the name of the catalog entry. The MENU statement specifies PROJECT as the name of the catalog entry. The menus are stored in the catalog entry PROCLIB.MENUCAT.PROJECT.PMENU.

```
   menu project;
```

Design the menu bar. The ITEM statements specify the items for the menu bar. The value of the MENU= option is used in a subsequent MENU statement. The Edit item uses a common predefined submenu; the menus for the other items are defined in this PROC step.

```
      item 'File' menu=f;
      item 'Edit' submenu=editmnu;
      item 'Scroll' menu=s;
      item 'Help' menu=h;
```

Design the File menu. This group of statements defines the selections available under File on the menu bar. The first ITEM statement specifies `Goback` as the first selection under File. The value of the SELECTION= option corresponds to the subsequent SELECTION statement, which specifies END as the command that is issued for that selection. The second ITEM statement specifies that the SAVE command is issued for that selection.

```
menu f;
   item 'Goback' selection=g;
   item 'Save';
   selection g 'end';
```

Add the EDITMNU submenu. The SUBMENU statement associates a predefined submenu that is located in the SAS file SASHELP.CORE.EDIT with the Edit item on the menu bar. The name of this SUBMENU statement is EDITMNU, which corresponds with the name in the SUBMENU= action-option in the ITEM statement for the Edit item.

```
submenu editmnu sashelp.core.edit;
```

Design the Scroll menu. This group of statements defines the selections available under Scroll on the menu bar.

```
menu s;
   item 'Next Obs' selection=n;
   item 'Prev Obs' selection=p;
   item 'Top';
   item 'Bottom';
   selection n 'forward';
   selection p 'backward';
```

Design the Help menu. This group of statements defines the selections available under Help on the menu bar. The SETHELP command specifies a HELP entry that contains user-written information for this FSEDIT application. The semicolon that appears after the HELP entry name enables the HELP command to be included in the string. The HELP command invokes the HELP entry.

```
menu h;
   item 'Keys';
   item 'About this application' selection=hlp;
   selection hlp 'sethelp user.menucat.staffhlp.help;help';
quit;
```

Associating a Menu Bar with an FSEDIT Session

The following SETPMENU command associates the customized menu bar with the FSEDIT window.

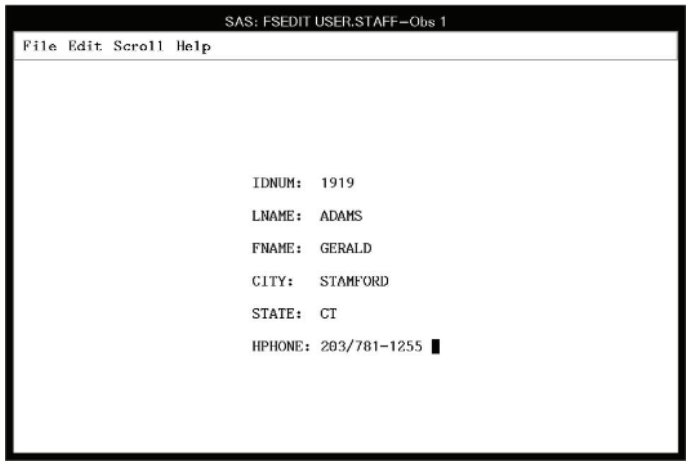
```
setpmenu proclib.menucat.project.pmenu;pmenu on
```

You can also specify the menu bar on the command line in the FSEDIT session or by issuing a CALL EXECCMD command in SAS Component Language (SCL).

For other methods of associating the customized menu bar with the FSEDIT window, see “Associating a Menu Bar with an FSEDIT Session” on page 1724.

The following FSEDIT window shows the menu bar:

Figure 46.4 *Example of a Menu Bar in an FSEDIT Window*



Example 2: Collecting User Input in a Dialog Box

Features: DIALOG statement
TEXT statement option
LEN=

Details

This example adds a dialog box to the menus created in "Example 1: Building a Menu Bar for an FSEDIT Application" on page 1713. The dialog box enables the user to use a WHERE clause to subset the SAS data set.

Tasks include these:

- collecting user input in a dialog box
- creating customized menus for an FSEDIT application

Program

```
libname proclib
'SAS-data-library';

proc pmenu catalog=proclib.menucat;

   menu project;
```

```
      item 'File' menu=f;
      item 'Edit' menu=e;
      item 'Scroll' menu=s;
      item 'Subset' menu=sub;
      item 'Help' menu=h;

      menu f;
         item 'Goback' selection=g;
         item 'Save';
         selection g 'end';

      menu e;
         item 'Cancel';
         item 'Add';

      menu s;
         item 'Next Obs' selection=n;
         item 'Prev Obs' selection=p;
         item 'Top';
         item 'Bottom';
         selection n 'forward';
         selection p 'backward';

      menu sub;
         item 'Where' dialog=d1;
         item 'Where Clear';

      menu h;
         item 'Keys';
         item 'About this application' selection=hlp;
         selection hlp 'sethelp proclib.menucat.staffhlp.help;help';

      dialog d1 'where @1';
         text #2 @3 'Enter a valid WHERE clause or UNDO';
         text #4 @3 'WHERE ';
         text #4 @10 len=40;
quit;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store menu definitions.

```
libname proclib
'SAS-data-library';
```

Specify the catalog for storing menu definitions. Menu definitions will be stored in the PROCLIB.MENUCAT catalog.

```
proc pmenu catalog=proclib.menucat;
```

Specify the name of the catalog entry. The MENU statement specifies PROJECT as the name of the catalog entry. The menus are stored in the catalog entry PROCLIB.MENUCAT.PROJECT.PMENU.

```
   menu project;
```

Design the menu bar. The ITEM statements specify the items for the menu bar. The value of the MENU= option is used in a subsequent MENU statement.

```
item 'File' menu=f;
item 'Edit' menu=e;
item 'Scroll' menu=s;
item 'Subset' menu=sub;
item 'Help' menu=h;
```

Design the File menu. This group of statements defines the selections under File on the menu bar. The first ITEM statement specifies `Goback` as the first selection under File. The value of the SELECTION= option corresponds to the subsequent SELECTION statement, which specifies END as the command that is issued for that selection. The second ITEM statement specifies that the SAVE command is issued for that selection.

```
menu f;
   item 'Goback' selection=g;
   item 'Save';
   selection g 'end';
```

Design the Edit menu. This group of statements defines the selections available under Edit on the menu bar.

```
menu e;
   item 'Cancel';
   item 'Add';
```

Design the Scroll menu. This group of statements defines the selections available under Scroll on the menu bar.

```
menu s;
   item 'Next Obs' selection=n;
   item 'Prev Obs' selection=p;
   item 'Top';
   item 'Bottom';
   selection n 'forward';
   selection p 'backward';
```

Design the Subset menu. This group of statements defines the selections available under Subset on the menu bar. The value d1 in the DIALOG= option is used in the subsequent DIALOG statement.

```
menu sub;
   item 'Where' dialog=d1;
   item 'Where Clear';
```

Design the Help menu. This group of statements defines the selections available under Help on the menu bar. The SETHELP command specifies a HELP entry that contains user-written information for this FSEDIT application. The semicolon enables the HELP command to be included in the string. The HELP command invokes the HELP entry.

```
menu h;
   item 'Keys';
   item 'About this application' selection=hlp;
   selection hlp 'sethelp proclib.menucat.staffhlp.help;help';
```

Design the dialog box. The DIALOG statement builds a WHERE command. The arguments for the WHERE command are provided by user input into the text entry fields described by the three TEXT statements. The @1 notation is a placeholder for user input in the text field. The TEXT statements specify the text in the dialog box and the length of the input field.

```
      dialog d1 'where @1';
         text #2 @3 'Enter a valid WHERE clause or UNDO';
         text #4 @3 'WHERE ';
         text #4 @10 len=40;
quit;
```

Associating a Menu Bar with an FSEDIT Window

The following SETPMENU command associates the customized menu bar with the FSEDIT window.

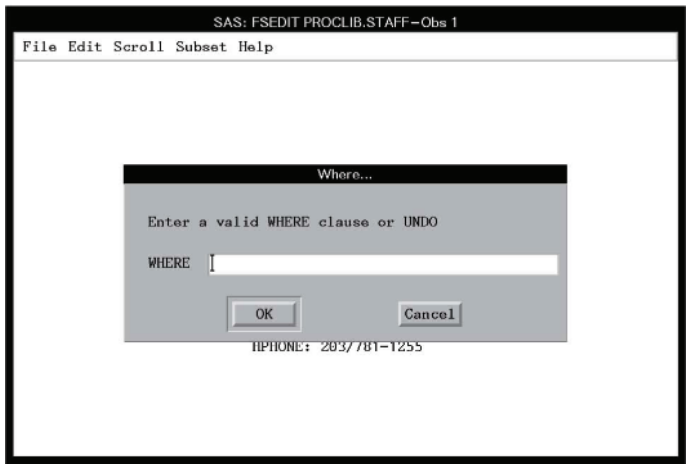
```
setpmenu proclib.menucat.project.pmenu;pmenu on
```

You can also specify the menu bar on the command line in the FSEDIT session or by issuing a CALL EXECCMD command in SAS Component Language (SCL). Refer to *SAS(R) Component Language 9.3: Reference* for complete documentation on SCL.

For other methods of associating the customized menu bar with the FSEDIT window, see "Associating a Menu Bar with an FSEDIT Session" on page 1724.

The following dialog box appears when the user chooses **Subset** and then **Where**.

Figure 46.5 *Example of a Where Dialog Box*



Example 3: Creating a Dialog Box to Search Multiple Variables

Features:

DIALOG statement
    SAS macro invocation

ITEM statement
    DIALOG= option

RADIOBOX statement option

DEFAULT=
RBUTTON statement option
SUBSTITUTE=
SAS macro invocation

Details

This example shows how to modify the menu bar in an FSEDIT session to enable a search for one value across multiple variables. The example creates customized menus to use in an FSEDIT session. The menu structure is the same as in the preceding example, except for the WHERE dialog box.

When selected, the menu item invokes a macro. The user input becomes values for macro parameters. The macro generates a WHERE command that expands to include all the variables needed for the search.

Tasks include these:

- associating customized menus with an FSEDIT session
- searching multiple variables with a WHERE clause
- extending PROC PMENU functionality with a SAS macro

Program

```
libname proclib
'SAS-data-library';

proc pmenu catalog=proclib.menucat;

   menu project;

      item 'File' menu=f;
      item 'Edit' menu=e;
      item 'Scroll' menu=s;
      item 'Subset' menu=sub;
      item 'Help' menu=h;

      menu f;
         item 'Goback' selection=g;
         item 'Save';
         selection g 'end';

      menu e;
         item 'Cancel';
         item 'Add';

      menu s;
         item 'Next Obs' selection=n;
         item 'Prev Obs' selection=p;
         item 'Top';
         item 'Bottom';
```

```
      selection n 'forward';
      selection p 'backward';

   menu sub;
      item 'Where' dialog=d1;
      item 'Where Clear';

   menu h;
      item 'Keys';
      item 'About this application' selection=hlp;
      selection hlp 'sethelp proclib.menucat.staffhlp.help;help';

    dialog d1 '%%wbuild(%1,%2,@1,%3)';

       text #1 @1 'Choose a region:';
       radiobox default=1;
          rbutton #3 @5 'Northeast' substitute='NE';
          rbutton #4 @5 'Northwest' substitute='NW';
          rbutton #5 @5 'Southeast' substitute='SE';
          rbutton #6 @5 'Southwest' substitute='SW';

       text #8 @1 'Choose a contaminant:';
       radiobox default=1;
          rbutton #10 @5  'Pollutant A' substitute='pol_a,2';
          rbutton #11 @5  'Pollutant B' substitute='pol_b,4';

       text #13 @1 'Enter Value for Search:';
       text #13 @25 len=6;

       text #15 @1 'Choose a comparison criterion:';
       radiobox default=1;
          rbutton #16 @5 'Greater Than or Equal To'
                         substitute='GE';
          rbutton #17 @5 'Less Than or Equal To'
                         substitute='LE';
          rbutton #18 @5 'Equal To' substitute='EQ';
quit;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store menu definitions.

```
libname proclib
'SAS-data-library';
```

Specify the catalog for storing menu definitions. Menu definitions will be stored in the PROCLIB.MENUCAT catalog.

```
proc pmenu catalog=proclib.menucat;
```

Specify the name of the catalog entry. The MENU statement specifies STAFF as the name of the catalog entry. The menus are stored in the catalog entry PROCLIB.MENUCAT.PROJECT.PMENU.

```
   menu project;
```

Design the menu bar. The ITEM statements specify the items for the menu bar. The value of the MENU= option is used in a subsequent MENU statement.

```
item 'File' menu=f;
item 'Edit' menu=e;
item 'Scroll' menu=s;
item 'Subset' menu=sub;
item 'Help' menu=h;
```

Design the File menu. This group of statements defines the selections under File on the menu bar. The first ITEM statement specifies `Goback` as the first selection under File. The value of the SELECTION= option corresponds to the subsequent SELECTION statement, which specifies END as the command that is issued for that selection. The second ITEM statement specifies that the SAVE command is issued for that selection.

```
menu f;
   item 'Goback' selection=g;
   item 'Save';
   selection g 'end';
```

Design the Edit menu. The ITEM statements define the selections under Edit on the menu bar.

```
menu e;
   item 'Cancel';
   item 'Add';
```

Design the Scroll menu. This group of statements defines the selections under Scroll on the menu bar. If the quoted string in the ITEM statement is not a valid command, then the SELECTION= option corresponds to a subsequent SELECTION statement, which specifies a valid command.

```
menu s;
   item 'Next Obs' selection=n;
   item 'Prev Obs' selection=p;
   item 'Top';
   item 'Bottom';
   selection n 'forward';
   selection p 'backward';
```

Design the Subset menu. This group of statements defines the selections under Subset on the menu bar. The DIALOG= option names a dialog box that is defined in a subsequent DIALOG statement.

```
menu sub;
   item 'Where' dialog=d1;
   item 'Where Clear';
```

Design the Help menu. This group of statements defines the selections under Help on the menu bar. The SETHELP command specifies a HELP entry that contains user-written information for this FSEDIT application. The semicolon that appears after the HELP entry name enables the HELP command to be included in the string. The HELP command invokes the HELP entry.

```
menu h;
   item 'Keys';
   item 'About this application' selection=hlp;
   selection hlp 'sethelp proclib.menucat.staffhlp.help;help';
```

Design the dialog box. WBUILD is a SAS macro. The double percent sign that precedes WBUILD is necessary to prevent PROC PMENU from expecting a field number to follow. The field numbers %1, %2, and %3 equate to the values that the

user specified with the radio buttons. The field number @1 equates to the search value that the user enters.

```
dialog d1 '%%wbuild(%1,%2,@1,%3)';
```

Add a radio button for region selection. The TEXT statement specifies text for the dialog box that appears on line 1 and begins in column 1. The RADIOBOX statement specifies that a radio button will appear in the dialog box. DEFAULT= specifies that the first radio button (Northeast) will be selected by default. The RBUTTON statements specify the mutually exclusive choices for the radio buttons: Northeast, Northwest, Southeast, or Southwest. SUBSTITUTE= gives the value that is substituted for the %1 in the DIALOG statement above if that radio button is selected.

```
text #1 @1 'Choose a region:';
radiobox default=1;
   rbutton #3 @5 'Northeast' substitute='NE';
   rbutton #4 @5 'Northwest' substitute='NW';
   rbutton #5 @5 'Southeast' substitute='SE';
   rbutton #6 @5 'Southwest' substitute='SW';
```

Add a radio button for pollutant selection. The TEXT statement specifies text for the dialog box that appears on line 8 (#8) and begins in column 1 (@1). The RADIOBOX statement specifies that a radio button will appear in the dialog box. DEFAULT= specifies that the first radio button (Pollutant A) will be selected by default. The RBUTTON statements specify the mutually exclusive choices for the radio buttons: Pollutant A or Pollutant B. SUBSTITUTE= gives the value that is substituted for the %2 in the preceding DIALOG statement if that radio button is selected.

```
text #8 @1 'Choose a contaminant:';
radiobox default=1;
   rbutton #10 @5  'Pollutant A' substitute='pol_a,2';
   rbutton #11 @5  'Pollutant B' substitute='pol_b,4';
```

Add an input field. The first TEXT statement specifies text for the dialog box that appears on line 13 and begins in column 1. The second TEXT statement specifies an input field that is 6 bytes long that appears on line 13 and begins in column 25. The value that the user enters in the field is substituted for the @1 in the preceding DIALOG statement.

```
text #13 @1 'Enter Value for Search:';
text #13 @25 len=6;
```

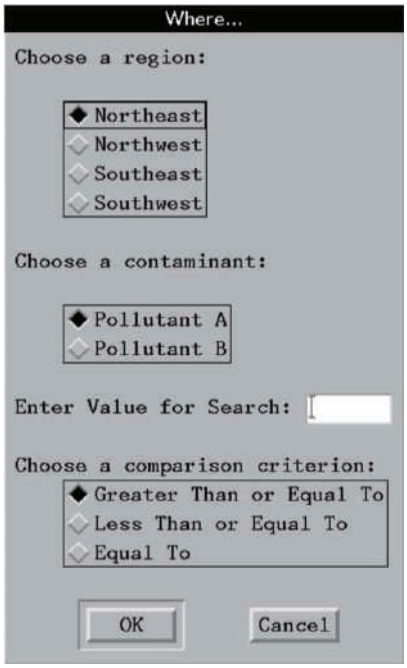
Add a radio button for comparison operator selection. The TEXT statement specifies text for the dialog box that appears on line 15 and begins in column 1. The RADIOBOX statement specifies that a radio button will appear in the dialog box. DEFAULT= specifies that the first radio button (Greater Than or Equal To) will be selected by default. The RBUTTON statements specify the mutually exclusive choices for the radio buttons. SUBSTITUTE= gives the value that is substituted for the %3 in the preceding DIALOG statement if that radio button is selected.

```
text #15 @1 'Choose a comparison criterion:';
radiobox default=1;
   rbutton #16 @5 'Greater Than or Equal To'
                  substitute='GE';
   rbutton #17 @5 'Less Than or Equal To'
                  substitute='LE';
```

```
                rbutton #18 @5 'Equal To' substitute='EQ';
   quit;
```

The following dialog box appears when the user selects Subset and then Where.

Output 46.1 *Example of a Where Dialog Box*



Details

Associating a Menu Bar with an FSEDIT Session

The SAS data set Proclib.Lakes has data about several lakes. Two pollutants, pollutant A and pollutant B, were tested at each lake. Tests were conducted for pollutant A twice at each lake, and the results are recorded in the variables POL_A1 and POL_A2. Tests were conducted for pollutant B four times at each lake, and the results are recorded in the variables POL_B1 - POL_B4. Each lake is located in one of four regions. The following example lists the contents of Proclib.Lakes:

Example Code 46.1 *Contents of the Proclib.Lakes Data Set*

```
                              PROCLIB.LAKES                              1

0.01
```

The "PROCLIB.LAKES" on page 2798 DATA step creates Proclib.Lakes.

The following statements initiate a PROC FSEDIT session for Proclib.Lakes:

```
proc fsedit data=proclib.lakes screen=proclib.lakes;
run;
```

To associate the customized menu bar menu with the FSEDIT session, do any one of the following:

- enter a SETPMENU command on the command line. The command for this example is

  ```
  setpmenu proclib.menucat.project.pmenu
  ```

  Turn on the menus by entering PMENU ON on the command line.
- enter the SETPMENU command in a Command window.
- include an SCL program with the FSEDIT session that uses the customized menus and turns on the menus, for example:

  ```
  fseinit:
    call execcmd('setpmenu proclib.menucat.project.pmenu;
                  pmenu on;');
  return;
  init:
  return;
  main:
  return;
  term:
  return;
  ```

How the WBUILD Macro Works

Consider how you would learn whether any of the lakes in the Southwest region tested for a value of .50 or greater for pollutant A. Without the customized menu item, you would issue the following WHERE command in the FSEDIT window:

```
where region="SW" and (pol_a1 ge .50 or pol_a2 ge .50);
```

Using the custom menu item, you would select **Southwest**, **Pollutant A**, enter .50 as the value, and choose **Greater Than or Equal To** as the comparison criterion. Two lakes, **New Dam** and **Border**, meet the criteria.

The WBUILD macro uses the four pieces of information from the dialog box to generate a WHERE command:

- One of the values for region, either **NE**, **NW**, **SE**, or **SW**, becomes the value of the macro parameter REGION.
- Either **pol_a,2** or **pol_b,4** become the values of the PREFIX and NUMVAR macro parameters. The comma is part of the value that is passed to the WBUILD macro and serves to delimit the two parameters, PREFIX and NUMVAR.
- The value that the user enters for the search becomes the value of the macro parameter VALUE.
- The operator that the user chooses becomes the value of the macro parameter OPERATOR.

To see how the macro works, again consider the following example, in which you want to know whether any of the lakes in the southwest tested for a value of .50 or greater for pollutant A. The following table contains the values of the macro parameters:

Table 46.1 *Values of the Macro Parameters*

REGION	**SW**
PREFIX	**pol_a**
NUMVAR	2
VALUE	.50
OPERATOR	GE

The first %IF statement checks to make sure that the user entered a value. If a value has been entered, then the macro begins to generate the WHERE command. First, the macro creates the beginning of the WHERE command:

```
where region="SW" and (
```

Next, the %DO loop executes. For pollutant A, it executes twice because NUMVAR=2. In the macro definition, the period in **&prefix.&i** concatenates **pol_a** with **1** and with **2**. At each iteration of the loop, the macro resolves PREFIX, OPERATOR, and VALUE, and it generates a part of the WHERE command. On the first iteration, it generates **pol_a1 GE .50**

The %IF statement in the loop checks to determine whether the loop is working on its last iteration. If it is not working, then the macro makes a compound WHERE command by putting an **OR** between the individual clauses. The next part of the WHERE command becomes **OR pol_a2 GE .50**

The loop ends after two executions for pollutant A, and the macro generates the end of the WHERE command:

```
)
```

Results from the macro are placed on the command line. The following code is the definition of the WBUILD macro. The underlined code shows the parts of the WHERE command that are text strings that the macro does not resolve:

```
%macro wbuild(region,prefix,numvar,value,operator);
       /* check to see if value is present */
    %if &value ne %then %do;
       where region="&region" AND (
              /* If the values are character,     */
              /* enclose &value in double quotation marks. */
         %do i=1 %to &numvar;
             &prefix.&i &operator &value
                /* if not on last variable,  */
                /* generate 'OR'             */
           %if &i ne &numvar %then %do;
                OR
           %end;
         %end;
          )
    %end;

%mend wbuild;
```

Example 4: Creating Menus for a DATA Step Window Application

Features: DIALOG statement
SELECTION statement
FILENAME statement

Details

This example defines an application that enables the user to enter human resources data for various departments, and to request reports from the data sets that are created by the data entry.

The first part of the example describes the PROC PMENU step that creates the menus. The subsequent sections describe how to use the menus in a DATA step window application.

Tasks include these:

- associating customized menus with a DATA step window
- creating menus for a DATA step window
- submitting SAS code from a menu selection
- creating a menu selection that calls a dialog box

Program

```
libname proclib
'SAS-data-library';

filename de     'external-file';
filename prt    'external-file';

 proc pmenu catalog=proclib.menus;

    menu select;

   item 'File' menu=f;
   item 'Data_Entry' menu=deptsde;
   item 'Print_Report' menu=deptsprt;

   menu f;
      item 'End this window' selection=endwdw;
      item 'End this SAS session' selection=endsas;
      selection endwdw 'end';
      selection endsas 'bye';

    menu deptsde;
       item 'For Dept01' selection=de1;
       item 'For Dept02' selection=de2;
       item 'Other Departments' dialog=deother;

       selection de1 'end;pgm;include de;change xx 01;submit';
       selection de2 'end;pgm;include de;change xx 02;submit';

       dialog deother 'end;pgm;include de;c deptxx @1;submit';
          text #1 @1 'Enter department name';
          text #2 @3 'in the form DEPT99:';
          text #2 @25 len=7;

     menu deptsprt;
```

```
        item 'For Dept01' selection=prt1;
        item 'For Dept02' selection=prt2;
        item 'Other Departments' dialog=prother;

        selection prt1
              'end;pgm;include prt;change xx 01 all;submit';
        selection prt2
              'end;pgm;include prt;change xx 02 all;submit';

     dialog prother 'end;pgm;include prt;c deptxx @1 all;submit';
        text #1 @1 'Enter department name';
        text #2 @3 'in the form DEPT99:';
        text #2 @25 len=7;

  run;

    menu entrdata;
       item 'File' menu=f;
       menu f;
          item 'End this window' selection=endwdw;
          item 'End this SAS session' selection=endsas;
          selection endwdw 'end';
          selection endsas 'bye';
  run;
quit;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store menu definitions.

```
libname proclib
'SAS-data-library';
```

Declare the DE and PRT filenames. The FILENAME statements define the external files in which the programs to create the windows are stored.

```
filename de     'external-file';
filename prt    'external-file';
```

Specify the catalog for storing menu definitions. Menu definitions will be stored in the PROCLIB.MENUCAT catalog.

```
 proc pmenu catalog=proclib.menus;
```

Specify the name of the catalog entry. The MENU statement specifies SELECT as the name of the catalog entry. The menus are stored in the catalog entry PROCLIB.MENUS.SELECT.PMENU.

```
    menu select;
```

Design the menu bar. The ITEM statements specify the three items on the menu bar. The value of the MENU= option is used in a subsequent MENU statement.

```
    item 'File' menu=f;
    item 'Data_Entry' menu=deptsde;
    item 'Print_Report' menu=deptsprt;
```

Design the File menu. This group of statements defines the selections under File. The value of the SELECTION= option is used in a subsequent SELECTION statement.

```
menu f;
   item 'End this window' selection=endwdw;
   item 'End this SAS session' selection=endsas;
   selection endwdw 'end';
   selection endsas 'bye';
```

Design the Data_Entry menu. This group of statements defines the selections under Data_Entry on the menu bar. The ITEM statements specify that For Dept01 and For Dept02 appear under Data_Entry. The value of the SELECTION= option equates to a subsequent SELECTION statement, which contains the string of commands that are actually submitted. The value of the DIALOG= option equates to a subsequent DIALOG statement, which describes the dialog box that appears when this item is selected.

```
menu deptsde;
   item 'For Dept01' selection=de1;
   item 'For Dept02' selection=de2;
   item 'Other Departments' dialog=deother;
```

Specify commands under the Data_Entry menu. The commands in single quotation marks are submitted when the user selects For Dept01 or For Dept02. The END command ends the current window and returns to the PROGRAM EDITOR window so that further commands can be submitted. The INCLUDE command includes the SAS statements that create the data entry window. The CHANGE command modifies the DATA statement in the included program so that it creates the correct data set. The SUBMIT command submits the DATA step program.

```
selection de1 'end;pgm;include de;change xx 01;submit';
selection de2 'end;pgm;include de;change xx 02;submit';
```

Design the DEOTHER dialog box. The DIALOG statement defines the dialog box that appears when the user selects Other Departments. The DIALOG statement modifies the command string so that the name of the department that is entered by the user is used to change `deptxx` in the SAS program that is included. The first two TEXT statements specify text that appears in the dialog box. The third TEXT statement specifies an input field. The name that is entered in this field is substituted for the @1 in the DIALOG statement.

```
dialog deother 'end;pgm;include de;c deptxx @1;submit';
   text #1 @1 'Enter department name';
   text #2 @3 'in the form DEPT99:';
   text #2 @25 len=7;
```

Design the Print_Report menu. This group of statements defines the choices under the Print_Report item. These ITEM statements specify that For Dept01 and For Dept02 appear in the menu. The value of the SELECTION= option equates to a subsequent SELECTION statement, which contains the string of commands that are actually submitted.

```
menu deptsprt;
   item 'For Dept01' selection=prt1;
   item 'For Dept02' selection=prt2;
   item 'Other Departments' dialog=prother;
```

Specify commands for the Print_Report menu. The commands in single quotation marks are submitted when the user selects For Dept01 or For Dept02. The END command ends the current window and returns to the PROGRAM EDITOR window so that further commands can be submitted. The INCLUDE command includes the SAS statements that print the report. (For more information, see "Printing a Program" on page 1734.) The CHANGE command modifies the PROC PRINT step in the included program so that it prints the correct data set. The SUBMIT command submits the PROC PRINT program.

```
selection prt1
      'end;pgm;include prt;change xx 01 all;submit';
selection prt2
      'end;pgm;include prt;change xx 02 all;submit';
```

Design the PROTHER dialog box. The DIALOG statement defines the dialog box that appears when the user selects Other Departments. The DIALOG statement modifies the command string so that the name of the department that is entered by the user is used to change `deptxx` in the SAS program that is included. The first two TEXT statements specify text that appears in the dialog box. The third TEXT statement specifies an input field. The name entered in this field is substituted for the @1 in the DIALOG statement.

```
dialog prother 'end;pgm;include prt;c deptxx @1 all;submit';
   text #1 @1 'Enter department name';
   text #2 @3 'in the form DEPT99:';
   text #2 @25 len=7;
```

End this RUN group.

```
run;
```

Specify a second catalog entry and menu bar. The MENU statement specifies ENTRDATA as the name of the catalog entry that this RUN group is creating. File is the only item on the menu bar. The selections available are End this window and End this SAS session.

```
menu entrdata;
   item 'File' menu=f;
   menu f;
      item 'End this window' selection=endwdw;
      item 'End this SAS session' selection=endsas;
      selection endwdw 'end';
      selection endsas 'bye';
run;
quit;
```

Other Examples

Associating a Menu with a Window

The first group of statements defines the primary window for the application. These statements are stored in the file that is referenced by the HRWDW fileref:

The WINDOW statement creates the HRSELECT window. MENU= associates the PROCLIB.MENUS.SELECT.PMENU entry with this window.

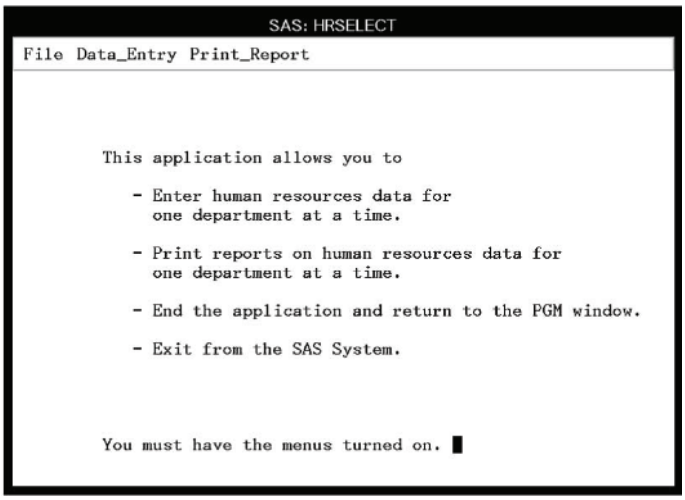
```
data _null_;
   window hrselect menu=proclib.menus.select
   #4  @10 'This application allows you to'
   #6  @13 '- Enter human resources data for'
   #7  @15 'one department at a time.'
   #9  @13 '- Print reports on human resources data for'
   #10 @15 'one department at a time.'
   #12 @13 '- End the application and return to the PGM window.'
   #14 @13 '- Exit from the SAS System.'
   #19 @10 'You must have the menus turned on.';
```

The DISPLAY statement displays the HRSELECT window.

```
   display hrselect;
run;
```

The HRSELECT window that is displayed by the DISPLAY statement:

Figure 46.6 *The HRSELECT Window*



Using a Data Entry Program

When the user selects `Data_Entry` from the menu bar in the HRSELECT window, a menu is displayed. When the user selects one of the listed departments or chooses to enter a different department, the following statements are invoked. These statements are stored in the file that is referenced by the DE fileref.

The WINDOW statement creates the HRDATA window. MENU= associates the PROCLIB.MENUS.ENTRDATA.PMENU entry with the window.

```
data proclib.deptxx;
    window hrdata menu=proclib.menus.entrdata
    #5  @10 'Employee Number'
    #8  @10 'Salary'
    #11 @10 'Employee Name'
    #5  @31 empno $4.
    #8  @31 salary 10.
    #11 @31 name $30.
    #19 @10 'Press ENTER to add the observation to the data set.';
```

The DISPLAY statement displays the HRDATA window.

```
    display hrdata;
run;
```

The %INCLUDE statement recalls the statements in the file HRWDW. The statements in HRWDW redisplay the primary window. See the HRSELECT window on page 1732

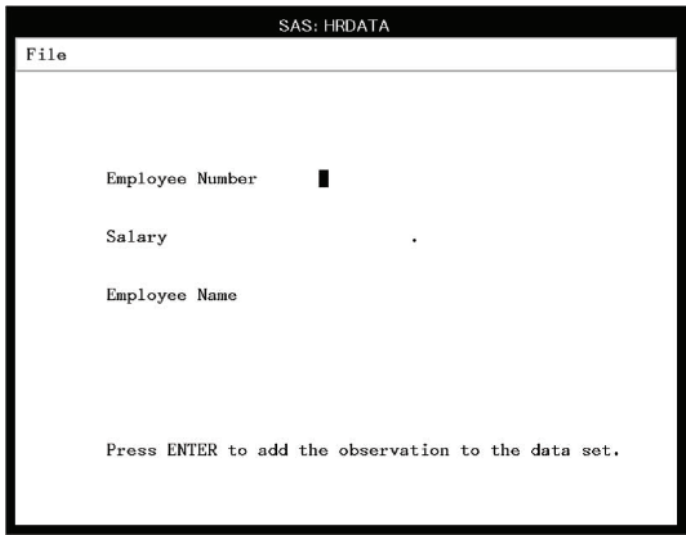
```
filename hrwdw 'external-file';
%include hrwdw;
run;
```

The SELECTION and DIALOG statements in the PROC PMENU step modify the DATA statement in this program so that the correct department name is used when the data set is created. That is, if the user selects `Other Departments` and enters `DEPT05`, then the DATA statement is changed by the command string in the DIALOG statement to

```
 data proclib.dept05;
```

The following display contains the data entry window, HRDATA.

Figure 46.7 The HRDATA Window



Printing a Program

When the user selects `Print_Report` from the menu bar, a menu is displayed. When the user selects one of the listed departments or chooses to enter a different department, the following statements are invoked. These statements are stored in the external file referenced by the PRT fileref.

PROC PRINTTO routes the output to an external file.

```
   proc printto
file='external-file' new;
   run;

   libname proclib
'SAS-data-library';

   proc print data=proclib.deptxx;
      title 'Information for deptxx';
   run;
```

This PROC PRINTTO step restores the default output destination. See Chapter 49, "PRINTTO Procedure," on page 1857.

```
   proc printto;
   run;
```

The %INCLUDE statement recalls the statements in the file HRWDW. The statements in HRWDW redisplay the primary window.

```
   filename hrwdw 'external-file';
   %include hrwdw;
   run;
```

Example 5: Associating Menus with a FRAME Application

Features: ITEM statement
MENU statement
SAS/AF software

Details

This example creates menus for a FRAME entry and gives the steps necessary to associate the menus with a FRAME entry from SAS/AF software.

Program

```
libname proclib
'SAS-data-library';

proc pmenu catalog=proclib.menucat;

   menu frame;

      item 'File' menu=f;
      item 'Help' menu=h;

      menu f;
         item 'Cancel';
         item 'End';

      menu h;
         item 'About the application' selection=a;
         item 'About the keys'   selection=k;

            selection a 'sethelp proclib.menucat.app.help;help';
            selection k 'sethelp proclib.menucat.keys.help;help';
run;
quit;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store menu definitions.

```
libname proclib
'SAS-data-library';
```

Specify the catalog for storing menu definitions. Menu definitions will be stored in the PROCLIB.MENUCAT catalog.

```
proc pmenu catalog=proclib.menucat;
```

Specify the name of the catalog entry. The MENU statement specifies FRAME as the name of the catalog entry. The menus are stored in the catalog entry PROCLIB.MENUS.FRAME.PMENU.

```
menu frame;
```

Design the menu bar. The ITEM statements specify the items in the menu bar. The value of MENU= corresponds to a subsequent MENU statement.

```
item 'File' menu=f;
item 'Help' menu=h;
```

Design the File menu. The MENU statement equates to the MENU= option in a preceding ITEM statement. The ITEM statements specify the selections that are available under File on the menu bar.

```
menu f;
   item 'Cancel';
   item 'End';
```

Design the Help menu. The MENU statement equates to the MENU= option in a preceding ITEM statement. The ITEM statements specify the selections that are available under Help on the menu bar. The value of the SELECTION= option equates to a subsequent SELECTION statement.

```
menu h;
   item 'About the application' selection=a;
   item 'About the keys'   selection=k;
```

Specify commands for the Help menu. The SETHELP command specifies a HELP entry that contains user-written information for this application. The semicolon that appears after the HELP entry name enables the HELP command to be included in the string. The HELP command invokes the HELP entry.

```
            selection a 'sethelp proclib.menucat.app.help;help';
            selection k 'sethelp proclib.menucat.keys.help;help';
run;
quit;
```

Steps to Associate Menus with a FRAME

1. In the BUILD environment for the FRAME entry, from the menu bar, select **View** ⇨ **Properties Window**.
2. In the Properties window, select the **Value** field for the pmenuEntry Attribute Name. The Select An Entry window appears.
3. In the Select An Entry window, enter the name of the catalog entry that is specified in the PROC PMENU step that creates the menus.

4 Test the FRAME as follows from the menu bar of the FRAME:**Build** ⇨ **Test**
Notice in the following display that the menus are now associated with the FRAME.

Figure 46.8 *The FRAME Window*

For more information about programming with FRAME entries, see *Getting Started with SAS/AF(R) 9.3 and Frames*.

47

PRESENV Procedure

Overview: PRESENV Procedure

What Does the PRESENV Procedure Do?

The PRESENV procedure preserves all global statements and macro variables in your SAS code from one SAS session to another. When this procedure is invoked at the end of a SAS session, all of the global statements and macro variables are written to a file. The Work data sets and the macro catalog are written to an auxiliary directory. You can then terminate the SAS session. You can restart the session at a later time, and the saved global statements and macro variable settings can be re-executed. The Work data sets can be copied back to the current Work directory, thereby allowing the session to resume.

Note: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

The PRESENV procedure works with the PRESENV system option to preserve your SAS program and data sets. You can turn the option on or off at any time. When the PRESENV system option is turned off, the global statements collection is suspended. When turned back on, the collection resumes. At no point is the collection discarded. However, the collection does not begin until the first time the option is turned on.

This functionality is very useful in a grid environment where an Enterprise Guide (EG) session needs to be terminated and started again on another node at a later time.

Concepts: PRESENV Procedure

Global Statements That Can Be Saved

If you turn on the PRESENV system option in an OPTIONS statement or at invocation time, and execute PROC PRESENV at the end of your job, then all of the following global statements that are used in your program are collected in memory:

- AXIS
- CATNAME
- FILENAME
- FOOTNOTE
- GOPTIONS
- LEGEND
- LIBNAME
- LOCK
- MISSING
- OPTIONS
- PATTERN
- SASFILE
- SYMBOL
- TITLE

Macro variables that are used in your program are also collected in memory, but other global statements, such as the X command, are not collected. Macros that are compiled during the program execution are stored in a Work directory, and that directory is copied as part of the PROC PRESENV execution.

Syntax: PRESENV Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Requirement: You must set the PRESENV system option to PRESENV (the default is NOPRESENV) to preserve the global statements. PROC PRESENV then saves a copy of those global statements to a file that you specify. Global statements are preserved from the time that the PRESENV system option is in effect.

PROC PRESENV PERMDIR=*libref* SASCODE=*fileref* <SHOW_COMMENTS>;

RUN;

Statement	Task	Example
PROC PRESENV	Preserve all global statements and macro variables from one SAS session to another	Ex. 1

PROC PRESENV Statement

Preserves all global statements and macro variables from one SAS session to another.

Syntax

PROC PRESENV PERMDIR=*libref* SASCODE=*fileref* <SHOW_COMMENTS>;

Required Arguments

PERMDIR=*libref*
specifies a libref where all of the Work data sets, catalogs, and macros are written.

SASCODE=*fileref*
specifies a fileref where a SAS program is written. The SAS program contains all of the code that is necessary to restore the environment.

Optional Argument

SHOW_COMMENTS
displays all global statements. Redundant global statements are commented out.

If this option is not used, then the global statements are suppressed.

Tip Use this option only for debugging your program, because this option can greatly increase the amount of text that is being generated.

Usage: PRESENV Procedure

Executing PROC PRESENV

To preserve your environment, execute the PRESENV procedure at the end of your job:

```
proc presenv save permdir=permdir sascode=sascode;
run;
```

The value of PERMDIR is a libref where all of the Work data sets and catalogs (including work.sasmacr) are written. The value of SASCODE is a fileref where a SAS program is written. The SAS program contains all of the code that is necessary to restore the environment.

Restoring the Environment in a Subsequent Job

To restore the environment in a subsequent job, invoke SAS without the PRESENV system option and submit the following code:

```
%include 'restore-file';
run;
```

Restore-file is the filename that is associated with the fileref in the SASCODE= argument of the original job. When you execute the program, all macros, macro variables, options, and global statements are restored to their original values.

Examples: PRESENV Procedure

Example 1: Preserve a SAS Environment

Features: PROC PRESENV statement
Macro variable definition
Macro definition
OPTIONS statement
DATA step

Details

This example shows a program with features that you want to save to use again in a later SAS session. Before you run this program, you invoke SAS and specify the PRESENV system option. Your SAS invocation command might look like this:

```
sas -presenv
```

Alternatively, you could specify the PRESENV system option in an OPTIONS statement at the beginning of your program.

This program sets the PS= and LS= system options and creates a data set called Mydata1 in the Work directory. This program also defines a macro variable MYMACVAR, defines a macro SOMEMAC, and creates a protected data set called Protected in the Work directory. At the end of the program, you define the location to save any data sets and variable definitions and you specify the name of the SAS code that restores these items in a subsequent SAS session.

Program

```
options ps=100 ls=100;

data mydata1;
a=1; b=2; c=3;
run;

%let mymacvar=123;
```

```
%macro somemac;
data mydata2;
y=3;
run;
%put Data set Mydata2 is from the saved macro somemac;
%mend;

data protected (read=mypass alter=mypass);
  x=1;
  y=2;
run;

libname preslib 'C:\Users\<userid>\sasuser\projectA\';
filename prescode 'my_sas_env';

proc presenv permdir=preslib sascode=prescode ;
run;
```

Program Description

Define system options. In the OPTIONS statement, you define the PS= and LS= system options.

```
options ps=100 ls=100;
```

Create a data set in the Work directory. You use a DATA step to create the Mydata1 data set. This data set contains one observation and three variables: A, B, and C.

```
data mydata1;
a=1; b=2; c=3;
run;
```

Define a macro variable and a macro. Use the %LET statement to define the macro variable MYMACVAR. Use the %MACRO and %MEND statements to define a new macro called SOMEMAC. The SOMEMAC macro creates a data set called Mydata2 with one observation and one variable. Then the function prints a message to the log.

```
%let mymacvar=123;

%macro somemac;
data mydata2;
y=3;
run;
%put Data set Mydata2 is from the saved macro somemac;
%mend;
```

Create a protected data set. Use a DATA step to create a data set called Protected that requires a password for Read and Write access. The data set contains one observation with two variables.

```
data protected (read=mypass alter=mypass);
  x=1;
  y=2;
run;
```

Save the data sets, variable definition, and macro definition for use in a later SAS session. Use the LIBNAME statement to define a location in which to save the data sets and macro definitions. Specify a fileref, Prescode, to use as a reference that you use to restore the current SAS environment. Call the PRESENV procedure and specify the Preslib and Prescode values that correspond to the current SAS environment. Remember the name my_sas_env so that you can restore the SAS environment in a later session.

```
libname preslib 'C:\Users\<userid>\sasuser\projectA\';
filename prescode 'my_sas_env';

proc presenv permdir=preslib sascode=prescode ;
run;
```

Output 47.1 *Output from Program That Calls PROC PRESENV*

The SAS System

Directory	
Libref	PRESLIB
Engine	V9
Physical Name	C:\Users\[redacted]\sasuser\projectA
Filename	C:\Users\[redacted]\sasuser\projectA
Owner Name	[redacted]
File Size	0KB
File Size (bytes)	0

Example 2: Restore a SAS Environment

Features: %INCLUDE statement

Details

This example shows how to restore the SAS environment to the state that it was in after running the previous example program.

Program

```
%include 'my_sas_env';

data _null_;
optval = getoption('ps');
put " ps = " optval;
optval = getoption('ls');
put " ls = " optval;
run;

%somemac;

data newdata;
x=&mymacvar;
y=2;
run;

proc print data=newdata; run;

data mydata3;
set mydata1;
run;

proc print data=mydata3; run;

proc print data=protected (read=mypass); run;
```

Program Description

Restore the previous SAS environment. Use the %INCLUDE statement to restore the SAS environment that is associated with the my_sas_env file. This restores the SAS environment to match the state when PROC PRESENV was run in a previous SAS session.

```
%include 'my_sas_env';
```

Verify the system options that were set for the my_sas_env environment. Use the GETOPTION function to request the values for the PS= and LS= system options. The PUT statement prints the values to the SAS log. These values match the values that were set in the previous example.

```
data _null_;
optval = getoption('ps');
put " ps = " optval;
optval = getoption('ls');
put " ls = " optval;
run;
```

Use a macro and a macro variable that were defined in the my_sas_env environment. Run the %SOMEMAC macro to generate the Mydata2 data set and print a message to the SAS log. Use the DATA step to create a data set called Newdata that contains the value of the MYMACVAR macro variable. Call PROC PRINT to print the contents of Newdata.

```
%somemac;

data newdata;
x=&mymacvar;
y=2;
run;

proc print data=newdata; run;
```

Work with data sets that were created in the my_sas_env environment. Use the DATA step to create a data set Mydata3 from the existing data set Mydata1. Mydata1 was created in the previous example. Call PROC PRINT to print the contents of the new data set Mydata3. Call PROC PRINT again to print the contents of the existing data set Protected. The Protected data set was created in the previous example and the protected status of the data set, which requires a password to Read or Alter it, remains in place.

```
data mydata3;
set mydata1;
run;

proc print data=mydata3; run;

proc print data=protected (read=mypass); run;
```

Output 47.2 *SAS Log That Shows Saved System Options*

```
1
2    %include 'my_sas_env';
NOTE: Libref PRESLIB was successfully assigned as follows:
      Engine:        V9
      Physical Name: C:\Users\<userid>\sasuser\projectA
40
41   data _null_;
42   optval = getoption('ps');
43   put " ps = " optval;
44   optval = getoption('ls');

PRINT Procedure

Overview: PRINT Procedure

What Does the PRINT Procedure Do?

The PRINT procedure prints the observations in a SAS data set or rows from a SAS Cloud Analytic Services (CAS) table using all or some of the variables. You can create a variety of reports ranging from a simple table to a highly customized report that groups the data and calculates totals and subtotals for numeric variables.

A Simple Report

The following output illustrates the simplest type of report that you can produce. The statements that produce the output follow. "Example 2: Selecting Variables to Print" on page 1797 creates the data set EXPREV.

```
options obs=10;
proc print data=exprev;
run;
```

TIP The OBS= system option is valid for all steps during your current SAS session or until you change the setting. To set the number of observations for a single PROC step, use the OBS= data set option:

```
proc print data=exprev(obs=10);
```

For more information, see "OBS= Data Set Option" in *SAS Data Set Options: Reference* and "OBS= System Option" in *SAS System Options: Reference* .

The SAS System

Obs	Country	Emp_ID	Order_Date	Ship_Date	Sale_Type	Quantity	Price	Cost
1	Antarctica	99999999	1/1/12	1/7/12	Internet	2	92.6	20.70
2	Puerto Rico	99999999	1/1/12	1/5/12	Catalog	14	51.2	12.10
3	Virgin Islands (U.S.)	99999999	1/1/12	1/4/12	In Store	25	31.1	15.65
4	Aruba	99999999	1/1/12	1/4/12	Catalog	30	123.7	59.00
5	Bahamas	99999999	1/1/12	1/4/12	Catalog	8	113.4	28.45
6	Bermuda	99999999	1/1/12	1/4/12	Catalog	7	41.0	9.25
7	Belize	120458	1/2/12	1/2/12	In Store	2	146.4	36.70
8	British Virgin Islands	99999999	1/2/12	1/5/12	Catalog	11	40.2	20.20
9	Canada	99999999	1/2/12	1/5/12	Catalog	100	11.8	5.00
10	Cayman Islands	120454	1/2/12	1/2/12	In Store	20	71.0	32.30

This next example creates the CAS table Mycas.Cars as a subset of the Sashelp.cars data set:

```
options cashost="cloud.example.com" casport=5555;
cas casauto;
libname mycas cas;

proc casutil outcaslib="casuser";
load data=sashelp.cars replace;
run;

data mycas.cars;
   set mycas.cars(where=(weight>6000));
   keep make model type;
run;

proc print data=mycas.cars;
   title "Cars Greater Than 6000 Pounds";
run;
```

Cars Greater Than 6000 Pounds

Obs	Make	Model	Type
1	Ford	Excursion 6.8 XLT	SUV
2	Hummer	H2	SUV
3	GMC	Yukon XL 2500 SLT	SUV

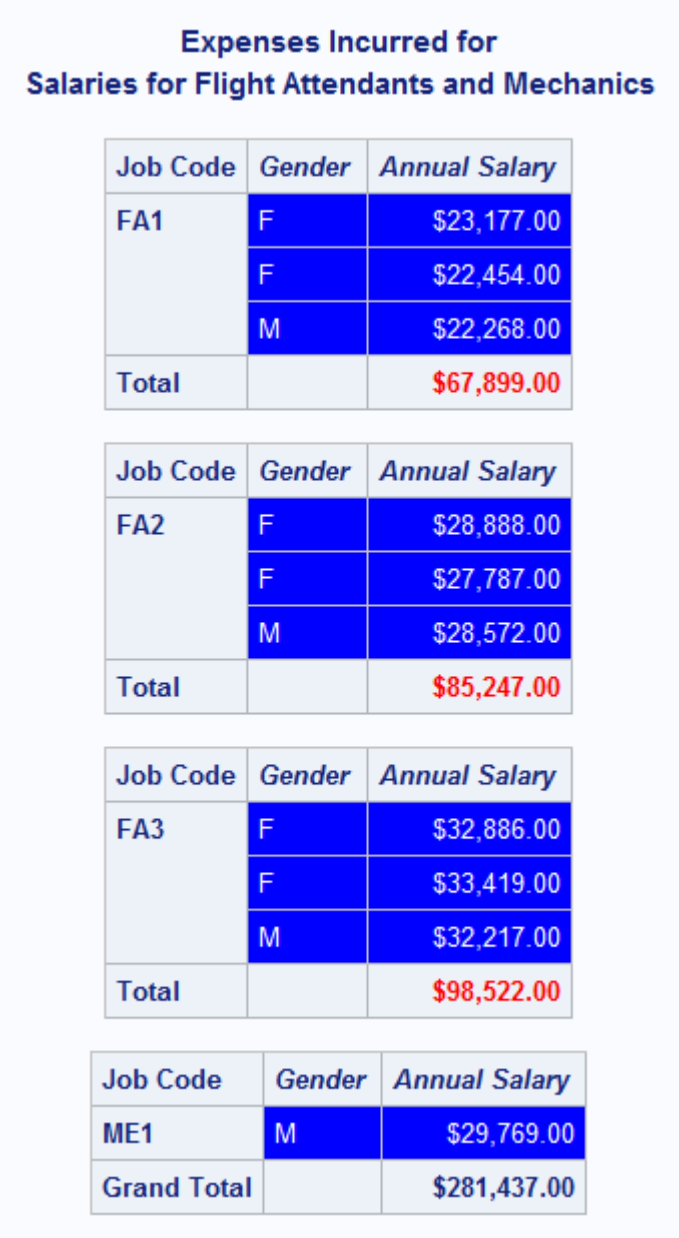
Customized Report

The following HTML report is a customized report that is produced by PROC PRINT using ODS. The statements that create this report do the following:

- customize the title and the column headings
- customize the appearance of the report
- place dollar signs and commas in numeric output
- selectively include and control the order of variables in the report
- group the data by JobCode
- sum the values for Salary for each job code and for all job codes, and add a label for the summary line and the grand total line

For an explanation of the program that produces this report, see "Program: Creating an HTML Report with the STYLE Option" on page 1849.

Figure 48.1 Customized Report Produced by PROC PRINT Using ODS



Expenses Incurred for
Salaries for Flight Attendants and Mechanics

Job Code	Gender	Annual Salary
FA1	F	$23,177.00
	F	$22,454.00
	M	$22,268.00
Total		$67,899.00

Job Code	Gender	Annual Salary
FA2	F	$28,888.00
	F	$27,787.00
	M	$28,572.00
Total		$85,247.00

Job Code	Gender	Annual Salary
FA3	F	$32,886.00
	F	$33,419.00
	M	$32,217.00
Total		$98,522.00

Job Code	Gender	Annual Salary
ME1	M	$29,769.00
Grand Total		$281,437.00

Syntax: PRINT Procedure

Interaction: A common practice is to sort a data set using PROC SORT before you use the PROC PRINT BY statement. If you sort a CAS table with VARCHAR variables using PROC SORT, VARCHAR variables are converted to CHAR variables.

Note: PROC PRINT supports the VARCHAR data type for CAS tables.

Tips:

Each password and encryption key option must be coded on a separate line to ensure that they are properly blotted in the log.

Supports the Output Delivery System. For details, see "Output Delivery System: Basic Concepts" in *SAS Output Delivery System: User's Guide*.

You can use the ATTRIB, FORMAT, LABEL, TITLE, and WHERE statements. See *SAS DATA Step Statements: Reference*. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

SAS includes checks to verify that the PROC PRINT output is accessible for the visually impaired. You can set the ACCESSIBLECHECK system option to have SAS verify if the output is accessible. For best practices about creating accessible output, see Creating Accessible Output in SAS Using ODS and ODS Graphics.

PROC PRINT <*options*>;

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...> <NOTSORTED>;

PAGEBY *BY-variable*;

SUMBY *BY-variable*;

ID *variable(s)*
</ STYLE <(*location(s)*)>=<*style-override*>>;

SUM *variable(s)*
</ STYLE <(*location(s)*)>=<*style-override*>>;

VAR *variable(s)*
</ STYLE <(*location(s)*)>=<*style-override*> >;

Statement	Task	Example
PROC PRINT	Print observations in a data set	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 6, Ex. 9
BY	Produce a separate section of the report for each BY group	Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 9
ID	Identify observations by the formatted values of the variables that you list instead of by observation numbers	Ex. 8
PAGEBY	Control page ejects that occur before a page is full	Ex. 4
SUMBY	Limit the number of sums that appear in the report	Ex. 5, Ex. 6, Ex. 7, Ex. 9
SUM	Total values of numeric variables	Ex. 7
VAR	Select variables that appear in the report and determine their order	Ex. 2, Ex. 3, Ex. 9

PROC PRINT Statement

Prints observations in a SAS data set using some or all of the variables.

Syntax

PROC PRINT <*options*>;

Summary of Optional Arguments

CONTENTS=*link-text* <#BYLINE> <#BYVAL> <#BYVAR>
: specifies text for the links in the table of contents.

DATA=*SAS-data-set*
: specifies the SAS data set to print.

Control column format

GRANDTOTAL_LABEL='*label*'
: displays a label on the grand total line.

HEADING=HORIZONTAL | VERTICAL
: controls the orientation of the column headings.

LABEL
: specifies to use the variables' labels as column headings.

SPLIT='*split-character*'
: specifies the split character, which controls line breaks in column headings.

STYLE <(*location(s)*)>=<*style-override(s)*>
: specify one or more ODS style overrides to modify the default style element and attributes in a specific area of a report.

SUMLABEL

NOSUMLABEL

SUMLABEL='*label*'
: specifies whether to display a label on the summary line for a BY group.

Control general format

BLANKLINE=*n*

BLANKLINE=(COUNT=*n* <STYLE=[*style-attibute-specification(s)*]>)
: writes a blank line after *n* observations.

DOUBLE
: writes a blank line between observations.

N<="*string-1*" <"*string-2*">>

prints the number of observations in the data set, in BY groups, or both and specifies explanatory text to print with the number.

NOOBS
suppresses the column in the output that identifies each observation by number.

OBS="*column-header*"
specifies a column heading for the column that identifies each observation by number.

ROUND
rounds unformatted numeric values to two decimal places.

Control page format

ROWS=*page-format*
formats the rows on a page.

UNIFORM
specifies to use each variable's formatted width as its column width on all pages.

WIDTH=FULL | MINIMUM | UNIFORM | UNIFORMBY
determines the column width for each variable.

Optional Arguments

BLANKLINE=*n*
BLANKLINE=(COUNT=*n* <STYLE=[*style-attibute-specification(s)*]>)
specifies to insert a blank line after every *n* observations. The observation count is reset to 0 at the beginning of each BY group for all ODS destinations.

n
COUNT=*n*
specifies the observation number after which SAS inserts a blank line.

STYLE=[*style-attribute-specification(s)*]
specifies the style attribute to use for the blank line.

Default DATA

Tip You can use the BACKGROUNDCOLOR style attribute to make a visual distinction between observations using color.

See The STYLE= option on page 1764 for valid style attributes.

Example "Example 2: Selecting Variables to Print" on page 1797

Tip SAS includes checks to verify that the PROC PRINT output is accessible for the visually impaired. When you specify the BLANKLINE= option, the output that PROC PRINT creates includes one or more lines that are not data. Screen readers and users might interpret these lines incorrectly. When you set the ACCESSIBLECHECK system option, SAS checks to see if the BLANKLINE option has been used to add blank lines to the output. If blank lines are in the output, SAS writes a warning message to the SAS log. For best practices about creating accessible output, see Creating Accessible Output in SAS Using ODS and ODS Graphics.

CONTENTS=*link-text* <#BYLINE> <#BYVAL> <#BYVAR>
specifies the text for the links in the table contents file to the output produced by the PROC PRINT statement.

link-text
specifies text to use in the table of contents.

#BYLINE
substitutes the entire BY line without leading or trailing blanks for #BYLINE in the text string. The BY line uses the format *variable-name=value*.

#BYVAL*n*
#BYVAL(*BY-variable-name*)
substitutes the current value of the specified BY variable for #BYVAL in the text string. Specify the variable with one of these values:

n
specifies a variable by its position in the BY statement. For example, #BYVAL2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAL(YEAR) specifies the BY variable, YEAR. *variable-name* is not case sensitive.

#BYVAR*n*
#BYVAR(*BY-variable-name*)
substitutes the name of the BY variable or the label associated with the variable (whatever the BY line would normally display) for #BYVAR in the text string. Specify the variable with one of these values:

n
specifies a variable by its position in the BY statement. For example, #BYVAR2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAR(SITES) specifies the BY variable, SITES. *variable-name* is not case sensitive.

Restrictions CONTENTS= does not affect the HTML body file. It affects only the HTML contents file.

CONTENTS= is not valid for the ODS LISTING destination.

See For information about HTML output, see Files Produced by the HTML Destination and "ODS HTML Statement" in *SAS Output Delivery System: User's Guide*.

DATA=*SAS-data-set*
specifies the SAS data set to print.

See "Input Data Sets" on page 26

DOUBLE
writes a blank line between observations.

Alias D

Restriction DOUBLE is valid only for the ODS LISTING destination.

Example "Example 2: Selecting Variables to Print" on page 1797

GRANDTOTAL_LABEL='*label*'
displays a label on the grand total line. You can include the #BYVAR and #BYVAL variables in '*label*'.

Aliases GRAND_LABEL

GRANDTOT_LABEL

GTOT_LABEL

GTOTAL_LABEL

Restriction The #BYVAR and #BYVAL variables are not sup ported for the LISTING destination.

Tip SAS includes checks to verify that the PROC PRINT output is accessible for the visually impaired. When you set the ACCESSIBLECHECK system option, SAS verifies whether a label is available for both the SUMLABEL and the GRANDTOTAL_LABEL options. If SAS detects that the output does not have a label for the summary and grand total values, SAS writes a message to the log. For best practices about creating accessible output, see Creating Accessible Output in SAS Using ODS and ODS Graphics.

Example "Example 6: Summing Numeric Variables with Multiple BY Variables" on page 1824

HEADING=HORIZONTAL | VERTICAL
controls the orientation of the column headings.

HORIZONTAL
prints all column headings horizontally.

Alias H

VERTICAL
prints all column headings vertically.

Alias V

Restriction For LISTING output, if the column heading is too long for the page, the variable name is used in place of a label.

Default Headings are either all horizontal or all vertical. If you omit HEADING=, PROC PRINT determines the direction of the column headings as follows:

If you do not use LABEL, spacing specifies whether column headings are vertical or horizontal.

If you use LABEL and at least one variable has a label, all headings are horizontal.

LABEL
specifies to use the variables' labels as column headings.

Alias L

Default PROC PRINT uses the name of the variable as the column heading in the following two circumstances:

1. if you omit the LABEL option in the PROC PRINT statement, even if the PROC PRINT step contains a LABEL statement
2. if a variable does not have a label

Interactions By default, if you specify LABEL and at least one variable has a label, PROC PRINT prints all column headings horizontally. Therefore, using LABEL might increase the number of pages of output. (Use HEADING=VERTICAL in the PROC PRINT statement to print vertical column headings.)

PROC PRINT sometimes conserves space by splitting labels across multiple lines. Use SPLIT= in the PROC PRINT statement to control where these splits occur. You do not need to use LABEL if you use SPLIT=.

Note The SAS system option LABEL must be in effect in order for any procedure to use labels. For more information see "LABEL System Option" in *SAS System Options: Reference*.

Tip To create a blank column heading for a variable, use this LABEL statement in your PROC PRINT step:

```
label variable-name='00'x;
```

See For information about using the LABEL statement to create temporary labels in procedures, see Chapter 3, "Statements with the Same Function in Multiple Procedures," on page 73.

For information about using the LABEL statement in a DATA step to create permanent labels, see "LABEL" in *SAS DATA Step Statements: Reference*.

Example "Example 4: Creating Separate Sections of a Report for Groups of Observations" on page 1809

N<="*string-1*" <"*string-2*">>
prints the number of observations in the data set, in BY groups, or both and specifies explanatory text to print with the number.

N Option Use	PROC PRINT Action
With neither a	Prints the number of observations in the data set at the end of the report and labels the number with the value of *string-1*.

N Option Use	PROC PRINT Action
BY nor a SUM statement	
With a BY statement	Prints the number of observations in the BY group at the end of each BY group and labels the number with the value of *string-1*.
With a BY statement and a SUM statement	Prints the number of observations in the BY group at the end of each BY group and prints the number of observations in the data set at the end of the report. The numbers for BY groups are labeled with *string-1*; the number for the entire data set is labeled with *string-2*.

Tip SAS includes checks to verify that the PROC PRINT output is accessible for the visually impaired. When you specify the N= option, the output that PROC PRINT creates includes a text line that is not data. Screen readers might interpret this line of text as data. When you set the ACCESSIBLECHECK system option, SAS verifies whether the output is accessible. If the output contains the text that is not data, SAS writes a warning message to the SAS log. For best practices about creating accessible output, see Creating Accessible Output in SAS Using ODS and ODS Graphics.

Examples "Example 3: Customizing Text in Column Headings" on page 1803

"Example 4: Creating Separate Sections of a Report for Groups of Observations" on page 1809

"Example 5: Summing Numeric Variables with One BY Group" on page 1819

NOOBS
suppresses the column in the output that identifies each observation by number.

Example "Example 4: Creating Separate Sections of a Report for Groups of Observations" on page 1809

OBS="*column-header*"
specifies a column heading for the column that identifies each observation by number.

Tip OBS= honors the split character. (See the discussion of the SPLIT= option on page 1764.)

Example "Example 3: Customizing Text in Column Headings" on page 1803

ROUND

rounds unformatted numeric values to two decimal places. (Formatted values are already rounded by the format to the specified number of decimal places.) For both formatted and unformatted variables, PROC PRINT uses these rounded values to calculate any sums in the report.

If you omit ROUND, PROC PRINT adds the actual values of the rows to obtain the sum *even though it displays the formatted (rounded) values*. Any sums are also rounded by the format, but they include only one rounding error, that of rounding the sum of the actual values. The ROUND option, on the other hand, rounds values before summing them, so there might be multiple rounding errors. The results without ROUND are more accurate, but ROUND is useful for published reports where it is important for the total to be the sum of the printed (rounded) values.

Be aware that the results from PROC PRINT with the ROUND option might differ from the results of summing the same data with other methods such as PROC MEANS or the DATA step. Consider a simple case in which the following is true:

- The data set contains three values for X: .003, .004, and .009.
- X has a format of 5.2.

Depending on how you calculate the sum, you can get three different answers: 0.02, 0.01, and 0.016. The following figure shows the results of calculating the sum with PROC PRINT (without and with the ROUND option) and PROC MEANS.

Figure 48.2 *Three Methods of Summing Variables*

```
                   PROC  PRINT  without        PROC  PRINT  with
 Actual  Va lues   the  ROUND   optio n        t he  ROUND  option          PROC  MEANS
===============================================================================
               ||                        ||                       ||
               ||   OBS             X    ||  OB S             X   || Analysis  Variable  : X
               ||                        ||                       ||
  .003         ||    1           0.00    ||   1            0.00   ||          Sum
  .004         ||    2           0.00    ||   2            0.00   ||-----------
  .009         ||    3           0.01    ||   3            0.01   ||  0.0160000
 =====         ||                =====   ||                =====  || -----------
  .016         ||                0.02    ||                0.01   ||
               ||                        ||                       ||
===============================================================================
```

Notice that the sum produced without the ROUND option (.02) is closer to the actual result (0.16) than the sum produced with ROUND (0.01). However, the sum produced with ROUND reflects the numbers that are displayed in the report.

Alias R

CAUTION **Do not use ROUND with PICTURE formats.** ROUND is for use with numeric values. SAS procedures treat variables that have picture formats as character variables. Using ROUND with such variables might lead to unexpected results.

ROWS=*page-format*
formats the rows on a page. Currently, PAGE is the only value that you can use for *page-format*:

PAGE
prints only one row of variables for each observation per page. When you use ROWS=PAGE, PROC PRINT does not divide the page into sections; it prints as many observations as possible on each page. If the observations do not fill the last page of the output, PROC PRINT divides the last page into sections and prints all the variables for the last few observations.

Restriction ROWS= is valid only for the ODS LISTING destination. Therefore, HTML output from PROC PRINT appears the same if you use ROWS=.

Tip The PAGE value can reduce the number of pages in the output if the data set contains large numbers of variables and observations. However, if the data set contains a large number of variables but few observations, the PAGE value can increase the number of pages in the output.

See "Page Layout for Limited Page Sizes" on page 1792 for discussion of the default layout.

Example "Example 8: Controlling the Layout of a Report with Many Variables" on page 1839

SPLIT='*split-character*'
specifies the split character, which controls line breaks in column headings. It also uses labels as column headings. PROC PRINT breaks a column heading when it reaches the split character and continues the header on the next line. The split character is not part of the column heading although each occurrence of the split character counts toward the 256-character maximum for a label.

Alias S=

Interactions You do not need to use both LABEL and SPLIT= because SPLIT= implies the use of labels.

The OBS= option honors the split character. (See the discussion of "OBS="*column-header*"" on page 1762.)

Note PROC PRINT does not split labels of BY variables in the heading preceding each BY group, a summary label, or a grand total level, even if you specify SPLIT=. Instead, PROC PRINT replaces the split character with a blank.

Example "Example 3: Customizing Text in Column Headings" on page 1803

STYLE <(*location(s)*)>=<*style-override(s)*>
specify one or more ODS style overrides to modify the default style element and attributes in a specific area of a report.

You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

style-override has the following form:

style-element-name | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2 ...*>]

location

identifies the part of the report that the STYLE option affects. If *location(s)* is not specified, PROC PRINT determines the location to where the style override is applied based on the statement, the specified style element, and the style attribute.

The following table shows the available locations and the other statements in which you can specify them.

Table 48.1 *Specifying Locations in the STYLE Option*

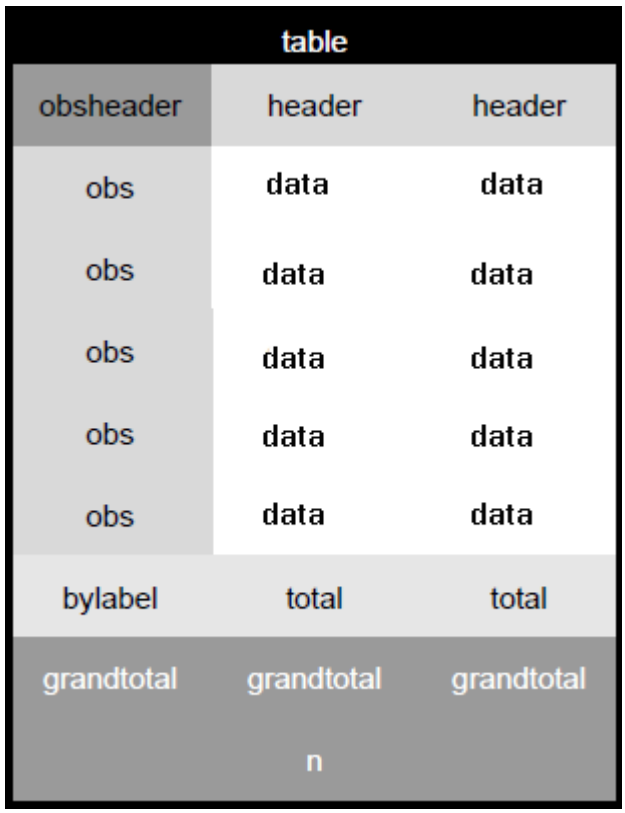
Location	Location Alias	Affected Report Part	Can Also Be Used in These Statements
BYLABEL	BYSUMLABEL BYLBL BYSUMLBL	Label for the BY variable on the line containing the SUM totals	None
DATA	COLUMN COL	All data except for data in the OBS column or the ID columns Or Data in the ID columns when the DATA location is specified in the STYLE= option of the ID statement	VAR ID SUM
GRANDTOTAL	GRANDTOT GRAND GTOTAL GTOT	SUM line containing the grand totals for the whole report	SUM
HEADER	HEAD HDR	All column headings except for the OBS	VAR ID

Location	Location Alias	Affected Report Part	Can Also Be Used in These Statements
		column or the ID columns [1] Or All column headings of the ID columns when the HEADER location is specified in the STYLE= option of the ID statement	SUM
N	None	N= table and contents	None
OBS	OBSDATA OBSCOLUMN OBSCOL	Data in the OBS column or the ID columns unless the DATA location is specified in the STYLE= option of the ID statement	None
OBSHEADER	OBSHEAD OBSHDR	Header of the OBS column or the ID columns unless the HEADER location is specified in the STYLE= option of the ID statement [1]	None
TABLE	REPORT	Structural part of the report - that is, the underlying table used to set things like the width of the border and the space between cells	None
TOTAL	TOT BYSUMLINE BYLINE	SUM line containing totals for each BY group	SUM

Location	Location Alias	Affected Report Part	Can Also Be Used in These Statements
	BYSUM		

1 Prior to SAS 9.4, if you specified the HEADER location in the STYLE= option of the PROC PRINT statement, all column headings rendered using the HEADER style attributes. In SAS 9.4, you use the OBSHEADER location in the STYLE= option of the PROC PRINT statement to format the OBS column and the ID columns. The PROC PRINT statement STYLE= option in your existing programs might need to include the OBSHEADER location as well as the HEADER location.

Figure 48.3 *PROC PRINT Areas and Corresponding Statements*



Style specifications in a statement other than the PROC PRINT statement override the same style specification in the PROC PRINT statement. However, style attributes that you specify in the PROC PRINT statement are inherited, provided that you do not override the style with style specifications in another statement. For example, if you specify a blue background and a white foreground for all column headings in the PROC PRINT statement, and you specify a light gray background for an ID column heading, the background for the ID column heading is light gray, and the foreground is white (as specified in the PROC PRINT statement). This PRINT procedure shows the inheritance of the color white in the ID column heading:

```
proc print data=exprev style(header)={backgroundcolor=blue color=white};
   id country / style(obsheader)=[backgroundcolor=light gray];
run;
```

The SAS System

Country	Emp_ID	Order_Date	Ship_Date	Sale_Type	Quantity	Price	Cost
Antarctica	99999999	1/1/12	1/7/12	Internet	2	92.6	20.70

If the same style attributes appear for the OBSHEADER location in the PROC PRINT statement and the HEADER location in the ID statement, the HEADER location attributes override the OBSHEADER attributes. All other style attributes for the ID columns in both the PROC PRINT statement and the ID statement are merged to create the style for the ID columns. For example, in the PROC PRINT statement, the attributes for the OBSHEADER location are `{fontsize=5 fontweight=bold}`. In the ID statement, the attributes for the HEADER location are `[fontsize=6 fontstyle=italic]`. The resulting style for the ID column is `[fontsize=6 fontweight=bold fontstyle=italic]`.

```
proc print data=exprev style(obsheader)={fontsize=5 fontweight=bold};
   id country / style(header)=[fontsize=6 fontstyle=italic];
run;
```

The SAS System

Country	Emp_ID	Order_Date	Ship_Date	Sale_Type	Quantity	Price	Cost
Antarctica	99999999	1/1/12	1/7/12	Internet	2	92.6	20.70

If the same style attributes appear for the OBS location in the PROC PRINT statement and the DATA location in the ID statement, the DATA location attributes override the OBS attributes. All other style attributes for the ID columns in both the PROC PRINT statement and the ID statement are merged to create the style for the ID columns. For example, in the PROC PRINT statement, the attributes for the OBS location are `{backgroundcolor=light gray color=blue}`. In the ID statement, the attributes for the DATA location are `[color=white fontstyle=italic]`. The resulting style for the ID column is `[backgroundcolor=light gray color=white fontstyle=italic]`.

```
proc print data=exprev style(obs)={backgroundcolor=light gray color=blue};
   id country / style(data)=[color=white fontstyle=italic];
run;
```

The SAS System

Country	Emp_ID	Order_Date	Ship_Date	Sale_Type	Quantity	Price	Cost
Antarctica	99999999	1/1/12	1/7/12	Internet	2	92.6	20.70
Puerto Rico	99999999	1/1/12	1/5/12	Catalog	14	51.2	12.10
Virgin Islands (U.S.)	99999999	1/1/12	1/4/12	In Store	25	31.1	15.65

style-element-name
is the name of a style element in a style template that is registered with the Output Delivery System. SAS provides some style templates. Users can create their own style templates with the TEMPLATE procedure. See *SAS Output Delivery System: Procedures Guide*.

When style elements are processed, more specific style elements override less specific style elements. For a table of default style elements and style attributes for each PROC PRINT location, see Table 48.95 on page 1789.

Tip You can use compound names and formats for style element names. An example of using a compound style element name is `style(obsheader)=data.italic.red;`. An example of using a format element name is `style=$cities`. For more information about using formats, see the *SAS Output Delivery System: Procedures Guide*.

style-attribute-specification
describes the style attribute to change. Each *style-attribute-specification* has this general form:

style-attribute-name=style-attribute-value

You can set these style attributes in the TABLE location:

BACKGROUNDCOLOR=	FONTWIDTH= [1]
BACKGROUNDIMAGE=	COLOR= [1]
BORDERCOLOR=	FRAME=
BORDERCOLORDARK=	HTMLCLASS=
BORDERCOLORLIGHT=	TEXTALIGN=
BORDERWIDTH=	OUTPUTWIDTH=
CELLPADDING=	POSTHTML=
CELLSPACING=	POSTIMAGE=
FONT= [1]	POSTTEXT=
FONTFAMILY= [1]	PREHTML=
FONTSIZE= [1]	PREIMAGE=
FONTSTYLE= [1]	PRETEXT=
FONTWEIGHT= [1]	RULES=

1 When you use these attributes, they affect only the text that is specified with the PRETEXT=, POSTTEXT=, PREHTML=, and POSTHTML= attributes. To alter the foreground color or the font for the text that appears in the table, you must set the corresponding attribute in a location that affects the cells rather than the table.

You can set these style attributes in all locations other than TABLE:

ASIS=	FONTWIDTH=
BACKGROUNDCOLOR=	HREFTARGET=
BACKGROUNDIMAGE=	CLASS=
BORDERCOLOR=	TEXTALIGN=
BORDERCOLORDARK=	NOBREAKSPACE=
BORDERCOLORLIGHT=	POSTHTML=
BORDERWIDTH=	POSTIMAGE=
HEIGHT=	POSTTEXT=
CELLWIDTH=	PREHTML=
FLYOVER=	PREIMAGE=
FONT=	PRETEXT=
FONTFAMILY=	PROTECTSPECIALCHARACTERS=
FONTSIZE=	TAGATTR=
FONTSTYLE=	URL=
FONTWEIGHT=	VERTICALALIGN=

Restriction STYLE= is not valid for the ODS LISTING or ODS OUTPUT destinations.

See For a table of style attributes that can be used with PROC TABULATE, PROC REPORT, and PROC PRINT, see Table 48.94 on page 1786.

For a table of default style elements and style attributes for each PROC PRINT location, see Table 48.95 on page 1789.

For more information about using styles with PROC PRINT, see "Use ODS Styles with PROC PRINT" on page 1780.

For information about style attributes and PROC TEMPLATE, see DEFINE Style Statement in *SAS Output Delivery System: Procedures Guide*.

SUMLABEL
NOSUMLABEL
SUMLABEL='*label*'
specifies whether to display a label on the summary line for a BY group.

SUMLABEL
specifies to use the variable label, if it exists, as the label on the summary line in place of the variable name.

NOSUMLABEL
specifies to leave the label on the summary line blank. Alternatively, you can use SUMLABEL="" (two single or double quotation marks with no space between them) to indicate a blank on the summary line.

SUMLABEL='*label*'
specifies the text to use as a label on the summary line of a BY group. You can include the #BYVAR and #BYVAL variables in '*label*'.

Restriction The #BYVAR and #BYVAL variables are not supported for the LISTING destination.

Default If you omit SUMLABEL, PROC PRINT uses the BY variable names in the summary line.

Tip SAS includes checks to verify that the PROC PRINT output is accessible for the visually impaired. When you set the ACCESSIBLECHECK system option, SAS verifies whether a label is available for both the SUMLABEL and the GRANDTOTAL_LABEL options. If SAS detects that the output does not have a label for the summary and grand total values, SAS writes a message to the log. For best practices about creating accessible output, see Creating Accessible Output in SAS Using ODS and ODS Graphics.

Examples "Example 5: Summing Numeric Variables with One BY Group" on page 1819

"Example 6: Summing Numeric Variables with Multiple BY Variables" on page 1824

UNIFORM
See WIDTH=UNIFORM on page 1771.

WIDTH=FULL | MINIMUM | UNIFORM | UNIFORMBY
determines the column width for each variable.

FULL
uses a variable's formatted width as the column width. If the variable does not have a format that explicitly specifies a field width, PROC PRINT uses the default width. For a character variable, the default width is the length of the variable. For a numeric variable, the default width is 12. When you use WIDTH=FULL, the column widths do not vary from page to page.

Tip Using WIDTH=FULL can reduce execution time.

MINIMUM
uses for each variable the minimum column width that accommodates all values of the variable.

Alias MIN

UNIFORM
uses each variable's formatted width as its column width on all pages. If the variable does not have a format that explicitly specifies a field width, PROC PRINT uses the widest data value as the column width. When you specify WIDTH=UNIFORM, PROC PRINT normally needs to read the data set twice. However, if all the variables in the data set have formats that explicitly specify a field width (for example, BEST12. but not BEST.), PROC PRINT reads the data set only once.

Alias U

Restriction When not all variables have formats that explicitly specify a width, you cannot use WIDTH=UNIFORM with an engine that supports concurrent access if another user is updating the data set at the same time.

Tips If the data set is large and you want a uniform report, you can save computer resources by using formats that explicitly specify a field width so that PROC PRINT reads the data only once.

WIDTH=UNIFORM is the same as UNIFORM.

UNIFORMBY
formats all columns uniformly within a BY group, using each variable's formatted width as its column width. If the variable does not have a format that explicitly specifies a field width, PROC PRINT uses the widest data value as the column width.

Alias UBY

Restriction You cannot use UNIFORMBY with a sequential data set.

Default If you omit WIDTH= and do not specify the UNIFORM option, PROC PRINT individually constructs each page of output. The procedure analyzes the data for a page and decides how best to display them. Therefore, column widths might differ from one page to another.

Restriction WIDTH= is valid only for the LISTING destination.

Tip Column width is affected not only by variable width but also by the length of column headings. Long column headings might lessen the usefulness of WIDTH=.

See For a discussion of default column widths, see "Column Width" on page 1794.

BY Statement

Produces a separate section of the report for each BY group.

See: Chapter 3, "Statements with the Same Function in Multiple Procedures," on page 73

Examples: "Example 4: Creating Separate Sections of a Report for Groups of Observations" on page 1809

"Example 5: Summing Numeric Variables with One BY Group" on page 1819

"Example 6: Summing Numeric Variables with Multiple BY Variables" on page 1824

"Example 7: Limiting the Number of Sums in a Report" on page 1835

"Example 9: Creating a Customized Layout with BY Groups and ID Variables" on page 1845

Syntax

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...> <NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, the observations in the data set must either be sorted using PROC SORT by all the variables that you specify, or they must be indexed appropriately. Variables in a BY statement are called *BY variables*.

See PROC DATASETS MODIFY statement SORTEDBY option

Optional Arguments

DESCENDING
specifies that the data set is sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The data is grouped in another way, such as chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, the procedure treats each contiguous set as a separate BY group.

Details

Use the BY Statement with an ID Statement

PROC PRINT uses a special layout if all BY variables appear in the same order at the beginning of the ID statement. (See "Example 9: Creating a Customized Layout with BY Groups and ID Variables" on page 1845.)

Use the BY Statement with the NOBYLINE Option

If you use the BY statement with the SAS system option NOBYLINE, which suppresses the BY line that normally appears in output produced with BY-group processing, PROC PRINT always starts a new page for each BY group. This behavior ensures that if you create customized BY lines by putting BY-group information in the title and suppressing the default BY lines with NOBYLINE, the information in the titles matches the report on the pages.

Use a BY Variable When You Print Unsorted Data

If you specify a BY variable whose values are not sorted, SAS stops printing the data set when it processes the first unsorted group. A message is written to the SAS log.

ID Statement

Identifies observations by using the formatted values of the variables that you list instead of by using observation numbers.

Examples: "Example 8: Controlling the Layout of a Report with Many Variables" on page 1839
"Example 9: Creating a Customized Layout with BY Groups and ID Variables" on page 1845

Syntax

ID *variable(s)*
</ STYLE <(*location(s)*)>=<*style-override(s)*> >;

Required Argument

variable(s)
specifies one or more variables to print instead of the observation number at the beginning of each row of the report.

Restriction If the ID variables occupy so much space that no room remains on the line for at least one other variable, PROC PRINT writes a

warning to the SAS log and does not treat all ID variables as ID variables.

Interaction If a variable in the ID statement also appears in the VAR statement, the output contains two columns for that variable.

Optional Argument

STYLE <(*location(s)*)>=<*style-override(s)*>
specifies one or more style overrides to use for ID columns created with the ID statement.

You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

style-override has the following form:

style-element-name | [*style-attribute-name-1*=*style-attribute-value-1*

<*style-attribute-name-2*=*style-attribute-value-2* ...>]

Restriction Style specifications for the OBSHEADER location is not valid in the ID statement.

Interaction If the STYLE(HEADER)= option is specified in the ID statement and the STYLE(OBSHEADER)= is specified in the PROC PRINT statement, the style attributes that are specified for the ID statement take precedence over the style elements that are specified in the PROC PRINT statement. Then, the style attributes in the PROC PRINT statement STYLE(OBSHEADER)= option are merged with the style attributes in the ID statement STYLE(HEADER)= option to render the output for the ID column heading.

Tip To specify different style overrides for different ID columns, use a separate ID statement for each variable and add a different STYLE option to each ID statement.

See For information about the arguments of this option and how it is used, see the STYLE= on page 1764 option in the PROC PRINT statement.

Details

Use the BY Statement with an ID Statement

PROC PRINT uses a special layout if all BY variables appear in the same order at the beginning of the ID statement. (See "Example 9: Creating a Customized Layout with BY Groups and ID Variables" on page 1845.)

PAGEBY Statement

Controls page ejects that occur before a page is full.

Requirement: BY statement

Example: "Example 4: Creating Separate Sections of a Report for Groups of Observations" on page 1809

Syntax

PAGEBY *BY-variable*;

Required Argument

BY-variable
identifies a variable appearing in the BY statement in the PROC PRINT step. If the value of the BY variable changes, or if the value of any BY variable that precedes it in the BY statement changes, PROC PRINT begins printing a new page.

Interaction If you use the BY statement with the SAS system option NOBYLINE, which suppresses the BY line that normally appears in output produced with BY-group processing, PROC PRINT always starts a new page for each BY group. This behavior ensures that if you create customized BY lines by putting BY-group information in the title and suppressing the default BY lines with NOBYLINE, the information in the titles matches the report on the pages. (See "Creating Titles That Contain BY-Group Information " on page 57.)

SUM Statement

Totals values of numeric variables.

Tip: SAS includes checks to verify that the PROC PRINT output is accessible for the visually impaired. When you use the SUM statement and set the

ACCESSIBLECHECK system option, SAS verifies whether a label has been specified for both the SUMLABEL and the GRANDTOTAL_LABEL options in the PROC PRINT statement. If the output does not have labels for the summary and grand total values, SAS writes a message to the SAS log. For best practices about creating accessible output, see Creating Accessible Output in SAS Using ODS and ODS Graphics.

Examples:

"Example 5: Summing Numeric Variables with One BY Group" on page 1819

"Example 6: Summing Numeric Variables with Multiple BY Variables" on page 1824

"Example 7: Limiting the Number of Sums in a Report" on page 1835

"Example 9: Creating a Customized Layout with BY Groups and ID Variables" on page 1845

Syntax

SUM *variable(s)*
</ STYLE <(*location(s)*)>=<*style-override(s)*> >;

Required Argument

variable(s)
identifies the numeric variables to total in the report.

Optional Argument

STYLE <(*location(s)*)>=<*style-override(s)*>
specifies one or more style overrides to use for cells containing sums that are created with the SUM statement.

You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

style-override has the following form:

style-element-name | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

Tips To specify different style overrides for different cells reporting sums, use a separate SUM statement for each variable and add a different STYLE option to each SUM statement.

If the STYLE option is used in multiple SUM statements that affect the same location, the STYLE option in the last SUM statement will be used.

See For information about the arguments of this option and how it is used, see the option STYLE= on page 1758 in the PROC PRINT statement.

Details

Use the SUM and BY Statements Together

When you use a SUM statement and a BY statement with one BY variable, PROC PRINT sums the SUM variables for each BY group that contains more than one observation and totals them over all BY groups. (See "Example 5: Summing Numeric Variables with One BY Group" on page 1819.)

When you use a SUM statement and a BY statement with multiple BY variables, PROC PRINT sums the SUM variables for each BY group that contains more than one observation, just as it does if you use only one BY variable. However, it provides sums only for those BY variables whose values change when the BY group changes. (See "Example 6: Summing Numeric Variables with Multiple BY Variables" on page 1824.)

Note: When the value of a BY variable changes, the SAS System considers that the values of all variables listed after it in the BY statement also change.

SUMBY Statement

Limits the number of sums that appear in the report.

Requirement: BY statement

Example: "Example 7: Limiting the Number of Sums in a Report" on page 1835

Syntax

SUMBY *BY-variable*;

Required Argument

BY-variable
identifies a variable that appears in the BY statement in the PROC PRINT step. If the value of the BY variable changes, or if the value of any BY variable that precedes it in the BY statement changes, PROC PRINT prints the sums of all variables listed in the SUM statement.

Details

What Variables Are Summed?

If you use a SUM statement, PROC PRINT subtotals only the SUM variables. Otherwise, PROC PRINT subtotals all the numeric variables in the data set except for the variables listed in the ID and BY statements.

VAR Statement

Selects variables that appear in the report and determines their order.

Tip: If you omit the VAR statement, PROC PRINT prints all variables in the data set.

Examples: "Example 2: Selecting Variables to Print" on page 1797

"Example 9: Creating a Customized Layout with BY Groups and ID Variables" on page 1845

Syntax

VAR *variable(s)*
</ STYLE <(*location(s)*)>=<*style-override(s)*> >;

Required Argument

variable(s)
identifies the variables to print. PROC PRINT prints the variables in the order in which you list them.

Interaction In the PROC PRINT output, variables that are listed in the ID statement precede variables that are listed in the VAR statement. If a variable in the ID statement also appears in the VAR statement, the output contains two columns for that variable.

Optional Argument

STYLE <(*location(s)*)>=<*style-override(s)*>
specifies one or more style overrides to use for all columns that are created by a VAR statement.

You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

style-override has the following form:

style-element-name | [*style-attribute-name-1=style-attribute-value-1*
<*style-attribute-name-2=style-attribute-value-2* ...>]

Tip To specify different style overrides for different columns, use a separate VAR statement to create a column for each variable and add a different STYLE option to each VAR statement.

See For information about the arguments of this option and how it is used, see the option STYLE= on page 1764 in the PROC PRINT statement.

Usage: PRINT Procedure

Use ODS Styles with PROC PRINT

Using Styles with Base SAS Procedures

Most Base SAS procedures that support ODS use one or more table templates to produce output objects. These table templates include templates for table elements: columns, headers, and footers. Each table element can specify the use of one or more style elements for various parts of the output. These style elements cannot be specified within the syntax of the procedure, but you can use customized styles for the ODS destinations that you use. For more information about customizing tables and styles, see "TEMPLATE Procedure: Creating a Style Template" in *SAS Output Delivery System: Procedures Guide*.

The Base SAS reporting procedures, PROC PRINT, PROC REPORT, and PROC TABULATE, enable you to quickly analyze your data and organize it into easy-to-read tables. You can use the STYLE= option with these procedure statements to modify the appearance of your report. The STYLE= option enables you to make changes in sections of output without changing the default style for all of the output. You can customize specific sections of procedure output by specifying the STYLE= option in specific statements within the procedure.

The following program uses the STYLE= option to create the colors in the PROC PRINT output below. For the complete input data set, see "EXPREV" on page 2790.

```
proc print data=exprev noobs sumlabel='Total' GRANDTOTAL_LABEL="Grand
Total"
      style(table)=[frame=box rules=groups]
      style(bysumline)=[background=red foreground=linen]
```

```
      style(grandtotal)=[foreground=green]
      style(header)=[font_style=italic background=orange];
   by sale_type order_date;
   sum price quantity;
   sumby sale_type;
   label sale_type='Sale Type' order_date='Sale Date';
format price dollar10.2 cost dollar10.2;
   var Country / style(data)=[font_face=arial font_weight=bold
background=linen];
   var Price / style(data)=[font_style=italic background=yellow];
   var Cost / style(data)=[foreground=hgt. background=lightgreen];
title 'Retail and Quantity Totals for Each Sale Type';
run;
```

Output 48.1 *Enhanced PROC PRINT Output*

Retail and Quantity Totals for Each Sale Type

Sale Type=Catalog Sale Date=1/1/12

Country	Price	Cost	Quantity
Puerto Rico	$51.20	$12.10	14
Aruba	$123.70	$59.00	30
Bahamas	$113.40	$28.45	8
Bermuda	$41.00	$9.25	7

Sale Type=Catalog Sale Date=1/2/12

Country	Price	Cost	Quantity
British Virgin Islands	$40.20	$20.20	11
Canada	$11.80	$5.00	100
Total	$381.30		170

Sale Type=In Store Sale Date=1/1/12

Country	Price	Cost	Quantity
Virgin Islands (U.S.)	$31.10	$15.65	25

Sale Type=In Store Sale Date=1/2/12

Country	Price	Cost	Quantity
Belize	$146.40	$36.70	2
Cayman Islands	$71.00	$32.30	20
Total	$248.50		47

Sale Type=Internet Sale Date=1/1/12

Country	Price	Cost	Quantity
Antarctica	$92.60	$20.70	2
Grand Total	$722.40		219

Styles, Style Elements, and Style Attributes

Understanding Styles, Style Elements, and Style Attributes

The appearance of SAS output is controlled by ODS style templates (ODS styles). ODS styles are produced from compiled STYLE templates written in PROC TEMPLATE style syntax. An ODS style template is a collection of style elements that provides specific visual attributes for your SAS output.

- A style element is a named collection of style attributes that apply to a particular part of the output. Each area of ODS output has a style element name that is associated with it. The style element name specifies where the style attributes are applied. For example, a style element might contain instructions for the presentation of column headings or for the presentation of the data inside the cells. Style elements might also specify default colors and fonts for output that uses the style.
- A style attribute is a visual property, such as color, font properties, and line characteristics, that is defined in ODS with a reserved name and value. Style attributes are collectively referenced by a style element within a style template. Each *style attribute* specifies a value for one aspect of the presentation. For example, the BACKGROUNDCOLOR= attribute specifies the color for the background of an HTML table or for a colored table in printed output. The FONTSTYLE= attribute specifies whether to use a Roman font or an italic font.

Note: Because styles control the presentation of the data, they have no effect on output objects that go to the LISTING, DOCUMENT, or OUTPUT destination.

Available styles are in the SASHELP.TMPLMST item store. In SAS Enterprise Guide, the list of style sheets is shown by the Style Wizard. In batch mode or SAS Studio, you can display the list of available style templates by using the LIST statement in PROC TEMPLATE:

```
proc template;
   list styles / store=sashelp.tmplmst;
run;
```

For complete information about viewing ODS styles, see "Viewing ODS Styles Supplied by SAS" in *SAS Output Delivery System: Advanced Topics*.

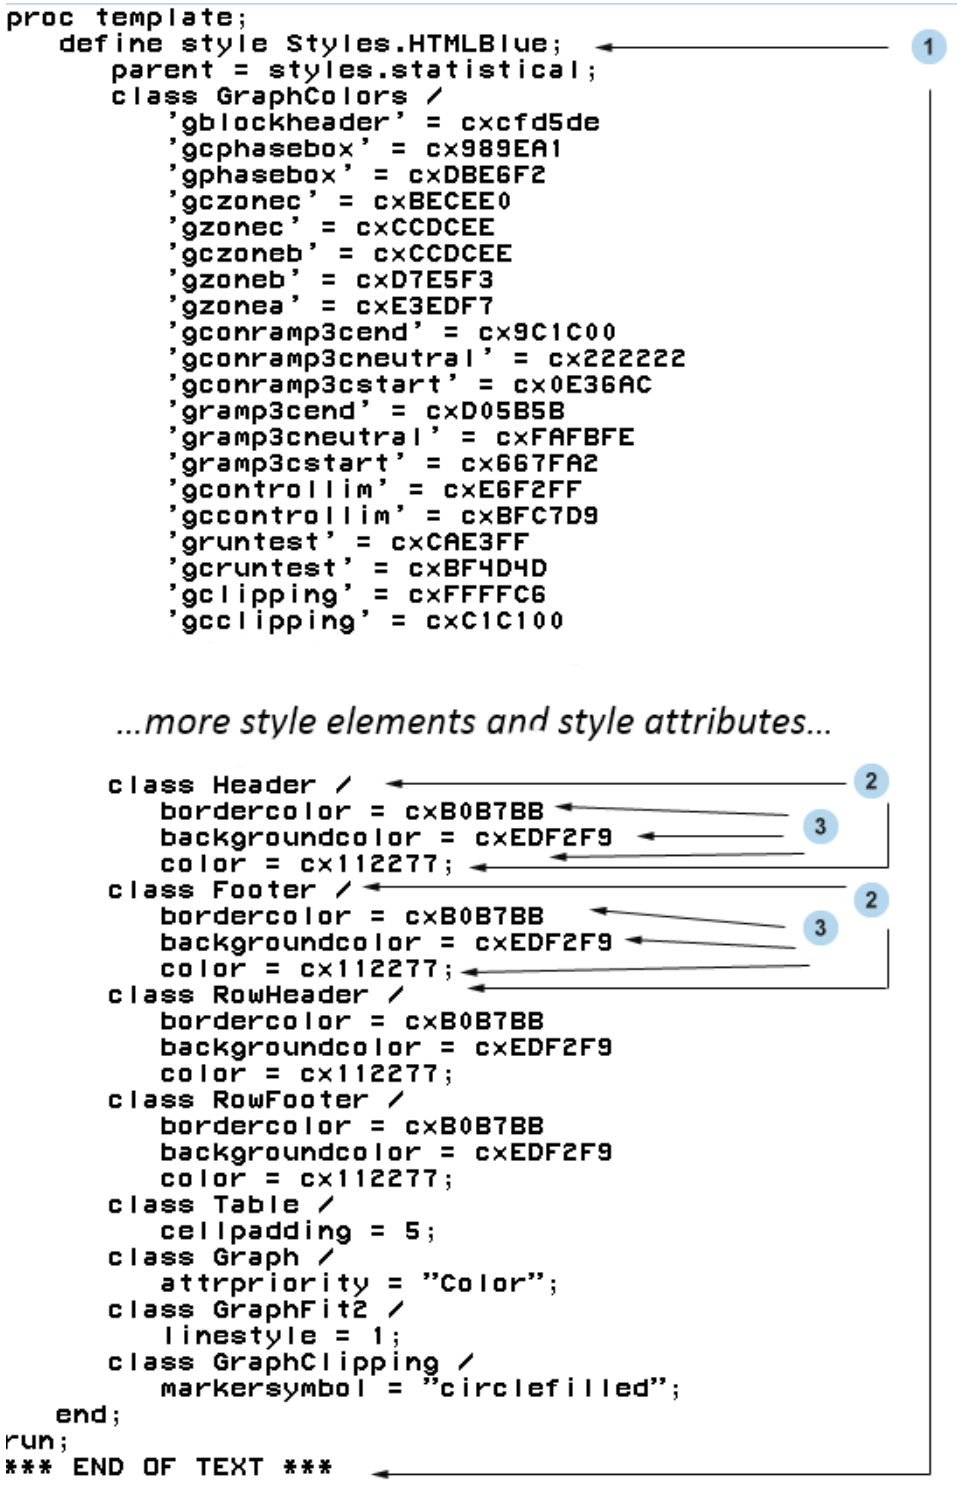
By default, HTML 4 output uses the HTMLBlue style template and HTML 5 output uses the HTMLEncore style template. To help you become familiar with styles, style elements, and style attributes, look at the relationship between them.

You can use the SOURCE statement in PROC TEMPLATE to display the structure of a style template. The following code prints the structure of the HTMLBlue style template to the SAS log:

```
proc template;
   source styles.HTMLBlue;
run;
```

The following figure illustrates the structure of a style. The figure shows the relationship between the style, the style elements, and the style attributes.

Figure 48.4 *Diagram of the HtmlBlue Style*



The following list corresponds to the numbered items in the preceding figure:

1 Styles.HtmlBlue is the *style*. Styles describe how to display presentation aspects (color, font, font size, and so on) of the SAS output. A style determines

the overall appearance of the ODS documents that use it. The default style for HTML output is HtmlBlue. Each style consists of style elements.

You can create new styles with the "DEFINE STYLE Statement" in *SAS Output Delivery System: Procedures Guide*. New styles can be created independently or from an existing style. You can use "PARENT= Statement" in *SAS Output Delivery System: Procedures Guide* to create a new style from an existing style. For complete documentation about ODS styles, see "Style Templates" in *SAS Output Delivery System: Advanced Topics*.

2 Header and Footer are examples of *style elements*. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program. For example, a style element might contain instructions for the presentation of column headings or for the presentation of the data inside table cells. Style elements might also specify default colors and fonts for output that uses the style. Style elements exist inside styles and consist of one or more style attributes. Style elements can be user-defined or supplied by SAS. User-defined style elements can be created by the "STYLE Statement" in *SAS Output Delivery System: Procedures Guide*.

Note: For a list of the default style elements used for HTML and markup languages and their inheritance, see "Style Elements" in *SAS Output Delivery System: Advanced Topics*.

3 BORDERCOLOR=, BACKGROUNDCOLOR=, and COLOR= are examples of *style attributes*. Style attributes specify a value for one aspect of the area of the output that its style element applies to. For example, the COLOR= attribute specifies the value `cx112277` for the font color. For a list of style attributes supplied by SAS, see "Style Attributes" in *SAS Output Delivery System: Advanced Topics*.

Style attributes can be referenced with style references. See "style-reference" in *SAS Output Delivery System: Advanced Topics* for more information about style references.

The following table shows commonly used style attributes that you can set with the STYLE= option in PROC PRINT, PROC TABULATE, and PROC REPORT. Most of these attributes apply to parts of the table other than cells (for example, table borders and the lines between columns and rows). Note that not all attributes are valid in all destinations. For more information about these style attributes, their valid values, and their applicable destinations, see "Style Attributes Tables" in *SAS Output Delivery System: Advanced Topics*.

Table 48.2 Style Attributes for PROC REPORT, PROC TABULATE, and PROC PRINT

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE
ASIS=	X	X		X		X
BACKGROUNDCOLOR=	X	X	X	X	X	X
BACKGROUNDIMAGE=	X	X	X	X	X	X
BORDERBOTTOMCOLOR=	X	X		X

BORDERWIDTH=	X	X	X	X	X	X
CELLPADDING=	X		X		X	
CELLSPACING=	X		X		X	
CELLWIDTH=	X	X	X	X		X
CLASS=	X	X	X	X	X	X
COLOR=	X	X	X			
FLYOVER=	X	X		X		X
FONT=	X	X	X	X	X	X
FONTFAMILY=	X	X	X	X	X	X
FONTSIZE=	X	X	X	X	X	X
FONTSTYLE=	X	X	X	X	X	X
FONTWEIGHT=	X	X	X	X	X	X
FONTWIDTH=	X	X	X	X		X
FRAME=	X		X		X	
HEIGHT=	X	X		X	X	X
HREFTARGET=		X		X		X
HTMLSTYLE=	X	X	X	X	X	
NOBREAKSPACE=[2]	X	X		X		X
OUTPUTWIDTH=	X	X	X	X	X	

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE
POSTHTML=[1]	X	X	X	X	X	X
POSTIMAGE=	X	X	X	X	X	X
POSTTEXT=[1]	X	X	X	X	X	X
PREHTML=[1]	X	X	X	X	X	X
PREIMAGE=	X	X	X	X	X	X
PRETEXT=[1]	X	X	X	X	X	X
PROTECTSPECIALCHARS=		X		X	X	X
RULES=	X		X		X	
TAGATTR=	X	X	X	X	X	X
TEXTALIGN=	X	X	X	X	X	X
URL=		X		X		X
VERTICALALIGN=		X		X		X
WIDTH=	X	X	X	X	X	

1 When you use these attributes in this location, they affect only the text that is specified with the PRETEXT=, POSTTEXT=, PREHTML=, and POSTHTML= attributes. To alter the foreground color or the font for the text that appears in the table, you must set the corresponding attribute in a location that affects the cells rather than the table. For complete documentation about style attributes and their values, see "Style Attributes" in *SAS Output Delivery System: Advanced Topics*.

2 To help prevent unexpected wrapping of long text strings when using PROC REPORT with the ODS RTF destination, set NOBREAKSPACE=OFF in a location that affects the LINE statement. The NOBREAKSPACE=OFF attribute must be set in the PROC REPORT code either on the LINE statement or on the PROC REPORT statement where style(lines) is specified.

Default Style Elements and Style Attributes for Table Regions

The following table lists the default style elements and style attributes for various locations of PROC PRINT output. The locations in this table correspond to the locations in Table 48.93 on page 1765. The table lists defaults for the most

commonly used ODS destinations: HTML, PDF, and RTF. Each destination has a default style template that is applied to all output that is written to the destination.

- The default style for HTML output is HTMLBlue.
- The default style for PRINTER output is Pearl.
- The default style for RTF output is RTF.

For complete documentation about the ODS destinations and their default styles, see "Style Templates" in *SAS Output Delivery System: Advanced Topics*.

Table 48.3 *Default Style Elements and Style Attributes for Report Regions*

Location	Style Element	HTML Style Attributes	PDF Style Attributes	RTF Style Attributes
BYLABEL	Byline	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = bold FONTSTYLE = roman COLOR = cx112277 BACKGROUNDCOLOR = cxedf2f9	FONTFAMILY = "Arial, 'Albany AMT'" FONTSIZE = 8pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxffffff	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 11pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BORDERWIDTH = NaN

		FONTSTYLE = roman BACKGROUNDCOLOR = cxffffff	COLOR = cx000000 BACKGROUNDCOLOR = cxffffff	COLOR = cx000000

Error Processing in the PRINT Procedure Output

If an error occurs in the PRINT procedure or if the procedure is halted, output might be created for the observations that were processed until the error. SAS writes a message to the SAS log and ends the PRINT procedure.

For LISTING output, if the page size is set too small, SAS cannot print both the data and any titles or footnotes on the same page. If this happens, only the data is printed to the LISTING destination and SAS writes a warning message to the log. To write both the data and titles or footnotes on the same page, make sure that the page size is adequate.

Results: PRINT Procedure

About PROC PRINT Output

By default, PROC PRINT produces an HTML5 report when you run SAS in the windowing environment. In all other operating modes, the default destination is LISTING. The PRINT procedure statements, PROC PRINT, BY, PAGEBY, SUMBY, ID, SUM, and VAR control the content of the report. The options for each statement control the appearance of the report.

To change the ODS destination for the report, use ODS statements before the PROC PRINT statement. If you do not want HTML output, be sure to close the ODS HTML destination before you run the procedure. For more information about using ODS, see the *SAS Output Delivery System: User's Guide*.

See the PRINT procedure examples on page 1797 for a sampling of the types of reports that the procedure produces.

Page Layout for HTML, the Default ODS Destination

A page of ODS HTML output is not limited in width or length. Therefore, each observation in a table is printed on a single line and all observations that are specified to print by the report appear on a single page of HTML output.

Each time that PROC PRINT runs, by default, SAS adds a page break after the output. A page break is rendered by separating output with a horizontal rule. For more information, see "ODS HTML Statement" in *SAS Output Delivery System: User's Guide*.

Page Layout for Limited Page Sizes

Observations

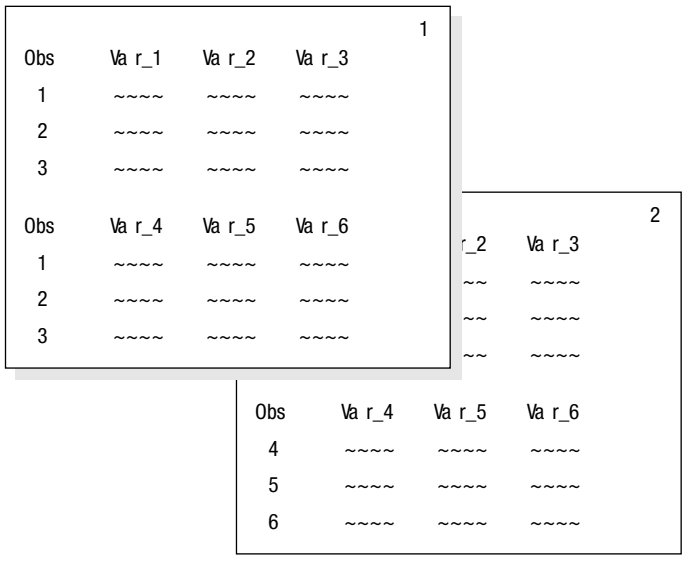
PROC PRINT uses an identical layout for all observations on a page for ODS destinations that produce output whose page size is limited in width and length. Some of these ODS destinations are RTF, PDF, and LISTING. First, it attempts to print observations on a single line, as shown in the following figure.

Figure 48.5 *Printing Observations on a Single Line*

				1
Obs	Var_1	Var_2	Var_3	
1	~~~~	~~~~	~~~~	
2	~~~~	~~~~	~~~~	
3	~~~~	~~~~	~~~~	
4	~~~~	~~~~	~~~~	
5	~~~~	~~~~	~~~~	
6	~~~~	~~~~	~~~~	

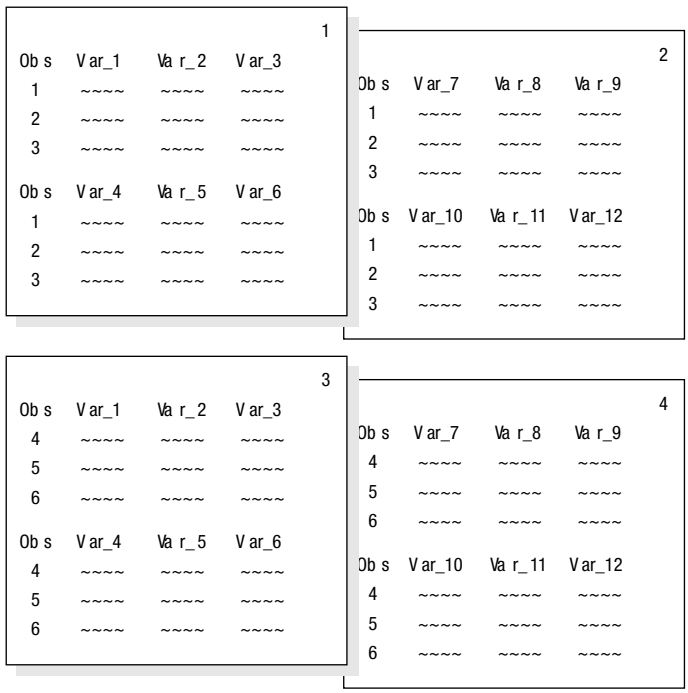
If PROC PRINT cannot fit all the variables on a single line, it splits the observations into two or more sections and prints the observation number or the ID variables at the beginning of each line. For example, in the following figure, PROC PRINT prints the values for the first three variables in the first section of each page and the values for the second three variables in the second section of each page.

Figure 48.6 *Splitting Observations into Multiple Sections on One Page*



If PROC PRINT cannot fit all the variables on one page, the procedure prints subsequent pages with the same observations until it has printed all the variables. For example, in the following figure, PROC PRINT uses the first two pages to print values for the first three observations and the second two pages to print values for the rest of the observations.

Figure 48.7 *Splitting Observations across Multiple Pages*



Note: For the LISTING destination, you can alter the page layout with the ROWS= option in the PROC PRINT statement. (See the discussion of ROWS= option on page 1764.)

Column Headings

The amount of spacing specifies whether PROC PRINT prints column headings horizontally or vertically. Figure 48.55 on page 1792, Figure 48.56 on page 1793, and Figure 48.57 on page 1793 all illustrate horizontal headings. The following figure illustrates vertical headings.

Figure 48.8 *Using Vertical Headings*

```
                                  1
        V      V      V
        a      a      a
  O     r      r      r
  b     _      _      _
  s     1      2      3

  1    ~~~~   ~~~~   ~~~~
  2    ~~~~   ~~~~   ~~~~
  3    ~~~~   ~~~~   ~~~~
  4    ~~~~   ~~~~   ~~~~
  5    ~~~~   ~~~~   ~~~~
  6    ~~~~   ~~~~   ~~~~
```

Note: If you use LABEL and at least one variable has a label, PROC PRINT prints all column headings horizontally unless you specify HEADING=VERTICAL.

Column Width

By default, PROC PRINT uses a variable's formatted width as the column width. (The WIDTH= option overrides this default behavior for the LISTING destination.) If the variable does not have a format that explicitly specifies a field width, PROC PRINT uses the widest data value for that variable on that page as the column width.

If the formatted value of a character variable or the data width of an unformatted character variable exceeds the line size minus the length of all the ID variables, PROC PRINT might truncate the value. Consider the following situation:

- The line size is 80.
- IdNumber is a character variable with a length of 10. It is used as an ID variable.
- State is a character variable with a length of 2. It is used as an ID variable.
- Comment is a character variable with a length of 200.

When PROC PRINT prints these three variables on a line, it uses 14 print positions for the two ID variables and the space after each one. This arrangement leaves 80–14, or 66, print positions for COMMENT. Longer values of COMMENT are truncated.

WIDTH= controls the column width for the LISTING destination.

Note: Column width is affected not only by variable width but also by the length of column headings. Long column headings might lessen the usefulness of WIDTH=.

Examples: PRINT Procedure

Example 1: Print a CAS Table

Features: PROC PRINT DATA=*CAS-table*

CAS language elements:
- CAS statement
- LIBNAME statement for the CAS engine
- PROC CASUTIL
- PROC MDSUMMARY

Data set: Sashelp.cars

Details

This example demonstrates the following tasks:

- establishes a CAS session
- associates the Mycas libref with the CAS engine and the CAS session
- creates the CAS table mycas.cars
- uses PROC MDSUMMARY to summarize the cars data
- prints 15 rows of the summarized CAS table

Program: Run in the SAS Windowing Environment

```
options cashost="cloud.example.com" casport=5555;
cas mysess sessopts=(caslib='casuser');
libname mycas cas sessref=mysess;

proc casutil outcaslib="casuser";
  load data=sashelp.cars replace;
```

```
run;

proc mdsummary data=mycas.cars;
  var mpg_highway;
  groupby origin type / out=mycas.mpghw_sum;
run;

options obs=15;
proc print data=mycas.mpghw_sum;
   var origin type _mean_;
   title "Average Highway Milages";
run;
```

Program Description

Start the CAS server, set up the CAS session, create a libref for the CAS engine, and connect the engine to the CAS session. The OPTIONS statement connects SAS to the CAS server. The CAS statement creates the Mysess session using the CASUSER caslib. The LIBNAME statement creates the Mycas libref for the CAS engine, which uses the Mysess CAS session.

```
options cashost="cloud.example.com" casport=5555;
cas mysess sessopts=(caslib='casuser');
libname mycas cas sessref=mysess;
```

Load the table Sashelp.cars into the caslib Casuser. The OUTCASLIB= option names the caslib to where the table is loaded. Use the LOAD statement to load the table from Sashelp.cars. The REPLACE option replaces the table and names the table to load.

```
proc casutil outcaslib="casuser";
  load data=sashelp.cars replace;
run;
```

Summarize the data using PROC MDSUMMARY. The VAR statement specifies the analysis variable to order the results. The GROUPBY statement creates BY groups and saves the output to the table Mycas.mpghw_sum.

```
proc mdsummary data=mycas.cars;
  var mpg_highway;
  groupby origin type / out=mycas.mpghw_sum;
run;
```

Print the first 15 rows of the summary results. With OBS=15, PROC PRINT prints only 15 rows of the CAS table. The VAR statement limits the output table to three columns, Origin, Type, and _Mean_.

```
options obs=15;
proc print data=mycas.mpghw_sum;
   var origin type _mean_;
   title "Average Highway Milages";
run;
```

Average Highway Milages

Obs	Origin	Type	_Mean_
1	Asia	Wagon	28.181818182
2	Europe	Sedan	27.115384615
3	Europe	Wagon	26.583333333
4	USA	SUV	20.04
5	USA	Wagon	29.714285714
6	Asia	Hybrid	56
7	Asia	SUV	21.68
8	USA	Sedan	28.544444444
9	USA	Truck	20.5
10	Asia	Truck	22
11	Europe	SUV	18.7
12	Asia	Sedan	29.968085106
13	Asia	Sports	26.647058824
14	Europe	Sports	25.130434783
15	USA	Sports	24.222222222

Example 2: Selecting Variables to Print

Features:
- PROC PRINT statement options
  - BLANKLINE
  - DOUBLE
  - STYLE
- VAR statement
- DATA step
- FOOTNOTE statement
- ODS HTML statement
- OPTIONS statement
- TITLE statement

Data set: EXPREV

ODS destinations: HTML, LISTING

Details

This example demonstrates the following tasks:

- selects three variables for the reports

- uses variable labels as column headings
- double spaces between rows of the report in the LISTING output
- creates a report for the default HTML destination and the LISTING destination at the same time
- creates a stylized HTML report

Program: Creating an HTML Report

```
options obs=10;

ods listing;

proc print data=exprev;

   var country price sale_type;
   title 'Monthly Price Per Unit and Sale Type for Each Country';
   footnote '*prices in USD';
run;
```

Program Description

HTML is the default destination when SAS opens in the windowing environment.

Set the OBS= system option to process 10 observations.

```
options obs=10;
```

Open the LISTING destination. By default in the windowing environment, the HTML default is open. The ODS LISTING statement opens the LISTING destination in order to create HTML and LISTING output at the same time.

```
ods listing;
```

Print the output The VAR statement specifies the variables to print.

```
proc print data=exprev;

   var country price sale_type;
   title 'Monthly Price Per Unit and Sale Type for Each Country';
   footnote '*prices in USD';
run;
```

Output: HTML and LISTING

Output 48.2 *Selecting Variables: Default HTML Output*

Monthly Price Per Unit and Sale Type for Each Country

Obs	Country	Price	Sale_Type
1	Antarctica	92.6	Internet
2	Puerto Rico	51.2	Catalog
3	Virgin Islands (U.S.)	31.1	In Store
4	Aruba	123.7	Catalog
5	Bahamas	113.4	Catalog
6	Bermuda	41.0	Catalog
7	Belize	146.4	In Store
8	British Virgin Islands	40.2	Catalog
9	Canada	11.8	Catalog
10	Cayman Islands	71.0	In Store

*prices in USD

Output 48.3 *Selecting Variables: LISTING Output*

```
                    Monthly Price Per Unit and Sale Type for Each
Country

                                                          Sale_
                     Obs    Country                Price   Type

                       1    Antarctica              92.6   Internet

                       2    Puerto Rico             51.2   Catalog

                       3    Virgin Islands (U.S.)   31.1   In Store

                       4    Aruba                  123.7   Catalog

                       5    Bahamas                113.4   Catalog

                       6    Bermuda                 41.0   Catalog

                       7    Belize                 146.4   In Store

                       8    British Virgin Islands  40.2   Catalog

                       9    Canada                  11.8   Catalog

                      10    Cayman Islands          71.0   In Store

                                        *prices in USD
```

Program: Create an HTML Report with the STYLE and BLANKLINE Options

```
options obs=5;

ods html file='your_file_styles.html';

proc print data=exprev
   style(header)={fontstyle=italic color= green}
   style(obs)={backgroundcolor=#a8a44ff8a color=blue}
   blankline=(count= 1 style={backgroundcolor=cx456789});

   var country price sale_type;

   title 'Monthly Price Per Unit and Sale Type for Each Country';
   footnote '*prices in USD';
run;
```

Program Description

You can go a step further and add more formatting to your HTML output. The following example uses the STYLE option to add shading and spacing to your HTML report.

```
options obs=5;

ods html file='your_file_styles.html';
```

Create stylized HTML output. The first STYLE option specifies that the column headings are written in green italic font. The second STYLE option specifies that observation number column has a background color of the RGB color a8a44ff8a and a text color of blue. The BLANKLINE option specifies to add a blank line between each observation and use a background color of the CMYK color cx456789. Because a style has not been defined for the OBSHEADER location, the Obs column heading in the output uses the default style color and not green.

```
proc print data=exprev
   style(header)={fontstyle=italic color= green}
   style(obs)={backgroundcolor=#a8a44ff8a color=blue}
   blankline=(count= 1 style={backgroundcolor=cx456789});

   var country price sale_type;

   title 'Monthly Price Per Unit and Sale Type for Each Country';
   footnote '*prices in USD';
run;
```

Output: HTML Output with Styles

Output 48.4 *Selecting Variables: HTML Output Using Styles*

Monthly Price Per Unit and Sale Type for Each Country

Obs	Country	Price	Sale_Type
1	Antarctica	92.6	Internet
2	Puerto Rico	51.2	Catalog
3	Virgin Islands (U.S.)	31.1	In Store
4	Aruba	123.7	Catalog
5	Bahamas	113.4	Catalog

*prices in USD

Program: Create a LISTING Report

```
options nodate pageno=1 linesize=80 pagesize=30 obs=10;

ods html close;
ods listing;

proc print data=exprev double;

   var country price sale_type;

   title 'Monthly Price Per Unit and Sale Type for Each Country';
   footnote '*prices in USD';
run;

ods listing close;
ods html;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. The PAGENO= option specifies the starting page number. The LINESIZE= option specifies the output line length, and the PAGESIZE= option specifies the number of lines on an output page. The OBS= option specifies the number of observations to display.

```
options nodate pageno=1 linesize=80 pagesize=30 obs=10;
```

Close the HTML destination and open the LISTING destination. HTML is the default destination when you start SAS. To create only a LISTING report, you can close the HTML destination and open the LISTING destination.

```
ods html close;
ods listing;
```

Print the data set EXPREV. EXPREV contains information about a company's product order type and price per unit for two months. DOUBLE inserts a blank line between observations. The DOUBLE option has no effect on the HTML output.

```
proc print data=exprev double;
```

Select the variables to include in the report. The VAR statement creates columns for Country, Price, and Sale_Type, in that order.

```
   var country price sale_type;
```

Specify a title and a footnote. The TITLE statement specifies the title for the report. The FOOTNOTE statement specifies a footnote for the report.

```
   title 'Monthly Price Per Unit and Sale Type for Each Country';
   footnote '*prices in USD';
run;
```

Close the LISTING destination and reopen the HTML destination. When you close and reopen the HTML destination, SAS saves HTML output to the current directory and not the Work library.

```
ods listing close;
ods html;
```

Output: LISTING

By default, PROC PRINT identifies each observation by number under the column heading `Obs`.

Output 48.5 *Selecting Variables: LISTING Output*

Monthly Price Per Unit and Sale Type for Each Country 1

Obs	Country	Price	Sale_ Type
1	Antarctica	92.6	Internet
2	Puerto Rico	51.2	Catalog
3	Virgin Islands (U.S.)	31.1	In Store
4	Aruba	123.7	Catalog
5	Bahamas	113.4	Catalog
6	Bermuda	41.0	Catalog
7	Belize	146.4	In Store
8	British Virgin Islands	40.2	Catalog
9	Canada	11.8	Catalog
10	Cayman Islands	71.0	In Store

*prices in USD

Example 3: Customizing Text in Column Headings

Features:
PROC PRINT statement options
- N
- OBS=
- SPLIT=
- STYLE

VAR statement option
- STYLE

LABEL statement

ODS PDF statement

FORMAT statement

TITLE statement

Data set: EXPREV

ODS destinations: LISTING, PDF

Details

This example demonstrates the following tasks:

- underlines the text in column headings for variables in LISTING output
- adds background color to the column headings for variables in PDF output
- customizes the column heading for the column that identifies observations by number
- shows the number of observations in the report
- writes the values of the variable Price with dollar signs and periods

Program: Create a LISTING Report

```
options nodate pageno=1 linesize=80 pagesize=30 obs=10;

ods html close;
ods listing;

proc print data=exprev split='*' n
obs='Observation*Number*===========';

   var country sale_type price;

   label country='Country Name**============'
         sale_type='Order Type**==========='
         price='Price Per Unit*in USD*==============';

   format price dollar10.2;
   title 'Order Type and Price Per Unit in Each Country';
run;

ods listing close;
ods html;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. The PAGENO= option specifies the starting page number. The LINESIZE= option specifies the output line length, and the PAGESIZE= option specifies the number of lines on an output page. The OBS= option specifies the number of observations to be displayed.

```
options nodate pageno=1 linesize=80 pagesize=30 obs=10;
```

Close the HTML destination and open the LISTING destination. By default, the HTML destination is open.

```
ods html close;
ods listing;
```

Print the report and define the column headings. SPLIT= identifies the asterisk as the character that starts a new line in column headings. The N option prints the number of observations at the end of the report. OBS= specifies the column heading for the column that identifies each observation by number. The split character (*) starts a new line in the column heading. The equal signs (=) in the value of OBS= underlines the column heading.

```
proc print data=exprev split='*' n
obs='Observation*Number*==========';
```

Select the variables to include in the report. The VAR statement creates columns for Country, Sale_Type, and Price, in that order.

```
    var country sale_type price;
```

Assign the variables' labels as column headings. The LABEL statement associates a label with each variable for the duration of the PROC PRINT step. When you use the SPLIT= option in the PROC PRINT statement, the procedure uses labels for column headings. The split character (*) starts a new line in the column heading. The equal signs (=) in the labels underlines the column headings.

```
    label country='Country Name**============'
          sale_type='Order Type**==========='
          price='Price Per Unit*in USD*==============';
```

Specify a title for the report, and format any variable containing numbers. The FORMAT statement assigns the DOLLAR10.2 format to the variable Price in the report. The TITLE statement specifies a title.

```
    format price dollar10.2;
    title 'Order Type and Price Per Unit in Each Country';
run;
```

Close the LISTING destination and re-open the HTML destination.

```
ods listing close;
ods html;
```

Output: LISTING

Output 48.6 *Customizing Column Headings: LISTING Output*

```
                Order Type and Price Per Unit in Each Country                1

    Observation    Country Name              Order Type    Price Per Unit
       Number                                                   in USD
    ===========    ============              ==========    ==============

          1        Antarctica                 Internet           $92.60
          2        Puerto Rico                Catalog            $51.20
          3        Virgin Islands (U.S.)      In Store           $31.10
          4        Aruba                      Catalog           $123.70
          5        Bahamas                    Catalog           $113.40
          6        Bermuda                    Catalog            $41.00
          7        Belize                     In Store          $146.40
          8        British Virgin Islands     Catalog            $40.20
          9        Canada                     Catalog            $11.80
         10        Cayman Islands             In Store           $71.00

                                    N = 10
```

Program: Creating a PDF Report

```
options obs=10;

ods pdf file='your_file.pdf';

proc print data=exprev n obs='Observation Number';

   var country sale_type price;
         label country='Country Name'
               sale_type='Order Type'
               price='Price Per Unit in USD';
         format price dollar10.2;
         title 'Order Type and Price Per Unit in Each Country';
run;

ods pdf close;
```

Program Description

You can easily create PDF output by adding a few ODS statements. In the following example, ODS statements were added to produce PDF output.

The OBS= system option specifies to process 10 observations.

```
options obs=10;
```

Create PDF output and specify the file to store the output in. The ODS PDF statement opens the PDF destination and creates PDF output. The FILE= argument specifies the external file that contains the PDF output.

```
ods pdf file='your_file.pdf';
```

Set the procedure options. The N option prints the number of observations at the end of the report. OBS= specifies the column heading for the column that identifies each observation by number.

```
proc print data=exprev n obs='Observation Number';
```

Process the variables in the data set. The VAR statement specifies the variables to print. The LABEL statement creates text to print in place of the variable names. The FORMAT statement specifies to format the price variables using the DOLLARw. format. The TITLE statement creates a title for the report.

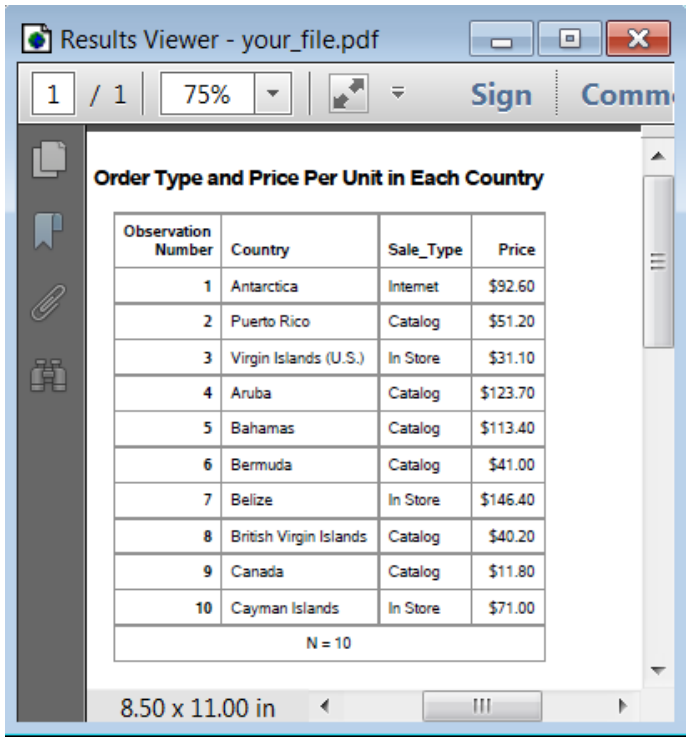
```
    var country sale_type price;
          label country='Country Name'
                sale_type='Order Type'
                price='Price Per Unit in USD';
          format price dollar10.2;
          title 'Order Type and Price Per Unit in Each Country';
run;
```

Close the PDF destination. The ODS PDF CLOSE statement closes the PDF destination.

```
ods pdf close;
```

Output: PDF

Output 48.7 *Customizing Column Heading: Default PDF Output*



Observation Number	Country	Sale_Type	Price
1	Antarctica	Internet	$92.60
2	Puerto Rico	Catalog	$51.20
3	Virgin Islands (U.S.)	In Store	$31.10
4	Aruba	Catalog	$123.70
5	Bahamas	Catalog	$113.40
6	Bermuda	Catalog	$41.00
7	Belize	In Store	$146.40
8	British Virgin Islands	Catalog	$40.20
9	Canada	Catalog	$11.80
10	Cayman Islands	In Store	$71.00
N = 10			

Program: Creating a PDF Report with the STYLE Option

```
options obs=10;

ods pdf file='your_file.pdf';

proc print data=exprev n obs='Observation Number'
     style(n)={backgroundcolor=light blue fontstyle=italic}
     style(header obs obsheader)={backgroundcolor=light yellow
color=blue
      fontstyle=italic};
     style(data)={backgroundcolor=very light blue}

   var country sale_type price / style(data)=[backgroundcolor=very
light blue];
   label country='Country Name'
         sale_type='Order Type'
         price='Price Per Unit in USD';
   format price dollar10.2;
run;

title 'Order Type and Price Per Unit in Each Country';

ods pdf close;
```

Program Description

The OBS= system option specifies to process 10 observations.

```
options obs=10;

ods pdf file='your_file.pdf';
```

Create stylized PDF output. The first STYLE option specifies that the background color of the cell containing the value for N be changed to light blue and that the font style be changed to italic. The second STYLE option specifies that the background color of the observation column, the observation header, and the other variable's headers be changed to a light yellow, the text color is changed to blue, and the font style is changed to italic.

```
proc print data=exprev n obs='Observation Number'
     style(n)={backgroundcolor=light blue fontstyle=italic}
     style(header obs obsheader)={backgroundcolor=light yellow
color=blue
      fontstyle=italic};
     style(data)={backgroundcolor=very light blue}
```

Create stylized PDF output. The STYLE option changes the color of the cells containing data to a very light blue.

```
   var country sale_type price / style(data)=[backgroundcolor=very
light blue];
   label country='Country Name'
         sale_type='Order Type'
         price='Price Per Unit in USD';
   format price dollar10.2;
```

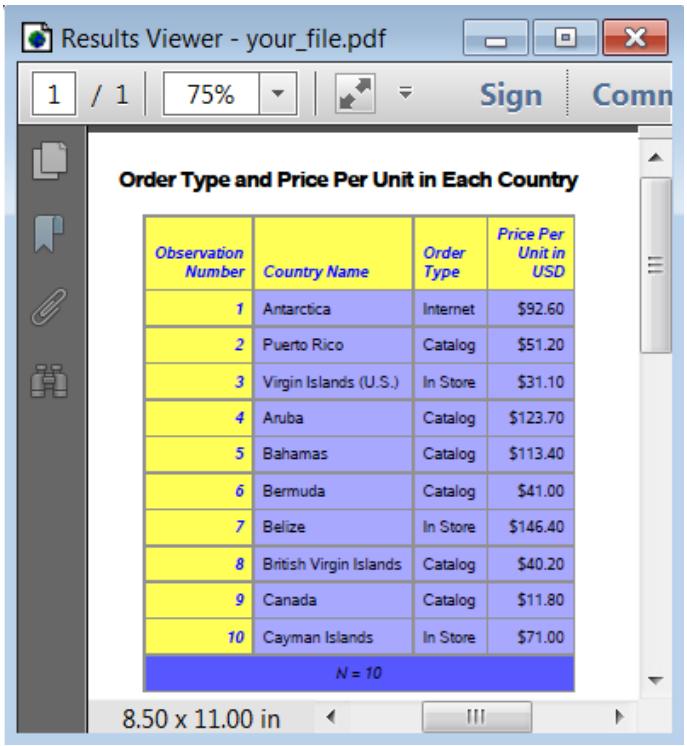
```
run;
title 'Order Type and Price Per Unit in Each Country';
```

Close the PDF destination. The ODS PDF CLOSE statement closes the PDF destination.

```
ods pdf close;
```

Output: PDF Report with Styles

Output 48.8 *Customizing Column Headings: PDF Using Styles*



Observation Number	Country Name	Order Type	Price Per Unit in USD
1	Antarctica	Internet	$92.60
2	Puerto Rico	Catalog	$51.20
3	Virgin Islands (U.S.)	In Store	$31.10
4	Aruba	Catalog	$123.70

Example 4: Creating Separate Sections of a Report for Groups of Observations

Features:

PROC PRINT statement options
- LABEL
- N=
- NOOBS
- STYLE

BY statement

PAGEBY statement

SORT procedure

FORMAT statement

LABEL statement
ODS RTF statement
TITLE statement

Data set: EXPREV

ODS destinations: HTML, RTF

Details

This example demonstrates the following:

- suppresses the printing of observation numbers at the beginning of each row
- presents the data for each sale type in a separate section of the report
- creates a default HTML report
- creates default and stylized RTF reports

Program: Creating an HTML Report

```
options obs=10;

proc sort data=exprev;
   by sale_type order_date quantity;
run;

proc print data=exprev n='Number of observations for the month: '
           noobs label;

   var quantity cost price;

   by sale_type order_date;
   pageby order_date;

   label sale_type='Order Type' order_date='Order Date';

   format price dollar7.2 cost dollar7.2;
   title 'Prices and Cost Grouped by Date and Order Type';
   title2 'in USD';
run;

proc options option=bufno define;
run;
```

Program Description

The HTML destination is open by default. No ODS HTML statement is needed.

The OBS= system option specifies to process 10 observations.

```
options obs=10;
```

Sort the EXPREV data set. PROC SORT sorts the observations by Sale_Type, Order_Date, and Quantity.

```
proc sort data=exprev;
   by sale_type order_date quantity;
run;
```

Print the report, specify the total number of observations in each BY group, and suppress the printing of observation numbers. N= prints the number of observations in a BY group at the end of that BY group. The explanatory text that the N= option provides precedes the number. NOOBS suppresses the printing of observation numbers at the beginning of the rows. LABEL uses the variables' labels as column headings.

```
proc print data=exprev n='Number of observations for the month: '
           noobs label;
```

Specify the variables to include in the report. The VAR statement creates columns for Quantity, Cost, and Price, in that order.

```
   var quantity cost price;
```

Create a separate section for each order type and specify page breaks for each BY group of Order_Date. The BY statement produces a separate section of the report for each BY group and prints a heading above each one. The PAGEBY statement starts a new page each time the value of Order_Date changes.

```
   by sale_type order_date;
   pageby order_date;
```

Establish the column headings. The LABEL statement associates labels with the variables Sale_Type and Order_Date for the duration of the PROC PRINT step. When you use the LABEL option in the PROC PRINT statement, the procedure uses labels for column headings.

```
   label sale_type='Order Type' order_date='Order Date';
```

Format the columns that contain numbers and specify a title and footnote. The FORMAT statement assigns a format to Price and Cost for this report. The TITLE statement specifies a title. The TITLE2 statement specifies a second title.

```
   format price dollar7.2 cost dollar7.2;
   title 'Prices and Cost Grouped by Date and Order Type';
   title2 'in USD';
run;

proc options option=bufno define;
run;
```

Output: HTML

Output 48.9 *Creating Separate Sections of a Report for Groups of Observations: HTML Output*

Prices and Cost Grouped by Date and Order Type in USD

Program: Creating an RTF Report

```
options obs=10;

ods rtf file='your_file.rtf' startpage=no;

proc sort data=exprev;
   by sale_type order_date quantity;
run;

proc print data=exprev n='Number of observations for each order type:'
           noobs label;
   var quantity cost price;
   by sale_type order_date;
   pageby order_date;
   label sale_type='Order Type' order_date='Order Date';
```

```
   format price dollar7.2 cost dollar7.2;
   title 'Price and Cost Grouped by Date and Order Type';
   title2 'in USD';
run;

ods rtf close;
```

Program Description

The OBS= system option specifies to process 10 observations.

```
options obs=10;
```

Create output for Microsoft Word and specify the file to store the output in. The ODS RTF statement opens the RTF destination and creates output formatted for Microsoft Word. The FILE= option specifies the external file that contains the RTF output. The STARTPAGE=NO option specifies that no new pages be inserted explicitly at the start of each by group.

```
ods rtf file='your_file.rtf' startpage=no;

proc sort data=exprev;
   by sale_type order_date quantity;
run;

proc print data=exprev n='Number of observations for each order type:'
           noobs label;
   var quantity cost price;
   by sale_type order_date;
   pageby order_date;
   label sale_type='Order Type' order_date='Order Date';
   format price dollar7.2 cost dollar7.2;
   title 'Price and Cost Grouped by Date and Order Type';
   title2 'in USD';
run;
```

Close the RTF destination. The ODS RTF CLOSE statement closes the RTF destination.

```
ods rtf close;
```

Output: RTF

Output 48.10 *Creating Separate Sections of a Report for Groups of Observations: Default RTF Output*

Price and Cost Grouped by Date and Order Type in USD

Order Type=Catalog Order Date=1/1/12

Quantity	Cost	Price
7	$9.25	$41.00
8	$28.45	$113.40
14	$12.10	$51.20
30	$59.00	$123.70
Number of observations for each order type:4		

Order Type=Catalog Order Date=1/2/12

Quantity	Cost	Price
11	$20.20	$40.20
100	$5.00	$11.80
Number of observations for each order type:2		

Order Type=In Store Order Date=1/1/12

Quantity	Cost	Price
25	$15.65	$31.10
Number of observations for each order type:1		

Order Type=In Store Order Date=1/2/12

Quantity	Cost	Price
2	$36.70	$146.40
20	$32.30	$71.00
Number of observations for each order type:2		

Order Type=Internet Order Date=1/1/12

Quantity	Cost	Price
2	$20.70	$92.60
Number of observations for each order type:1		

Program: Creating an RTF Report with the STYLE Option

```
options obs=10;

ods rtf file='your_file.rtf' startpage=no;

proc sort data=exprev;
   by sale_type order_date quantity;
run;

proc print data=exprev n='Number of observations for the month: '
           noobs label style(N)={backgroundcolor=very light gray};
   var quantity / style(header)=[backgroundcolor=light yellow];
   var cost / style(header)=[backgroundcolor=light blue foreground =
white];
   var price / style(header)=[backgroundcolor=light green];
   by sale_type order_date;
   pageby order_date;
   label sale_type='Order Type' order_date='Order Date';
   format price dollar7.2 cost dollar7.2;

title 'Prices and Cost Grouped by Date and Order Type';
title2 '*prices in USD';
run;

ods rtf close;
```

Program Description

The OBS= system option specifies to process 10 observations.

```
options obs=10;

ods rtf file='your_file.rtf' startpage=no;

proc sort data=exprev;
   by sale_type order_date quantity;
run;
```

Create a stylized RTF report. The first STYLE option specifies that the background color of the cell containing the number of observations be changed to light gray. The second STYLE option specifies that the background color of the column heading for the variable Quantity be changed to light yellow. The third STYLE option specifies that the background color of the column heading for the variable Cost be changed to light blue and the font color be changed to white. The fourth STYLE option specifies that the background color of the column heading for the variable Price be changed to light green.

```
proc print data=exprev n='Number of observations for the month: '
           noobs label style(N)={backgroundcolor=very light gray};
   var quantity / style(header)=[backgroundcolor=light yellow];
   var cost / style(header)=[backgroundcolor=light blue foreground =
white];
   var price / style(header)=[backgroundcolor=light green];
   by sale_type order_date;
```

```
   pageby order_date;
   label sale_type='Order Type' order_date='Order Date';
   format price dollar7.2 cost dollar7.2;

title 'Prices and Cost Grouped by Date and Order Type';
title2 '*prices in USD';
run;

ods rtf close;
```

Output: RTF with Styles

Output 48.11 *Creating Separate Sections of a Report for Groups of Observations: RTF Output Using Styles*

Prices and Cost Grouped by Date and Order Type
**prices in USD*

2	$20.70	$92.60
Number of observations for the month: 1		

Example 5: Summing Numeric Variables with One BY Group

Features:
- PROC PRINT statement options
  - N=
  - SUMLABEL
- BY statement
- SUM statement
- ODS CSVALL statement
- SORT procedure
- TITLE statement
  - #BYVAL specification
- SAS system options:
  - BYLINE
  - NOBYLINE

Data set: EXPREV

ODS destinations: HTML, CSV

Details

This example demonstrates the following tasks:

- sums expenses and revenues for each region and for all regions.
- shows the number of observations in each BY group and in the whole report.
- creates a customized title, containing the name of the region. This title replaces the default BY line for each BY group.
- creates a default HTML file.
- creates a CSV file.

Program: Creating an HTML Report

```
options obs=10 nobyline;

proc sort data=exprev;
   by sale_type;
run;

proc print data=exprev noobs label sumlabel
```

```
            n='Number of observations for the order type: '
            'Number of observations for the data set: ';

   var country order_date quantity price;

   label  sale_type='Sale Type'
          price='Total Retail Price* in USD'
          country='Country' order_date='Date' quantity='Quantity';

   sum price quantity;
   by sale_type;

   format price dollar7.2;

   title 'Retail and Quantity Totals for #byval(sale_type) Sales';
run;

options byline;
```

Program Description

The HTML destination is open by default. This program uses the default filename for the HTML output. No ODS HTML statement is needed.

Start each BY group on a new page and suppress the printing of the default BY line. The SAS system option NOBYLINE suppresses the printing of the default BY line. When you use PROC PRINT with the NOBYLINE option, each BY group starts on a new page. The OBS= option specifies the number of observations to process.

```
options obs=10 nobyline;
```

Sort the data set. PROC SORT sorts the observations by Sale_Type.

```
proc sort data=exprev;
   by sale_type;
run;
```

Print the report, suppress the printing of observation numbers, and print the total number of observations for the selected variables. NOOBS suppresses the printing of observation numbers at the beginning of the rows. SUMLABEL prints the BY variable label on the summary line of each. N= prints the number of observations in a BY group at the end of that BY group and (because of the SUM statement) prints the number of observations in the data set at the end of the report. The first piece of explanatory text that N= provides precedes the number for each BY group. The second piece of explanatory text that N= provides precedes the number for the entire data set.

```
proc print data=exprev noobs label sumlabel
           n='Number of observations for the order type: '
           'Number of observations for the data set: ';
```

Select the variables to include in the report. The VAR statement creates columns for Country, Order_Date, Quantity, and Price, in that order.

```
   var country order_date quantity price;
```

Assign the variables' labels as column headings. The LABEL statement associates a label with each variable for the duration of the PROC PRINT step.

```
   label  sale_type='Sale Type'
```

```
    price='Total Retail Price* in USD'
    country='Country' order_date='Date' quantity='Quantity';
```

Sum the values for the selected variables. The SUM statement alone sums the values of Price and Quantity for the entire data set. Because the PROC PRINT step contains a BY statement, the SUM statement also sums the values of Price and Quantity for each sale type that contains more than one observation.

```
    sum price quantity;
    by sale_type;
```

Format the numeric values for a specified column. The FORMAT statement assigns the DOLLAR7.2. format to Price for this report.

```
    format price dollar7.2;
```

Specify and format a dynamic (or current) title. The TITLE statement specifies a title. The #BYVAL specification places the current value of the BY variable Sale_Type in the title. Because NOBYLINE is in effect, each BY group starts on a new page, and the title serves as a BY line.

```
    title 'Retail and Quantity Totals for #byval(sale_type) Sales';
run;
```

Generate the default BY line. The SAS system option BYLINE resets the printing of the default BY line.

```
options byline;
```

Output: HTML

Output 48.12 *Summing Numeric Variables with One BY Group HTML Output*

Retail and Quantity Totals for Catalog Sales

Country	Date	Quantity	Total Retail Price* in USD
Bermuda	1/1/12	7	$41.00
Bahamas	1/1/12	8	$113.40
Puerto Rico	1/1/12	14	$51.20
Aruba	1/1/12	30	$123.70
British Virgin Islands	1/2/12	11	$40.20
Canada	1/2/12	100	$11.80
Sale Type		**170**	**$381.30**
Number of observations for the order type: 6			

Retail and Quantity Totals for In Store Sales

Country	Date	Quantity	Total Retail Price* in USD
Virgin Islands (U.S.)	1/1/12	25	$31.10
Belize	1/2/12	2	$146.40
Cayman Islands	1/2/12	20	$71.00
Sale Type		**47**	**$248.50**

Number of observations for the order type: 3

Retail and Quantity Totals for Internet Sales

Country	Date	Quantity	Total Retail Price* in USD
Antarctica	1/1/12	2	$92.60
		219	**$722.40**

Number of observations for the order type: 1
Number of observations for the data set: 10

Program: Creating a CSV File

```
options obs=10 nobyline;

ods csvall file='your_file.csv';

proc sort data=exprev;
   by sale_type;
run;

proc print data=exprev noobs label sumlabel
           n='Number of observations for the order type: '
           'Number of observations for the data set: ';

var country order_date quantity price;

   label  price='Total Retail Price* in USD'
          country='Country' order_date='Date' quantity='Quantity';

   sum price quantity;
   by sale_type;

   format price dollar7.2;

   title 'Retail and Quantity Totals for #byval(sale_type) Sales';
run;

options byline;

ods csvall close;
```

Program Description

```
options obs=10 nobyline;
```

Produce CSV formatted output and specify the file to store it in. The ODS CSVALL statement opens the CSVALL destination and creates a file containing tabular output with titles, notes, and BY lines. The FILE= argument specifies the external file that contains the CSV output.

```
ods csvall file='your_file.csv';

proc sort data=exprev;
   by sale_type;
run;

proc print data=exprev noobs label sumlabel
           n='Number of observations for the order type: '
           'Number of observations for the data set: ';

var country order_date quantity price;

   label  price='Total Retail Price* in USD'
          country='Country' order_date='Date' quantity='Quantity';

   sum price quantity;
   by sale_type;

   format price dollar7.2;

   title 'Retail and Quantity Totals for #byval(sale_type) Sales';
run;

options byline;
```

Close the CSVALL destination. The ODS CSVALL CLOSE statement closes the CSVALL destination.

```
ods csvall close;
```

Output: CSV File

- GRANDTOTAL_LABEL=
- N=
- NOOBS
- STYLE
- SUMLABEL=

BY statement

SUM statement

ODS HTML statement

LABEL statement
FORMAT statement
SORT procedure
TITLE statement

Data set: EXPREV

ODS destinations: HTML, LISTING

Details

This example demonstrates the following tasks:

- sums quantities and retail prices for the following items:
  - each order date
  - each sale type with more than one row in the report
  - all rows in the report
- shows the number of observations in each BY group and in the whole report
- displays a customized label in place of the BY group variable name on the summary line
- displays a customized label for the grand total line
- creates a default HTML report
- creates a stylized HTML report

Program: Creating an HTML Report

```
options obs=10;

proc sort data=exprev;
   by sale_type order_date;
run;

proc print data=exprev n noobs sumlabel='Totals'
grandtotal_label='Grand Total';
   by sale_type order_date;
   sum price quantity cost;

   label  sale_type='Sale Type' order_date='Sale Date';
   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Date and Sale Type';
run;
```

Program Description

```
options obs=10;
```

Produce HTML output and specify the file to store the output in. The HTML destination is open by default. The ODS HTML FILE= statement creates a file that contains HTML output. The FILE= argument specifies the external file that contains the HTML output.

```
proc sort data=exprev;
   by sale_type order_date;
run;

proc print data=exprev n noobs sumlabel='Totals'
grandtotal_label='Grand Total';
   by sale_type order_date;
   sum price quantity cost;

   label  sale_type='Sale Type' order_date='Sale Date';
   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Date and Sale Type';
run;
```

Output: HTML

Output 48.14 *Summing Numeric Variables with Multiple BY Variables: In Store Sales: Default HTML Output*

Retail and Quantity Totals for Each Sale Date and Sale Type

Sale Type=Catalog Sale Date=1/1/12

Program: Creating a LISTING Report

```
options nodate pageno=1 linesize=80 pagesize=40 obs=15;

ods html close;
ods listing;

proc sort data=exprev;
   by sale_type order_date;
run;

proc print data=exprev n noobs sumlabel=Totals'
grandtotal_label='Grand Total';

   by sale_type order_date;
   sum price quantity;

   label  sale_type='Sale Type'
          order_date='Sale Date';
   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Date and Sale Type';
run;
```

```
ods listing close;
ods html;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. The PAGENO= option specifies the starting page number. The LINESIZE= option specifies the output line length, and the PAGESIZE= option specifies the number of lines on an output page. OBS= specifies to stop process in the data set after observation 15.

```
options nodate pageno=1 linesize=80 pagesize=40 obs=15;
```

Close the HTML destination and open the LISTING destination. The HTML destination is open by default.

```
ods html close;
ods listing;
```

Sort the data set. PROC SORT sorts the observations by Sale_Type and Order_Date.

```
proc sort data=exprev;
   by sale_type order_date;
run;
```

Print the report, suppress the printing of observation numbers, print the total number of observations for the selected variables and use the BY variable labels in place of the BY variable names in the summary line. The N option prints the number of observations in a BY group at the end of that BY group and prints the total number of observations used in the report at the bottom of the report. NOOBS suppresses the printing of observation numbers at the beginning of the rows. The SUMLABEL option prints 'Totals' in the summary line in place of the BY variable labels.

```
proc print data=exprev n noobs sumlabel=Totals'
grandtotal_label='Grand Total';
```

Create a separate section of the report for each BY group, and sum the values for the selected variables. The BY statement produces a separate section of the report for each BY group. The SUM statement alone sums the values of Price and Quantity for the entire data set. Because the program contains a BY statement, the SUM statement also sums the values of Price and Quantity for each BY group that contains more than one observation.

```
   by sale_type order_date;
   sum price quantity;
```

Establish a label for selected variables, format the values of specified variables, and create a title. The LABEL statement associates a label with the variables Sale_Type and Order_Date for the duration of the PROC PRINT step. The labels are used in the BY line at the beginning of each BY group and in the summary line in place of BY variables. The FORMAT statement assigns a format to the variables Price and Cost for this report. The TITLE statement specifies a title.

```
   label  sale_type='Sale Type'
```

```
          order_date='Sale Date';
   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Date and Sale Type';
run;
```

Close the LISTING destination and re-open the HTML destination.

```
ods listing close;
ods html;
```

Output: LISTING

The report uses default column headings (variable names) because neither the SPLIT= nor the LABEL option is used. Nevertheless, the BY line at the top of each section of the report shows the BY variables' labels and their values. The BY variables' labels identifies the subtotals in the report summary line.

PROC PRINT sums Price and Quantity for each BY group that contains more than one observation. However, sums are shown only for the BY variables whose values change from one BY group to the next. For example, in the first BY group, where the sale type is **`Catalog Sale`** and the sale date is **`>1/1/12`**, Quantity and Price are summed only for the sale date because the next BY group is for the same sale type.

Output 48.16 *PROC PRINT LISTING Output Showing Total Values for Price and Quantity*

```

```

Example 7: Limiting the Number of Sums in a Report

Features:	BY statement SUM statement SUMBY statement FORMAT statement LABEL statement ODS PDF statement SORT procedure TITLE statement
Data set:	EXPREV
ODS destination:	PDF

Details

This example demonstrates the following tasks:

- creates a separate section of the report for each combination of sale type and sale date
- sums quantities and retail prices only for each sale type and for all sale types, not for individual dates
- creates a PDF file

Program: Creating a PDF File

```
options obs=10;

ods html close;
ods pdf file='your_file.pdf';

proc sort data=exprev;
   by sale_type order_date;
run;

proc print data=exprev noobs sumlabel='Total' grandtotal_label='Grand
Total';

   by sale_type order_date;
   sum price quantity;
```

```
   sumby sale_type;

   label sale_type='Sale Type' order_date='Sale Date';

   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Type';
run;

ods pdf close;
```

Program Description

The OBS= system option specifies to process 10 observations.

```
options obs=10;
```

Produce PDF output and specify the file to store the output in. The ODS HTML CLOSE statement closes the default destination. The ODS PDF statement opens the PDF destination and creates a file that contains PDF output. The FILE= argument specifies the external file that contains the PDF output.

```
ods html close;
ods pdf file='your_file.pdf';
```

Sort the data set. PROC SORT sorts the observations by Sales_Type and Order_Date.

```
proc sort data=exprev;
   by sale_type order_date;
run;
```

Print the report and remove the observation numbers. NOOBS suppresses the printing of observation numbers at the beginning of the rows. SUMLABEL uses the label for the BY variables on the summary line of each BY group.

```
proc print data=exprev noobs sumlabel='Total' grandtotal_label='Grand
Total';
```

Sum the values for each region. The SUM and BY statements work together to sum the values of Price and Quantity for each BY group as well as for the whole report. The SUMBY statement limits the subtotals to one for each type of sale.

```
   by sale_type order_date;
   sum price quantity;
   sumby sale_type;
```

Assign labels to specific variables. The LABEL statement associates a label with the variables Sale_Type and Order_Date for the duration of the PROC PRINT step. These labels are used in the BY group title or the summary line.

```
   label sale_type='Sale Type' order_date='Sale Date';
```

Assign a format to the necessary variables and specify a title. The FORMAT statement assigns the COMMA10. format to Cost and Price for this report. The TITLE statement specifies a title.

```
   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Type';
run;
```

Close the PDF destination. The ODS PDF CLOSE statement closes the PDF destination.

```
ods pdf close;
```

Program: Creating a PDF Report with the STYLE Option

```
options obs=10;
```

```
ods pdf file='your_file.pdf';

proc sort data=exprev;
   by sale_type order_date;
run;

proc print data=exprev noobs sumlabel='Total' grandtotal_label='Grand
Total';

   by sale_type order_date;

   sum quantity price / style(TOTAL)=[backgroundcolor=light blue
color=white];
   sum quantity price / style(GRANDTOTAL)=[backgroundcolor=green
color=white];
   sumby sale_type;

   label sale_type='Sale Type' order_date='Sale Date';

   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Type';
run;

ods pdf close;
```

Program Description

```
options obs=10;

ods pdf file='your_file.pdf';

proc sort data=exprev;
   by sale_type order_date;
run;

proc print data=exprev noobs sumlabel='Total' grandtotal_label='Grand
Total';

   by sale_type order_date;
```

Create stylized PDF output. The STYLE option in the first SUM statement specifies that the background color of cells containing totals for the variable Price be changed to light blue and the font color be changed to white. The STYLE option in the second SUM statement specifies that the background color of the cell containing the grand total for the Quantity variable be changed to yellow and the font color be changed to red.

```
   sum quantity price / style(TOTAL)=[backgroundcolor=light blue
color=white];
   sum quantity price / style(GRANDTOTAL)=[backgroundcolor=green
color=white];
   sumby sale_type;

   label sale_type='Sale Type' order_date='Sale Date';

   format price dollar10.2 cost dollar10.2;
   title 'Retail and Quantity Totals for Each Sale Type';
run;
```

```
ods pdf close;
```

Example 8: Controlling the Layout of a Report with Many Variables

Features: PROC PRINT statement options
ROWS=
ID statement options

STYLE

ODS RTF statement

SAS data set options

OBS=

Data set: EMPDATA

ODS destinations: LISTING, RTF

Details

This example shows two ways of printing a data set with a large number of variables: one is the default, printing multiple rows when there are a large number of variables, and the other uses ROWS= option to print one row. The ROWS= option is valid only for the LISTING destination. For detailed explanations of the layouts of these two reports, see the option ROWS= on page 1764 and "Page Layout for Limited Page Sizes" on page 1792.

These reports use a page size of 24 and a line size of 64 to help illustrate the different layouts.

Program: Creating a LISTING Report

```
data empdata;
   input IdNumber $ 1-4 LastName $ 8-18 FirstName $ 19-28
      City $ 29-41 State $ 42-43
      Gender $ 45 JobCode $ 49-51 Salary 55-60 @63 Birth date7.
      @73 Hired date7. HomePhone $ 83-95;
   format birth hired date9.;
   datalines;

212/588-1092
;

                  proc print data=empdata(obs=12);
                     id idnumber;
                     title 'Personnel Data';
                  run;

                  proc print data=empdata(obs=12) rows=page;
```

```
   id idnumber;
   title 'Personnel Data';
run;
```

Program Description

Create the EMPDATA data set. The data set EMPDATA contains personal and job-related information about a company's employees. The DATA step creates this data set.

```
data empdata;
   input IdNumber $ 1-4 LastName $ 8-18 FirstName $ 19-28
      City $ 29-41 State $ 42-43
      Gender $ 45 JobCode $ 49-51 Salary 55-60 @63 Birth date7.
      @73 Hired date7. HomePhone $ 83-95;
   format birth hired date9.;
   datalines;
1919   Adams      Gerald    Stamford     CT M   TA2   34376   15SEP70   07JUN05
203/781-1255
1653   Alexander  Susan     Bridgeport   CT F   ME2   35108   18OCT72   12AUG98
203/675-7715

. . . more lines of data . . .

1407   Grant      Daniel    Mt. Vernon   NY M   PT1   68096   26MAR77   21MAR98
914/468-1616
1114   Green      Janice    New York     NY F   TA2   32928   21SEP77   30JUN06
212/588-1092
;
```

Print only the first 12 observations in a data set. The OBS= data set option uses only the first 12 observations to create the report. (This is just to conserve space here.) The ID statement identifies observations with the formatted value of IdNumber rather than with the observation number. This report is shown in "Output: LISTING" on page 1842.

```
proc print data=empdata(obs=12);
   id idnumber;
   title 'Personnel Data';
run;
```

Print a report that contains only one row of variables on each page. ROWS=PAGE prints only one row of variables for each observation on a page. This report is shown in Output 48.283 on page 1843.

```
proc print data=empdata(obs=12) rows=page;
   id idnumber;
   title 'Personnel Data';
run;
```

Output: LISTING

In the traditional procedure output, each page of this report contains values for all variables in each observation. In the HTML output, this report is identical to the report that uses ROWS=PAGE.

Note that PROC PRINT automatically splits the variable names that are used as column headings at a change in capitalization if the entire name does not fit in the column. Compare the column headings for LastName (which fits in the column) and FirstName (which does not fit in the column).

Output 48.19 *Default Layout for a Report with Many Variables: LISTING Output*

```

Program: Creating an RTF Report

```
options pageno=1;

ods rtf file='your_file.rtf';

proc print data=empdata(obs=12);
   id idnumber;
   title 'Personnel Data';
run;

ods rtf close;
```

Program Description

The RTF output shows all data in one row. The ROWS= option is valid only for the LISTING destination.

```
options pageno=1;
```

Create output for Microsoft Word and specify the file to store the output in. The ODS RTF statement opens the RTF destination and creates output formatted for Microsoft Word. The FILE= argument specifies the external file that contains the RTF output.

```
ods rtf file='your_file.rtf';

proc print data=empdata(obs=12);
   id idnumber;
   title 'Personnel Data';
run;
```

Close the RTF destination. The ODS RTF CLOSE statement closes the RTF destination.

```
ods rtf close;
```

Output: RTF

Output 48.21 *Layout for a Report with Many Variables: RTF Output*

Example 9: Creating a Customized Layout with BY Groups and ID Variables

Features: PROC PRINT statement options
SUMLABEL
GRANDTOTAL_LABEL
BY statement
ID statement
SUM statement
VAR statement
SORT procedure

Data set: EMPDATA

ODS destinations: LISTING, HTML

Details

This customized report demonstrates the following tasks:

- selects variables to include in the report and the order in which they appear
- selects observations to include in the report
- groups the selected observations by JobCode
- sums the salaries for each job code and for all job codes
- displays numeric data with commas and dollar signs

Program: Creating a LISTING Report

```
options nodate pageno=1 linesize=64 pagesize=60;
proc sort data=empdata out=tempemp;
   by jobcode gender;
run;

proc print data=tempemp split='*' sumlabel='Total'
grandtotal_label='Grand Total';

   id jobcode;
   by jobcode;
   var gender salary;

   sum salary;
```

```
   label jobcode='Job Code*========'
         gender='Gender*======'
         salary='Annual Salary*=============';
   format salary dollar11.2;
   where jobcode contains 'FA' or jobcode contains 'ME';
   title 'Salary Expenses';
run;
```

Program Description

Create and sort a temporary data set. PROC SORT creates a temporary data set in which the observations are sorted by JobCode and Gender.

```
options nodate pageno=1 linesize=64 pagesize=60;
proc sort data=empdata out=tempemp;
   by jobcode gender;
run;
```

Identify the character that starts a new line in column headings. SPLIT= identifies the asterisk as the character that starts a new line in column headings.

```
proc print data=tempemp split='*' sumlabel='Total'
grandtotal_label='Grand Total';
```

Specify the variables to include in the report. The VAR statement and the ID statement together select the variables to include in the report. The ID statement and the BY statement produce the special format.

```
   id jobcode;
   by jobcode;
   var gender salary;
```

Calculate the total value for each BY group. The SUM statement totals the values of Salary for each BY group and for the whole report.

```
   sum salary;
```

Assign labels to the appropriate variables. The LABEL statement associates a label with each variable for the duration of the PROC PRINT step. When you use SPLIT= in the PROC PRINT statement, the procedure uses labels for column headings.

```
   label jobcode='Job Code*========'
         gender='Gender*======'
         salary='Annual Salary*=============';
```

Create formatted columns. The FORMAT statement assigns a format to Salary for this report. The WHERE statement selects for the report only the observations for job codes that contain the letters 'FA' or 'ME'. The TITLE statement specifies the report title.

```
   format salary dollar11.2;
   where jobcode contains 'FA' or jobcode contains 'ME';
   title 'Salary Expenses';
run;
```

Output: LISTING

The ID and BY statements work together to produce this layout. The ID variable is listed only once for each BY group. The BY lines are suppressed. Instead, the value of the ID variable, JobCode, identifies each BY group.

Output 48.22 *Creating a Customized Layout with BY Groups and ID Variables: LISTING Output*

```
Salary Expenses                                    1

   ===========             =============
   Grand Total              $593,735.00
```

Program: Creating an HTML Report

```
proc sort data=empdata out=tempemp;
```

```
   by jobcode gender;
run;

ods html file='your_file.html';

proc print data=tempemp (obs=10) sumlabel='Total'
grandtotal_lable='Grand Total';

 id jobcode;
   by jobcode;
   var gender salary;

   sum salary;

   label jobcode='Job Code'
         gender='Gender'
         salary='Annual Salary';

   format salary dollar11.2;
   where jobcode contains 'FA' or jobcode contains 'ME';
   title 'Salary Expenses';
run;
```

Program Description

```
proc sort data=empdata out=tempemp;
   by jobcode gender;
run;
```

Produce HTML output and specify the file to store the output in. The HTML destination is the default ODS destination. The ODS HTML statement FILE= option specifies the external file that contains the HTML output.

```
ods html file='your_file.html';
```

Define the procedure options. The (obs=10) data set option sets the number of observations to process. The SUMLABEL option indicates to use the label 'Total' on the summary line for each BY group. The GRANDTOTAL_LABEL option indicates to use the label 'Grand Total' on the grand total line after all BY groups in the report.

```
proc print data=tempemp (obs=10) sumlabel='Total'
grandtotal_lable='Grand Total';

 id jobcode;
   by jobcode;
   var gender salary;

   sum salary;

   label jobcode='Job Code'
         gender='Gender'
         salary='Annual Salary';

   format salary dollar11.2;
   where jobcode contains 'FA' or jobcode contains 'ME';
   title 'Salary Expenses';
run;
```

Output: HTML

Output 48.23 *Creating a Customized Layout with BY Groups and ID Variables: Default HTML Output*

Salary Expenses

JobCode	Gender	Salary
FA1	F	$23,177.00
	F	$22,454.00
	M	$22,268.00
Total		$67,899.00

JobCode	Gender	Salary
FA2	F	$28,888.00
	F	$27,787.00
	M	$28,572.00
Total		$85,247.00

JobCode	Gender	Salary
FA3	F	$32,886.00
	F	$33,419.00
	M	$32,217.00
Total		$98,522.00

JobCode	Gender	Salary
ME1	M	$29,769.00
Grand Total		$281,437.00

Program: Creating an HTML Report with the STYLE Option

```
proc sort data=empdata out=tempemp;
   by jobcode gender;
run;

proc print data=tempemp (obs=10)sumlabel='Total'
grandtotal_label='Grand Total'
```

```
   style(HEADER)={fontstyle=italic}
   style(DATA)={backgroundcolor=blue foreground=white};
 id jobcode;
   by jobcode;
   var gender salary;
   sum salary  / style(total)={color=red};
   label jobcode='Job Code'
         gender='Gender'
         salary='Annual Salary';
   format salary dollar11.2;
   where jobcode contains 'FA' or jobcode contains 'ME';
   title 'Expenses Incurred for';
   title2 'Salaries for Flight Attendants and Mechanics';
run;
```

Program Description

```
proc sort data=empdata out=tempemp;
   by jobcode gender;
run;
```

Create stylized HTML output. The first STYLE option specifies that the font of the headers be changed to italic. The second STYLE option specifies that the background of cells that contain data be changed to blue and the foreground of these cells be changed to white. The SUMLABEL and GRANDTOTAL_LABEL options use a label in the summary and grand total lines, respectively, in place of variable names.

```
proc print data=tempemp (obs=10)sumlabel='Total'
grandtotal_label='Grand Total'
   style(HEADER)={fontstyle=italic}
   style(DATA)={backgroundcolor=blue foreground=white};
 id jobcode;
   by jobcode;
   var gender salary;
```

Create total values that are written in red. The STYLE option specifies that the color of the foreground of the cell that contain the totals be changed to red.

```
   sum salary  / style(total)={color=red};
   label jobcode='Job Code'
         gender='Gender'
         salary='Annual Salary';
   format salary dollar11.2;
   where jobcode contains 'FA' or jobcode contains 'ME';
   title 'Expenses Incurred for';
   title2 'Salaries for Flight Attendants and Mechanics';
run;
```

Output: HTML with Styles

Output 48.24 *Creating a Customized Layout with BY Groups and ID Variables: HTML Output Using Styles*

Example 10: Printing All the Data Sets in a SAS Library

Features: Macro facility
DATASETS procedure

	PRINT procedure
Data sets:	PROCLIB.DELAY and PROCLIB.INTERNAT from the Raw Data and DATA Steps appendix
ODS destination:	HTML

Details

This example prints all the data sets in a SAS library. You can use the same programming logic with any procedure. Just replace the PROC PRINT step near the end of the example with whatever procedure step you want to execute. The example uses the macro language. For details about the macro language, see *SAS Macro Language: Reference*.

Program: Printing All of the Data Sets in a Library

```
libname printlib 'SAS-data-library';
libname proclib 'SAS-data-library';
options nodate pageno=1;

proc datasets library=proclib memtype=data nolist;
   copy out=printlib;
      select delay internat;
run;

%macro printall(libname,worklib=work);

   %local num i;

   proc datasets library=&libname memtype=data nodetails;
      contents out=&worklib..temp1(keep=memname) data=_all_ noprint;
   run;

   data _null_;
      set &worklib..temp1 end=final;
      by memname notsorted;
      if last.memname;
      n+1;
      call symput('ds'||left(put(n,8.)),trim(memname));

      if final then call symput('num',put(n,8.));

   run;

   %do i=1 %to &num;
      proc print data=&libname..&&ds&i noobs;
         title "Data Set &libname..&&ds&i";
      run;
   %end;
%mend printall;

%printall(printlib)
```

Program Description

```
libname printlib 'SAS-data-library';
libname proclib 'SAS-data-library';
options nodate pageno=1;
```

Copy the desired data sets from the WORK library to a permanent library. PROC DATASETS copies two data sets from the WORK library to the PRINTLIB library in order to limit the number of data sets available to the example.

```
proc datasets library=proclib memtype=data nolist;
   copy out=printlib;
      select delay internat;
run;
```

Create a macro and specify the parameters. The %MACRO statement creates the macro PRINTALL. When you call the macro, you can pass one or two parameters to it. The first parameter is the name of the library whose data set you want to print. The second parameter is a library used by the macro. If you do not specify this parameter, the WORK library is the default.

```
%macro printall(libname,worklib=work);
```

Create the local macro variables. The %LOCAL statement creates two local macro variables, NUM and I, to use in a loop.

```
   %local num i;
```

Produce an output data set. This PROC DATASETS step reads the library that you specify as a parameter when you invoke the macro. The CONTENTS statement produces an output data set called TEMP1 in WORKLIB. This data set contains an observation for each variable in each data set in the library LIBNAME. By default, each observation includes the name of the data set that the variable is included in as well as other information about the variable. However, the KEEP= data set option writes only the name of the data set to TEMP1.

```
   proc datasets library=&libname memtype=data nodetails;
      contents out=&worklib..temp1(keep=memname) data=_all_ noprint;
   run;
```

Specify the unique values in the data set, assign a macro variable to each one, and assign DATA step information to a macro variable. This DATA step increments the value of N each time it reads the last occurrence of a data set name (when IF LAST.MEMNAME is true). The CALL SYMPUT statement uses the current value of N to create a macro variable for each unique value of MEMNAME in the data set TEMP1. The TRIM function removes extra blanks in the TITLE statement in the PROC PRINT step that follows.

```
   data _null_;
      set &worklib..temp1 end=final;
      by memname notsorted;
      if last.memname;
      n+1;
      call symput('ds'||left(put(n,8.)),trim(memname));
```

Determine the number of observations in the DATA step. When it reads the last observation in the data set (when FINAL is true), the DATA step assigns the value

of N to the macro variable NUM. At this point in the program, the value of N is the number of observations in the data set.

```
      if final then call symput('num',put(n,8.));
```

Run the DATA step. The RUN statement is crucial. It forces the DATA step to run, thus creating the macro variables that are used in the CALL SYMPUT statements before the %DO loop, which uses them, executes.

```
   run;
```

Print the data sets and end the macro. The %DO loop issues a PROC PRINT step for each data set. The %MEND statement ends the macro.

```
   %do i=1 %to &num;
      proc print data=&libname..&&ds&i noobs;
         title "Data Set &libname..&&ds&i";
      run;
   %end;
%mend printall;
```

Print all the data sets in the PRINTLIB library. This invocation of the PRINTALL macro prints all the data sets in the library PRINTLIB.

```
%printall(printlib)
```

Output: HTML

Output 48.25 *Data Set PRINTLIB.DELAY*

Data Set printlib.DELAY

PRINTTO Procedure

Overview: PRINTTO Procedure

What Does the PRINTTO Procedure Do?

The PRINTTO procedure defines destinations, other than ODS destinations, for SAS procedure output and for the SAS log. By default, SAS procedure output and the SAS log are routed to the default procedure output file and the default SAS log file for your method of operation. The PRINTTO procedure does not define ODS destinations. See the following table for SAS log and procedure output default destinations.

You can store the SAS log or procedure output in an external file or in a SAS catalog entry. To write SAS output to a file or a catalog entry, the ODS LISTING destination must be open. With additional programming, you can use SAS output as input data within the same job.

Table 49.1 *Default Destinations for SAS Log and Procedure Output*

Method of Running SAS	Default SAS Log Destination	Default Procedure Output Destination
Windowing environment	LOG window	Results Viewer window
Interactive line mode	Display monitor (as statements are entered)	Display monitor (as each step executes)
Noninteractive mode or batch mode	Depends on the host operating system	Depends on the operating environment

Operating Environment Information: For information and examples specific to your operating system or environment, see the documentation for your operating environment.

Syntax: PRINTTO Procedure

See: "PRINTTO Procedure: UNIX" in *SAS Companion for UNIX Environments*
"PRINTTO Procedure: Windows" in *SAS Companion for Windows*
"PRINTTO Procedure Statement: z/OS" in *SAS Companion for z/OS*

PROC PRINTTO <*options*>;

Statement	Task	Example
PROC PRINTTO	Define destinations, other than ODS destinations, for SAS procedure output and for the SAS log	Ex. 1, Ex. 2, Ex. 3, Ex. 4

PROC PRINTTO Statement

Defines destinations, other than ODS destinations, for SAS procedure output and for the SAS log.

Restrictions: To route SAS log and procedure output directly to a printer, you must use a FILENAME statement with the PROC PRINTTO statement. See "Route SAS Log or Procedure Output Directly to a Printer" on page 1864 and "Example 4: Routing to a Printer" on page 1878.

The PRINTTO procedure does not define ODS destinations.

When SAS is started in objectserver mode, the PRINTTO procedure does not route log messages to the log specified by the ALTLOG= system option.

Note: LOG=LOG and PRINT=PRINT route the log and procedure output to the default destinations. However, specifying LOG=PRINT or PRINT=LOG to route log or procedure output to the same default destination is not valid.

Tips: To reset the destination for the SAS log and procedure output to the default, use the PROC PRINTTO statement without options.

To route the SAS log and procedure output to the same file, specify the same file with both the LOG= and PRINT= options.

Examples: "Example 1: Routing to External Files" on page 1865

"Example 2: Routing to SAS Catalog Entries" on page 1869

"Example 3: Using Procedure Output as an Input File" on page 1873

"Example 4: Routing to a Printer" on page 1878

Syntax

PROC PRINTTO <*options*>;

Summary of Optional Arguments

LABEL='*description*'
: provides a description for a SAS log or procedure output stored in a SAS catalog entry.

LOG=LOG | *file-specification* | *SAS-catalog-entry*
: routes the SAS log to a permanent external file or SAS catalog entry.

NEW
: replaces the file instead of appending to it.

PRINT= PRINT | *file-specification* | *SAS-catalog-entry*
: routes procedure output to a permanent external file or SAS catalog entry or printer.

UNIT=*nn*
: routes the output to the file identified by the fileref.

Without Arguments

When no options are specified, the PROC PRINTTO statement does the following:

- closes any files opened by a PROC PRINTTO statement
- points both the SAS log and SAS procedure output to their default destinations

- closes the LISTING destination

Interaction: To close the appropriate file and to return only the SAS log or procedure output to its default destination, use LOG=LOG or PRINT=PRINT.

Examples:

"Example 1: Routing to External Files" on page 1865

"Example 2: Routing to SAS Catalog Entries" on page 1869

Optional Arguments

LABEL='*description*'

provides a description for a catalog entry that contains a SAS log or procedure output.

Range 1–256 characters

Interaction Use the LABEL= option only when you specify a catalog entry as the value for the LOG= option or the PRINT= option.

Example "Example 2: Routing to SAS Catalog Entries" on page 1869

LOG=LOG | *file-specification* | *SAS-catalog-entry*

routes the SAS log to one of three locations:

LOG

routes the SAS log to its default destination.

file-specification

routes the SAS log to an external file. *file-specification* can be one of the following:

'external-file'

the name of an external file specified in quotation marks.

Restriction *external-file* cannot be longer than 1024 characters.

log-filename

is an unquoted alphanumeric text string. SAS creates a log that uses *log-filename*.log as the log filename.

Operating environment For more information about *log-filename*, see the documentation for your operating environment.

fileref

a fileref previously assigned to an external file.

SAS-catalog-entry

routes the SAS log to a SAS catalog entry. By default, *libref* is SASUSER, *catalog* is PROFILE, and *type* is LOG. Express *SAS-catalog-entry* in one of the following ways:

***libref.catalog.entry*<.LOG>**

a SAS catalog entry stored in the SAS library and SAS catalog specified.

***catalog.entry*<.LOG>**

a SAS catalog entry stored in the specified SAS catalog in the default SAS library SASUSER.

***entry*.LOG**
a SAS catalog entry stored in the default SAS library and catalog: SASUSER.PROFILE.

fileref
a fileref previously assigned to a SAS catalog entry. Search for "FILENAME, CATALOG Access Method" in the SAS online documentation.

Default LOG

Interactions The SAS log and procedure output cannot be routed to the same catalog entry at the same time.

The NEW option replaces the existing contents of a file with the new log. Otherwise, the new log is appended to the file.

To route the SAS log and procedure output to the same file, specify the same file with both the LOG= and PRINT= options.

When routing the log to a SAS catalog entry, you can use the LABEL option to provide a description for the entry in the catalog directory.

When the log is routed to a file other than the default log file and programs are submitted from multiple sources, the final SAS system messages that contain the real and CPU times are written to the default SAS log.

Tips After routing the log to an external file or a catalog entry, you can specify LOG to route the SAS log back to its default destination.

When routing the SAS log, include a RUN statement in the PROC PRINTTO statement. If you omit the RUN statement, the first line of the following DATA or PROC step is not routed to the new file. (This occurs because a statement does not execute until a step boundary is crossed.)

If you create a macro that contains a password and you do not want the password to appear in the SAS log, use the LOG=*file-specification* option to redirect the log to an external file.

When you specify LOG=, SAS stores the path of the SAS log file in the &SYSPRINTTOLOG automatic macro variable. You can use this macro variable to restore the previous SAS log file location. For more information, see "Restore the Previous SAS Log or LISTING Output File Location" on page 1865.

Examples "Example 1: Routing to External Files" on page 1865

"Example 2: Routing to SAS Catalog Entries" on page 1869

"Example 3: Using Procedure Output as an Input File" on page 1873

NEW
clears any information that exists in a file and prepares the file to receive the SAS log or procedure output.

Default If you omit NEW, the new information is appended to the existing file.

Interaction If you specify both LOG= and PRINT=, NEW applies to both.

Examples "Example 1: Routing to External Files" on page 1865

"Example 2: Routing to SAS Catalog Entries" on page 1869

"Example 3: Using Procedure Output as an Input File" on page 1873

PRINT= PRINT | *file-specification* | *SAS-catalog-entry*
routes procedure output to one of three locations:

PRINT
routes procedure output to its default destination.

Tip After routing it to an external file or a catalog entry, you can specify PRINT to route subsequent procedure output to its default destination.

file-specification
routes procedure output to an external file. *file-specification* can be one of the following:

'external-file'
the name of an external file specified in quotation marks.

Restriction *external-file* cannot be longer than 1024 characters.

print-filename
is an unquoted alphanumeric text string. SAS creates a print file that uses *print-filename* as the print filename.

Operating Environment Information: For more information about using *print-filename*, see the documentation for your operating environment.

fileref
a fileref previously assigned to an external file.

Operating Environment Information: For additional information about *file-specification* for the PRINT option, see the documentation for your operating environment.

SAS-catalog-entry
routes procedure output to a SAS catalog entry. By default, *libref* is SASUSER, *catalog* is PROFILE, and *type* is OUTPUT. Express *SAS-catalog-entry* in one of the following ways:

***libref.catalog.entry*<.OUTPUT>**
a SAS catalog entry stored in the SAS library and SAS catalog specified.

***catalog.entry*<.OUTPUT>**
a SAS catalog entry stored in the specified SAS catalog in the default SAS library SASUSER.

***entry*.OUTPUT**
a SAS catalog entry stored in the default SAS library and catalog: SASUSER.PROFILE.

fileref
a fileref previously assigned to a SAS catalog entry. Search for "FILENAME, CATALOG Access Method" in the SAS online documentation.

Alias FILE=, NAME=

Default PRINT

Interactions When you specify PRINT, FILE=, or NAME=, and the LISTING destination is not open, the PRINTTO procedure opens the LISTING destination for the duration of routing the procedure output. If the LISTING destination was open before PRINT, FILE=, or NAME= was specified, it remains open after the output has been routed to its destination.

The procedure output and the SAS log cannot be routed to the same catalog entry at the same time.

The NEW option replaces the existing contents of a file with the new procedure output. If you omit NEW, the new output is appended to the file.

To route the SAS log and procedure output to the same file, specify the same file with both the LOG= and PRINT= options.

When routing procedure output to a SAS catalog entry, you can use the LABEL option to provide a description for the entry in the catalog directory.

Tip When you specify PRINT=, SAS stores the path of the LISTING output file in the &SYSPRINTTOLIST automatic macro variable. You can use this macro variable to restore the previous LISTING output file location. For more information, see "Restore the Previous SAS Log or LISTING Output File Location" on page 1865.

Example "Example 3: Using Procedure Output as an Input File" on page 1873

UNIT=*nn*
routes the output to the file identified by the fileref FT*nn*F001, where *nn* is an integer between 1 and 99.

Range 1–99, integer only.

Tips You can define this fileref yourself. However, some operating systems predefine certain filerefs in this form.

When you specify UNIT=, SAS stores the path of the LISTING output file in the &SYSPRINTTOLIST automatic macro variable. You can use this macro variable to restore the previous LISTING output file location. For

more information, see "Restore the Previous SAS Log or LISTING Output File Location" on page 1865.

Usage: PRINTTO Procedure

Set Page Numbers Using SAS System Options

When the NUMBER SAS system option is in effect, there is a single page-numbering sequence for all output in the current job or session. When NONUMBER is in effect, output pages are not numbered.

You can specify the beginning page number for the output that you are currently producing by using the PAGENO= in an OPTIONS statement.

Route SAS Log or Procedure Output Directly to a Printer

To route SAS log or procedure output directly to a printer, use a FILENAME statement to associate a fileref with the printer name, and then use that fileref in the LOG= or PRINT= option. For an example, see "Example 4: Routing to a Printer" on page 1878.

For more information, see "FILENAME Statement" in *SAS Global Statements: Reference*.

Operating Environment Information: For examples of printer names, see the documentation for your operating system.

The PRINTTO procedure does not support the COLORPRINTING system option. If you route the SAS log or procedure output to a color printer, the output does not print in color.

PROC PRINTTO and the LISTING Destination

The LISTING destination must be opened to route procedure output to an external file. When you specify the PRINT= option, SAS opens the LISTING destination if it is not already open. After the procedure output has been routed to the external file, SAS closes the LISTING destination. The LISTING destination is also closed if it is

opened when you use `proc printto;` to reset the output destinations. SAS does not open the LISTING destination when you specify the LOG= option.

If the LISTING destination is open before the PROC PRINTTO PRINT= option executes, it remains open after the output is routed to the external file.

Restore the Previous SAS Log or LISTING Output File Location

When you specify the LOG=, PRINT=, or the UNIT= options in the PROC PRINTTO statement, SAS stores the appropriate file location in automatic macro variables:

SYSPRINTTOLOG	contains the path of the SAS log file location prior to redirection by the PRINTTO procedure
SYSPRINTTOLIST	contains the path of the LISTING output file location prior to redirection by the PRINTTO procedure

To restore the previous file locations, you specify the appropriate automatic macro variable as the value of the LOG=, PRINT=, or UNIT= options. Here are some examples:

```
/* Restore the previous log and the listing file locations. */
proc printto log=&sysprinttolog print=&sysprinttolist;
   run;

/* Restore the previous listing file location. */
proc printto unit=&sysprinttolist;
   run;
```

Examples: PRINTTO Procedure

Example 1: Routing to External Files

Features:

PRINTTO statement without options

PRINTTO statement options

- LOG=
- NEW
- PRINT=

Details

This example uses PROC PRINTTO to route the log and procedure output to an external file and then reset both destinations to the default.

Program

```
options nodate pageno=1 linesize=80 pagesize=60 source;

proc printto log='log-file';
   run;

data numbers;
   input x y z;
   datalines;
 14.2   25.2   96.8
 10.8   51.6   96.8
  9.5   34.2  138.2
  8.8   27.6   83.2
 11.5   49.4  287.0
  6.3   42.0  170.7
;

proc printto print='output-file'
new;
run;

proc print data=numbers;
   title 'Listing of NUMBERS Data Set';
run;

proc printto;
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page. The SOURCE option writes lines of source code to the default destination for the SAS log.

```
options nodate pageno=1 linesize=80 pagesize=60 source;
```

Route the SAS log to an external file. PROC PRINTTO uses the LOG= option to route the SAS log to an external file. By default, this log is appended to the current contents of *log-file*.

```
proc printto log='log-file';
```

```
   run;
```

Create the NUMBERS data set. The DATA step uses list input to create the NUMBERS data set.

```
data numbers;
   input x y z;
   datalines;
 14.2   25.2   96.8
 10.8   51.6   96.8
  9.5   34.2  138.2
  8.8   27.6   83.2
 11.5   49.4  287.0
  6.3   42.0  170.7
;
```

Route the procedure output to an external file. PROC PRINTTO routes output to an external file. Because the LISTING destination must be open in order to route SAS output to an external file, SAS opens the LISTING destination if it is not already open. You do not need to include the ODS LISTING statement. Because NEW is specified, any output written to *output-file* will overwrite the file's current contents. If SAS opened the LISTING destination to process the PROC PRINTTO output, SAS closes the LISTING destination after the output is written to *output-file*.

```
proc printto print='output-file'
new;
run;
```

Print the NUMBERS data set. The PROC PRINT output is written to the specified external file.

```
proc print data=numbers;
   title 'Listing of NUMBERS Data Set';
run;
```

Reset the SAS log and procedure output destinations to default. PROC PRINTTO routes subsequent logs and procedure output to their default destinations and closes both of the current files.

```
proc printto;
run;
```

Log

Example Code 49.1 *Portion of Log Routed to the Default Destination*

```
01   options nodate pageno=1 linesize=80 pagesize=60 source;
02
03   proc printto log='c:\em\log1.log';
04   run;

NOTE: PROCEDURE PRINTTO used (Total process time):
      real time           0.01 seconds
      cpu time            0.00 seconds

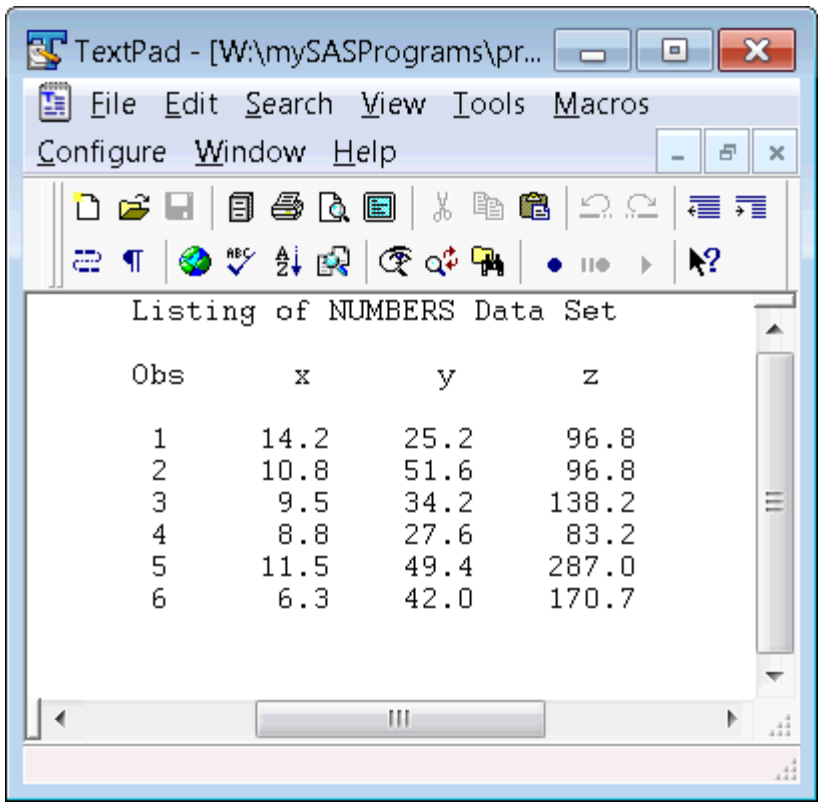
20   proc print data=numbers;
21      title 'Listing of NUMBERS Data Set';
22   run;

NOTE: There were 6 observations read from the data set WORK.NUMBERS.
NOTE: PROCEDURE PRINT used (Total process time):
      real time           0.56 seconds
      cpu time            0.09 seconds

23
24   proc printto;
25   run;
```

Output

Output 49.1 *Procedure Output Routed to an External File*



Example 2: Routing to SAS Catalog Entries

Features:

PRINTTO statement without options

PRINTTO statement options

- LABEL=
- LOG=
- NEW
- PRINT=

Details

This example uses PROC PRINTTO to route the SAS log and procedure output to a SAS catalog entry and then to reset both destinations to the default.

Program

```
options source;

libname lib1 'SAS-library';

proc printto log=test.log label='Inventory program' new;
run;

data lib1.inventry;
   length Dept $ 4 Item $ 6 Season $ 6 Year 4;
   input dept item season year @@;
   datalines;
3070 20410  spring 2011 3070 20411  spring 2012
3070 20412  spring 2012 3070 20413  spring 2012
3070 20414  spring 2011 3070 20416  spring 2009
3071 20500  spring 2011 3071 20501  spring 2009

3071 20505  spring 2010 3071 20506  spring 2009
3071 20507  spring 2009 3071 20424  spring 2011
;

proc printto print=lib1.cat1.inventry.output
             label='Inventory program' new;
run;

proc report data=lib1.inventry nowindows headskip;
   column dept item season year;
   title 'Current Inventory Listing';
run;

proc printto;
run;
```

Program Description

Set the SAS system options. The SOURCE option specifies to write source statements to the SAS log.

```
options source;
```

Assign a libref.

```
libname lib1 'SAS-library';
```

Route the SAS log to a SAS catalog entry. PROC PRINTTO routes the SAS log to a SAS catalog entry named SASUSER.PROFILE.TEST.LOG. The PRINTTO procedure uses the default libref and catalog SASUSER.PROFILE because only the entry name and type are specified. LABEL= assigns a description for the catalog entry.

```
proc printto log=test.log label='Inventory program' new;
run;
```

Create the LIB1.INVENTORY data set. The DATA step creates a permanent SAS data set.

```
data lib1.inventry;
```

```
   length Dept $ 4 Item $ 6 Season $ 6 Year 4;
   input dept item season year @@;
   datalines;
3070 20410  spring 2011 3070 20411  spring 2012
3070 20412  spring 2012 3070 20413  spring 2012
3070 20414  spring 2011 3070 20416  spring 2009
3071 20500  spring 2011 3071 20501  spring 2009
3071 20502  spring 2011 3071 20503  spring 2011
3071 20505  spring 2010 3071 20506  spring 2009
3071 20507  spring 2009 3071 20424  spring 2011
;
```

Route the procedure output to a SAS catalog entry. PROC PRINTTO routes opens the LISTING destination in order to route the procedure output from the subsequent PROC REPORT step to the SAS catalog entry LIB1.CAT1.INVENTRY.OUTPUT. LABEL= assigns a description for the catalog entry. After the procedure output is routed to the SAS catalog, PROC PRINTTO closes the LISTING destination.

```
proc printto print=lib1.cat1.inventry.output
             label='Inventory program' new;
run;

proc report data=lib1.inventry nowindows headskip;
   column dept item season year;
   title 'Current Inventory Listing';
run;
```

Reset the SAS log and procedure output back to the default and close the file. PROC PRINTTO closes the current files that were opened by the previous PROC PRINTTO step and reroutes subsequent SAS logs and procedure output to their default destinations.

```
proc printto;
run;
```

Log

To view this log using SAS Explorer, select **Sasuser** ⇨ **Profile**. Double-click **Test**. The log opens in NOTEPAD.

Example Code 49.3 *SAS Log Routed to SAS Catalog Entry SASUSER.PROFILE.TEST.LOG.*

```
NOTE: PROCEDURE PRINTTO used (Total process time):
      real time           0.00 seconds

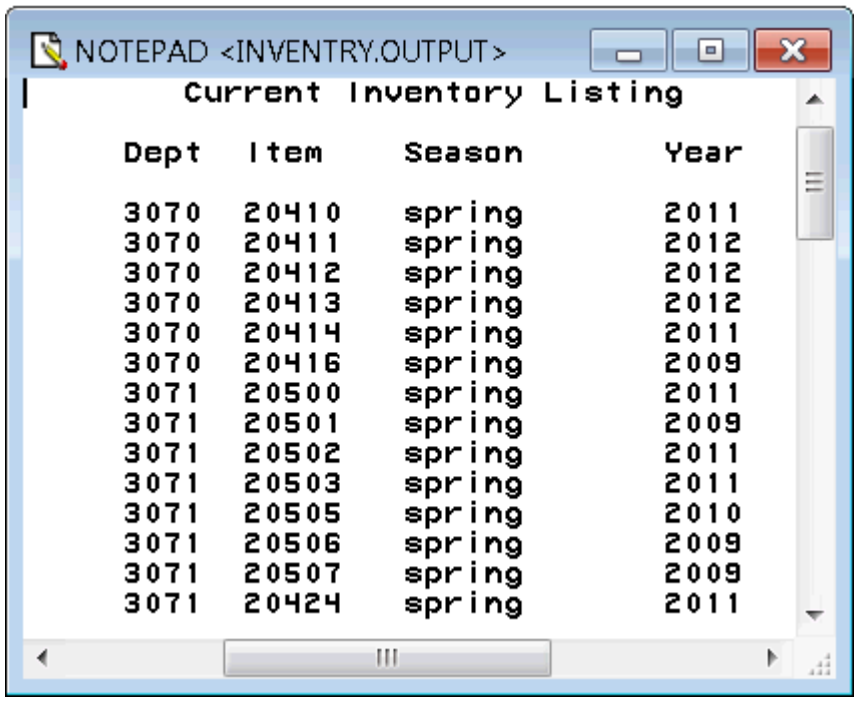
Output

To view this log using SAS Explorer, select **Lib1** ⇨ **Cat1**. Double-click **Inventry**. The output opens in NOTEPAD.

Output 49.2 *Procedure Output Routed to SAS Catalog Entry LIB1.CAT1.INVENTRY.OUTPUT.*



Example 3: Using Procedure Output as an Input File

Features:

PRINTTO statement without options

PRINTTO statement options
- LOG=
- NEW
- PRINT=

Details

This example uses PROC PRINTTO to route procedure output to an external file and then uses that file as input to a DATA step.

Program

```
data test;
   do n=1 to 1000;
      x=int(ranuni(77777)*7);
      y=int(ranuni(77777)*5);
```

```
         output;
      end;
   run;

filename routed 'output-filename';

proc printto print=routed new;
   run;

   proc freq data=test;
      tables x*y / chisq;
   run;

   proc printto print=print;
   run;

   data probtest;
      infile routed;
      input word1 $ @;
      if word1='Chi-Squa' then
         do;
            input df chisq prob;
            keep chisq prob;
            output;
         end;
   run;

   proc print data=probtest;
      title 'Chi-Square Analysis for Table of X by Y';
   run;
```

Program Description

Generate random values for the variables. The DATA step uses the RANUNI function to randomly generate values for the variables X and Y in the data set A.

```
data test;
   do n=1 to 1000;
      x=int(ranuni(77777)*7);
      y=int(ranuni(77777)*5);
      output;
   end;
run;
```

Assign a fileref and route procedure output to the file that is referenced. The FILENAME statement assigns a fileref to an external file. PROC PRINTTO routes subsequent procedure output to the file that is referenced by the fileref ROUTED. PROC PRINTTO opens the LISTING destination for the duration of routing the procedure option. See PROC FREQ Output Routed to the External File Referenced as ROUTED below.

```
filename routed 'output-filename';

proc printto print=routed new;
   run;
```

Produce the frequency counts. PROC FREQ computes frequency counts and a chi-square analysis of the variables X and Y in the data set TEST. This output is routed to the file that is referenced as ROUTED.

```
proc freq data=test;
   tables x*y / chisq;
run;
```

Close the file. You must use another PROC PRINTTO to close the file that is referenced by fileref ROUTED so that the following DATA step can read it. The step also routes subsequent procedure output to the default destination. PRINT= causes the step to affect only procedure output, not the SAS log.

```
proc printto print=print;
run;
```

Create the data set PROBTEST. The DATA step uses ROUTED, the file containing PROC FREQ output, as an input file and creates the data set PROBTEST. This DATA step reads all records in ROUTED but creates an observation only from a record that begins with **`Chi-Squa`**.

```
data probtest;
   infile routed;
   input word1 $ @;
   if word1='Chi-Squa' then
      do;
         input df chisq prob;
         keep chisq prob;
         output;
      end;
run;
```

Print the PROBTEST data set. PROC PRINT produces a simple listing of data set PROBTEST. This output is routed to the default destination. See PROC PRINT Output of Data Set PROBTEST, Routed to Default Destination in the Output section.

```
proc print data=probtest;
   title 'Chi-Square Analysis for Table of X by Y';
run;
```

Output

Output 49.3 *PROC FREQ Output Routed to the External File Referenced as ROUTED*

Chi-Square Analysis for Table of X by Y

Obs	chisq	prob
1	27.2971	0.2908

Example 4: Routing to a Printer

Features: PRINTTO statement option
PRINT=

Details

This example uses PROC PRINTTO to route procedure output directly to a printer.

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

filename your_fileref printer
'printer-name';

proc printto print=your_fileref;
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Associate a fileref with the printer name. The FILENAME statement associates a fileref with the printer name that you specify. If you want to associate a fileref with the default printer, omit '*printer-name*'.

```
filename your_fileref printer
'printer-name';
```

Specify the file to route to the printer. The PRINT= option specifies the file that PROC PRINTTO routes to the printer.

```
proc printto print=your_fileref;
run;
```

PRODUCT_STATUS Procedure

Overview: PRODUCT_STATUS Procedure

What Does the PRODUCT_STATUS Procedure Do?

PROC PRODUCT_STATUS returns a list of the SAS Foundation products that are installed on your system, along with the version numbers of those products. It provides a quick method to determine whether a SAS product is available for your use. The results from PROC PRODUCT_STATUS are returned to the SAS log.

Special Considerations

PROC PRODUCT_STATUS does not return information about web applications or other Java-based products.

If your site has installed a SAS Metadata Server, then you should use the SAS ViewRegistry utility instead of PROC PRODUCT_STATUS.

The SYSVLONG and SYSVLONG4 automatic macro variables return only the version information for the SAS host image that is installed at your site. They do not return information for all of the SAS Foundation products that are installed at your site. For more information, see "SYSVLONG Automatic Macro Variable" in *SAS Macro Language: Reference* and "SYSVLONG4 Automatic Macro Variable" in *SAS Macro Language: Reference*.

Syntax: PRODUCT_STATUS Procedure

PROC PRODUCT_STATUS;

Statement	Task
"Example: Results from PROC PRODUCT_STATUS"	Specify the names and versions of the SAS Foundation products that are installed on your operating system.

PROC PRODUCT_STATUS Statement

Returns the names and versions of the SAS Foundation products that are installed on your operating system.

Restriction: PROC PRODUCT_STATUS is deprecated for SAS Viya 3.5 and will not be available in future SAS Viya releases. PROC PRODUCT_STATUS is available to SAS 9.4 users.

Syntax

PROC PRODUCT_STATUS;

Details

The PROC PRODUCT STATUS statement does not have any arguments.

Example: Results from PROC PRODUCT_STATUS

```
proc product_status;
run;
```

Here is a partial output that contains an example of the results that are produced by PROC PRODUCT_STATUS.

```
For Base SAS Software ...
   Custom version information: 9.4_M3
   Image version information: 9.04.01M3D041815
For SAS/STAT ...
   Custom version information: 14.1
For SAS/GRAPH ...
   Custom version information: 9.4_M3
For SAS/ETS ...
   Custom version information: 14.1
For SAS/FSP ...
   Custom version information: 9.4_M3
For SAS/OR ...
   Custom version information: 14.1

PROTO Procedure

Overview: PROTO Procedure

What Does the PROTO Procedure Do?

The PROTO procedure enables you to register, in batch mode, external functions that are written in the C or C++ programming languages. You can use these functions in SAS as well as in C-language structures and types. After the C-language functions are registered in PROC PROTO, they can be called from any SAS function or subroutine that is declared in the FCMP procedure.

Concepts: PROTO Procedure

Registering Function Prototypes

Function prototypes are registered (declared) in the PROTO procedure. For more information, see "FUNCTION-PROTOTYPE-N Statement" on page 1898.

Supported C Return Types

The following C return types are supported in the PROTO procedure.

Table 51.1 *Supported C Return Types*

Function Prototype	SAS Variable Type	C Variable Type
short	numeric	short, short *, short **
short *	numeric, array	short, short *, short **
int	numeric	int, int *, int **

Function Prototype	SAS Variable Type	C Variable Type
int *	numeric, array	int, int *, int **
long	numeric	long, long *, long **
long *	numeric, array	long, long *, long **
double	numeric	double, double *, double **
double *	numeric, array	double, double *, double **
char *	character	char *, char **
struct *	struct	struct *, struct **
void		void

Supported C Argument Types

The following C argument types are supported in the PROTO procedure.

Table 51.2 *Supported C Argument Types*

Function Prototype	SAS Variable Type	C Variable Type
short	numeric	short, short *, short **
short *	numeric, array	short, short *, short **
short **	array	short *, short **
int	numeric	int, int *, int **
int *	numeric, array	int, int *, int **
int **	array	int *, int **
long	numeric	long, long *, long **
long *	numeric, array	long, long *, long **
long **	array	long *, long **

Function Prototype	SAS Variable Type	C Variable Type
double	numeric	double, double *, double **
double *	numeric, array	double, double *, double **
double **	array	double *, double **
char *	character	char *, char **
char **	character	char *, char **
struct *	structure	struct *, struct **
struct **	structure	struct *, struct **

C Structures in SAS

Basic Concepts

Many C language libraries contain functions that have structure pointers as arguments. In SAS, structures can be defined only in PROC PROTO. After being defined, they can be declared and instantiated within many PROC PROTO compatible procedures, such as PROC COMPILE.

A C structure is a template that is applied to a contiguous piece of memory. Each entry in the template is given a name and a type. The type of each element determines the number of bytes that are associated with each entry and how each entry is to be used. Because of various alignment rules and base type sizes, SAS relies on the current machine compiler to determine the location of each entry in the memory of the structure.

Declaring and Referencing Structures in SAS

The syntax of a structure declaration in SAS is the same as for C non-pointer structure declarations. A structure declaration has the following form:

struct *structure_name structure_instance*;

Each structure is set to zero values at declaration time. The structure retains the value from the previous pass through the data to start the next pass.

Structure elements are referenced by using the static period (.) notation of C. There is no pointer syntax for SAS. If a structure points to another structure, the only way to reference the structure that is pointed to is by assigning the pointer to a declared structure of the same type. You use that declared structure to access the elements.

If a structure entry is a short, int, or long type, and it is referenced in an expression, it is first cast to a double type and then used in the calculations. If a structure entry is a pointer to a base type, then the pointer is dereferenced and the value is returned. If the pointer is null, then a missing value is returned. The missing value assignments that are made in the PROC PROTO code are used when conversions fail or when missing values are assigned to non-double structure entities.

The length of arrays must be known to SAS so that an array entry in a structure can be used in the same way as an array in SAS, as long as its dimension is declared in the structure. This requirement includes arrays of short, int, and long types. If the entry is actually a pointer to an array of a double type, then the array elements can be accessed by assigning that pointer to a SAS array. Pointers to arrays of other types cannot be accessed by using the array syntax.

Structure Example

```
proc proto package =
sasuser.mylib.struct
   label = "package of structures";

   #define MAX_IN 20;

   typedef char * ptr;
   struct foo {
      double hi;
      int mid;
      ptr buf1;
      long * low;
      struct {
         short ans[MAX_IN + 1];
         struct {     /* inner */
            int inner;
         } n2;
         short outer;
      } n;
   };

   typedef struct foo *str;

   struct foo2 {
      str tom;
   };

   str get_record(char *name, int userid);
run;

proc fcmp library = sasuser.mylib;
   struct foo result;
```

```
   result = get_record("Mary", 32);
   put result=;
run;
```

Enumerations in SAS

Enumerations are mnemonics for integer numbers. Enumerations enable you to set a literal name as a specific number and aid in the readability and supportability of C programs. Enumerations are used in C language libraries to simplify the return codes. After a C program is compiled, you can no longer access enumeration names.

Enumerated Types Example

The following example shows how to set up two enumerated value types in PROC PROTO: YesNoMaybeType, and Tens. Both are referenced in the structure ESTRUCTURE:

```
proc proto package=sasuser.mylib.str2
   label="package of structures";

   #define E_ROW 52;
   #define L_ROW 124;
   #define S_ROW 15;

   typedef double ExerciseArray[S_ROW][2];
   typedef double LadderArray[L_ROW];
   typedef double SamplingArray[S_Row];

   typedef enum
   {
      True, False, Maybe
   }  YesNoMaybeType;

   typedef enum {
      Ten=10, Twenty=20, Thirty=30, Forty=40, Fifty=50
      } Tens;

   typedef struct {
      short           rows;
      short           cols;
      YesNoMaybeType  type;
      Tens            dollar;
      ExerciseArray   dates;
    } EStructure;
run;
```

The following PROC FCMP example shows how to access these enumerated types. In this example, the enumerated values that are set up in PROC PROTO are implemented in SAS as macro variables. Therefore, they must be accessed using the & symbol:

```
proc fcmp library=sasuser.mylib;
```

```
   struct EStructure mystruct;

   mystruct.type=&True;
   mystruct.dollar=&Twenty;
run;
```

C-Source Code in SAS

You can use PROC PROTO in a limited way to compile external C functions. The C source code can be specified in PROC PROTO in the following way:

```
C-function-prototype;
externc function-name;
   ... C-source-statements ...
externcend;
```

The function name tells PROC PROTO which function's source code is specified between the EXTERNC and EXTERNCEND statements. When PROC PROTO compiles source code, it includes any structure definitions and C function prototypes that are currently declared. However, typedef and #define are not included.

This functionality is provided to enable the creation of simple "helper" functions that facilitate the interface to preexisting external C libraries. Any valid C statement is permitted except for the #include statement. Only a limited subset of the C-stdlib functions is available. However, you can call any other C function that is already declared within the current PROC PROTO step.

The following C-stdlib functions are supported:

Table 51.3 *Supported stdlib Functions*

Function	Description
double sin(double x)	returns the sine of x (radians)
double cos(double x)	returns the cosine of x (radians)
double tan(double x)	returns the tangent of x (radians)
double asin(double x)	returns the arcsine of x (-pi/2 to pi/2 radians)
double acos(double x)	returns the arccosine of x (0 to pi radians)
double atan(double x)	returns the arctangent of x (-pi/2 to pi/2 radians)
double atan2(double x, double y)	returns the arctangent of y/x (-pi to pi radians)
double sinh(double x)	returns the hyperbolic sine of x (radians)

Function	Description
double cosh(double x)	returns the hyperbolic cosine of x (radians)
double tanh(double x)	returns the hyperbolic tangent of x (radians)
double exp(double x)	returns the exponential value of x
double log(double x)	returns the logarithm of x
double log2(double x)	returns the logarithm of x base-2
double log10(double x)	returns the logarithm of x base-10
double pow(double x, double y)	returns x raised to the y power of x**y
double sqrt(double x)	returns the square root of x
double ceil(double x)	returns the smallest integer not less than x
double fmod(double x, double y)	returns the remainder of (x/y)
double floor(double x)	returns the largest integer not greater than x
int abs(int x)	returns the absolute value of x
double fabs(double)	returns the absolute value of x
int min(int x, int y)	returns the minimum of x and y
double fmin(double x, double y)	returns the minimum of x and y
int max(int x, int y)	returns the maximum of x and y
double fmax(double x, double y)	returns the maximum of x and y
char* malloc(int x)	allocates memory of size x
void free(char*)	frees memory allocated with malloc

The following example shows a simple C function written directly in PROC PROTO:

```
proc proto
package=sasuser.mylib.foo;
   struct mystruct {
      short a;
      long b;
   };
   int fillMyStruct(short a, short b,
struct mystruct * s);
```

```
   externc  fillMyStruct;
      int fillMyStruct(short a, short b,
struct mystruct * s) {
         s ->a = a;
         s ->b = b;
         return(0);
      }
   externcend;
run;
```

Limitations for C Language Specifications

The limitations for the C language specifications in the PROTO procedure are as follows:

- #define statements must be followed by a semicolon (;) and must be numeric in value.
- The #define statement functionality is limited to simple replacement and unnested expressions. The only symbols that are affected are array dimension references.
- The C preprocessor statements #include and #if are not supported. The SAS macro %INC can be used in place of #include.
- A maximum of two levels of indirection are allowed for structure elements. Elements like "double ***" are not allowed. If these element types are needed in the structure, but are not accessed in SAS, you can use placeholders.
- The float type is not supported.
- Unsigned is the only type specifier that is currently supported.
- A specified bit size for structure variables is not supported.
- Function pointers and definitions of function pointers are not supported.
- The union type is not supported. However, if you plan to use only one element of the union, you can declare the variable for the union as the type for that element.
- All non-pointer references to other structures must be defined before they are used.
- You cannot use the ENUM key word in a structure. In order to specify ENUM in a structure, use the TYPEDEF key word.
- Structure elements with the same alphanumeric name but with different cases (for example, ALPHA, Alpha, and alpha) are not supported. SAS is not case-sensitive. Therefore, all structure elements must be unique when compared in a case-insensitive program.

Syntax: PROTO Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC PROTO PACKAGE=*entry* <*options*>;

MAPMISS *type1=value1 type2=value2 ...*;

LINK *load-module* <NOUNLOAD>;

function–prototype–1 <*function-prototype-n* ...;>

Statement	Task	Example
PROC PROTO	Register, in batch mode, external functions that are written in the C or C++ programming languages	Ex. 1
LINK	Specify the name, path, and load module that contains your functions	
MAPMISS	Specify alternative values, by type, to pass to functions if values are missing	
FUNCTION-PROTOTYPE-N	Registers function prototypes in the PROTO procedure.	

PROC PROTO Statement

Register, in batch mode, external functions that are written in the C or C++ programming languages.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Example: "Example: Splitter Function Example" on page 1910

Syntax

PROC PROTO PACKAGE=*entry* <*options*>;

Summary of Optional Arguments

ENCRYPT

HIDE
: for XML databases only, enables the code to be encoded within a data set.

LABEL=*package-label*
: specifies a text string to describe or label a package.

NOSIGNALS
: specifies that none of the functions in a package will produce exceptions.

STDCALL
: for Windows PC platforms only, indicates that functions be called using the "_ stdcall" convention.

STRUCTPACK*n*

PACK*n*
: for 32 bit Windows PC platforms or Power Architecture platform running on Linux only, specifies that all structures in a package be compiled with a specific N-BYTE packing pragma.

Required Arguments

PACKAGE=*entry*
specifies the SAS entry where the prototype information is saved. *Entry* is a three-level name having the following form: `library.dataset.package`. *Package* enables you to specify grouping in the GUI. *Package* must be unique for the first 8 characters.

function-prototype-1
function-prototype-n
contains the C code of the function prototypes.

Optional Arguments

ENCRYPT | HIDE
specifies that encoding within a database is allowed.

Restriction This option is available for XML databases only.

LABEL=*package-label*
specifies a text string that is used to describe or label the package. The maximum length of the label is 256 characters.

NOSIGNALS
specifies that none of the functions in a package will produce exceptions or signals.

STDCALL
for Windows PC platforms only, indicates that all functions in the package are called using the "_stdcall" convention.

STRUCTPACK*n* | PACK*n*
for 32 bit Windows PC platforms or the Power Architecture platform running on Linux only, specifies that all structures in this package were compiled with the given N-BYTE packing pragma. That is, STRUCTURE4 specifies that all structures in the package were compiled with the “#pragma pack(4)” option.

LINK Statement

Specifies the name of the load module that contains your functions. Specifying the path is optional.

Restriction: The LINK statement is not supported for z/OS or MVS environments.

Windows specifics: The image specified in the LINK statement must not contain an extension for the image to load.

Note:

Syntax

LINK *load-module* <NOUNLOAD>;

Required Argument

load-module
specifies the load module that contains your functions. You can add more LINK statements to include as many libraries as you need for your prototypes. *Load-module* can have the following forms, depending on your operating environment:

```
'c:\mylibs\xxx.dll';
'c:\mylibs\xxx';
'/users/me/mylibs/xxx';
```

Tip If the full pathname for a module is larger than 32 bytes, use the PROTOLIBS system option to specify the path. Then use the LINK statement to specify the module name.

Optional Argument

NOUNLOAD

IMPORTANT Starting in SAS 9.4M7, you can use the NOUNLOAD option to prevent the PROTO procedure from crashing due to runtime incompatibilities in certain libraries..

specifies that selected libraries remain loaded when the SAS session ends.

Details

Specifying Extensions and Functions

You do not need to specify your module's extension. SAS loads your module with the extension that is specific to your operating environment.

All functions must be declared externally in your load module so that SAS can find them. For most platforms, external declaration is the default behavior for the compiler. However, many C compilers do not export function names by default. The following examples show how to declare your functions for external loading for most PC compilers:

```
_declspec(dllexport) int myfunc(int, double);
_declspec(dllexport) int price2(int a, double foo);
```

The PROTOLIBS System Option

CAUTION
Security Issue Calling a third-party library to a valid path for a load library that is set by the LINK statement can cause a security issue.

Beginning with SAS 9.4M6, the SAS administrator at your site can use the PROTOLIBS system option to control the function of the LINK statement. The administrator can use the PROTOLIBS option to specify a list of valid paths where modules that are specified by the LINK statement can be loaded. The administrator can also use the PROTOLIBS option to disable the LINK statement.

The PROTOLIBS option is a restricted option. Only the SAS administrator at your site can specify a value for it. The default value of the PROTOLIBS option is NONE, which means that the LINK statement is disabled.

You can use the VALUE argument of PROC OPTIONS to find where you can register load modules.

For more information, see PROTOLIBS System Option.

MAPMISS Statement

Specifies alternative values, by type, to pass to functions if values are missing.

Syntax

MAPMISS <POINTER=*pointer-value* > <INT=*integer-value* > <DOUBLE=*double-value*>
< LONG=*long-value* > <SHORT=*short-value*>;

Optional Arguments

POINTER=*pointer-value*
specifies the pointer value to pass to functions for pointer values that are missing.

Default null

INT=*integer-value*
specifies an integer value to pass to functions for integer values that are missing.

DOUBLE=*double-value*
specifies a double value to pass to functions for double values that are missing.

LONG=*long-value*
specifies a long value to pass to functions for long values that are missing.

SHORT=*short-value*
specifies a short value to pass to functions for short values that are missing.

Details

The MAPMISS statement is used to specify alternative values, by data type or pointer value. These values are passed to functions if values are missing. The values are specified as arguments in the MAPMISS statement.

If you set POINTER=NULL, a null value pointer is passed to the functions for pointer variables that are missing. If you do not specify a mapping for a type that is used as an argument to a function, the function is not called when an argument of that type is missing.

MAPMISS values have no affect on arrays because array elements are not checked for missing values when they are passed as parameters to C functions.

FUNCTION-PROTOTYPE-N Statement

Registers function prototypes in the PROTO procedure.

Syntax

function-prototype-1 <*function-prototype-n* ...> *return-type function-name*
(*argument-type* <*argument-name*> / <*iotype*>
<*argument-label*>, ...) <*options*>;

Required Arguments

return-type
specifies a C language type for the returned value.

Tip *Return-type* can be preceded by either the UNSIGNED or EXCELDATE modifiers. You need to use EXCELDATE if the return type is a Microsoft Excel date.

See "Supported C Return Types" on page 1886

function-name
specifies the name of the function to be registered.

Tip Function names within a given package must be unique in the first 32 characters.

argument-type
specifies the C language type for the function argument.

You must specify *argument-type* for each argument in the function's argument list. The argument list must be enclosed in parentheses. If the argument is an array, then you must specify the argument name prefixed to square brackets that contain the array size (for example, `double A[10]`). If the size is not known or if you want to disable verification of the length, then use type**name* instead (for example, `double*A`).

Tip *Argument-type* can be preceded by either the UNSIGNED, CONST, or EXCELDATE modifiers. You need to use EXCELDATE if the return type is a Microsoft Excel date.

See "Supported C Argument Types" on page 1887

argument-name
specifies the name of the argument.

iotype
specifies the I/O type of the argument. Use I for input, O for output, and U for update.

Alias IO

Tips In the program code, use IOTYPE=I | O | U.

By default, all parameters that are pointers are assumed to be input type U. All non-pointer values are assumed to be input type I. This behavior parallels the C language parameter passing scheme.

See "Example: Splitter Function Example" on page 1910 for an example of how *iotype* is used.

argument-label
specifies a description or label for the argument.

LABEL="*text-string*"
specifies a description or a label for the function. Enclose the text string in quotation marks.

Note The LABEL option can be used with the PROTO procedure.

KIND | GROUP=*group-type*
specifies the group that the function belongs to. The KIND= or GROUP= option allows for convenient grouping of functions in a package.

You can use any string (up to 40 characters) in quotation marks to group similar functions.

Note The KIND or GROUP option can be used with the PROTO procedure.

Tip The following special cases provided for Risk Dimensions do not require quotation marks: INPUT (Instrument Input), TRANS (Risk Factor Transformation), PRICING (Instrument Pricing), and PROJECT. The default is PRICING.

Usage: PROTO Procedure

Basic C Language Types

The SAS language supports two data types: character and numeric. These types correspond to an array of characters and a double (double-precision floating point) data type in the C programming language. When SAS variables are used as arguments to external C functions, they are converted (cast) into the proper types.

Working with Character Variables

You can use character variables for arguments that require a "char *" value only. The character string that is passed is a null string that is terminated at the current length of the string. The current length of the character string is the minimum of the allocated length of the string and the length of the last value that was stored in the string. The allocated length of the string (by default, 32 bytes) can be specified by using the LENGTH statement. Functions that return "char *" can return a null or zero-delimited string that is copied to the SAS variable. If the current length of the character string is less than the allocated length, the character string is padded with blanks.

In the following example, the allocated length of *str* is 10, but the current length is 5. When the string is null-terminated at the allocated length, "hello " is passed to the function xxx:

```
length str $ 10;
str = "hello";
call xxx(str);
```

To avoid the blank padding, use the SAS TRIM function on the parameter within the function call:

```
length str $ 10;
str = "hello";
call xxx(trim(str));
```

In this case, the value "hello" is passed to the function xxx.

Working with Numeric Variables

You can use numeric variables for an argument that requires a short, int, long, or double data type, as well as for pointers to those types. Numeric variables are converted to the required type automatically. If the conversion fails, then the function is not called and the output to the function is set to missing. If pointers to these types are requested, the address of the converted value is passed. On return from the call, the value is converted back to a double type and stored in the SAS variable. SAS scalar variables cannot be passed as arguments that require two or more levels of indirection. For example, a SAS variable cannot be passed as an argument that requires a cast to a "long **" type.

Working with Missing Values

SAS variables that contain missing values are converted according to how the function that is being called has mapped missing values when using the PROTO procedure. All variables that are returned from the function are checked for the mapped missing values and converted to SAS missing values.

For example, if an argument to a function is missing, and the argument is to be converted to an integer, and an integer was mapped to –99, then –99 is passed to the function. If the same function returns an integer with the value –99, then the variable that this value is returned to would have a value of missing.

Function Names

External functions and FCMP functions can have the same name as long as they are saved to different packages. When these packages are loaded, a warning message in the log identifies which package contains the default definition for a given

function. To use a function definition from a package other than the default, call the function using *package-name.function-name*.

When you load multiple packages of external functions, all function names must be unique. If two or more external functions of the same name are loaded, the first function that is loaded will be used. Duplicate external functions are ignored. A warning message in the log indicates which package contains the function that will be used, and which package contained the discarded definition.

Interfacing with External C Functions

To make it easier to interface with external C functions, many PROTO-compatible procedures have been enhanced to support most of these C types.

In working with arrays, it is important to note that SAS arrays are passed to EXTERNC routines as single dimensional arrays. They will be read as single dimensional arrays when returning to an FCMP function.

The following example shows log output that is generated when you use arrays and the double ** variable type.

```
proc proto package=work.proto_ds.test;
   void idmat(double** a,int m,int n);
   externc idmat;
   void idmat(double** a,int m,int n)
   {
      int i=0,j=0;
      for(i=0;i<m;i++)
      {
         for(j=0;j<n;j++)
         {
          if(i==j)
             a[0][i*m+j]=1;
          else
             a[0][i*m+j]=0;
       }
    }
};
externcend;
run;

proc fcmp outlib=work.proto_ds.test inlib=work.proto_ds;
   subroutine sas_idmat(b[*,*]);
      outargs b;
      m=dim(b,1);
      n=dim(b,2);
      call idmat(b,m,n);
      put b=;
      put ' ';
   endsub;
quit;
run;
```

```
options cmplib=work.proto_ds;

data cmat;
   array ctmp[3,3] _temporary_;
   array c[3,3];
   output;
   call sas_idmat(ctmp);
   do i=1 to dim(c,1);
      do j=1 to dim(c,2);
         c[i,j]=ctmp[i,j];
      end;
   end;
   output;
   drop i j;
run;
```

SAS writes the following results to the log:

```
b[1, 1]=1 b[1, 2]=0 b[1, 3]=0 b[2, 1]=0 b[2, 2]=1 b[2, 3]=0 b[3, 1]=0 b[3, 2]=0 b[3,
3]=1
```

There is no way to return and save a pointer to any type in a SAS variable. Pointers are always dereferenced, and their contents are converted and copied to SAS variables.

The EXTERNC statement is used to specify C variables in PROTO compatible procedures. The syntax of the EXTERNC statement has the following form:

EXTERNC DOUBLE | INT | LONG | SHORT | CHAR <[*][*]> *var-1* <*var-2 ... var-n*>;

The following table (Table 51.100 on page 1903) shows how these variables are treated when they are positioned on the left side of an expression. The table shows the automatic casting that is performed for a short type on the right side of an assignment. (Explicit type conversions can be forced in any expression, with a unary operator called a cast.) The table lists all the allowed combinations of short types that are associated with SAS variables.

Note: A table for int, long, and double types can be created by substituting any of these types for "short" in this table.

If any of the pointers are null and require dereferencing, then the result is set to missing if there is a missing value set for the result variable. For more information, see "MAPMISS Statement" on page 1897.

Table 51.4 *Automatic Type Casting for the short Data Type in an Assignment Statement*

Type for Left Side of Assignment	Type for Right Side of Assignment	Cast Performed
short	SAS numeric	y = (short) x
short	short	y = x

Type for Left Side of Assignment	Type for Right Side of Assignment	Cast Performed
short	short *	y = * x
short	short **	y = ** x
short *	SAS numeric	* y = (short) x
short *	short	y = & x
short *	short *	y = x
short *	short **	y = * x
short **	SAS numeric	**y = (short) x
short **	short *	y = & x
short **	short **	y = x
SAS numeric	short	y = (double) x
SAS numeric	short *	y = (double) * x
SAS numeric	short **	y = (double) ** x

The following table shows how these variables are treated when they are passed as arguments to an external C function.

Table 51.5 *Types That Are Allowed for External C Arguments*

Function Prototype	SAS Variable Type	C Variable Type
short	numeric	short, short *, short **
short *	numeric, array	short, short *, short **
short **	array	short *, short **
int	numeric	int, int *, int **
int *	numeric, array	int, int *, int **
int **	array	int *, int **

Function Prototype	SAS Variable Type	C Variable Type
long	numeric	long, long *, long **
long *	numeric, array	long, long *, long **
long **	array	long *, long **
double	numeric	double, double *, double **
double *	numeric, array	double, double *, double **
double **	array	double *, double **
char *	character	char *, char **
char **	character	char *, char **
struct *	structure	struct *, struct **
struct **	structure	struct *, struct **

Note: Automatic conversion between two different C types is never performed.

Scope of Packages in PROC PROTO

PROC PROTO packages are loaded in the order that is specified in the CMPLIB= system option, and the contents are used globally. Packages that are loaded through a PROC statement option are considered local in scope. Local definitions are loaded last, and in all cases, local scope overrides global scope.

Definitions are loaded regardless of whether they have unique names or duplicate names. Multiple definitions of certain PROC PROTO elements (for example, enumeration names and function prototypes) can cause name conflicts and generate errors. To prevent name conflicts between PROC PROTO packages, ensure that elements such as enumerated types and function definitions have unique names.

The following example loads three PROC PROTO packages, and shows how the order in which typedef and #define statements override one another.

This part of the example loads the first two PROC PROTO packages:

```
proc proto package = work.p1.test1;
```

```
    typedef struct { int a; int b; } AB_t;
    #define NUM 1;
    int p1(void);
    externc p1;
        int p1(void)
        {
            return NUM;
        }
    externcend;
run;

proc proto package = work.p2.test2;
    typedef struct { int a; int b; } AB_t;
    #define NUM 2;
    int p2(void);
    externc p2;
        int p2(void)
        {
            return NUM;
        }
    externcend;
run;

options CMPLIB = (work.p1 work.p2);

proc fcmp;
   x = p1();
   put "Should be 2: " x=;
run;
```

The result from executing the programs above is 2, because the packages are loaded in order.

In the following example, PROC PROTO adds a third package and includes it in PROC FCMP locally, keeping the CMPLIB= system option set as above:

```
proc proto package = work.p3.test3;
    typedef struct { int a; int b; } AB_t;
    #define NUM 3;
    int p3(void);
    externc p3;
        int p3(void)
        {
            return NUM;
        }
    externcend;
run;

proc fcmp libname = work.p3;
   x = p1();
   put "Should be 3: " x=;
run;
```

In this example, the local definition of NUM in *work.p3* is used instead of the global definitions that are loaded through *work.p1* and *work.p2*.

C Helper Functions and CALL Routines

What Are C Helper Functions and CALL Routines?

Several helper functions and CALL routines are provided with the package to handle C-language constructs in PROC FCMP. Most C-language constructs must be defined in a catalog package that is created by PROC PROTO before the constructs can be referenced or used by PROC FCMP. The ISNULL function and the STRUCTINDEX and SETNULL CALL routines have been added to extend the SAS language to handle C-language constructs that do not naturally fit into the SAS language.

The following C helper functions and CALL routines are available:

Table 51.6 *C Helper Functions and CALL Routines*

C Helper Function or CALL Routine	Description
"ISNULL C Helper Function" on page 1907	Determines whether a pointer element of a structure is null
"SETNULL C Helper CALL Routine" on page 1908	Sets a pointer element of a structure to null
"STRUCTINDEX C Helper CALL Routine" on page 1908	Enables you to access each structure element in an array of structures

ISNULL C Helper Function

The ISNULL function determines whether a pointer element of a structure is NULL. The function has the following form:

double **ISNULL** (*pointer-element*);

Pointer-element refers to the pointer element.

In the following example, the LINKLIST structure and the GET_LIST function are defined by using PROC PROTO. The GET_LIST function is an external C routine that generates a linked list with as many elements as requested:

```
struct linklist{
   double value;
   struct linklist * next;
```

```
};

struct linklist * get_list(int);
```

The following example shows how to use the ISNULL helper function to loop over the linked list that is created by the GET_LIST function:

```
struct linklist list;

list = get_list(3);
put list.value=;

do while (^isnull(list.next));
   list = list.next;
   put list.value=;
end;
```

Example Code 51.1 *Looping over a Linked List*

```
LIST.value=0
LIST.value=1
LIST.value=2
```

SETNULL C Helper CALL Routine

The SETNULL CALL routine sets a pointer element of a structure to null. It has the following form:

CALL SETNULL(*pointer-element*);

Pointer-element is a pointer to a structure.

If you specify a variable that has a pointer value (a structure entry), then SETNULL sets the pointer to null:

```
call setnull(12.next);
```

The following example assumes that the same LINKLIST structure that is described in "ISNULL C Helper Function" on page 1907 is defined using PROC PROTO. The SETNULL CALL routine can be used to set the next element to null:

```
proc proto;
   struct linklist list;
   call setnull(list.next);
run;
```

STRUCTINDEX C Helper CALL Routine

The STRUCTINDEX CALL routine enables you to access each structure element in an array of structures. When a structure contains an array of structures, you can access each structure element of the array by using the STRUCTINDEX CALL routine. The STRUCTINDEX CALL routine has the following form:

CALL STRUCTINDEX(*struct_array*, *index*, *struct_element*);

Struct_array specifies an array; *index* is a 1–based index as used in SAS arrays; and *struct_element* points to an element in the array.

The following example consists of two parts. Copy and paste the two parts of the example into your SAS editor, and run them as one SAS program.

In the first part of this example, the following structures and function are defined using PROC PROTO:

```
options cmplib=(work.proto_ds work.fcmp_ds);
proc proto package=work.proto_ds.cfcns;
     struct POINT {
           short s;
           int i;
           long l;
           double d;
     };
     struct POINT_ARRAY {
           int length;
           struct POINT * p;
           char name[32];
     };
     struct POINT * struct_array( int );

     externc struct_array;
         struct POINT * struct_array( int num ) {
              return(malloc(sizeof(struct POINT) * num));
         }
     externcend;
run;
```

In the second part of this example, the PROC FCMP code segment shows how to use the STRUCTINDEX CALL routine to get and set each POINT structure element of an array called P in the POINT_ARRAY structure:

```
proc fcmp;
struct point_array pntarray;
struct point pnt;

   /* Call struct_array to allocate an array of 2 POINT structures. */
pntarray.p = struct_array(2);
pntarray.plen = 2;
pntarray.name = "My funny structure";

   /* Get each element using the STRUCTINDEX CALL routine and set
values. */
do i = 1 to 2;
   call structindex(pntarray.p, i, pnt);
   put "Before setting the" i "element: " pnt=;
   pnt.s = 1;
   pnt.i = 2;
   pnt.l = 3;
   pnt.d = 4.5;
   put "After setting the" i "element: " pnt=;
end;
```

```
run;
```

Example Code 51.2 *Results from the STRUCTINDEX CALL Routine*

```
Before setting the 1 element: PNT {s=0, i=0, l=0, d=0}
After setting the 1 element: PNT {s=1, i=2, l=3, d=4.5}
Before setting the 2 element: PNT {s=0, i=0, l=0, d=0}
After setting the 2 element: PNT {s=1, i=2, l=3, d=4.5}
```

Example: Splitter Function Example

Features: INT statements
KIND= prototype argument
PROC FCMP

Details

This example shows how to use PROC PROTO to prototype two external C language functions called SPLIT and CASHFLOW. These functions are contained in the two shared libraries that are specified by the LINK statements.

Program

```
options nodate pageno=1 linesize=80 pagesize=40;

proc proto package =
sasuser.myfuncs.mathfun
           label = "package of math functions";

           link "link-library";
           link "link-library";

   int split(int x "number to split")
       label = "splitter function" kind=PRICING;

   int cashflow(double amt, double rate, int periods,
                double * flows / iotype=0)
       label = "cash flow function" kind=PRICING;

run;

proc fcmp libname=sasuser.myfuncs;
   array flows[20];
   a = split(32);
   put a;
```

```
   b = cashflow(1000, .07, 20, flows);
   put b;
   put flows;
run;

run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGNO= specifies the starting page number. LINESIZE= specifies the output line length. PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Specify the catalog entry where the function package information is saved. The catalog entry is a three-level name.

```
proc proto package =
sasuser.myfuncs.mathfun
           label = "package of math functions";
```

Specify the libraries that contain the SPLIT and CASHFLOW functions. You can add more LINK statements to include as many libraries as you need for your prototypes.

```
           link "link-library";
           link "link-library";
```

Prototype the SPLIT function. The INT statement prototypes the SPLIT function and assigns a label to the function.

```
int split(int x "number to split")
    label = "splitter function" kind=PRICING;
```

Prototype the CASHFLOW function. The INT statement prototypes the CASHFLOW function and assigns a label to the function.

```
int cashflow(double amt, double rate, int periods,
             double * flows / iotype=O)
    label = "cash flow function" kind=PRICING;
```

Execute the PROTO procedure. The RUN statement executes the PROTO procedure.

```
run;
```

Call the SPLIT and CASHFLOW functions. PROC FCMP calls the SPLIT and CASHFLOW functions. Output from PROC FCMP is created.

```
proc fcmp libname=sasuser.myfuncs;
   array flows[20];
   a = split(32);
   put a;
   b = cashflow(1000, .07, 20, flows);
   put b;
   put flows;
```

```
run;
```

Execute the FCMP procedure. The RUN statement executes the FCMP procedure.

```
run;
```

Output: Prototyping Functions

Output 51.1 *Results from Prototyping the SPLIT and CASHFLOW Functions*

```
                                        The SAS System                      1

PRTDEF Procedure

Overview: PRTDEF Procedure

What Does the PRTDEF Procedure Do?

The PRTDEF procedure creates printer definitions in batch mode either for an individual user or for all SAS users at your site. Your system administrator can create printer definitions in the SAS registry and make these printers available to all SAS users at your site by using PROC PRTDEF with the USESASHELP option. An individual user can create personal printer definitions in the SAS registry by using PROC PRTDEF.

See Also

Chapter 53, “PRTEXP Procedure,” on page 1933

Syntax: PRTDEF Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC PRTDEF <*options*>;

Statement	Task	Example
PROC PRTDEF	Create printer definitions in batch mode either for an individual user or for all SAS users at your site	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5

PROC PRTDEF Statement

Creates printer definitions in batch mode.

Examples:
“Example 1: Defining Multiple Printer Definitions” on page 1922
“Example 2: Creating a Ghostview Printer in SASUSER to Preview PostScript Printer Output in SASUSER” on page 1923
“Example 3: Creating a Single Printer Definition That Is Available to All Users” on page 1925
“Example 4: Adding, Modifying, and Deleting Printer Definitions” on page 1927
“Example 5: Deleting a Single Printer Definition” on page 1929

Syntax

PROC PRTDEF <*options*>;

Optional Arguments

DATA=*SAS-data-set*
specifies the SAS data set that contains the printer attributes.

Requirement Printer attributes variables that must be specified are DEST, DEVICE, MODEL, and NAME, except when the value of the

variable OPCODE is DELETE. In that case, only the NAME variable is required.

See "Input Data Set Variables That Are Used To Create Printer Definitions" on page 1916

DELETE
specifies that the default operation is to delete the printer definitions from the registry.

Interaction If both DELETE and REPLACE are specified, then DELETE is the default operation.

Tip If the user-defined printer definition is deleted, then the administrator-defined printer can still appear if it exists in the Sashelp catalog.

Example "Example 5: Deleting a Single Printer Definition" on page 1929

FOREIGN
specifies that the registry entries are being created for export to a different host. As a consequence, tests of any host-dependent items, such as the TRANTAB, are skipped.

LIST
specifies that a list of printers that is created or replaced is written to the log.

Examples "Example 2: Creating a Ghostview Printer in SASUSER to Preview PostScript Printer Output in SASUSER" on page 1923

"Example 4: Adding, Modifying, and Deleting Printer Definitions" on page 1927

REPLACE
specifies that the default operation is to modify existing printer definitions. Any printer name that already exists is modified by using the information in the printer attributes data set. Any printer name that does not exist is added.

Interaction If both REPLACE and DELETE are specified, then a DELETE is performed.

Example "Example 2: Creating a Ghostview Printer in SASUSER to Preview PostScript Printer Output in SASUSER" on page 1923

USESASHELP
specifies that the printer definitions are to be placed in the Sashelp library, where they are available to all users. If the USESASHELP option is not specified, then the printer definitions are placed in the current Sasuser library, where they are available to the local user only.

Windows Specifics: You can create printer definitions with PROC PRTDEF in the Windows operating environment. However, because Universal Printing is turned off by default in Windows, these printer definitions do not appear in the Print window. If you want to use your printer definitions when Universal Printing is turned off, then either specify the printer definition as part of the

PRINTERPATH system option or, from the Output Delivery System (ODS), issue the following code:

```
ODS PRINTER SAS PRINTER=myprinter;
```

where *myprinter* is the name of your printer definition.

Restriction To use the USESASHELP option, you must have permission to write to the Sashelp catalog.

Example "Example 3: Creating a Single Printer Definition That Is Available to All Users" on page 1925

Usage: PRTDEF Procedure

Input Data Set Variables That Are Used To Create Printer Definitions

Summary of Valid Variables

To create your printer definitions, you must create a SAS data set whose variables contain the appropriate printer attributes. The following table lists and describes both the required and optional variables for this data set.

Table 52.1 *Required and Optional Variable for Creating Printer Definition Records*

Variable Name	Variable Description
Required	
DEST	Destination
DEVICE	Device
MODEL	Prototype
NAME	Printer name
Optional	

Variable Name	Variable Description
BOTTOM	Default bottom margin
CHARSET	Default font character set
DESC	Description
FONTSIZE	Point size of the default font
HOSTOPT	Host options
LEFT	Default left margin
LRECL	Output buffer size
OPCODE	Operation code
PAPERIN	Paper source or input tray
PAPEROUT	Paper destination or output tray
PAPERSIZ	Paper size
PAPERTYP	Paper type
PREVIEW	Preview
PROTOCOL	Protocol
RES	Default printer resolution
RIGHT	Default right margin
STYLE	Default font style
TOP	Default top margin
TRANTAB	Translation table
TYPEFACE	Default font
UNITS	CM or IN units
VIEWER	Viewer
WEIGHT	Default font weight

Required Variables

To create or modify a printer, you must supply the NAME, MODEL, DEVICE, and DEST variables. All the other variables use default values from the printer prototype that is specified by the MODEL variable.

To delete a printer, specify only the required NAME variable.

The following variables are required in the input data set:

DEST
specifies the output destination for the printer.

Operating Environment Information: DEST is case sensitive for some devices.

Restriction DEST is limited to 1023 characters.

DEVICE
specifies the type of I/O device to use when sending output to the printer. Valid devices are listed in the Printer Definition wizard and in the SAS Registry Editor.

Restriction DEVICE is limited to 31 characters.

MODEL
specifies the printer prototype to use when defining the printer.

For a valid list of prototypes or model descriptions, you can look in the SAS Registry Editor under CORE\PRINTING\PROTOTYPES.

Restriction MODEL is limited to 127 characters.

Tip While in interactive mode, you can invoke the registry with the REGEDIT command.

NAME
specifies the printer definition name that is associated with the rest of the attributes in the printer definition.

The name is unique within a given registry. If a new printer definition contains a name that already exists, then the record is not processed unless the REPLACE option has been specified or unless the value of the OPCODE variable is **`Modify`**.

Restriction NAME is limited to 127 characters, must have at least one nonblank character, and cannot contain a backslash. Leading and trailing blanks are stripped from the name.

Optional Variables

The following variables are optional in the input data set:

BOTTOM
specifies the default bottom margin in the units that are specified by the UNITS variable.

CHARSET
specifies the default font character set.

Restriction The value must be one of the character set names in the typeface that is specified by the TYPEFACE variable.

DESC
specifies the description of the printer.

Default DESC defaults to the prototype that is used to create the printer.

Restriction The description can have a maximum of 1023 characters.

FONTSIZE
specifies the point size of the default font.

HOSTOPT
specifies any host options for the output destination. The host options are not case sensitive.

Restriction The host options can have a maximum of 1023 characters.

LEFT
specifies the default left margin in the units that are specified by the UNITS variable.

LRECL
specifies the buffer size or record length to use when sending output to the printer.

Default If LRECL is less than zero when modifying an existing printer, the printer's buffer size is reset to the size that is specified by the printer prototype.

OPCODE
is a character variable that specifies what action (Add, Delete, or Modify) to perform on the printer definition.

Add
creates a new printer definition in the registry. If the REPLACE option has been specified, then this operation will also modify an existing printer definition.

Delete
removes an existing printer definition from the registry.

Restriction This operation requires only the NAME variable to be defined. The other variables are ignored.

Modify
changes an existing printer definition in the registry or adds a new one.

Restriction OPTCODE is limited to eight characters.

Tip If a user modifies and saves new attributes on a printer in the SASHELP library, then these modifications are stored in the SASUSER library. Values that are specified by the user will override values that are set by the administrator, but they will not replace them.

PAPERIN
specifies the default paper source or input tray.

Restriction The value of PAPERIN must be one of the paper source names in the printer prototype that is specified by the MODEL variable.

PAPEROUT
specifies the default paper destination or output tray.

Restriction The value of PAPEROUT must be one of the paper destination names in the printer prototype that is specified by the MODEL variable.

PAPERSIZ
specifies the default paper source or input tray.

Restriction The value of PAPERSIZ must be one of the paper size names listed in the printer prototype that is specified by the MODEL variable.

PAPERTYP
specifies the default paper type.

Restriction The value of PAPERTYP must be one of the paper source names listed in the printer prototype that is specified by the MODEL variable.

PREVIEW
specifies the printer application to use for print preview.

Restriction PREVIEW is limited to 127 characters.

PROTOCOL
specifies the I/O protocol to use when sending output to the printer.

Operating Environment Information: On mainframe systems, the protocol describes how to convert the output to a format that can be processed by a protocol converter that connects the mainframe to an ASCII device.

Restriction PROTOCOL is limited to 31 characters.

RES
specifies the default printer resolution.

Restriction The value of RES must be one of the resolution values available to the printer prototype that is specified by the MODEL variable.

RIGHT
specifies the default right margin in the units that are specified by the UNITS variable.

STYLE
specifies the default font style.

Restriction The value of STYLE must be one of the styles available to the typeface that is specified by the TYPEFACE variable.

TOP
specifies the default top margin in the units that are specified by the UNITS variable.

TRANTAB
specifies which translation table to use when sending output to the printer.

Operating Environment Information: The translation table is needed when an EBCDIC host sends data to an ASCII device.

Restriction TRANTAB is limited to eight characters.

TYPEFACE
specifies the typeface of the default font.

Restriction The typeface must be one of the typeface names available to the printer prototype that is specified by the MODEL variable.

UNITS
specifies the units CM or IN that are used by margin variables.

VIEWER
specifies the host system command that is to be used during print previews. As a result, PROC PRTDEF causes a preview printer to be created.

Preview printers are specialized printers that are used to display printer output on the screen before printing.

Restriction VIEWER is limited to 127 characters.

Tip The values of the PREVIEW, PROTOCOL, DEST, and HOSTOPT variables are ignored when a value for VIEWER has been specified. Place *%s* where the input filename would normally be in the viewer command. *%s* can be used as many times as needed.

WEIGHT
specifies the default font weight.

Restriction The value must be one of the valid weights for the typeface that is specified by the TYPEFACE variable.

Examples: PRTDEF Procedure

Example 1: Defining Multiple Printer Definitions

Features: PROC PRTDEF statement options
DATA=

Details

This example shows you how to set up various printers.

Program

```
data printers;
input name $ 1-14 model $ 16-42 device $ 46-53 dest $ 57-70;
datalines;
Myprinter      PostScript Level 1 (Color)    PRINTER   printer1
Laserjet       PCL 5 (DeltaRow)              PIPE      lp -dprinter5
Color LaserJet PostScript Level 2 (Color)    PIPE      lp -dprinter2
;

proc prtdef data=printers;
run;
```

Program Description

Create the PRINTERS data set. The INPUT statement contains the names of the four required variables. Each data line contains the information that is needed to produce a single printer definition.

```
data printers;
input name $ 1-14 model $ 16-42 device $ 46-53 dest $ 57-70;
datalines;
Myprinter      PostScript Level 1 (Color)    PRINTER   printer1
Laserjet       PCL 5 (DeltaRow)              PIPE      lp -dprinter5
Color LaserJet PostScript Level 2 (Color)    PIPE      lp -dprinter2
;
```

Specify the input data set that contains the printer attributes and create the printer definitions. PROC PRTDEF creates the printer definitions for the SAS registry, and the DATA= option specifies PRINTERS as the input data set that contains the printer attributes.

```
proc prtdef data=printers;
run;
```

Log

Example Code 52.1 *The SAS Log After Defining Printers*

```
1    data printers;
2    input name $ 1-14 model $ 16-42 device $ 46-53 dest $ 57-70;
3    datalines;

NOTE: The data set WORK.PRINTERS has 3 observations and 4 variables.
NOTE: DATA statement used (Total process time):
      real time           0.03 seconds
      cpu time            0.03 seconds

7    ;
8    proc prtdef data=printers;
9    run;

NOTE: 3 printer definitions added to the registry.
NOTE: 0 printer definitions modified in the registry.
NOTE: 0 printer definitions deleted from the registry.
NOTE: PROCEDURE PRTDEF used (Total process time):
      real time           0.15 seconds
      cpu time            0.01 seconds
```

Example 2: Creating a Ghostview Printer in SASUSER to Preview PostScript Printer Output in SASUSER

Features: PROC PRTDEF statement options
- DATA=
- LIST
- REPLACE

Details

This example creates a Ghostview printer definition in the Sasuser library for previewing PostScript output.

Program

```
data gsview;
   name = "Ghostview";
   desc = "Print Preview with Ghostview";
   model= "PostScript Level 2 (Color)";
   viewer = 'ghostview %s';
   device = "Dummy";
   dest = " ";
run;

proc prtdef data=gsview list replace;
run;
```

Program Description

Create the GSVIEW data set, and specify the printer name, printer description, printer prototype, and commands to be used for print preview. The GSVIEW data set contains the variables whose values contain the information that is needed to produce the printer definitions. The NAME variable specifies the printer name that will be associated with the rest of the attributes in the printer definition data record. The DESC variable specifies the description of the printer. The MODEL variable specifies the printer prototype to use when defining this printer. The VIEWER variable specifies the host system commands to be used for print preview. GSVIEW must be installed on your system and the value for VIEWER must include the path to find it. You must enclose the value in single quotation marks because of the `%s`. If you use double quotation marks, SAS will assume that `%s` is a macro variable. DEVICE and DEST are required variables, but no value is needed in this example. Therefore, a “dummy” or blank value should be assigned.

```
data gsview;
   name = "Ghostview";
   desc = "Print Preview with Ghostview";
   model= "PostScript Level 2 (Color)";
   viewer = 'ghostview %s';
   device = "Dummy";
   dest = " ";
run;
```

Specify the input data set that contains the printer attributes, create the printer definitions, write the printer definitions to the SAS log, and replace a printer definition in the SAS registry. The DATA= option specifies GSVIEW as the input

data set that contains the printer attributes. PROC PRTDEF creates the printer definitions. The LIST option specifies that a list of printers that are created or replaced will be written to the SAS log. The REPLACE option specifies that a printer definition will replace a printer definition in the registry if the name of the printer definition matches a name already in the registry. If the printer definition names do not match, then the new printer definition is added to the registry.

```
proc prtdef data=gsview list replace;
run;
```

Log

Example Code 52.2 *The SAS Log After Defining a GhostView Printer*

```
10   data gsview;
11   name = "Ghostview";
12   desc = "Print Preview with Ghostview";
13   model= "PostScript Level 2 (Color)";
14   viewer = 'ghostview %s';
15   device = "Dummy";
16   dest = " ";

NOTE: The data set WORK.GSVIEW has 1 observations and 6 variables.
NOTE: DATA statement used (Total process time):
      real time           0.00 seconds
      cpu time            0.00 seconds

17   proc prtdef data=gsview list replace;
18   run;

NOTE: Printer Ghostview created.
NOTE: 1 printer definitions added to the registry.
NOTE: 0 printer definitions modified in the registry.
NOTE: 0 printer definitions deleted from the registry.
NOTE: PROCEDURE PRTDEF used (Total process time):
      real time           0.01 seconds
      cpu time            0.01 seconds
```

Example 3: Creating a Single Printer Definition That Is Available to All Users

Features: PROC PRTDEF statement options
- DATA=
- USESASHELP

Restriction: To use the USESASHELP option, you must have permission to write to the Sashelp catalog.

Details

This example creates a definition for a Tektronix Phaser 780 printer with a Ghostview print previewer with the following specifications:

- bottom margin set to 1 inch
- font size set to 14 point
- paper size set to A4

Program

```
data tek780;
   name = "Tek780";
   desc = "Test Lab Phaser 780P";
   model = "Tek Phaser 780 Plus";
   device = "PRINTER";
   dest = "testlab3";
   preview = "Ghostview";
   units = "cm";
   bottom = 2.5;
   fontsize = 14;
   papersiz = "ISO A4";
run;

proc prtdef data=tek780 usesashelp;
run;
```

Program Description

Create the TEK780 data set and supply appropriate information for the printer destination. The TEK780 data set contains the variables whose values contain the information that is needed to produce the printer definitions. In the example, assignment statements are used to assign these variables. The NAME variable specifies the printer name that is associated with the rest of the attributes in the printer definition data record. The DESC variable specifies the description of the printer. The MODEL variable specifies the printer prototype to use when defining this printer. The DEVICE variable specifies the type of I/O device to use when sending output to the printer. The DEST variable specifies the output destination for the printer. The PREVIEW variable specifies which printer is used for print preview. The UNITS variable specifies whether the margin variables are measured in centimeters or inches. The BOTTOM variable specifies the default bottom margin in the units that are specified by the UNITS variable. The FONTSIZE variable specifies the point size of the default font. The PAPERSIZ variable specifies the default paper size.

```
data tek780;
```

```
   name = "Tek780";
   desc = "Test Lab Phaser 780P";
   model = "Tek Phaser 780 Plus";
   device = "PRINTER";
   dest = "testlab3";
   preview = "Ghostview";
   units = "cm";
   bottom = 2.5;
   fontsize = 14;
   papersiz = "ISO A4";
run;
```

Create the TEK780 printer definition and make the definition available to all users. The DATA= option specifies TEK780 as the input data set. The USESASHELP option specifies that the printer definition will be available to all users.

```
proc prtdef data=tek780 usesashelp;
run;
```

Example 4: Adding, Modifying, and Deleting Printer Definitions

Features: PROC PRTDEF statement options
DATA=
LIST

Details

This example does the following:

- adds two printer definitions
- modifies a printer definition
- deletes two printer definitions

Program

```
data printers;
length name   $ 80
   model  $ 80
   device $ 8
   dest   $ 80
   opcode $ 3
   ;
input opcode $& name $& model $& device $& dest $&;
```

```
datalines;
add  Color PostScript   PostScript Level 2 (Color)       DISK
sasprt.ps
mod  LaserJet 5         PCL 5 (DeltaRow)                 DISK
sasprt.pcl
del  Gray Postscript    PostScript Level 1 (Gray Scale)  DISK
sasprt.ps
del  test               PostScript Level 2 (Color)       DISK
sasprt.ps
add  ColorPS            PostScript Level 2 (Color)       DISK
sasprt.ps
;

proc prtdef data=printers replace list;
run;
```

Program Description

Create the PRINTERS data set and specify which actions to perform on the printer definitions. The PRINTERS data set contains the variables whose values contain the information that is needed to produce the printer definitions. The MODEL variable specifies the printer prototype to use when defining this printer. The DEVICE variable specifies the type of I/O device to use when sending output to the printer. The DEST variable specifies the output destination for the printer. The OPCODE variable specifies which action (add, delete, or modify) to perform on the printer definition. The first Add operation creates a new printer definition for Color PostScript in the SAS registry. The second Add operation creates a new printer definition for ColorPS in the SAS registry. The Mod operation modifies the existing printer definition for LaserJet 5 in the registry. The Del operation deletes the printer definitions for test from the registry. The **&** specifies that two or more blanks separate character values. This allows the name and model value to contain blanks.

```
data printers;
length name   $ 80
   model  $ 80
   device $ 8
   dest   $ 80
   opcode $ 3
   ;
input opcode $& name $& model $& device $& dest $&;
datalines;
add  Color PostScript   PostScript Level 2 (Color)       DISK
sasprt.ps
mod  LaserJet 5         PCL 5 (DeltaRow)                 DISK
sasprt.pcl
del  Gray Postscript    PostScript Level 1 (Gray Scale)  DISK
sasprt.ps
del  test               PostScript Level 2 (Color)       DISK
sasprt.ps
add  ColorPS            PostScript Level 2 (Color)       DISK
sasprt.ps
;
```

Create multiple printer definitions and write them to the SAS log. The DATA= option specifies the input data set PRINTERS that contains the printer attributes. PROC PRTDEF creates five printer definitions, two of which have been deleted. The LIST option specifies that a list of printers that are created or replaced will be written to the log.

```
proc prtdef data=printers replace list;
run;
```

Log

Example Code 52.3 *The SAS Log After Modifying and Deleting Printers*

```
15   data printers;
16   length name   $ 80
17      model  $ 80
18      device $ 8
19      dest   $ 80
20      opcode $ 3
21      ;
22   input opcode $& name $& model $& device $& dest $&;
23   datalines;

NOTE: The data set WORK.PRINTERS has 5 observations and 5 variables.
NOTE: DATA statement used (Total process time):
      real time           0.01 seconds
      cpu time            0.01 seconds

29   ;
30   proc prtdef data=printers list replace;
31   run;

NOTE: Printer Color PostScript modified.
NOTE: Printer LaserJet 5 modified.
NOTE: Printer Gray Postscript deleted.
NOTE: Printer test deleted.
NOTE: Printer ColorPS modified.
NOTE: PROCEDURE PRTDEF used (Total process time):
      real time           0.04 seconds
      cpu time            0.03 seconds
```

Example 5: Deleting a Single Printer Definition

Features: PROC PRTDEF statement option
DELETE

Details

This example shows you how to delete a printer from the registry.

Program

```
data deleteprt;
name='printer1';
run;

proc prtdef data=deleteprt delete list;
run;
```

Program Description

Create the DELETEPRT data set. The NAME variable contains the name of the printer to delete.

```
data deleteprt;
name='printer1';
run;
```

Delete the printer definition from the registry and write the deleted printer to the log. The DATA= option specifies DELETEPRT as the input data set. PROC PRTDEF creates printer definitions for the SAS registry. DELETE specifies that the printer is to be deleted. LIST specifies to write the deleted printer to the log.

```
proc prtdef data=deleteprt delete list;
run;
```

Log

Example Code 52.4 *The SAS Log After Deleting a Single Printer*

```
45   data deleteprt;
46      name='printer1';
47      run;

NOTE: The data set WORK.DELETEPRT has 1 observations and 1 variables.
NOTE: DATA statement used (Total process time):
      real time           0.01 seconds
      cpu time            0.00 seconds

48      proc prtdef data=deleteprt delete list;
49      run;

NOTE: Printer printer1 deleted.
NOTE: 0 printer definitions added to the registry.
NOTE: 0 printer definitions modified in the registry.
NOTE: 1 printer definitions deleted from the registry.
NOTE: PROCEDURE PRTDEF used (Total process time):
      real time           0.00 seconds
      cpu time            0.00 seconds
```

53

PRTEXP Procedure

Overview: PRTEXP Procedure

What Does the PRTEXP Procedure Do?

The PRTEXP procedure enables you to replicate, modify, and create printer definitions from the SAS registry, either for an individual user or for all SAS users at your site. PROC PRTEXP then writes these attributes to the SAS log or to a SAS data set. You can specify that PROC PRTEXP search for these attributes in the SASHELP portion of the registry or the entire SAS registry.

If you write printer definitions to a SAS data set, you can later replicate and modify them. You can then use PROC PRTDEF to create the printer definitions in the SAS registry from your input data set. For a complete discussion of PROC PRTDEF and the variables and attributes that are used to create the printer definitions, see "Input Data Set Variables That Are Used To Create Printer Definitions" on page 1916.

See Also

Chapter 52, "PRTDEF Procedure," on page 1913

Syntax: PRTEXP Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Tip: If neither the SELECT nor the EXCLUDE statement is used, then all of the printers will be included in the output.

PROC PRTEXP <*options*>;

SELECT *printer(s)*;

EXCLUDE *printer(s)*

Statement	Task	Example
PROC PRTEXP	Obtain printer attributes from the SAS registry	Ex. 1, Ex. 2
EXCLUDE	Obtain printer attributes for all printers except for the specified printers	
SELECT	Obtain printer attributes for the specified printers	Ex. 1, Ex. 2

PROC PRTEXP Statement

Replicates, modifies, and creates printer definitions.

Examples: "Example 1: Writing Attributes to the SAS Log" on page 1936
"Example 2: Writing Attributes to a SAS Data Set" on page 1937

Syntax

PROC PRTEXP <*options*>;

Optional Arguments

USESASHELP
specifies that SAS search only the SASHELP portion of the registry for printer definitions.

Default The default is to search both the SASUSER and SASHELP portions of the registry for printer definitions.

OUT=*SAS-data-set*
specifies the SAS data set that contains the printer definitions.

The data set that is specified by the OUT=*SAS-data-set* option is the same type of data set that is specified by the DATA=*SAS-data-set* option in PROC PRTDEF to define each printer.

Default If OUT=*SAS-data-set* is not specified, then the data that is needed to define each printer is written to the SAS log.

EXCLUDE Statement

Names the printers whose information does not appear in output.

Syntax

EXCLUDE *printer(s)*;

Required Argument

printer(s)
specifies one or more printers that you do not want the output to contain information about.

SELECT Statement

Names the printers whose information is contained in the output.

Examples: "Example 1: Writing Attributes to the SAS Log" on page 1936
"Example 2: Writing Attributes to a SAS Data Set" on page 1937

Syntax

SELECT *printer(s)*;

Required Argument

printer(s)
specifies one or more printers that you would like the output to contain information about.

Examples: PRTEXP Procedure

Example 1: Writing Attributes to the SAS Log

Features: PROC PRTEXP statement option
USESASHELP
SELECT statement

Details

This example shows you how to write the attributes that are used to define a printer to the SAS log.

Program

Specify the printer that you want information about, specify that only the SASHELP portion of the registry be searched, and write the information to the SAS log. The SELECT statement specifies that you want the attribute information that is used to define the printer PostScript to be included in the output. The USESASHELP option specifies that only the SASHELP registry is to be searched for PostScript's printer definitions. The data that is needed to define each printer is written to the SAS log because the OUT= option was not used to specify a SAS data set.

```
proc prtexp usesashelp;
select postscript;
run;
```

Log

Example Code 53.1 *The SAS Log After Extracting Printer Information from the SASHELP Portion of the Registry*

```
379  proc prtexp usesashelp;
380  select postscript;
381  run;

NAME:     PostScript
MODEL:    PostScript Level 1 (Color)
DEVICE:   DISK
DEST:     sasprt.ps
HOSTOPT:
PROTOCOL:
TRANTAB:
DESC:     Generic PostScript Level 1 Printer
PREVIEW:  Adobe Reader
VIEWER:
PAPERSIZ:
PAPERTYP:
PAPERIN:
PAPEROUT:
RES:      300 DPI
TOP:      0.50
LEFT:     0.50
RIGHT:    0.50
BOTTOM:   0.50
UNITS:    IN
TYPEFACE: <MTmonospace>
WEIGHT:   Normal
STYLE:    Regular
CHARSET:  Western
FONTSIZE: 8.00
LRECL:    .
```

Example 2: Writing Attributes to a SAS Data Set

Features: PROC PRTEXP statement option
OUT=
SELECT statement

Details

This example shows you how to create a SAS data set that contains the data that PROC PRTDEF would use to define the printers PCL4, PCL5, PCL5E, and PCLC.

Program

Specify the printers that you want information about and create the PRDVTER data set. The SELECT statement specifies the printers PCL4, PCL5, PCL5E, and PCLC. The OUT= option creates the SAS data set PRDVTER, which contains the same attributes that are used by PROC PRTDEF to define the printers PCL4, PCL5, PCL5E, and PCLC. SAS will search both the SASUSER and SASHELP registries, because USESASHELP was not specified.

```
proc prtexp out=PRDVTER;
   select pcl4 pcl5 pcl5e pcl5c;
run;

proc print data=prdvter;
run;
```

Output

The following data set is a partial view of the Prdvter data set that contains 26 variables and four observations.

Output 53.1 *The Output Data Set for Prdvter*

The SAS System

Obs	DEST	HOSTOPT	DESC	VIEWER	NAME	MODEL	PREVIEW	TYPEFACE
1	sasprt.pcl		Generic PCL 4 Printer		PCL4	PCL 4	Adobe Reader	
2	sasprt.pcl		Generic PCL 5 Printer		PCL5	PCL 5 (DeltaRow)	Adobe Reader	
3	sasprt.pcl		Generic PCL 5 RGB Color Printer with Alpha Blending		PCL5c	PCL 5rgba (DeltaRow)	Adobe Reader	
4	sasprt.pcl		Generic PCL 5e Printer		PCL5e	PCL 5e (DeltaRow)	Adobe Reader	

54

PWENCODE Procedure

Overview: PWENCODE Procedure

What Does the PWENCODE Procedure Do?

The PWENCODE procedure enables you to encode passwords. Encoding obfuscates the data. Unlike encryption, encoding is a reversible permutation of the data and uses no keys.

Encoded passwords can be used in place of plaintext passwords in SAS programs that access relational database management systems (RDBMSs) and various servers. Examples are SAS/CONNECT servers, SAS/SHARE servers, SAS Integrated Object Model (IOM) servers, SAS Metadata Servers, and more.

Concepts: PWENCODE Procedure

Using Encoded Passwords in SAS Programs

When a password is encoded with PROC PWENCODE, the output string includes a tag that identifies the string as having been encoded. An example of a tag is `{sas001}`. The tag indicates the encoding method. SAS servers and SAS/ACCESS engines recognize the tag and decode the string before using it. Encoding a password enables you to write SAS programs without having to specify a password in plaintext.

Note: PROC PWENCODE passwords can contain up to a maximum of 512 characters, which include alphanumeric characters, spaces, and special characters. Data set passwords, however, must follow SAS naming rules. For information about SAS naming rules, see "Rules for Most SAS Names" in *SAS Language Reference: Concepts*.

The encoded password is never written to the SAS log in plain text. Instead, each character of the password is replaced by an X in the SAS log.

Encoding versus Encryption

Encoding techniques disguise passwords and the approach is intended to prevent casual, non-malicious viewing of passwords. With encoding, one character set is translated to another character set through some form of table lookup.

Encryption, by contrast, involves the transformation of data from one form to another through the use of mathematical operations and, usually, a "key" value. Encryption is generally more difficult to break than encoding. Several options for PROC PWENCODE designate encryption techniques that align with industry standards. These options support longer encryption keys (for example, 256-bit). Salting and multiple iterations are provided to the AES encryption algorithm to create passwords that are harder to break.

Encoding methods for PROC PWENCODE are now SAS001 – SAS005. Starting in SAS 9.4M5, PROC PWENCODE provides stronger password protection using the SAS005 method of encoding.

Password protection is an important part of your security strategy, but you should not rely only on password protection for all your data security needs; a determined

and knowledgeable attacker can break passwords. Data should also be protected by other security controls such as file system permissions, other access control mechanisms, and encryption of data at rest and in transit.

Encoding Methods

Starting in SAS 9.4M5,the SAS005 method for encoding passwords is added. When SAS005 is specified for PROC PWENCODE, a more secure 256-bit fixed key is generated. SAS005, like SAS004, uses a 256-bit fixed key plus a 64-bit random salt. However, it is hashed for additional iterations.

Table 54.1 *Supported Encoding Methods*

Encoding Method	Uses Data Encryption Algorithm	Encoded Password/key Description
`sas001`	None	Uses base64 to encode passwords.
`sas002`, which can also be specified as `sasenc`	SASProprietary, which is included in SAS software.	Uses a 32-bit fixed key.
`sas003`	AES (Advanced Encryption Standard).	Uses a 256-bit fixed key plus a 16-bit random salt value.
`sas004`	AES (Advanced Encryption Standard).	Uses a 256-bit fixed key and a 64-bit random salt value.
`sas005`	AES (Advanced Encryption Standard).	Uses a 256-bit fixed key, a 64-bit random salt value, and is hashed for additional iterations.

IMPORTANT Starting with SAS 9.4M8, SAS Foundation servers use the cryptographic libraries provided and installed on the operating system to provide encryption for data at rest and data in motion. With this change, SAS no longer provides the cryptographic libraries for SAS Foundation servers as part of the SAS Installation. AES encryption is supported using the operating system cryptographic libraries. Prior to SAS 9.4M8, AES encryption was supported as part of SAS/SECURE.

For more information, see "Cryptographic Library Support Starting with SAS 9.4M8" in *Encryption in SAS*.

Note: The METHOD= option supports the SAS003, SAS004, and SAS005 values. Prior to SAS 9.4M8, you needed SAS/SECURE to support SAS003–SAS005. With SAS 9.4M8, SAS003-SAS005 are supported using the operating system's cryptopgraphic libraries. SAS Proprietary encoding that supports SAS002 is available with all SAS software. For more information, see SAS/SECURE.

Syntax: PWENCODE Procedure

PROC PWENCODE IN='*password*' <OUT=*fileref*> <METHOD=*encoding-method*>;

Statement	Task	Example
PROC PWENCODE	Encode a password	Ex. 1, Ex. 2, Ex. 3, Ex. 4

PROC PWENCODE Statement

Encodes a password.

Examples:

"Example 1: Encoding a Password" on page 1944
"Example 2: Using an Encoded Password in a SAS Program" on page 1945
"Example 3: Saving an Encoded Password to the Paste Buffer" on page 1947
"Example 4: Specifying Method= SAS003 to Encode a Password" on page 1948
"Example 5: Specifying Method= SAS005 to Encode a Password" on page 1949

Syntax

PROC PWENCODE IN='*password*' <OUT=*fileref*> <METHOD=*encoding-method*>;

Required Argument

IN='*password*'
specifies the password to encode. The password can contain up to a maximum of 512 characters, which include alphanumeric characters, spaces, and special characters.

Note: Data set passwords must follow SAS naming rules. If the IN=*password* follows SAS naming rules, it can also be used for SAS data sets. For information

about SAS naming rules, see "Rules for Most SAS Names" in *SAS Language Reference: Concepts*.

If the password contains embedded single or double quotation marks, use the standard SAS rules for quoting character constants. These rules can be found in the SAS Constants in Expressions chapter of *SAS Language Reference: Concepts*.

Note: Each character of the encoded password is replaced by an X when written to the SAS log.

See "Example 1: Encoding a Password" on page 1944

"Example 2: Using an Encoded Password in a SAS Program" on page 1945

"Example 3: Saving an Encoded Password to the Paste Buffer" on page 1947

Optional Arguments

OUT=*fileref*

specifies a fileref to which the output string is to be written. If the OUT= option is not specified, the output string is written to the SAS log.

Note: The global macro variable

```
_PWENCODE
```

is set to the value that is written to the OUT= fileref or to the value that is displayed in the SAS log.

See "Example 2: Using an Encoded Password in a SAS Program" on page 1945

METHOD=*encoding-method*

specifies the encoding method. Here are the supported values for *encoding-method*.

- *SAS001*
- *SAS002*
- *SAS003*
- *SAS004*
- *SAS005*

The SAS003, SAS004, and SAS005 encoded passwords use a 256-bit fixed key plus a random salt value that is applied to the encoding method. Therefore, each time you use PROC PWENCODE to encode the same password, you get a different encoded password, because the salt values are random.

For more information about each of these encoding methods, see "Encoding Methods " on page 1941.

Note: The METHOD= option supports the SAS003, SAS004, and SAS005 values. Prior to SAS 9.4M8, you needed SAS/SECURE to provide support of SAS003-SAS005 encoding methogs. With SAS 9.4M8, SAS003-SAS005 are supported using the operating system's cryptopgraphic libraries. SAS Proprietary encoding that supports SAS002 is available with all SAS software. For more information, see SAS/SECURE.

If the METHOD= option is omitted, the default encoding method is used. The default method is **sas002** in most cases. **SAS002** is also the default method used if you specify an invalid method.

When the FIPS 140-2 compliance option, -encryptfips, is specified, the encoding method defaults to **sas003**. For more information about FIPS, see "FIPS 140-2 Standards Compliance" in *Encryption in SAS*.

Examples: PWENCODE Procedure

Example 1: Encoding a Password

Features: IN= argument

Details

This example shows a simple case of encoding a password and writing the encoded password to the SAS log.

Program

Encode the password.

```
proc pwencode in='my password';
run;
```

Log

Note that each character of the password is replaced by an X in the SAS log.

```
19   proc pwencode in=XXXXXXXXXXXXX;
20   run;

{SAS002}DBCC571245AD0B31433834F80BD2B99E16B3C969

NOTE: PROCEDURE PWENCODE used (Total process time):
      real time           0.01 seconds
      cpu time            0.01 seconds
```

Example 2: Using an Encoded Password in a SAS Program

Features: IN= argument
OUT= option

Details

This example illustrates the following:

- encoding a password and saving it to an external file
- reading the encoded password with a DATA step, storing it in a macro variable, and using it in a SAS/ACCESS LIBNAME statement

Program 1: Encoding the Password

```
filename pwfile
'external-filename';

proc pwencode in='mypass1' out=pwfile;
run;
```

Program Description

Declare a fileref.

```
filename pwfile
'external-filename';
```

Encode the password and write it to the external file. The OUT= option specifies which external fileref the encoded password is written to.

```
proc pwencode in='mypass1' out=pwfile;
run;
```

Program 2: Using the Encoded Password

```
filename pwfile
'external-filename';

options symbolgen;

data _null_;
infile pwfile truncover;
input line :$50.;
call symputx('dbpass',line);
run;

libname x odbc dsn=SQLServer user=testuser password="&dbpass";
```

Program Description

Declare a fileref for the encoded-password file.

```
filename pwfile
'external-filename';
```

Set the SYMBOLGEN SAS system option. This step shows that the actual password cannot be revealed, even when the macro variable that contains the encoded password is resolved in the SAS log. This step is not required in order for the program to work properly.

```
options symbolgen;
```

Read the file and store the encoded password in a macro variable. The DATA step stores the encoded password in the macro variable DBPASS.

```
data _null_;
infile pwfile truncover;
input line :$50.;
call symputx('dbpass',line);
run;
```

Use the encoded password to access a DBMS. You must use double quotation marks (“ ”) so that the macro variable resolves properly.

```
libname x odbc dsn=SQLServer user=testuser password="&dbpass";
```

Log

```
1    filename pwfile 'external-filename';
2    options symbolgen;
3    data _null_;
4    infile pwfile truncover;
5    input line :$50.;
6    call symputx('dbpass',line);
7    run;

NOTE: The infile PWFILE is:
      Filename=external-filename
      RECFM=V,LRECL=256,File Size (bytes)=4,
      Last Modified=12Apr2012:13:23:49,
      Create Time=12Apr2012:13:23:39

NOTE: 1 record was read from the infile PWFILE.
      The minimum record length was 4.
      The maximum record length was 4.
NOTE: DATA statement used (Total process time):
      real time           0.57 seconds
      cpu time            0.04 seconds
8
9   libname x odbc
SYMBOLGEN:  Macro variable DBPASS resolves to {sas002}bXlwYXNzMQ==
9 !               dsn=SQLServer user=testuser password="&dbpass";
NOTE: Libref X was successfully assigned as follows:
      Engine:        ODBC
      Physical Name: SQLServer
```

Example 3: Saving an Encoded Password to the Paste Buffer

Features:

IN= argument

OUT= option

FILENAME statement with CLIPBRD access method

DETAILS

This example saves an encoded password to the paste buffer. You can then paste the encoded password into another SAS program or into the password field of an authentication dialog box.

Program

```
filename clip clipbrd;

proc pwencode in='my password' out=clip;
run;
```

Program Description

Declare a fileref with the CLIPBRD access method.

```
filename clip clipbrd;
```

Encode the password and save it to the paste buffer. The OUT= option saves the encoded password to the fileref that was declared in the previous statement.

```
proc pwencode in='my password' out=clip;
run;
```

Log

Note that each character of the password is replaced by an X in the SAS log.

```
24
25   filename clip clipbrd;
26     proc pwencode in=XXXXXXXXXXXXX out=clip;
27   run;

NOTE: PROCEDURE PWENCODE used (Total process time):
      real time           0.00 seconds
      cpu time            0.00 seconds
```

Example 4: Specifying Method= SAS003 to Encode a Password

Features: METHOD= argument

Details

This example shows a simple case of encoding a password using the **sas003** encoding method and writing the encoded password to the SAS log. SAS003 uses a 16-bit salt to encode a password.

Program

Encode the password using SAS003. The encoded password is a 256-bit key with a 16 bit random salt.

```
proc pwencode in='mypassword' method=sas003;
run;
```

Log

Note that each character of the password is replaced by an X in the SAS log. SAS003 encoding uses AES encryption plus a 16-bit salt. Because SAS003 uses random salting, each time you run the following code, a different password is generated.

```
8   proc pwencode in=XXXXXXXXXXXXX method=sas003;
29   run;

{SAS003}4837B146585CED2C9FED14A3C946D68E4389

NOTE: PROCEDURE PWENCODE used (Total process time):
      real time           0.00 seconds
      cpu time            0.00 seconds
```

Example 5: Specifying Method= SAS005 to Encode a Password

Features: METHOD= argument

Details

This example shows a simple case of encoding a password using the **sas005** encoding method and writing the encoded password to the SAS log. SAS005 uses a 256-bit fixed key that uses a 64-bit random salt to encode the password.

Program

Encode the password using SAS005.

```
proc pwencode in='mypassword' method=sas005;
run;
```

Log

Note that each character of the password is replaced by an X in the SAS log. SAS005 encoding uses AES encryption with a 256-bit fixed key and a 64-bit random salt value. SAS005 increases security for stored passwords by using the SHA-256 hashing algorithm and is hashed for additional iterations. Because SAS005 uses random salting, each time you run the following code, a different password is generated.

```
230  proc pwencode in=XXXXXXXXXXXX method=sas005;
231  run;

{SAS005}ADD8AB7108595A7D1A69190D78CDFE6145C1EB849CC7A43D

NOTE: PROCEDURE PWENCODE used (Total process time):
      real time           0.01 seconds
      cpu time            0.01 seconds
```

55

QDEVICE Procedure

Overview: QDEVICE Procedure

What Does the QDEVICE Procedure Do?

The QDEVICE procedure produces reports about graphics devices and universal printers. You can use the information in these reports to determine the best device or printer to use for a specific application.

Six different reports are available. These reports summarize information such as color support, default output sizes, margin sizes, resolution, supported fonts, hardware symbols, hardware fill types, hardware line styles, and device options.

You can send the output of this procedure to the SAS log or to an output SAS data set.

Concepts: QDEVICE Procedure

Reports for Windows Operating Environments

By default, SAS starts on Windows using the NOUNIVERSALPRINT (NOUPRINT) system option in order to use Windows printing. The SYSPRINT= system option determines the default Windows printer. Because printers on Windows are associated with a SAS printer interface device, reports that you create for the default Windows printer have a device name of one of the following SAS printer interface devices:

- WINPRTC (color)
- WINPRTG (gray scale)
- WINPRTM (monochrome)

If SAS starts with Universal Printing active on Windows, the default printer report is for the default SAS universal printer and not a Windows printer.

See "Example 4: Generate a Report for the Default Printer" on page 1989 for example reports.

Syntax: QDEVICE Procedure

Default: If you do not specify a report to create, a printer, or a device, the procedure generates a GENERAL report for the default display device if you are running SAS using the windowing environment, or the default universal printer in other modes.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Note: You can specify more than one DEVICE, PRINTER, or VAR statement. Statements are processed in the order in which they are specified.

PROC QDEVICE
<REPORT=GENERAL | FONT | DEVOPTION | LINESTYLE | RECTANGLE | SYMBOL>
<OUT=*SAS-data-set*>
<CATALOG=*catalog-name*>
<DEVLOC=GDEVICE*n* | SASHELP | _ALL_ | *libref*>
<REGISTRY=SASHELP | SASUSER>
<SUPPORT=YES | NO | ALL>
<UNITS=IN | CM;>

DEVICE <*device-name(s)*> <_ALL_> <_HTML_> <_LISTING_> <_RTF_>;

PRINTER <*printer-name(s)*> <_ALL_> <_PCL_> <_PDF_> <_PRINTER_> <_PS_>;

VAR *variable-1* <*variable-2* ...>;

Statement	Task	Example
PROC QDEVICE	Specify an (optional) output data set, which report to generate, which locations to search, whether to list supported or non-supported features, and sizing information	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7
DEVICE	Specify which SAS/GRAPH devices to generate a report for	Ex. 2, Ex. 7
PRINTER	Specify which universal printers to generate a report for	Ex. 6, Ex. 3
VAR	Specify the information (variables) to include in the generated reports	Ex. 5

PROC QDEVICE Statement

Controls the input data that is examined, the contents of a report, and the type of output to create.

Syntax

PROC QDEVICE
<REPORT=GENERAL | FONT | DEVOPTION | LINESTYLE | RECTANGLE | SYMBOL>
<OUT=*SAS-data-set*>
<CATALOG=*catalog-name*>
<DEVLOC=GDEVICE*n* | SASHELP | _ALL_ | *libref*>
<REGISTRY=SASHELP | SASUSER>
<SUPPORT=YES | NO | ALL>
<UNITS=IN | CM>;

Summary of Optional Arguments

CATALOG=*catalog-name*
: specifies the name of a SAS device catalog to search for a device.

DEVLOC=GDEVICE*n* | SASHELP | _ALL_ | *libref*
: specifies the library or libraries where the device catalog is located.

OUT=*SAS-data-set*
: specifies an output SAS data set for the report.

REGISTRY=SASHELP | SASUSER
: specifies which section of the SAS registry to search when querying a universal printer.

REPORT=DEVOPTION | FONT | GENERAL | LINESTYLE | RECTANGLE | SYMBOL
: specifies the type of report that you want to generate.

SUPPORT=YES | NO | ALL
: specifies whether to report only supported features, only unsupported features, or all features.

UNITS=IN | CM
: specifies whether the values for the certain variables are reported in inches (IN) or centimeters (CM) in the GENERAL report.

Optional Arguments

CATALOG=*catalog-name*
specifies the name of a SAS device catalog to search for a device.

Aliases
: C=
: CAT=

Default
: DEVICES

Interaction
: The CATALOG= option works with the DEVLOC= option. When you specify the CATALOG= option, SAS looks in the library that is specified by the DEVLOC= option (for example, sashelp.mycatalog).

Example "Example 7: Specify a User Library and Catalog for a Report" on page 1997

DEVLOC=GDEVICE*n* | SASHELP | _ALL_ | *libref*
specifies the library or libraries where the device catalog is located. You can specify these libraries:

GDEVICE*n*
specifies to search one of the SAS/GRAPH device libraries for a device. *n* can be 0–9.

SASHELP
specifies to search the Sashelp library for a device.

ALL
specifies to search the libraries Gdevice0 – Gdevice9 and the Sashelp library, in this order, for a device. All occurrences of a device from any of these libraries are reported.

libref
specifies a valid SAS library to search.

Defaults If you do not specify the DEVLOC= option, libraries are searched in the following order:

1. Gdevice0–Gdevice9
2. Sashelp

The first occurrence of the specified device is reported unless you specify DEVLOC=_ALL_.

Interaction The DEVLOC= option works with the CATALOG= option. When you specify the CATALOG= option, SAS looks in the library that is specified by the DEVLOC= option (for example, sashelp.mycatalog).

Example "Example 7: Specify a User Library and Catalog for a Report" on page 1997

OUT=*SAS-data-set*
specifies an output SAS data set for the report.

Default SAS Log

REGISTRY=SASHELP | SASUSER
specifies which section of the SAS registry to search when querying a universal printer.

SASHELP
search the SASHELP section of the registry.

SASUSER
search the SASUSER section of the registry.

Alias REG

Default SASHELP and SASUSER

REPORT=DEVOPTION | FONT | GENERAL | LINESTYLE | RECTANGLE | SYMBOL
specifies the type of report that you want to generate. You can request only one type of report. See "Valid Variables for All Reports" on page 1960 for the descriptions of the variables that are included in each report.

DEVOPTION
produces a report of the hardware device options supported by the specified device.

Restriction This report is unavailable for universal printers.

FONT
produces a report of all system and device-resident fonts supported by the specified device or printer.

See See "SAS/GRAPH, System, and Device-Resident Fonts" in *SAS/GRAPH: Reference* for a description of font categories.

GENERAL
produces a report of general information about the specified device or printer. This report includes information such as destination, margin sizes, default font information, resolution, color information, and size by pixels. This is the default report.

LINESTYLE
produces a report of the hardware line styles supported by the specified device.

Restriction This report is unavailable for universal printers.

RECTANGLE
produces a report of the hardware fill types supported by the specified device.

Restriction This report is unavailable for universal printers.

SYMBOL
produces a report of the hardware symbols supported by the specified device.

Restriction This report is unavailable for universal printers.

Default GENERAL

See See "Valid Variables for All Reports" on page 1960 for the descriptions of the variables that are included in each report.

SUPPORT=YES | NO | ALL
specifies whether to report only supported features, only unsupported features, or all features.

YES
reports only hardware features and options that are supported.

NO
reports only the hardware features and options that are not supported.

ALL
reports both supported and unsupported hardware features and options.

Default YES

Restriction This option applies only to devices when producing a DEVOPTION, LINESTYLE, RECTANGLE, or SYMBOL report.

UNITS=IN | CM
specifies whether the values for the certain variables are reported in inches (IN) or centimeters (CM) in the GENERAL report.

The HEIGHT, WIDTH, LEFT, LMIN, RIGHT, RMIN, BOTTOM, BMIN, TOP, TMIN, HRES, and VRES variables are reported in inches or centimeters. HRES and VRES values are reported as pixels-per-inch or pixels-per-centimeter.

Default IN

Restriction This option applies only when producing a GENERAL report.

DEVICE Statement

Specifies which SAS/GRAPH devices to generate a report for.

Requirement: You must specify at least one device name, _ALL_, _HTML_, _LISTING_, or _RTF_.

Syntax

DEVICE *<device-name(s)>* <_ALL_> <_HTML_> <_LISTING_> <_RTF_>;

Optional Arguments

device-name(s)
specifies the device for which you want to generate a report. Separate device names with a blank space. Enclose device names that contain spaces in quotation marks. You can use the wildcard characters * and ? to report all devices with similar names.

*
* represents any number of characters in that position of the device name.

Requirement Device names that contain wildcard characters must be enclosed in quotation marks.

Note You can specify the * and ? wildcard characters in the same device name.

Example 'svg*'

Example "Example 3: Generate a Report for SAS/GRAPH Device Drivers and Universal Printers" on page 1988

?

? represents one character in the device name. You can specify multiple consecutive ? characters in the device name.

Requirement Device names that contain wildcard characters must be enclosed in quotation marks.

Note You can specify the * and ? wildcard characters in the same device name.

Example 'tiff?300'

ALL
generates reports for all devices.

HTML
determines the default device that is used by the ODS HTML destination and generates a report for that device. The device is based on the default HTML version that is assigned in the ODS key of the SAS registry.

LISTING
determines the default device that is used by the ODS Listing destination and generates a report for that device. The default value is a host–specific display device.

RTF
determines the default device that is used by the ODS RTF destination and generates a report for that device.

PRINTER Statement

Specifies which universal printers to generate a report for.

Requirement: You must specify at least one printer name, _ALL_, _PCL_, _PDF_, _PRINTER_, or _PS_.

Syntax

PRINTER <*printer-name(s)*> <_ALL_> <_PCL_> <_PDF_> <_PRINTER_> <_PS_>;

Optional Arguments

printer-name(s)
specifies the universal printers for which you want to generate a report. If the printer name contains spaces, enclose the printer name in quotation marks.

Separate printer names with a blank space. You can use the wildcard characters * and ? to report all printers with similar names.

*
indicates to report all printers that match any number of characters in the position of the * in the printer name.

Requirement Printer names that contain wildcard characters must be enclosed in quotation marks.

Note You can specify the * and ? wildcard characters in the same printer name.

Example 'pcl*' reports on the printers pcl4, pcl5, pcl5c, and pcl5e

?
indicates to report all printers that match the printer name, where the character in the ? position can be any character. You can use multiple ? characters in *printer-name* to represent the same number of characters in the same position in the printer name.

Requirement Printer names that contain wildcard characters must be enclosed in quotation marks.

Note You can specify the * and ? wildcard characters in the same printer name.

Example 'tiff?' reports on the printers tiffa and tiffk. It does not report on the printer tiff because the tiff printer is only four characters.

Example "Example 3: Generate a Report for SAS/GRAPH Device Drivers and Universal Printers" on page 1988

ALL
generates reports for all universal printers.

PCL
determines the default printer that is used by the ODS PCL destination and generates a report for that printer.

PDF
determines the default printer that is used by the ODS PDF destination and generates a report for that printer.

PRINTER
determines the default printer that is used by the ODS PRINTER destination and generates a report for that printer.

Windows specifics By default, SAS uses Windows printing and not Universal Printing. When SAS uses Windows printing, the report that is generated when you specify the _PRINTER_ argument has information for the SAS printer interface device that is associated with the default Windows printer. The default Windows printer is specified by the SYSPRINT= system option. The SAS printer interface devices are WINPRTC (color), WINPRTG (gray scale), or WINPRTM (monochrome). The

report displays the printer interface device in the **Name** field and the printer name in the **Description** field.

_PS_
determines the default printer that is used by the ODS PS destination and generates a report for that printer.

VAR Statement

Specifies which variables to include in a report. The order of the variables in the report is determined by the order in which they are specified in the VAR statement.

Default: If you do not specify a VAR statement, all of the variables for the report are included in a default order.

Tip: If you specify the VAR statement, you must specify at least one variable. Otherwise, the statement is ignored.

Syntax

VAR *variable-1* <*variable-2* ...>;

Valid Variables for All Reports

DESC
displays the default description of the device or printer.

LOCATION
for the device entry that was found, displays the physical location of the Gdevice0-Gdevice9 library, the Sashelp library, or the library that is specified by the DEVLOC= option. For universal printers, this variable displays the SAS registry (SASHELP or SASUSER) where the printer was found.

NAME
displays the name of the device or printer.

TYPE
displays the type of device or printer. Here are the types of devices and printers:

- Graph Device
- Printer Interface Device
- Shortcut Device
- System Display
- System Metafile
- Universal Previewer
- Universal Printer

See "Device Categories and Modifying Default Output Attributes" in *SAS/GRAPH: Reference*

DEVOPTION Report Variables

For more information, see "Create a DEVOPTION Report" on page 1977.

BIT
displays the bit position in the DEVOPTS string for the corresponding device option.

See "DEVOPTS Device Parameter" in *SAS/GRAPH: Reference*

BITSTRING
displays the bit pattern of the corresponding device option.

See "DEVOPTS Device Parameter" in *SAS/GRAPH: Reference*

DESC
displays the default description of the device or printer.

LOCATION
for the device entry that was found, displays the physical location of the Gdevice0-Gdevice9 library, the Sashelp library, or the library that is specified by the DEVLOC= option.

NAME
displays the name of the device or printer.

ODESC
displays the descriptions of the hardware options in effect for the device.

OPTION
displays the names of the hardware options in effect for the device.

SUPPORT
displays the device options.

Interaction The value of the SUPPORT variable is affected by the SUPPORT= option in the PROC QDEVICE statement. If SUPPORT=YES, the report shows the supported device options. If SUPPORT=NO, the report shows device options that are not supported. If SUPPORT=ALL, the report shows all supported and non-supported device options.

TYPE
displays the type of device or printer.

Here are the types of devices and printers:

- Graph Device
- Printer Interface Device
- Shortcut Device
- System Display

- System Metafile

See "Device Categories and Modifying Default Output Attributes" in *SAS/GRAPH: Reference*

FONT Report Variables

For more information, see "Create a FONT Report" on page 1975.

ALIAS
reports an alternate name for a font that is registered by the FONTREG procedure.

DESC
displays the default description of the device or printer.

FONT
displays the name of the default font.

See "Default Fonts" in *SAS/GRAPH: Reference*

"Variable Labels in a FONT Report" on page 1976

FSTYLE
displays the font style, such as Roman or Italic, for each font and font weight, in an output data set.

Restriction When the report output is directed to the SAS log, the FONT report displays only font family names, such as Courier, Helvetica, Times, and so on. The specific font style is not reported.

Note If the font name is acquired from a CHARREC list in a device entry, the style is not available. See "CHARREC Device Parameter" in *SAS/GRAPH: Reference* for more information.

See "Variable Labels in a FONT Report" on page 1976

FTYPE
displays the type of font, such as Printer Resident, System, or Software.

Note The values for the FTYPE variable in the output data set are Printer Resident, System, or Software. The value Software appears only in a FONT report for a SAS/GRAPH device that has hardware font support disabled.

FWEIGHT
displays the font weight, such as Normal or Bold, for each font and font style, in an output data set.

Restriction When the report output is directed to the SAS log, the FONT report displays only font family names, such as Courier, Helvetica, Times, and so on. The specific font weight is not reported.

Note If the font name is acquired from a CHARREC list in a device entry, the weight is not available. See "CHARREC Device Parameter" in *SAS/GRAPH: Reference* for more information.

FVERSION
specifies the font version.

Restriction When the report output is directed to the SAS log, the FONT report displays only font family names, such as Courier, Helvetica, Times, and so on. The specific font version is not reported.

LOCATION
for the device entry that was found, displays the physical location of the Gdevice0-Gdevice9 library, the Sashelp library, or the library that is specified by the DEVLOC= option. For universal printers, this variable displays the SAS registry (SASHELP or SASUSER) where the printer was found.

NAME
displays the name of the device or printer.

TYPE
displays the type of device or printer. Here are the types of devices and printers:

- Graph Device
- Printer Interface Device
- Shortcut Device
- System Display
- System Metafile
- Universal Previewer
- Universal Printer

See "Device Categories and Modifying Default Output Attributes" in *SAS/GRAPH: Reference*

GENERAL Report Variables

For more information, see "Create a GENERAL Report" on page 1972.

ALIAS
reports an alternate name for a font that is registered by the FONTREG procedure.

ANIMATION
specifies whether animation is active, enabled, disabled, or unsupported for a Universal Printer:

Active indicates that the graphs in the ODS HTML output are grouped together in the animation. Animate=Start and Animate=Stop are ignored.

Enabled	indicates that animation is supported. Animate=Start and Animate=Stop must be specified to start and stop the animation.
Disabled	indicates that animation is supported but has been disabled for the device or printer.
Unsupported	indicates that animation is not supported for the device or printer.

BMIN
displays the minimum size of the bottom margin.

BOTTOM
displays the current size of bottom margin.

CLRSPACE
displays the type of color support (color space) such as RGB, RGBA, CMYK, HLS, and so on.

See "Color-Naming Schemes" in *SAS/GRAPH: Reference*

COLS
displays the number of horizontal columns in the output.

See "Cells" in *SAS/GRAPH: Reference*

COMPRESSION
indicates the condition under which compression is used. Compression can always be in effect, in effect only when specified by a compression option, or never used by the device or printer.

Here are the compression values on the report:

Always	indicates that compression is always in effect.
Option	indicates that compression is specified by the UPRINTCOMPRESSION system option or the COMPRESS= option in the ODS PRINTER statement.
Never	specifies that compression is never used by the device or printer.

COMPMETHOD
indicates the compression method that is used if compression is supported by device or printer.

Note When Compression is Never and no compression is available, the Compression Method value does not appear in the SAS log.

DESC
displays the default description of the device or printer.

DEST
displays the default destination of the device or universal printer if the device or printer does not send output directly to a printer or a display device. If the device sends output directly to a printer or a display device, the value of DEST is blank.

A destination can have a blank value when output is going to a monitor, or on Windows, the output is going to a printer.

EMBEDDING
indicates whether font embedding is supported.

ALWAYS Font embedding is always in effect for the device or printer.

OPTION The FONTEMBEDDING system option controls whether font embedding is supported.

NEVER Font embedding is not supported.

FHEIGHT
displays the height, in the respective units, of the default font.

Note If the font name is acquired from a CHARREC list in a device entry, the height is not available. See "CHARREC Device Parameter" in *SAS/GRAPH: Reference* for more information.

FONT
displays the name of the default font.

See "Default Fonts" in *SAS/GRAPH: Reference*

FORMAT
displays the output format type (for example, EMF, EMF Plus, EMF Dual, PostScript, GIF, Host Display, and so on).

See "Commonly Used Devices" in *SAS/GRAPH: Reference*

FSTYLE
displays the style of the default font (for example, Roman, Regular, and so on).

Interaction The results of specifying the FSTYLE variable in a GENERAL report where the output is directed to the SAS log differs from the results that you get when you specify the FSTYLE variable for a FONTS report. In a GENERAL report, the font style is reported to the SAS log. In a FONT report, the SAS log report displays only the font family names. The specific font style is not reported.

Note If the font name is acquired from a CHARREC list in a device entry, the style is not available. See "CHARREC Device Parameter" in *SAS/GRAPH: Reference* for more information.

FWEIGHT
displays the weight of the default font (for example, Normal, Medium, and so on).

Interaction The results of specifying the FWEIGHT variable in a GENERAL report where the output is directed to the SAS log differs from the results that you get when you specify the FWEIGHT variable for a FONTS report. In a GENERAL report, the font weight is reported to the SAS log. In a FONT report, the SAS log report displays only the font family names. The specific font weights are not reported.

Note If the font name is acquired from a CHARREC list in a device entry, the weight is not available. See "CHARREC Device Parameter" in *SAS/GRAPH: Reference* for more information.

FVERSION
specifies the version of the font.

HEIGHT
displays the default vertical height of output (in UNITS) sent to the device or printer.

HRES
displays the horizontal resolution (pixels per UNIT) of output sent to the device or printer. Horizontal resolution is calculated by the formula `HRES=XPIXELS/WIDTH`.

Interaction If either the HRES or VRES variables are specified in the VAR statement, the horizontal and vertical resolutions are displayed together in the SAS log using the label XxY Resolution. In an output data set, HRES and VRES are reported separately.

See "Using the XPIXELS=, XMAX=, YPIXELS=, and YMAX= Graphics Options to Set the Resolution for the Traditional Devices" in *SAS/GRAPH: Reference*

IOTYPE
displays the type of input/output used by the device or printer (for example, DISK, PRINTER, PIPE, GTERM, and so on).

See "FILENAME Statement" in *SAS Global Statements: Reference* and "DEVTYPE Device Parameter" in *SAS/GRAPH: Reference*

LEFT
displays the size of the left margin of output.

LMIN
displays the minimum left margin.

LOCATION
for the device entry that was found, displays the physical location of the Gdevice0-Gdevice9 library, the Sashelp library, or the library that is specified by the DEVLOC= option. For universal printers, this variable displays the SAS registry (SASHELP or SASUSER) where the printer was found.

MAXCOLORS
displays the maximum number of colors that are supported by the device or printer.

See "Maximum Number of Colors Displayed on a Device" in *SAS/GRAPH: Reference*

MODULE
specifies the name of the device driver module.

NAME
displays the name of the device or printer.

PROTOTYPE
displays the prototype (model) that was used to define the universal printer.

See "What Is Universal Printing?" in *SAS 9.4 Universal Printing*

RIGHT
displays the size of the right margin.

RMIN
displays the minimum size of the right margin.

ROWS
displays the number of vertical rows in the output.

See "Cells" in *SAS/GRAPH: Reference*

TMIN
displays the minimum top margin of output.

TOP
displays the size of the top margin.

TYPE
displays the type of device or printer. Here are the types of devices and printers:

- Graph Device
- Printer Interface Device
- Shortcut Device
- System Display
- System Metafile
- Universal Previewer
- Universal Printer

See "Device Categories and Modifying Default Output Attributes" in *SAS/GRAPH: Reference*

UNITS
displays the units (IN for inches or CM for centimeters) in which sizes are displayed. In the SAS log, the value of UNITS appears respectively, as inches or centimeters. In an output data set, the value of UNITS appears as IN or CM.

Interaction If the VAR statement does not specify any variables for size, margins, or resolution, the SAS log shows the units that are used to measure size, margins or resolution. Here is an example:

```
 Name: EMF
Units: inches
```

If the VAR statement specifies any variables for size, margins, or resolution, the SAS log shows the units with the value. Here is an example:

```
XxY Resolution: 96x96 pixels per inch
```

VISUAL
displays the visual color type (for example, Indexed Color, Direct Color, True Color, Monochrome, or Gray Scale).

VRES
displays the vertical resolution (pixels per UNIT) of output sent to the device or printer.

Vertical resolution is calculated by the formula `VRES=YPIXELS/HEIGHT`.

Interaction If either the HRES or VRES variables are specified in the VAR statement, the horizontal and vertical resolutions are displayed together in the SAS log using the label XxY Resolution. In an output data set, HRES and VRES are reported separately.

See "Using the XPIXELS=, XMAX=, YPIXELS=, and YMAX= Graphics Options to Set the Resolution for the Traditional Devices" in *SAS/GRAPH: Reference*

WIDTH
displays the width of output (in UNITS) sent to device or printer.

XPIXELS
displays the width of the output in pixels.

See "XPIXELS Device Parameter and Graphics Option" in *SAS/GRAPH: Reference* and "Using the XPIXELS=, XMAX=, YPIXELS=, and YMAX= Graphics Options to Set the Resolution for the Traditional Devices" in *SAS/GRAPH: Reference*

YPIXELS
displays the height of the output in pixels.

See "YPIXELS Device Parameter and Graphics Option" in *SAS/GRAPH: Reference* and "Using the XPIXELS=, XMAX=, YPIXELS=, and YMAX= Graphics Options to Set the Resolution for the Traditional Devices" in *SAS/GRAPH: Reference*

LINESTYLE Report Variables

For more information, see "Create a LINESTYLE Report" on page 1981.

DESC
displays the default description of the device or printer.

LINE
displays the line styles supported by the device or printer.

Interaction In a SAS log LINESTYLE report, the LINE and SUPPORT variables are reported together. If either the LINE variable or the SUPPORT variable is specified in the VAR statement, the line styles are reported using the Supported Line Styles or Unsupported Line Styles variable labels.

See "Line Types" in *SAS/GRAPH: Reference*

LOCATION
displays the physical location of the Gdevice0-Device9 or Sashelp library that contains the Devices catalog where the device entry was found or the library that is specified by the DEVLOC= option.

NAME
displays the name of the device.

SUPPORT
displays the device lines styles.

Interaction The value of the SUPPORT variable is affected by the SUPPORT= option in the PROC QDEVICE statement. If SUPPORT=YES, the report shows the supported line styles. If SUPPORT=NO, the report shows line styles that are not supported. If SUPPORT=ALL, the report shows all supported and non-supported line styles.

TYPE
displays the type of device or printer:

- Graph Device
- Printer Interface Device
- Shortcut Device
- System Display
- System Metafile

See "Device Categories and Modifying Default Output Attributes" in *SAS/GRAPH: Reference*

RECTANGLE Report Variables

For more information, see "Create a RECTANGLE Report" on page 1982.

DESC
displays the default description of the device or printer.

FILL
displays the hardware fill types that are supported by the device.

Interaction In a SAS log RECTANGLE report, the FILL and SUPPORT variables are reported together. If either the FILL variable or the SUPPORT variable is specified in the VAR statement, the fill names are reported using either the label Supported Hardware Fills or the label Unsupported Hardware Fills.

See "PATTERN Statement" in *SAS/GRAPH: Reference*

LOCATION
displays the physical location of the Gdevice0-Device9 or Sashelp library that contains the Devices catalog where the device entry was found or the library that is specified by the DEVLOC= option.

NAME
displays the name of the device.

SUPPORT
displays the hardware fills.

Interaction The value of the SUPPORT variable is affected by the SUPPORT= option in the PROC QDEVICE statement. If SUPPORT=YES, the report shows the supported hardware fills. If SUPPORT=NO, the report shows hardware fills that are not supported. If SUPPORT=ALL, the report shows all supported and non-supported hardware fills.

TYPE
displays the type of device or printer.

Here is a list of types:

- Graph Device
- Printer Interface Device
- Shortcut Device
- System Display
- System Metafile

See "Device Categories and Modifying Default Output Attributes" in *SAS/GRAPH: Reference*

SYMBOL Report Variables

For more information, see "Create a SYMBOL Report" on page 1984.

DESC
displays the default description of the device or printer.

LOCATION
displays the physical location of the Gdevice0-Device9 or Sashelp library that contains the Devices catalog where the device entry was found or the library that is specified by the DEVLOC= option.

NAME
displays the name of the device.

SUPPORT
displays the device or printer symbols.

Interaction The value of the SUPPORT variable is affected by the SUPPORT= option in the PROC QDEVICE statement. If SUPPORT=YES, the report shows the supported symbols. If SUPPORT=NO, the report shows symbols that are not supported. If SUPPORT=ALL, the report shows all supported and non-supported symbols.

SYMBOL
specifies the name of hardware symbols.

Interaction In a SAS log SYMBOL report, if either the SYMBOL or SUPPORT variable is specified in the VAR statement, symbol names are

reported using the Supported Hardware Symbols label or Unsupported Hardware Symbols label.

See "SYMBOL, NOSYMBOL Device Parameters and Graphics Options" in *SAS/GRAPH: Reference* and "SYMBOLS Device Parameter" in *SAS/GRAPH: Reference*

TYPE
displays the type of device or printer.

Here is a list of types:

- Graph Device
- Printer Interface Device
- Shortcut Device
- System Display
- System Metafile

See "Device Categories and Modifying Default Output Attributes" in *SAS/GRAPH: Reference*

Usage: QDEVICE Procedure

Variables Common to All Reports

You can use the following variables in any of the reports:

- NAME
- DESC
- TYPE
- LOCATION

For a description of the variables, see "Valid Variables for All Reports" on page 1960.

Create a GENERAL Report

The GENERAL report produces a report of general information about the specified device or printer. This information includes margin sizes, default font information, resolution, and color information.

About GENERAL Report Variables

For a description of the variables, see "GENERAL Report Variables" on page 1963.

The following table lists the variables that you can use in a GENERAL report as well as the labels for the variables that are used either in the SAS log or the output data set. If you do not specify the VAR statement, the variables appear in the order in which they appear in the table.

Variable	SAS Log Label	Output Data Set Label
NAME	Name	NAME OF DEVICE OR PRINTER
DESC	Description	DESCRIPTION OF DEVICE OR PRINTER
MODULE	Module	DRIVER MODULE
TYPE	Type	TYPE OF DEVICE OR PRINTER
LOCATION	"Device Catalog" for a device "Registry" for a printer	LOCATION OF DEVICE OR PRINTER DEFINITION
PROTOTYPE	Prototype	PRINTER PROTOTYPE
FONT	Default Typeface	FONT TYPEFACE DEFAULT
ALIAS	Typeface Alias	FONT TYPEFACE ALIAS
FSTYLE	Font Style	FONT STYLE DEFAULT
FWEIGHT	Font Weight	FONT WEIGHT DEFAULT
FHEIGHT	Font Height	FONT HEIGHT DEFAULT

Variable	SAS Log Label	Output Data Set Label
FVERSION	Font Version	FONT VERSION
MAXCOLORS	Maximum Colors	MAXIMUM NUMBER OF SUPPORTED COLORS
VISUAL	Visual Color	TYPE OF VISUAL COLOR
CLRSPACE	Color Support	TYPE OF COLOR SUPPORT
DEST	Destination	OUTPUT DESTINATION DEFAULT
IOTYPE	I/O Type	TYPE OF I/O DEFAULT
FORMAT	Data Format	OUTPUT DATA FORMAT
HEIGHT	Height	HEIGHT OF OUTPUT
WIDTH	Width	WIDTH OF OUTPUT
UNITS	Units [1]	UNITS FOR SIZE, MARGINS AND RESOLUTION
YPIXELS	Ypixels	VERTICAL PIXELS
XPIXELS	Xpixels	HORIZONTAL PIXELS
ROWS	Rows (vpos)	ROWS
COLS	Columns (hpos)	COLUMNS
LEFT	Left Margin	LEFT MARGIN
LMIN	Minimum Left Margin	MINIMUM LEFT MARGIN
RIGHT	Right Margin	RIGHT MARGIN
RMIN	Minimum Right Margin	MINIMUM RIGHT MARGIN
BOTTOM	Bottom Margin	BOTTOM MARGIN
BMIN	Minimum Bottom Margin	MINIMUM BOTTOM MARGIN
TOP	Top Margin	TOP MARGIN

Variable	SAS Log Label	Output Data Set Label
TMIN	Minimum Top Margin	MINIMUM TOP MARGIN
HRES	XxY Resolution	HORIZONTAL PIXELS PER UNIT
VRES	XxY Resolution	VERTICAL PIXELS PER UNIT
COMPRESSION	Compression Enabled	COMPRESSION ENABLED
COMPMETHOD	Compression Method	COMPRESSION METHOD
EMBEDDING	Font Embedding	FONT EMBEDDING SUPPORT
ANIMATION	Animation	ANIMATION SUPPORT

1 If the type of units is displayed with the value of a variable, such as 0 inches for the left margin, the Units label is not displayed in the output to the SAS log.

System Options That Affect the Value of Size Variables

For universal printers, the values of the HEIGHT, WIDTH, LEFT, RIGHT, BOTTOM, TOP, LMIN, RMIN, BMIN, and TMIN variables are affected by the settings of the PAPERSIZE, LEFTMARGIN, RIGHTMARGIN, BOTTOMMARGIN, and TOPMARGIN SAS system options. The default paper size is determined by the SAS locale (which affects the default size for universal printers). For SAS/GRAPH devices, these variable values are not affected by the system option settings.

For more information, see *SAS System Options: Reference*.

Example: GENERAL Report

The following QDEVICE procedure creates a GENERAL report for the SVG universal printer:

```
proc qdevice;
   printer svg;
run;
```

Here is the GENERAL report in the SAS log:

```
16   proc qdevice;
17   printer svg;
18    run;

                Name: SVG
         Description: Scalable Vector Graphics 1.1
              Module: SASPDSVG
                Type: Universal Printer
            Registry: SASHELP
           Prototype: SVG 1.1
    Default Typeface: Cumberland AMT
      Typeface Alias: Courier
          Font Style: Regular
         Font Weight: Normal
         Font Height: 8 points
        Font Version: Version 1.03
      Maximum Colors: 16777216
        Visual Color: Direct Color
       Color Support: RGBA
         Destination: sasprt.svg
            I/O Type: DISK
         Data Format: SVG
              Height: 6.25 inches
               Width: 8.33 inches
             Ypixels: 600
             Xpixels: 800
          Rows(vpos): 50
       Columns(hpos): 114
         Left Margin: 0 inches
  Minimum Left Margin: 0 inches
        Right Margin: 0 inches
 Minimum Right Margin: 0 inches
       Bottom Margin: 0 inches
Minimum Bottom Margin: 0 inches
          Top Margin: 0 inches
   Minimum Top Margin: 0 inches
      XxY Resolution: 96x96 pixels per inch
  Compression Enabled: Never
   Compression Method: Deflate
      Font Embedding: Option
           Animation: Enabled
```

Create a FONT Report

The FONT report produces a report of all system and device-resident fonts that are supported by the specified device or printer.

About FONT Report Variables

For a description of the variables, see “FONT Report Variables” on page 1962.

The following table lists the variables that you can use in a FONT report as well as the labels for the variables that are used either in the SAS log or the output data

set. If you do not specify the VAR statement, the variables appear in the order in which they appear in the table.

Variable	SAS Log Label	Output Data Set Label
NAME	Name	NAME OF DEVICE OR PRINTER
DESC	Description	DESCRIPTION OF DEVICE OR PRINTER
TYPE	Type	TYPE OF DEVICE OR PRINTER
LOCATION	"Device Catalog" for a device "Registry" for a printer	LOCATION OF DEVICE OR PRINTER DEFINITION
FONT	Depends on the font or type	FONT TYPEFACE
ALIAS	(alias: *alias*) to the right of the font name	FONT TYPEFACE ALIAS
FTYPE	Depends on the type of font	FONT TYPE
FSTYLE	None	FONT STYLE
FWEIGHT	None	FONT WEIGHT
FVERSION	None	FONT VERSION

Variable Labels in a FONT Report

When you specify the FONT, FTYPE, FSTYLE, or the FWEIGHT variables in a FONT report, the variable labels that appear in the SAS log vary. The variable labels in the output data set are always the same: FONT TYPEFACE DEFAULT, FONT TYPE, FONT STYLE DEFAULT, and FONT WEIGHT DEFAULT, respectively.

If the VAR statement specifies one or more of the variables FONT, FTYPE, FSTYLE, FWEIGHT, or FVERSION, the SAS log reports only the font type labels and the font family names. The font styles, weights, and versions are not reported to the SAS log. The font type label that appears is dependent on the font type. Some example labels are Supported Font Typefaces, Supported Resident Typefaces, Supported TrueType Typefaces, and Supported Type1 Typefaces.

Example: FONT Report

The following QDEVICE procedure creates a FONT report for the ACTIVEX graphics device:

```
proc qdevice report=font;
   device activex;
run;
```

Here is a partial FONT report in the SAS log:

```
41   proc qdevice report=font;
42   device activex;
43   run;

                    Name: ACTIVEX
             Description: ActiveX enabled GIF Driver
                    Type: Graph Device
          Device Catalog: your-font-catalog-path
Supported Font Typefaces: System (7x16) 8pt
                          System (9x20) 10pt
                          Terminal (8x12) 7pt
                          Terminal (4x6) 4pt
                          Terminal (5x12) 7pt
                          Terminal (6x8) 5pt
                          Terminal (7x12) 7pt
                          Terminal (10x18) 11pt
                          Terminal (12x16) 10pt
                          Fixedsys (8x15) 7pt
                          Fixedsys (10x20) 11pt
                          Modern
                          Roman
                          Script
                          Courier (8x13) 8pt
```

Create a DEVOPTION Report

The DEVOPTION report produces a report of the hardware device options that are supported by the specified device. This report is unavailable for universal printers.

About DEVOPTION Report Variables

For a description of the variables, see "DEVOPTION Report Variables" on page 1961.

The following table lists the variables that you can use in a DEVOPTION report as well as the labels for the variables that are used either in the SAS log or the output data set. If you do not specify the VAR statement, the variables appear in the order in which they appear in the table.

Variable	SAS Log Label	Output Data Set Label
NAME	Name	NAME OF DEVICE OR PRINTER
DESC	Description	DESCRIPTION OF DEVICE OR PRINTER
TYPE	Type	TYPE OF DEVICE OR PRINTER
LOCATION	Device Catalog	LOCATION OF DEVICE OR PRINTER DEFINTION
BIT	Bit Position	DEVICE OPTION BIT POSITON
BITSTRING	Bit Pattern	DEVICE OPTION BIT PATTERN
OPTION	Device Option	DEVICE OPTION NAME
ODESC	Option Description	DEVICE OPTION DESCRIPTION
SUPPORT	Support	DEVICE OPTION SUPPORT

Example: DEVOPTION Report

The following QDEVICE procedure creates a DEVOPTION report for the SASEMF graphics device, reporting supported options because the default for SUPPORT is YES:

```
proc qdevice report=devoption;
   device sasemf;
run;
```

Here is the report in the SAS log:

```
104  proc qdevice report=devoption;
105     device sasemf;
106  run;

NOTE: Writing HTML Body file: sashtml.htm
              Name: SASEMF
       Description: Enhanced Metafile Driver
              Type: Shortcut Device
    Device Catalog: your-sas-path\sashelp
       Bit Pattern: 8000000000000000
     Device Option: GDCIRCLEARC
Option Description: Hardware is capable of drawing circles
           Support: Yes

      Bit Position: 1
       Bit Pattern: 4000000000000000
     Device Option: GDPIEFILL
Option Description: Device has hardware pie-fill capability
           Support: Yes

      Bit Position: 3
       Bit Pattern: 1000000000000000
     Device Option: GDCRT
Option Description: Hardware is a CRT or the device acts like a CRT
           Support: Yes

      Bit Position: 5
       Bit Pattern: 0400000000000000
     Device Option: GDPOLYGONFILL
Option Description: Device has polygonfill capability
           Support: Yes

      Bit Position: 7
       Bit Pattern: 0100000000000000
     Device Option: GDRGB
Option Description: Hardware is capable of defining colors in one or more color
spaces
           Support: Yes

      Bit Position: 8
       Bit Pattern: 0080000000000000
     Device Option: GDMBPOLY
Option Description: Hardware can draw polygons with multiple boundaries
           Support: Yes

      Bit Position: 9
       Bit Pattern: 0040000000000000
     Device Option: GDOPACITY
Option Description: Hardware is capable of supporting opacity
           Support: Yes

      Bit Position: 11
       Bit Pattern: 0010000000000000
     Device Option: GDLWIDTH
Option Description: Hardware can draw lines of varying widths
           Support: Yes

      Bit Position: 14
       Bit Pattern: 0002000000000000
     Device Option: GDHRDCHR
Option Description: Hardware characters are supported by the device
           Support: Yes
```

```
      Bit Position: 15
       Bit Pattern: 0001000000000000
     Device Option: GDXLIMIT
Option Description: There is no limit on max value allowed for x coordinate
           Support: Yes

      Bit Position: 16
       Bit Pattern: 0000800000000000
     Device Option: GDYLIMIT
Option Description: There is no limit on max value allowed for y coordinate
           Support: Yes

      Bit Position: 18
       Bit Pattern: 0000200000000000
     Device Option: GDTXJUSTIFY
Option Description: Hardware is capable of justifying proportional text
           Support: Yes

      Bit Position: 24
       Bit Pattern: 0000008000000000
     Device Option: GDUNICODE
Option Description: Device supports the use of the Unicode font attribute
           Support: Yes

      Bit Position: 25
       Bit Pattern: 0000004000000000
     Device Option: GDPOLYLINE
Option Description: Hardware is capable of supporting polylines
           Support: Yes

      Bit Position: 28
       Bit Pattern: 0000000800000000
     Device Option: GDTRUETYPE
Option Description: Device supports the use of TrueType fonts
           Support: Yes

      Bit Position: 36
       Bit Pattern: 0000000008000000
     Device Option: GDIMAGE
Option Description: Device is capable of drawing images
           Support: Yes

      Bit Position: 39
       Bit Pattern: 0000000001000000
     Device Option: GDIMGROTATE
Option Description: Device is incapable of doing image rotation
           Support: Yes
```

```
      Bit Position: 40
       Bit Pattern: 0000000000800000
     Device Option: GDTRUECOLOR
Option Description: Hardware is a 24-bit true color device
           Support: Yes

      Bit Position: 44
       Bit Pattern: 0000000000080000
     Device Option: GDTEXTCLIP
Option Description: Hardware will clip text at the device limits
           Support: Yes

      Bit Position: 50
       Bit Pattern: 0000000000002000
     Device Option: GDAUTOSIZE
Option Description: Autosize text to fit rows and columns
           Support: Yes

      Bit Position: 54
       Bit Pattern: 0000000000000200
     Device Option: GDPOLYOUTLINE
Option Description: Device draws polygon outlines
           Support: Yes

      Bit Position: 55
       Bit Pattern: 0000000000000100
     Device Option: GDPRINTERPATH
Option Description: Device temporarily sets printerpath to that of the device name
           Support: Yes

      Bit Position: 56
       Bit Pattern: 0000000000000080
     Device Option: GDOPTPASSTHRU
Option Description: PAPERSIZE option sets default value of PAPERSIZE goption
           Support: Yes

      Bit Position: 57
       Bit Pattern: 0000000000000040
     Device Option: GDPIEOUTLINE
Option Description: Driver draws pie slice outlines (empty pies)
           Support: Yes
```

Create a LINESTYLE Report

The LINESTYLE report produces a report of the hardware (dashed) line styles that are supported by the specified device.

About LINESTYLE Report Variables

For a description of the variables, see “LINESTYLE Report Variables” on page 1968.

The following table lists the variables that you can use in a LINESTYLE report as well as the labels for the variables that are used either in the SAS log or the output data set. If you do not specify the VAR statement, the variables appear in the order in which they appear in the table.

Variable	SAS Log Label	Output Data Set Label
NAME	Name	NAME OF DEVICE OR PRINTER
DESC	Description	DESCRIPTION OF DEVICE OR PRINTER
TYPE	Type	TYPE OF DEVICE OR PRINTER
LOCATION	Device Catalog	LOCATION OF DEVICE OR PRINTER DEFINTION
LINE	Supported Line Styles Unsupported Line Styles	HARDWARE DASHED LINE NUMBER
SUPPORT	Supported Line Styles Unsupported Line Styles	HARDWARE DASHED LINE SUPPORT

Example: LINESTYLE Report

The following QDEVICE procedure creates a LINESTYLE report of the LJ5PS device, reporting the supported line styles because the default for SUPPORT is YES:

```
proc qdevice report=linestyle;
   device lj5ps;
run;
```

Here is the LINESTYLE report in the SAS log:

```
202  proc qdevice report=linestyle;
203     device lj5ps;
204  run;

                 Name: LJ5PS
          Description: LaserJet 5P -- 600 dpi -- PostScript
                 Type: Graph Device
       Device Catalog: your-sas-path\sashelp
Supported Line Styles: 1-44
```

Create a RECTANGLE Report

A RECTANGLE report produces a report of the hardware fill types that are supported by the specified device.

About RECTANGLE Report Variables

For a description of the variables, see "RECTANGLE Report Variables" on page 1969.

The following table lists the variables that you can use in a RECTANGLE report as well as the labels for the variables that are used either in the SAS log or the output data set. If you do not specify the VAR statement, the variables appear in the order in which they appear in the table.

Variable	SAS Log Label	Output Data Set Label
NAME	Name	NAME OF DEVICE OR PRINTER
DESC	Description	DESCRIPTION OF DEVICE or PRINTER
TYPE	Type	TYPE OF DEVICE OR PRINTER
LOCATION	Device Catalog	LOCATION OF DEVICE OR PRINTER DEFINTION
FILL	Supported Hardware Fills	HARDWARE RECTANGLE FILL NAME
SUPPORT	Supported Hardware Fills Unsupported Hardware Fills	HARDWARE RECTANGLE FILL SUPPORT

Example: RECTANGLE Report

The following QDEVICE procedure creates a RECTANGLE report for the SASPRTG universal printer, reporting the supported hardware fills because the default for SUPPORT is YES.

```
proc qdevice report=rectangle;
   device sasprtg;
run;
```

Here is the RECTANGLE report in the SAS log:

```
205  proc qdevice report=rectangle;
206     device sasprtg;
207  run;

                    Name: SASPRTG
             Description: POSTSCRIPT LEVEL 1
                    Type: Printer Interface Device
          Device Catalog: your-sas-path\sashelp
Supported Hardware Fills: Empty,Solid
```

SASPRTG is a printer interface device. Because Universal Printing is active, SASPRTG interfaces with the default universal printer. For this reason, the report shows information about the PostScript Level 1 printer as a universal printer.

Create a SYMBOL Report

A SYMBOL report produces a report of the hardware symbols that are supported by the specified device.

About SYMBOL Report Variables

For a description of the variables, see "SYMBOL Report Variables" on page 1970.

The following table lists the variables that you can use in a SYMBOL report as well as the labels for the variables that are used either in the SAS log or the output data set. If you do not specify the VAR statement, the variables appear in the order in which they appear in the table.

Variable	SAS Log Label	Output Data Set Label
NAME	Name	NAME OF DEVICE OR PRINTER
DESC	Description	DESCRIPTION OF DEVICE OR PRINTER
TYPE	Type	TYPE OF DEVICE OR PRINTER
LOCATION	Device Catalog	LOCATION OF DEVICE OR PRINTER DEFINTION
SYMBOL	Supported Hardware Symbols Unsupported Hardware Symbols	HARDWARE SYMBOL NAME
SUPPORT	Support	DEVICE OPTION SUPPORT

Example: SYMBOL Report

The following QDEVICE procedure creates a SYMBOL report for the CGM device, reporting the supported hardware symbols because the default for SUPPORT is YES:

```
proc qdevice report=symbol;
   device cgm;
run;
```

Here is the SYMBOL report in the SAS log:

```
235  proc qdevice report=symbol;
236     device cgm;
237  run;

                     Name: CGM
              Description: CGM generator--binary output
                     Type: Graph Device
            Device Catalog: your-sas-path\sashelp
Supported Hardware Symbols: Plus,X,Star
```

Examples: QDEVICE Procedure

Example 1: Generate a Report for the Default Display Device

Features: PROC QDEVICE

Details

The following example creates a General report for the default display device. This example assumes that you are running in an interactive mode on Windows.

For the WIN device, the number of colors is controlled by your Windows display settings. The size is controlled by your monitor and resolution settings.

Program

```
proc qdevice;
run;
```

Log

If you do not specify the OUT= option, the QDEVICE procedure sends its output to the SAS log. The output for the Windows operating environment is shown below as it appears in the SAS log.

Example Code 55.1 *The SAS Log After Running PROC QDEVICE*

```
                Name: WIN
         Description: Microsoft Windows Display
                Type: System Display
      Device Catalog: your-device-catalog
    Default Typeface: Sasfont
          Font Style: Roman
         Font Weight: Normal
         Font Height: 7 points
       Maximum Colors: 2147483647
        Visual Color: True Color
       Color Support: RGB
            I/O Type: GTERM
         Data Format: Host Display
              Height: 5.75 inches
               Width: 9.25 inches
             Ypixels: 690
             Xpixels: 1110
          Rows(vpos): 46
       Columns(hpos): 111
         Left Margin: 0 inches
  Minimum Left Margin: 0 inches
        Right Margin: 0 inches
 Minimum Right Margin: 0 inches
       Bottom Margin: 0 inches
Minimum Bottom Margin: 0 inches
           Top Margin: 0 inches
   Minimum Top Margin: 0 inches
      XxY Resolution: 120x120 pixels per inch
  Compression Enabled: Never
      Font Embedding: Never
           Animation: Unsupported
```

Example 2: Generate a General Report for All Devices

Features: PROC QDEVICE statement option: OUT=
DEVICE statement

Details

The following example creates a General report for all devices and writes the results to WORK.ALLDEVICES.

You can use the _ALL_ keyword to generate a report for all devices.

Program

```
proc qdevice out=allDevices;
   device _all_;
run;
```

Output

The following image shows a portion of the report as it appears in the Viewtable window.

Output 55.1 *The Output Data Set Report for All Devices*

	NAME OF DEVICE OR PRINTER	DESCRIPTION OF DEVICE OR PRINTER	DRIVER MODULE	TYPE OF DEVICE OR PRINTER
1	ACTIVEX	ActiveX enabled GIF Driver	SASGDGIF	Graph Device
2	ACTXIMG	ActiveX enabled Image Driver	SASGDGIF	Graph Device
3	BMP	BMP File Format--256 colors	SASGDDMX	System Metafile
4	CGM	CGM generator--binary output	SASGDCGM	Graph Device
5	CGMC	CGM generator w/colors--binary output	SASGDCGM	Graph Device
6	CGMOF97L	CGM for Office 97 landscape mode	SASGDCGM	Graph Device
7	CGMOF97P	CGM for Microsoft Office 97 portrait	SASGDCGM	Graph Device
8	CGMOFML	CGM for MS Office w/ Metric Scaling land	SASGDCGM	Graph Device
9	CGMOFMP	CGM for MS Office w/ Metric Scaling port	SASGDCGM	Graph Device

Example 3: Generate a Report for SAS/GRAPH Device Drivers and Universal Printers

Features: PROC QDEVICE statement option: OUT=
DEVICE statement
PRINTER statement

Details

The following example creates a General report for all devices that end in EMF and the PDF and SVG? universal printers. The results are written to the WORK.MYREPORT data set. If you do not specify the REPORT= option, the QDEVICE procedure generates a General report.

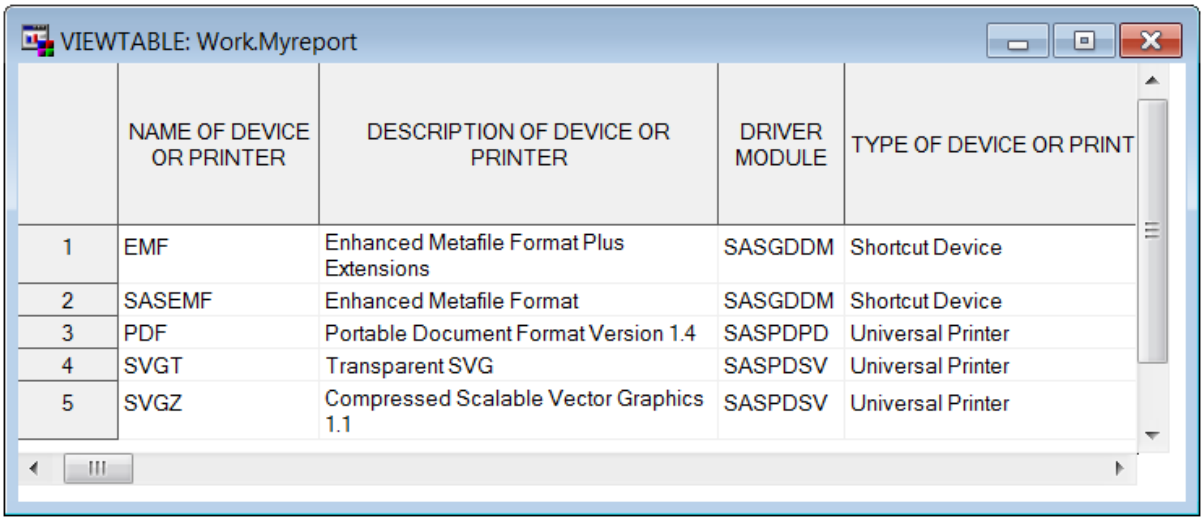
Program

```
proc qdevice out=myreport;
  device '*emf';
  printer pdf 'svg?';
run;
```

Output

The following image shows a portion of the report as it appears in the Viewtable window.

Output 55.2 *The Output Data Set Report for the EMF Device, and PDF and SVG Printers*



VIEWTABLE: Work.Myreport

	NAME OF DEVICE OR PRINTER	DESCRIPTION OF DEVICE OR PRINTER	DRIVER MODULE	TYPE OF DEVICE OR PRINT
1	EMF	Enhanced Metafile Format Plus Extensions	SASGDDM	Shortcut Device
2	SASEMF	Enhanced Metafile Format	SASGDDM	Shortcut Device
3	PDF	Portable Document Format Version 1.4	SASPDPD	Universal Printer
4	SVGT	Transparent SVG	SASPDSV	Universal Printer
5	SVGZ	Compressed Scalable Vector Graphics 1.1	SASPDSV	Universal Printer

Example 4: Generate a Report for the Default Printer

Features: PROC QDEVICE statement
PRINTER statement

Details

By default, printing in SAS under Windows is done by the default Windows printer and not by Universal Printing. Therefore, the results that you see for the QDEVICE procedure when you use the `printer _PRINTER_` statement differ. Under Windows, where the NOUPRINT system option is the default, the report is based on the printer interface device that interfaces with the default Windows printer. Under UNIX, where the UPRINT system option is set, the report is based on the default SAS universal printer.

Because the REPORT= option is not specified, the QDEVICE procedure generates a General report. The OUT= option is not specified and the results are written to the SAS log. The _PRINTER_ keyword determines the default printer to report on and generates a report for that printer.

For more information, see these topics:

- "Printing" in *SAS Companion for Windows*
- "UNIVERSALPRINT" in *SAS Companion for Windows*
- "What Is Universal Printing?" in *SAS 9.4 Universal Printing*

Program: Windows

```
proc qdevice;
  printer _PRINTER_;
run;
```

Log: Default Windows Printer Report

Example Code 55.2 *The SAS Log Output Report for the Default Windows Printer*

```
1    proc qdevice;
2       printer _PRINTER_;
3       run;

NOTE: The "\\wprt02nc0\clxmfpj21" printer will be used by default with the ODS
PRINTER destination.

                 Name: WINPRTC
          Description: \\WPRT02NC0\CLXMFPJ21
               Module: SASGDDMX
                 Type: Printer Interface Device
       Device Catalog: your-sas-path\sashelp
     Default Typeface: SAS Monospace
           Font Style: Roman
          Font Weight: Normal
          Font Height: 10 points
         Font Version: mfgpctt-v4.4 Thu Sep 16 14:30:47 EDT 1999
       Maximum Colors: 2097152
         Visual Color: True Color
        Color Support: RGB
              I/O Type: PRINTER
          Data Format: Host Printer
               Height: 10.67 inches
                Width: 8.15 inches
              Ypixels: 6392

             I/O Type: DISK
          Data Format: PostScript
               Height: 10 inches
                Width: 7.5 inches
              Ypixels: 3000
              Xpixels: 2250
           Rows(vpos): 81
        Columns(hpos): 112
          Left Margin: 0.5 inches
  Minimum Left Margin: 0 inches
         Right Margin: 0.5 inches
 Minimum Right Margin: 0 inches
        Bottom Margin: 0.5 inches
Minimum Bottom Margin: 0 inches
           Top Margin: 0.5 inches
   Minimum Top Margin: 0 inches
       XxY Resolution: 300x300 pixels per inch
  Compression Enabled: Never
       Font Embedding: Option
            Animation: Unsupported
```

Example 5: Generate a Font Report

Features:

PROC QDEVICE statement options
- REPORT=
- OUT=

PRINTER statement

Details

The first example generates a report of all the printer-resident and system fonts available for the printer. The results are written to the Work.Myfonts data set.

The second example is a SAS program that uses a macro, the DATA step, and the PRINT procedure to create a list of fonts for devices.

Program

```
proc qdevice report=font out=myfonts;
  printer 'postscript level 2';
run;
```

Output

The following output shows the report as it appears in the Viewtable window.

Output 55.3 *The Output Data Set for a Font Report*

	NAME OF DEVICE OR	DESCRIPTION OF DEVICE OR PRINTER	TYPE OF DEVICE OR	LOCATION OF DEVICE OR	FONT TY
1	POSTSCRIPT LEVEL 2	Generic PostScript Level 2 Printer	Universal Printer	SASHELP	Adobe C

Program

```
/* Macro FONTLIST - Report fonts supported by a device */

%macro fontlist(type, name);

proc qdevice report=font out=fonts;
   &type &name;
   var font ftype fstyle fweight;
run;

data;
   set fonts;
   drop ftype;
   length type $16;
   if ftype = "System"
     then do;
        if substr(font,2,3) = "ttf" then type = "TrueType";
```

```
          else if substr(font,2,3) = "at1" then type = "Adobe Type1";
          else if substr(font,2,3) = "cff" then type = "Adobe CFF/
Type2";
          else if substr(font,2,3) = "pfr" then type = "Bitstream PFR";
          else type = "System";
        if type ^= "System" then font = substr(font,7,length(font)-6);
          else if substr(font,1,1) = "@"
               then font = substr(font, 2,length(font)-1);
       end;
       else type = "Printer Resident";
run;

proc sort;
   by font;
run;

title "Fonts Supported by the %upcase(&name) &type";

proc print label;
   label fstyle="Style" fweight="Weight" font="Font" type="Type";
run;

%mend fontlist;

%fontlist(device, pcl5c)
```

Program Description

Create the macro fontlist. The %macro statement begins the macro. The input to the macro is the type, whether it is a device or printer, and the name of the device or printer.

```
/* Macro FONTLIST - Report fonts supported by a device */

%macro fontlist(type, name);
```

Create a data set, fonts, for the device. The macro input variables, type and name, are used to create a Font report using the QDEVICE procedure. The output is written to the data set fonts.

```
proc qdevice report=font out=fonts;
   &type &name;
   var font ftype fstyle fweight;
run;
```

Categorize the font type. Fonts can be a type System, TrueType, Adobe Type1, Adobe CFF/Type2, Bitstream PFR, or Printer Resident.

```
data;
   set fonts;
   drop ftype;
   length type $16;
   if ftype = "System"
     then do;
        if substr(font,2,3) = "ttf" then type = "TrueType";
```

```
          else if substr(font,2,3) = "at1" then type = "Adobe Type1";
          else if substr(font,2,3) = "cff" then type = "Adobe CFF/
Type2";
          else if substr(font,2,3) = "pfr" then type = "Bitstream PFR";
          else type = "System";
        if type ^= "System" then font = substr(font,7,length(font)-6);
          else if substr(font,1,1) = "@"
               then font = substr(font, 2,length(font)-1);
       end;
       else type = "Printer Resident";
run;
```

Sort the font data set by the font name.

```
proc sort;
   by font;
run;
```

Print the fonts for a device or printer.

```
title "Fonts Supported by the %upcase(&name) &type";

proc print label;
   label fstyle="Style" fweight="Weight" font="Font" type="Type";
run;
```

End the macro.

```
%mend fontlist;
```

Use the macro &fontlist to create and output data set for the PCL5c device.

```
%fontlist(device, pcl5c)
```

Output

Output 55.4 *A Partial View of the Fonts Supported by the PCL5c Device*

Fonts Supported by the PCL5C device

Obs	Font	Style	Weight	Type
1	CG Courier	Italic	Bold	Printer Resident
2	CG Courier	Italic	Normal	Printer Resident

20	EW CG Times	Roman	Bold	Printer Resident

Example 6: Generate a Device Option Report

Features:

PROC QDEVICE statement options
- REPORT=
- SUPPORT=
- OUT=

DEVICE statement

Details

The following example creates a Device Options (DEVOPTIONS) report for the PNG device. The report is written to an output data set.

Program

```
proc qdevice report=devoption support=all out=devop;
  device png;
run;

proc print data=devop;
   var bit bitstring option odesc;
   where Support="Yes";
   title "Supported PNG Device Options";
run;
```

Program Description

Report the options for the PNG device. The REPORT=DEVOPTION option specifies to create a device options report. SUPPORT=ALL specifies to report all device features. The option OUT=DEVOP creates the data set WORK.DEVOP. The DEVICE PNG statement specifies to report on the PNG device.

```
proc qdevice report=devoption support=all out=devop;
  device png;
run;
```

Print the device options report. Printing the WORK.DEVOP data set, the printed report shows the BIT, BITSTRING, OPTION, and ODESC variables for the device options where Support="Yes".

```
proc print data=devop;
   var bit bitstring option odesc;
   where Support="Yes";
   title "Supported PNG Device Options";
run;
```

Output

Output 55.5 *The Output Data Set for the PNG Device*

Supported PNG Device Options

Obs	BIT	BITSTRING	OPTION	ODESC
1	0	8000000000000000	GDCIRCLEARC	Hardware is capable of drawing circles
2	1	4000000000000000	GDPIEFILL	Device has hardware pie-fill capability
4	3	1000000000000000	GDCRT	Hardware is a CRT or the device acts like a CRT
5	4	0800000000000000	GDTRANSPARENCY	Device supports transparency
6	5	0400000000000000	GDPOLYGONFILL	Device has polygonfill capability
8	7	0100000000000000	GDRGB	Hardware is capable of defining colors in one or more color spaces
9	8	0080000000000000	GDMBPOLY	Hardware can draw polygons with multiple boundaries
10	9	0040000000000000	GDOPACITY	Hardware is capable of supporting opacity
13	14	0002000000000000	GDHRDCHR	Hardware characters are supported by the device
14	15	0001000000000000	GDXLIMIT	There is no limit on max value allowed for x coordinate
15	16	0000800000000000	GDYLIMIT	There is no limit on max value allowed for y coordinate
17	18	0000200000000000	GDTXJUSTIFY	Hardware is capable of justifying proportional text
20	24	0000008000000000	GDUNICODE	Device supports the use of the Unicode font attribute
21	25	0000004000000000	GDPOLYLINE	Hardware is capable of supporting polylines
24	28	0000000800000000	GDTRUETYPE	Device supports the use of TrueType fonts
32	36	0000000008000000	GDIMAGE	Device is capable of drawing images
35	39	0000000001000000	GDIMGROTATE	Device is incapable of doing image rotation
36	40	0000000000800000	GDTRUECOLOR	Hardware is a 24-bit true color device
37	41	0000000000400000	GDFONTATTR	Device supports setting font attributes
38	42	0000000000200000	GDSCANLNFNT	Device will use scan line font rendering
40	44	0000000000080000	GDTEXTCLIP	Hardware will clip text at the device limits
46	50	0000000000002000	GDAUTOSIZE	Autosize text to fit rows and columns
50	54	0000000000000200	GDPOLYOUTLINE	Device draws polygon outlines
51	55	0000000000000100	GDPRINTERPATH	Device temporarily sets printerpath to that of the device name
52	56	0000000000000080	GDOPTPASSTHRU	PAPERSIZE option sets default value of PAPERSIZE goption
53	57	0000000000000040	GDPIEOUTLINE	Driver draws pie slice outlines (empty pies)
54	60	0000000000000008	GDNOROTATE	Force the graphics sublib not to rotate the graph

Example 7: Specify a User Library and Catalog for a Report

Features: PROC QDEVICE statement options
CATALOG=

DEVLOC=
PRINTER statement

Details

This example creates a general report for a GIF printer in a user-specified library and catalog using the DEVLOC= and CATALOG= options in the PROC QDEVICES statement. The results are written to the SAS log.

Program

Assign the device library and catalog

```
libname devlib 'c:\em';
proc qdevice report=general devloc=devlib cat=mydevices;
   device gif;
run;
```

Log

Example Code 55.4 *The SAS Log Report for a Specific Device Library and Catalog*

```
144  libname devlib 'c:\em';
NOTE: Libref DEVLIB was successfully assigned as follows:
      Engine:        V9
      Physical Name: C:\em
145  proc qdevice report=general devloc=devlib cat=mydevices;
146     device gif;
147  run;

RANK Procedure

Overview: RANK Procedure

What Does the RANK Procedure Do?

The RANK procedure computes ranks for one or more numeric variables across the observations of a SAS data set and writes the ranks to a new SAS data set. PROC RANK by itself produces no printed output.

Ranking Data

The following output shows the results of ranking the values of one variable with a simple PROC RANK step. In this example, the new ranking variable shows the order of finish of five golfers over a four-day competition. The player with the lowest number of strokes finishes in first place. The following statements produce the output:

```
proc rank data=golf out=rankings;
   var strokes;
   ranks Finish;
run;

proc print data=rankings;
run;
```

Output 56.1 *Assignment of the Lowest Rank Value to the Lowest Variable Value*

The SAS System 1

Obs	Player	Strokes	Finish
1	Jack	279	2
2	Jerry	283	3
3	Mike	274	1
4	Randy	296	4
5	Tito	302	5

In the following output, the candidates for city council are ranked by district according to the number of votes that they received in the election. They are also ranked according to the number of years that they have served in office.

This example shows how PROC RANK can do the following tasks:

- reverse the order of the rankings so that the highest value receives the rank of 1, the next highest value receives the rank of 2, and so on
- rank the observations separately by values of multiple variables
- rank the observations within BY groups
- handle tied values

For an explanation of the program that produces this report, see "Example 2: Ranking Values within BY Groups" on page 2019.

Output 56.2 *Assignment of the Lowest Rank Value to the Highest Variable Value within Each BY Group*

```
                    Results of City Council Election                    1

---------------------------------- District=1 ----------------------------------

                                                    Vote    Years
              Obs    Candidate    Vote    Years    Rank     Rank

               1     Cardella     1689      8        1       1
               2     Latham       1005      2        3       2
               3     Smith        1406      0        2       3
               4     Walker        846      0        4       3

                              N = 4

---------------------------------- District=2 ----------------------------------

                                                    Vote    Years
             Obs    Candidate      Vote    Years    Rank     Rank

              5     Hinkley         912      0        3       3
              6     Kreitemeyer    1198      0        2       3
              7     Lundell        2447      6        1       1
              8     Thrash          912      2        3       2

                              N = 4
```

Concepts: RANK Procedure

Computer Resources

For any variable that is being ranked, PROC RANK stores in memory the value of that variable for every observation.

Statistical Applications

Ranks are useful for investigating the distribution of values for a variable. The ranks divided by *n* or *n*+1 form values in the range 0 to 1, and these values estimate the cumulative distribution function. You can apply inverse cumulative distribution functions to these fractional ranks to obtain probability quantile scores. You can compare these scores to the original values to judge the fit to the distribution. For example, if a set of data has a normal distribution, the normal scores should be a linear function of the original values, and a plot of scores versus original values should be a straight line.

Many nonparametric methods are based on analyzing ranks of a variable:

- A two-sample *t* test applied to the ranks is equivalent to a Wilcoxon rank sum test using the *t* approximation for the significance level. If you apply the *t* test to the normal scores rather than to the ranks, the test is equivalent to the van der Waerden test. If you apply the *t* test to median scores (GROUPS=2), the test is equivalent to the median test.
- A one-way analysis of variance applied to ranks is equivalent to the Kruskal-Wallis *k*-sample test; the F test generated by the parametric procedure applied to the ranks is often better than the X^2 approximation used by Kruskal-Wallis. This test can be extended to other rank scores (Quade 1966).
- You can obtain a Friedman's two-way analysis for block designs by ranking within BY groups and then performing a main-effects analysis of variance on these ranks (Conover 1998).
- You can investigate regression relationships by using rank transformations with a method described by Iman and Conover (1979).

Treatment of Tied Values

When PROC RANK ranks values, if two or more values of an analysis variable that are within a BY group are equal, then tied values are present in the data. Because the values are indistinguishable and there is usually no further obvious information about which the ranks can reasonably be based, PROC RANK does not assign different ranks to the values. Tied values could be arbitrarily assigned different ranks. But in statistical applications such as nonparametric statistical tests using ranks, it is conventional to assign the same rank to tied values.

These statistical tests commonly assume that the data is from a continuous distribution, in which the probability of a tie is theoretically zero. In practice, whether because of inaccuracies in measurement, the finite accuracy of representation within a digital computer, or other reasons, tied values often occur. It is also conventional in these statistical tests to assign the average rank to a group of tied values. Assignment of the average rank is preferred because it

preserves the sum of the ranks and therefore does not distort the estimate of the cumulative distribution function.

For applications within and outside of statistics, the RANK procedure provides the TIES= option to control the treatment of tied values. The default value for this option depends on the specified ranking or scoring method, which you can specify with the options of the PROC RANK statement. For ranking and scoring methods, when TIES=LOW, TIES=HIGH, or TIES=MEAN, tied values are initially treated as if they are distinguishable. These methods all begin by sorting the values of the analysis variable within a BY group, and then assigning to each nonmissing value an ordinal number that indicates its position in the sequence.

Subsequently, for non-scoring methods, PROC RANK resolves tied values by selecting the minimum with TIES=LOW, selecting the maximum with TIES=HIGH, or calculating the average of the ordinals in a group of tied values with TIES=MEAN. PROC RANK then obtains the rank from this value through one or more further transformations such as scaling, translation, and truncation.

Scoring methods include normal and Savage scoring, which are requested by the NORMAL= and SAVAGE options. Non-scoring methods include ordinal ranking, the default, and those methods that are requested by the FRACTION, NPLUS1, GROUPS=, and PERCENT options. For the scoring methods NORMAL= and SAVAGE, PROC RANK obtains the probability quantile scores with the appropriate formulas as if no tied values were present within the data. PROC RANK then resolves tied values by selecting the minimum, selecting the maximum, or calculating the average of all scores within a tied group.

For all ranking and scoring methods, when TIES=DENSE, tied values are treated as indistinguishable, and each value within a tied group is assigned the same ordinal. As with the other TIES= resolution methods, all ranking and scoring methods begin by sorting the values of the analysis variable and then assigning ordinals. However, a group of tied values is treated as a single value. The ordinal assigned to the group differs by only +1 from the ordinal that is assigned to the value just prior to the group, if there is one. The ordinal differs by only -1 from the ordinal assigned to the value just after the group, if there is one. Therefore, the smallest ordinal within a BY group is 1, and the largest ordinal is the number of unique, nonmissing values in the BY group.

After the ordinals are assigned, PROC RANK calculates ranks and scores using the number of unique, nonmissing values instead of the number of nonmissing values for scaling. Because of its tendency to distort the cumulative distribution function estimate, dense ranking is not generally acceptable for use in nonparametric statistical tests.

Note that PROC RANK bases its computations on the internal numeric values of the analysis variables. The procedure does not format or round these values before analysis. When values differ in their internal representation, even slightly, PROC RANK does not treat them as tied values. If this is a concern for your data, then round the analysis variables by an appropriate amount before invoking PROC RANK. For information about the ROUND function, see “ROUND Function” in *SAS Functions and CALL Routines: Reference*.

In-Database Processing for PROC RANK

In-database processing has several advantages over processing within SAS. These advantages include increased security, reduced network traffic, and the potential for faster processing. Increased security is possible because sensitive data does not have to be extracted from the DBMS.

Faster processing is possible for the following reasons:

- Data is manipulated locally, on the DBMS, using high-speed secondary storage devices instead of being transported across a relatively slow network connection.
- The DBMS might have more processing resources at its disposal.
- The DBMS might be capable of optimizing a query for execution in a highly parallel and scalable fashion.

In-database processing for PROC RANK supports the following database management systems:

- Amazon Redshift
- Aster
- DB2
- Google BigQuery
- Greenplum
- Hadoop
- HAWQ
- Impala
- Microsoft SQL Server
- Netezza
- Oracle
- PostgreSQL
- SAP HANA
- Snowflake
- Teradata
- Vertica
- Yellowbrick

Note: When using the Google BigQuery data source, columns in the BY statement in PROC RANK cannot be of data type FLOAT64 for in-database processing.

The presence of table statistics might affect the performance of the RANK procedure's in-database processing. If your DBMS is not configured to automatically generate table statistics, then manual generation of table statistics might be necessary to achieve acceptable in-database performance.

Note: For DB2, generation of table statistics (either automatic or manual) is highly recommended for all but the smallest input tables.

If the RANK procedure's input data set is a table or view that resides within a database from which rows would normally be retrieved with the SAS/ACCESS interface to a supported DBMS, then PROC RANK can perform much or all of its work within the DBMS. There are several other factors that determine whether such in-database processing can occur. In-database processing will not occur in the following circumstances:

- if the RENAME= data set option is specified on the input data set.
- if a WHERE statement appears in the context of the RANK procedure or a WHERE= data set option is specified on the input data set, and the WHERE statement or option contains a reference to a SAS function that has no equivalent in the DBMS or a format that has not been installed for use by SAS within the DBMS.
- if any variable specified in a BY statement has an associated format. Formatted BY variables are not supported by PROC RANK for in-database processing.
- if a FORMAT statement appears within the procedure context and applies to a variable specified in a BY statement, then in-database processing cannot be performed. Formatted BY variables are not supported by RANK for in-database processing. With a DBMS, formats can be associated with variables only if a FORMAT or ATTRIB statement appears within the procedure context.
- The TIES=CONDENSE option is not supported for the RANK procedure's in-database processing in an Oracle DBMS. If you use this option, it will prevent SQL generation and execution of in-database processing.

When PROC RANK can process data within the DBMS, it generates an SQL query. The structure of the SQL query that is generated during an in-database invocation of PROC RANK depends on several factors, including these:

- the target DBMS
- the ranking methods that are used
- the number of variables that are ranked
- the inclusion of BY and WHERE statements
- the PROC RANK options that are used, such as TIES= and DESCENDING

The SQL query expresses the required calculations and is submitted to the DBMS. The results of this query will either remain as a new table within the DBMS if the output of the RANK procedure is directed there, or it will be returned to SAS. The settings for the MSGLEVEL option and the SQLGENERATION option determine whether messages will be printed to the SAS log, which indicates whether in-database processing was performed. Generated SQL can be examined by setting the SQL_IP_TRACE option or the SASTRACE= option. SQL_IP_TRACE shows the SQL that is generated by PROC RANK. For more information, see the SASTRACE=

option in *SAS/ACCESS for Relational Databases: Reference* or the SQL_IP_TRACE option in *SAS(R) Analytics Accelerator 1.3 for Teradata: Guide*.

For more information about the settings for system options, library options, data set options, and statement options that affect in-database performance for SAS procedures, see the SQLGENERATION= LIBNAME Option and the SQLGENERATION= option in *SAS/ACCESS for Relational Databases: Reference*.

Syntax: RANK Procedure

Tips:

You can use the ATTRIB, FORMAT, LABEL, and WHERE statements with the RANK procedure. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

You can also use any global statement. For a list, see "Global Statements" on page 25 and "Dictionary of SAS Global Statements" in *SAS Global Statements: Reference*.

For in-database processing to occur, your data must reside within a supported version of the DBMS that has been properly configured for SAS in-database processing. For more information, see "In-Database Processing for PROC RANK" on page 2006.

PROC RANK <*options*>;

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

VAR *data-set-variables(s)*;

RANKS *new-variables(s)*;

Statement	Task	Example
PROC RANK	Compute the ranks for one or more numeric variables in a SAS data set and writes the ranks to a new SAS data set	Ex. 1, Ex. 2, Ex. 3
BY	Calculate a separate set of ranks for each BY group	Ex. 2, Ex. 3
RANKS	Identify a variable to which the ranks are assigned	Ex. 1, Ex. 2
VAR	Specify the variables to rank	Ex. 1, Ex. 2, Ex. 3

PROC RANK Statement

Computes the ranks for one or more numeric variables.

Restrictions: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Only one ranking method can be specified in a single PROC RANK step.

Examples: "Example 1: Ranking Values of Multiple Variables" on page 2017

"Example 2: Ranking Values within BY Groups" on page 2019

"Example 3: Partitioning Observations into Groups Based on Ranks" on page 2022

Syntax

PROC RANK <*options*>;

Summary of Optional Arguments

Compute fractional ranks

NPLUS1
: computes fractional ranks by dividing each rank by the denominator *n*+1.

Create an output data set

OUT=*SAS-data-set*
: names the output data set.

Preserve values

PRESERVERAWBYVALUES
: preserves raw values of all BY variables.

Reverse the order of the rankings

DESCENDING
: reverses the direction of the ranks.

Specify how to rank tied values

TIES=HIGH | LOW | MEAN | DENSE
: specifies how to compute normal scores or ranks for tied data values.

Specify the input data set

DATA=*SAS-data-set*
: specifies the input SAS data set.

Specify the ranking method

FRACTION

computes fractional ranks by dividing each rank by the number of observations having nonmissing values of the ranking variable.

GROUPS=*number-of-groups*
assigns group values ranging from 0 to *number-of-groups* minus 1.

NORMAL=BLOM | TUKEY | VW
computes normal scores from the ranks.

PERCENT
calculates the percentage of observations with nonmissing values in the rank.

SAVAGE
computes Savage (or exponential) scores from the ranks.

Optional Arguments

DATA=*SAS-data-set*
specifies the input SAS data set.

Restrictions You cannot use PROC RANK with an engine that supports concurrent access if another user is updating the data set at the same time.

For in-database processing to occur, the data set specification must refer to a table that resides on a supported DBMS.

See "Input Data Sets" on page 26

DESCENDING
reverses the direction of the ranks. With DESCENDING, the largest value receives a rank of 1, the next largest value receives a rank of 2, and so on. Otherwise, values are ranked from smallest to largest.

See "Example 1: Ranking Values of Multiple Variables" on page 2017

"Example 2: Ranking Values within BY Groups" on page 2019

FRACTION
computes fractional ranks by dividing each rank by the number of observations having nonmissing values of the ranking variable.

Alias F

Interaction TIES=HIGH is the default with the FRACTION option. With TIES=HIGH, fractional ranks are considered values of a right-continuous, empirical cumulative distribution function.

See NPLUS1 option

GROUPS=*number-of-groups*
assigns group values ranging from 0 to *number-of-groups* minus 1. Common specifications are GROUPS=100 for percentiles, GROUPS=10 for deciles, and GROUPS=4 for quartiles. For example, GROUPS=4 partitions the original values into four groups. The smallest values receive, by default, a quartile value of 0 and the largest values receiving a quartile value of 3.

The formula for calculating group values is as follows:

$$\mathrm{FLOOR}(rank * k/(n+1))$$

FLOOR is the FLOOR function, *rank* is the value's order rank, *k* is the value of GROUPS=, and *n* is the number of observations having nonmissing values of the ranking variable for TIES=LOW, TIES=MEAN, and TIES=HIGH. For TIES=DENSE, *n* is the number of observations that have unique nonmissing values.

If the number of observations is evenly divisible by the number of groups, each group has the same number of observations, provided there are no tied values at the boundaries of the groups. Grouping observations by a variable that has many tied values can result in unbalanced groups because PROC RANK always assigns observations with the same value to the same group.

Tip Use DESCENDING to reverse the order of the group values.

See "Example 3: Partitioning Observations into Groups Based on Ranks" on page 2022

NORMAL=BLOM | TUKEY | VW

computes normal scores from the ranks. The resulting variables appear normally distributed. *n* is the number of observations that have nonmissing values of the ranking variable for TIES=LOW, TIES=MEAN, and TIES=HIGH. For TIES=DENSE, *n* is the number of observations that have unique nonmissing values. The formulas are as follows:

BLOM

$y_i=\Phi^{-1}((r_i-3/8)/(n+1/4))$

TUKEY

$y_i=\Phi^{-1}((r_i-1/3)/(n+1/3))$

VW

$y_i=\Phi^{-1}((r_i)/(n+1))$

In these formulas, Φ^{-1} is the inverse cumulative normal (PROBIT) function, r_i is the rank of the *i*th observation, and *n* is the number of nonmissing observations for the ranking variable.

VW stands for van der Waerden. With NORMAL=VW, you can use the scores for a nonparametric location test. All three normal scores are approximations to the exact expected order statistics for the normal distribution (also called *normal scores*). The BLOM version appears to fit slightly better than the others (Blom 1958; Tukey 1962).

Restriction Use of the NORMAL= option will prevent in-database processing.

Interaction If you specify the TIES= option, then PROC RANK computes the normal score from the ranks based on non-tied values and applies the TIES= specification to the resulting score.

NPLUS1

computes fractional ranks by dividing each rank by the denominator *n*+1, where *n* is the number of observations that have nonmissing values of the ranking

variable for TIES=LOW, TIES=MEAN, and TIES=HIGH. For TIES=DENSE, *n* is the number of observations that have unique nonmissing values.

Aliases FN1

N1

Interaction TIES=HIGH is the default with the NPLUS1 option.

See FRACTION option

OUT=*SAS-data-set*

names the output data set. If *SAS-data-set* does not exist, PROC RANK creates it. If you omit OUT=, the data set is named using the DATA*n* naming convention.

Interaction When in-database processing is being performed and OUT= also refers to a supported DBMS table, and if both IN= and OUT= reference the same library, then all processing can occur on the DBMS with results directly populating the output table. In this case, no results will be returned to SAS.

PRESERVERAWBYVALUES

preserves raw values of all BY variables. when those variables are propagated to the output data set. If the PRESERVERAWBYVALUES option is not specified, and one BY variable is specified, then a representative value for each BY group is written to the output data set. If multiple BY variables are specified, then a representative set of values for each BY group is written to the output data set.

PERCENT

divides each rank by the number of observations that have nonmissing values of the variable and multiplies the result by 100 to get a percentage. *n* is the number of observations that have nonmissing values of the ranking variable for TIES=LOW, TIES=MEAN, and TIES=HIGH. For TIES=DENSE, *n* is the number of observations that have unique nonmissing values.

Alias P

Interaction TIES=HIGH is the default with the PERCENT option.

Tip You can use PERCENT to calculate cumulative percentages, but you use GROUPS=100 to compute percentiles.

SAVAGE

computes Savage (or exponential) scores from the ranks by the following formula (Lehman 1998):

$$y_i = \left[\sum_{j=n-r_i+1} \left(\frac{1}{j}\right) \right] - 1$$

Interaction If you specify the TIES= option, then PROC RANK computes the Savage score from the ranks based on non-tied values and applies the TIES= specification to the resulting score.

TIES=HIGH | LOW | MEAN | DENSE

specifies how to compute normal scores or ranks for tied data values.

HIGH
assigns the largest of the corresponding ranks (or largest of the normal scores when NORMAL= is specified).

LOW
assigns the smallest of the corresponding ranks (or smallest of the normal scores when NORMAL= is specified).

MEAN
assigns the mean of the corresponding rank (or mean of the normal scores when NORMAL= is specified).

DENSE
computes scores and ranks by treating tied values as a single-order statistic. For the default method, ranks are consecutive integers that begin with the number one and end with the number of unique, nonmissing values of the variable that is being ranked. Tied values are assigned the same rank.

Note: CONDENSE is an alias for DENSE.

Default MEAN (unless the FRACTION option or PERCENT option is in effect).

Interaction If you specify the NORMAL= option, then the TIES= specification applies to the normal score, not to the rank that is used to compute the normal score.

See "Treatment of Tied Values" on page 2004

"Example 1: Ranking Values of Multiple Variables" on page 2017

"Example 2: Ranking Values within BY Groups" on page 2019

BY Statement

Produces a separate set of ranks for each BY group.

Interactions: If the NOTSORTED option is specified in a BY statement, then in-database processing cannot be performed.

Application of a format to any BY variable of the input data set, using a FORMAT statement for example, will prevent in-database processing.

See: "BY" on page 74

"Example 3: Partitioning Observations into Groups Based on Ranks" on page 2022

Examples: "Example 2: Ranking Values within BY Groups" on page 2019

"Example 3: Partitioning Observations into Groups Based on Ranks" on page 2022

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then the observations in the data set must either be sorted by all the variables that you specify or be indexed appropriately. Variables in a BY statement are called *BY variables*.

Note: When using the Google BigQuery data source, columns in the BY statement in PROC RANK cannot be of data type FLOAT64 for in-database processing.

Optional Arguments

DESCENDING
specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The observations are grouped in another way, such as chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, the procedure treats each contiguous set as a separate BY group.

If you are using a SAS/ACCESS engine, and you specify a BY statement, then the data is always returned in sorted order. If you specify the NOTSORTED option, then it is ignored and in-database processing is performed.

RANKS Statement

Creates new variables for the rank values.

Default: If you omit the RANKS statement, the rank values replace the original variable values in the output data set.

Requirement: If you use the RANKS statement, you must also use the VAR statement.

Examples: "Example 1: Ranking Values of Multiple Variables" on page 2017
"Example 2: Ranking Values within BY Groups" on page 2019

Syntax

RANKS *new-variables(s)*;

Required Argument

new-variable(s)
specifies one or more new variables that contain the ranks for the variable(s) listed in the VAR statement. The first variable listed in the RANKS statement contains the ranks for the first variable listed in the VAR statement. The second variable listed in the RANKS statement contains the ranks for the second variable listed in the VAR statement, and so on.

VAR Statement

Specifies the input variables.

Default: If you omit the VAR statement, PROC RANK computes ranks for all numeric variables in the input data set.

Examples: "Example 1: Ranking Values of Multiple Variables" on page 2017
"Example 2: Ranking Values within BY Groups" on page 2019
"Example 3: Partitioning Observations into Groups Based on Ranks" on page 2022

Syntax

VAR *data-set-variables(s)*;

Required Argument

data-set-variable(s)
specifies one or more variables for which ranks are computed.

Details

Using the VAR Statement with the RANKS Statement

The VAR statement is required when you use the RANKS statement. Using these statements together creates the ranking variables named in the RANKS statement that corresponds to the input variables specified in the VAR statement. If you omit

the RANKS statement, the rank values replace the original values in the output data set.

Results: RANK Procedure

Missing Values

Missing values are not ranked and are left missing when ranks or rank scores replace the original values in the output data set.

Output Data Set

The RANK procedure creates a SAS data set containing the ranks or rank scores but does not create any printed output. You can use PROC PRINT, PROC REPORT, or another SAS reporting tool to print the output data set.

The output data set contains all the variables from the input data set plus the variables named in the RANKS statement. If you omit the RANKS statement, the rank values replace the original variable values in the output data set.

Numeric Precision

For in-database processing, the mathematical operations expressed by the RANK procedure in SQL, and the order in which they are performed, are essentially the same as those performed within SAS. However, in-database processing might result in small numerical differences when compared to results produced directly by SAS.

Examples: RANK Procedure

Example 1: Ranking Values of Multiple Variables

Features:

PROC RANK statement options
- DESCENDING
- TIES=

RANKS statement

VAR statement

PRINT procedure

Details

This example performs the following actions:

- reverses the order of the ranks so that the highest value receives the rank of 1
- assigns the best possible rank to tied values
- creates ranking variables and prints them with the original variables

Ramey      68 72
Roe        68 75
Sanders    56 79
Simms      68 77
Strickland 82 79
;

proc rank data=cake out=order descending ties=low;

   var present taste;
```

```
   ranks PresentRank TasteRank;
run;

proc print data=order;
   title "Rankings of Participants' Scores";
run;
```

Program Description

Set the SAS system options. The NODATE option specifies to omit the date and time at which the SAS job begins. The PAGENO= option specifies the page number for the next page of output that SAS produces. The LINESIZE= option specifies the line size. The PAGESIZE= option specifies the number of lines for a page of SAS output.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Create the CAKE data set. This data set contains each participant's last name, score for presentation, and score for taste in a cake-baking contest.

```
data cake;
   input Name $ 1-10 Present 12-13 Taste 15-16;
   datalines;
Davis      77 84
Orlando    93 80
Ramey      68 72
Roe        68 75
Sanders    56 79
Simms      68 77
Strickland 82 79
;
```

Generate the ranks for the numeric variables in descending order and create the Order output data set. DESCENDING reverses the order of the ranks so that the high score receives the rank of 1. TIES=LOW gives tied values the best possible rank. OUT= creates the Order output data set.

```
proc rank data=cake out=order descending ties=low;
```

Create two new variables that contain ranks. The VAR statement specifies the variables to rank. The RANKS statement creates two new variables, PresentRank and TasteRank, that contain the ranks for the variables Present and Taste, respectively.

```
   var present taste;
   ranks PresentRank TasteRank;
run;
```

Print the data set. PROC PRINT prints the Order data set. The TITLE statement specifies a title.

```
proc print data=order;
   title "Rankings of Participants' Scores";
run;
```

Output: Listing

Output 56.3 *Rankings of Participants' Scores*

Rankings of Participants' Scores 1

Obs	Name	Present	Taste	Present Rank	Taste Rank
1	Davis	77	84	3	1
2	Orlando	93	80	1	2
3	Ramey	68	72	4	7
4	Roe	68	75	4	6
5	Sanders	56	79	7	3
6	Simms	68	77	4	5
7	Strickland	82	79	2	3

Example 2: Ranking Values within BY Groups

Features:

PROC RANK statement options
- DESCENDING
- TIES=

BY statement

RANKS statement

VAR statement

PRINT procedure

Details

This example performs the following actions:

- ranks observations separately within BY groups
- reverses the order of the ranks so that the highest value receives the rank of 1
- assigns the best possible rank to tied values
- creates ranking variables and prints them with the original variables

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

data elect;
   input Candidate $ 1-11 District 13 Vote 15-18 Years 20;
```

```
   datalines;
Cardella    1 1689 8
Latham      1 1005 2
Smith       1 1406 0
Walker      1  846 0
Hinkley     2  912 0
Kreitemeyer 2 1198 0
Lundell     2 2447 6
Thrash      2  912 2
;

proc rank data=elect out=results ties=low descending;

   by district;

   var vote years;
   ranks VoteRank YearsRank;
run;

proc print data=results n;
   by district;
   title 'Results of City Council Election';
run;
```

Program Description

Set the SAS system options. The NODATE option specifies to omit the date and time at which the SAS job begins. The PAGENO= option specifies the page number for the next page of output that SAS produces. The LINESIZE= option specifies the line size. The PAGESIZE= option specifies the number of lines for a page of SAS output.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Create the Elect data set. This data set contains each candidate's last name, district number, vote total, and number of years' experience on the city council.

```
data elect;
   input Candidate $ 1-11 District 13 Vote 15-18 Years 20;
   datalines;
Cardella    1 1689 8
Latham      1 1005 2
Smith       1 1406 0
Walker      1  846 0
Hinkley     2  912 0
Kreitemeyer 2 1198 0
Lundell     2 2447 6
Thrash      2  912 2
;
```

Generate the ranks for the numeric variables in descending order and create the Results output data set. DESCENDING reverses the order of the ranks so that the highest vote total receives the rank of 1. TIES=LOW gives tied values the best possible rank. OUT= creates the Results output data set.

```
proc rank data=elect out=results ties=low descending;
```

Create a separate set of ranks for each BY group. The BY statement separates the rankings by values of District.

```
   by district;
```

Create two new variables that contain ranks. The VAR statement specifies the variables to rank. The RANKS statement creates the new variables, VoteRank and YearsRank, that contain the ranks for the variables Vote and Years, respectively.

```
   var vote years;
   ranks VoteRank YearsRank;
run;
```

Print the data set. PROC PRINT prints the Results data set. The N option prints the number of observations in each BY group. The TITLE statement specifies a title.

```
proc print data=results n;
   by district;
   title 'Results of City Council Election';
run;
```

Output: Listing

In the following output, Hinkley and Thrash tied with 912 votes in the second district. They both receive a rank of 3 because TIES=LOW.

Output 56.4 *Results of City Council Election*

```
                    Results of City Council Election                    1

---------------------------------- District=1 ----------------------------------

                                                 Vote    Years
              Obs    Candidate    Vote    Years  Rank     Rank

               1     Cardella     1689      8      1       1
               2     Latham       1005      2      3       2
               3     Smith        1406      0      2       3
               4     Walker        846      0      4       3

                              N = 4

---------------------------------- District=2 ----------------------------------

                                                  Vote    Years
             Obs    Candidate      Vote    Years  Rank     Rank

              5     Hinkley         912      0      3       3
              6     Kreitemeyer    1198      0      2       3
              7     Lundell        2447      6      1       1
              8     Thrash          912      2      3       2

                              N = 4
```

Example 3: Partitioning Observations into Groups Based on Ranks

Features:

PROC RANK statement option
GROUPS=

BY statement

VAR statement

PRINT procedure

SORT procedure

Details

This example performs the following actions:

- partitions observations into groups on the basis of values of two input variables
- groups observations separately within BY groups
- replaces the original variable values with the group values

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

data swim;
   input Name $ 1-7 Gender $ 9 Back 11-14 Free 16-19;
   datalines;
Andrea  F 28.6 30.3
Carole  F 32.9 24.0
Clayton M 27.0 21.9
Curtis  M 29.0 22.6
Doug    M 27.3 22.4
Ellen   F 27.8 27.0
Jan     F 31.3 31.2
Jimmy   M 26.3 22.5
Karin   F 34.6 26.2
Mick    M 29.0 25.4
Richard M 29.7 30.2
Sam     M 27.2 24.1
Susan   F 35.1 36.1
;

proc sort data=swim out=pairs;
   by gender;
run;
```

```
proc rank data=pairs out=rankpair groups=3;
   by gender;
   var back free;
run;
proc print data=rankpair n;
   by gender;
   title 'Pairings of Swimmers for Backstroke and Freestyle';
run;
```

Program Description

Set the SAS system options. The NODATE option specifies to omit the date and time at which the SAS job began. The PAGENO= option specifies the page number for the next page of output that SAS produces. The LINESIZE= option specifies the line size. The PAGESIZE= option specifies the number of lines for a page of SAS output.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Create the Swim data set. This data set contains swimmers' first names and their times, in seconds, for the backstroke and the freestyle. This example groups the swimmers into pairs, within male and female classes, based on times for both strokes so that every swimmer is paired with someone who has a similar time for each stroke.

```
data swim;
   input Name $ 1-7 Gender $ 9 Back 11-14 Free 16-19;
   datalines;
Andrea  F 28.6 30.3
Carole  F 32.9 24.0
Clayton M 27.0 21.9
Curtis  M 29.0 22.6
Doug    M 27.3 22.4
Ellen   F 27.8 27.0
Jan     F 31.3 31.2
Jimmy   M 26.3 22.5
Karin   F 34.6 26.2
Mick    M 29.0 25.4
Richard M 29.7 30.2
Sam     M 27.2 24.1
Susan   F 35.1 36.1
;
```

Sort the Swim data set and create the Pairs output data set. PROC SORT sorts the data set by Gender. This action is required to obtain a separate set of ranks for each group. OUT= creates the Pairs output data set.

```
proc sort data=swim out=pairs;
   by gender;
run;
```

Generate the ranks that are partitioned into three groups and create an output data set. GROUPS=3 assigns one of three possible group values (0,1,2) to each swimmer for each stroke. OUT= creates the Rankpair output data set.

```
proc rank data=pairs out=rankpair groups=3;
```

Create a separate set of ranks for each BY group. The BY statement separates the rankings by Gender.

```
   by gender;
```

Replace the original values of the variables with the rank values. The VAR statement specifies that Back and Free are the variables to rank. With no RANKS statement, PROC RANK replaces the original variable values with the group values in the output data set.

```
   var back free;
run;
```

Print the data set. PROC PRINT prints the Rankpair data set. The N option prints the number of observations in each BY group. The TITLE statement specifies a title.

```
proc print data=rankpair n;
   by gender;
   title 'Pairings of Swimmers for Backstroke and Freestyle';
run;
```

Output: Listing

In the following output, the group values pair swimmers with similar times to work on each stroke. For example, Andrea and Ellen work together on the backstroke because they have the fastest times in the female class. The groups of male swimmers are unbalanced because there are seven male swimmers; for each stroke, one group has three swimmers.

Output 56.5 *Pairings of Swimmers for Backstroke and Freestyle*

Pairings of Swimmers for Backstroke and Freestyle 1

Gender=F

REGISTRY Procedure

Overview: REGISTRY Procedure

What Does the REGISTRY Procedure Do?

The REGISTRY procedure maintains the SAS registry. The registry consists of two parts. One part is stored in the Sashelp library, and the other part is stored in the Sasuser library.

The REGISTRY procedure enables you to do the following:

- Import registry files to populate the Sashelp and Sasuser registries.

- Export all or part of the registry to another file.
- List the contents of the registry in the SAS log.
- Compare the contents of the registry to a file.
- Uninstall a registry file.
- Deliver detailed status information when a key or value will be overwritten or uninstalled.
- Clear out entries in the Sasuser registry.
- Validate that the registry exists.
- List diagnostic information.

For more information, see "The SAS Registry" in *SAS Language Reference: Concepts*.

Syntax: REGISTRY Procedure

PROC REGISTRY <*options*>;

Statement	Task	Example
PROC REGISTRY	Manage registry files	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6

PROC REGISTRY Statement

Maintains the SAS registry.

Examples:

"Example 1: Importing a File to the SAS Registry" on page 2038
"Example 3: Comparing the Registry to an External File" on page 2040
"Example 2: Listing and Exporting the Registry File" on page 2039
"Example 4: Comparing Registry Files" on page 2042
"Example 5: Specifying an Entire Key Sequence with the STARTAT= Option" on page 2043
"Example 6: Displaying a List of Fonts" on page 2044

Syntax

PROC REGISTRY <*options*>;

Summary of Optional Arguments

CLEARSASUSER
: erases from the Sasuser registry the keys that were added by a user.

COMPAREREG1='*libname.registry-name-1*'
: compares two registry files.

COMPAREREG2='*libname.registry-name-2*'
: compares two registry files.

COMPARETO=*file-specification*
: compares the contents of a registry to a file.

DEBUGOFF
: disables registry debugging.

DEBUGON
: enables registry debugging.

EXPORT=*file-specification*
: writes the contents of a registry to the specified file.

FOLLOWLINKS
: follows links that are found when processing the LIST command.

FULLSTATUS
: provides additional information in the SAS log about the results of the IMPORT= and UNINSTALL= options.

IMPORT=*file-specification*
: imports the specified file to a registry.

KEYSONLY
: limits the LIST, LISTUSER, LISTHELP, and LISTREG options output to display keys only.

LEVELS=*n*
: limits the number of levels to display for the LIST, LISTUSER, LISTHELP, and LISTREG options.

LIST
: writes the contents of the registry to the SAS log. This option is used with the STARTAT= option to list specific keys.

LISTHELP
: writes the contents of the Sashelp portion of the registry to the SAS log.

LISTREG='*libname.registry-name*'
: sends the contents of a registry to the log.

LISTUSER
: writes the contents of the Sasuser portion of the registry to the SAS log.

STARTAT='*key-name*'
: starts exporting or writing or comparing the contents of a registry at the specified key.

UNINSTALL=*file-specification*
: deletes from the specified registry all the keys and values that are in the specified file.

UPCASE
: uses uppercase for all incoming key names.

UPCASEALL

uses uppercase for all keys, names, and item values when you import a file.

USESASHELP
performs the specified operation on the Sashelp portion of the SAS registry.

Optional Arguments

CLEARSASUSER
erases from the Sasuser portion of the SAS registry the keys that were added by a user.

COMPAREREG1='*libname.registry-name-1*'
specifies one of two registries to compare. The results appear in the SAS log.

libname
is the name of the library in which the registry file resides.

registry-name-1
is the name of the first registry.

Requirement COMPAREREG1 must be used with COMPAREREG2.

Interaction To specify a single key and all of its subkeys, specify the STARTAT= option.

Example "Example 4: Comparing Registry Files" on page 2042

COMPAREREG2='*libname.registry-name-2*'
specifies the second of two registries to compare. The results appear in the SAS log.

libname
is the name of the library in which the registry file resides.

registry-name-2
is the name of the second registry.

Requirement COMPAREREG2 must be used with COMPAREREG1.

Example "Example 4: Comparing Registry Files" on page 2042

COMPARETO=*file-specification*
compares the contents of a file that contains registry information to a registry. It returns information about keys and values that it finds in the file that are not in the registry. It reports the following items as differences:

- keys that are defined in the external file but not in the registry
- value names for a given key that are in the external file but not in the registry
- differences in the content of like-named values in like-named keys

COMPARETO= does not report as differences any keys and values that are in the registry but not in the file because the registry could easily be composed of pieces from many different files.

File-specification is one of the following values:

'external-file'
is the path and name of an external file that contains the registry information.

fileref
is a fileref that has been assigned to an external file.

Requirement You must have previously associated the fileref with an external file in a FILENAME statement, a FILENAME function, the Explorer window, or an appropriate operating environment command.

Interaction By default, PROC REGISTRY compares *file-specification* to the Sasuser portion of the registry. To compare *file-specification* to the Sashelp portion of the registry, specify the option USESASHELP.

See Usage: REGISTRY Procedure on page 2034 for information about how to structure a file that contains registry information

Example "Example 3: Comparing the Registry to an External File" on page 2040

DEBUGON
enables registry debugging by providing more descriptive log entries.

DEBUGOFF
disables registry debugging.

EXPORT=*file-specification*
writes the contents of a registry to the specified file, where *file-specification* is one of the following values:

'external-file'
is the name of an external file that contains the registry information.

fileref
is a fileref that has been assigned to an external file.

Requirement You must have previously associated the fileref with an external file in a FILENAME statement, a FILENAME function, the Explorer window, or an appropriate operating environment command.

If *file-specification* already exists, then PROC REGISTRY overwrites it. Otherwise, PROC REGISTRY creates the file.

Interactions By default, EXPORT= writes the Sasuser portion of the registry to the specified file. To write the Sashelp portion of the registry, specify the USESASHELP option. You must have Write permission to the Sashelp library to use USESASHELP.

To export a single key and all of its subkeys, specify the STARTAT= option.

Example "Example 2: Listing and Exporting the Registry File" on page 2039

FOLLOWLINKS
follows links that are found when processing the LIST option.

Normally the LIST option displays the values of the link items. If you use the FOLLOWLINKS option, the links are treated as keys, and items contained in the links are displayed.

FULLSTATUS
lists the keys, subkeys, and values that were added or deleted as a result of running the IMPORT= and UNINSTALL options.

IMPORT=*file-specification*
specifies the file to import into the SAS registry. PROC REGISTRY does not overwrite the existing registry. Instead, it updates the existing registry with the contents of the specified file.

Note: The .sasxreg file extension is not required.

File-specification is one of the following values:

'external-file'
is the path and name of an external file that contains the registry information.

fileref
is a fileref that has been assigned to an external file.

Requirement You must have previously associated the fileref with an external file in a FILENAME statement, a FILENAME function, the Explorer window, or an appropriate operating environment command.

Interactions By default, IMPORT= imports the file to the Sasuser portion of the SAS registry. To import the file to the Sashelp portion of the registry, specify the USESASHELP option. You must have Write permission to Sashelp to use USESASHELP.

To obtain additional information in the SAS log as you import a file, use FULLSTATUS.

See Usage: REGISTRY Procedure on page 2034 for information about how to structure a file that contains registry information

Example “Example 1: Importing a File to the SAS Registry” on page 2038

KEYSONLY
limits the LIST, LISTUSER, LISTHELP, and LISTREG options output to display keys only.

LEVELS=*n*
limits the number of levels to display for the LIST, LISTUSER, LISTHELP, and LISTREG options.

Requirement LEVEL ≥ 1. LEVELS=0 behaves as if LEVELS was not specified.

LIST
writes the contents of the entire SAS registry to the SAS log.

Interaction To write a single key and all of its subkeys, use the STARTAT= option.

LISTHELP
writes the contents of the Sashelp portion of the registry to the SAS log.

Interaction To write a single key and all of its subkeys, use the STARTAT= option.

LISTREG='*libname.registry-name*'
lists the contents of the specified registry in the log.

libname
is the name of the library in which the registry file resides.

registry-name
is the name of the registry.

Here is an example:

```
proc registry listreg='sashelp.regstry';
run;
```

Interaction To list a single key and all of its subkeys, use the STARTAT= option.

LISTUSER
writes the contents of the Sasuser portion of the registry to the SAS log.

Interaction To write a single key and all of its subkeys, use the STARTAT= option.

Example "Example 2: Listing and Exporting the Registry File" on page 2039

STARTAT='*key-name*'
exports or writes the contents of a single key and all of its subkeys.

You must specify an entire key sequence if you want to start listing at any subkey under the root key.

Interaction Use STARTAT= with the EXPORT=, LIST, LISTHELP, LISTUSER, COMPAREREG1=, COMPAREREG2= and the LISTREG options.

Example "Example 4: Comparing Registry Files" on page 2042

UNINSTALL=*file-specification*
deletes from the specified registry all the keys and values that are in the specified file.

File-specification is one of the following values:

'external-file'
is the name of an external file that contains the keys and values to delete.

fileref
is a fileref that has been assigned to an external file. To assign a fileref, you can do the following:

- use the Explorer Window
- use the "FILENAME Statement" in *SAS Global Statements: Reference*

Interactions By default, UNINSTALL deletes the keys and values from the Sasuser portion of the SAS registry. To delete the keys and values from the Sashelp portion of the registry, specify the USESASHELP option. You must have Write permission to Sashelp to use this option.

Use FULLSTATUS to obtain additional information in the SAS log as you uninstall a registry.

See Usage: REGISTRY Procedure on page 2034 for information about how to structure a file that contains registry information

UPCASE
uses uppercase for all incoming key names.

UPCASEALL
uses uppercase for all keys, names, and item values when you import a file.

USESASHELP
performs the specified operation on the Sashelp portion of the SAS registry.

Interaction Use USESASHELP with the IMPORT=, EXPORT=, COMPARETO, or UNINSTALL option. To use USESASHELP with IMPORT= or UNINSTALL, you must have Write permission to Sashelp.

Usage: REGISTRY Procedure

Structure of a Registry File

You can create registry files with the SAS Registry Editor or with any text editor.

A registry file must have a particular structure. Each entry in the registry file consists of a key name, followed on the next line by one or more values. The key name identifies the key or subkey that you are defining. Any values that follow specify the names or data to associate with the key.

Specifying Key Names

Key names are entered on a single line between square brackets ([and]). To specify a subkey, enter multiple key names between the brackets, starting with the root key. Separate the names in a sequence of key names with a backslash (\). The length of a single key name or a sequence of key names cannot exceed 255 characters (including the square brackets and the backslashes). Key names can contain any character except the backslash.

Examples of valid key name sequences follow. These sequences are typical of the SAS registry:

- [CORE\EXPLORER\MENUS\ENTRIES\CLASS]
- [CORE\EXPLORER\NEWMEMBER\CATALOG]
- [CORE\EXPLORER\NEWENTRY\CLASS]
- [CORE\EXPLORER\ICONS\ENTRIES\LOG]

Specifying Values for Keys

Enter each value on the line that follows the key name that it is associated with. You can specify multiple values for each key, but each value must be on a separate line.

The general form of a value is:

value-name=value-content

A *value-name* can be an at sign (@), which indicates the default value name, or it can be any text string in double quotation marks. If the text string contains an ampersand (&), then the character (either uppercase or lowercase) that follows the ampersand is a shortcut for the value name. For more information, see "Sample Registry Entries" on page 2036.

The entire text string cannot contain more than 255 characters (including quotation marks and ampersands). It can contain any character except a backslash (\).

Value-content can be any of the following:

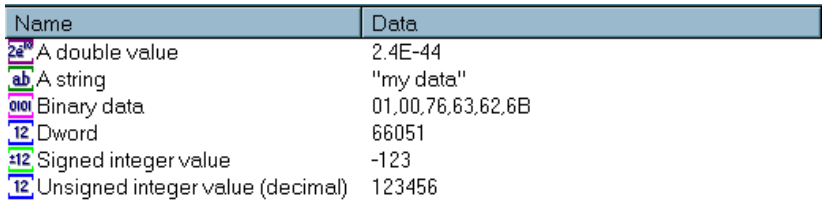
- the string **`double:`** followed by a numeric value.
- a string. You can put any character inside the quotation marks, including nothing ("").

  Note: To include a backslash in the string that is enclosed in quotation marks, use two adjacent backslashes. To include a double quotation mark, use two adjacent double quotation marks.

- the string **hex:** followed by any number of hexadecimal characters, up to the 255-character limit, separated by commas. If you extend the hexadecimal characters beyond a single line, then end the line with a backslash to indicate that the data continues on the next line. Hexadecimal values can also be referred to as "binary values" in the Registry Editor.
- the string **dword:** followed by an unsigned long hexadecimal value.
- the string **int:** followed by a signed long integer value.
- the string **uint:** followed by an unsigned long integer value.

The following display shows how the different types of values that are described above appear in the Registry Editor:

Figure 57.1 *Types of Registry Values, Displayed in the Registry Editor*



The following list contains a sample of valid registry values:

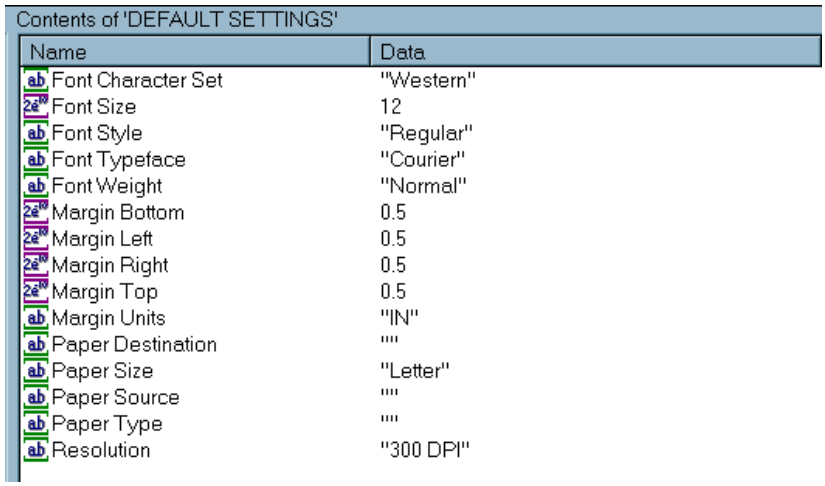
- a double value=double:2.4E-44
- a string="my data"
- binary data=hexadecimal: 01,00,76,63,62,6B
- dword=dword:00010203
- signed integer value=int:-123
- unsigned integer value (decimal)=dword:0001E240

Sample Registry Entries

Registry entries can vary in content and appearance, depending on their purpose.

The following display shows a registry entry that contains default PostScript printer settings:

Figure 57.2 *Portion of a Registry Editor Showing Settings for a PostScript Printer*



To see what the actual registry text file looks like, you can use PROC REGISTRY to write the contents of the registry key to the SAS log, using the LISTUSER and STARTAT= options.

The following example shows the syntax for sending a Sasuser registry entry to the log:

```
proc registry
     listuser
     startat='sasuser-registry-key-name';
run;
```

The following example shows a value for the STARTAT= option:

```
proc registry
     listuser
     startat='HKEY_SYSTEM_ROOT\CORE\PRINTING\PRINTERS\PostScript
\DEFAULT
SETTINGS';
run;
```

In the following example, the list of subkeys begins at the CORE\PRINTING\PRINTERS\PostScript\DEFAULT SETTINGS key.

Example Code 57.1 *A Registry Entry for a PostScript Printer*

```
NOTE: Contents of SASUSER REGISTRY starting at subkey [CORE\
PRINTING\PRINTERS\PostScript\DEFAULT SETTINGS key]

  Font Character Set="Western"
  Font Size=double:12
  Font Style="Regular"
  Font Typeface="Courier"
  Font Weight="Normal"
  Margin Bottom=double:0.5
  Margin Left=double:0.5
  Margin Right=double:0.5
  Margin Top=double:0.5
  Margin Units="IN"
  Paper Destination=""
  Paper Size="Letter"
  Paper Source=""
  Paper Type=""
  Resolution="300 DPI"
```

Examples: REGISTRY Procedure

Example 1: Importing a File to the SAS Registry

Features: IMPORT=
FILENAME statement

Details

This example imports a file into the Sasuser portion of the SAS registry. The following source file contains examples of valid key name sequences in a registry file:

```
[HKEY_USER_ROOT\AllGoodPeopleComeToTheAidOfTheirCountry]
 @="This is a string value"
  "Value2"=""
  "Value3"="C:\\This\\Is\\Another\\String\\Value"
```

Program

```
filename source 'external-file';

proc registry import=source;
run;
```

Program Description

Assign a fileref to a file that contains valid text for the registry. The FILENAME statement assigns the fileref SOURCE to the external file that contains the text to read into the registry.

```
filename source 'external-file';
```

Invoke PROC REGISTRY to import the file that contains input for the registry. PROC REGISTRY reads the input file that is identified by the fileref SOURCE. IMPORT= writes to the Sasuser portion of the SAS registry by default.

```
proc registry import=source;
run;
```

Log

Example Code 57.2 *Results from Importing a File to the SAS Registry*

```
Parsing REG file and loading the registry please wait....
Registry IMPORT is now complete.
```

Example 2: Listing and Exporting the Registry File

Features: EXPORT=
LISTUSER

Details

The registry file is usually very large. To export a portion of the registry, use the STARTAT= option.

This example lists the Sasuser portion of the SAS registry and exports it to an external file.

Program

```
proc registry
   listuser
   export='external-file';
run;
```

Program Description

Write the contents of the Sasuser portion of the registry to the SAS log. The LISTUSER option causes PROC REGISTRY to write the entire Sasuser portion of the registry to the log.

```
proc registry
   listuser
```

Export the registry to the specified file. The EXPORT= option writes a copy of the Sasuser portion of the SAS registry to the external file.

```
   export='external-file';
run;
```

Log

Example Code 57.3 *Results from Listing and Exporting a SAS Registry File*

```
Starting to write out the registry file, please wait...
The export to file external-file is now complete.
Contents of SASUSER REGISTRY.
[  HKEY_USER_ROOT]
[    CORE]
[      EXPLORER]
[        CONFIGURATION]
        Initialized= "True"
[        FOLDERS]
[          UNXHOST1]
          Closed= "658"
          Icon= "658"
          Name= "Home Directory"
          Open= "658"
          Path= "~"
```

Example 3: Comparing the Registry to an External File

Features: COMPARETO= option

FILENAME statement

Details

This example compares the Sasuser portion of the SAS registry to an external file. Comparisons such as this one are useful if you want to know the difference between a backup file that was saved with a .txt file extension and the current registry file.

To compare the Sashelp portion of the registry with an external file, specify the USESASHELP option.

This SAS log shows two differences between the Sasuser portion of the registry and the specified external file. In the registry, the value of "Initialized" is "True"; in the external file, it is "False". In the registry, the value of "Icon" is "658"; in the external file it is "343".

Program

```
filename testreg 'external-file';

proc registry
   compareto=testreg;
run;
```

Program Description

Assign a fileref to the external file that contains the text to compare to the registry. The FILENAME statement assigns the fileref TESTREG to the external file.

```
filename testreg 'external-file';
```

Compare the specified file to the Sasuser portion of the SAS registry. The COMPARETO option compares the contents of a file to a registry. It returns information about keys and values that it finds in the file that are not in the registry.

```
proc registry
   compareto=testreg;
run;
```

Log

Example Code 57.4 *Results from Comparing the Registry to an External File*

```
Parsing REG file and comparing the registry please wait....
COMPARE DIFF: Value "Initialized" in
[HKEY_USER_ROOT\CORE\EXPLORER\CONFIGURATION]: REGISTRY TYPE=STRING, CURRENT
VALUE="True"
COMPARE DIFF: Value "Initialized" in
[HKEY_USER_ROOT\CORE\EXPLORER\CONFIGURATION]: FILE TYPE=STRING, FILE
VALUE="False"
COMPARE DIFF: Value "Icon" in
[HKEY_USER_ROOT\CORE\EXPLORER\FOLDERS\UNXHOST1]: REGISTRY TYPE=STRING,
CURRENT VALUE="658"
COMPARE DIFF: Value "Icon" in
[HKEY_USER_ROOT\CORE\EXPLORER\FOLDERS\UNXHOST1]: FILE TYPE=STRING, FILE
VALUE="343"
Registry COMPARE is now complete.
COMPARE: There were differences between the registry and the file.
```

Example 4: Comparing Registry Files

Features: COMPAREREG1= and COMPAREREG2= options
STARTAT= option

Details

This example uses the REGISTRY procedure options COMPAREREG1= and COMPAREREG2= to specify two registry files for comparison.

Program

```
libname proclib 'SAS-library';
proc registry compareregl='sasuser.regstry'
   startat='CORE\EXPLORER'
   compareregl='proclib.regstry';
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library contains a registry file.

```
libname proclib 'SAS-library';
```

Start PROC REGISTRY and specify the first registry file to be used in the comparison.

```
proc registry comparereg1='sasuser.regstry'
```

Limit the comparison to the registry keys including and following the specified registry key. The STARTAT= option limits the scope of the comparison to the EXPLORER subkey under the CORE key. By default the comparison includes the entire contents of both registries.

```
   startat='CORE\EXPLORER'
```

Specify the second registry file to be used in the comparison.

```
   comparereg2='proclib.regstry';
run;
```

Log

Example Code 57.5 *Results from Comparing Two Registry Files*

```
NOTE: Comparing registry SASUSER.REGSTRY to registry PROCLIB.REGSTRY
NOTE: Diff in Key (CORE\EXPLORER\MENUS\FILES\SAS) Item (1;&Open)

NOTE: Diff in Key (CORE\EXPLORER\MENUS\FILES\TXT) Item (5;&Remote Submit)
SASUSER.REGSTRY Type: String len  35 data SIGNCHECK;PGM;INCLUDE '%s';RSUBMIT;
PROCLIB.REGSTRY Type: String len  33 data SIGNCHECK;WHOSTEDIT '%s';RSUBMIT;
```

Example 5: Specifying an Entire Key Sequence with the STARTAT= Option

Features: EXPORT option

STARTAT= option

Details

The following example shows how to use the STARTAT= option. You must specify an entire key sequence if you want to start listing any subkey under the root key. The root key is optional.

Program

```
proc registry export = my-fileref
startat='core\explorer\icons';
run;
```

Example 6: Displaying a List of Fonts

Features: LISTHELP option
STARTAT option

Details

The following example writes a list of ODS fonts to the SAS log.

Program

```
proc registry clearsasuser; run;
proc registry listhelp startat='ods\fonts'; run;
proc registry clearsasuser; run;
```

Log

Example Code 57.6 *Results from Displaying a List of Fonts from the SAS Registry*

REPORT Procedure

Overview: REPORT Procedure

What Does the REPORT Procedure Do?

The REPORT procedure combines features of the PRINT, MEANS, and TABULATE procedures with features of the DATA step in a single report-writing tool that can produce a variety of reports. You can use PROC REPORT in the following ways:

- in a nonwindowing environment. In this case, you submit a series of statements with the PROC REPORT statement, just as you do in other SAS procedure. You can submit these statements from the Program Editor (default is NOWINDOWS) in the PROC REPORT statement, or you can run SAS in batch, noninteractive, or interactive line mode. (See the information about "Ways to Run Your SAS Session " in *SAS Language Reference: Concepts*.)
- in an interactive report window environment with a prompting facility that guides you as you build a report. For details, see "REPORT Procedure Windows" on page 2229.
- in an interactive report window environment without the prompting facility. For details, see "REPORT Procedure Windows" on page 2229.
- the ability to create accessible output tables. When the ACCESSIBLETABLE system option is specified, changes are made to the layout of some tables to make them accessible. You can use the ACCESSIBLECHECK system option to check if your tables are accessible. When the ACCESSIBLETABLE system option is used and the CAPTION= option is used with PROC REPORT, captions are visible in the output.

For more information about creating accessible tables with PROC REPORT, see "Overview of Table Accessibility " in *Creating Accessible SAS Output Using ODS and ODS Graphics* . This feature applies to SAS 9.4M6 and later releases.

What Types of Reports Can PROC REPORT Produce?

A **detail report** contains one row for every observation selected for the report. Each of these rows is a report row, a **detail report row**. A **summary report** consolidates data so that each row represents multiple observations. Each of these rows is also called a detail row or a **summary report row**.

Both detail and summary reports can contain **summary report lines** (break lines) as well as report rows. A summary line summarizes numerical data for a set of detail rows or for all detail rows. PROC REPORT provides both default and customized summaries. (See "Using Break Lines" on page 2066.)

This overview illustrates the types of reports that PROC REPORT can produce. The statements that create the data sets and formats used in these reports are in "Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171. The formats are stored in a permanent SAS library. See the REPORT procedure examples for more reports and for the statements that create them.

What Do the Various Types of Reports Look Like?

The data set that these reports use contains one day's sales figures for eight stores in a chain of grocery stores.

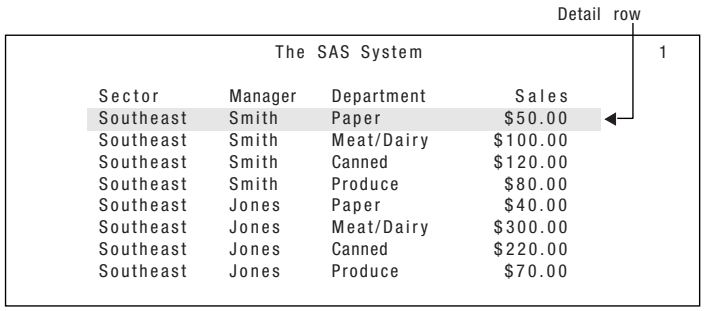
A simple PROC REPORT step produces a report similar to one produced by a simple PROC PRINT step. Figure 58.61 on page 2050 illustrates the simplest type of report that you can produce with PROC REPORT. The statements that produce the report follow. The data set and formats that the program uses are created in "Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171. Although the WHERE and FORMAT statements are not essential, here they limit the amount of output and make the values easier to understand.

```
libname proclib
'SAS-library';

options nodate pageno=1 linesize=64 pagesize=60
        fmtsearch=(proclib);

proc report data=grocery;
   where sector='se';
   format sector $sctrfmt. manager $mgrfmt.
          dept $deptfmt. sales dollar10.2;
run;
```

Figure 58.1 *Simple Detail Report with a Detail Row for Each Observation*

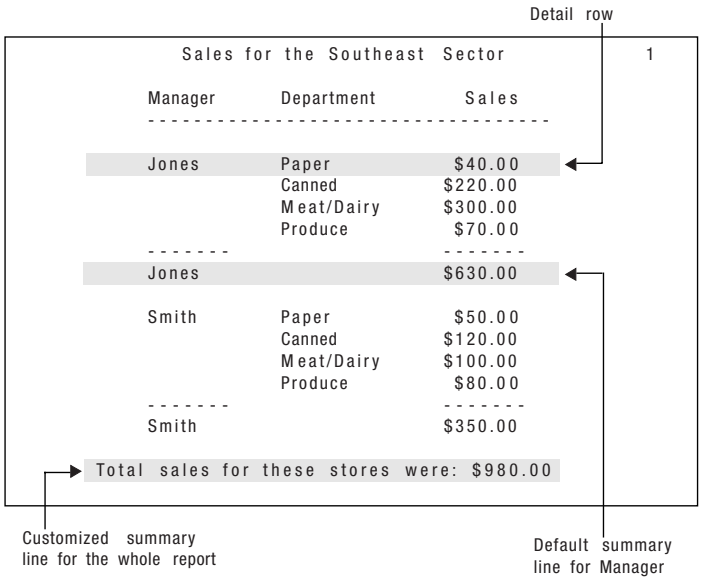


The report in the following figure uses the same observations as the above figure. However, the statements that produce this report

- order the rows by the values of Manager and Department.
- create a default summary line for each value of Manager.
- create a customized summary line for the whole report. A customized summary lets you control the content and appearance of the summary information, but you must write additional PROC REPORT statements to create one.

For an explanation of the program that produces this report, see "Example 2: Ordering the Rows in a Report" on page 2174.

Figure 58.2 *Ordered Detail Report with Default and Customized Summaries*

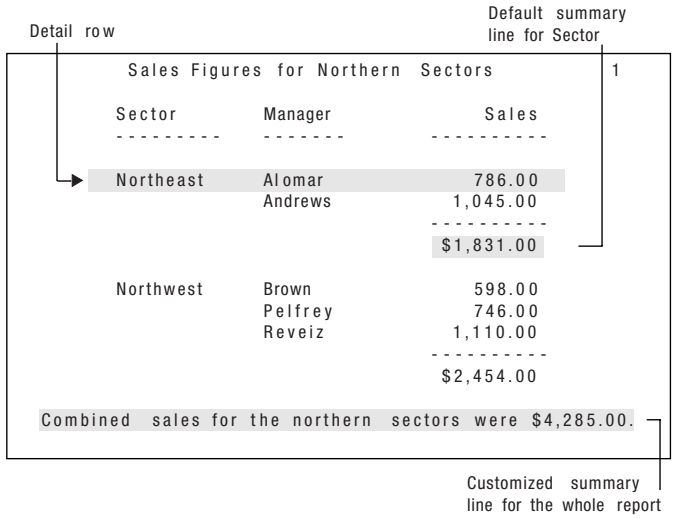


The summary report in the following figure contains one row for each store in the northern sector. Each detail row represents four observations in the input data set, one observation for each department. Information about individual departments does not appear in this report. Instead, the value of Sales in each detail row is the sum of the values of Sales in all four departments. In addition to consolidating multiple observations into one row of the report, the statements that create this report

- customize the text of the column headings
- create default summary lines that total the sales for each sector of the city
- create a customized summary line that totals the sales for both sectors

For an explanation of the program that produces this report, see "Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183.

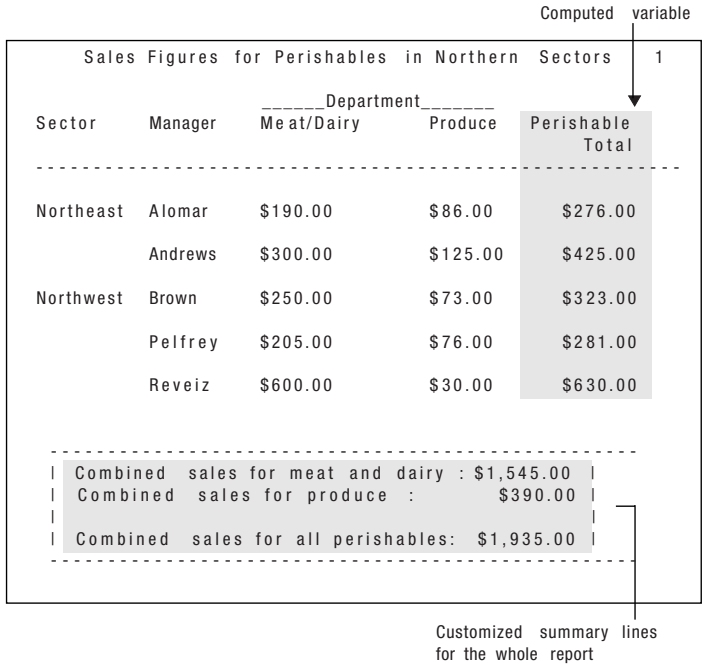
Figure 58.3 *Summary Report with Default and Customized Summaries*



The summary report in the following figure is similar to the above figure. The major difference is that it also includes information for individual departments. Each selected value of Department forms a column in the report. In addition, the statements that create this report compute and display a variable that is not in the input data set

For an explanation of the program that produces this report, see "Example 6: Creating a Column for Each Value of a Variable" on page 2187.

Figure 58.4 *Summary Report with a Column for Each Value of a Variable*

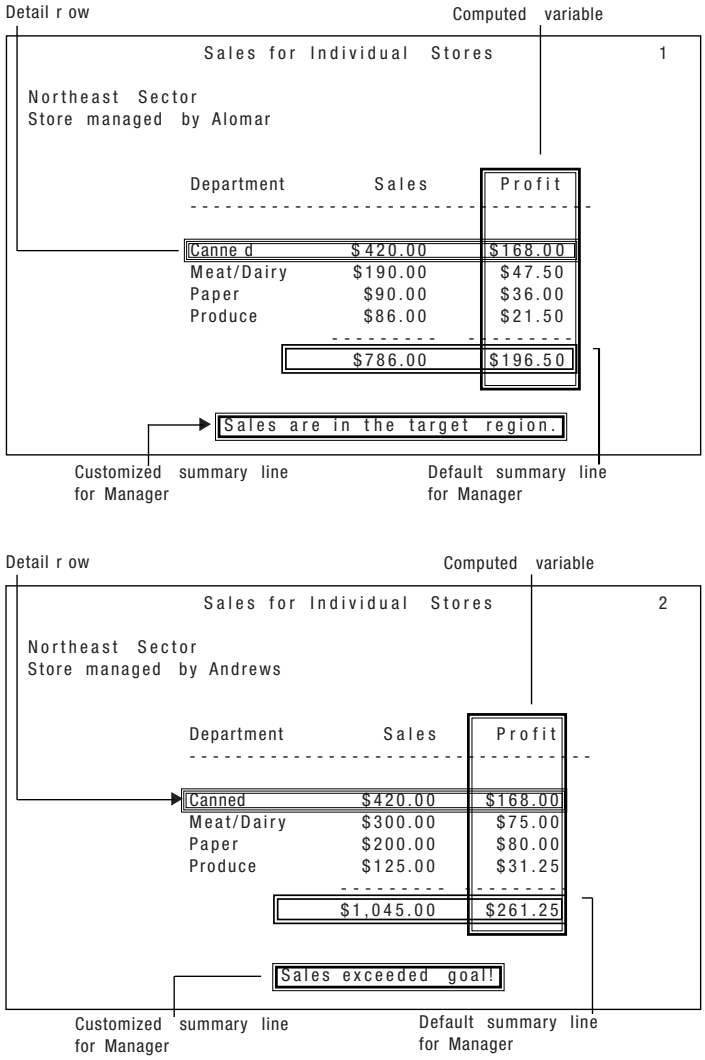


The customized report in the following figure shows each manager's store on a separate page. Only the first two pages appear here. The statements that create this report create

- a customized heading for each page of the report
- a computed variable (Profit) that is not in the input data set
- a customized summary with text that is dependent on the total sales for that manager's store

For an explanation of the program that produces this report, see "Example 7: Writing a Customized Summary on Each Page" on page 2190.

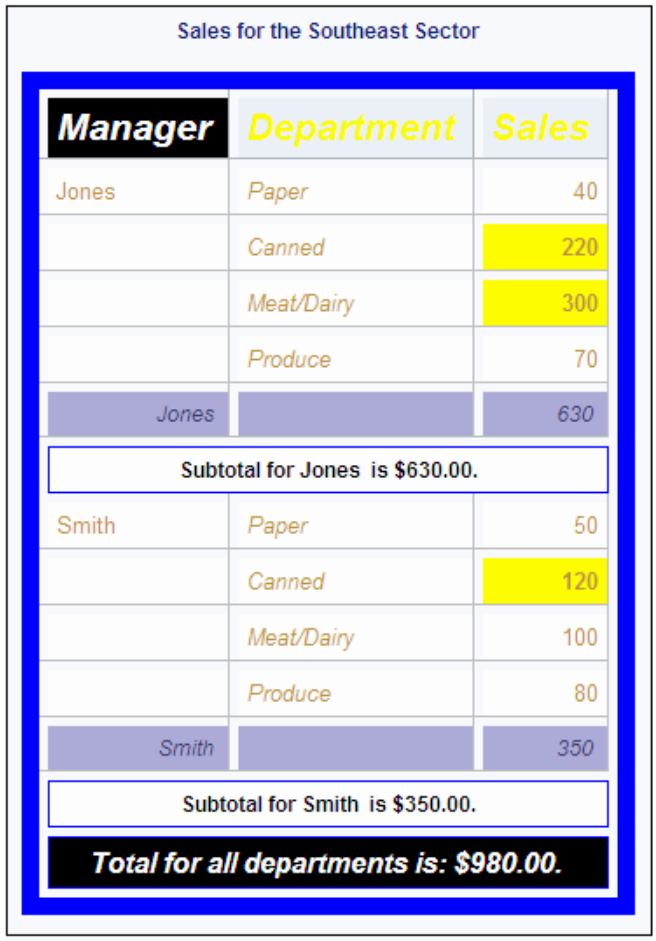
Figure 58.5 *Customized Summary Report*



The report in the following figure uses customized style elements to control things like font faces, font sizes, and justification, as well as the width of the border of the table and the width of the spacing between cells. This report was created by using the HTML destination of the Output Delivery System (ODS) and the STYLE= option in several statements in the procedure.

For an explanation of the program that produces this report, see "Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212. For information about ODS, see "Output Delivery System" on page 72.

Figure 58.6 HTML Output



Sales for the Southeast Sector

Manager	Department	Sales
Jones	Paper	40
	Canned	220
	Meat/Dairy	300
	Produce	70
Jones		630
Subtotal for Jones is $630.00.		
Smith	Paper	50
	Canned	120
	Meat/Dairy	100
	Produce	80
Smith		350
Subtotal for Smith is $350.00.		
Total for all departments is: $980.00.		

Concepts: REPORT Procedure

Laying Out a Report

Planning the Layout

Report writing is simplified if you approach it with a clear understanding of what you want the report to look like. The most important thing to determine is the

layout of the report. To design the layout, ask yourself the following types of questions:

- What do I want to display in each column of the report?
- In what order do I want the columns to appear?
- Do I want to display a column for each value of a particular variable?
- Do I want a row for every observation in the report, or do I want to consolidate information for multiple observations into one row?
- In what order do I want the rows to appear?

When you understand the layout of the report, use the COLUMN and DEFINE statements in PROC REPORT to construct the layout.

The COLUMN statement lists the items that appear in the columns of the report, describes the arrangement of the columns, and defines headings that span multiple columns. A report item can be

- a data set variable
- a statistic calculated by the procedure
- a variable that you compute from other items in the report

Omit the COLUMN statement if you want to include all variables in the input data set in the same order as they occur in the data set.

The DEFINE statement defines the characteristics of an item in the report. These characteristics include how PROC REPORT uses the item in the report, the text of the column heading, and the format to use to display values.

Note: The DEFINE statement equates to the DEFINITION window if you are using the WINDOWS environment.

Usage of Variables in a Report

Much of a report's layout is determined by the usages that you specify for variables in the DEFINE statements. For data set variables, these usages are

DISPLAY ORDER ACROSS GROUP ANALYSIS

A report can contain variables that are not in the input data set. These variables must have a usage of COMPUTED.

Display Variables

A report that contains one or more display variables has a row for every observation in the input data set. Display variables do not affect the order of the rows in the report. If no order variables appear to the left of a display variable, then the order of the rows in the report reflects the order of the observations in the data

set. By default, PROC REPORT treats all character variables as display variables. For an example, see "Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171.

Order Variables

A report that contains one or more order variables has a row for every observation in the input data set. If no display variable appears to the left of an order variable, then PROC REPORT orders the detail rows according to the ascending, formatted values of the order variable. You can change the default order with ORDER= and DESCENDING in the DEFINE statement.

If the report contains multiple order variables, then PROC REPORT establishes the order of the detail rows by sorting these variables from left to right in the report. PROC REPORT does not repeat the value of an order variable from one row to the next if the value does not change, unless an order variable to its left changes values. For an example, see "Example 2: Ordering the Rows in a Report" on page 2174.

The order of observations is not inherently defined for DBMS tables. If you specify the ORDER=DATA option for input data in a DBMS table, the order of rows written to a database table from PROC REPORT is not likely to be preserved.

Group Variables

If a report contains one or more group variables, then PROC REPORT tries to consolidate into one row all observations from the data set that have a unique combination of formatted values for all group variables.

When PROC REPORT creates groups, it orders the detail rows by the ascending, formatted values of the group variable. You can change the default order with ORDER= and DESCENDING in the DEFINE statement or with the DEFINITION window.

If the report contains multiple group variables, then the REPORT procedure establishes the order of the detail rows by sorting these variables from left to right in the report. PROC REPORT does not repeat the values of a group variable from one row to the next if the value does not change, unless a group variable to its left changes values.

If you are familiar with procedures that use class variables, then you see that group variables are class variables that are used in the row dimension in PROC TABULATE.

Note: You cannot always create groups. PROC REPORT cannot consolidate observations into groups if the report contains any order variables or any display variables that do not have one or more statistics associated with them. (See the COLUMN statement on page 2109.) In the interactive report window environment, if PROC REPORT cannot immediately create groups, then the procedure changes all display and order variables to group variables so that it can create the group

variable that you requested. In the nonwindowing (default) environment, it returns to the SAS log a message that explains why it could not create groups. Instead, it creates a detail report that displays group variables the same way as it displays order variables. Even when PROC REPORT creates a detail report, the variables that you define as group variables retain that usage in their definitions.

See "Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183.

Analysis Variables

An analysis variable is a numeric variable that is used to calculate a statistic for all the observations represented by a cell of the report. (Across variables, in combination with group variables or order variables, determine which observations a cell represents.) You associate a statistic with an analysis variable in the variable's definition or in the COLUMN statement. By default, PROC REPORT uses numeric variables as analysis variables that are used to calculate the Sum statistic.

The value of an analysis variable depends on where it appears in the report:

- In a detail report, the value of an analysis variable in a detail row is the value of the statistic associated with that variable calculated for a single observation. Calculating a statistic for a single observation is not practical. However, using the variable as an analysis variable enables you to create summary lines for sets of observations or for all observations.
- In a summary report, the value displayed for an analysis variable is the value of the statistic that you specify calculated for the set of observations represented by that cell of the report.
- In a summary line for any report, the value of an analysis variable is the value of the statistic that you specify calculated for all observations represented by that cell of the summary line.

For more information, see the "BREAK Statement" on page 2097 and "RBREAK Statement" on page 2134 statements.

For examples, refer to "Example 2: Ordering the Rows in a Report" on page 2174, "Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177, "Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183, and "Example 6: Creating a Column for Each Value of a Variable" on page 2187.

Note: Be careful when you use SAS dates in reports that contain summary lines. SAS dates are numeric variables. Unless you explicitly define dates as some other type of variable (ORDER, GROUP, or DISPLAY), PROC REPORT summarizes them.

Across Variables

PROC REPORT creates a column for each value of an across variable. PROC REPORT orders the columns by the ascending, formatted values of the across variable. You can change the default order with ORDER= and DESCENDING in the DEFINE statement. If no other variable helps define the column, then PROC REPORT displays the N statistic (the number of observations in the input data set that belong to that cell of the report.) See the COLUMN statement on page 2109.

Note: When a display variable and an across variable share a column, the report must also contain another variable that is not in the same column. When referring to columns created by an across variable, you must use the _cn_ syntax.

If you are familiar with procedures that use class variables, then you see that across variables are like class variables that are used in the column dimension with PROC TABULATE. Generally, you use Across variables in conjunction with order or group variables. For an example, see "Example 6: Creating a Column for Each Value of a Variable" on page 2187.

Computed Variables

Computed variables are variables that you define for the report. They are not in the input data set, and PROC REPORT does not add them to the input data set. However, computed variables are included in an output data set if you create one.

You add a computed variable by

- including the computed variable in the COLUMN statement
- defining the variable's usage as COMPUTED in the DEFINE statement
- computing the value of the variable in a compute block associated with the variable

For examples, refer to "Example 6: Creating a Column for Each Value of a Variable" on page 2187, "Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195, and "Example 10: Creating an Output Data Set and Storing Computed Variables" on page 2202.

Interactions of Position and Usage

The position and usage of each variable in the report determine the report's structure and content. PROC REPORT orders the rows of the report according to the formatted values of order and group variables, considered from left to right as specified in the COLUMN statement. Similarly, PROC REPORT orders columns for an across variable from left to right, according to the values of the variable.

Several items can collectively define the contents of a column in a report. For example, in the following figure, the values that appear in the third and fourth columns are collectively determined by Sales, an analysis variable, and by Department, an across variable. You create this type of report with the COLUMN statement or, in the interactive report window environment, by placing report items above or below each other. This arrangement is called stacking items in the report because each item generates a heading, and the headings are stacked one above the other.

```
options nodate pageno=1 fmtsearch=(proclib);
proc report data=grocery split='*';
   column sector manager department,sales perish;
   define sector / group format=$sctrfmt. 'Sector' '';
   define manager / group format=$mgrfmt. 'Manager* ';
   define department/ across format=$deptfmt. '_Department_';
   define sales / analysis sum format=dollar11.2 ' ';
   define perish / computed format=dollar11.2 'Perishable Total';
   break after manager / skip;
   compute perish;
      perish=_c3_+_c4_;
   endcomp;
   title "Sales Figures for Perishables in Northern Sectors";
   where sector contains 'n' and (department='p1' or department='p2');
run;
title;
```

Figure 58.7 *Stacking Department and Sales*

Sales Figures for Perishables in Northern Sectors

Sector	Manager	_____Department_____ Meat/Dairy	Produce	Perishable Total
Northeast	Aloma r	$190.00	$86.00	$276.00
	Andrews	$300.00	$125.00	$425.00
Northwest	Brown	$250.00	$73.00	$323.00
	Pelfrey	$205.00	$76.00	$281.00
	Reveiz	$600.00	$30.00	$630.00

When you use multiple items to define the contents of a column, at most one of the following can be in a column:

- a display variable with or without a statistic above or below it
- an analysis variable with or without a statistic above or below it
- an order variable
- a group variable
- a computed variable

More than one of these items in a column creates a conflict for PROC REPORT about which values to display.

The following table shows which report items can share a column.

Note: You cannot stack order variables with other report items.

Table 58.1 *Report Items That Can Share Columns*

	Display	Analysis	Order	Group	Computed	Across	Statistic
Display						X*	X
Analysis						X	X
Order							
Group						X	
Computed variable						X	
Across	X*	X			X	X	X
Statistic	X	X				X	

*When a display variable and an across variable share a column, the report must also contain another variable that is not in the same column.

When a column is defined by stacked report items, PROC REPORT formats the values in the column by using the format that is specified for the lowest report item in the stack that does not have an ACROSS usage.

The following items can stand alone in a column:

- display variable
- analysis variable
- order variable
- group variable
- computed variable
- across variable
- N statistic

Note: The values in a column that is occupied only by an across variable are frequency counts.

Using Compute Blocks

What Is a Compute Block?

A **compute block** is one or more programming statements that appear between a COMPUTE statement and an ENDCOMP statement. Between these two statements, you can use other SAS statements (assignment, CALL DEFINE, and LINE statements) that customize your output. PROC REPORT processes a data set by reading the variables in the order in which they appear from left to right in the COLUMN statement. The procedure builds the report one column and one row at a time, and COMPUTE statements are executed as the report is built.

You create a compute block with the COMPUTE statement. A COMPUTE statement can contain a number of arguments of the following types:

report-item
A report item can be a data set variable, a statistic, or a computed variable.

location
Specifies at what point in the process the compute block executes in relation to the value for *target*. The location can be at the top or bottom of the report; before or after a set of observations.

target
Controls when the compute block executes. You can specify a *target* if you specify a location (BEFORE or AFTER) for the COMPUTE statement. A target can be a group or order variable or a _PAGE_ variable.

Note: When you use the COMPUTE statement, you do not have to use a corresponding BREAK or RBREAK statement. See "Using Break Lines" on page 2066. Also see "Example 2: Ordering the Rows in a Report" on page 2174, which uses COMPUTE AFTER but does not use the RBREAK statement. Use these statements only when you want to implement one or more BREAK statement or RBREAK statement options. See "Example 7: Writing a Customized Summary on Each Page" on page 2190, which uses both COMPUTE AFTER MANAGER and BREAK AFTER MANAGER.)

For an in-depth look at Using a Compute Block, refer to The REPORT Procedure: A Primer for the Compute Block .

The Purpose of Compute Blocks

A compute block that is associated with a report item can perform the following tasks:

- define a variable that appears in a column of the report but is not in the input data set.
- define display attributes for a report item. (See “CALL DEFINE Statement” on page 2105.)
- define or change the value for a report item, such as showing the word “Total” on a summary line.

A compute block that is associated with a location can write a customized summary.

In addition, all compute blocks can use most SAS language elements to perform calculations. (See “The Contents of Compute Blocks” on page 2062.) A PROC REPORT step can contain multiple compute blocks, but they cannot be nested.

The Contents of Compute Blocks

A compute block begins with a COMPUTE statement and ends with an ENDCOMP statement. Within a compute block, you can use these SAS language elements:

- %INCLUDE statement
- these DATA step statements:

ARRAY	END
array-reference	IF-THEN/ELSE
assignment	LENGTH
CALL	RETURN
CONTINUE	sum
DO (all forms) END	

- comments
- null statements
- macro variables and macro invocations
- all DATA step functions

Within a compute block, you can also use these PROC REPORT features:

- Compute blocks for a customized summary can contain one or more LINE statements, which place customized text and formatted values in the summary. (See the “LINE Statement” on page 2132.)
- Compute blocks for a report item can contain one or more CALL DEFINE statements, which set attributes like color and format each time a value for the item is placed in the report. (See the “CALL DEFINE Statement” on page 2105.)
- Any compute block can reference the automatic variable _BREAK_. (See “The Automatic Variable _BREAK_” on page 2068.)

Four Ways to Reference Report Items in a Compute Block

A compute block can reference any report item that forms a column in the report (whether the column is visible). You reference report items in a compute block in one of four ways:

- by name.
- by a compound name that identifies both the variable and the name of the statistic that you calculate with it. A compound name has this form

variable-name.statistic

- by an alias that you create in the COLUMN statement or in the DEFINITION window.
- by column number, in the form

'_C*n*_'

where *n* is the number of the column (from left to right) in the report.

Note: The only time a column number is necessary is when a COMPUTED variable is sharing a column with an ACROSS variable.

Note: Even though the columns that you define with NOPRINT and NOZERO do not appear in the report, you must count them when you are referencing columns by number. See the discussion of "NOPRINT" on page 2125 and "NOZERO" on page 2126.

Note: Referencing variables that have missing values leads to missing values. If a compute block references a variable that has a missing value, then PROC REPORT displays that variable as a blank (for character variables) or as a period (for numeric variables).

The following table shows how to use each type of reference in a compute block.

Variable Type	Referenced By	Example
Group	Name*	Department
Order	Name*	Department
Computed	Name*	Department
Display	Name*	Department

Variable Type	Referenced By	Example
Display sharing a column with a statistic	A compound name*	Sales.sum
Analysis	A compound name*	Sales.mean
Any type sharing a column with an across variable	Column number **	'_c3_'

*If the variable has an alias, then you must reference it with the alias.

**Even if the variable has an alias, you must reference it by column number.

Refer to "Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177, which references analysis variables by their aliases; "Example 6: Creating a Column for Each Value of a Variable" on page 2187, which references variables by column number; and "Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195, which references group variables and computed variables by name.

Compute Block Processing

In general, compute blocks are executed in the following order:

1. COMPUTE report-item;
2. COMPUTE BEFORE;
3. COMPUTE BEFORE target;
4. COMPUTE BEFORE _PAGE_;
5. COMPUTE AFTER;
6. COMPUTE AFTER target;
7. COMPUTE AFTER _PAGE_;

The COMPUTE statement's behavior is dependent on the arguments that you include. The following syntax and behavior explains the actions of the compute block based on specific arguments in the COMPUTE statement.

Note: PROC REPORT assigns values to the columns in a row of a report from left to right. Consequently, you cannot base the calculation of a computed variable on any variable that appears to its right in the report. For information about how PROC REPORT (in general) builds a report, see Results: REPORT Procedure on page 2158.

COMPUTE *report-item*;

When you include the *report-item* argument, the compute block executes on every observation when that particular column is processed. In general, this statement is used for a specific *report-item* column so that you can calculate a value, change a value, change a format, apply style attributes, or create a temporary variable.

COMPUTE BEFORE;

With this syntax, the compute block is executed before the first detail row. The block is executed only once. Overall summary values for the analysis variables are available in the compute block. In addition, values of temporary variables that are created in this block are available to other compute blocks. Values for group or order variables are not available in this block. Text that is generated by LINE statements appears below the headers and above the first detail row in the report. CALL DEFINE statements set attributes on rows that are created by an RBREAK BEFORE statement.

COMPUTE BEFORE *target*;

When you use this syntax, the compute block is executed when the value of the target variable changes. In this syntax:

- *target* specifies either a group variable or an order variable.
- BEFORE is a value for *location*. This value specifies that the compute block is executed at the top (or beginning) of the section for a specific value of *target*.
- The value of the target variable for this specific section of the report is available to the compute block.
- The values of temporary variables created in this block are available to other compute blocks.
- Summary values for this specific *target* value are available to the compute block.
- CALL DEFINE statements set attributes on rows that are created by a BREAK BEFORE *target* statement.

COMPUTE BEFORE _PAGE_;

The compute block is executed once for each page. The page break can be generated either by the destination to which you send the output or by using the following BREAK statement syntax:

```
BREAK <location> <break-var> /PAGE;
```

Typically, this block outputs text by using a LINE statement. The text appears at the top of the page above the headers. However, it is still part of the table. Any variable that is listed in the LINE statement takes its value from the first detail row in the report.

COMPUTE AFTER;

The compute block is executed after the last detail row, and the block is executed only once (for each report). Overall summary values for the analysis variables are also available in the compute block. Values for group or order variables are not available in this block. Text that is generated by LINE statements appears after the last detail row in the report. This block is executed after each BY value if the PROC REPORT code contains a BY statement. CALL DEFINE statements set attributes on rows created by an RBREAK AFTER statement.

COMPUTE AFTER *target*;

With this syntax, the compute block is executed when the value of the target (break) variable changes. In this syntax:

- *target* specifies a variable that is defined as either a group variable or an order variable.
- AFTER is a value for *location*. This value specifies that the compute block is executed at the bottom (or end) of the section for a specific value of *target*.
- The value of the target variable for this specific section of the report is available to the compute block.
- Summary values for this specific *target* value are available to the compute block.
- CALL DEFINE statements set attributes on rows created by a BREAK AFTER *target* statement.

COMPUTE AFTER _PAGE_;

The compute block is executed once for each page. The page break can be generated either by the destination to which you send the output or by using the following BREAK statement syntax:

```
BREAK <location> <break-var> /PAGE;
```

Any variable that is listed in the LINE statement takes its value from the last detail row in the report. The text is placed at the end of the table, but it is still part of the table.

Note: The exact location of the text might change for each page, based on the amount of information that is output to each page. The text is placed on the last page of a table if it spans multiple pages.

Using Break Lines

What Are Break Lines?

Break lines are lines of text (including blanks) that appear at particular locations, called **breaks**, in a report. A report can contain multiple breaks. Generally, break lines are used to visually separate parts of a report, to summarize information, or both. They can occur in the following locations:

- at the beginning or end of a report
- at the top or bottom of each page
- between sets of observations (whenever the value of a group or order variable changes)

Break lines can contain the following items:

- text
- values calculated for either a set of rows or for the whole report

Creating Break Lines

There are two ways to create break lines. The first way is simpler. It produces a default summary. The second way is more flexible. It produces a customized summary and provides a way to slightly modify a default summary. Default summaries and customized summaries can appear at the same location in a report.

Default summaries are produced with the BREAK statement, the RBREAK statement. You can use default summaries to visually separate parts of the report, to summarize information for numeric variables, or both. Options provide some control over the appearance of the break lines, but if you choose to summarize numeric variables, then you have no control over the content and the placement of the summary information. (A break line that summarizes information is a summary line.)

Customized summaries are produced in a compute block. You can control both the appearance and content of a customized summary, but you must write the code to do so.

Order of Break Lines

You control the order of the lines in a customized summary. However, PROC REPORT controls the order of lines in a default summary and the placement of a customized summary relative to a default summary. When a default summary contains multiple break lines, the order in which the break lines appear is as follows:

1. summary line
2. page break

For LISTING output, the order in which the break lines appear is as follows:

1. overlining or double overlining (in LISTING output only)
2. summary line
3. underlining or double underlining
4. blank line (in LISTING output only)
5. page break

If you define a customized summary for the same location, then customized break lines appear after underlining or double underlining. This occurs only in LISTING output.

The Automatic Variable _BREAK_

PROC REPORT automatically creates a variable called _BREAK_. This variable contains the following:

- a blank if the current line is not part of a break
- the value of the break variable if the current line is part of a break between sets of observations
- the value **_RBREAK_** if the current line is part of a break at the beginning or end of the report
- the value **_PAGE_** if the current line is part of a break at the beginning or end of a page

Using Compound Names

When you use a statistic in a report, you generally refer to it in compute blocks by a compound name like Sales.sum. However, in different parts of the report, that same name has different meanings. Consider the report in the following output. The statements that create the output follow. The user-defined formats that are used are created by a PROC FORMAT step on page 2173.

```
libname proclib
'SAS-library';

options nodate pageno=1 fmtsearch=(proclib);
proc report data=grocery;
   column sector manager sales;
   define sector / group format=$sctrfmt.;
   define sales  / analysis sum
                   format=dollar9.2;
   define manager / group format=$mgrfmt.;
   break after sector / summarize;
   rbreak after / summarize;
   compute after;
      sector='Total:';
   endcomp;
run;
```

Example Code 58.1 *Three Different Meanings of Sales.sum*

```
                          The SAS System
1

                Sector     Manager      Sales
                Northeast  Alomar     $786.00     1
                           Andrews  $1,045.00
                ---------             ---------
                Northeast             $1,831.00     2

                Northwest  Brown      $598.00
                           Pelfrey    $746.00
                           Reveiz   $1,110.00
                ---------             ---------
                Northwest             $2,454.00

                Southeast  Jones      $630.00
                           Smith      $350.00
                ---------             ---------
                Southeast                $980.00

                Southwest  Adams      $695.00
                           Taylor     $353.00
                ---------             ---------
                Southwest             $1,048.00

                =========             =========
                Total:                $6,313.00     3
                =========             =========
```

Here Sales.sum has three different meanings:

1. In detail rows, the value is the sales for one manager's store in a sector of the city. For example, the first detail row of the report shows that the sales for the store that Alomar manages were $786.00.
2. In the group summary lines, the value is the sales for all the stores in one sector. For example, the first group summary line shows that sales for the Northeast sector were $1,831.00.
3. In the report summary line, the value $6,313.00 is the sales for all stores in the city.

Note: When you refer in a compute block to a statistic that has an alias, do not use a compound name. Generally, you must use the alias. However, if the statistic shares a column with an across variable, then you must reference it by column number. (See "Four Ways to Reference Report Items in a Compute Block" on page 2063.)

ODS Destinations Supported by PROC REPORT

PROC REPORT supports all ODS destinations. For more information, see "Understanding ODS Destinations" in *SAS Output Delivery System: User's Guide* .

The PROC REPORT STYLE= option supports all ODS destinations except LISTING and OUTPUT. For more information, see "Using ODS Styles with PROC REPORT" on page 2142.

PROC REPORT supports the ODS DOCUMENT procedure. The DOCUMENT destination enables you to restructure, navigate, and replay your data in different ways and to different destinations without rerunning your analysis or repeating your database query. The DOCUMENT destination makes your entire output stream available in "raw" form and accessible to you to customize. The output is kept in the original internal representation as a data component plus a table definition. For more information, see "DOCUMENT Procedure" in *SAS Output Delivery System: Procedures Guide*.

PROC REPORT supports the OUTPUT destination for SAS output data sets. Because ODS already knows the logical structure of the data and its native form, ODS can output a SAS data set that represents exactly the same resulting data set that the procedure worked with internally. For more information, see "ODS OUTPUT Statement" in *SAS Output Delivery System: User's Guide*.

Threaded Processing of Input DATA Sets

The THREAD option enables or disables parallel processing of the input data set. Threaded processing achieves a degree of parallelism in the processing operations. This parallelism is intended to reduce the real time to completion for a given operation and therefore limit the cost of additional CPU resources. For more information, see "Support for Parallel Processing" in *SAS Language Reference: Concepts*.

The value of the SAS system option CPUCOUNT= affects the performance of the threaded sort. CPUCOUNT= suggests how many system CPUs are available for use by the threaded procedures.

For more information, see the "THREADS System Option" in *SAS System Options: Reference* and the "CPUCOUNT= System Option" in *SAS System Options: Reference*.

Calculated statistics can vary slightly, depending on the order in which observations are processed. Such variations are due to numerical errors that are introduced by floating–point arithmetic, the results of which should be considered approximate and not exact. The order of observation processing can be affected by nondeterministic effects of multithreaded or parallel processing. The order of processing can also be affected by inconsistent or nondeterministic ordering of observations that are produced by a data source, such as a DBMS that delivers query results through an ACCESS engine. For more information, see "Numerical Accuracy in SAS Software" in *SAS Language Reference: Concepts* and "Threading in Base SAS" in *SAS Language Reference: Concepts*.

Syntax: REPORT Procedure

Restriction: PROC REPORT does not support VARCHAR data types.

Accessibility note: Starting with SAS 9.4M6, you can use the ACCESSIBLECHECK and ACCESSIBLETABLE system options. ACCESSIBLETABLE changes the layout of some tables to make them accessible and adds visual captions to tables. ACCESSIBLECHECK checks to see if the table is accessible and outputs information to the SAS log. For more information, see "Overview of Table Accessibility " in *Creating Accessible SAS Output Using ODS and ODS Graphics* .

Starting with SAS 9.4M6, you can use the ACCESSIBLETABLE system option along with the CAPTION= option and the CONTENTS= option to see visible captions for tables and visible changes in the Table of Contents using By directives.

Accessibility note: Starting with SAS 9.4M6, you can use the ACCESSIBLETABLE system option along with the CAPTION= option and the CONTENTS= option to see visible captions for tables and visible changes in the Table of Contents using By directives.

Tips: Supports the Output Delivery System. For details, see "Output Delivery System: Basic Concepts" in *SAS Output Delivery System: User's Guide*.

You can use the ATTRIB, FORMAT, LABEL, and WHERE statements with the PROC SORT procedure. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

For in-database processing to occur, your data must reside within a supported version of a DBMS that has been properly configured for SAS in-database processing. For more information, see "In-Database Processing for PROC REPORT" on page 2154.

PROC REPORT<*options*>;
  BREAK *location break-variable* </ *options*>
  BY *variable-1*
    <<DESCENDING> *variable-2* ...> <NOTSORTED>;
  COLUMN*column-specification(s)*;
    COMPUTE *location* <*target*>
      </ STYLE=<*style-override(s)*> >;
        LINE *specification(s)*;
        . . . select SAS language elements . . .
        ENDCOMP;
    COMPUTE *report-item* </ *type-specification*>;
        CALL DEFINE (*column-id* ', < ' *attribute-name*', *value*>
          | _ROW_, < '*attribute-name*', *value*>);
        . . . select SAS language elements . . .
        ENDCOMP;
  DEFINE *report-item* / <*options*>;

FREQ *variable*;

RBREAK *location* </ *options*>;

WEIGHT *variable*;

Statement	Task	Example
PROC REPORT	Produce a summary or detail report	Ex. 1, Ex. 2, Ex. 6, Ex. 4, Ex. 9, Ex. 10, Ex. 13
BREAK	Produce a default summary at a change in the value of a group or order variable	Ex. 2, Ex. 5, Ex. 6, Ex. 7
BY	Create a separate report for each BY group	
CALL DEFINE	Set the value of an attribute for a particular column in the current row	Ex. 5, Ex. 13
COLUMN	Describe the arrangement of all columns and of headings that span more than one column	Ex. 1, Ex. 3, Ex. 6, Ex. 4, Ex. 8, Ex. 9
COMPUTE	Specify one or more programming statements that PROC REPORT executes as it builds the report	Ex. 2, Ex. 3, Ex. 5, Ex. 6, Ex. 7, Ex. 8, Ex. 10, Ex. 13
ENDCOMP	Specify one or more programming statements that PROC REPORT executes as it builds the report	Ex. 2
DEFINE	Describe how to use and display a report item	Ex. 2, Ex. 3, Ex. 5, Ex. 6, Ex. 4, Ex. 7, Ex. 8, Ex. 10, Ex. 10, Ex. 11, Ex. 13
FREQ	Treat observations as if they appear multiple times in the input data set	
LINE	Provide a subset of features of the PUT statement for writing customized summaries	Ex. 2, Ex. 3, Ex. 5, Ex. 6, Ex. 7
RBREAK	Produce a default summary at the beginning or end of a report or at the beginning and end of each BY group	Ex. 1, Ex. 8
WEIGHT	Specify weights for analysis variables in the statistical calculations	

PROC REPORT Statement

Combines features of the PRINT, MEANS, and TABULATE procedures with features of the DATA step in a single report-writing tool that can produce a variety of reports.

Examples:

"Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171

"Example 2: Ordering the Rows in a Report" on page 2174

"Example 6: Creating a Column for Each Value of a Variable" on page 2187

"Example 4: Displaying Multiple Statistics for One Variable" on page 2181

"Example 9: How PROC REPORT Handles Missing Values" on page 2198

"Example 10: Creating an Output Data Set and Storing Computed Variables" on page 2202

"Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212

"Example 14: Using the CELLWIDTH= Style Attribute with PROC REPORT" on page 2220

Syntax

PROC REPORT <*options*>;

Summary of Optional Arguments

CAPTION=*text* <#BYLINE> <#BYVAL> <#BYVAR>

DATA=*SAS-data-set*
: specifies the input data set.

NOALIAS
: uses a report that was created before compute blocks required aliases.

NOCENTER
: See CENTER | NOCENTER.

NOCOMPLETECOLS
: See COMPLETECOLS | NOCOMPLETECOLS.

NOCOMPLETEROWS
: See COMPLETEROWS | NOCOMPLETEROWS.

NOTHREADS
: See THREADS | NOTHREADS.

NOWINDOWS
: See WINDOWS | NOWINDOWS.

OUT=*SAS-data-set*
: specifies the output data set.

PCTLDEF=
See QNTLDEF=.

THREADS

NOTHREADS
overrides the SAS system option THREADS | NOTHREADS.

WINDOWS

NOWINDOWS
selects the interactive report window or the nonwindowing environment.

Control classification levels

COMPLETECOLS

NOCOMPLETECOLS
creates all possible combinations of the across variable values.

COMPLETEROWS

NOCOMPLETEROWS
creates all possible combinations of the group variable values.

Control ODS output

CONTENTS='*link-text*' <#BYLINE> <#BYVAL> <#BYVAR>
specifies text for the table of contents entry for the output.

SPANROWS
specifies that a single cell occupies the column in all the rows for which the value is the same.

STYLE<(*location(s)*)>=<*style-override(s)*>
specifies one or more style overrides to use for different parts of the report.

Control the interactive report window environment

COMMAND
displays command lines rather than menu bars in all REPORT windows.

HELP=*libref.catalog*
identifies the library and catalog containing user-defined help for the report.

PROMPT
opens the REPORT window and starts the PROMPT facility.

Control the layout of the report

BOX
uses formatting characters to add line-drawing characters to the report.

BYPAGENO=*number*
resets the page number between BY groups.

CENTER

NOCENTER
specifies whether to center or left-justify the report and summary text.

COLWIDTH=*column-width*
specifies the default number of characters for columns containing computed variables or numeric data set variables.

FORMCHAR <(*position(s)*)>='*formatting-character(s)*'

defines the characters to use as line-drawing characters in the report.

LS=*line-size*
specifies the length of a line of the report.

MISSING
considers missing values as valid values for group, order, or across variables.

PANELS=*number-of-panels*
specifies the number of panels on each page of the report.

PS=*page-size*
specifies the number of lines in a page of the report. This option affects only the LISTING output.

PSPACE=*space-between-panels*
specifies the number of blank characters between panels.

SHOWALL
overrides options in the DEFINE statement that suppress the display of a column.

SPACING=*space-between-columns*
specifies the number of blank characters between columns.

WRAP
displays one value from each column of the report, on consecutive lines if necessary, before displaying another value from the first column.

Control the statistical analysis

EXCLNPWGT
excludes observations with nonpositive weight values from the analysis.

QMARKERS=*number*
specifies the sample size to use for the P^2 quantile estimation method.

QMETHOD=OS | P2
specifies the quantile estimation method.

QNTLDEF=1 | 2 | 3 | 4 | 5
specifies the mathematical definition to calculate quantiles.

VARDEF=*divisor*
specifies the divisor to use in the calculation of variances.

Customize column headings

NAMED
writes name= in front of each value in the report, where name= is the column heading for the value.

NOHEADER
suppresses column headings.

SPLIT='*character*'
specifies the split character.

ODS Listing

HEADLINE
underlines all column headings and the spaces between them.

HEADSKIP
writes a blank line beneath all column headings.

Store and retrieve report definitions, PROC REPORT statements, and your report profile

LIST
: writes to the SAS log the PROC REPORT code that creates the current report.

NOEXEC
: suppresses the building of the report.

OUTREPT=*libref.catalog.entry*
: stores in the specified catalog the report definition that is defined by the PROC REPORT step that you submit.

PROFILE=*libref.catalog*
: identifies the report profile to use.

REPORT=*libref.catalog.entry*
: specifies the report definition to use.

Optional Arguments

BOX
uses formatting characters to add line-drawing characters to the report. These characters

- surround each page of the report
- separate column headings from the body of the report
- separate rows and columns from each other
- separate values in a summary line from other values in the same columns
- separate a customized summary from the rest of the report

Restriction: This option affects only the LISTING output. It has no affect on other ODS output.

Interaction: You cannot use BOX if you use WRAP in the PROC REPORT statement or in the ROPTIONS window or if you use FLOW in any item definition.

See: the discussion of "FORMCHAR <(*position(s)*)>='*formatting-character(s)*' " on page 2081

BYPAGENO=*number*
If a BY statement is present, specifies the page number at the start of each BY group.

Range: any positive integer greater than 0.

Restriction: This option has no effect if a BY statement is not present.

Interaction: The BYPAGENO= option also affects the ODS ESCAPECHAR THISPAGE function.

CAPTION=*text* <#BYLINE> <#BYVAL> <#BYVAR>
specifies a caption text string to add before each table. If no string is specified, the caption defaults to the text specified by the CONTENTS= option.

This option makes table captions both visual and accessible if the ACCESSIBLETABLE system option is specified.

If the NOACCESSIBLETABLE system option is specified, then no caption is displayed, however the caption text is still accessible.

Starting with SAS 9.4M6, these options are available if a BY statement is in effect:

#BYLINE
substitutes the entire BY line without leading or trailing blanks for #BYLINE in the text string. The BY line uses the format *variable-name=value*.

#BYVAL*n*
#BYVAL(*BY-variable-name*)
substitutes the current value of the specified BY variable for #BYVAL in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAL2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAL(YEAR) specifies the BY variable, YEAR. *Variable-name* is not case sensitive.

#BYVAR*n*
#BYVAR(*BY-variable-name*)
substitutes the name of the BY-variable or the label associated with the variable (whatever the BY line would normally display) for #BYVAR in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAR2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAR(SITES) specifies the BY variable, SITES. *Variable-name* is not case sensitive.

Restrictions The ACCESSIBLETABLE system option must be specified to enable captions.

The CAPTION= option is not valid in the LISTING destination.

Note This feature applies to SAS 9.4M6 and to later releases.

Tip You can use the PROC DOCUMENT OBBNOTE option to display or edit the caption.

See "Overview of Table Accessibility " in *Creating Accessible SAS Output Using ODS and ODS Graphics*

CENTER | NOCENTER

specifies whether to center or left-justify the report and summary text (customized break lines).

PROC REPORT honors the first of these centering specifications that it finds:

- the CENTER or NOCENTER option in the PROC REPORT statement or the CENTER toggle in the ROPTIONS window
- the CENTER or NOCENTER option stored in the report definition that is loaded with REPORT= in the PROC REPORT statement
- the SAS system option CENTER or NOCENTER

Interaction When CENTER is in effect, PROC REPORT ignores spacing that precedes the leftmost variable in the report.

COLWIDTH=*column-width*

specifies the default number of characters for columns containing computed variables or numeric data set variables.

When setting the width for a column, PROC REPORT first looks at WIDTH= in the definition for that column. If WIDTH= is not present, then PROC REPORT uses a column width large enough to accommodate the format for the item. If no format is associated with the item, then the column width depends on variable types as shown in the following table.

Table 58.2 *Using References in a Compute Block*

Variable	Resulting Column Width
Character variable in the input data set	Length of the variable
Numeric variable in the input data set	Value of the COLWIDTH= option
Computed variable (numeric or character)	Value of the COLWIDTH= option

For information about formats, see the discussion of "FORMAT=*format*" on page 2123.

Default 9

Range 1 to the line size

Restriction This option affects only the LISTING output. It has no affect on other ODS output. For the formatted ODS destinations, use the STYLE= option with the WIDTH=, CELLWIDTH=, or OUTPUTWIDTH= style attributes. Refer to "Style Attributes Tables" in *SAS Output Delivery System: Advanced Topics* for details. See how style attributes WIDTH= and CELLWIDTH= can be used with PROC

REPORT in "Example 14: Using the CELLWIDTH= Style Attribute with PROC REPORT" on page 2220.

COMMAND
displays command lines rather than menu bars in all REPORT windows.

After you have started PROC REPORT in the interactive report window environment, you can display the menu bars in the current window by issuing the COMMAND command. You can display the menu bars in all PROC REPORT windows by issuing the PMENU command. The PMENU command affects all the windows in your SAS session. Both of these commands are toggles.

You can store a setting of COMMAND in your report profile. PROC REPORT honors the first of these settings that it finds:

- the COMMAND option in the PROC REPORT statement
- the setting in your report profile

Restriction This option has no effect in the nonwindowing environment.

COMPLETECOLS | NOCOMPLETECOLS
creates all possible combinations for the values of the across variables even if one or more of the combinations do not occur within the input data set. Consequently, the column headings are the same for all logical pages of the report within a single BY group.

Default COMPLETECOLS

Interaction The PRELOADFMT option in the DEFINE statement ensures that PROC REPORT uses all user-defined format ranges for the combinations of across variables, even when a frequency is zero.

COMPLETEROWS | NOCOMPLETEROWS
displays all possible combinations of the values of the group variables, even if one or more of the combinations do not occur in the input data set. Consequently, the row headings are the same for all logical pages of the report within a single BY group.

Default NOCOMPLETEROWS

Interaction The PRELOADFMT option in the DEFINE statement ensures that PROC REPORT uses all user-defined format ranges for the combinations of group variables, even when a frequency is zero.

CONTENTS='*link-text*' <#BYLINE> <#BYVAL> <#BYVAR>
specifies the text for the entries in the table of contents created by default or by options settings in ODS destinations that support the STYLE= option.

Starting in SAS 9.4M6, if the ACCESSIBLETABLE system option is specified, you can use the By directives to create visual output in the Table of Contents.

Starting with SAS 9.4M6, these options are available if a BY statement is in effect:

#BYLINE
substitutes the entire BY line without leading or trailing blanks for #BYLINE in the text string. The BY line uses the format *variable-name=value*.

#BYVAL*n*
#BYVAL(*BY-variable-name*)
substitutes the current value of the specified BY variable for #BYVAL in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAL2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAL(YEAR) specifies the BY variable, YEAR. *Variable-name* is not case sensitive.

#BYVAR*n*
#BYVAR(*BY-variable-name*)
substitutes the name of the BY-variable or the label associated with the variable (whatever the BY line would normally display) for #BYVAR in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAR2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAR(SITES) specifies the BY variable, SITES. *Variable-name* is not case sensitive.

Restriction The ACCESSIBLETABLE system option must be specified to use the By Directives to create visible output text in the Table of Contents. You can use CONTENTS='*link-text*' without the ACCESSSIBLETABLE option.

Note The use of the By directives with the CONTENT= option applies to SAS 9.4M6 and to later releases.

Tip All ODS destinations except OUTPUT and LISTING support the STYLE= option.

See Creating Accessible Tables with the REPORT Procedure in *Creating Accessible SAS Output Using ODS and ODS Graphics*

DATA=*SAS-data-set*
specifies the input data set.

See "Input Data Sets" on page 26

EXCLNPWGT

excludes observations with nonpositive weight values (zero or negative) from the analysis. By default, PROC REPORT treats observations with negative weights like observations with zero weights and counts them in the total number of observations.

Alias EXCLNPWGTS

Requirement You must use a WEIGHT statement.

See "WEIGHT Statement" on page 2139

FORMCHAR <(*position(s)*)>='*formatting-character(s)*'

defines the characters to use as line-drawing characters in the report.

position(s)

identifies the position of one or more characters in the SAS formatting-character string. A space or a comma separates the positions.

Default Omitting (*position(s)*) is the same as specifying all 20 possible SAS formatting characters, in order.

Note PROC REPORT uses 12 of the 20 formatting characters that SAS provides. Table 58.107 on page 2081 shows the formatting characters that PROC REPORT uses. Figure 58.68 on page 2083 illustrates the use of some commonly used formatting character in the output from PROC REPORT.

formatting-character(s)

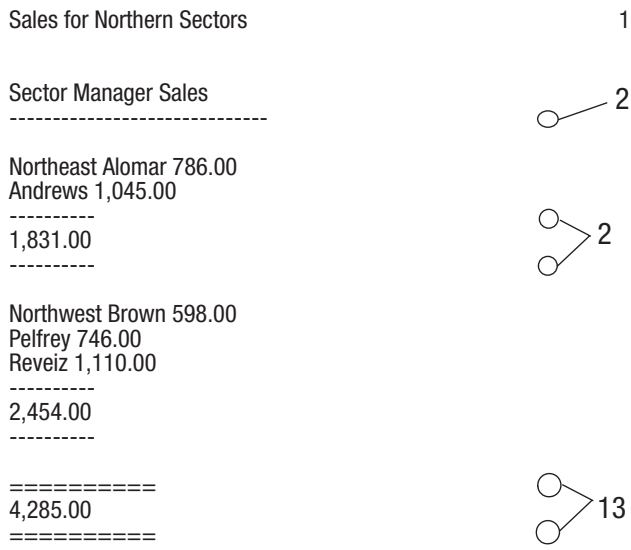
lists the characters to use for the specified positions. PROC REPORT assigns characters in *formatting-character(s)* to *position(s)*, in the order in which they are listed. For example, the following option assigns the asterisk (*) to the third formatting character, the number sign (#) to the seventh character, and does not alter the remaining characters: `formchar(3,7)='*#'`

Table 58.3 *Formatting Characters Used by PROC REPORT*

Position	Default	Used to Draw
1	|	Right and left borders and the vertical separators between columns
2	-	Top and bottom borders and the horizontal separators between rows. Also, underlining and overlining in break lines as well as the underlining that the HEADLINE option draws

3	-	Top character in the left border
4	-	Top character in a line of characters that separates columns
5	-	Top character in the right border
6	|	Leftmost character in a row of horizontal separators
7	+	Intersection of a column of vertical characters and a row of horizontal characters
8	|	Rightmost character in a row of horizontal separators
9	-	Bottom character in the left border
10	-	Bottom character in a line of characters that separate columns
11	-	Bottom character in the right border
13	=	Double overlining and double underlining in break lines

Figure 58.8 *Formatting Characters in PROC REPORT Output*



Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction The SAS system option FORMCHAR= specifies the default formatting characters. The system option defines the entire string of formatting characters. The FORMCHAR= option in a procedure can redefine selected characters.

Tip You can use any character in *formatting-characters*, including hexadecimal characters. If you use hexadecimal characters, then you must put `x` after the closing quotation mark. For example, the following option assigns the hexadecimal character 2-D to the third formatting character, the hexadecimal character 7C to the seventh character, and does not alter the remaining characters:

```
formchar(3,7)='2D7C'x
```

HEADLINE

underlines all column headings and the spaces between them at the top of each page of the report.

The HEADLINE option underlines with the second formatting character. (See the discussion of "FORMCHAR <(*position(s)*)>='*formatting-character(s)*' " on page 2081.)

Default hyphen (-)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Tip In LISTING output, you can underline column headings without underlining the spaces between them, by using two hyphens `('--')` as the last line of each column heading instead of using HEADLINE.

HEADSKIP
writes a blank line beneath all column headings (or beneath the underlining that the HEADLINE option writes) at the top of each page of the report.

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

HELP=*libref.catalog*
identifies the library and catalog containing user-defined help for the report. This help can be in CBT or HELP catalog entries. You can write a CBT or HELP entry for each item in the report with the BUILD procedure in SAS/AF software. Store all such entries for a report in the same catalog.

Specify the entry name for help for a particular report item in the DEFINITION window for that report item or in a DEFINE statement.

Restriction This option works only in the Report Window.

LIST
writes to the SAS log the PROC REPORT code that creates the current report.

This listing might differ in these ways from the statements that you submit:

- It shows some defaults that you might not have specified.
- It omits some statements that are not specific to the REPORT procedure, whether you submit them with the PROC REPORT step or had previously submitted them. These statements include

BY FOOTNOTE FREQ TITLE WEIGHT WHERE

- It omits these PROC REPORT statement options:

LIST
OUT=
OUTREPT=
PROFILE=
REPORT=
WINDOWS | NOWINDOWS

- It includes these style(<*location*>)= options:

CENTER SPACING
HEADER USAGE
LEFT WIDTH
RIGHT

Note: WIDTH and SPACING are LISTING only.

- It omits SAS system options.
- It resolves automatic macro variables.

Restriction The LIST option does not support styles by columns if you specify style(column)= in the DEFINE statement.

LS=*line-size*
specifies the length of a line of the report.

PROC REPORT honors the line size specifications that it finds in the following order of precedence:

- the LS= option in the PROC REPORT statement or LINESIZE= in the ROPTIONS window
- the LS= setting stored in the report definition loaded with REPORT= in the PROC REPORT statement
- the SAS system option LINESIZE=

Note: The PROC REPORT LS= option takes precedence over all other line size options.

Range 64-256 (integer)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

MISSING
considers missing values as valid values for group, order, or across variables. Special missing values used to represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a different value. A group for each missing value appears in the report. If you omit the MISSING option, then PROC REPORT does not include observations with a missing value for any group, order, or across variables in the report.

See The "Missing Values" in *SAS Language Reference: Concepts*.

Example "Example 9: How PROC REPORT Handles Missing Values" on page 2198

NAMED
writes *name*= in front of each value in the report, where *name* is the column heading for the value.

Interaction When you use the NAMED option, PROC REPORT automatically uses the NOHEADER option.

Tip Use NAMED in conjunction with the WRAP option to produce a report that wraps all columns for a single row of the report onto consecutive lines rather than placing columns of a wide report on separate pages.

NOALIAS
lets you use a report that was created before compute blocks required aliases. If you use NOALIAS, then you cannot use aliases in compute blocks.

NOCENTER
See "CENTER|NOCENTER " on page 2078.

NOCOMPLETECOLS
See "COMPLETECOLS|NOCOMPLETECOLS" on page 2079.

NOCOMPLETEROWS
See "COMPLETEROWS|NOCOMPLETEROWS" on page 2079.

NOEXEC
suppresses the building of the report. Use NOEXEC with OUTREPT= to store a report definition in a catalog entry. Use NOEXEC with LIST and REPORT= to display a listing of the specified report definition.

Alias NOEXECUTE

NOHEADER
suppresses column headings, including headings that span multiple columns.

When you suppress the display of column headings in the interactive report window environment, you cannot select any report items.

NOTHREADS
See "THREADS|NOTHREADS" on page 2095.

NOWINDOWS
See "WINDOWS|NOWINDOWS " on page 2096.

Alias NOWD

Default The default mode is now the nonwindowing environment. You no longer have to specify NOWINDOWS or NOWD.

OUT=*SAS-data-set*
names the output data set. If this data set does not exist, then PROC REPORT creates it. The data set contains one observation for each report row and one observation for each unique summary line. If you use both customized and default summaries at the same place in the report, then the output data set contains only one observation because the two summaries differ only in how they present the data. Information about customization (underlining, color, text, and so on) is not data and is not saved in the output data set.

The output data set contains one variable for each column of the report. PROC REPORT tries to use the name of the report item as the name of the corresponding variable in the output data set. However, it cannot perform this substitution if a data set variable is under or over an across variable or if a data set variable appears multiple times in the COLUMN statement without aliases. In these cases, the name of the variable is based on the column number (_C1_, _C2_, and so on).

Output data set variables that are derived from input data set variables retain the formats of their counterparts in the input data set. PROC REPORT derives labels for these variables from the corresponding column headings in the report unless the only item defining the column is an across variable. In that case, the variables have no label. If multiple items are stacked in a column, then the labels of the corresponding output data set variables come from the analysis variable in the column.

The output data set also contains a character variable named _BREAK_. If an observation in the output data set derives from a detail row in the report, then

the value of _BREAK_ is missing or blank. If the observation derives from a summary line, then the value of _BREAK_ is the name of the break variable that is associated with the summary line, or **_RBREAK_**. If the observation derives from a COMPUTE BEFORE _PAGE_ or COMPUTE AFTER _PAGE_ statement, then the value of _BREAK_ is **_PAGE_**. Note, however, that for COMPUTE BEFORE _PAGE_ and COMPUTE AFTER _PAGE_, the **_PAGE_** value is written only to the output data set; it is not available as a value of the automatic variable _BREAK_ during execution of the procedure.

Tip An output data set can be created by using an ODS OUTPUT statement. The data set created by ODS OUTPUT is the same as the one created by the OUT= option. Refer to the "ODS OUTPUT Statement" in *SAS Output Delivery System: User's Guide*.

Examples "Example 10: Creating an Output Data Set and Storing Computed Variables" on page 2202

"Example 10: Creating an Output Data Set and Storing Computed Variables" on page 2202

OUTREPT=*libref.catalog.entry*

stores in the specified catalog entry the REPORT definition that is defined by the PROC REPORT step that you submit. PROC REPORT assigns the entry a type of REPT.

The stored report definition might differ in these ways from the statements that you submit:

- It omits some statements that are not specific to the REPORT procedure, whether you submit them with the PROC REPORT step or whether they are already in effect when you submit the step. These statements include

BY	TITLE
FOOTNOTE	WEIGHT
FREQ	WHERE

- It includes these PROC REPORT statement options. Others are omitted.

BOX	NOHEADER
CENTER	PAGESIZE
COLWIDTH	PANELS
COMPLETECOLS	PCTLDEF
COMPLETEROWS	PSPACE
FORMCHAR	QMARKERS
HEADLINE	QMETHOD
HEADSKIP	SHOWALL
HELP	SPACING
LINESIZE	SPLIT
MISSING	VARDEF
NAMED	WRAP

- It omits SAS system options.

- It resolves automatic macro variables.

PANELS=*number-of-panels*
specifies the number of panels on each page of the report. If the width of a report is less than half of the line size, then you can display the data in multiple sets of columns so that rows that would otherwise appear on multiple pages appear on the same page. Each set of columns is a *panel*. A familiar example of this type of report is a telephone book, which contains multiple panels of names and telephone numbers on a single page.

When PROC REPORT writes a multipanel report, it fills one panel before beginning the next.

The number of panels that fits on a page depends on the following:

- width of the panel
- space between panels
- line size

Default 1

Note This option affects only the LISTING output. It has no affect on other ODS output. However, the COLUMNS= option in the ODS PRINTER, ODS PDF, and ODS RTF statements produces similar results. For details, see the statements in *SAS Output Delivery System: User's Guide*.

Tip If *number-of-panels* is larger than the number of panels that can fit on the page, then PROC REPORT creates as many panels as it can. Let PROC REPORT put your data in the maximum number of panels that can fit on the page by specifying a large number of panels (for example, 99).

See For information about the space between panels and the line size, see the discussions of PSPACE= on page 2090 and the discussion of LS= on page 2085.

PCTLDEF=
See QNTLDEF= on page 2090.

PROFILE=*libref.catalog*
identifies the report profile to use. A report profile does the following:

- specifies the location of menus that define alternative menu bars and menus for the REPORT and COMPUTE windows
- sets defaults for WINDOWS, PROMPT, and COMMAND

PROC REPORT uses the entry REPORT.PROFILE in the catalog that you specify as your profile. If no such entry exists, or if you do not specify a profile, then PROC REPORT uses the entry REPORT.PROFILE in SASUSER.PROFILE. If you have no profile, then PROC REPORT uses default menus and the default settings of the options.

You create a profile from the PROFILE window while using PROC REPORT in an interactive report window environment. To create a profile:

- Invoke PROC REPORT with the WINDOWS option.
- Select **Tools** ⇨ **Report Profile**.
- Fill in the fields to meet your needs.
- Select **OK** to exit the PROFILE window. When you exit the window, PROC REPORT stores the profile in SASUSER.PROFILE.REPORT.PROFILE. Use the CATALOG procedure or the Explorer window to copy the profile to another location.

Note: If, after opening the PROFILE window, you decide not to create a profile, then select **CANCEL** to close the window.

PROMPT

opens the REPORT window and starts the PROMPT facility. This facility guides you through creating a new report or adding more data set variables or statistics to an existing report.

If you start PROC REPORT with prompting, then the first window gives you a chance to limit the number of observations that are used during prompting. When you exit the prompter, PROC REPORT removes these limits:

- the PROMPT option in the PROC REPORT statement
- the setting in your report profile

If you omit PROMPT from the PROC REPORT statement, then the procedure uses the setting in your report profile, if you have one. If you do not have a report profile, then PROC REPORT does not use the prompt facility. For information about report profiles, see "PROFILE Window" on page 2246.

Restriction When you use the PROMPT option, you open the REPORT window. When the REPORT window is open, you cannot send procedure output to any ODS destination.

Tip You can store a setting of PROMPT in your report profile. PROC REPORT honors the first of these settings that it finds.

PS=*page-size*

specifies the number of lines in a page of the report.

PROC REPORT honors the first of these page size specifications that it finds:

- the PS= option in the PROC REPORT statement
- the PS= setting in the report definition specified with REPORT= in the PROC REPORT statement
- the SAS system option PAGESIZE=

Range 15-32,767 (integer)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

PSPACE=*space-between-panels*
specifies the number of blank characters between panels. PROC REPORT separates all panels in the report by the same number of blank characters. For each panel, the sum of its width and the number of blank characters separating it from the panel to its left cannot exceed the line size.

Default 4

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

QMARKERS=*number*
specifies the default number of markers to use for the P^2 estimation method. The number of markers controls the size of fixed memory space.

Default The default value depends on which quantiles you request. For the median (P50), *number* is 7. For the quartiles (P25 and P75), *number* is 25. For the quantiles P1, P5, P10, P90, P95, or P99, *number* is 105. If you request several quantiles, then PROC REPORT uses the largest default value of *number*.

Range any odd integer greater than 3

Tip Increase the number of markers above the default settings to improve the accuracy of the estimates; you can reduce the number of markers to conserve computing resources.

QMETHOD=OS | P2
specifies the method that PROC REPORT uses to process the input data when it computes quantiles. If the number of observations is less than or equal to the value of the QMARKERS= option, and the value of the QNTLDEF= option is 5, then both methods produce the same results.

OS
uses order statistics. PROC UNIVARIATE uses this technique.

Note: This technique can be very memory intensive.

P2
uses the P^2 method to approximate the quantile.

Default OS

Restriction When QMETHOD=P2, PROC REPORT does not compute MODE and weighted quantiles.

Tip When QMETHOD=P2, reliable estimates of some quantiles (P1, P5, P95, P99) might not be possible for some data sets such as data sets with heavily tailed or skewed distributions.

QNTLDEF=1 | 2 | 3 | 4 | 5
specifies the mathematical definition that the procedure uses to calculate quantiles when the value of the QMETHOD= option is OS. When QMETHOD=P2, you must use QNTLDEF=5.

Alias PCTLDEF=

Default 5

See "Quantile and Related Statistics" on page 2706

REPORT=*libref.catalog.entry*
specifies the report definition to use. PROC REPORT stores all report definitions as entries of type REPT in a SAS catalog.

Interaction If you use REPORT=, then you cannot use the COLUMN statement.

See "OUTREPT=*libref.catalog.entry*" on page 2087

SHOWALL
overrides options in the DEFINE statement that suppress the display of a column.

See NOPRINT and NOZERO in "DEFINE Statement" on page 2116

SPACING=*space-between-columns*
specifies the number of blank characters between columns. For each column, the sum of its width and the blank characters between it and the column to its left cannot exceed the line size.

Default 2

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interactions PROC REPORT separates all columns in the report by the number of blank characters specified by SPACING= in the PROC REPORT statement unless you use SPACING= in the DEFINE statement to change the spacing to the left of a specific item.

When CENTER is in effect, PROC REPORT ignores spacing that precedes the leftmost variable in the report.

SPANROWS
specifies that when the value of a GROUP or ORDER column is the same in multiple rows, the value is displayed in a single cell that occupies that column in all the rows for which the value is the same. A box is essentially created for that part of the column, and no rows appear in that box.

The SPANROWS option also allows GROUP and ORDER variables values to repeat when the values break across pages. Only the PDF, PS, and TAGSETS.RTF destinations support this part of the feature.

Notes The SPANROWS option has no effect on the Report Window, data sets, LISTING, or OUTPUT destinations.

When the LINE statement occurs at the bottom of a page, the GROUP and ORDER variables values do not repeat when the values break across RTF and TAGSETS.RTF pages.

Tip If a summary row appears in the middle of a set of rows that would otherwise be spanned by a single cell, the summary row introduces its own cell in that column. This action breaks the spanning cell into two cells even when the value of the GROUP or ORDER variable that comes after the summary row is unchanged.

SPLIT='*character*'
specifies the split character. PROC REPORT breaks column text when it reaches that character and continues the text on the next line. The split character itself is not part of the column heading or text value although each occurrence of the split character counts toward the 256-character maximum for a label.

Default slash (/)

Restriction This option works only in the column heading on ODS destinations other than LISTING output.

Interaction The FLOW option in the DEFINE statement honors the split character.

STYLE<(*location(s)*)>=<*style-override(s)*>
specifies one or more style overrides to use for different parts of the report.

location(s)
identifies the part of the report that the STYLE= option affects. The following table shows what parts of a report are affected by values of *location*.

The valid and default values for *location* vary by what statement the STYLE= option appears in. The following table shows valid and default *location* values for each statement. To specify more than one value of *location* in the same STYLE= option, separate each value with a space.

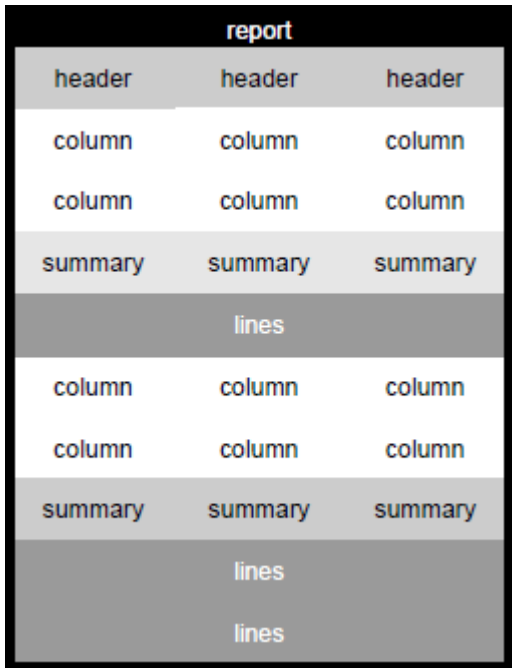
Table 58.4 *Locations and Default Style Elements for Each Statement in PROC REPORT*

Statement	Valid Location Values	Default Location Value	Part of Report Affected	Default Style Element
PROC REPORT	COLUMN HEADER | HDR SUMMARY REPORT LINES CALLDEF	REPORT	Report as a whole	Table
BREAK	SUMMARY LINES	SUMMARY	Summary lines	DataEmphasis

Statement	Valid Location Values	Default Location Value	Part of Report Affected	Default Style Element
CALL DEFINE	CALLDEF	CALLDEF	Cells identified by a CALL DEFINE statement	Data
COMPUTE	LINES	LINES	Lines generated by LINE statements	LineContent
DEFINE	COLUMN HEADER| HDR	COLUMN HEADER	Column cells Column headings	COLUMN: Data HEADER: Header
RBREAK	SUMMARY LINES	SUMMARY	Summary lines Lines generated by LINE statements	DataEmphasis

All names shown in the following table can be used in place of *location(s)* in the PROC statement. The DEFINE statement accepts column and header. The BREAK and RBREAK statement accept summary and lines.

Figure 58.9 *PROC REPORT Locations and Corresponding Statements*



Specifications in a PROC REPORT statement other than the PROC REPORT location override the same specification in the PROC REPORT statement. However, any style attributes that you specify in the PROC REPORT

statement and do not override in another PROC REPORT statement are inherited. For example, if you specify a blue background and a white foreground for all column headings in the PROC REPORT statement, and you specify a gray background for the column headings of a variable in the PROC REPORT DEFINE statement, then the background for that particular column heading is gray, and the foreground is white (as specified in the PROC REPORT statement).

style-override
specifies one or more style attributes or style elements to override the default style element and attributes in a specific area of a report. You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

Note: These style overrides take precedence over those specified in the PROC statement.

style-override has the following form:

style-element-name | [*style-attribute-name-1*=*style-attribute-value-1*

<*style-attribute-name-2*=*style-attribute-value-2* ...>]

Note: You can use braces ({ and }) instead of square brackets ([and]).

style-element-name
is the name of a style element that is part of an ODS style template. SAS provides some style templates. Users can create their own style templates with the TEMPLATE procedure. See *SAS Output Delivery System: Procedures Guide*

See For information about using styles with PROC REPORT, see "Using ODS Styles with PROC REPORT" on page 2142.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions " on page 2149.

style-attribute-name
specifies the attribute to change. For a list of the commonly used style attributes that you can set with the STYLE= option in PROC PRINT, PROC TABULATE, and PROC REPORT, see Table 58.114 on page 2146.

See For information about using styles with PROC REPORT, see "Using ODS Styles with PROC REPORT" on page 2142.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions " on page 2149.

style-attribute-value
specifies a value for the attribute. Each attribute has a different set of valid values. A SAS format can also be used as an attribute value for conditional formatting.

See For information about using styles with PROC REPORT, see "Using ODS Styles with PROC REPORT" on page 2142.

For information about using SAS formats as style attribute values, see "Using a Format to Assign a Style Attribute Value" on page 2152.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions " on page 2149.

Restriction All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Tip FONT names that contain characters other than letters or underscores must be enclosed in quotation marks.

See "Style Elements and Style Attributes for Table Regions " on page 2149 for details.

Example "Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212

THREADS | NOTHREADS
enables or disables parallel processing of the input data set. This option overrides the SAS system option THREADS | NOTHREADS unless the system option is restricted. (See Restriction.) See "Support for Parallel Processing" in *SAS Language Reference: Concepts* for more information.

Default value of SAS system option THREADS | NOTHREADS.

Restriction Your site administrator can create a restricted options table. A restricted options table specifies SAS system option values that are established at start-up and cannot be overridden. If the THREADS | NOTHREADS system option is listed in the restricted options table, any attempt to set these system options is ignored and a warning message is written to the SAS log.

Interaction PROC REPORT uses the value of the SAS system option THREADS except when a BY statement is specified or the value of the SAS system option CPUCOUNT is less than 2. You can specify the THREADS option in the PROC REPORT statement to force PROC REPORT to use parallel processing in these situations.

Note When threaded processing, also known as parallel processing, is in effect, observations might be returned in an unpredictable order. However, the observations are sorted correctly when a BY statement is specified.

VARDEF=*divisor*
specifies the divisor to use in the calculation of the variance and standard deviation. The following table shows the possible values for *divisor* and associated divisors.

Table 58.5 *Possible Values for VARDEF=*

Value	Divisor	Formula for Divisor
DF	Degrees of freedom	$n - 1$
N	Number of observations	n
WDF	Sum of weights minus one	$(\Sigma_i w_i) - 1$
WEIGHT | WGT	Sum of weights	$\Sigma_i w_i$

The procedure computes the variance as $CSS/divisor$, where CSS is the corrected sums of squares and equals $\Sigma (x_i - \bar{x})^2$. When you weight the analysis variables, CSS equals $\Sigma w_i(x_i - \bar{x}_w)^2$, where $\bar{x}_w$ is the weighted mean.

Default DF

Requirement To compute the standard error of the mean and Student's *t*-test, use the default value of VARDEF=.

Tips When you use the WEIGHT statement and VARDEF=DF, the variance is an estimate of σ^2 , where the variance of the *i*th observation is $var(x_i) = \sigma^2/w_i$ and w_i is the weight for the *i*th observation. This yields an estimate of the variance of an observation with unit weight.

When you use the WEIGHT statement and VARDEF=WGT, the computed variance is asymptotically (for large *n*) an estimate of $\sigma^2/\overline{w}$, where $\overline{w}$ is the average weight. This yields an asymptotic estimate of the variance of an observation with average weight.

See "WEIGHT" on page 82

WINDOWS | NOWINDOWS
selects an interactive report window or nonwindowing environment.

When you use WINDOWS, SAS opens the REPORT window for the interactive report interface, which enables you to modify a report repeatedly and to see the modifications immediately. When you use NOWINDOWS, PROC REPORT runs

without the REPORT window and sends its output to the open output destinations.

Alias WD | NOWD

Default NOWD. You no longer have to specify NOWINDOWS or NOWD to work in the nonwindowing environment.

Restriction When you use the WINDOWS option, you can send the output only to a SAS data set or to a Printer destination.

See If you are using the WINDOWS environment, see information about the report profile in PROFILE= on page 2088.

Example "Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171

WRAP

displays one value from each column of the report, on consecutive lines if necessary, before displaying another value from the first column. By default, PROC REPORT displays only values for as many columns as it can fit on one page. It fills a page with values for these columns before starting to display values for the remaining columns on the next page.

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction When WRAP is in effect, PROC REPORT ignores PAGE in any item definitions.

Tip Typically, you use WRAP in conjunction with the NAMED option in order to avoid wrapping column headings.

BREAK Statement

Produces a default summary at a break (a change in the value of a group or order variable). The information in a summary applies to a set of observations. The observations share a unique combination of values for the break variable and all other group or order variables to the left of the break variable in the report.

Examples:

"Example 2: Ordering the Rows in a Report" on page 2174

"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

"Example 6: Creating a Column for Each Value of a Variable" on page 2187

"Example 7: Writing a Customized Summary on Each Page" on page 2190

Syntax

BREAK *location break-variable* </ *options*>;

Summary of Optional Arguments

COLOR=*color*
: specifies the color of the break lines in the REPORT window.

CONTENTS='*link-text*'
: specifies the link text used in the table of contents.

DOL
: double overlines each value.

DUL
: double underlines each value.

OL
: overlines each value.

PAGE
: starts a new page after the last break line.

SKIP
: writes a blank line for the last break line.

STYLE<*location(s)*>=<*style-override*>
: specifies a style override to use for default summary lines, customized summary lines or both.

SUMMARIZE
: writes a summary line in each group of break lines.

SUPPRESS
: suppresses the printing of the value of the break variable in the summary line and of any underlining or overlining in the break lines in the column containing the break variable.

UL
: underlines each value.

Required Arguments

location
controls the placement of the break lines and is either

AFTER
places the break lines immediately after the last row of each set of rows that have the same value for the break variable.

BEFORE
places the break lines immediately before the first row of each set of rows that have the same value for the break variable.

break-variable
is a group or order variable. The REPORT procedure writes break lines each time the value of this variable changes.

Optional Arguments

COLOR=*color*
specifies the color of the break lines in the REPORT window. The default color is the color of **Foreground** in the SASCOLOR window. You can use the following colors:

Table 58.6 *Colors Allowed for Break Lines*

BLACK	MAGENTA
BLUE	ORANGE
BROWN	PINK
CYAN	RED
GRAY	WHITE
GREEN	YELLOW

Default The color of **Foreground** in the SASCOLOR window. (For more information, see the online Help for the SASCOLOR window.)

Restriction This option affects only output in the interactive report window environment.

Note Not all operating environments and devices support all colors, and on some operating systems and devices, one color might map to another color. For example, if the DEFINITION window displays the word BROWN in yellow characters, then selecting BROWN results in a yellow item.

CONTENTS='*link-text*'
specifies the text for the entries in the table of contents created by default or by options settings in ODS destinations that support the STYLE= option. If the PAGE= option and the CONTENTS= option with *link-text* is specified, PROC REPORT uses the value of *link-text* as a link for tables created in the table of contents.

Default If the BREAK AFTER statement does not have a CONTENTS= option specified, but does have the PAGE option specified, then the default link text in the table of contents is “Table N” where N is an integer.

Restriction If CONTENTS= is specified, but no PAGE option is specified, then PROC REPORT generates a warning message in the SAS log file.

Interactions If the DEFINE statement has a page option and there is a BREAK BEFORE statement with a PAGE option and the CONTENTS= option has a value other than empty quotation marks specified, then PROC REPORT adds a directory to the table of contents and

puts links to the tables in that directory. For more information about this interaction, see the CONTENTS= option in the DEFINE statement on page 2116.

If there is a BREAK BEFORE statement specified and a CONTENTS=' ' option and a PAGE= option specified, then PROC REPORT does not create a directory in the table of contents. Instead, PROC REPORT uses the CONTENTS= value from the DEFINE statement to create links to the table of contents. If there is no CONTENTS= option in the DEFINE statement, then PROC REPORT creates links using the default text described in the DEFINE statement. Refer to the DEFINE statement on page 2116 CONTENTS= option for an explanation of the default text information.

For RTF output, the CONTENTS= option has no effect on the RTF body file unless you turn on the CONTENTS=YES option in the ODS RTF statement. In that case, a Table of Contents page is inserted at the front of your RTF output file. Your CONTENTS= option text from PROC REPORT then shows up in this separate Table of Contents page.

Note If a BREAK BEFORE statement is present and the PAGE option is specified but no CONTENTS= option is specified, then the default link text is the location variable plus the value of the location variable. The location variable is associated with the BREAK variable. The value is the BREAK variable value. As shown in the following code, the value is rep and the location is before rep. `break before rep / summarize page;`

Tips If the CONTENTS= option is specified where the value is empty quotation marks, then no table link is created in the table of contents. An example of this code is `CONTENTS=''`

If there are multiple BREAK BEFORE statements, then the link text is the concatenation of all of the CONTENTS= values or of all the default values.

DOL

(for double overlining) uses the 13th formatting character to overline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default equal sign (=)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the OL and DOL options, then PROC REPORT honors only OL.

See The discussion of FORMCHAR= on page 2081.

DUL
(for double underlining) uses the 13th formatting character to underline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default equal sign (=)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the UL and DUL options, then PROC REPORT honors only UL.

See The discussion of FORMCHAR= on page 2081.

OL
(for overlining) uses the second formatting character to overline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default hyphen (-)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the OL and DOL options, then PROC REPORT honors only OL.

See The discussion of FORMCHAR= on page 2081.

PAGE
in LISTING output, starts a new page. In the ODS destinations that support the STYLE= option, the PAGE option starts a new table. All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Restriction In the OUTPUT destination, this option has no effect.

Interaction If you use PAGE in the BREAK statement and you create a break at the end of the report, then the summary for the whole report appears on a separate page.

Example "Example 7: Writing a Customized Summary on Each Page" on page 2190

SKIP
writes a blank line for the last break line.

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

STYLE<*location(s)*>=<*style-override*>
specifies the style override to use for default summary lines that are created with the BREAK statement.

You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

style-override has the following form:

style-element-name | [*style-attribute-name-1=style-attribute-value-1*
<*style-attribute-name-2=style-attribute-value-2* ...>]

Restriction All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Tip FONT names that contain characters other than letters or underscores must be enclosed in quotation marks.

See "Style Elements and Style Attributes for Table Regions " on page 2149

SUMMARIZE
writes a summary line in each group of break lines. A summary line for a set of observations contains values for the following:

- the break variable (which you can suppress with the SUPPRESS option)
- other group or order variables to the left of the break variable
- statistics
- analysis variables
- computed variables

The following table shows how PROC REPORT calculates the value for each type of report item in a summary line that is created by the BREAK statement:

Report Item	Value
Break variable	Current value of the variable (or a missing value if you use SUPPRESS)
A group or order variable to the left of the break variable	Current value of the variable
A group or order variable to the right of the break variable, or a display variable anywhere in the report	Missing*

Report Item	Value
A statistic	Value of the statistic over all observations in the set
An analysis variable	Value of the statistic specified as the usage option in the item's definition. PROC REPORT calculates the value of the statistic over all observations in the set. The default usage is SUM.
A computed variable	Results of the calculations based on the code in the corresponding compute block. (See "COMPUTE Statement" on page 2112.)

* If you reference a variable with a missing value in a customized summary line, then PROC REPORT displays that variable as a blank (for character variables) or a period (for numeric variables).

Note: PROC REPORT cannot create groups in a report that contains order or display variables.

Accessibility note: If the SUPPRESS option and SUMMARIZE options are both specified, the summary row headers are not displayed and the table is not accessible.

Examples:
"Example 2: Ordering the Rows in a Report" on page 2174

"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

"Example 7: Writing a Customized Summary on Each Page" on page 2190

SUPPRESS

suppresses printing of

- the value of the break variable in the summary line
- any underlining and overlining in the break lines in the column that contains the break variable

Interaction: If you use SUPPRESS, then the value of the break variable is unavailable for use in customized break lines unless you assign a value to it in the compute block that is associated with the break. (See "COMPUTE Statement" on page 2112.)

Accessibility note: If the SUPPRESS option and SUMMARIZE options are both specified, the summary row headers are not displayed and the table is not accessible.

Example "Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

UL

(for underlining) uses the second formatting character to underline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default hyphen (-)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the UL and DUL options, then PROC REPORT honors only UL.

See the discussion of FORMCHAR= on page 2081.

Details

Order of Break Lines

When a default summary contains more than one break line, the following is the order in which the break lines appear:

1. overlining or double overlining (OL or DOL)
2. summary line (SUMMARIZE)
3. underlining or double underlining (UL or DUL)
4. skipped line (SKIP)
5. page break (PAGE)

Note: If you define a customized summary for the break, then customized break lines appear after underlining or double underlining. For more information about customized break lines, see "COMPUTE Statement" on page 2112 and "LINE Statement" on page 2132.

BY Statement

Creates a separate report on a separate page for each BY group.

Restriction: If you use the BY statement, then you must use the PROC REPORT statement in the nonwindowing environment (NOWINDOWS or NOWD option).

Interaction: If you use the RBREAK statement in a report that uses BY processing, then PROC REPORT creates a default summary for each BY group. In this case, you cannot summarize information for the whole report.

Tip: Using the BY statement does not make the FIRST. and LAST. variables available in compute blocks.

See: "BY" on page 74

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...> <NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then the observations in the data set either must be sorted by all the variables that you specify or must be indexed appropriately. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the data set is sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. For example, the data are grouped in chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

CALL DEFINE Statement

Sets the value of an attribute for a particular column in the current row. The CALL DEFINE statement is often used to write report definitions that other people use in an interactive report window environment. Only the FORMAT, URL, URLBP, and URLP attributes have an effect in the

nonwindowing environment. In fact, URL, URLBP, and URLP are effective only in the nonwindowing environment. The STYLE= and URL attributes are effective only when you are using ODS to create output.

Restriction: Valid only in a compute block that is attached to a report item.

Tip: All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Example:

```
compute sales;
      if sales.sum>100 and _break_=' ' then
          call define(_col_, "style",
                  "style=[backgroundcolor=yellow
                          fontfamily=helvetica
                          fontweight=bold]");
endcomp;

compute weight;
      if weight > 100.0 then
          call define(_row_, "style/merge", "style={font_weight=bold}");
endcomp;
```

Examples:

"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

"Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212

"Example 15: Using STYLE/MERGE in PROC REPORT CALL DEFINE Statement" on page 2223

"Example 16: Using STYLE/REPLACE in PROC REPORT CALL DEFINE Statement" on page 2225

Syntax

CALL DEFINE (*column-id* | _ROW_, ' *attribute-name*', *value*);

Required Arguments

column-id
specifies a column name or a column number (that is, the position of the column from the left edge of the report). A column ID can be one of the following:

- a character literal (in quotation marks) that is the column name
- a character expression that resolves to the column name
- a numeric literal that is the column number
- a numeric expression that resolves to the column number
- a name of the form '_C*n*_', where *n* is the column number
- the automatic variable _COL_, which identifies the column that contains the report item that the compute block is attached to

ROW
is an automatic variable that indicates the entire current row.

attribute-name
is the attribute to define. For attribute names, refer to Table 58.111 on page 2107.

Note: The attributes BLINK, HIGHLIGHT, and RVSVIDEO do not work on all devices.

value
sets the value for the attribute. For values for each attribute, refer to Table 58.111 on page 2107.

Table 58.7 *Attribute Descriptions*

Attribute	Description	Values	Affects
BLINK	Controls blinking of current value	1 turns blinking on; 0 turns it off	Interactive report window environment
COLOR	Controls the color of the current value in the REPORT window	'blue', 'red', 'pink', 'green', 'cyan', 'yellow', 'white', 'orange', 'black', 'magenta', 'gray', 'brown'	Interactive report window environment
COMMAND	Specifies that a series of commands follows	A quoted string of SAS commands to submit to the command line	Interactive report window environment
FORMAT	Specifies a format for the column	A SAS format or a user-defined format	Interactive report window and nonwindowing environments
HIGHLIGHT	Controls highlighting of the current value	1 turns highlighting on; 0 turns it off	Interactive report window environment
RVSVIDEO	Controls display of the current value	1 turns reverse video on; 0 turns it off	Interactive report window environment
STYLE	Specifies the style override of the column or row	an ODS style attribute	All ODS destinations.
STYLE/ MERGE	Merge the style specified with the existing styles in the same row or column	an ODS style attribute	All ODS destinations.
STYLE/ REPLACE	Replace the existing style in the row or column	an ODS style attribute	All ODS destinations.

Attribute	Description	Values	Affects
URL	Makes the contents of each cell of the column a link to the specified Uniform Resource Locator (URL)	A quoted URL (either single or double quotation marks can be used)	ODS HTML, HTML5, RTF, PDF, PowerPoint, EPUB destinations
URLBP	Makes the contents of each cell of the column a link. The link points to a Uniform Resource Locator that is a concatenation of 1 the string that is specified by the BASE= option in the ODS HTML statement 2 the string that is specified by the PATH= option in the ODS HTML statement 3 the value of the URLBP attribute 1	A quoted URL (either single or double quotation marks can be used)	ODS HTML and HTML5 destinations
URLP	Makes the contents of each cell of the column a link. The link points to a Uniform Resource Locator that is a concatenation of 1 the string that is specified by the PATH= option in the ODS HTML statement 2 the value of the URLP attribute	A quoted URL (either single or double quotation marks can be used)	ODS HTML and HTML5 destinations

1 For information about the BASE= and PATH= options, see the documentation for the ODS HTML Statement in *SAS Output Delivery System: User's Guide*.

Details

Using Style Attributes with the CALL DEFINE Statement

The STYLE attribute specifies the style-override to use in the cells that are affected by the CALL DEFINE statement.

The STYLE= value functions like the STYLE= option in other statements in PROC REPORT. However, instead of acting as an option in a statement, it becomes the value for the STYLE attribute. For example, the following CALL DEFINE statement sets the background color to yellow and the font size to 7 for the specified column:

```
call define(_col_, "style",
            "style=[backgroundcolor=yellow fontsize=7]");
```

For information about style precedence, see "Order of Precedence When Applying Style Attributes to Data Cells" on page 2151.

Restriction: All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Interaction: If you set a style override for the CALLDEF location in the PROC REPORT statement and you want to use that exact style override in a CALL DEFINE statement, use an empty string as the value for the STYLE attribute, as shown here:

```
call define (_col_, "STYLE", "" );
```

Tip: FONT names that contain characters other than letters or underscores must be enclosed in quotation marks.

Featured in: "Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212

Using STYLE/REPLACE and STYLE/MERGE Style Attributes

The STYLE/MERGE and STYLE/REPLACE attributes work only with styles specified by the CALL DEFINE statement. You cannot merge or replace a style that is specified by a STYLE(COLUMN)= option. A good time to use STYLE/REPLACE and STYLE/MERGE is when you have two or more COMPUTE blocks that have a CALL DEFINE statement, and these CALL DEFINE statements refer to the same cell.

STYLE= and STYLE/REPLACE attributes specify the style element to be used for ODS. If a style already exists for a cell or row, these STYLE attributes tell CALL DEFINE to replace the style specified by the STYLE= option. For an example program, see "Example 16: Using STYLE/REPLACE in PROC REPORT CALL DEFINE Statement" on page 2225.

The STYLE/MERGE attribute tells CALL DEFINE to merge the style specified by the STYLE= value with the existing style attributes that are in the same cell or row. If there is no previously existing STYLE= value to merge, STYLE/MERGE acts the same as the STYLE or STYLE/REPLACE attributes. For an example program, see "Example 15: Using STYLE/MERGE in PROC REPORT CALL DEFINE Statement" on page 2223.

COLUMN Statement

Describes the arrangement of all columns and of headings that span more than one column.

Restriction: You cannot use the COLUMN statement if you use REPORT= in the PROC REPORT statement.

Examples:
"Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171

"Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177

"Example 6: Creating a Column for Each Value of a Variable" on page 2187

"Example 4: Displaying Multiple Statistics for One Variable" on page 2181
"Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195
"Example 9: How PROC REPORT Handles Missing Values" on page 2198

Syntax

COLUMN *column-specification(s)*;

Required Argument

column-specification(s)
is one or more of the following:

- *report-item(s)*
- *report-item-1*, *report-item-2* <. . . , *report-item-n*>
- (*'header-1 '* < . . . *'header-n '*> *report-item(s)*)
- *report-item=name*

where *report-item* is the name of a data set variable, a computed variable, or a statistic. See "Statistics That Are Available in PROC REPORT" on page 2140 for a list of available statistics.

report-item(s)
identifies items that each form a column in the report.

Examples "Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171

"Example 9: How PROC REPORT Handles Missing Values" on page 2198

report-item-1, report-item-2 <. . . , report-item-n>
identifies report items that collectively determine the contents of the column or columns. These items are said to be stacked in the report because each item generates a heading, and the headings are stacked one above the other. The heading for the leftmost item is on top. If one of the items is an analysis variable, a computed variable, a group variable, or a statistic, then its values fill the cells in that part of the report. Otherwise, PROC REPORT fills the cells with frequency counts.

If you stack a statistic with an analysis variable, then the statistic that you name in the column statement overrides the statistic in the definition of the analysis variable. For example, the following PROC REPORT step produces a report that contains the minimum value of Sales for each sector:

```
proc report data=grocery;
column sector sales,min;
define sector/group;
define sales/analysis sum;
run;
```

If you stack a display variable under an across variable, then all the values of that display variable appear in the report.

Interaction A series of stacked report items can include only one analysis variable or statistic. If you include more than one analysis variable or statistic, then PROC REPORT returns an error because it cannot determine which values to put in the cells of the report.

Tip You can use parentheses to group report items whose headings should appear at the same level rather than stacked one above the other.

Examples "Example 6: Creating a Column for Each Value of a Variable" on page 2187

"Example 4: Displaying Multiple Statistics for One Variable" on page 2181

"Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195

('header-1' <... 'header-n '> report-item(s))
creates one or more headings that span multiple columns.

header
is a string of characters that spans one or more columns in the report. PROC REPORT prints each heading on a separate line. You can use split characters in a heading to split one heading over multiple lines. See the discussion of SPLIT= on page 2092.

In LISTING output, if the first and last characters of a heading are one of the following characters, then PROC REPORT uses that character to expand the heading to fill the space over the column or columns. Note that the <> and the >< must be paired. `- = . _ * + <> ><`

Similarly, if the first character of a heading is < and the last character is >, or vice versa, then PROC REPORT expands the heading to fill the space over the column by repeating the first character before the text of the heading and the last character after it.

Note: The use of expanding characters is supported only in LISTING destinations. Therefore, PROC REPORT simply removes the expanding characters when the output is directed to any other destination. Refer to "Understanding ODS Destinations" in *SAS Output Delivery System: User's Guide* for more information.

report-item(s)
specifies the columns to span.

Example "Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195

report-item=name
specifies an alias for a report item. You can use the same report item more than once in a COLUMN statement. However, you can use only one DEFINE statement for any given name. (The DEFINE statement designates characteristics such as formats and customized column headings. If you omit a DEFINE statement for an item, then the REPORT procedure uses defaults.) Assigning an alias in the COLUMN statement does not by itself alter the report. However, it does enable you to use separate DEFINE statements for each occurrence of a variable or statistic.

Note You cannot always use an alias. When you refer in a compute block to a report item that has an alias, you must use the alias. However, if the report item shares a column with an across variable, then you must reference the column by column number. (See "Four Ways to Reference Report Items in a Compute Block" on page 2063.)

Example "Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177

COMPUTE Statement

Starts a compute block containing one or more programming statements that PROC REPORT executes as it builds the report.

Restriction: If you are sending a report to multiple ODS destinations or to an ODS document that is replayed later, avoid the use of non-deterministic functions in a COMPUTE block (for example, LAG, DIF, RANUNI, DATETIME, and so on). If you need to use data created by such functions in your report, call the functions in a DATA step and store the results in the data set before running PROC REPORT.

Interaction: An ENDCOMP statement must mark the end of the group of statements in the compute block.

Note: A compute block can be associated with a report item or with a location (at the top or bottom of a report; at the top or bottom of a page; before or after a set of observations). You create a compute block with the COMPUTE window or with the COMPUTE statement. One form of the COMPUTE statement associates the compute block with a report item. Another form associates the compute block with a location. For a list of the SAS language elements that you can use in compute blocks, see "The Contents of Compute Blocks" on page 2062.

Tip: For information about how to use compute blocks, see The REPORT Procedure: A Primer for the Compute Block

Examples:
"Example 2: Ordering the Rows in a Report" on page 2174
"Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177
"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183
"Example 6: Creating a Column for Each Value of a Variable" on page 2187
"Example 7: Writing a Customized Summary on Each Page" on page 2190

"Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195
"Example 10: Creating an Output Data Set and Storing Computed Variables" on page 2202
"Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212

Syntax

COMPUTE *location* <*target*>
</ STYLE=<*style-override(s)* > >;

LINE *specification(s)*;

. . . select SAS language elements . . .

ENDCOMP;

COMPUTE *report-item* </ *type-specification*>;

CALL DEFINE (*column-id*, '*attribute-name*', *value*);

. . . select SAS language elements . . .

ENDCOMP;

Required Arguments

You must specify either a location or a report item in the COMPUTE statement.

location
determines where the compute block executes in relation to *target*.

AFTER
executes the compute block at a break in one of the following places:

- immediately after the last row of a set of rows that have the same value for the variable that you specify as *target* or, if there is a default summary on that variable, immediately after the creation of the preliminary summary line. (See Results: REPORT Procedure on page 2158.)
- in LISTING output, near the bottom of each page, immediately before any footnotes, if you specify _PAGE_ as *target*.
- at the end of the report if you omit a target.

BEFORE
executes the compute block at a break in one of the following places:

- immediately before the first row of a set of rows that have the same value for the variable that you specify as *target* or, if there is a default summary on that variable, immediately after the creation of the preliminary summary line. (See Results: REPORT Procedure on page 2158.)
- in LISTING output, near the top of each page, between any titles and the column headings, if you specify _PAGE_ as *target*.
- immediately before the first detail row if you omit a target.

Note If a report contains more columns than fit on a printed page, PROC REPORT generates an additional page or pages to contain the remaining columns. In this case, when you specify _PAGE_ as *target*, the COMPUTE block does NOT re-execute for each of these additional pages; the COMPUTE block re-executes only after all columns have been printed.

Examples "Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177

"Example 7: Writing a Customized Summary on Each Page" on page 2190

report-item
specifies a data set variable, a computed variable, or a statistic to associate the compute block with. If you are working in the nonwindowing environment, then you must include the report item in the COLUMN statement. If the item is a computed variable, then you must include a DEFINE statement for it.

Note The position of a computed variable is important. PROC REPORT assigns values to the columns in a row of a report from left to right. Consequently, you cannot base the calculation of a computed variable on any variable that appears to its right in the report.

Examples "Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

"Example 6: Creating a Column for Each Value of a Variable" on page 2187

Optional Arguments

STYLE<(*location(s)*)>=<*style-override(s)*>
specifies the style to use for the text that is created by any LINE statements in this compute block.

You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

style-override has the following form:

style-element-name | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

Restriction All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Tip FONT names that contain characters other than letters or underscores must be enclosed in quotation marks.

See "Style Elements and Style Attributes for Table Regions " on page 2149

Example "Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212

target

controls when the compute block executes. If you specify a location (BEFORE or AFTER) for the COMPUTE statement, then you can also specify *target*, which can be one of the following:

break-variable

is a group or order variable.

When you specify a break variable, PROC REPORT executes the statements in the compute block each time the value of the break variable changes.

PAGE </ justification>

in LISTING output destinations, causes the compute block to execute once for each page, either immediately after printing any titles or immediately before printing any footnotes. *justification* controls the placement of text and values. It can be one of the following:

CENTER

centers each line that the compute block writes.

LEFT

left-justifies each line that the compute block writes.

RIGHT

right-justifies each line that the compute block writes.

Default CENTER

Example "Example 7: Writing a Customized Summary on Each Page" on page 2190

type-specification

specifies the type. (Optional) Also specifies the length of *report-item*. If the report item that is associated with a compute block is a computed variable, then PROC REPORT assumes that it is a numeric variable unless you use a type specification to specify that it is a character variable. A type specification has the form

CHARACTER <LENGTH=*length*>

where

CHARACTER

specifies that the computed variable is a character variable. If you do not specify a length, then the variable's length is 8.

Alias CHAR

Example "Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195

LENGTH=*length*
specifies the length of a computed character variable.

Default 8

Range 1 to 200

Interaction If you specify a length, then you must use CHARACTER to indicate that the computed variable is a character variable.

Example "Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195

DEFINE Statement

Describes how to use and display a report item.

Restriction: A weight cannot be applied to a *report-item* alias without also applying it to the report-item. The WEIGHT= option must appear in the DEFINE statement for the *report-item*.

Accessibility note: When the DEFINE statement includes an ORDER or GROUP option, the SPANROWS option must also be included in the PROC REPORT statement to generate an accessible table.

Tip: If you do not use a DEFINE statement, then PROC REPORT uses default characteristics.

Examples:
"Example 2: Ordering the Rows in a Report" on page 2174
"Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177
"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183
"Example 6: Creating a Column for Each Value of a Variable" on page 2187
"Example 4: Displaying Multiple Statistics for One Variable" on page 2181
"Example 7: Writing a Customized Summary on Each Page" on page 2190
"Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195
"Example 10: Creating an Output Data Set and Storing Computed Variables" on page 2202
"Example 11: Using a Format to Create Groups" on page 2206
"Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212
"Example 12: Using Multilabel Formats" on page 2209
"Example 14: Using the CELLWIDTH= Style Attribute with PROC REPORT" on page 2220

Syntax

DEFINE *report-item* / <*options*>;

Summary of Optional Arguments

Control the placement of values and column headings

CENTER
: centers the formatted values of the report item within the column width and center the column heading over the values.

COLOR=*color*
: specifies the color in the REPORT window of the column heading and of the values of the item that you define.

column-header
: defines the column heading for the report item.

LEFT
: left-justifies the formatted values of the report item within the column width and left-justifies the column headings over the values.

RIGHT
: right-justifies the formatted values of the report item within the column width and right-justifies the column headings over the values.

Customize the appearance of a report item

EXCLUSIVE
: excludes all combinations of the item that are not found in the preloaded range of user-defined formats.

FORMAT=*format*
: assigns a SAS or user-defined format to the item.

MISSING
: considers missing values as valid values for the item.

MLF
: enables PROC REPORT to use the format label or labels to create subgroup combinations that have multilabel formats.

ORDER=DATA | FORMATTED | FREQ | INTERNAL
: orders the values of a group, order, or across variable according to the specified order.

PRELOADFMT
: specifies that all formats are preloaded for the item.

SPACING=*horizontal-positions*
: for LISTING output, defines the number of blank characters to leave between the column being defined and the column immediately to its left.

statistic
: associates a statistic with an analysis variable.

STYLE<(*location(s)*)>=<*style-overrides(s)*>

specifies a style element (for the Output Delivery System) for the report item.

WEIGHT=*weight-variable*
specifies a numeric variable whose values weight the value of the analysis variable.

WIDTH=*column-width*
defines the width of the column in which PROC REPORT displays the report item.

Specify how to use a report item

ACROSS
defines the item, which must be a data set variable, as an across variable.

ANALYSIS
defines the item, which must be a data set variable, as an analysis variable.

COMPUTED
defines the item as a computed variable.

DISPLAY
defines the item, which must be a data set variable, as a display variable.

GROUP
defines the item, which must be a data set variable, as a group variable.

ORDER
defines the item, which must be a data set variable, as an order variable.

Specify options for a report item

CONTENTS='*link-text*'
creates a link in the table of contents.

DESCENDING
reverses the order in which PROC REPORT displays rows or values of a group, order, or across variable.

FLOW
wraps the value of a character variable in its column.

ID
specifies that the item that you are defining is an ID variable.

NOPRINT
suppresses the display of the report item.

NOZERO
suppresses the display of the report item if its values are all zero or missing.

PAGE
inserts a page break just before printing the first column containing values of the report item.

Required Argument

report-item
specifies the name or alias (established in the COLUMN statement) of the data set variable, computed variable, or statistic to define. The following are types of names that can be used for *report-item*:

- a SAS identifier (determined by the VALIDVARNAME option)
- a name literal
- a numbered range list
- a name range list
- a special name list
- a name prefix list
- a statistic

Notes The names in variable range lists refer to variables in the input data set, not statistic names, or computed variable names. Use only one name for each DEFINE statement. That one name, however, can be a range list. Example syntax using a variable range list is: `DEFINE Var1-Var3/ width=10 center "#Visit#Date";`

Do not specify a usage option in the definition of a statistic. The name of the statistic tells PROC REPORT how to use it.

See "Names in the SAS Language" in *SAS Language Reference: Concepts*, "SAS Variable Lists" in *SAS Language Reference: Concepts*, and "VALIDVARNAME= System Option" in *SAS System Options: Reference*.

Optional Arguments

ACROSS

defines *report-item*, which must be a data set variable, as an across variable. (See "Across Variables" on page 2058.)

Example "Example 6: Creating a Column for Each Value of a Variable" on page 2187

ANALYSIS

defines *report-item*, which must be a data set variable, as an analysis variable. (See "Analysis Variables" on page 2057.)

By default, PROC REPORT calculates the Sum statistic for an analysis variable. Specify an alternate statistic with the *statistic* option in the DEFINE statement.

Note: Naming a statistic in the DEFINE statement implies the ANALYSIS option, so you never need to specify ANALYSIS. However, specifying ANALYSIS can make your code easier for novice users to understand.

Note: Special missing values show up as missing values when they are defined as ANALYSIS variables.

Examples "Example 2: Ordering the Rows in a Report" on page 2174

"Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177

"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

CENTER
centers the formatted values of the report item within the column width and centers the column heading over the values. This option has no effect on the CENTER option in the PROC REPORT statement, which centers the report on the page.

Restriction This option affects the header and the data of LISTING output. In ODS output, only the data is affected by this option.

COLOR=*color*
specifies the color in the REPORT window of the column heading and of the values of the item that you are defining. You can use the following colors:

BLACK	MAGENTA
BLUE	ORANGE
BROWN	PINK
CYAN	RED
GRAY	WHITE
GREEN	YELLOW

Note: Not all operating environments and devices support all colors, and in some operating environments and devices, one color might map to another color. For example, if the DEFINITION window displays the word BROWN in yellow characters, then selecting BROWN results in a yellow item.

Default The color of **Foreground** in the SASCOLOR window. (For more information, see the online Help for the SASCOLOR window.)

Restriction This option affects output in the interactive report window environment only.

column-header
defines the column heading for the report item. Enclose each heading in single or double quotation marks. When you specify multiple column headings, PROC REPORT uses a separate line for each one. The split character also splits a column heading over multiple lines.

In LISTING output, if the first and last characters of a heading are one of the following characters, then PROC REPORT uses that character to expand the heading to fill the space over the column: `:- = \_ .* +`

Similarly, if the first character of a heading is < and the last character is >, or vice versa, then PROC REPORT expands the heading to fill the space over the column by repeating the first character before the text of the heading and the last character after it.

The following table shows the default variables and statistics:

Item	Header
Variable without a label	Variable name
Variable with a label	Variable label
Statistic	Statistic name

Tips If you want to use names when labels exist, then submit the following SAS statement before invoking PROC REPORT: `options nolabel;`

HEADLINE underlines all column headings and the spaces between them. In LISTING output, you can underline column headings without underlining the spaces between them, by using the special characters `'--'` as the last line of each column heading instead of using HEADLINE. (See "Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183.)

See SPLIT= on page 2092

Examples "Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177

"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

"Example 6: Creating a Column for Each Value of a Variable" on page 2187

COMPUTED

defines the specified item as a computed variable. Computed variables are variables that you define for the report. They are not in the input data set, and PROC REPORT does not add them to the input data set.

In the interactive report window environment, you add a computed variable to a report from the COMPUTED VAR window.

In the nonwindowing environment, you add a computed variable as by

- including the computed variable in the COLUMN statement
- defining the variable's usage as COMPUTED in the DEFINE statement
- computing the value of the variable in a compute block associated with the variable

Examples "Example 6: Creating a Column for Each Value of a Variable" on page 2187

"Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195

CONTENTS='*link-text*'

specifies the text for the entries in the table of contents created by default or by options settings in ODS destinations that support the STYLE= option. If the DEFINE statement has the PAGE= option and the CONTENTS= option specified with a *link-text* value assigned, then PROC REPORT adds a directory to the table of contents and uses the value of *link-text* as a link for tables created in the table of contents.

Default If the DEFINE statement has a PAGE option, but does not have a CONTENTS= option specified, then a directory is created with the directory text as COLA-COLB. COLA is the name or alias of the leftmost column and COLB is the name or alias of the rightmost column. If the table has only one column, then the directory text is the column name or alias.

Restriction If CONTENTS= is specified, but no PAGE option is specified, then PROC REPORT generates a warning message in the SAS log file.

Interactions If the DEFINE statement has a page option and there is a BREAK BEFORE statement with a PAGE option and the CONTENTS= option specified has a value other than empty quotation marks, then PROC REPORT adds a directory to the table of contents and puts links to the tables in that directory.

If the DEFINE statement has a PAGE option and there is a BREAK BEFORE statement with no PAGE option, then PROC REPORT does not create a directory in the table of contents. Instead, PROC REPORT uses the CONTENTS= value from the DEFINE statement to create links to the table of contents. If there is no CONTENTS= option in the DEFINE statement, then PROC REPORT creates links using the default text COLA–COLB. Refer to the Default explanation above.

If there is a BREAK BEFORE statement with a CONTENTS='' option specified and a PAGE option specified, then PROC REPORT does not create a directory in the table of contents. Instead, PROC REPORT uses the CONTENTS= value from the DEFINE statement to create links to the table of contents. If there is no CONTENTS= option in the DEFINE statement, then PROC REPORT creates links using the default text COLA–COLB. Refer to the Default explanation above.

Tips If the DEFINE statement specifies the CONTENTS= option where the value is empty quotation marks, then the directory to the table of contents is not added. An example of this code is as follows:

```
CONTENTS=''
```

If there are multiple BREAK BEFORE statements, then the link text is the concatenation of all of the CONTENTS= values or of all the default values.

All ODS destinations except OUTPUT and LISTING support the STYLE= option.

DESCENDING
reverses the order in which PROC REPORT displays rows or values of a group, order, or across variable.

Tip By default, PROC REPORT orders group, order, and across variables by their formatted values. Use the ORDER= option in the DEFINE statement to specify an alternate sort order.

DISPLAY
defines *report-item*, which must be a data set variable, as a display variable. (See "Display Variables" on page 2055.)

EXCLUSIVE
excludes from the report and the output data set all combinations of the group variables and the across variables that are not found in the preloaded range of user-defined formats.

Requirement You must specify the PRELOADFMT option in the DEFINE statement in order to preload the variable formats.

FLOW
wraps the value of a character variable in its column. The FLOW option honors the split character. If the text contains no split character, then PROC REPORT tries to split text at a blank.

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

FORMAT=*format*
assigns a SAS or user-defined format to the item. This format applies to *report-item* as PROC REPORT displays it; the format does not alter the format associated with a variable in the data set. For data set variables, PROC REPORT honors the first of these formats that it finds:

- the format that is assigned with FORMAT= in the DEFINE statement
- the format that is assigned in a FORMAT statement when you invoke PROC REPORT
- the format that is associated with the variable in the data set

If none of these formats is present, then PROC REPORT uses BEST*w*. for numeric variables and $*w*. for character variables. The value of *w* is the default column width. For character variables in the input data set, the default column width is the variable's length. For numeric variables in the input data set and for computed variables (both numeric and character), the default column width is the value specified by COLWIDTH= in the PROC REPORT statement or in the ROPTIONS window.

In the interactive report window environment, if you are unsure what format to use, then type a question mark (?) in the format field in the DEFINITION window to access the FORMATS window.

Alias F=

Examples "Example 2: Ordering the Rows in a Report" on page 2174

"Example 4: Displaying Multiple Statistics for One Variable" on page 2181

GROUP

defines *report-item*, which must be a data set variable, as a group variable. (See "Group Variables" on page 2056.)

Accessibility note When the DEFINE statement includes an ORDER or GROUP option, the SPANROWS option must also be included in the PROC REPORT statement to generate an accessible table.

Examples "Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

"Example 4: Displaying Multiple Statistics for One Variable" on page 2181

"Example 11: Using a Format to Create Groups" on page 2206

ID

specifies that the item that you are defining is an ID variable. An ID variable and all columns to its left appear at the left of every page of a report. ID ensures that you can identify each row of the report when the report contains more columns than fits on one page.

LEFT

left-justifies the formatted values of the report item within the column width and left-justifies the column headings over the values. If the format width is the same as the width of the column, then the LEFT option has no effect on the placement of values.

Restriction This option affects the header and the data of LISTING output. In ODS output, only the data is affected by this option.

MISSING

considers missing values as valid values for the report item. Special missing values that represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a separate value.

Default If you omit the MISSING option, then PROC REPORT excludes from the report and the output data sets all observations that have a missing value for any group, order, or across variable.

MLF

enables PROC REPORT to use the format label or labels for a given range or for overlapping ranges to create subgroup combinations that use multilabel

formatting. These multilabel formats are used only with group and across variables.

MLF is supported on all ODS destinations, the LISTING destination, data sets, and the REPORT WINDOW.

Note: PROC REPORT supports assigning a numeric variable that has a multilabel format to a character variable.

Requirement Use PROC FORMAT and the MULTILABEL option in the VALUE statement to create a multilabel format.

Tips The MLF option has no effect unless the variable is associated with a multilabel format. If there is no MULTILABEL format associated with the column, then an additional FORMAT statement or FORMAT= option in the DEFINE statement is needed to associate an existing format or informat with one or more variables. If MULTILABEL format is already associated with the column (using any regular method to associate a format with the variable), then no additional FORMAT statement or FORMAT= option is needed.

If the MLF option is omitted, PROC REPORT uses the primary format labels to determine the subgroup combinations. The primary format labels correspond to the first external format value.

See MULTILABEL option on page 1124 in the VALUE statement of the FORMAT procedure.

Example “Example 12: Using Multilabel Formats” on page 2209

NOPRINT

suppresses the display of the report item. Use this option

- if you do not want to show the item in the report but you need to use its values to calculate other values that you use in the report.
- to establish the order of rows in the report.
- if you do not want to use the item as a column but want to have access to its values in summaries. (See “Example 7: Writing a Customized Summary on Each Page” on page 2190.)

Interactions Even though the columns that you define with NOPRINT do not appear in the report, you must count them when you are referencing columns by number. (See “Four Ways to Reference Report Items in a Compute Block” on page 2063.)

SHOWALL in the PROC REPORT statement or the ROPTIONS window overrides all occurrences of NOPRINT.

Examples “Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable” on page 2177

"Example 7: Writing a Customized Summary on Each Page" on page 2190

NOZERO
suppresses the display of the report item if its values are all zero or missing.

Interactions Even though the columns that you define with NOZERO do not appear in the report, you must count them when you are referencing columns by number. (See "Four Ways to Reference Report Items in a Compute Block" on page 2063.)

SHOWALL in the PROC REPORT statement or in the ROPTIONS window overrides all occurrences of NOZERO.

ORDER
defines *report-item*, which must be a data set variable, as an order variable. (See "Order Variables" on page 2056.)

Accessibility note When the DEFINE statement includes an ORDER or GROUP option, the SPANROWS option must also be included in the PROC REPORT statement to generate an accessible table.

Example "Example 2: Ordering the Rows in a Report" on page 2174

ORDER=DATA | FORMATTED | FREQ | INTERNAL
orders the values of a group, order, or across variable according to the specified order, where

DATA
orders values according to their order in the input data set.

Note If you specify the ORDER=DATA option for input data in a DBMS table, the order of rows written to a database table from PROC REPORT is not likely to be preserved.

FORMATTED
orders values by their formatted (external) values. If no format has been assigned to a class variable, then the default format, BEST12., is used.

FREQ
orders values by ascending frequency count.

INTERNAL
orders values by their unformatted values. This order depends on your operating environment. This sort sequence is particularly useful for displaying dates chronologically.

Specifying ORDER=INTERNAL usually, but not always, produces the same results as PROC SORT. For more information about ordering data, see "Controlling the Order of Data Values" on page 27.

Default FORMATTED

Interaction DESCENDING in the item's definition reverses the sort sequence for an item. By default, the order is ascending.

Note The default value for the ORDER= option in PROC REPORT is not the same as the default value in other SAS procedures. In other SAS procedures, the default is ORDER=INTERNAL. The default for the option in PROC REPORT might change in a future release to be consistent with other procedures. Therefore, in production jobs where it is important to order report items by their formatted values, specify ORDER=FORMATTED even though it is currently the default. Doing so ensures that PROC REPORT continues to produce the reports that you expect even if the default changes.

Example "Example 2: Ordering the Rows in a Report" on page 2174

PAGE

inserts a page break just before printing the first column containing values of the report item.

Restriction This option has no affect on the OUTPUT destination.

Interaction PAGE is ignored if you use WRAP in the PROC REPORT statement or in the ROPTIONS window.

Tip In the listing destination, a PAGE option in the DEFINE statement causes PROC REPORT to print this column and all columns to its right on a new page. However, for nonlisting destinations, the page break does not occur until all the rows in the report have been printed. Therefore, PROC REPORT prints all the rows for all the columns to the left of the PAGE column and then starts over at the top of the report and prints the PAGE column and the columns to the right.

PRELOADFMT

specifies that the format is preloaded for the variable.

Restriction PRELOADFMT applies only to group and across variables.

Requirement PRELOADFMT has no effect unless you specify either EXCLUSIVE or ORDER=DATA and you assign a format to the variable.

Interactions To limit the report to the combination of formatted variable values that are present in the input data set, use the EXCLUSIVE option in the DEFINE statement.

To include all ranges and values of the user-defined formats in the output, use the COMPLETEROWS option in the PROC REPORT statement.

Notes If you do not specify NOCOMPLETECOLS when you define the across variables, then the report includes a column for every formatted variable. If you specify COMPLETEROWS when you define the group variables, then the report includes a row for every formatted value. Some combinations of rows and columns might not make sense when the report includes a column for every formatted value of the across variable and a row for every formatted value of the group variable.

When preloading a character format, there must be at least one representative raw value that produces the label. If a range does not have any raw values, the range is considered unreachable and an error is generated. For example, you cannot preload a multi-label character format with both Other= and Low-High ranges. Other is a special keyword that refers to values or ranges that remain after all labels have been defined. For character formats, missing values are included in the low range so that there are no raw values left to occupy the Other range.

Example "Example 12: Using Multilabel Formats" on page 2209

RIGHT

right-justifies the formatted values of the specified item within the column width and right-justifies the column headings over the values. If the format width is the same as the width of the column, then RIGHT has no effect on the placement of values.

Restriction This option affects the header and the data of LISTING output. In ODS output, only the data is affected by this option.

SPACING=*horizontal-positions*

defines the number of blank characters to leave between the column being defined and the column immediately to its left. For each column, the sum of its width and the blank characters between it and the column to its left cannot exceed the line size.

Default 2

Restriction This option has no effect on ODS destinations other than the LISTING destination.

Interactions When PROC REPORT's CENTER option is in effect, PROC REPORT ignores spacing that precedes the leftmost variable in the report.

SPACING= in an item's definition overrides the value of SPACING= in the PROC REPORT statement or in the ROPTIONS window.

statistic

associates a statistic with an analysis variable. You must associate a statistic with every analysis variable in its definition. PROC REPORT uses the statistic that you specify to calculate values for the analysis variable for the observations that are represented by each cell of the report. You cannot use *statistic* in the definition of any other type of variable.

See "Statistics That Are Available in PROC REPORT" on page 2140 for a list of available statistics.

Default SUM

Note PROC REPORT uses the name of the analysis variable as the default heading for the column. You can customize the column heading with the *column-header* option in the DEFINE statement.

Examples "Example 2: Ordering the Rows in a Report" on page 2174

"Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177

"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183

STYLE<(*location(s)*)>=<*style-overrides(s)*>
specifies the style element to use for column headings and for text inside cells for this report item.

You can specify a style override in two ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.

style-override has the following form:

style-element-name | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

Restriction All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Tip FONT names that contain characters other than letters or underscores must be enclosed in quotation marks.

See "Style Elements and Style Attributes for Table Regions " on page 2149

Example "Example 13: Specifying Style Elements for ODS Output in Multiple Statements" on page 2212

WEIGHT=*weight-variable*
specifies a numeric variable whose values weight the values of the analysis variable that is specified in the DEFINE statement. The variable value does not have to be an integer. The following table describes how PROC REPORT treats various values of the WEIGHT variable.

Weight Value	PROC REPORT Response
0	Counts the observation in the total number of observations
Less than 0	Converts the value to zero and counts the observation in the total number of observations
Missing	Excludes the observation

To exclude observations that contain negative and zero weights from the analysis, use the EXCLNPWGT option in the PROC REPORT statement. Note that most SAS/STAT procedures, such as PROC GLM, exclude negative and zero weights by default.

Alias WGT=

Restrictions to compute weighted quantiles, use QMETHOD=OS in the PROC REPORT statement.

A weight cannot be applied to a *report-item* alias without also applying it to the *report-item*. The WEIGHT= option must appear in the DEFINE statement for the *report-item*.

Tips When you use the WEIGHT= option, consider which value of the VARDEF= option in the PROC REPORT statement is appropriate.

Use the WEIGHT= option in separate variable definitions in order to specify different weights for the variables.

WIDTH=*column-width*

defines the width of the column in which PROC REPORT displays *report-item*. This option affects only LISTING output.

For information about formats, see the discussion of "FORMAT=*format*" on page 2123.

Default A column width that is just large enough to handle the format. If there is no format, then PROC REPORT uses the value of the COLWIDTH= option in the PROC REPORT statement.

Range 1 to the value of the SAS system option LINESIZE=

Restriction This option has no effect on ODS destinations other than LISTING output. For ODS destinations, use the STYLE= option with the WIDTH= style attribute or the CELLWIDTH= style attribute. Refer to "Style Attributes Tables" in *SAS Output Delivery System: Advanced Topics* for details. See how style attributes WIDTH= and CELLWIDTH= can be used with PROC REPORT in "Example 14: Using the CELLWIDTH= Style Attribute with PROC REPORT" on page 2220.

Interaction WIDTH= in an item definition overrides the value of COLWIDTH= in the PROC REPORT statement or the ROPTIONS window.

Tip When you stack items in the same column in a report, the width of the item that is at the bottom of the stack determines the width of the column.

ENDCOMP Statement

Marks the end of one or more programming statements that PROC REPORT executes as it builds the report.

Restriction: A COMPUTE statement must precede the ENDCOMP statement.

See: COMPUTE statement

Example: "Example 2: Ordering the Rows in a Report" on page 2174

Syntax

ENDCOMP;

FREQ Statement

Treats observations as if they appear multiple times in the input data set.

Tip: The effects of the FREQ and WEIGHT statements are similar except when calculating degrees of freedom.

See: For an example that uses the FREQ statement, see "Example" on page 80

Syntax

FREQ *variable*;

Required Argument

variable
specifies a numeric variable whose value represents the frequency of the observation. If you use the FREQ statement, then the procedure assumes that each observation represents *n* observations, where *n* is the value of *variable*. If *n* is not an integer, then SAS truncates it. If *n* is less than 1 or is missing, then the procedure does not use that observation to calculate statistics.

Details

Frequency Information Is Not Saved

When you store a report definition, PROC REPORT does not store the FREQ statement.

LINE Statement

Provides a subset of the features of the PUT statement for writing customized summaries.

Restrictions: This statement is valid only in a compute block that is associated with a location in the report.

You cannot use the LINE statement in conditional statements (IF-THEN, IF-THEN/ELSE, and SELECT) because it is not executed until PROC REPORT has executed all other statements in the compute block.

Accessibility note: Using the LINE statement causes an inaccessible table to be generated.

Examples:
"Example 2: Ordering the Rows in a Report" on page 2174
"Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177
"Example 5: Consolidating Multiple Observations into One Row of a Report" on page 2183
"Example 6: Creating a Column for Each Value of a Variable" on page 2187
"Example 7: Writing a Customized Summary on Each Page" on page 2190

Syntax

LINE *specification(s)*;

Required Argument

specification(s)
can have one of the following forms. You can mix different forms of specifications in one LINE statement.

item item-format
specifies the item to display and the format to use to display it, where

item
is the name of a data set variable, a computed variable, or a statistic in the report. For information about referencing report items, see "Four Ways to Reference Report Items in a Compute Block" on page 2063.

item-format
is a SAS format or user-defined format. You must specify a format for each item.

Example "Example 2: Ordering the Rows in a Report" on page 2174

'character-string'
specifies a string of text to display. When the string is a blank and nothing else is in *specification(s)*, PROC REPORT prints a blank line.

Note: A hexadecimal value (such as **'DF'x**) that is specified within *character-string* is not resolved because it is specified within quotation marks. To resolve a hexadecimal value, use the **%sysfunc(byte(num))** function, where **num** is the hexadecimal value. Be sure to enclose *character-string* in double quotation marks (" ") so that the macro function resolves.

Example "Example 2: Ordering the Rows in a Report" on page 2174

number-of-repetitions'character-string'*
specifies a character string and the number of times to repeat it.

Example "Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177

pointer-control
specifies the column in which PROC REPORT displays the next specification. You can use either of the following forms for pointer controls:

@column-number
specifies the number of the column in which to begin displaying the next item in the specification list.

+column-increment
specifies the number of columns to skip before beginning to display the next item in the specification list.

Both *column-number* and *column-increment* can be either a variable or a literal value.

Restriction The pointer controls are designed for LISTING output. They have no effect on other ODS destinations.

Details

Differences between the LINE and PUT Statements

The LINE statement does not support the following features of the PUT statement:

- automatic labeling signaled by an equal sign (=), also known as named output
- the _ALL_, _INFILE_, and _PAGE_ arguments and the OVERPRINT option

- grouping items and formats to apply one format to a list of items
- pointer control using expressions
- line pointer controls (# and /)
- trailing at signs (@ and @@)
- format modifiers
- array elements

RBREAK Statement

Produces a default summary at the beginning or end of a report or at the beginning or end of each BY group.

Examples: "Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171

"Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195

Syntax

RBREAK *location* </ *options*>;

Summary of Optional Arguments

COLOR=*color*
: specifies the color of the break lines in the REPORT window.

CONTENTS='*link-text*'
: specifies the link text used in the table of contents.

DOL
: double overlines each value.

DUL
: double underlines each value.

OL
: overlines each value.

PAGE
: starts a new page after the last break line of a break located at the beginning of the report.

SKIP
: writes a blank line for the last break line of a break located at the beginning of the report.

STYLE<(*location(s)*)>=<*style-overrides(s)*>
: specifies a style element (for the Output Delivery System) for default summary lines, customized summary lines, or both.

SUMMARIZE
includes a summary line as one of the break lines.

UL
underlines each value.

Required Argument

location
controls the placement of the break lines and is either of the following:

AFTER
places the break lines at the end of the report.

BEFORE
places the break lines at the beginning of the report.

Optional Arguments

COLOR=*color*
specifies the color of the break lines in the REPORT window. You can use the following colors:

BLACK	MAGENTA
BLUE	ORANGE
BROWN	PINK
CYAN	RED
GRAY	WHITE
GREEN	YELLOW

Default The color of **Foreground** in the SASCOLOR window. (For more information, see the online Help for the SASCOLOR window.)

Restriction This option affects output in the interactive report window environment only.

Note Not all operating environments and devices support all colors, and in some operating environments and devices, one color might map to another color. For example, if the DEFINITION window displays the word BROWN in yellow characters, then selecting BROWN results in a yellow item.

CONTENTS='*link-text*'
specifies the text for the entries in the table of contents created by default or by options settings in ODS destinations that support the STYLE= option. Only the RBREAK BEFORE statement with the PAGE and SUMMARIZE options specified creates a table within the table of contents. If the CONTENTS= option plus the

PAGE and SUMMARIZE options are specified, then PROC REPORT uses the value of *link-text* and places that text in the table of contents for the tables that are created. If the value of CONTENTS= is empty quotation marks, then no link is created in the table of contents.

Default If an RBREAK BEFORE statement is present and the PAGE and SUMMARIZE options are specified, but no CONTENTS= option is specified, then the default link text in the table of contents will show **Summary**.

Restriction If CONTENTS= is specified, but no PAGE option is specified, then PROC REPORT generates a warning message in the SAS log file. Only RBREAK BEFORE / with the SUMMARIZE and PAGE options specified can actually create a table in the table of contents.

Tips HTML output can now have additional anchor tags.

All ODS destinations except OUTPUT and LISTING support the STYLE= option.

DOL

(for double overlining) uses the 13th formatting character to overline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default equal sign (=)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the OL and DOL options, then PROC REPORT honors only OL.

See The discussion of FORMCHAR= on page 2081.

DUL

(for double underlining) uses the 13th formatting character to underline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default equal sign (=)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the UL and DUL options, then PROC REPORT honors only UL.

See The discussion of FORMCHAR= on page 2081.

OL
(for overlining) uses the second formatting character to overline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default hyphen (-)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the OL and DOL options, then PROC REPORT honors only OL.

See the discussion of FORMCHAR= on page 2081.

PAGE
starts a new page after the last break line of a break located at the beginning of the report. On RBREAK BEFORE, the PAGE option starts a new table.

Restriction This option has no affect on the OUTPUT destination.

SKIP
writes a blank line after the last break line of a break located at the beginning of the report.

Restriction This option has no effect on ODS destinations other than the LISTING destination.

STYLE<(*location(s)*)>=<*style-overrides(s)*>
specifies the style element to use for default summary lines that are created with the RBREAK statement.

Restriction All ODS destinations except OUTPUT and LISTING support the STYLE= option.

Tip FONT names that contain characters other than letters or underscores must be enclosed in quotation marks.

See "Style Elements and Style Attributes for Table Regions " on page 2149

SUMMARIZE
includes a summary line as one of the break lines. A summary line at the beginning or end of a report contains values for the following:

- statistics
- analysis variables
- computed variables

The following table shows how PROC REPORT calculates the value for each type of report item in a summary line created by the RBREAK statement:

Report Item	Resulting Value
Statistic	Value of the statistic over all observations in the set
Analysis variable	Value of the statistic specified as the usage option in the DEFINE statement. PROC REPORT calculates the value of the statistic over all observations in the set. The default usage is SUM.
Computed variable	Results of the calculations based on the code in the corresponding compute block. (See "COMPUTE Statement" on page 2112.)

Examples "Example 1: Selecting Variables and Creating a Summary Line for a Report" on page 2171

"Example 8: Displaying a Calculated Percentage Column in a Report" on page 2195

UL

(for underlining) uses the second formatting character to underline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option.

Default hyphen (-)

Restriction This option affects only the LISTING output. It has no affect on other ODS output.

Interaction If you specify both the UL and DUL options, then PROC REPORT honors only UL.

See The discussion of FORMCHAR= on page 2081.

Details

Order of Break Lines

When a default summary contains more than one break line, the order in which the break lines appear is

1 overlining or double overlining (OL or DOL, LISTING output only)

2 summary line (SUMMARIZE)

3 underlining or double underlining (UL or DUL, LISTING output only)

4 skipped line (SKIP, LISTING output only)

5 page break (PAGE)

Note: If you define a customized summary for the break, then customized break lines appear after underlining or double underlining. For more information about customized break lines, see the COMPUTE statement on page 2112 and the LINE statement "LINE Statement" on page 2132.

WEIGHT Statement

Specifies weights for analysis variables in the statistical calculations.

See: For information about calculating weighted statistics see "Calculating Weighted Statistics" on page 83. For an example that uses the WEIGHT statement, see "Weighted Statistics Example" on page 84.

Syntax

WEIGHT *variable*;

Required Argument

variable
specifies a numeric variable whose values weight the values of the analysis variables. The value of the variable does not have to be an integer.

Table 58.8 *Variable Values and How PROC REPORT Responds*

Weight Value	PROC REPORT Response
0	Counts the observation in the total number of observations
Less than 0	Converts the value to zero and counts the observation in the total number of observations
Missing	Excludes the observation

Restriction PROC REPORT will not compute MODE when a weight variable is active. Instead, try using PROC UNIVARIATE when MODE needs to be computed and a weight variable is active.

Tip When you use the WEIGHT statement, consider which value of the VARDEF= option is appropriate. See VARDEF= on page 2096 and the calculation of weighted statistics in "Keywords and Formulas" on page 2700 for more information.

Details

Weight Information Is Not Saved

When you store a report definition, PROC REPORT does not store the WEIGHT statement.

Usage: REPORT Procedure

Statistics That Are Available in PROC REPORT

Use the following keywords to specify statistic keywords in the KEYWORD or KEYLABEL statement.

Table 58.9 *Statistics Available in PROC REPORT*

Descriptive statistic keywords	
CSS	PCTSUM
CV	RANGE
MAX	STD
MEAN	STDERR
MIN	SUM
MODE	SUMWGT

N	USS
NMISS	VAR
PCTN	
Quantile statistic keywords	
MEDIAN | P50	Q3 | P75
P1	P60
P5	P70
P10	P80
P20	P90
P30	P95
P40	P99
Q1 | P25	QRANGE
Hypothesis testing keyword	
PRT | PROBT	T

These statistics, the formulas that are used to calculate them, and their data requirements are discussed in "Keywords and Formulas" on page 2700.

To compute standard error and the Student's **t**-test, you must use the default value of VARDEF=, which is DF.

Every statistic except N must be associated with a variable. You associate a statistic with a variable either by placing the statistic above or below a numeric display variable or by specifying the statistic as a usage option in the DEFINE statement or in the DEFINITION window for an analysis variable.

You can place N anywhere because it is the number of observations in the input data set that contribute to the value in a cell of the report. The value of N does not depend on a particular variable.

Note: If you use the MISSING option in the PROC REPORT statement, then N includes observations with missing group, order, or across variables.

Using ODS Styles with PROC REPORT

Using Styles with Base SAS Procedures

Most Base SAS procedures that support ODS use one or more table templates to produce output objects. These table templates include templates for table elements: columns, headers, and footers. Each table element can specify the use of one or more style elements for various parts of the output. These style elements cannot be specified within the syntax of the procedure, but you can use customized styles for the ODS destinations that you use. For more information about customizing tables and styles, see "TEMPLATE Procedure: Creating a Style Template" in *SAS Output Delivery System: Procedures Guide*.

The Base SAS reporting procedures, PROC PRINT, PROC REPORT, and PROC TABULATE, enable you to quickly analyze your data and organize it into easy-to-read tables. You can use the STYLE= option with these procedure statements to modify the appearance of your report. The STYLE= option enables you to make changes in sections of output without changing the default style for all of the output. You can customize specific sections of procedure output by specifying the STYLE= option in specific statements within the procedure.

The following program uses the STYLE= option to create the background colors in the PROC REPORT output below:

```
title "Height and Weight by Gender and Age";
proc report nowd data=sashelp.class
   style(header)=[background=white];
   col age (('Gender' sex),(weight height));
   define age / style(header)=[background=lightgreen];
   define sex / across style(header)=[background=yellow] ' ';
   define weight / style(header)=[background=orange];
   define height / style(header)=[background=tan];
run;
```

Output 58.1 *Enhanced PROC REPORT Output*

Height and Weight by Gender and Age

	Gender			
	F		M	
Age	Weight	Height	Weight	Height
253	811	545.3	1089.5	639.1

Styles, Style Elements, and Style Attributes

Understanding Styles, Style Elements, and Style Attributes

The appearance of SAS output is controlled by ODS style templates (ODS styles). ODS styles are produced from compiled STYLE templates written in PROC TEMPLATE style syntax. An ODS style template is a collection of style elements that provides specific visual attributes for your SAS output.

- A style element is a named collection of style attributes that apply to a particular part of the output. Each area of ODS output has a style element name that is associated with it. The style element name specifies where the style attributes are applied. For example, a style element might contain instructions for the presentation of column headings or for the presentation of the data inside the cells. Style elements might also specify default colors and fonts for output that uses the style.
- A style attribute is a visual property, such as color, font properties, and line characteristics, that is defined in ODS with a reserved name and value. Style attributes are collectively referenced by a style element within a style template. Each *style attribute* specifies a value for one aspect of the presentation. For example, the BACKGROUNDCOLOR= attribute specifies the color for the background of an HTML table or for a colored table in printed output. The FONTSTYLE= attribute specifies whether to use a Roman font or an italic font.

Note: Because styles control the presentation of the data, they have no effect on output objects that go to the LISTING, DOCUMENT, or OUTPUT destination.

Available styles are in the SASHELP.TMPLMST item store. In SAS Enterprise Guide, the list of style sheets is shown by the Style Wizard. In batch mode or SAS Studio, you can display the list of available style templates by using the LIST statement in PROC TEMPLATE:

```
proc template;
   list styles / store=sashelp.tmplmst;
run;
```

For complete information about viewing ODS styles, see "Viewing ODS Styles Supplied by SAS" in *SAS Output Delivery System: Advanced Topics*.

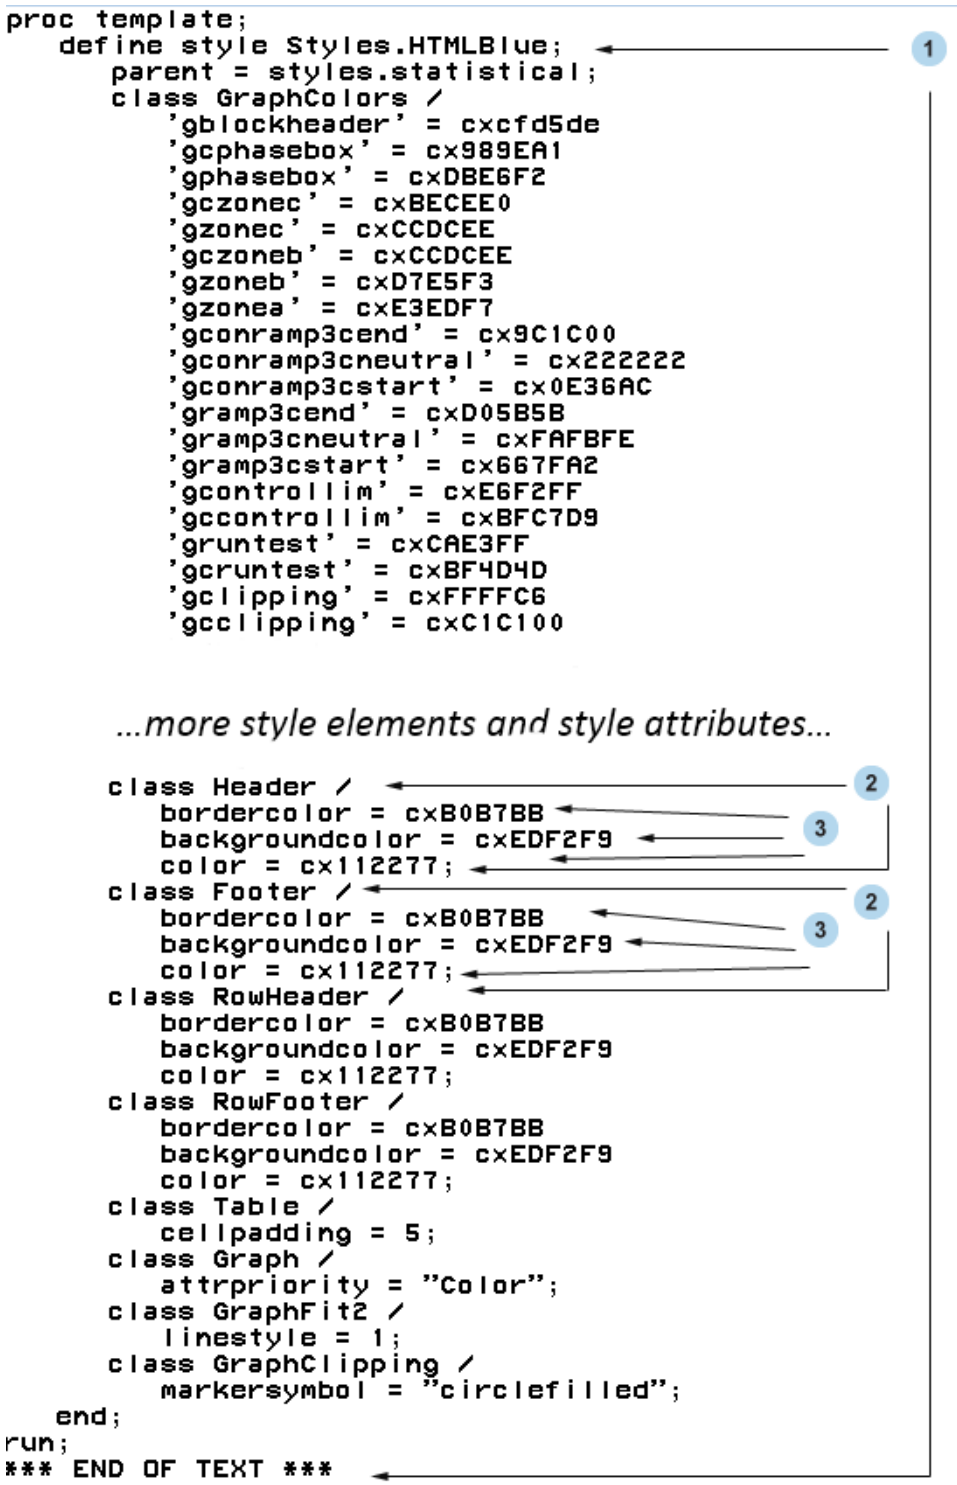
By default, HTML 4 output uses the HTMLBlue style template and HTML 5 output uses the HTMLEncore style template. To help you become familiar with styles, style elements, and style attributes, look at the relationship between them.

You can use the SOURCE statement in PROC TEMPLATE to display the structure of a style template. The following code prints the structure of the HTMLBlue style template to the SAS log:

```
proc template;
   source styles.HTMLBlue;
run;
```

The following figure illustrates the structure of a style. The figure shows the relationship between the style, the style elements, and the style attributes.

Figure 58.10 Diagram of the HtmlBlue Style



The following list corresponds to the numbered items in the preceding figure:

1 Styles.HtmlBlue is the *style*. Styles describe how to display presentation aspects (color, font, font size, and so on) of the SAS output. A style determines the overall appearance of the ODS documents that use it. The default style for HTML output is HtmlBlue. Each style consists of style elements.

You can create new styles with the "DEFINE STYLE Statement" in *SAS Output Delivery System: Procedures Guide*. New styles can be created independently or from an existing style. You can use "PARENT= Statement" in *SAS Output Delivery System: Procedures Guide* to create a new style from an existing style. For complete documentation about ODS styles, see "Style Templates" in *SAS Output Delivery System: Advanced Topics*.

2 Header and Footer are examples of *style elements*. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program. For example, a style element might contain instructions for the presentation of column headings or for the presentation of the data inside table cells. Style elements might also specify default colors and fonts for output that uses the style. Style elements exist inside styles and consist of one or more style attributes. Style elements can be user-defined or supplied by SAS. User-defined style elements can be created by the "STYLE Statement" in *SAS Output Delivery System: Procedures Guide*.

Note: For a list of the default style elements used for HTML and markup languages and their inheritance, see "Style Elements" in *SAS Output Delivery System: Advanced Topics*.

3 BORDERCOLOR=, BACKGROUNDCOLOR=, and COLOR= are examples of *style attributes*. Style attributes specify a value for one aspect of the area of the output that its style element applies to. For example, the COLOR= attribute specifies the value `cx112277` for the font color. For a list of style attributes supplied by SAS, see "Style Attributes" in *SAS Output Delivery System: Advanced Topics*.

Style attributes can be referenced with style references. See "style-reference" in *SAS Output Delivery System: Advanced Topics* for more information about style references.

The following table shows commonly used style attributes that you can set with the STYLE= option in PROC PRINT, PROC TABULATE, and PROC REPORT. Most of these attributes apply to parts of the table other than cells (for example, table borders and the lines between columns and rows). Note that not all attributes are valid in all destinations. For more information about these style attributes, their valid values, and their applicable destinations, see "Style Attributes Tables" in *SAS Output Delivery System: Advanced Topics*.

Table 58.10 *Style Attributes for PROC REPORT, PROC TABULATE, and PROC PRINT*

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE
ASIS=	X	X		X		X

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE
BACKGROUNDCOLOR=	X	X	X	X	X	X
BACKGROUNDIMAGE=	X	X	X	X	X	X
BORDERBOTTOMCOLOR=	X	X		X		
BORDERBOTTOMSTYLE=	X	X	X	X		
BORDERBOTTOMWIDTH=	X	X	X	X		
BORDERLEFTCOLOR=	X	X		X		
BORDERLEFTSTYLE=	X	X	X	X		
BORDERLEFTWIDTH=	X	X	X	X		
BORDERCOLOR=	X	X		X	X	X
BORDERCOLORDARK=	X	X	X	X	X	X
BORDERCOLORLIGHT=	X	X	X	X	X	X
BORDERRIGHTCOLOR=	X	X		X		
BORDERRIGHTSTYLE=	X	X	X	X		
BORDERRIGHTWIDTH=	X	X	X	X		
BORDERTOPCOLOR=	X	X		X		

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE
BORDERTOPSTYLE=	X	X	X	X		
BORDERTOPWIDTH=	X	X	X	X		
BORDERWIDTH=	X	X	X	X	X	X
CELLPADDING=	X		X		X	
CELLSPACING=	X		X		X	
CELLWIDTH=	X	X	X	X		X
CLASS=	X	X	X	X	X	X
COLOR=	X	X	X			
FLYOVER=	X	X		X		X
FONT=	X	X	X	X	X	X
FONTFAMILY=	X	X	X	X	X	X
FONTSIZE=	X	X	X	X	X	X
FONTSTYLE=	X	X	X	X	X	X
FONTWEIGHT=	X	X	X	X	X	X
FONTWIDTH=	X	X	X	X		X
FRAME=	X		X		X	
HEIGHT=	X	X		X	X	X
HREFTARGET=		X		X		X
HTMLSTYLE=	X	X	X	X	X	
NOBREAKSPACE=[2]	X	X		X		X
OUTPUTWIDTH=	X	X	X	X	X	
POSTHTML=[1]	X	X	X	X	X	X

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE
POSTIMAGE=	X	X	X	X	X	X
POSTTEXT=[1]	X	X	X	X	X	X
PREHTML=[1]	X	X	X	X	X	X
PREIMAGE=	X	X	X	X	X	X
PRETEXT=[1]	X	X	X	X	X	X
PROTECTSPECIALCHARS=		X		X	X	X
RULES=	X		X		X	
TAGATTR=	X	X	X	X	X	X
TEXTALIGN=	X	X	X	X	X	X
URL=		X		X		X
VERTICALALIGN=		X		X		X
WIDTH=	X	X	X	X	X	

1 When you use these attributes in this location, they affect only the text that is specified with the PRETEXT=, POSTTEXT=, PREHTML=, and POSTHTML= attributes. To alter the foreground color or the font for the text that appears in the table, you must set the corresponding attribute in a location that affects the cells rather than the table. For complete documentation about style attributes and their values, see "Style Attributes" in *SAS Output Delivery System: Advanced Topics*.

2 To help prevent unexpected wrapping of long text strings when using PROC REPORT with the ODS RTF destination, set NOBREAKSPACE=OFF in a location that affects the LINE statement. The NOBREAKSPACE=OFF attribute must be set in the PROC REPORT code either on the LINE statement or on the PROC REPORT statement where style(lines) is specified.

Style Elements and Style Attributes for Table Regions

The following table lists the default style elements and style attributes for various regions of PROC REPORT output. The locations in this table correspond to the locations in on page 2092. The table lists defaults for the most commonly used ODS destinations: HTML, PDF, and RTF. Each destination has a default style template that is applied to all output that is written to the destination.

- The default style for HTML output is HTMLBlue.
- The default style for PRINTER output is Pearl.
- The default style for RTF output is RTF.

For complete documentation about the ODS destinations and their default styles, see "Style Templates" in *SAS Output Delivery System: Advanced Topics*.

Table 58.11 *Default Style Elements and Style Attributes for Table Locations*

Locations	Style Element	HTML Style Attributes	PDF Style Attributes	RTF Style Attributes
Header	Header	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = bold FONTSTYLE = roman COLOR = cx112277 BACKGROUNDCOLOR = cxedf2f9	FONTFAMILY = "Arial, 'Albany AMT'" FONTSIZE = 8pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxffffff BORDERWIDTH = NaN	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 11pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxbbbbbb
Column	Data	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = medium FONTSTYLE = roman BACKGROUNDCOLOR = cxffffff	FONTFAMILY ="'Albany AMT', Albany" FONTSIZE = 8pt FONTWEIGHT = medium FONTSTYLE = roman COLOR = cx000000 BORDERWIDTH = NaN COLOR = cx000000	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 10pt FONTWEIGHT = medium FONTSTYLE = roman COLOR = cx000000
Summary	DataEmphasis	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = medium FONTSTYLE = roman BACKGROUNDCOLOR = cxffffff	FONTFAMILY ="'Albany AMT', Albany" FONTSIZE = 8pt FONTWEIGHT = medium FONTSTYLE = roman COLOR = cx000000 BORDERWIDTH = NaN	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 10pt FONTWEIGHT = medium FONTSTYLE = italic COLOR = cx000000

Order of Precedence When Applying Style Attributes to Data Cells

PROC REPORT determines the style attributes to apply to a particular cell from a default order of precedence. Each step in the order of precedence specifies more granularity.

For example, use the style precedence for non-summary rows shown below. First, for a particular cell, PROC REPORT uses the default style attributes. Next, for each cell in a column, PROC REPORT overrides the default style attributes. By step five, the previous styles that were applied are overwritten, but only for the cells specified by the *column-id*.

The following lists the style precedence for the summary rows and the non-summary rows.

Style precedence for non-summary rows.

1. PROC REPORT uses the default style attributes from the default style element (Data).
2. The STYLE (COLUMN)= option in the PROC REPORT statement overrides the default style attributes.
3. A STYLE (COLUMN)= option in the DEFINE statement applies to all of the cells in the column.
4. A row style that is specified by the _ROW_ argument in the CALL DEFINE statement applies to all of the cells in the row.
5. A style specified by the *column-id* _COL_ in the CALL DEFINE statement applies to all of the cells in the column.

Style precedence for summary rows.

1. PROC REPORT uses the default style attributes from the default style elements for summary rows (DataEmphasis).
2. The STYLE (SUMMARY)= option in the PROC REPORT statement overrides the default style attributes for the summary.
3. The style specified by the STYLE= option in the BREAK statement, applies to the summary cells.
4. The row style specified by a CALL DEFINE statement with the _ROW_ argument.
5. The style specified by a CALL DEFINE statement with the column-id _COL_, the column name, or the column number applies to all of the summary cells in the column.

Using a Format to Assign a Style Attribute Value

You can use a format to assign a style attribute value. For example, the following code assigns a red background color to cells in the Difference column for which the value is negative.

```
proc format;
value proffmt low-<0='red'
0-high='green';
run;

proc report data=sashelp.prdsale;
column country predict actual diff;
define country /group;
define diff /'Difference' computed format=dollar12.2
   style(column)=[backgroundcolor=proffmt.];

compute diff;
diff = predict.sum - actual.sum;
endcomp;
run;
```

Country	Predicted Sales	Actual Sales	Difference
CANADA	$233,019.00	$246,990.00	$-13,971.00
GERMANY	$231,554.00	$245,998.00	$-14,444.00
U.S.A.	$241,722.00	$237,349.00	$4,373.00

Controlling the Spacing between Rows

There is frequently a need to “shrink” a report to fit more rows on a page. Shrinking a report involves changing both the font size and the spacing between the rows. In order to give maximum flexibility to the programmer, ODS uses the font size that is specified for the REPORT location to calculate the spacing between the rows. Therefore, to shrink a table, change the font size for both the REPORT location and the COLUMN location. Here is an example:

```
proc report
data=libref.data_set-name
            style(report)=[fontsize=8pt]
            style(column)=[font=(Arial, 8pt)];
```

Printing a Report

Printing with ODS

Printing reports with the Output Delivery System is much simpler and provides more attractive output than the older methods of printing that are documented here. For best results, use an output destination in the ODS printer family or RTF. For details about these destinations and on using the ODS statements, see *SAS Output Delivery System: User's Guide*.

Printing from Noninteractive or Batch Mode

If you use noninteractive or batch mode, then SAS writes the output either to the display or to external files, depending on the operating environment and on the SAS options that you use. Refer to the SAS documentation for your operating environment for information about how these files are named and where they are stored.

You can print the output file directly or use PROC PRINTTO to redirect the output to another file. In either case, no form is used, but carriage-control characters are written if the destination is a print file.

Use operating environment commands to send the file to the printer.

Using PROC PRINTTO

PROC PRINTTO defines destinations for the SAS output and the SAS log. (See Chapter 49, "PRINTTO Procedure," on page 1857.)

PROC PRINTTO does not use a form, but it does write carriage-control characters if you are writing to a print file.

Note: You need two PROC PRINTTO steps. The first PROC PRINTTO step precedes the PROC REPORT step. It redirects the output to a file. The second PROC PRINTTO step follows the PROC REPORT step. It reestablishes the default destination and frees the output file. You cannot print the file until PROC PRINTTO frees it.

Storing and Reusing a Report Definition

The OUTREPT= option in the PROC REPORT statement stores a report definition in the specified catalog entry.

Note: A report definition might differ from the SAS program that creates the report. See the discussion of OUTREPT= on page 2087.

You can use a report definition to create an identically structured report for any SAS data set that contains variables with the same names as the ones that are used in the report definition. Use the REPORT= option in the PROC REPORT statement to load a report definition when you start PROC REPORT. For information, see "REPORT=*libref.catalog.entry*" on page 2091.

In-Database Processing for PROC REPORT

In-database processing has several advantages over processing within SAS. These advantages include increased security, reduced network traffic, and the potential for faster processing. Increased security is possible because sensitive data does not have to be extracted from the database management system (DBMS). Faster processing is possible because data is manipulated locally, on the DBMS, using high-speed secondary storage devices instead of being transported across a relatively slow network connection. The DBMS is used because it might have more processing resources at its disposal, and it might be capable of optimizing a query for execution in a highly parallel and scalable fashion.

When the DATA= input data set is stored as a table or view in a DBMS, the PROC REPORT procedure can use in-database processing to perform most of its work within the database. In-database processing can provide the advantages of faster processing and reduced data transfer between the database and SAS software.

In-database processing for PROC REPORT supports the following database management systems:

- Amazon Redshift
- Aster
- DB2
- Google BigQuery
- Greenplum
- Hadoop
- HAWQ
- Impala

- Microsoft SQL Server
- Netezza
- Oracle
- PostgreSQL
- SAP HANA
- Snowflake
- Teradata
- Vertica
- Yellowbrick

PROC REPORT performs in-database processing by using SQL implicit pass-through. The procedure generates SQL queries that are based on the statements and the PROC REPORT options that are used as well as the output statistics that are specified in the procedure. The database executes these SQL queries and the results of the query are then transmitted to PROC REPORT. To examine the generated SQL, set the SASTRACE= option.

If the SAS format definitions have not been deployed in the database, the in-database aggregation occurs on the raw values, and the relevant formats are applied by SAS as the results' set is merged into the PROC REPORT internal structures. For more information, see the section "Deploying and Using SAS Formats" in *SAS/ACCESS for Relational Databases: Reference*.

In-database processing will not occur if the PROC REPORT step contains variables with usage types DISPLAY or ORDER.

The following statistics are supported for in-database processing: N, NMISS, MIN, MAX, MEAN, RANGE, SUM, SUMWGT, CSS, USS, VAR, STD, STDERR, and CV.

Weighting for in-database processing is supported only for N, NMISS, MIN, MAX, RANGE, SUM, SUMWGT, and MEAN.

The SQLGENERATION system option or LIBNAME statement option controls whether and how in-database procedures are run inside the database. By default, the in-database procedures are run inside the database when possible. There are many data set options that prevent in-database processing. For a complete listing, refer to "In-Database Procedures" in *SAS/ACCESS for Relational Databases: Reference*.

For more information about in-database processing, see *SAS/ACCESS for Relational Databases: Reference*.

CAS Processing for PROC REPORT

If your input data set originates from SAS Cloud Analytic Services (CAS), some of the PROC REPORT analysis can be performed by the CAS server. Reports that require significant summarization of data can benefit from CAS processing. When run against a CAS table, PROC REPORT executes on the analytic server and uses

the appropriate statistical actions. For an overview about how procedures run in CAS, see Chapter 5, "CAS Processing of Base Procedures," on page 93.

The CAS LIBNAME statement option controls whether and how CAS procedures are run inside CAS. By default, the CAS procedures are run inside CAS when possible. However, there are many data set options that can prevent CAS processing.

When the DATA= input data set references an in-memory table or view in CAS, the REPORT procedure can use CAS actions to perform some of its work within the server. To reference an in-memory table or view, you must specify the CAS engine LIBNAME statement and specify the CAS engine libref option IN= or DATA=. By default, PROC REPORT uses CAS processing whenever a CAS engine libref is specified on the input.

The following example shows how to run SAS 9.4 PROC REPORT that uses CAS processing. The LIBNAME statement assigns a CAS engine libref named mycas that you use to connect to the CAS session casauto.

```
option casport=10935 cashost="cloud.example.com";
cas casauto ;

libname mycas cas;
data mycas.cars;
   set sashelp.cars;
run;

proc report data=mycas.cars;
title;
column ('Horsepower by Make and Drivetrain as a Percent of All
Horsepower'
origin drivetrain horsepower,(sum pctsum));
define origin / group;
define drivetrain / group;
define horsepower / '';
define sum / 'HP by Make and Drivetrain';
define pctsum / 'Percent of HP' format=percent6.;
rbreak after / summarize style=[font_style=italic];
run;
```

CAS processing does not occur if the PROC REPORT step contains variables with usage types DISPLAY or ORDER. If a DISPLAY or ORDER variable is found, all of the data is brought back to the client and PROC REPORT runs on the SAS client server.

The following statistics are supported for CAS processing:

CSS	RANGE
CV	STDERR
MAX	SUM
MEAN	SUMWGT
MIN	STD
N	USS
NMISS	VAR

Note: Weighting for CAS processing is supported only for N, NMISS, MIN, MAX, RANGE, SUM, SUMWGT, and MEAN.

The computations and processing are done in CAS. However, the rendering of the final table is done by the SAS client.

For information about how to use the CAS LIBNAME statement, see "CAS LIBNAME Statement" in *SAS Cloud Analytic Services: User's Guide*.

Substituting BY Line Values in a Text String

Starting with SAS 9.4M6, #BYLINE, #BYVAR, and #BYVAL substitutions are available in the following options:

- The CONTENTS= option in the PROC REPORT statement.
- The CAPTION= option in the PROC REPORT statement

To use the #BYVAR and #BYVAL substitutions, insert the item in the text string at the position where you want the substitution text to appear. Both #BYVAR and #BYVAL specifications must be followed by a delimiting character. The character can be either a space or other non-alphanumeric character, such as a quotation mark. If no delimiting character is provided, then the specification is ignored and its text remains intact and is displayed with the rest of the string. To allow a #BYVAR or #BYVAL substitution to be followed immediately by other text, with no delimiter, use a trailing dot (as with macro variables). The trailing dot is not displayed in the resolved text. If you want a period to be displayed as the last character in the resolved text, use two dots after the #BYVAR or #BYVAL substitution.

The substitution for #BYVAR or #BYVAL does not occur in the following cases:

- if you use a #BYVAR or #BYVAL specification for a variable that is not named in the BY statement. For example, you might use #BYVAL2 when there is only one BY-variable or #BYVAL(ABC) when ABC is non-existent or is not a BY-variable.
- if there is no BY statement

Results: REPORT Procedure

How PROC REPORT Builds a Report

Sequence of Events

This section explains the general process of building a report. For examples that illustrate this process, see "Report-Building Examples" on page 2160. The sequence of events is the same whether you use programming statements or the interactive report window environment.

To understand the process of building a report, you must understand the difference between report variables and temporary variables. **Report variables** are variables that are specified in the COLUMN statement. A report variable can come from the input data set or can be computed (that is, the DEFINE statement for that variable specifies the COMPUTED option). A report variable might or might not appear in a compute block. Variables that appear only in one or more compute blocks are **temporary variables**. Temporary variables do not appear in the report and are not written to the output data set (if one is requested).

PROC REPORT initializes report variables to missing at the beginning of each row of the report. The value for a **temporary variable** is initialized to missing before PROC REPORT begins to construct the rows of the report, and it remains missing until you specifically assign a value to it. PROC REPORT retains the value of a **temporary variable** from the execution of one compute block to another.

PROC REPORT constructs a report as follows:

1. It consolidates the data by group, order, and across variables. It calculates all statistics for the report, the statistics for detail rows as well as the statistics for summary lines in breaks. Statistics include those statistics that are computed for analysis variables. PROC REPORT calculates statistics for summary lines whether they appear in the report.
2. It initializes all temporary variables to missing.
3. It begins constructing the rows of the report.
   a. At the beginning of each row, it initializes all report variables to missing.
   b. It fills in values for report variables from left to right.

- Values for computed variables come from executing the statements in the corresponding compute blocks.
- Values for all other variables come from the data set or the summary statistics that were computed at the beginning of the report-building process.

c Whenever it comes to a break, PROC REPORT first constructs the break lines that are created with the BREAK or RBREAK statement or with options in the BREAK window.

d If there is a compute block attached to the break, PROC REPORT then executes the statements in the compute block. See "Construction of Summary Lines" on page 2159 for details.

Note: You can also use statistics with PROC REPORT as follows.

- Use group statistics in compute blocks for a break before the group variable.
- Use statistics for the whole report in a compute block at the beginning of the report.

This document references these statistics with the appropriate compound name. For information about referencing report items in a compute block, see "Four Ways to Reference Report Items in a Compute Block" on page 2063.

Note: You cannot use the LINE statement in conditional statements (IF-THEN, IF-THEN/ELSE, and SELECT) because it is not executed until PROC REPORT has executed all other statements in the compute block.

4 After each report row is completed, PROC REPORT sends the row to all of the ODS destinations that are currently open.

Construction of Summary Lines

PROC REPORT constructs a summary line for a break if either of the following conditions is true:

- You summarize numeric variables in the break.
- You use a compute block at the break. (You can attach a compute block to a break without using a BREAK or RBREAK statement or without selecting any options in the BREAK window.)

  For more information about using compute blocks, see "Using Compute Blocks" on page 2061 and "COMPUTE Statement" on page 2112.

The summary line that PROC REPORT constructs at this point is preliminary. If no compute block is attached to the break, then the preliminary summary line becomes the final summary line. However, if a compute block is attached to the break, then the statements in the compute block can alter the values in the preliminary summary line.

PROC REPORT prints the summary line only if you summarize numeric variables in the break.

Report-Building Examples

Building a Report That Uses Groups and a Report Summary

The report in "Report with Groups and a Report Summary" on page 2161 contains five columns:

- Sector and Department are group variables.
- Sales is an analysis variable that is used to calculate the Sum statistic.
- Profit is a computed variable whose value is based on the value of Department.
- The N statistic indicates how many observations each row represents.

At the end of the report a break summarizes the statistics and computed variables in the report and assigns to Sector the value of `TOTALS:`.

The following statements produce "Report with Groups and a Report Summary" on page 2161. The user-defined formats that are used are created by a PROC FORMAT step on page 2171.

```
libname proclib
'SAS-library';

options nodate pageno=1 linesize=64
        pagesize=60 fmtsearch=(proclib);

ods html close;
ods listing;
proc report data=grocery headline headskip;
    column sector department sales Profit N ;
    define sector / group format=$sctrfmt.;
    define department   / group format=$deptfmt.;
    define sales  / analysis sum
                    format=dollar9.2;
    define profit / computed format=dollar9.2;

    compute before;
    totprof = 0;
    endcomp;

    compute profit;
    if sector ne ' ' or department ne ' ' then do;
       if department='np1' or department='np2'
          then profit=0.4*sales.sum;
       else profit=0.25*sales.sum;
       totprof = totprof + profit;
       end;
    else
       profit = totprof;
    endcomp;
```

```
    rbreak after / dol dul summarize;
    compute after;
       sector='TOTALS:';
    endcomp;

    where sector contains 'n';
    title 'Report for Northeast and Northwest Sectors';
  run;
ods listing close;
```

Example Code 58.2 *Report with Groups and a Report Summary*

```
      Report for Northeast and Northwest Sectors          1

Sector     Department      Sales     Profit          N
-------------------------------------------------------

Northeast  Canned         $840.00    $336.00          2
           Meat/Dairy     $490.00    $122.50          2
           Paper          $290.00     $116.00         2
           Produce        $211.00     $52.75          2
Northwest  Canned       $1,070.00    $428.00          3
           Meat/Dairy   $1,055.00    $263.75          3
           Paper          $150.00     $60.00          3
           Produce        $179.00     $44.75          3
=========              =========  =========  =========
TOTALS:                $4,285.00  $1,423.75         20
=========              =========  =========  =========
```

A description of how PROC REPORT builds this report follows:

1 PROC REPORT starts building the report by consolidating the data (Sector and Department are group variables) and by calculating the statistics (Sales.sum and N) for each detail row and for the break at the end of the report.

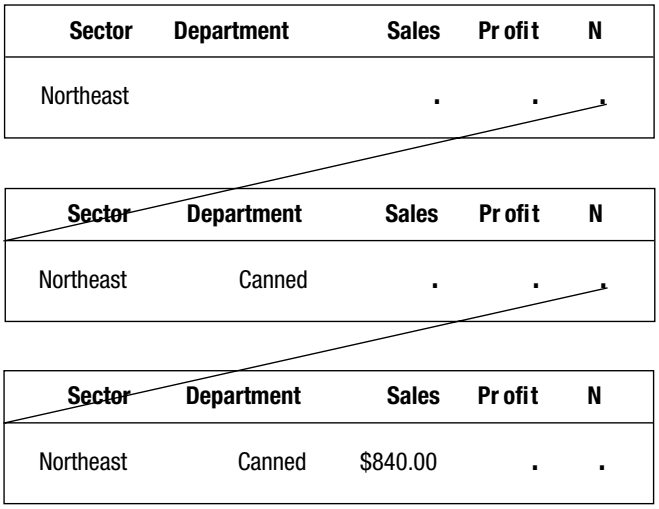
2 Now, PROC REPORT is ready to start building the first row of the report. This report does not contain a break at the beginning of the report or a break before any groups, so the first row of the report is a detail row. The procedure initializes all report variables to missing, as the following figure illustrates. Missing values for a character variable are represented by a blank, and missing values for a numeric variable are represented by a period.

Figure 58.11 *First Detail Row with Values Initialized*

Sector	Department	Sales	Profit	N
		.	.	.

3 The following figure illustrates the construction of the first three columns of the row. PROC REPORT fills in values for the row from left to right. Values come from the statistics that were computed at the beginning of the report-building process.

Figure 58.12 First Detail Row with Values Filled in from Left to Right



Sector	Department	Sales	Profit	N
Northeast		.	.	.

Sector	Department	Sales	Profit	N
Northeast	Canned	.	.	.

Sector	Department	Sales	Profit	N
Northeast	Canned	$840.00	.	.

4 The next column in the report contains the computed variable Profit. When it gets to this column, PROC REPORT executes the statements in the compute block that is attached to Profit. Nonperishable items (which have a value of **np1** or **np2**) return a profit of 40%; perishable items (which have a value of **p1** or **p2**) return a profit of 25%.

```
if department='np1' or department='np2'
   then profit=0.4*sales.sum;
else profit=0.25*sales.sum;
```

The row now looks like the following figure.

Note: The position of a computed variable is important. PROC REPORT assigns values to the columns in a row of a report from left to right. Consequently, you cannot base the calculation of a computed variable on any variable that appears to its right in the report.

Figure 58.13 A Computed Variable Added to the First Detail Row

Sector	Department	Sales	Profit	N
Northeast	Canned	$840.00	$336.00	.

5 The totprof variable is a temporary variable held in memory to keep a running total of the total profits. When each Sector and Department profits have been calculated, the value stored in variable totprof is then moved to Profit and reported in the TOTALS summary line.

```
totprof = totprof + profit;
       end;
    else
       profit = totprof;
```

6 Next, PROC REPORT fills in the value for the N statistic. The value comes from the statistics that are created at the beginning of the report-building process. The following figure illustrates the completed row.

Figure 58.14 First Complete Detail Row

Sector	Department	Sales	Profit	N
Northeast	Canned	$840.00	$336.00	2

7 The procedure writes the completed row to the report.

8 PROC REPORT repeats steps 2, 3, 4, 5, and 6 for each detail row in the report.

9 At the break at the end of the report, PROC REPORT constructs the break lines described by the RBREAK statement. These lines include double underlining, double overlining, and a preliminary version of the summary line. The statistics for the summary line were calculated earlier. (See step 1.) The value for the computed variable is calculated when PROC REPORT reaches the appropriate column, just as it is in detail rows. PROC REPORT uses these values to create the preliminary version of the summary line. (See the following figure.)

Figure 58.15 Preliminary Summary Line

Sector	Department	Sales	Profit	N
		$4,285.00	$1,423.75	20

10 If no compute block is attached to the break, then the preliminary version of the summary line is the same as the final version. However, in this example, a compute block is attached to the break. Therefore, PROC REPORT now executes the statements in that compute block. In this case, the compute block contains one statement:

```
sector='TOTALS:';
```

This statement replaces the value of Sector, which in the summary line is missing by default, with the word `TOTALS:`. After PROC REPORT executes the statement, it modifies the summary line to reflect this change to the value of Sector. The final version of the summary line appears in the following figure.

Figure 58.16 Final Summary Line

Sector	Department	Sales	Profit	N
TOTALS:		$4,285.00	$1,423.75	20

11 Finally, PROC REPORT writes all the break lines, with underlining, overlining, and the final summary line, to the report. See See "Report with Groups and a Report Summary" on page 2161.

Building a Report That Uses Temporary Variables

PROC REPORT initializes report variables to missing at the beginning of each row of the report. The value for a temporary variable is initialized to missing before PROC REPORT begins to construct the rows of the report, and it remains missing

until you specifically assign a value to it. PROC REPORT retains the value of a temporary variable from the execution of one compute block to another.

Because all compute blocks share the current values of all variables, you can initialize temporary variables at a break at the beginning of the report or at a break before a break variable. This report initializes the temporary variable Sctrtot at a break before Sector.

Note: PROC REPORT creates a preliminary summary line for a break before it executes the corresponding compute block. If the summary line contains computed variables, then the computations are based on the values of the contributing variables in the preliminary summary line. If you want to recalculate computed variables based on values that you set in the compute block, then you must do so explicitly in the compute block. This report illustrates this technique. If no compute block is attached to a break, then the preliminary summary line becomes the final summary line.

The report in "Report with Temporary Variables" on page 2166 contains five columns:

- Sector and Department are group variables.
- Sales is an analysis variable that is used twice in this report: once to calculate the Sum statistic, and once to calculate the Pctsum statistic.
- Sctrpct is a computed variable whose values are based on the values of Sales and a temporary variable, Sctrtot, which is the total sales for a sector.

At the beginning of the report, a customized report summary tells what the sales for all stores are. At a break before each group of observations for a department, a default summary summarizes the data for that sector. At the end of each group a break inserts a blank line.

The following statements produce "Report with Temporary Variables" on page 2166. The user-defined formats that are used are created by a PROC FORMAT step on page 2171.

Note: Calculations of the percentages do not multiply their results by 100 because PROC REPORT prints them with the PERCENT. format.

```
libname proclib
'SAS-library';

options nodate pageno=1 linesize=64
        pagesize=60 fmtsearch=(proclib);
ods html close;
ods listing;
proc report data=grocery noheader;
  column sector department sales
         Sctrpct sales=Salespct;

  define sector     / 'Sector' group
                      format=$sctrfmt.;
  define department / group format=$deptfmt.;
  define sales      / analysis sum
```

```
                    format=dollar9.2 ;
  define sctrpct    / computed
                    format=percent9.2 ;
  define salespct   / pctsum format=percent9.2;

  compute before;
     line ' ';
     line @16 'Total for all stores is '
          sales.sum dollar9.2;
     line ' ';
     line @29 'Sum of' @40 'Percent'
          @51 'Percent of';
     line @6 'Sector' @17 'Department'
          @29 'Sales'
          @40 'of Sector' @51 'All Stores';
     line @6 55*'=';
     line ' ';
  endcomp;

  break before sector / summarize ul;
  compute before sector;
     sctrtot=sales.sum;
     sctrpct=sales.sum/sctrtot;
  endcomp;

  compute sctrpct;
     sctrpct=sales.sum/sctrtot;
  endcomp;

  break after sector/skip;
  where sector contains 'n';
  title 'Report for Northeast and Northwest Sectors';
run;
ods listing close;
```

Example Code 58.3 *Report with Temporary Variables*

```
      Report for Northeast and Northwest Sectors          1

          Total for all stores is $4,285.00

                        Sum of     Percent    Percent of
Sector     Department   Sales      of Sector  All Stores
=======================================================

Northeast               $1,831.00   100.00%     42.73%
---------               ---------  ---------  ---------
Northeast  Canned          $840.00    45.88%     19.60%
           Meat/Dairy      $490.00    26.76%     11.44%
           Paper           $290.00    15.84%      6.77%
           Produce         $211.00    11.52%      4.92%

Northwest               $2,454.00   100.00%     57.27%
---------               ---------  ---------  ---------
Northwest  Canned        $1,070.00    43.60%     24.97%
           Meat/Dairy    $1,055.00    42.99%     24.62%
           Paper           $150.00     6.11%      3.50%
           Produce         $179.00     7.29%      4.18%
```

A description of how PROC REPORT builds this report follows:

1 PROC REPORT starts building the report by consolidating the data (Sector and Department are group variables) and by calculating the statistics (Sales.sum and Sales.pctsum) for each detail row, for the break at the beginning of the report, for the breaks before each group, and for the breaks after each group.

2 PROC REPORT initializes the temporary variable, Sctrtot, to missing. (See the following figure.)

Figure 58.17 *Initialized Temporary Variables*

Report Variables					Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
		.	.	.	.

3 Because this PROC REPORT step contains a COMPUTE BEFORE statement, the procedure constructs a preliminary summary line for the break at the beginning of the report. This preliminary summary line contains values for the statistics (Sales.sum and Sales.pctsum) and the computed variable (Sctrpct).

At this break, Sales.sum is the sales for all stores, and Sales.pctsum is the percentage those sales represent for all stores (100%). PROC REPORT takes the values for these statistics from the statistics that were computed at the beginning of the report-building process.

The value for Sctrpct comes from executing the statements in the corresponding compute block. Because the value of Sctrtot is missing, PROC REPORT cannot calculate a value for Sctrpct. Therefore, in the preliminary summary line (which is not printed in this case), this variable also has a missing value. (See the following figure.)

The statements in the COMPUTE BEFORE block do not alter any variables. Therefore, the final summary line is the same as the preliminary summary line.

Note: The COMPUTE BEFORE statement creates a break at the beginning of the report. You do not need to use an RBREAK statement.

Figure 58.18 *Preliminary and Final Summary Line for the Break at the Beginning of the Report*

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
		$4,285.00	.	100.00%	.

4 Because the program does not include an RBREAK statement with the SUMMARIZE option, PROC REPORT does not write the final summary line to the report. Instead, it uses LINE statements to write a customized summary that embeds the value of Sales.sum into a sentence and to write customized column headings. (The NOHEADER option in the PROC REPORT statement suppresses the default column headings, which would have appeared before the customized summary.)

5 Next, PROC REPORT constructs a preliminary summary line for the break before the first group of observations. (This break both uses the SUMMARIZE option in the BREAK statement with a compute block attached to it. Either of these conditions generates a summary line.) The preliminary summary line contains values for the break variable (Sector), the statistics (Sales.sum and Sales.pctsum), and the computed variable (Sctrpct). At this break, Sales.sum is the sales for one sector (the northeast sector). PROC REPORT takes the values for Sector, Sales.sum, and Sales.pctsum from the statistics that were computed at the beginning of the report-building process.

The value for Sctrpct comes from executing the statements in the corresponding compute blocks. Because the value of Sctrtot is still missing, PROC REPORT cannot calculate a value for Sctrpct. Therefore, in the preliminary summary line, Sctrpct has a missing value. (See the following figure.)

Figure 58.19 *Preliminary Summary Line for the Break before the First Group of Observations*

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northeast		$1,831.00	.	42.73%	.

6 PROC REPORT creates the final version of the summary line by executing the statements in the COMPUTE BEFORE SECTOR compute block. These statements execute once each time the value of Sector changes.

- The first statement assigns the value of Sales.sum, which in that part of the report represents total sales for one Sector, to the variable Sctrtot.

- The second statement completes the summary line by recalculating Sctrpct from the new value of Sctrtot. The following figure shows the final summary line.

Note: In this example, you must recalculate the value for Sctrpct in the final summary line. If you do not recalculate the value for Sctrpct, then it is missing because the value of Sctrtot is missing when the COMPUTE Sctrpct block executes.

Figure 58.20 *Final Summary Line for the Break before the First Group of Observations*

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northeast		$1,831.00	100.00%	42.73%	$1,831.00

7 Because the program contains a BREAK BEFORE statement with the SUMMARIZE option, PROC REPORT writes the final summary line to the report. The UL option in the BREAK statement underlines the summary line.

8 Now, PROC REPORT is ready to start building the first report row. It initializes all report variables to missing. Values for temporary variables do not change. The following figure illustrates the first detail row at this point.

Figure 58.21 *First Detail Row with Initialized Values*

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
		.	.	.	$1,831.00

9 The following figure illustrates the construction of the first three columns of the row. PROC REPORT fills in values for the row from left to right. The values come from the statistics that were computed at the beginning of the report-building process.

Figure 58.22 *Filling in Values from Left to Right*

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northeast		.	.	.	$1,831.00

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northeast	Canned	.	.	.	$1,831.00

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northeast	Canned	$840.00	.	.	$1,831.00

10 The next column in the report contains the computed variable Sctrpct. When it gets to this column, PROC REPORT executes the statement in the compute block attached to Sctrpct. This statement calculates the percentage of the sector's total sales that this department accounts for.

```
sctrpct=sales.sum/sctrtot;
```

The row now looks like the following figure.

Figure 58.23 *First Detail Row with the First Computed Variable Added*

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northeast	Canned	$840.00	45.88%	.	$1,831.00

11 The next column in the report contains the statistic Sales.pctsum. PROC REPORT gets this value from the statistics that are created at the beginning of the report-building process. The first detail row is now complete. (See the following figure.)

Figure 58.24 *First Complete Detail Row*

	Report Variables				Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northeast	Canned	$840.00	45.88%	19.60%	$1,831.00

12 PROC REPORT writes the detail row to the report. It repeats steps 8, 9, 10, 11, and 12 for each detail row in the group.

13 After writing the last detail row in the group to the report, PROC REPORT constructs the default group summary. Because no compute block is attached to this break and because the BREAK AFTER statement does not include the SUMMARIZE option, PROC REPORT does not construct a summary line. The only action at this break is that the SKIP option in the BREAK AFTER statement writes a blank line after the last detail row of the group.

14 Now the value of the break variable changes from `Northeast` to `Northwest`. PROC REPORT constructs a preliminary summary line for the break before this group of observations. As at the beginning of any row, PROC REPORT initializes all report variables to missing but retains the value of the temporary variable. Next, it completes the preliminary summary line with the appropriate values for the break variable (Sector), the statistics (Sales.sum and Sales.pctsum), and the computed variable (Sctrpct). At this break, Sales.sum is the sales for the Northwest sector. Because the COMPUTE BEFORE Sector block has not yet executed, the value of Sctrtot is still $1,831.00, the value for the Northeast sector. Thus, the value that PROC REPORT calculates for Sctrpct in this preliminary summary line is incorrect. (See the following figure.) The statements in the compute block for this break calculate the correct value. (See the following step.)

Figure 58.25 *Preliminary Summary Line for the Break before the Second Group of Observations*

		Report Variables			Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northwest		$2,454.00	134.00%	57.27%	$1,831.00

CAUTION

Synchronize values for computed variables in break lines to prevent incorrect results. If the PROC REPORT step does not recalculate Sctrpct in the compute block that is attached to the break, then the value in the final summary line is not synchronized with the other values in the summary line, and the report is incorrect.

15 PROC REPORT creates the final version of the summary line by executing the statements in the COMPUTE BEFORE Sector compute block. These statements execute once each time the value of Sector changes.

- The first statement assigns the value of Sales.sum, which in that part of the report represents sales for the Northwest sector, to the variable Sctrtot.
- The second statement completes the summary line by recalculating Sctrpct from the new, appropriate value of Sctrtot. The following figure shows the final summary line.

Figure 58.26 *Final Summary Line for the Break before the Second Group of Observations*

		Report Variables			Temporary Variable
Sector	Department	Sales.sum	Sctrpct	Sales.pctsum	Sctrtot
Northwest		$2,454.00	100.00%	57.27%	$2,454.00

Because the program contains a BREAK BEFORE statement with the SUMMARIZE option, PROC REPORT writes the final summary line to the report. The UL option in the BREAK statement underlines the summary line.

16 Now, PROC REPORT is ready to start building the first row for this group of observations. It repeats steps 8 through 16 until it has processed all observations in the input data set (stopping with step 14 for the last group of observations).

Examples: REPORT Procedure

Example 1: Selecting Variables and Creating a Summary Line for a Report

;

proc format library=proclib;
   value $sctrfmt 'se' = 'Southeast'
                  'ne' = 'Northeast'
                  'nw' = 'Northwest'
                  'sw' = 'Southwest';

   value $mgrfmt '1' = 'Smith'   '2' = 'Jones'
                 '3' = 'Reveiz'  '4' = 'Brown'
                 '5' = 'Taylor'  '6' = 'Adams'
                 '7' = 'Alomar'  '8' = 'Andrews'
                 '9' = 'Pelfrey';

   value $deptfmt 'np1' = 'Paper'
                  'np2' = 'Canned'
                  'p1'  = 'Meat/Dairy'
                  'p2'  = 'Produce';
run;

options fmtsearch=(proclib);

proc report data=grocery;

   column manager department sales;

   rbreak after / summarize style=[font_weight=bold];

   where sector='se';

   format manager $mgrfmt. department $deptfmt.
          sales dollar11.2;

   title 'Sales for the Southeast Sector';
   title2 "for &sysdate";
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Create the GROCERY data set. GROCERY contains one day's sales figures for eight stores in the Grocery Mart chain. Each observation contains one day's sales data for one department in one store.

```
data grocery;
   input Sector $ Manager $ Department $ Sales @@;
   datalines;
```

```
se 1 np1 50    se 1 p1 100   se 1 np2 120   se 1 p2 80
se 2 np1 40    se 2 p1 300   se 2 np2 220   se 2 p2 70
nw 3 np1 60    nw 3 p1 600   nw 3 np2 420   nw 3 p2 30
nw 4 np1 45    nw 4 p1 250   nw 4 np2 230   nw 4 p2 73
nw 9 np1 45    nw 9 p1 205   nw 9 np2 420   nw 9 p2 76
sw 5 np1 53    sw 5 p1 130   sw 5 np2 120   sw 5 p2 50
sw 6 np1 40    sw 6 p1 350   sw 6 np2 225   sw 6 p2 80
ne 7 np1 90    ne 7 p1 190   ne 7 np2 420   ne 7 p2 86
ne 8 np1 200   ne 8 p1 300   ne 8 np2 420   ne 8 p2 125
;
```

Create the $SCTRFMT., $MGRFMT., and $DEPTFMT. formats. PROC FORMAT creates permanent formats for Sector, Manager, and Department. The LIBRARY= option specifies a permanent storage location so that the formats are available in subsequent SAS sessions. These formats are used for examples throughout this section.

```
proc format library=proclib;
   value $sctrfmt 'se' = 'Southeast'
                  'ne' = 'Northeast'
                  'nw' = 'Northwest'
                  'sw' = 'Southwest';

   value $mgrfmt '1' = 'Smith'   '2' = 'Jones'
                 '3' = 'Reveiz'  '4' = 'Brown'
                 '5' = 'Taylor'  '6' = 'Adams'
                 '7' = 'Alomar'  '8' = 'Andrews'
                 '9' = 'Pelfrey';

   value $deptfmt 'np1' = 'Paper'
                  'np2' = 'Canned'
                  'p1'  = 'Meat/Dairy'
                  'p2'  = 'Produce';
run;
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options. By default, REPORT procedure runs without the REPORT window and sends its output to the open output destinations.

```
proc report data=grocery;
```

Specify the report columns. The report contains a column for Manager, Department, and Sales. Because there is no DEFINE statement for any of these variables, PROC REPORT uses the character variables (Manager and Department) as display variables and the numeric variable (Sales) as an analysis variable that is used to calculate the sum statistic.

```
   column manager department sales;
```

Produce a report summary. The RBREAK statement produces a default summary at the end of the report. SUMMARIZE sums the value of Sales for all observations in the report. STYLE= is used to bold the summarized value.

```
   rbreak after / summarize style=[font_weight=bold];
```

Select the observations to process. The WHERE statement selects for the report only the observations for stores in the southeast sector.

```
where sector='se';
```

Format the report columns. The FORMAT statement assigns formats to use in the report. You can use the FORMAT statement only with data set variables.

```
format manager $mgrfmt. department $deptfmt.
       sales dollar11.2;
```

Specify the titles. SYSDATE is an automatic macro variable that returns the date on which the SAS job or SAS session began. The TITLE2 statement uses double rather than single quotation marks so that the macro variable resolves.

```
   title 'Sales for the Southeast Sector';
   title2 "for &sysdate";
run;
```

Output: HTML

Output 58.2 *Selecting Variables and Creating a Summary Line for a Report*

Sales for the Southeast Sector for 03MAY14

Manager	Department	Sales
Smith	Paper	$50.00
Smith	Meat/Dairy	$100.00
Smith	Canned	$120.00
Smith	Produce	$80.00
Jones	Paper	$40.00
Jones	Meat/Dairy	$300.00
Jones	Canned	$220.00
Jones	Produce	$70.00
		$980.00

Example 2: Ordering the Rows in a Report

Features: PROC REPORT statement options
COLUMN statement
DEFINE statement options

ANALYSIS
FORMAT=
ORDER
ORDER=
SUM

BREAK statement options
AFTER
SUMMARIZE
STYLE=

LIBNAME statement

OPTIONS statement

WHERE statement

TITLE statement

Data set: GROCERY

Format: $MGRFMT

Format: $DEPTFMT

Details

This example does the following:

- arranges the rows alphabetically by the formatted values of Manager and the internal values of Department (so that sales for the two departments that sell nonperishable goods precede sales for the two departments that sell perishable goods)
- controls the default column width and the spacing between columns
- creates a default summary of Sales for each manager
- creates a customized summary of Sales for the whole report

Program

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc report data=grocery;

   column manager department sales;

   define manager / order order=formatted format=$mgrfmt.;
   define department / order order=internal format=$deptfmt.;

   define sales / analysis sum format=dollar7.2;

   break after manager / summarize
                         style=[font_style=italic];
```

```
  where sector='se';

  title 'Sales for the Southeast Sector';
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options. By default, PROC REPORT runs without the REPORT window and sends its output to the open output destinations.

```
proc report data=grocery;
```

Specify the report columns. The report contains a column for Manager, Department, and Sales.

```
  column manager department sales;
```

Define the sort order variables. The values of all variables with the ORDER option in the DEFINE statement determine the order of the rows in the report. In this report, PROC REPORT arranges the rows first by the value of Manager (because it is the first variable in the COLUMN statement) and then by the values of Department. ORDER= specifies the sort order for a variable. This report arranges the rows according to the formatted values of Manager and the internal values of Department (np1, np2, p1, and p2). FORMAT= specifies the formats to use in the report.

```
  define manager / order order=formatted format=$mgrfmt.;
  define department / order order=internal format=$deptfmt.;
```

Define the analysis variable. Sum calculates the sum statistic for all observations that are represented by the current row. In this report each row represents only one observation. Therefore, the Sum statistic is the same as the value of Sales for that observation in the input data set. Using Sales as an analysis variable in this report enables you to summarize the values for each group and at the end of the report.

```
  define sales / analysis sum format=dollar7.2;
```

Produce a report summary. This BREAK statement produces a default summary after the last row for each manager. PROC REPORT sums the values of Sales for each manager because Sales is an analysis variable that is used to calculate the Sum statistic. SKIP writes a blank line after the summary line.

```
  break after manager / summarize
                        style=[font_style=italic];
```

Select the observations to process. The WHERE statement selects for the report only the observations for stores in the southeast sector.

```
  where sector='se';
```

Specify the title.

```
  title 'Sales for the Southeast Sector';
run;
```

Output: HTML

Output 58.3 *Ordering the Rows in a Report*

Sales for the Southeast Sector

Manager	Department	Sales
Jones	Paper	$40.00
	Canned	$220.00
	Meat/Dairy	$300.00
	Produce	$70.00
Jones		*$630.00*
Smith	Paper	$50.00
	Canned	$120.00
	Meat/Dairy	$100.00
	Produce	$80.00
Smith		*$350.00*

SYSDATE

Data set: GROCERY

Format: $MGRFMT

Format: $DEPTFMT

Details

The customized summary at the end of this report displays the minimum and maximum values of Sales over all departments for stores in the southeast sector. To determine these values, PROC REPORT needs the MIN and MAX statistic for Sales in every row of the report. However, to keep the report simple, the display of these statistics is suppressed.

Program

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc report data=grocery;

   column manager department sales
          sales=salesmin
          sales=salesmax;

   define manager / order
                    order=formatted
                    format=$mgrfmt.
                    'Manager';
   define department    / order
                    order=internal
                    format=$deptfmt.
                    'Department';

   define sales / analysis sum format=dollar7.2 'Sales';

   define salesmin / analysis min noprint;
   define salesmax / analysis max noprint;
```

```
compute after;
      line 'Departmental sales ranged from'
            salesmin dollar7.2  " " 'to' " " salesmax dollar7.2;
   endcomp;

   where sector='se';

   title 'Sales for the Southeast Sector';
   title2 "for &sysdate";
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options. By default, PROC REPORT runs without the REPORT window and sends its output to the open output destinations.

```
proc report data=grocery;
```

Specify the report columns. The report contains columns for Manager and Department. It also contains three columns for Sales. The column specifications SALES=SALESMIN and SALES=SALESMAX create aliases for Sales. These aliases enable you to use a separate definition of Sales for each of the three columns.

```
column manager department sales
       sales=salesmin
       sales=salesmax;
```

Define the sort order variables. The values of all variables with the ORDER option in the DEFINE statement determine the order of the rows in the report. In this report, PROC REPORT arranges the rows first by the value of Manager (because it is the first variable in the COLUMN statement) and then by the values of Department. The ORDER= option specifies the sort order for a variable. This report arranges the values of Manager by their formatted values and arranges the values of Department by their internal values (np1, np2, p1, and p2). FORMAT= specifies the formats to use in the report. Text in quotation marks specifies column headings.

```
define manager / order
                 order=formatted
                 format=$mgrfmt.
                 'Manager';
define department    / order
                 order=internal
                 format=$deptfmt.
                 'Department';
```

Define the analysis variable. The value of an analysis variable in any row of a report is the value of the statistic that is associated with it (in this case Sum), calculated for all observations that are represented by that row. In a detail report

each row represents only one observation. Therefore, the Sum statistic is the same as the value of Sales for that observation in the input data set.

```
define sales / analysis sum format=dollar7.2 'Sales';
```

Define additional analysis variables for use in the summary. These DEFINE statements use aliases from the COLUMN statement to create separate columns for the MIN and MAX statistics for the analysis variable Sales. NOPRINT suppresses the printing of these statistics. Although PROC REPORT does not print these values in columns, it has access to them so that it can print them in the summary.

```
define salesmin / analysis min noprint;
define salesmax / analysis max noprint;
```

Produce a customized summary. This COMPUTE statement begins a compute block that executes at the end of the report. The line statement writes the text shown in the quotation marks, the value of Salesmin with the DOLLAR7.2 format, a space in quotation marks, the text in quotation marks “to”, a space, the value of Salesmax with the DOLLAR7.2 format. (Note that the program must reference the variables by their aliases.) The ENDCOMP statement ends the compute block.

```
compute after;
      line 'Departmental sales ranged from'
            salesmin dollar7.2  " " 'to' " " salesmax dollar7.2;
endcomp;
```

Select the observations to process. The WHERE statement selects for the report only the observations for stores in the southeast sector.

```
where sector='se';
```

Specify the titles. SYSDATE is an automatic macro variable that returns the date on which the SAS job or SAS session began. The TITLE2 statement uses double rather than single quotation marks so that the macro variable resolves.

```
title 'Sales for the Southeast Sector';
title2 "for &sysdate";
run;
```

Output: HTML

Output 58.4 *Using Aliases to Obtain Multiple Statistics for the Same Variable*

Sales for the Southeast Sector for 27MAY14

Manager	Department	Sales
Jones	Paper	$40.00
	Canned	$220.00
	Meat/Dairy	$300.00
	Produce	$70.00
Smith	Paper	$50.00
	Canned	$120.00
	Meat/Dairy	$100.00
	Produce	$80.00
Departmental sales ranged from $40.00 to $300.00		

Example 4: Displaying Multiple Statistics for One Variable

Features: PROC REPORT statement options
COLUMN statement
specifying statistics for stacked variables
DEFINE statement options
FORMAT=
GROUP
LIBNAME statement
OPTIONS statement
TITLE statement

Data set: GROCERY

Format: $MGRFMT

Details

The report in this example displays six statistics for the sales for each manager's store.

Program

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc report data=grocery;

column sector manager (Sum Min Max Range Mean Std),sales;

   define manager / group format=$mgrfmt.;
   define sector / group format=$sctrfmt.;
   define sales / format=dollar11.2 ;

   title 'Sales Statistics for All Sectors';
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options.

```
proc report data=grocery;
```

Specify the report columns. This COLUMN statement creates a column for Sector, Manager, and each of the six statistics that are associated with Sales.

```
column sector manager (Sum Min Max Range Mean Std),sales;
```

Define the group variables and the analysis variable. In this report, Sector and Manager are group variables. Each detail row of the report consolidates the information for all observations with the same values of the group variables. FORMAT= specifies the formats to use in the report.

```
   define manager / group format=$mgrfmt.;
   define sector / group format=$sctrfmt.;
   define sales / format=dollar11.2 ;
```

Specify the title.

```
   title 'Sales Statistics for All Sectors';
run;
```

Output: HTML

Output 58.5 *Displaying Multiple Statistics for One Variable*

Sales Statistics for All Sectors

		Sum	Min	Max	Range	Mean	Std
Sector	**Manager**	**Sales**	**Sales**	**Sales**	**Sales**	**Sales**	**Sales**
Northeast	Alomar	$786.00	$86.00	$420.00	$334.00	$196.50	$156.57
	Andrews	$1,045.00	$125.00	$420.00	$295.00	$261.25	$127.83

Format: $DEPTFMT

Details

This example creates a summary report that does the following:

- consolidates information for each combination of Sector and Manager into one row of the report
- contains default summaries of sales for each sector
- contains a customized summary of sales for all sectors
- uses one format for sales in detail rows and a different format in summary rows
- uses customized column headings

Program

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc report data=grocery;

   column sector manager sales;

   define sector / group format=$sctrfmt.'Sector';
   define manager / group format=$mgrfmt.'Manager';
   define sales / analysis sum format=comma10.2 'Sales';

   break after sector / summarize
                        style=[font_style=italic]
                        suppress;

   compute after;
      line 'Combined sales for the northern sectors were '
           sales.sum dollar9.2 '.';
   endcomp;

   compute sales;
```

```
      if _break_ ne ' ' then
      call define(_col_,"format","dollar11.2");
   endcomp;

   where sector contains 'n';

   title 'Sales Figures for Northern Sectors';
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options. By default, PROC REPORT runs without the REPORT window and sends its output to the open output destinations.

```
proc report data=grocery;
```

Specify the report columns. The report contains columns for Sector, Manager, and Sales.

```
   column sector manager sales;
```

Define the group and analysis variables. In this report, Sector and Manager are group variables. Sales is an analysis variable that is used to calculate the Sum statistic. Each detail row represents a set of observations that have a unique combination of formatted values for all group variables. The value of Sales in each detail row is the sum of Sales for all observations in the group. FORMAT= specifies the format to use in the report. Text in quotation marks in a DEFINE statement specifies the column heading.

```
   define sector / group format=$sctrfmt.'Sector';
   define manager / group format=$mgrfmt.'Manager';
   define sales / analysis sum format=comma10.2 'Sales';
```

Produce a report summary. This BREAK statement produces a default summary after the last row for each sector. SUMMARIZE writes the value of Sales in the summary line. The summary value is for each sector. It sums all managers in the sector sales. SUPPRESS prevents PROC REPORT from displaying the value of Sector in the summary line. The summary lines are italicized.

```
   break after sector / summarize
                        style=[font_style=italic]
                        suppress;
```

Produce a customized summary. This compute block creates a customized summary at the end of the report. The LINE statement writes the quoted text and the value of Sales.sum (with a format of DOLLAR9.2) in the summary. An ENDCOMP statement must end the compute block.

```
   compute after;
```

```
      line 'Combined sales for the northern sectors were '
           sales.sum dollar9.2 '.';
   endcomp;
```

Specify a format for the summary rows. In detail rows, PROC REPORT displays the value of Sales with the format that is specified in its definition (COMMA10.2). The compute block specifies an alternate format to use in the current column on summary rows. Summary rows are identified as a value other than a blank for _BREAK_.

```
   compute sales;
      if _break_ ne ' ' then
      call define(_col_,"format","dollar11.2");
   endcomp;
```

Select the observations to process. The WHERE statement selects for the report only the observations for stores in the northeast and northwest sectors. The TITLE statement specifies the title.

```
   where sector contains 'n';
```

Specify the title.

```
   title 'Sales Figures for Northern Sectors';
run;
```

Output: HTML

Output 58.6 *Consolidating Multiple Observations into One Row of a Report*

Sales Figures for Northern Sectors

Sector	Manager	Sales
Northeast	Alomar	786.00
	Andrews	1,045.00
		$1,831.00
Northwest	Brown	598.00
	Pelfrey	746.00
	Reveiz	1,110.00
		$2,454.00

Combined sales for the northern sectors were $4,285.00

Example 6: Creating a Column for Each Value of a Variable

Features:

Format: $SCTRFMT

Format: $MGRFMT

Format: $DEPTFMT

Details

The report in this example does the following:

- consolidates multiple observations into one row
- contains a column for each value of Department that is selected for the report (the departments that sell perishable items)
- contains a variable that is not in the input data set
- uses customized column headings, some of which contain blanks
- uses variable values in a customized summary

Program

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc report data=grocery split='*';

   column sector manager department,sales perish;

   define sector / group format=$sctrfmt. 'Sector' '';
   define manager / group format=$mgrfmt. 'Manager* ';

   define department / across format=$deptfmt. 'Department';

   define sales / analysis sum format=dollar11.2 ' ';

   define perish / computed format=dollar11.2
               'Perishable*Total';

   compute perish;
      perish=sum(_c3_, _c4_);
   endcomp;

   compute after;
            line  'Combined sales for meat and dairy : '
            _c3_ dollar11.2 '';
      line  'Combined sales for produce : '
            _c4_ dollar11.2 '';
      line  'Combined sales for all perishables: '
            _c5_ dollar11.2 '';
         endcomp;

   where sector contains 'n'
         and (department='p1' or department='p2');

   title 'Sales Figures for Perishables in Northern Sectors';
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options. By default, PROC REPORT runs without the REPORT window and sends its output to the open output destinations. SPLIT= defines the split character as an asterisk (*) because the default split character (/) is part of the name of a department.

```
proc report data=grocery split='*';
```

Specify the report columns. Department and Sales are separated by a comma in the COLUMN statement, so they collectively determine the contents of the column

that they define. Each item generates a heading, but the heading for Sales is set to blank in its definition. Because Sales is an analysis variable, its values fill the cells that are created by these two variables.

```
column sector manager department,sales perish;

define sector / group format=$sctrfmt. 'Sector' '';
define manager / group format=$mgrfmt. 'Manager* ';
```

Define the across variable. PROC REPORT creates a column and a column heading for each formatted value of the across variable Department. PROC REPORT orders the columns by these values. PROC REPORT also generates a column heading that spans all these columns. Quoted text in the DEFINE statement for Department customizes this heading.

```
define department / across format=$deptfmt. 'Department';
```

Define the analysis variable. Sales is an analysis variable that is used to calculate the sum statistic. In each case, the value of Sales is the sum of Sales for all observations in one department in one group. (In this case, the value represents a single observation.)

```
define sales / analysis sum format=dollar11.2 ' ';
```

Define the computed variable. The COMPUTED option indicates that PROC REPORT must compute values for Perish. You compute the variable's values in a compute block that is associated with Perish.

```
define perish / computed format=dollar11.2
            'Perishable*Total';
```

Calculate values for the computed variable. This compute block computes the value of Perish from the values for the Meat/Dairy department and the Produce department. Because the variables Sales and Department collectively define these columns, there is no way to identify the values to PROC REPORT by name. Therefore, the assignment statement uses column numbers to unambiguously specify the values to use. Each time PROC REPORT needs a value for Perish, it sums the values in the third and fourth columns of that row of the report.

```
compute perish;
   perish=sum(_c3_, _c4_);
endcomp;
```

Produce a customized summary. This compute block creates a customized summary at the end of the report. LINE statements write the quoted text in the specified columns and the values of the variables _C3_, _C4_, and _C5_ with the DOLLAR11.2 format.

```
compute after;
         line  'Combined sales for meat and dairy : '
         _c3_ dollar11.2 '';
   line  'Combined sales for produce : '
         _c4_ dollar11.2 '';
   line  'Combined sales for all perishables: '
         _c5_ dollar11.2 '';
      endcomp;

where sector contains 'n'
      and (department='p1' or department='p2');
```

Specify the title.

```
   title 'Sales Figures for Perishables in Northern Sectors';
run;
```

Output: HTML

Output 58.7 *Creating a Column for Each Value of a Variable*

Sales Figures for Perishables in Northern Sectors

		Department		
		Meat/Dairy	Produce	
Sector	Manager			Perishable Total
Northeast	Alomar	$190.00	$86.00	$276.00
	Andrews	$300.00	$125.00	$425.00
Northwest	Brown	$250.00	$73.00	$323.00
	Pelfrey	$205.00	$76.00	$281.00
	Reveiz	$600.00	$30.00	$630.00

Combined sales for meat and dairy: $1,545.00
Combined sales for produce: $390.00

Details

The report in this example displays a record of one day's sales for each store. The rows are arranged so that all the information about one store is together, and the information for each store begins on a new page. Some variables appear in columns. Others appear only in the page heading that identifies the sector and the store's manager.

The heading that appears at the top of each page is created with the _PAGE_ argument in the COMPUTE statement.

Profit is a computed variable based on the value of Sales and Department.

The text that appears at the bottom of the page depends on the total of Sales for the store. Only the first two pages of the report appear here.

Program

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc report data=grocery;

   title 'Sales for Individual Stores';

   column sector manager department sales Profit;

   define sector / group noprint;
   define manager / group noprint;
   define profit / computed format=dollar11.2;
   define sales / analysis sum format=dollar11.2;
   define department / group format=$deptfmt.;

   compute profit;
```

```
   if department='np1' or department='np2'
      then profit=0.4*sales.sum;
   else profit=0.25*sales.sum;
endcomp;

 compute before _page_ / style={just=left};
   line sector $sctrfmt. ' Sector';
   line 'Store managed by ' manager $mgrfmt.;
      endcomp;

break after manager / summarize style=[font_style=italic] page;

compute after manager;

   length text $ 35;

   if sales.sum lt 500 then
      text='Sales are below the target region.';
   else if sales.sum ge 500 and sales.sum lt 1000 then
      text='Sales are in the target region.';
   else if sales.sum ge 1000 then
      text='Sales exceeded goal!';
   line text $35.;
endcomp;
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options. By default, PROC REPORT runs without the REPORT window and sends its output to the open output destinations.

```
proc report data=grocery;
```

Specify the title.

```
title 'Sales for Individual Stores';
```

Specify the report columns. The report contains a column for Sector, Manager, Department, Sales, and Profit, but the NOPRINT option suppresses the printing of the columns for Sector and Manager. The page heading (created later in the program) includes their values. To get these variable values into the page heading, Sector and Manager must be in the COLUMN statement.

```
column sector manager department sales Profit;
```

Define the group, computed, and analysis variables. In this report, Sector, Manager, and Department are group variables. Each detail row of the report consolidates the information for all observations with the same values of the group variables. Profit is a computed variable whose values are calculated in the next section of the program. FORMAT= specifies the formats to use in the report.

```
define sector / group noprint;
define manager / group noprint;
define profit / computed format=dollar11.2;
define sales / analysis sum format=dollar11.2;
define department / group format=$deptfmt.;
```

Calculate the computed variable. Profit is computed as a percentage of Sales. For nonperishable items, the profit is 40% of the sale price. For perishable items the profit is 25%. Notice that in the compute block, you must reference the variable Sales with a compound name (Sales.sum) that identifies both the variable and the statistic that you calculate with it.

```
compute profit;
   if department='np1' or department='np2'
      then profit=0.4*sales.sum;
   else profit=0.25*sales.sum;
endcomp;
```

Create a customized page heading. This compute block executes at the top of each page, after PROC REPORT writes the title. It writes the page heading for the current manager's store. The STYLE= option left-justifies the text in the LINE statements. The LINE statements write a variable value with the format specified immediately after the variable's name.

```
 compute before _page_ / style={just=left};
   line sector $sctrfmt. ' Sector';
   line 'Store managed by ' manager $mgrfmt.;
      endcomp;
```

Produce a report summary. This BREAK statement creates a default summary after the last row for each manager. SUMMARIZE writes the value of Sales (the only analysis or computed variable) in the summary line. The PAGE option starts a new page after each default summary so that the page heading that is created in the preceding compute block always pertains to the correct manager. The STYLE= option italicizes the summary information.

```
break after manager / summarize style=[font_style=italic] page;
```

Produce a customized summary. This compute block places conditional text in a customized summary that appears after the last detail row for each manager.

```
compute after manager;
```

Specify the length of the customized summary text. The LENGTH statement assigns a length of 35 to the temporary variable TEXT. In this particular case, the LENGTH statement is unnecessary because the longest version appears in the first IF/THEN statement. However, using the LENGTH statement ensures that even if the order of the conditional statements changes, TEXT is long enough to hold the longest version.

```
   length text $ 35;
```

Specify the conditional logic for the customized summary text. You cannot use the LINE statement in conditional statements (IF-THEN, IF-THEN/ELSE, and SELECT) because it does not take effect until PROC REPORT has executed all other statements in the compute block. These IF-THEN/ELSE statements assign a value to TEXT based on the value of Sales.sum in the summary row. A LINE statement writes that variable, whatever its value happens to be.

```
      if sales.sum lt 500 then
         text='Sales are below the target region.';
      else if sales.sum ge 500 and sales.sum lt 1000 then
         text='Sales are in the target region.';
      else if sales.sum ge 1000 then
         text='Sales exceeded goal!';
      line text $35.;
   endcomp;
   run;
```

Output: HTML

Output 58.8 *Writing a Customized Summary on Each Page*

Sales for Individual Stores

Northeast Sector
Store managed by Alomar

Department	Sales	Profit
Canned	$420.00	$168.00
Meat/Dairy	$190.00	$47.50
Paper	$90.00	$36.00
Produce	$86.00	$21.50
	$786.00	*$196.50*

Sales are in the target region.

Sales for Individual Stores

Northeast Sector
Store managed by Andrews

Department	Sales	Profit
Canned	$420.00	$168.00

Format: $DEPTFMT

Details

The summary report in this example shows the total sales for each store and the percentage that these sales represent of sales for all stores. Each of these columns has its own heading. A single heading also spans all the columns.

The report includes a computed character variable, COMMENT, that flags stores with an unusually high percentage of sales.

Program

```
libname proclib 'SAS-library';
options fmtsearch=(proclib);
proc report data=grocery;
```

```
   title;

   column ('Individual Store Sales as a Percent of All Sales'
            sector manager sales,(sum pctsum) comment);

   define manager / group
                    format=$mgrfmt.;
   define sector / group
                   format=$sctrfmt.;
   define sales / format=dollar11.2
                  '';
   define sum / format=dollar9.2
                'Total Sales';

   define pctsum / 'Percent of Sales' format=percent6.;
   define comment / computed style(column)=[cellwidth=2.5in];

   compute comment / char length=40;

      if sales.pctsum gt .15 and _break_ = ' '
      then comment='Sales substantially above expectations.';
      else comment=' ';
   endcomp;

   rbreak after / summarize style=[font_style=italic];
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options. Specify the data set and other options.

```
proc report data=grocery;
   title;
```

Specify the report columns. The COLUMN statement uses the text in quotation marks as a spanning heading. The heading spans all the columns in the report because they are all included in the pair of parentheses that contains the heading. The COLUMN statement associates two statistics with Sales: Sum and Pctsum. The Sum statistic sums the values of Sales for all observations that are included in a row of the report. The Pctsum statistic shows what percentage of Sales sum is for all observations in the report.

```
   column ('Individual Store Sales as a Percent of All Sales'
            sector manager sales,(sum pctsum) comment);
```

Define the group and analysis columns. In this report, Sector and Manager are group variables. Each detail row represents a set of observations that have a unique combination of formatted values for all group variables. Sales is, by default, an analysis variable that is used to calculate the Sum statistic. However, because

statistics are associated with Sales in the column statement, those statistics override the default. FORMAT= specifies the formats to use in the report. Text between quotation marks specifies the column heading.

```
define manager / group
                  format=$mgrfmt.;
define sector / group
                 format=$sctrfmt.;
define sales / format=dollar11.2
               '';
define sum / format=dollar9.2
             'Total Sales';
```

Define the percentage and computed columns. The DEFINE statement for Pctsum specifies a column heading and a format. The PERCENT. format presents the value of Pctsum as a percentage rather than a decimal. The DEFINE statement for COMMENT defines a computed variable and assigns it a column.

```
define pctsum / 'Percent of Sales' format=percent6.;
define comment / computed style(column)=[cellwidth=2.5in];
```

Calculate the computed variable. Options in the COMPUTE statement define COMMENT as a character variable with a length of 40.

```
compute comment / char length=40;
```

Specify the conditional logic for the computed variable. For every store where sales exceed 15% of the sales for all stores, the compute block creates a comment that says **`Sales substantially above expectations`**. Of course, on the summary row for the report, the value of Pctsum is 100. However, it is inappropriate to flag this row as having exceptional sales. The automatic variable _BREAK_ distinguishes detail rows from summary rows. In a detail row, the value of _BREAK_ is blank. The THEN statement executes only on detail rows where the value of Pctsum exceeds 0.15.

```
    if sales.pctsum gt .15 and _break_ = ' '
    then comment='Sales substantially above expectations.';
    else comment=' ';
endcomp;
```

Produce the report summary. This RBREAK statement creates a default summary at the end of the report. SUMMARIZE writes the values of Sales.sum and Sales.pctsum in the summary line. STYLE= italicizes the summary line.

```
    rbreak after / summarize style=[font_style=italic];
run;
```

Output: HTML

Output 58.9 *Calculating Percentages*

Individual Store Sales as a Percent of All Sales				
Sector	**Manager**	**Total Sales**	**Percent of Sales**	**comment**
Northeast	Alomar	$786.00	12%	
	Andrews	$1,045.00	17%	Sales substantially above expectations.

   define sales / format=dollar9.2;

   rbreak after / summarize style=[fontstyle=italic];

   title 'Summary Report for All Sectors and Managers';
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Create the GROCMISS data set. GROCMISS is identical to GROCERY except that it contains some observations with missing values for Sector, Manager, or both.

```
data grocmiss;
   input Sector $ Manager $ Department $ Sales @@;
datalines;
se 1 np1 50    .  1 p1 100   se . np2 120   se 1 p2 80
se 2 np1 40    se 2 p1 300   se 2 np2 220   se 2 p2 70
nw 3 np1 60    nw 3 p1 600   .  3 np2 420   nw 3 p2 30
nw 4 np1 45    nw 4 p1 250   nw 4 np2 230   nw 4 p2 73
nw 9 np1 45    nw 9 p1 205   nw 9 np2 420   nw 9 p2 76
sw 5 np1 53    sw 5 p1 130   sw 5 np2 120   sw 5 p2 50
.  . np1 40    sw 6 p1 350   sw 6 np2 225   sw 6 p2 80
ne 7 np1 90    ne . p1 190   ne 7 np2 420   ne 7 p2 86
ne 8 np1 200   ne 8 p1 300   ne 8 np2 420   ne 8 p2 125
;
```

Specify the report options. By default, PROC REPORT runs without the REPORT window and sends its output to the open output destinations.

```
proc report data=grocmiss;
```

Specify the report columns. The report contains columns for Sector, Manager, the N statistic, and Sales.

```
   column sector manager N sales;
```

Define the group and analysis variables. In this report, Sector and Manager are group variables. Sales is, by default, an analysis variable that is used to calculate the Sum statistic. Each detail row represents a set of observations that have a unique combination of formatted values for all group variables. The value of Sales in each detail row is the sum of Sales for all observations in the group. In this PROC REPORT step, the procedure does not include observations with a missing value for the group variable. FORMAT= specifies formats to use in the report.

```
   define sector / group format=$sctrfmt.;
   define manager / group format=$mgrfmt.;
   define sales / format=dollar9.2;
```

Produce a report summary. This RBREAK statement creates a default summary at the end of the report. SUMMARIZE writes the values of N and Sales.sum in the summary line. STYLE= italicizes the summary line.

```
   rbreak after / summarize style=[fontstyle=italic];
```

Specify the title.

```
   title 'Summary Report for All Sectors and Managers';
run;
```

OUTPUT: HTML

Output 58.10 *Output with No Missing Values*

Summary Report for All Sectors and Managers

Sector	Manager	N	Sales
Northeast	Alomar	3	$596.00
	Andrews	4	$1,045.00
Northwest	Brown	4	$598.00
	Pelfrey	4	$746.00
	Reveiz	3	$690.00
Southeast	Jones	4	$630.00

Example 10: Creating an Output Data Set and Storing Computed Variables

Features:

PROC REPORT statement options
- OUT=

COLUMN

DEFINE statement options
- GROUP
- COMPUTED
- ANALYSIS
- SUM

COMPUTE

Data set options

WHERE=
LIBNAME statement
OPTIONS statement
TITLE

Data set: GROCERY

Format: $MGRFMT

Details

This example uses WHERE processing as it builds an output data set. This technique enables you to do WHERE processing after you have consolidated multiple observations into a single row.

Note: This technique is needed because you cannot subset on the results of analysis variables. You cannot subset on a value calculated by PROC REPORT.

The first PROC REPORT step creates a report in which each row represents all the observations from the input data set for a single manager. The second PROC REPORT step builds a report from the output data set.

Program to Create Output Data Set

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc report data=grocery
            out=profit( where=(sales gt 1000 and _break_='') );
   column manager sales manager_pct;

   define manager / group;
   define manager_pct / computed;
   compute before;
      total_sales = sales.sum;
   endcomp;
   compute manager_pct;
      manager_pct = sales.sum /total_sales;
   endcomp;
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the report options and columns. By default, PROC REPORT runs without the REPORT window and sends its output to the open output destinations. OUT= creates the output data set PROFIT. The output data set contains a variable for each column in the report (Manager, Sales, and the computed column manager_pct) as well as for the variable _BREAK_, which is not used in this example. Each observation in the data set represents a row of the report. Because Manager is a group variable and Sales is an analysis variable that is used to calculate the Sum statistic, each row in the report (and therefore each observation in the output data set) represents multiple observations from the input data set. In particular, each value of Sales in the output data set is the total of all values of Sales for that manager. The WHERE= data set option in the OUT= option filters those rows as PROC REPORT creates the output data set. Only those observations with sales that exceed $1,000 become observations in the output data set.

```
proc report data=grocery
            out=profit( where=(sales gt 1000 and _break_='') );
   column manager sales manager_pct;
```

Define the group and analysis variables and compute the values for the percent of sales. The overall sum is placed in a temporary variable, total_sales, and the values for the percent of sales is computed.

```
   define manager / group;
   define manager_pct / computed;
   compute before;
      total_sales = sales.sum;
   endcomp;
   compute manager_pct;
      manager_pct = sales.sum /total_sales;
   endcomp;
run;
```

OUTPUT: HTML

Here is the data set created by PROC REPORT. It is used as the input set in the next PROC REPORT step.

Output 58.12 *The Output Data Set PROFIT*

	Manager	Sales	manager_pct	_BREAK_
1	3	1110	0.1758276572	
2	8	1045	0.1655314431	

Program That Uses the Output Data Set

Specify the report options and columns, define the group and analysis columns, and specify the titles. DATA= specifies the output data set from the first PROC REPORT step as the input data set for this report. The TITLE statements specify a title for the report.

```
proc report data=profit;
   column manager sales manager_pct;
   define manager / group format=$mgrfmt.;
   define sales / analysis sum format=dollar11.2;
   define manager_pct /'Percent of Total Sales' format=percent8.2;
   title 'Managers with Daily Sales';
   title2 'of over';
   title3 'One Thousand Dollars';
run;
```

OUTPUT: HTML

Output 58.13 *Report Based on the Output Data Set*

Managers with Daily Sales
of over
One Thousand Dollars

Manager	Sales	Percent of Total Sales
Andrews	$1,045.00	16.55%
Reveiz	$1,110.00	17.58%

Example 11: Using a Format to Create Groups

- STYLE=

LINE statement
FORMAT procedure
LIBNAME statement
OPTIONS statement
TITLE

Data set: GROCERY

Format: $MGRFMT

Details

This example shows how to use formats to control the number of groups that PROC REPORT creates. The program creates a format for Department that classifies the four departments as one of two types: perishable or nonperishable. Consequently, when Department is an across variable, PROC REPORT creates only two columns instead of four. The column heading is the formatted value of the variable.

Program

```
libname proclib 'SAS-library';

options fmtsearch=(proclib);

proc format;
   value $perish 'p1','p2'='Perishable'
                 'np1','np2'='Nonperishable';
run;

proc report data=grocery;
```

```
   column manager department,sales sales;

   define manager / group order=formatted
                    format=$mgrfmt.;
   define department / across order=formatted
                format=$perish. '';

   define sales / analysis sum
                  format=dollar9.2 style=[cellwidth=13];

   compute after / style=[font_style=italic];
      line 'Total sales for these stores were: '
            sales.sum dollar9.2;
   endcomp;

title 'Sales Summary for All Stores';
run;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Create the $PERISH. format. PROC FORMAT creates a format for Department. This variable has four different values in the data set, but the format has only two values.

```
proc format;
   value $perish 'p1','p2'='Perishable'
                 'np1','np2'='Nonperishable';
run;
```

Specify the report options. By default, the REPORT procedure runs without the REPORT window and sends its output to the open output destinations.

```
proc report data=grocery;
```

Specify the report columns. Department and Sales are separated by a comma in the COLUMN statement, so they collectively determine the contents of the column that they define. Because Sales is an analysis variable, its values fill the cells that are created by these two variables. The report also contains a column for Manager and a column for Sales by itself (which is the sales for all departments).

```
   column manager department,sales sales;
```

Define the group and across variables. Manager is a group variable. Each detail row of the report consolidates the information for all observations with the same value of Manager. Department is an across variable. PROC REPORT creates a column and a column heading for each formatted value of Department. ORDER=FORMATTED

arranges the values of Manager and Department alphabetically according to their formatted values. FORMAT= specifies the formats to use. The empty quotation marks in the definition of Department specify a blank column heading, so no heading spans all the departments. However, PROC REPORT uses the formatted values of Department to create a column heading for each individual department.

```
define manager / group order=formatted
                 format=$mgrfmt.;
define department / across order=formatted
             format=$perish. '';
```

Define the analysis variable. Sales is an analysis variable that is used to calculate the Sum statistic. Sales appears twice in the COLUMN statement, and the same definition applies to both occurrences. FORMAT= specifies the format to use in the report. STYLE= specifies the width of the column. Notice that the column headings for the columns that both Department and Sales create are a combination of the heading for Department and the (default) heading for Sales.

```
define sales / analysis sum
               format=dollar9.2 style=[cellwidth=13];
```

Produce a customized summary. This COMPUTE statement begins a compute block that produces a customized summary at the end of the report. The LINE statement places the quoted text and the value of Sales.sum (with the DOLLAR9.2 format) in the summary. The STYLE= option italicizes the total sales. An ENDCOMP statement must end the compute block.

```
compute after / style=[font_style=italic];
   line 'Total sales for these stores were: '
         sales.sum dollar9.2;
endcomp;
```

Specify the title.

```
title 'Sales Summary for All Stores';
run;
```

Output: HTML

Output 58.14 *Using a Format to Create Groups*

Sales Summary for All Stores

	Nonperishable	Perishable	
Manager	**Sales**	**Sales**	**Sales**
Adams	$265.00	$430.00	$695.00
Alomar	$510.00	$276.00	$786.00
Andrews	$620.00	$425.00	$1,045.00
Brown	$275.00	$323.00	$598.00
Jones	$260.00	$370.00	$630.00
Pelfrey	$465.00	$281.00	$746.00
Reveiz	$480.00	$630.00	$1,110.00
Smith	$170.00	$180.00	$350.00
Taylor	$173.00	$180.00	$353.00
Total sales for these stores were: $6,313.00			

Example 12: Using Multilabel Formats

Features:

PROC REPORT statement

COLUMN statement

DEFINE statement options
- FORMAT=
- GROUP
- MLF
- ORDER=
- PRELOADFMT
- MEAN

FORMAT procedure option
- MULTILABEL
- NOTSORTED

LIBNAME statement

OPTIONS statement

TITLE statement

WHERE statement

Details

This example uses a multilabel format to create a report that does the following:

- shows how to specify a multilabel format in the VALUE statement of PROC FORMAT
- shows how to activate multilabel format processing using the MLF option with the DEFINE statement
- shows how using NOTSORTED and PRELOADFMT use the sort order shown in PROC FORMAT.

Program

```
proc format;
  value agelfmt (multilabel notsorted)
     11='11'
     12='12'
     13='13'
     14='14'
     15='15'
     16='16'
     11-12='11 or 12'
     13-14='13 or 14'
     15-16='15 or 16'
     low-13='13 and below'
     14-high='14 and above' ;
run;

ods html file="example.html";

title "GROUP Variable with MLF Option";

proc report data=sashelp.class;

   col age ('Mean' height weight);

   define age / group mlf format=agelfmt. 'Age Group' order=data
preloadfmt;
   define height / mean format=6.2 'Height (in.)';
   define weight / mean format=6.2 'Weight (lbs.)';
run;
```

Program Description

Create the AGE1FMT. format. The FORMAT procedure creates a multilabel format for ages by using the MULTILABEL option. A multilabel format is one in which multiple labels can be assigned to the same value. Each value is represented in the

table for each range in which it occurs. Use the NOTSORTED to ensure that the sort order is kept.

```
proc format;
  value agelfmt (multilabel notsorted)
     11='11'
     12='12'
     13='13'
     14='14'
     15='15'
     16='16'
     11-12='11 or 12'
     13-14='13 or 14'
     15-16='15 or 16'
     low-13='13 and below'
     14-high='14 and above' ;
run;
```

Specify the ODS HTML output filename.

```
ods html file="example.html";
```

Specify a title.

```
title "GROUP Variable with MLF Option";
```

Specify the report options. By default, the REPORT procedure runs without the REPORT window and sends its output to the open output destination.

```
proc report data=sashelp.class;
```

Specify the report columns. The report contains a column for Age, Height, and Weight. The Mean of the Height and Weight are calculated.

```
   col age ('Mean' height weight);
```

Define the variables. AGE is a group variable. The AGE variable uses the MLF option to activate multilabel format processing. MLF should be used only with group and across variables. FORMAT= specifies that the multilabel format, AGE1FMT. is used. The ORDER=DATA option along with the NOTSORTED option on PROC FORMAT, keeps the desired sort order. Each detail row of the report consolidates the information for all observations with the same values of the group variables. The mean is calculated for the HEIGHT and WEIGHT column values. PRELOADFMT option specifies that the format is preloaded for the variable.

```
   define age / group mlf format=agelfmt. 'Age Group' order=data
preloadfmt;
   define height / mean format=6.2 'Height (in.)';
   define weight / mean format=6.2 'Weight (lbs.)';
run;
```

Output: HTML

Output 58.15 *Using Multilabel Formats*

GROUP Variable with MLF Option

	Mean	
Age Group	Height (in.)	Weight (lbs.)
11	54.40	67.75
12	59.44	94.40
13	61.43	88.67
14	64.90	101.88
15	65.63	117.38
16	72.00	150.00
11 or 12	58.00	86.79
13 or 14	63.41	96.21
15 or 16	66.90	123.90
13 and below	59.03	87.35
14 and above	66.01	114.11

Example 13: Specifying Style Elements for ODS Output in Multiple Statements

Features:

PROC REPORT statement optionsSTYLE= option
    STYLE=

DEFINE statement options
    ORDER
    STYLE=

BREAK statement options
    AFTER
    SUMMARIZE

COMPUTE statement options

   column manager department sales;

   define manager / order
                    order=formatted
                    format=$mgrfmt.
                    'Manager'

                    style(header)=[color=white
```

```
                                    backgroundcolor=black];
   define department / order
                       order=internal
                       format=$deptfmt.
                       'Department'
                       style(column)=[fontstyle=italic];
   break after manager / summarize;
   compute after manager
           / style=[fontstyle=roman fontsize=3 fontweight=bold
             backgroundcolor=white color=black];
      line 'Subtotal for ' manager $mgrfmt. 'is '
           sales.sum dollar7.2 '.';
   endcomp;
   compute sales;
      if sales.sum>100 and _break_=' ' then
      call define(_col_, "style",
                  "style=[backgroundcolor=yellow
                          fontfamily=helvetica
                          fontweight=bold]");
   endcomp;
   compute after;
       line 'Total for all departments is: '
            sales.sum dollar7.2 '.';
   endcomp;
   where sector='se';
   title 'Sales for the Southeast Sector';
run;
ods pdf close;
ods rtf close;
```

Program Description

Declare the PROCLIB library. The PROCLIB library is used to store user-created formats.

```
libname proclib 'SAS-library';
```

Specify the format search library. The SAS system option FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options fmtsearch=(proclib);
```

Specify the ODS output filenames. By opening multiple ODS destinations, you can produce multiple output files in a single execution. HTML output is produced by default. The ODS PDF statement produces output in Portable Document Format (PDF). The ODS RTF statement produces output in Rich Text Format (RTF). The output from PROC REPORT goes to each of these files.

```
ods pdf file='external-PDF-file';
ods rtf file='external-RTF-file';
```

Specify the report options. By default, PROC REPORT runs without the REPORT window. In this case, SAS writes the output to the traditional procedure output, the HTML body file, and the RTF and PDF files.

```
proc report data=grocery
```

Specify the style attributes for the report. This STYLE= option sets the style element for the structural part of the report. Because no style element is specified, PROC REPORT uses all the style attributes of the default style element for this location except for the ones that are specified here.

```
style(report)=[cellspacing=5 borderwidth=10 bordercolor=blue]
```

Specify the style attributes for the column headings. This STYLE= option sets the style element for all column headings. Because no style element is specified, PROC REPORT uses all the style attributes of the default style element for this location except for the ones that are specified here.

```
style(header)=[color=yellow
               fontstyle=italic fontsize=6]
```

Specify the style attributes for the report columns. This STYLE= option sets the style element for all the cells in all the columns. Because no style element is specified, PROC REPORT uses all the style attributes of the default style element for this location except for the ones that are specified here.

```
style(column)=[color=moderate brown
               fontfamily=helvetica fontsize=4]
```

Specify the style attributes for the compute block lines. This STYLE= option sets the style element for all the LINE statements in all compute blocks. Because no style element is specified, PROC REPORT uses all the style attributes of the default style element for this location except for the ones that are specified here.

```
style(lines)=[color=white backgroundcolor=black
              fontstyle=italic fontweight=bold fontsize=5]
```

Specify the style attributes for the report summaries. This STYLE= option sets the style element for all the default summary lines. Because no style element is specified, PROC REPORT uses all the style attributes of the default style element for this location except for the ones that are specified here.

```
style(summary)=[color=cx3e3d73 backgroundcolor=cxaeadd9
                fontfamily=helvetica fontsize=3 textalign=r];
```

Specify the report columns. The report contains columns for Manager, Department, and Sales.

```
column manager department sales;
```

Define the first sort order variable. In this report Manager is an order variable. PROC REPORT arranges the rows first by the value of Manager (because it is the first variable in the COLUMN statement). ORDER= specifies that values of Manager are arranged according to their formatted values. FORMAT= specifies the format to use for this variable. Text in quotation marks specifies the column headings.

```
define manager / order
                 order=formatted
                 format=$mgrfmt.
                 'Manager'
```

Specify the style attributes for the first sort order variable column heading. The STYLE= option sets the foreground and background colors of the column heading for the Manager column heading.

```
style(header)=[color=white
              backgroundcolor=black];
```

Define the second sort order variable. In this report Department is an order variable. PROC REPORT arranges the rows first by the value of Manager (because it is the first variable in the COLUMN statement), then by the value of Department. ORDER= specifies that values of Department are arranged according to their internal values. FORMAT= specifies the format to use for this variable. Text in quotation marks specifies the column heading.

```
define department / order
                    order=internal
                    format=$deptfmt.
                    'Department'
```

Specify the style attributes for the second sort order variable column. The STYLE= option sets the font of the cells in the column Department to italic. The style attributes for the cells match the ones that were established for the COLUMN location in the PROC REPORT statement.

```
style(column)=[fontstyle=italic];
```

Produce a report summary. The BREAK statement produces a default summary after the last row for each manager. SUMMARIZE writes the values of Sales (the only analysis or computed variable in the report) in the summary line. PROC REPORT sums the values of Sales for each manager because Sales is an analysis variable that is used to calculate the Sum statistic.

```
break after manager / summarize;
```

Produce a customized summary. The COMPUTE statement begins a compute block that produces a customized summary at the end of the report. This STYLE= option specifies the style element to use for the text that is created by the LINE statement in this compute block. This style element switches the foreground and background colors that were specified for the LINES location in the PROC REPORT statement. It also changes the font style, the font weight, and the font size.

```
compute after manager
        / style=[fontstyle=roman fontsize=3 fontweight=bold
          backgroundcolor=white color=black];
```

Specify the text for the customized summary. The LINE statement places the quoted text and the values of Manager and Sales.sum (with the formats $MGRFMT. and DOLLAR7.2) in the summary. An ENDCOMP statement must end the compute block.

```
   line 'Subtotal for ' manager $mgrfmt. 'is '
        sales.sum dollar7.2 '.';
endcomp;
```

Produce a customized background for the analysis column. This compute block specifies a background color and a bold font for all cells in the Sales column that contain values of 100 or greater and that are not summary lines.

```
compute sales;
   if sales.sum>100 and _break_=' ' then
```

```
    call define(_col_, "style",
                "style=[backgroundcolor=yellow
                        fontfamily=helvetica
                        fontweight=bold]");
endcomp;
```

Produce a customized end-of-report summary. This COMPUTE statement begins a compute block that executes at the end of the report. The LINE statement writes the quoted text and the value of Sales.sum (with the DOLLAR7.2 format). An ENDCOMP statement must end the compute block.

```
compute after;
    line 'Total for all departments is: '
         sales.sum dollar7.2 '.';
endcomp;
```

Select the observations to process. The WHERE statement selects for the report only the observations for stores in the southeast sector.

```
where sector='se';
```

Specify the title.

```
title 'Sales for the Southeast Sector';
run;
```

Close the ODS destinations.

```
ods pdf close;
ods rtf close;
```

Example 14: Using the CELLWIDTH= Style Attribute with PROC REPORT

Features:

PROC REPORT statement options
STYLE=

COLUMN statement

DEFINE statement options
STYLE(COLUMN)=

TITLE statement

Details

This example uses PROC REPORT to create a table and uses ODS style attributes. This example

- sets the cell width of the total report
- defines the cell width for the columns in the ODS output.

Note: CELLWIDTH= and WIDTH= are aliases.

Refer to "Style Attributes Tables" in *SAS Output Delivery System: Advanced Topics* for details.

Note: The DEFINE statement WIDTH= option changes the width only for tables output in LISTING output.

Program

```
proc report data=sashelp.class;
   col name age sex;
   define name / style(column)=[cellwidth=1in];
define age / style(column)=[cellwidth=.5in];
define sex / style(column)=[cellwidth=.5in];
title "Using the CELLWIDTH= Style with PROC REPORT";
run;
```

Program Description

Specify the cell width for all the columns in the ODS output. By default, the REPORT procedure runs without the REPORT window and sends its output to the open output destination. ODS HTML is the output destination used as the default in this example.

```
proc report data=sashelp.class;
```

Specify the Columns to be used.

```
   col name age sex;
```

Define the column widths using the CELLWIDTH= style attribute. Define the dimensions of the NAME, AGE, and SEX column using the STYLE= option.

```
   define name / style(column)=[cellwidth=1in];
define age / style(column)=[cellwidth=.5in];
```

```
define sex / style(column)=[cellwidth=.5in];
```

Specify a table title. Provide a table name and run the SAS program.

```
title "Using the CELLWIDTH= Style with PROC REPORT";
run;
```

Output: HTML

Output 58.19 *Using the CELLWIDTH= Style Attributes with PROC REPORT*

Using CELLWIDTH= Style with PROC REPORT

Name	Age	Sex
Alfred	14	M
Alice	13	F
Barbara	13	F
Carol	14	F
Henry	14	M
James	12	M
Jane	12	F
Janet	15	F
Jeffrey	13	M
John	12	M
Joyce	11	F
Judy	14	F
Louise	12	F
Mary	15	F
Philip	16	M

Ronald	15	M
Thomas	11	M
William	15	M

Example 15: Using STYLE/MERGE in PROC REPORT CALL DEFINE Statement

Features:

PROC REPORT statement
COLUMN statement
COMPUTE statement
CALL DEFINE statement options
    STYLE
    STYLE/MERGE
TITLE statement

Details

This example uses PROC REPORT to create a table that uses the STYLE/MERGE option in the CALL DEFINE statement.

Program

```
proc report data=sashelp.class;
col name sex age height weight;
define name--weight / display;
   compute sex;
    if sex = 'M' then
        call define('name', "style", "style=[background=cyan]");
    endcomp;
   compute age;
    if age > 13 then
        call define('name', "style/merge", "style=[color=red]");
    endcomp;
title "Using STYLE/MERGE Style with PROC REPORT";
run;
```

Program Description

Specify the cell width for all the columns in the ODS output. By default, the REPORT procedure runs without the REPORT window and sends its output to the

open output destination. ODS HTML is the output destination used as the default in this example.

```
proc report data=sashelp.class;
```

Specify the Columns to be used.

```
col name sex age height weight;
```

Display all of the Columns.

```
define name--weight / display;
```

Apply style attributes. Apply the cyan color to the background of the names that are males.

```
compute sex;
 if sex = 'M' then
     call define('name', "style", "style=[background=cyan]");
 endcomp;
```

Merge style attributes. Apply the color red to the names that are over the age 13. That name color is merged with cells that have the cyan background color.

```
compute age;
 if age > 13 then
     call define('name', "style/merge", "style=[color=red]");
 endcomp;
```

Specify a table title. Provide a table name and run the SAS program.

```
title "Using STYLE/MERGE Style with PROC REPORT";
run;
```

Output: HTML

Output 58.20 *Using STYLE/MERGE*

Using STYLE/MERGE

Name	Sex	Age	Height	Weight
Alfred	M	14	69	112.5
Alice	F	13	56.5	84
Barbara	F	13	65.3	98
Carol	F	14	62.8	102.5
Henry	M	14	63.5	102.5
James	M	12	57.3	83
Jane	F	12	59.8	84.5
Janet	F	15	62.5	112.5
Jeffrey	M	13	62.5	84
John	M	12	59	99.5
Joyce	F	11	51.3	50.5
Judy	F	14	64.3	90
Louise	F	12	56.3	77
Mary	F	15	66.5	112
Philip	M	16	72	150

Thomas	M	11	57.5	85
William	M	15	66.5	112

Example 16: Using STYLE/REPLACE in PROC REPORT CALL DEFINE Statement

Features:
- PROC REPORT statement
- COLUMN statement
- COMPUTE statement
- CALL DEFINE statement options
  - STYLE

STYLE/REPLACE
TITLE statement

Details

This example uses PROC REPORT to create a table that uses the STYLE/REPLACE option in the CALL DEFINE statement.

Program

```
proc report data=sashelp.class;
col name sex age height weight;
define name--weight / display;
   compute sex;
    if sex = 'M' then
        call define('name', "style", "style=[background=cyan]");
    endcomp;
   compute age;
    if age > 13 then
        call define('name', "style/replace", "style=[color=red]");
    endcomp;
title "Using STYLE/REPLACE";
run;
```

Program Description

Specify the cell width for all the columns in the ODS output. By default, the REPORT procedure runs without the REPORT window and sends its output to the open output destination. ODS HTML is the output destination used as the default in this example.

```
proc report data=sashelp.class;
```

Specify the Columns to be used.

```
col name sex age height weight;
```

Display all of the Columns.

```
define name--weight / display;
```

Apply style attributes. Apply the cyan color to the background of the names that are males.

```
   compute sex;
    if sex = 'M' then
```

```
        call define('name', "style", "style=[background=cyan]");
    endcomp;
```

Replace style attributes. Apply the color red to the names that are over the age 13. For the names that are over the age of 13, the red name color replaces the background color cyan.

```
    compute age;
     if age > 13 then
        call define('name', "style/replace", "style=[color=red]");
     endcomp;
```

Specify a table title. Provide a table name and run the SAS program.

```
title "Using STYLE/REPLACE";
run;
```

Output: HTML

Output 58.21 *Using STYLE/REPLACE*

Using STYLE/REPLACE

Name	Sex	Age	Height	Weight
Alfred	M	14	69	112.5
Alice	F	13	56.5	84

59

REPORT Procedure Windows

Overview of REPORT Procedure Windows

The interactive report window environment in PROC REPORT provides essentially the same functionality as the statements, with one major exception: you cannot use the Output Delivery System from the interactive report window environment.

Dictionary

BREAK Window

Controls PROC REPORT's actions at a change in the value of a group or order variable or at the top or bottom of a report.

Details

Path

Edit ⇨ Summarize information

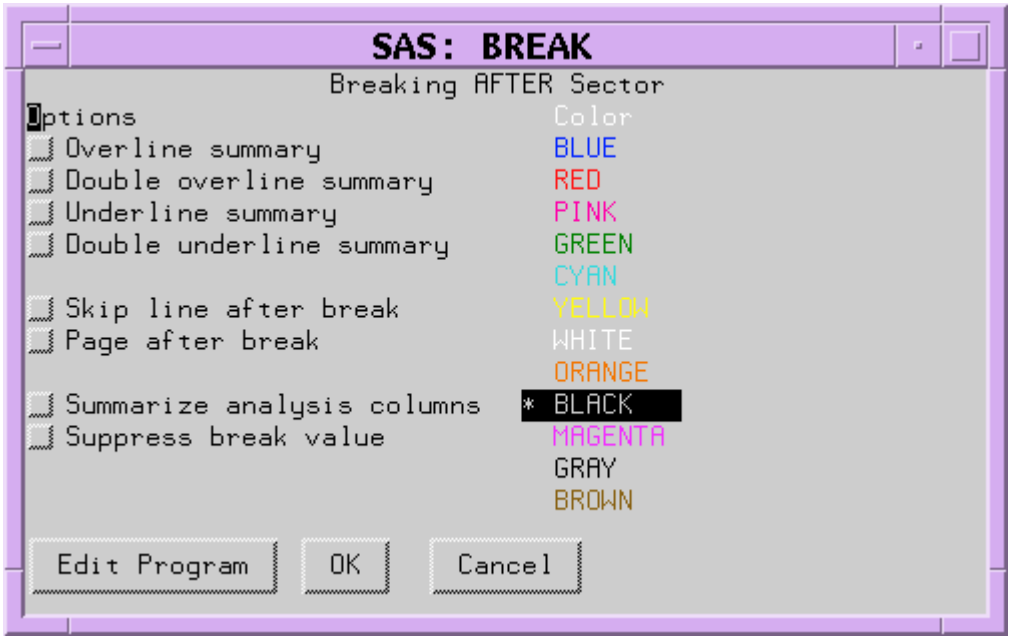
After you select **Summarize information**, PROC REPORT offers you four choices for the location of the break:

- **Before Item**
- **After Item**
- **At the top**
- **At the bottom**

After you select a location, the BREAK window appears.

Note: To create a break before or after detail lines (when the value of a group or order variable changes), you must select a variable before you open the BREAK window.

Description



Note: For information about changing the formatting characters that are used by the line drawing options in this window, see the discussion of "FORMCHAR <(*position(s)*)>='*formatting-character(s)*' " on page 2081

Options

Overline summary
uses the second formatting character to overline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default hyphen (-)

Interaction If you specify options to overline and to double overline, then PROC REPORT overlines.

Double overline summary
uses the 13th formatting character to overline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default equal sign (=)

Interaction If you specify options to overline and to double overline, then PROC REPORT overlines.

Underline summary
uses the second formatting character to underline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default hyphen (-)

Interaction If you specify options to underline and to double underline, then PROC REPORT underlines.

Double underline summary
uses the 13th formatting character to underline each value

- that appears in the summary line
- that would appear in the summary line if you specified the SUMMARIZE option

Default equal sign (=)

Interaction If you specify options to underline and to double underline, then PROC REPORT underlines.

Skip line after break
writes a blank line for the last break line.

This option has no effect if you use it in a break at the end of a report.

Page after break
starts a new page after the last break line. This option has no effect in a break at the end of a report.

Interaction If you use this option in a break on a variable and you create a break at the end of the report, then the summary for the whole report is on a separate page.

Summarize analysis columns
writes a summary line in each group of break lines. A summary line contains values for

- statistics
- analysis variables
- computed variables

A summary line between sets of observations also contains

- the break variable (which you can suppress with **Suppress break value**)
- other group or order variables to the left of the break variable.

The following table shows how PROC REPORT calculates the value for each type of report item in a summary line created by the BREAK window:

Report Item	Resulting Value
The break variable	The current value of the variable (or a missing value if you select `suppress break value`)
A group or order variable to the left of the break variable	The current value of the variable
A group or order variable to the right of the break variable, or a display variable anywhere in the report	Missing*
A statistic	The value of the statistic over all observations in the set
An analysis variable	The value of the statistic specified as the usage option in the item's definition. PROC REPORT calculates the value of the statistic over all observations in the set. The default usage is SUM.
A computed variable	The results of the calculations based on the code in the corresponding compute block. (See the "COMPUTE Statement" on page 2112 statement.)

*If you reference a variable with a missing value in a customized summary line, then PROC REPORT displays that variable as a blank (for character variables) or a period (for numeric variables).

Suppress break value
suppresses printing of

- the value of the break variable in the summary line
- any underlining and overlining in the break lines in the column containing the break variable

If you select **Suppress break value**, then the value of the break variable is unavailable for use in customized break lines unless you assign it a value in the compute block that is associated with the break.

Color

From the list of colors, select the one to use in the REPORT window for the column heading and the values of the item that you are defining. The default is the color of **Foreground** in the SASCOLOR window. (For more information, see the online Help for the **SASCOLOR** window.)

Note: Not all operating environments and devices support all colors, and in some operating environments and devices, one color might map to another color. For example, if the DEFINITION window displays the word BROWN in yellow characters, then selecting BROWN results in a yellow item.

Buttons

Edit Program
opens the COMPUTE window and enables you to associate a compute block with a location in the report.

OK
applies the information in the BREAK window to the report and closes the window.

Cancel
closes the BREAK window without applying information to the report.

COMPUTE Window

Attaches a compute block to a report item or to a location in the report. Use the SAS Text Editor commands to manipulate text in this window.

Details

Path

From **Edit Program** in the COMPUTED VAR, DEFINITION, or BREAK window.

Description

For information about the SAS language features that you can use in the COMPUTE window, see "The Contents of Compute Blocks" on page 2062.

COMPUTED VAR Window

Adds a variable that is not in the input data set to the report.

Details

Path

Select a column. Then select **Edit** ⇨ **Add Item** ⇨ **Computed Column**.

After you select **Computed Column**, PROC REPORT prompts you for the location of the computed column relative to the column that you have selected. After you select a location, the COMPUTED VAR window appears.

Description

Enter the name of the variable at the prompt. If it is a character variable, then select the **Character data** check box and, if you want, enter a value in the **Length** field. The length can be any integer between 1 and 200. If you leave the field blank, then PROC REPORT assigns a length of 8 to the variable.

After you enter the name of the variable, select **Edit Program** to open the COMPUTE window. Use programming statements in the COMPUTE window to define the computed variable. After closing the COMPUTE and COMPUTED VAR windows, open the DEFINITION window to describe how to display the computed variable.

Note: The position of a computed variable is important. PROC REPORT assigns values to the columns in a row of a report from left to right. Consequently, you cannot base the calculation of a computed variable on any variable that appears to its right in the report.

DATA COLUMNS Window

Lists all variables in the input data set so that you can add one or more data set variables to the report.

Details

Path

Select a report item. Then select **Edit** ⇨ **Add Item** ⇨ **Data Column**.

After you select **Data column**, PROC REPORT prompts you for the location of the computed column relative to the column that you have selected. After you select a location, the DATA COLUMNS window appears.

Description

Select one or more variables to add to the report. When you select the first variable, it moves to the top of the list in the window. If you select multiple variables, then subsequent selections move to the bottom of the list of selected variables. An asterisk (*) identifies each selected variable. The order of selected variables from top to bottom determines their order in the report from left to right.

DATA SELECTION Window

Loads a data set into the current report definition.

Details

Path

File ⇨ Open Data Set

Description

The first list box in the DATA SELECTION window lists all the librefs defined for your SAS session. The second one lists all the SAS data sets in the selected library.

Note: You must use data that is compatible with the current report definition. The data set that you load must contain variables whose names are the same as the variable names in the current report definition.

Buttons

OK
loads the selected data set into the current report definition.

Cancel
closes the DATA SELECTION window without loading new data.

DEFINITION Window

Displays the characteristics associated with an item in the report and lets you change them.

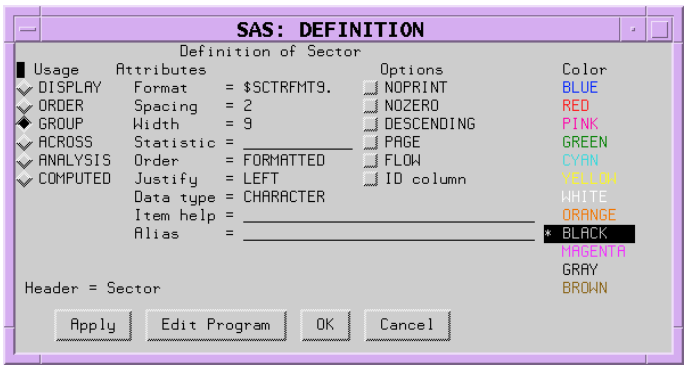
Details

Path

Select a report item. Then select **Edit** ⇨ **Define**.

Note: Alternatively, double-click on the selected item. (Not all operating environments support this method of opening the DEFINITION window.)

Description



Usage

For an explanation of each type of usage, see “Laying Out a Report ” on page 2054.

DISPLAY
: defines the selected item as a display variable. DISPLAY is the default for character variables.

ORDER
: defines the selected item as an order variable.

GROUP
: defines the selected item as a group variable.

ACROSS
: defines the selected item as an across variable.

ANALYSIS
: defines the selected item as an analysis variable. You must specify a statistic (see the discussion of the Statistic= attribute on page 2238) for an analysis variable. ANALYSIS is the default for numeric variables.

COMPUTED
: defines the selected item as a computed variable. Computed variables are variables that you define for the report. They are not in the input data set, and PROC REPORT does not add them to the input data set. However, computed variables are included in an output data set if you create one.

  In the interactive report window environment, you add a computed variable to a report from the COMPUTED VAR window.

Attributes

Format=
assigns a SAS or user-defined format to the item. This format applies to the selected item as PROC REPORT displays it; the format does not alter the format that is associated with a variable in the data set. For data set variables, PROC REPORT honors the first of these formats that it finds:

- the format that is assigned with FORMAT= in the DEFINITION window
- the format that is assigned in a FORMAT statement when you start PROC REPORT
- the format that is associated with the variable in the data set

If none of these formats is present, then PROC REPORT uses BEST*w*. for numeric variables and $*w*. for character variables. The value of *w* is the default column width. For character variables in the input data set, the default column width is the variable's length. For numeric variables in the input data set and for computed variables (both numeric and character), the default column width is the value of the COLWIDTH= attribute in the ROPTIONS window.

If you are unsure what format to use, then type a question mark (?) in the format field in the DEFINITION window to access the FORMATS window.

Spacing=
defines the number of blank characters to leave between the column being defined and the column immediately to its left. For each column, the sum of its width and the blank characters between it and the column to its left cannot exceed the line size.

Default 2

Interactions When PROC REPORT's CENTER option is in effect, PROC REPORT ignores spacing that precedes the leftmost variable in the report.

SPACING= in an item definition overrides the value of SPACING= in the PROC REPORT statement or the ROPTIONS window.

Width=
defines the width of the column in which PROC REPORT displays the selected item.

Default A column width that is just large enough to handle the format. If there is no format, then PROC REPORT uses the value of COLWIDTH=.

Range 1 to the value of the SAS system option LINESIZE=

Note When you stack items in the same column in a report, the width of the item that is at the bottom of the stack determines the width of the column.

Statistic=
associates a statistic with an analysis variable. You must associate a statistic with every analysis variable in its definition. PROC REPORT uses the statistic that you specify to calculate values for the analysis variable for the

observations represented by each cell of the report. You cannot use *statistic* in the definition of any other type of variable.

Note: PROC REPORT uses the name of the analysis variable as the default heading for the column. You can customize the column heading with the **Header** field of the DEFINITION window.

You can use the following values for *statistic*:

Descriptive statistic keywords	
CSS	PCTSUM
CV	RANGE
MAX	STD
MEAN	STDERR
MIN	SUM
N	SUMWGT
NMISS	USS
PCTN	VAR
Quantile statistic keywords	
MEDIAN | P50	Q3 | P75
P1	P90
P5	P95
P10	P99
Q1 | P25	QRANGE
Hypothesis testing keyword	
PRT|PROBT	T

Explanations of the keywords, the formulas that are used to calculate them, and the data requirements are discussed in Appendix 1, "SAS Elementary Statistics Procedures," on page 2699.

Default SUM

Requirement To compute standard error and the Student's *t*-test you must use the default value of VARDEF=, which is DF.

See For definitions of these statistics, see "Keywords and Formulas" on page 2700.

Order=

orders the values of a GROUP, ORDER, or ACROSS variable according to the specified order, where

DATA
orders values according to their order in the input data set.

FORMATTED
orders values by their formatted (external) values. By default, the order is ascending.

FREQ
orders values by ascending frequency count.

INTERNAL
orders values by their unformatted values, which yields the same order that PROC SORT would yield. This order is operating environment-dependent. This sort sequence is particularly useful for displaying dates chronologically.

Default FORMATTED

Interaction DESCENDING in the item's definition reverses the sort sequence for an item.

Note The default value for the ORDER= option in PROC REPORT is not the same as the default value in other SAS procedures. In other SAS procedures, the default is ORDER=INTERNAL. The default for the option in PROC REPORT might change in a future release to be consistent with other procedures. Therefore, in production jobs where it is important to order report items by their formatted values, specify ORDER=FORMATTED even though it is currently the default. Doing so ensures that PROC REPORT will continue to produce the reports that you expect even if the default changes.

Justify=

You can justify the placement of the column heading and of the values of the item that you are defining within a column in one of three ways:

LEFT
left-justifies the formatted values of the item that you are defining within the column width and left-justifies the column heading over the values. If the format width is the same as the width of the column, then LEFT has no effect on the placement of values.

RIGHT
right-justifies the formatted values of the item that you are defining within the column width and right-justifies the column heading over the values. If the format width is the same as the width of the column, then RIGHT has no effect on the placement of values.

CENTER
centers the formatted values of the item that you are defining within the column width and centers the column heading over the values. This option has no effect on the setting of the SAS system option CENTER.

When justifying values, PROC REPORT justifies the field width defined by the format of the item within the column. Thus, numbers are always aligned.

Data type=
shows you if the report item is numeric or character. You cannot change this field.

Item Help=
references a HELP or CBT entry that contains Help information for the selected item. Use PROC BUILD in SAS/AF software to create a HELP or CBT entry for a report item. All HELP and CBT entries for a report must be in the same catalog, and you must specify that catalog with the HELP= option in the PROC REPORT statement or from the **User Help** fields in the ROPTIONS window.

To access a Help entry from the report, select the item and issue the HELP command. PROC REPORT first searches for and displays an entry named *entry-name*.CBT. If no such entry exists, then PROC REPORT searches for *entry-name*.HELP. If neither a CBT nor a HELP entry for the selected item exists, then the opening frame of the Help for PROC REPORT is displayed.

Alias=
By entering a name in the **Alias** field, you create an alias for the report item that you are defining. Aliases let you distinguish between different uses of the same report item. When you refer in a compute block to a report item that has an alias, you must use the alias. (See "Example 3: Using Aliases to Obtain Multiple Statistics for the Same Variable" on page 2177.)

Options

NOPRINT
suppresses the display of the item that you are defining. Use this option

- if you do not want to show the item in the report but you need to use the values in it to calculate other values that you use in the report.
- to establish the order of rows in the report.
- if you do not want to use the item as a column but want to have access to its values in summaries. (See "Example 7: Writing a Customized Summary on Each Page" on page 2190.)

Interactions Even though the columns that you define with NOPRINT do not appear in the report, you must count them when you are referencing columns by number. (See "Four Ways to Reference Report Items in a Compute Block" on page 2063 .)

SHOWALL in the PROC REPORT statement or the ROPTIONS window overrides all occurrences of NOPRINT.

NOZERO
suppresses the display of the item that you are defining if its values are all zero or missing.

Interactions Even though the columns that you define with NOZERO do not appear in the report, you must count them when you are referencing columns by number. (See "Four Ways to Reference Report Items in a Compute Block" on page 2063.)

SHOWALL in the PROC REPORT statement or the ROPTIONS window overrides all occurrences of NOZERO.

DESCENDING
reverses the order in which PROC REPORT displays rows or values of a group, order, or across variable.

PAGE
inserts a page break just before printing the first column containing values of the selected item.

Interaction PAGE is ignored if you use WRAP in the PROC REPORT statement or in the ROPTIONS window.

FLOW
wraps the value of a character variable in its column. The FLOW option honors the split character. If the text contains no split character, then PROC REPORT tries to split text at a blank.

ID column
specifies that the item that you are defining is an ID variable. An ID variable and all columns to its left appear at the left of every page of a report. ID ensures that you can identify each row of the report when the report contains more columns than will fit on one page.

Color

From the list of colors, select the one to use in the REPORT window for the column heading and the values of the item that you are defining. The default is the color of **Foreground** in the SASCOLOR window. (For more information, see the online Help for the SASCOLOR window.)

Note: Not all operating environments and devices support all colors, and in some operating environments and devices, one color might map to another color. For example, if the DEFINITION window displays the word BROWN in yellow characters, then selecting BROWN results in a yellow item.

Buttons

Apply
applies the information in the open window to the report and keeps the window open.

Edit Program
opens the COMPUTE window and enables you to associate a compute block with the variable that you are defining.

OK
applies the information in the DEFINITION window to the report and closes the window.

Cancel
closes the DEFINITION window without applying changes made with **APPLY**.

DISPLAY PAGE Window

Displays a particular page of the report.

Details

Path

View ⇨ Display Page

Description

You can access the last page of the report by entering a large number for the page number. When you are on the last page of the report, PROC REPORT sends a note to the message line of the REPORT window.

EXPLORE Window

Lets you experiment with your data.

Restriction: You cannot open the EXPLORE window unless your report contains at least one group or order variable.

Details

Path

Edit ⇨ Explore Data

Description

In the EXPLORE window, you can

- subset the data with list boxes
- suppress the display of a column with the **Remove Column** check box
- change the order of the columns with **Rotate columns**

Note: The results of your manipulations in the EXPLORE window appear in the REPORT window but are not saved in report definitions.

Window Features

list boxes
: The EXPLORE window contains three list boxes. These boxes contain the value **All levels** as well as actual values for the first three group or order variables in your report. The values reflect any WHERE clause processing that is in effect. For example, if you use a WHERE clause to subset the data so that it includes only the northeast and northwest sectors, then the only values that appear in the list box for Sector are **All levels**, **Northeast**, and **Northwest**. Selecting **All levels** in this case displays rows of the report for only the northeast and northwest sectors. To see data for all the sectors, you must clear the WHERE clause before you open the EXPLORE window.

  Selecting values in the list boxes restricts the display in the REPORT window to the values that you select. If you select incompatible values, then PROC REPORT returns an error.

Remove Column
: Above each list box in the EXPLORE window is a check box labeled **Remove Column**. Selecting this check box and applying the change removes the column from the REPORT window. You can easily restore the column by clearing the check box and applying that change.

Buttons

OK
: applies the information in the EXPLORE window to the report and closes the window.

Apply
: applies the information in the EXPLORE window to the report and keeps the window open.

Rotate columns
: changes the order of the variables displayed in the list boxes. Each variable that can move one column to the left does; the leftmost variable moves to the third column.

Cancel
: closes the EXPLORE window without applying changes made with **APPLY**.

FORMATS Window

Displays a list of formats and provides a sample of each one.

Details

Path

From the DEFINE window, type a question mark (?) in the **Format** field and select any of the Buttons except **Cancel**, or press Enter.

Description

When you select a format in the FORMATS window, a sample of that format appears in the **Sample:** field. Select the format that you want to use for the variable that you are defining.

Buttons

OK
writes the format that you have selected into the **Format** field in the DEFINITION window and closes the FORMATS window. To see the format in the report, select **Apply** in the DEFINITION window.

Cancel
closes the FORMATS window without writing a format into the **Format** field.

LOAD REPORT Window

Loads a stored report definition.

Details

Path

File ⇨ Open Report

Description

The first list box in the LOAD REPORT window lists all the librefs that are defined for your SAS session. The second list box lists all the catalogs that are in the

selected library. The third list box lists descriptions of all the stored report definitions (entry types of REPT) that are in the selected catalog. If there is no description for an entry, then the list box contains the entry's name.

Buttons

OK
loads the current data into the selected report definition.

Cancel
closes the LOAD REPORT window without loading a new report definition.

Note: Issuing the END command in the REPORT window returns you to the previous report definition (with the current data).

MESSAGES Window

Automatically opens to display notes, warnings, and errors returned by PROC REPORT.

Details

You must close the MESSAGES window by selecting **OK** before you can continue to use PROC REPORT.

PROFILE Window

Customizes some features of the PROC REPORT environment by creating a report profile.

Details

Path

Tools ⇨ Report Profile

Description

The PROFILE window creates a report profile that

- specifies the SAS library, catalog, and entry that define alternative menus to use in the REPORT and COMPUTE windows. Use PROC PMENU to create catalog

entries of type PMENU that define these menus. PMENU entries for both windows must be in the same catalog.

- sets defaults for WINDOWS, PROMPT, and COMMAND. PROC REPORT uses the default option whenever you start the procedure unless you specifically override the option in the PROC REPORT statement.

Specify the catalog that contains the profile to use with the PROFILE= option in the PROC REPORT statement. (See the discussion of "PROFILE=*libref.catalog*" on page 2088.)

Buttons

OK
stores your profile in a file that is called SASUSER.PROFILE.REPORT.PROFILE.

Note: Use PROC CATALOG or the EXPLORER window to copy the profile to another location.

Cancel
closes the window without storing the profile.

PROMPTER Window

Prompts you for information as you add items to a report.

Details

Path

Specify the PROMPT option when you start PROC REPORT or select PROMPT from the ROPTIONS window. The PROMPTER window appears the next time you add an item to the report.

Description

The prompter guides you through parts of the windows that are most commonly used to build a report. As the content of the PROMPTER window changes, the title of the window changes to the name of the window that you would use to perform a task if you were not using the prompter. The title change is to help you begin to associate the windows with their functions and to learn what window to use if you later decide to change something.

If you start PROC REPORT with prompting, then the first window gives you a chance to limit the number of observations that are used during prompting. When you exit the prompter, PROC REPORT removes the limit.

Buttons

OK
applies the information in the open window to the report and continues the prompting process.

Note: When you select **OK** from the last prompt window, PROC REPORT removes any limit on the number of observations that it is working with.

Apply
applies the information in the open window to the report and keeps the window open.

Backup
returns you to the previous PROMPTER window.

Exit Prompter
closes the PROMPTER window without applying any more changes to the report. If you have limited the number of observations to use during prompting, then PROC REPORT removes the limit.

REPORT Window

Is the surface on which the report appears.

Details

Path

Use WINDOWS or PROMPT in the PROC REPORT statement.

Description

You cannot write directly in any part of the REPORT window except column headings. To change other aspects of the report, you select a report item (for example, a column heading) as the target of the next command and issue the command. To select an item, use a mouse or cursor keys to position the cursor over it. Then click the mouse button or press Enter. To execute a command, make a selection from the menu bar at the top of the REPORT window. PROC REPORT displays the effect of a command immediately unless the DEFER option is on.

Note: Issuing the END command in the REPORT window returns you to the previous report definition with the current data. If there is no previous report definition, then END closes the REPORT window.

Note: In the REPORT window, there is no Save As option from the File menu to save your report to a file. Instead:

1. From the REPORT window, select Save Data Set. In the dialog box, enter a SAS library and filename in which to save this data set.
2. From the Program Editor window, execute a PROC PRINT.
3. In the File menu, select Save As to save the generated output to a file.

ROPTIONS Window

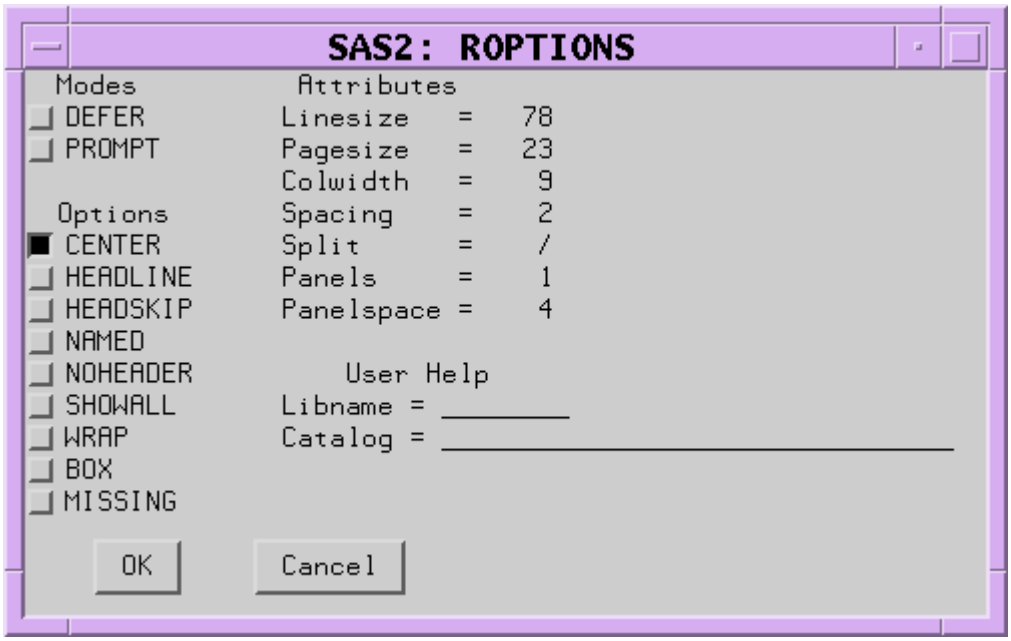
Displays choices that control the layout and display of the entire report and identifies the SAS library and catalog containing CBT or HELP entries for items in the report.

Details

Path

Tools ⇨ **Options** ⇨ **Report**

Description



Modes

DEFER
stores the information for changes and makes the changes all at once when you turn DEFER mode off or select **View** ⇨ **Refresh**.

DEFER is particularly useful when you know that you need to make several changes to the report but do not want to see the intermediate reports.

By default, PROC REPORT redisplays the report in the REPORT window each time you redefine the report by adding or deleting an item, by changing information in the DEFINITION window, or by changing information in the BREAK window.

PROMPT
opens the PROMPTER window the next time you add an item to the report.

Options

CENTER
centers the report and summary text (customized break lines). If CENTER is not selected, then the report is left-justified.

PROC REPORT honors the first of these centering specifications that it finds:

- the CENTER or NOCENTER option in the PROC REPORT statement or the CENTER toggle in the ROPTIONS window
- the CENTER or NOCENTER option stored in the report definition loaded with REPORT= in the PROC REPORT statement
- the SAS system option CENTER or NOCENTER

When PROC REPORT's CENTER option is in effect, PROC REPORT ignores spacing that precedes the leftmost variable in the report.

HEADLINE
underlines all column headings and the spaces between them at the top of each page of the report.

HEADLINE underlines with the second formatting character. (See the discussion of "FORMCHAR <(*position(s)*)>='*formatting-character(s)*' " on page 2081.)

Default hyphen (-)

Tip In traditional (monospace) SAS output, you can underline column headings without underlining the spaces between them, by using `'--'` as the last line of each column heading instead of using HEADLINE.

HEADSKIP
writes a blank line beneath all column headings (or beneath the underlining that the HEADLINE option writes) at the top of each page of the report.

NAMED
writes *name*= in front of each value in the report, where *name* is the column heading for the value.

Interaction When you use NAMED, PROC REPORT automatically uses NOHEADER.

Tip Use NAMED in conjunction with WRAP to produce a report that wraps all columns for a single row of the report onto consecutive lines rather than placing columns of a wide report on separate pages.

NOHEADER
suppresses column headings, including headings that span multiple columns.

Once you suppress the display of column headings in the interactive report window environment, you cannot select any report items.

SHOWALL
overrides the parts of a definition that suppress the display of a column (NOPRINT and NOZERO). You define a report item with a DEFINE statement or in the DEFINITION window.

WRAP
displays one value from each column of the report, on consecutive lines if necessary, before displaying another value from the first column. By default, PROC REPORT displays values for only as many columns as it can fit on one page. It fills a page with values for these columns before starting to display values for the remaining columns on the next page.

Interaction When WRAP is in effect, PROC REPORT ignores PAGE in any item definitions.

Tip Typically, you use WRAP in conjunction with NAMED to avoid wrapping column headings.

BOX
uses formatting characters to add line-drawing characters to the report. These characters

- surround each page of the report
- separate column headings from the body of the report
- separate rows and columns from each other

Interaction You cannot use BOX if you use WRAP in the PROC REPORT statement or ROPTIONS window or if you use FLOW in any item's definition.

See For information about formatting characters, see the discussion of "FORMCHAR <(*position(s)*)>='*formatting-character(s)*' " on page 2081.

MISSING
considers missing values as valid values for group, order, or across variables. Special missing values that are used to represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a different value. A group for each missing value appears in the report. If you omit the

MISSING option, then PROC REPORT does not include observations with a missing value for one or more group, order, or across variables in the report.

Attributes

LINESIZE=
specifies the line size for a report. PROC REPORT honors the first of these line-size specifications that it finds:

- LS= in the PROC REPORT statement or LINESIZE= in the ROPTIONS window
- the LS= setting stored in the report definition loaded with REPORT= in the PROC REPORT statement
- the SAS system option LINESIZE=

Range 64-256 (integer)

Tip If the line size is greater than the width of the REPORT window, then use SAS interactive report window environment commands RIGHT and LEFT to display portions of the report that are not currently in the display.

PAGESIZE=
specifies the page size for a report. PROC REPORT honors the first of these page size specifications that it finds:

- PS= in the PROC REPORT statement or PAGESIZE= in the ROPTIONS window
- the PS= setting stored in the report definition loaded with REPORT= in the PROC REPORT statement
- the SAS system option PAGESIZE=

Range 15-32,767 (integer)

COLWIDTH=
specifies the default number of characters for columns containing computed variables or numeric data set variables.

When setting the width for a column, PROC REPORT first looks at WIDTH= in the definition for that column. If WIDTH= is not present, then PROC REPORT uses a column width large enough to accommodate the format for the item. (For information about formats, see the discussion of "Format=" on page 2238.) If no format is associated with the item, then the column width depends on variable type:

Variable	Resulting Column Width
Character variable in the input data set	Length of the variable
Numeric variable in the input data set	Value of the COLWIDTH= option

Variable	Resulting Column Width
Computed variable (numeric or character)	Value of the COLWIDTH= option

Default 9

Range 1 to the line size

SPACING=*space-between-columns*
specifies the number of blank characters between columns. For each column, the sum of its width and the blank characters between it and the column to its left cannot exceed the line size.

Default 2

Interactions PROC REPORT separates all columns in the report by the number of blank characters specified by SPACING= in the PROC REPORT statement or the ROPTIONS window unless you use SPACING= in the definition of a particular item to change the spacing to the left of that item.

When CENTER is in effect, PROC REPORT ignores spacing that precedes the leftmost variable in the report.

SPLIT='*character*'
specifies the split character. PROC REPORT breaks a column heading when it reaches that character and continues the heading on the next line. The split character itself is not part of the column heading although each occurrence of the split character counts toward the 40-character maximum for a label.

Default slash (/)

Interaction The FLOW option in the DEFINE statement honors the split character.

Tip If you are typing over a heading (rather than entering one from the PROMPTER or DEFINITION window), then you do not see the effect of the split character until you refresh the screen by adding or deleting an item, by changing the contents of a DEFINITION or BREAK window, or by selecting**View** ⇨ **Refresh**.

PANELS=*number-of-panels*
specifies the number of panels on each page of the report. If the width of a report is less than half of the line size, then you can display the data in multiple sets of columns so that rows that would otherwise appear on multiple pages appear on the same page. Each set of columns is a *panel*. A familiar example of this type of report is a telephone book, which contains multiple panels of names and telephone numbers on a single page.

When PROC REPORT writes a multipanel report, it fills one panel before beginning the next.

The number of panels that fits on a page depends on the

- width of the panel
- space between panels
- line size

Default 1

Tip If *number-of-panels* is larger than the number of panels that can fit on the page, then PROC REPORT creates as many panels as it can. Let PROC REPORT put your data in the maximum number of panels that can fit on the page by specifying a large number of panels (for example, 99).

See For information about specifying the space between panels see the discussion of PSPACE=. For information about setting the line size, see the discussion of "LINESIZE=" on page 2252.

PSPACE=*space-between-panels*
specifies the number of blank characters between panels. PROC REPORT separates all panels in the report by the same number of blank characters. For each panel, the sum of its width and the number of blank characters separating it from the panel to its left cannot exceed the line size.

Default 4

User Help
identifies the library and catalog containing user-defined Help for the report. This Help can be in CBT or HELP catalog entries. You can write a CBT or HELP entry for each item in the report with the BUILD procedure in SAS/AF software. You must store all such entries for a report in the same catalog.

Specify the entry name for Help for a particular report item in the DEFINITION window for that report item or in a DEFINE statement.

SAVE DATA SET Window

Lets you specify an output data set in which to store the data from the current report.

Details

Path

File ⇨ Save Data Set

Description

To specify an output data set, enter the name of the SAS library and the name of the data set (called **member** in the window) that you want to create in the Save Data Set window.

Buttons

OK
creates the output data set and closes the Save Data Set window.

Cancel
closes the Save Data Set window without creating an output data set.

SAVE DEFINITION Window

Saves a report definition for subsequent use with the same data set or with a similar data set.

Details

Path

File ⇨ Save Report

Description

The SAVE DEFINITION window prompts you for the complete name of the catalog entry in which to store the definition of the current report and for an optional description of the report. This description shows up in the LOAD REPORT window and helps you select the appropriate report.

SAS stores the report definition as a catalog entry of type REPT. You can use a report definition to create an identically structured report for any SAS data set that contains variables with the same names as those variables that are used in the report definition.

Buttons

OK
creates the report definition and closes the SAVE DEFINITION window.

Cancel
closes the SAVE DEFINITION window without creating a report definition.

SOURCE Window

Lists the PROC REPORT statements that build the current report.

Details

Path

Tools ⇨ Report Statements

STATISTICS Window

Displays statistics that are available in PROC REPORT.

Details

Path

Edit ⇨ Add item ⇨ Statistic

After you select **Statistic**, PROC REPORT prompts you for the location of the statistic relative to the column that you have selected. After you select a location, the STATISTICS window appears.

Description

Select the statistics that you want to include in your report and close the window. When you select the first statistic, it moves to the top of the list in the window. If you select multiple statistics, then subsequent selections move to the bottom of the list of selected statistics. An asterisk (*) indicates each selected statistic. The order of selected statistics from top to bottom determines their order in the report from left to right.

Note: If you double-click on a statistic, then PROC REPORT immediately adds it to the report. The STATISTICS window remains open.

To compute standard error and the Student's *t* test, you must use the default value of VARDEF=, which is DF.

To add all selected statistics to the report, select **File** ⇨ **Accept Selection**. Selecting **File** ⇨ **Close** closes the STATISTICS window without adding the selected statistics to the report.

WHERE Window

Selects observations from the data set that meet the conditions that you specify.

Details

Path

Subset ⇨ **Where**

Description

Enter a *where-expression* in the **Enter WHERE clause** field. A *where-expression* is an arithmetic or logical expression that generally consists of a sequence of operands and operators. For information about constructing a *where-expression*, see the documentation of the "WHERE" in *SAS DATA Step Statements: Reference*.

Note: You can clear all *where-expressions* by leaving the **Enter WHERE clause** field empty and by selecting **OK**.

Buttons

OK
applies the *where-expression* to the report and closes the WHERE window.

Cancel
closes the WHERE window without altering the report.

WHERE ALSO Window

Selects observations from the data set that meet the conditions that you specify and any other conditions that are already in effect.

Details

Path

Subset ⇨ Where Also

Description

Enter a *where-expression* in the **Enter where also clause** field. A *where-expression* is an arithmetic or logical expression that generally consists of a sequence of operands and operators. For information about constructing a *where-expression*, see the documentation of the "WHERE" in *SAS DATA Step Statements: Reference*.

Buttons

OK
adds the *where-expression* to any other *where-expressions* that are already in effect and applies them all to the report. It also closes the WHERE ALSO window.

Cancel
closes the WHERE ALSO window without altering the report.

60

S3 Procedure

Overview: S3 Procedure

What Does the S3 Procedure Do?

Use the S3 procedure to perform object management for objects in Amazon S3. For example, you can create buckets and add files to S3. Common object types for use with SAS are files and directories.

Note:

The S3 procedure is not supported on z/OS platforms.

Before you can use the S3 procedure, you need an Amazon Web Service (AWS) key ID and secret. When using temporary credentials, you also need a security token. For more information, see the Amazon S3 documentation.

When the data that you add to or retrieve from S3 is larger than 5 MB, the procedure creates additional threads. These threads enable parallel processing for faster transfer speeds.

Concepts: S3 Procedure

Support for IMDS

Beginning in SAS 9.4M8, support has been added for EC2 Instance Metadata Service version 2 (IMDSv2). IMDSv1 continues to be supported. When deployed to Amazon EKS, SAS uses IMDS to obtain an IAM role that enables you to access S3 resources.

SAS first attempts to use IMDSv2 to obtain a session token. If using IMDSv2 fails, then IMDSv1 is used.

Specify the following options in your Amazon environment:

- When you set http-tokens to required, you must use IMDSv2. If http-tokens is set to optional, then either IMDSv1 or IMDSv2 can be used.

- Set the http_put_response_hop_limit to 2 when you use IMDSv2.

PROC S3 Configuration

Overview of PROC S3 Configuration

The S3 procedure reads configuration and security information from configuration files, options in the PROC S3 statement, or from an Amazon EC2 instance role. When configuration files are used, these configuration files can be either AWS Command-Line Interface (CLI) configuration files or a local PROC S3 configuration file. PROC S3 reads both types of configuration files when it runs.

Options that are specified in AWS CLI configuration files override options that are specified in the PROC S3 configuration file. Options that you specify in the S3 procedure override options that are set in configuration files.

AWS CLI Configuration Files

Unless you specify otherwise, PROC S3 reads AWS CLI configuration files from their default locations in your home directory and uses the default profile. The AWS CLI configuration files are called config and credentials. You can specify an alternative location for the config file with the AWSCONFIG= option. You can specify an alternative location for the credentials file with the AWSCREDENTIALS= option.

The config file contains multiple sets of options called *profiles*. Specify which configuration profile to use with the PROFILE= option in the PROC S3 statement.

PROC S3 Configuration File

You can create a local PROC S3 configuration file to use for connection options. The default PROC S3 configuration file is tks3.conf on Windows or .tks3.conf on UNIX. It is located in your home directory. If the local configuration file with the default name exists, the S3 procedure reads it automatically. If the PROC S3 configuration file uses a different name or is in a different location, specify its name and path with the CONFIG= option in the PROC S3 statement.

Note: If an option is specified in the AWS CLI configuration file as well as in the local PROC S3 configuration file, then the value in the AWS CLI configuration file takes precedence.

The PROC S3 configuration file contains case-sensitive name-value pairs that you specify as name=value. Do not enclose values in quotation marks. The file can contain one or more sets of the following name-value pairs:

region
specifies the AWS region to connect to. See the Region argument for the list of valid region values.

keyId
specifies the AWS access key ID. This value is a 20-character, alphanumeric string.

secret
specifies the AWS secret access key. This value is a 40-character string.

Note: See "Securing the PROC S3 Configuration File" for information about restricting access to this information.

sessionToken
specifies the session token. Specify this value if you are using temporary AWS security credentials.

Note: See "Securing the PROC S3 Configuration File" for information about restricting access to this information.

ssl
specifies whether SSL or TLS should be used for connections. Specify *true* or *yes* to use SSL or TLS. Any other value deactivates SSL or TLS.

Here is a sample PROC S3 configuration file:

```
ssl=yes
keyID=AKFKI8OMEVIM3XJHKEUQ
secret=wb89GergI/3xejxudQugFj5Wi4iqlFJhGpLvYVv
region=usstd
```

Securing the PROC S3 Configuration File

Because the secret and sessionToken values are confidential, use your operating system to restrict access to the file. For example, in UNIX you might issue this command to restrict access to just yourself:

```
chmod 700 /u/$user/.tks3.conf
```

In Microsoft Windows, use the file properties to restrict access to the PROC S3 configuration file. You can access the file properties by right-clicking the file, selecting **Properties**, and then selecting the **Security** tab.

Defining Custom Regions

You can define custom regions in addition to the predefined list of regions that is supplied with the S3 environment. One way to manage custom regions is by using the REGION statement with PROC S3. If you define custom regions with PROC S3, the region definition lasts for the duration of your SAS session. You need to redefine the region in subsequent SAS sessions.

Note: Support for custom regions was added to PROC S3 for SAS Viya in a July 2021 update to SAS Viya 3.5. Support for custom regions was added to PROC S3 for SAS 9 in SAS 9.4M8.

Another way to manage custom regions is with the TKS3_CUSTOM_REGION environment variable. You can define this environment variable in the Autoexec file or by using SAS Environment Manager. In this way, the custom region definition is automatically used when you start a subsequent SAS session.

Here is the syntax to set the TKS3_CUSTOM_REGION environment variable:

TKS3_CUSTOM_REGION=<'>*region-name*<'>,*HTTP-host*,*HTTP-port*,*SSL-HTTP-port*,*SSLRequired*,*SSLAllowed*

region-name
specifies the custom region name. Enclose the name in quotation marks if it contains spaces or special characters.

HTTP-host
specifies the host name of the server for the region.

HTTP-port
specifies the port number of the server when communicating without SSL. Use 0 to use the default port number for the HTTP protocol.

SSL-HTTP-port
specifies the port number of the server when communicating with SSL. Use 0 to use the default port number for the HTTPS protocol.

SSLRequired
specifies whether all communications with the S3 environment must use SSL. Values are TRUE or FALSE.

SSLAllowed
specifies whether communications with the S3 environment can use SSL. Values are TRUE or FALSE.

Interaction This value is ignored if the *SSLRequired* value is TRUE.

Here is a sample setting for this environment variable that uses a BackBlaze B2 server.

```
TKS3_CUSTOM_REGION=us-west-002,s3.us-west-002.backblazeb2.com,0,0,TRUE,TRUE
```

In Linux, define multiple regions by separating sets of values with a colon (:). In Windows, separate sets of values with a semicolon (;).

Using Server-Side Encryption with AWS Data

Manage Encryption Keys with the ENCKEY Statement

Use the ENCKEY statement to name and manage encryption keys. Use the ADD option to add a new name and encryption key. You can then call the named encryption key when you transfer data between the Amazon S3 environment and SAS using the GET, GETDIR, PUT, and PUTDIR statements. You can also request a list of currently registered encryption keys with the ENCKEY statement LIST option or delete a previously registered encryption key with the REMOVE option.

You can specify an encryption key in three forms: an Amazon Key Management Service (KMS) key, a customer-supplied server-side encryption key (SSE-C) key represented as a character string, or an SSE-C key represented by a hexadecimal value.

You can specify a KMS key from the Amazon S3 environment. This type of key works with AWS server-side encryption and is managed in the S3 environment as part of the IAM service.

For SSE-C encryption keys, you can specify the key as a 32-byte character string or as a 64-digit hexadecimal value. User-specified keys are then used by the S3 environment to encrypt data using the AES256 encryption algorithm.

As a best practice, manage encryption keys in a separate SAS program. You can then use the %INCLUDE statement to read in your named encryptions and work with the encryption key names. For an example, see “Example 3: Manage Encryptions with S3 Data” on page 2284.

Use Encryption Keys with SAS/ACCESS

After you add an encryption key, you can use that key with SAS/ACCESS Interface to Amazon Redshift. In a LIBNAME statement, use the BL_ENCKEY= option to call an encryption key by the name that you assigned with the ENCKEY statement. This enables encryption during bulk loading or unloading between the Amazon Redshift environment and SAS. Alternatively, you can specify the BL_ENCKEY= data set option when referring to a specific Amazon Redshift data set, such as in a DATA step or in a call to PROC SQL.

Note: Only IAM:KMS keys are supported for SAS/ACCESS Interface to Amazon Redshift.

For more information, see "Encryption with Amazon Redshift" in *SAS/ACCESS for Relational Databases: Reference*.

Transfer Acceleration

Transfer acceleration is a special mode that is used to load or write data. In this mode, an alternative host enables faster data transfer. For more information, see your AWS documentation.

The GET, GETDIR, PUT, and PUTDIR statements take advantage of this faster data transfer method when transfer acceleration is enabled.

Syntax: S3 Procedure

```
PROC S3 <options>;
   BUCKET "bucket-name";
   COPY <SRCKEY="key-name"> "source-s3-location" <ENCKEY="key-name">
     "destination-s3-location";
   CREATE "bucket-name";
   DELETE "s3-location";
   DESTROY "bucket-name";
   ENCKEY <ADD> | <REPLACE> NAME="key-name" ID="key-ID"
     <CONTEXT="key-context">;
   GET <ENCKEY="key-name"> "s3-location" "local-file-path";
   GETACCEL "bucket-name";
   GETDIR <ENCKEY="key-name"> "s3-location" "local-path";
   INFO <ENCKEY="key-name"> "s3-location";
   LIST <OUT=libref.file><_SHORT_> "s3-location";
   MKDIR "s3-location";
   PUT <ENCKEY="key-name"> "local-path" "s3-location";
   PUTDIR <ENCKEY="key-name"> "local-path" "s3-location";
   REGION <ADD HOST="AWS-server" NAME="region-name" <PORT=port-value>
     <REPLACE> <SSLALLOWED><SSLPORT=SSL-port> <SSLREQUIRED>> |
     <LIST> | <REMOVE NAME="region-name">;
   RMDIR "s3-location";
RUN;
```

Statement	Task	Example
PROC S3	Specifies the connection parameters to S3.	Ex. 1, Ex. 2, Ex. 3, Ex. 4
BUCKET	Specifies whether to enable transfer acceleration for a bucket.	
COPY	Copies an S3 object to an S3 destination.	Ex. 2, Ex. 3
CREATE	Creates an S3 bucket.	Ex. 1
DELETE	Deletes an S3 location or object.	Ex. 2
DESTROY	Deletes an S3 bucket.	
ENCKEY	Enables you to work with encryption keys.	Ex. 3
GET	Retrieves an S3 object.	Ex. 3
GETACCEL	Retrieves the transfer acceleration status for a bucket.	
GETDIR	Retrieves the contents of an S3 directory.	Ex. 3
INFO	Lists information about an S3 location or object.	
LIST	Lists the contents of an S3 location.	Ex. 1
MKDIR	Specifies a directory to create in an S3 location.	Ex. 2
PUT	Specifies a local object to write to an S3 location.	Ex. 1, Ex. 3
PUTDIR	Specifies a local directory to write to an S3 location.	Ex. 3
REGION	Enables you to add, list, or remove custom regions.	Ex. 4
RMDIR	Deletes a directory from an S3 location.	

PROC S3 Statement

Specifies the connection parameters for connecting to AWS S3.

Examples:

"Example 1: Create a Bucket and Add a File" on page 2281
"Example 2: Manage the Contents of a Bucket" on page 2282
"Example 3: Manage Encryptions with S3 Data" on page 2284
"Example 4: Define a Custom Region with PROC S3" on page 2288

Syntax

PROC S3 <AWSCONFIG="*AWS-CLI-file-path*"> <CONFIG="*local-configuration-file-path*"> <PROFILE="*configuration-profile-name*"> <AWSCREDENTIALS="*AWS-credentials-file-path*"> <ROLENAME="*IAM-role-name*" | ROLEARN="*IAM-role-ARN*> <KEYID="*AWS-key-ID*"> <SECRET="*AWS-secret*"> <SESSION="*session-token*"> <SSL | NOSSL> <REGION=*AWS-region*>;

Optional Arguments

AWSCONFIG="*AWS-CLI-file-path*"
specifies the path of the AWS CLI configuration file, called config. This file contains connection parameters to access AWS S3. If a value is specified in the AWS CLI configuration file and in the PROC S3 configuration file, the value in the AWS CLI file takes precedence.

Note: Support for this option was added in SAS 9.4M5.

AWSCREDENTIALS="*AWS-credentials-file-path*"
specifies the path of the AWS credentials file. This file contains the credentials that are used to access AWS S3.

Note: Support for this option was added in SAS Viya 3.4.

CONFIG="*local-configuration-file-path*"
specifies the path and filename of the PROC S3 configuration file that contains connection parameters to access AWS S3. If you specify this option, then the specified configuration file is read instead of the default PROC S3 configuration file in the default location.

The default PROC S3 configuration file is file .tks3.conf in your home directory in UNIX or file tks3.conf in your home directory in Windows. You do not need to specify the CONFIG= option if your configuration file is in the default location.

For more information, see "PROC S3 Configuration File" on page 2261.

KEYID="*AWS-key-ID*"
specifies the AWS access key ID. This value is a 20-character, alphanumeric string. A sample key ID value is AKIAIOSFODNN7EXAMPLE.

PROFILE="*profile-name*"
specifies the profile to use in the AWS CLI file config. Sets of options are grouped into profiles. If you do not specify the PROFILE= option, PROC S3 uses the default profile.

Note: Support for this option was added in SAS 9.4M5.

REGION=*AWS-region*
specifies the AWS region to connect to. Here are the valid region values.

You might need to activate a region for your account if it does not appear in your list of regions. See your AWS documentation for more information.

Table 60.1 PROC S3 Region Values

PROC S3 Region Value	Description	Corresponding AWS S3 Region
afcapetown	Africa (Cape Town)	af-south-1
aphongkong	Asia Pacific (Hong Kong)	ap-east-1
aphyderabad	Asia Pacific (Hyderabad)	ap-south-2
apindia	Asia Pacific (India)	ap-south-1
apjakarta	Asia Pacific (Jakarta)	ap-southeast-3
aposaka[1]	Asia Pacific (Osaka)	ap-northeast-3
apseoul	Asia Pacific (Seoul)	ap-northeast-2
apsingapore	Asia Pacific (Singapore)	ap-southeast-1
apsydney	Asia Pacific (Sydney)	ap-southeast-2
aptokyo	Asia Pacific (Tokyo)	ap-northeast-1
cacentral	Canada (Central)	ca-central-1
cnbeijing	China (Beijing)	cn-north-1
cnningxia	China (Ningxia)	cn-northwest-1
eufrankfurt	EU (Frankfurt)	eu-central-1
euireland	EU (Ireland)	eu-west-1
eulondon	EU (London)	eu-west-2
eumilan	EU (Milan)	eu-south-1
euparis	EU (Paris)	eu-west-3
euspain	EU (Spain)	eu-south-2
eustockholm	EU (Stockholm)	eu-north-1
euzurich	EU (Zurich)	eu-central-2
fips	US Government Cloud (FIPS)	fips-us-gov-west-1

PROC S3 Region Value	Description	Corresponding AWS S3 Region
fipseast	US Government Cloud (FIPS)	fips-us-gov-east-1
mebahrain	Middle East (Bahrain)	me-south-1
meuae	Middle East (UAE)	me-central-1
sa	South America (Sao Paulo)	sa-east-1
useast	US East (Virginia)	us-east-1
useastoh	US East (Ohio)	us-east-2
usgov	US Government Cloud	us-gov-west-1
usgoveast	US East Government Cloud	us-gov-east-1
uswest	US West (Oregon)	us-west-2
uswestca	US West (California)	us-west-1

1 Contact your AWS sales representative to get access to the Asia Pacific (Osaka) region.

ROLENAME="*IAM-role-name*"
specifies an IAM role name that enables you to get access credentials to S3 via the AssumeRole IAM operation.

Interaction Specify either the ROLENAME= option or the ROLEARN= option. Do not specify both.

Note Support for this option was added in SAS 9.4M7.

Example
```
proc s3 rolename="s3AccessRole" <additional-options>;
```

ROLEARN="*IAM-role-ARN*"
specifies an Amazon Resource Name (ARN) that identifies an IAM role. The associated IAM role enables you to get access credentials to S3 via the AssumeRole IAM operation.

Interaction Specify either the ROLEARN= option or the ROLENAME= option. Do not specify both.

Note Support for this option was added in SAS 9.4M7.

Example
```
proc s3 rolearn="arn:aws:iam::123456789012:role/s3AccessRole"
       <additional-options>;
```

SECRET="*AWS-secret*"
specifies the AWS secret access key. This value is a 40-character string. A sample secret access value is wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY.

SESSION="*session-token*"
specifies the AWS session token. Use this value if you are using temporary AWS security credentials.

For more information, see "PROC S3 Configuration" on page 2261.

Note Support for this option was added in the May 2021 update for SAS 9.4M7 and SAS Viya 3.5.

SSL | NOSSL
SSL specifies that SSL or TLS should be enabled during data transfer. NOSSL specifies that SSL or TLS should be disabled during data transfer.

You can use the SSL value to override an `ssl=no` setting in the PROC S3 configuration file. If there is no value specified for SSL in the PROC S3 statement or in a PROC S3 configuration file, then SSL or TLS is used during data transfer by default.

Interaction: If you specify NOSSL in the PROC S3 statement, then enabling server-side encryption with the ENCKEY statement fails.

BUCKET Statement

Sets the acceleration transfer mode for the specified bucket.

Note: Support for this statement was added in SAS 9.4M5.

Syntax

BUCKET *"bucket-name"* ACCELERATE | NOACCELERATE;

Required Arguments

bucket-name
specifies the name of the S3 bucket for which you are setting transfer acceleration mode. For more information, see "Transfer Acceleration" on page 2265.

ACCELERATE
enables transfer acceleration for the specified bucket.

NOACCELERATE
disables transfer acceleration for the specified bucket.

COPY Statement

Copies an object from an S3 source location to an S3 destination.

See: "Example 2: Manage the Contents of a Bucket" on page 2282

Syntax

COPY <SRCKEY="*key-name*"> "*source-s3-location*" <ENCKEY="*key-name*"> "*destination-s3-location*";

Required Arguments

source-s3-location
specifies the S3 location of the object to be copied. Fully qualify the S3 location from the bucket name to the object name.

destination-s3-location
specifies the S3 location to which an object should be copied. Fully qualify the S3 location from the bucket name to the object name.

Optional Arguments

ENCKEY="*key-name*"
specifies an encryption key name that identifies the encryption for the created object. The name must match an encryption key name that you specified in an ENCKEY statement.

The ENCKEY= option defaults to no encryption. You can use the value _*DEFAULT*_ to use the default encryption key. Your default encryption key is automatically created.

SRCKEY="*key-name*"
specifies the encryption of the source object. The name must match an encryption key name that you specified in an ENCKEY statement.

Note: This value is not applied to the created object if the ENCKEY= option is not specified.

CREATE Statement

Creates a bucket.

See: "Example 1: Create a Bucket and Add a File" on page 2281

Syntax

CREATE "*bucket-name*";

Required Argument

bucket-name
specifies the name of the S3 bucket that you are creating. The name of the S3 bucket that you create must be unique across S3.

DELETE Statement

Deletes an S3 location or object.

See: "Example 2: Manage the Contents of a Bucket" on page 2282

Syntax

DELETE "*s3-location*";

Required Argument

s3-location
specifies the S3 location that you are deleting. Fully qualify the S3 location from the bucket name to the object name.

DESTROY Statement

Deletes an S3 bucket.

Syntax

DESTROY "*bucket-name*";

Required Argument

bucket-name
specifies the name of an S3 bucket that you are deleting. The bucket that you specify must exist in S3 and must be empty.

ENCKEY Statement

Specifies the encryption key for an S3 location.

Note: Support for this statement was added in SAS 9.4M6.

See: "Example 3: Manage Encryptions with S3 Data" on page 2284

Syntax

Form 1: **ENCKEY** ADD | REPLACE NAME="*key-name*"ID="*key-ID*" <CONTEXT="*key-context*">;

Form 2: **ENCKEY** ADD | REPLACE NAME="*key-name*" KEY="*key-string*" <ALGORITHM="*S3-encryption-algorithm*"> <CONTEXT="*key-context*">;

Form 3: **ENCKEY** ADD | REPLACE NAME="*key-name*" HEXKEY="*hexadecimal-value*" <ALGORITHM="*S3-encryption-algorithm*"> <CONTEXT="*key-context*">;

Form 4: **ENCKEY** LIST <NAME="*key-name*">;

Form 5: **ENCKEY** REMOVE NAME="*key-name*";

Arguments

ADD
indicates that you are adding an encryption key.

Requirement: Specify the HEXKEY=, ID=, or KEY= options with ADD, depending on the type of key that you are using.

ALGORITHM="*S3-encryption-algorithm*"
specifies the S3 encryption algorithm that is used in the S3 location.

The only value that is currently supported is AES256. This value is the default when you do not specify the ALGORITHM= option.

CONTEXT="*key-context*"
specifies the key context for the encryption key.

HEXKEY="*hexadecimal-value*"
specifies an encryption key in the form of a 64-digit hexadecimal value.

ID="*key-ID*"
specifies the key ID for the encryption key.

KEY="*key-string*"
specifies an encryption key as a 32-byte character string.

LIST
requests a list of defined encryption keys.

NAME="*key-name*"
specifies the encryption key name. This is a user-friendly name that you can use to refer to an encryption key. The value is case insensitive.

NAME= is required with the ADD, REPLACE, or REMOVE options. When used with the LIST option, NAME= is optional.

REMOVE
removes an encryption key from the list of defined keys.

Requirement: Specify the NAME= option with REMOVE.

REPLACE
specifies that the existing encryption key should be replaced. If not set, any attempt to redefine an encryption key fails.

Requirement: Specify the HEXKEY=, ID=, or KEY= options with REPLACE, depending on the type of key that you are using.

Details

The ENCKEY statement is used to support server-side encryption in an AWS S3 environment.

- Use Form 1 of the ENCKEY statement to add or replace an IAM:KMS encryption key.
- Use Form 2 of the ENCKEY statement to add or replace an encryption key in the form of a string. The string must be 32 bytes long.
- Use Form 3 of the ENCKEY statement to add or replace an encryption key expressed as hexadecimal characters. Do not use the “0x” prefix when you specify the hexadecimal key string. The hexadecimal string should be 64 digits long.
- Use Form 4 of the ENCKEY statement to view the list of defined encryption keys.
- Use Form 5 of the ENCKEY statement to remove an encryption key.

Note: If you specify the NOSSL option in the PROC S3 statement, then using encryption with the ENCKEY statement fails.

You must specify one of these options in the ENCKEY statement: ADD, LIST, REMOVE, or REPLACE.

Encryption keys are specified for the duration of your SAS session.

The encryption key *_DEFAULT_* cannot be modified. The *_DEFAULT_* encryption key is defined by the AWS environment.

For more information, see Protecting Data Using Server-Side Encryption in your AWS documentation.

GET Statement

Retrieves an S3 object.

Note: This statement uses transfer acceleration when it is available. For more information, see “Transfer Acceleration” on page 2265.

Syntax

GET <ENCKEY="*key-name*"> "*s3-location*" "*local-file-path*";

Required Arguments

s3-location
specifies the name of an S3 object to retrieve. Fully qualify the location from the bucket name to the object name.

local-file-path
specifies a local file in which to store the object. Examples are **`C:\public\filename`** for Windows or **`/u/$USER/filename`** for UNIX.

Optional Argument

ENCKEY="*key-name*"
specifies an encryption key name that identifies the encryption to use during data retrieval. The name must match an encryption key name that you specified in an ENCKEY statement. The name must also correspond to the encryption key that was used when the object was created in the S3 environment. Otherwise, S3 returns an error.

GETACCEL Statement

Retrieves the transfer acceleration status for a bucket.

Note: Support for this statement was added in SAS 9.4M5.

Syntax

GETACCEL "*bucket-name*";

Required Argument

bucket-name
specifies the name of an S3 bucket for which you want the transfer acceleration status. For more information, see "Transfer Acceleration" on page 2265.

GETDIR Statement

Retrieves the contents of an S3 directory.

Note: This statement uses transfer acceleration when it is available. For more information, see "Transfer Acceleration" on page 2265.

Syntax

GETDIR <ENCKEY="*key-name*"> "*s3-location*" "*local-path*";

Required Arguments

s3-location
specifies the name of an S3 directory to retrieve. Fully qualify the location from the bucket name to the directory.

local-path
specifies a directory that is local to the SAS client. Examples are `C:\public` for Windows or `/u/$USER/` for UNIX.

Optional Argument

ENCKEY="*key-name*"
specifies an encryption key name that identifies the encryption to use during data retrieval. The name must match an encryption key name that you specified in an ENCKEY statement.

Note: Encryption fails if any files in the source location do not use the specified encryption key.

INFO Statement

Requests information in the SAS log about an S3 location.

Note: Information about a file includes the region, path, and the date and time at which the file was last modified.

Syntax

INFO <ENCKEY="*key-name*"> "*s3-location*";

Required Argument

s3-location
specifies a fully qualified path from the bucket name to the object name.

Optional Argument

ENCKEY="*key-name*"
specifies an encryption key name. The name must match an encryption key name that you specified in an ENCKEY statement.

Note: The ENCKEY= option is required if any objects in the S3 location are encrypted.

LIST Statement

Requests information in the SAS log about the contents of an S3 location.

Syntax

LIST <_SHORT_> "*s3-location*" <OUT=*filename* >;

Required Argument

s3-location
specifies a fully qualified path from the bucket name to the object name. The object that you specify is typically a container, such as a bucket or a directory.

Optional Arguments

SHORT
specifies that you want a list of object names only.

OUT=*filename*
specifies an output file for the output of the LIST statement.

Provide the filename as *libname.file* or as a *fileref*.

Note Support for this option was added in SAS 9.4M7 and SAS Viya 3.5.

Example
```
list "/myS3location" out=sasuser.list;
```

MKDIR Statement

Specifies a directory to create in an S3 location.

See: "Example 2: Manage the Contents of a Bucket" on page 2282

Syntax

MKDIR *"s3-location"*;

Required Argument

s3-location
specifies a fully qualified path from the bucket name to the directory name that you want to create.

PUT Statement

Specifies a local object to write to an S3 location.

Note: This statement uses transfer acceleration when it is available. For more information, see "Transfer Acceleration" on page 2265.

Syntax

PUT <ENCKEY=*"key-name"*> *"local-path"* *"s3-location"*;

Required Arguments

local-path
specifies a file or directory that is local to the SAS client.

s3-location
specifies a location in S3. Fully qualify the path from the bucket name to the object name.

Optional Argument

ENCKEY=*"key-name"*
specifies an encryption key name that identifies the encryption to use when storing data in S3. The name must match an encryption key name that you specified in an ENCKEY statement.

Example To specify your default encryption key:

```
put enckey=_default_ "/home/demouser/s3/foo.txt" "/mybucket/foo.txt";
```

PUTDIR Statement

Specifies a local directory to write to an S3 location.

Note: This statement uses transfer acceleration when it is available. For more information, see "Transfer Acceleration" on page 2265.

Syntax

PUTDIR <ENCKEY="*key-name*"> "*local-path*" "*s3-location*";

Required Arguments

local-path
specifies a directory that is local to the SAS client.

s3-location
specifies a location in S3. Fully qualify the path from the bucket name to the object name.

Optional Argument

ENCKEY="*key-name*"
specifies an encryption key name that identifies the encryption to use when writing to S3. The name must match an encryption key name that you specified in an ENCKEY statement.

Note: All files in the S3 location are encrypted with the specified encryption key.

REGION Statement

Enables you to add, list, or remove custom regions.

Notes: Support for this statement in SAS Viya 3.5 starts in July 2021.
Support for this statement in SAS 9 starts in SAS 9.4M8.

See: "Example 4: Define a Custom Region with PROC S3" on page 2288

Syntax

Form 1: **REGION** ADD HOST="*AWS-server*" NAME="*region-name*" <PORT=*port-value*> <REPLACE> <SSLALLOWED><SSLPORT=*SSL-port*> <SSLREQUIRED> ;

Form 2: **REGION** LIST;

Form 3: **REGION** REMOVE NAME="*region-name*";

Arguments

ADD
specifies that you are adding a custom region for the S3 environment.

HOST="*AWS-server*"
specifies the server that PROC S3 connects to on AWS.

Note Support for the HOST= option was added in the August 2021 update for SAS Viya 3.5.

Example
```
host="myhost.amazonaws.com"
```

LIST
requests a list of all defined S3 regions.

NAME="*region-name*"
specifies the name of the region that you are adding or removing.

PORT=*port-value*
specifies the HTTP port value to use to connect to S3 without SSL.

If you do not specify a port value, the default value is used.

REMOVE
specifies to remove the region that you identify with the NAME= option.

Restriction You cannot remove any of the predefined S3 regions. See the PROC S3 statement REGION= argument for the list of predefined region values.

REPLACE
indicates that a custom region should be added and should overwrite a region of the same name, if it exists.

Restriction You cannot replace any of the predefined regions for S3. See the REGION= argument for the list of predefined region values.

SSLALLOWED
indicates that SSL is allowed when communicating with the S3 environment.

Interaction This value is ignored if SSLREQUIRED is specified.

SSLPORT=*SSL-port*
specifies the HTTP port value to use to connect to S3 with SSL.

If you do not specify a port value, the default value is used.

SSLREQUIRED
indicates that all communications with the S3 environment must be made using SSL.

RMDIR Statement

Specifies a directory to delete from an S3 location.

Syntax

RMDIR "*s3-location*";

Required Argument

s3-location
specifies a directory in S3. Fully qualify the path from the bucket name to the directory name. The directory that you specify must be empty.

Examples: S3 Procedure

Example 1: Create a Bucket and Add a File

Features: PROC S3 statement, CONFIG= option
CREATE statement
PUT statement
LIST statement

Details

This example uses the CREATE statement in PROC S3 to create a bucket in S3. Next, the example shows how to add a file to the bucket and then list the contents of the bucket.

Program

```
proc s3 config="/u/marti/.tks3.conf";
   create "/myBucket";
   put "/u/marti/project/licj.csv" "/myBucket/licj.csv";
   list "/myBucket";
run;
```

Program Description

Execute the PROC S3 statement and specify the location of the PROC S3 configuration file. Connect to S3 with connection options that are contained in the .tks3.conf file in the specified directory.

```
proc s3 config="/u/marti/.tks3.conf";
```

Create a bucket in S3. Use the CREATE statement to create the bucket *myBucket*.

```
   create "/myBucket";
```

Store a copy of a local file in the new S3 bucket. Execute the PUT statement to copy the local file licj.csv into a file of the same name in the S3 bucket *myBucket*.

```
   put "/u/marti/project/licj.csv" "/myBucket/licj.csv";
```

List the contents of the S3 bucket. Use the LIST statement to see a list of the contents of *myBucket*.

```
   list "/myBucket";
run;
```

If the file licj.csv is the only file in the bucket, then the following message is printed to the SAS log.

Output 60.1 *List of Bucket Contents*

```
licj.csv    2791403 2015-06-05T19:27:35.000Z
```

Example 2: Manage the Contents of a Bucket

Features:

PROC S3 statement

MKDIR statement

COPY statement

DELETE statement

Details

This example shows how to create a directory in a bucket and how to copy and delete files.

Program

```
proc s3;
   mkdir "/myBucket/csv";
   copy "/myBucket/licj.csv" "/myBucket/csv/licj.csv";
   delete "/myBucket/licj.csv";
run;
```

Program Description

Connect to S3 using the default configuration file. Use the PROC S3 statement to connect to S3 with connection options that are specified in the .tks3.conf file in your home directory. This is the default configuration file location.

```
proc s3;
```

Create a new directory. Use the MKDIR statement to create a directory, csv, in the *myBucket*. A note is printed to the SAS log.

```
   mkdir "/myBucket/csv";
```

Copy a file into the new directory. Use the COPY statement to copy a file, licj.csv, from *myBucket* into the `csv` directory.

```
   copy "/myBucket/licj.csv" "/myBucket/csv/licj.csv";
```

Delete the original copy of the file. Use the DELETE statement to delete the original copy of the licj.csv file from *myBucket*. Only the copy of the file in `/myBucket/csv` remains.

```
   delete "/myBucket/licj.csv";
run;
```

Output 60.2 *Managing Data in a Bucket*

```
NOTE: Created directory /myBucket/csv.

NOTE: Deleted object /myBucket/licj.csv.
```

Example 3: Manage Encryptions with S3 Data

Features:
PROC S3 statement
COPY statement
ENCKEY statement
GET statement
GETDIR statement
PUT statement
PUTDIR statement

Details

This example shows how to work with encryption keys. As a best practice, manage encryption keys in a separate SAS program that you include into another SAS program that interacts with the AWS environment. In this example, the program that manages encryption keys is called keys.sas. All encryptions use the default AES256 encryption algorithm that is supported by the S3 environment.

PROGRAM: Keys.sas

```
/* keys.sas */
proc s3;

   /* IAM:KMS keys */
   enckey add name="foo" id="98v27390-1si1-8sc9-38k0-k893j354nw5g";
   enckey add name="bar" id="22f87852-0ak1-5xy2-01j1-l852g809gx4q";

   /* SSE-C keys (user-specified) as character string */
   enckey add name="foo2" key="ke-sj-eb-ok-qk-zi-nb-lu-fh-wi-zi";
   enckey add name="bar2" key="wl-tk-64-rk-i0-zn-wk-7c-s8-a8-jk";

   /* SSE-C (user-specified) keys as hex data */
   enckey replace name="foo2"

hexkey="e1d2e3bb4a5f6079889706b3c4d1e2f999f2c3bb4c5f6079888706f6a4b3e2d
a";
   enckey replace name="bar2"

hexkey="9892940203456892093758029375728394010928374674839201837583920192
2";

run;
```

Program Description

Add an IAM:KMS encryption key. Use the ENCKEY statement with the ADD option to add two encryption keys named foo and bar. You supply the ID= value that is defined by the IAM service in the AWS environment. Use the NAME= option to provide a user-friendly identifier for the encryption key.

```
/* keys.sas */
proc s3;

   /* IAM:KMS keys */
   enckey add name="foo" id="98v27390-1si1-8sc9-38k0-k893j354nw5g";
   enckey add name="bar" id="22f87852-0ak1-5xy2-01j1-l852g809gx4q";
```

Add an SSE-C key with a character string. You can use the ENCKEY statement and the ADD option to add a user-specified encryption key. Specify a 32-byte character string as the KEY= value and provide a user-friendly value for NAME=.

```
   /* SSE-C keys (user-specified) as character string */
   enckey add name="foo2" key="ke-sj-eb-ok-qk-zi-nb-lu-fh-wi-zi";
   enckey add name="bar2" key="wl-tk-64-rk-i0-zn-wk-7c-s8-a8-jk";
```

Replace existing encryption keys with a user-defined hexadecimal key. Use the REPLACE option with the NAME= option to identify an encryption key that you want to replace. You can specify an encryption key with a 64-digit hexadecimal value with the HEXKEY= option.

```
   /* SSE-C (user-specified) keys as hex data */
   enckey replace name="foo2"

hexkey="e1d2e3bb4a5f6079889706b3c4d1e2f999f2c3bb4c5f6079888706f6a4b3e2d
a";
   enckey replace name="bar2"

hexkey="9892940203456892093758029375728394010928374674839201837583920192
2";

run;
```

```
1          /* keys.sas */
2          proc s3;
3          /* IAM:KMS keys */
4          enckey add name="foo" id="98v27390-1si1-8sc9-38k0-k893j354nw5g";
5          enckey add name="bar" id="22f87852-0ak1-5xy2-01j1-l852g809gx4q";
6          /* user-defined keys as character string */
7          enckey add name="foo2" key="ke-sj-eb-ok-qk-zi-nb-lu-fh-wi-zi";
8          enckey add name="bar2" key="wl-tk-64-rk-i0-zn-wk-7c-s8-a8-jk";
9          /* user-defined keys as hex data */
10         enckey replace name="foo2"
11
hexkey="e1d2e3bb4a5f6079889706b3c4d1e2f999f2c3bb4c5f6079888706f6a4b3e2da";
12         enckey replace name="bar2"
13

```

Program: S3data.sas

```
/* s3data.sas */
%include "keys.sas";

proc s3;
  enckey list;

  put enckey="foo" "/home/demouser/s3/foo.txt" "/mybucket/foo.txt";
  copy srckey="foo" "/mybucket/foo.txt" enckey="bar" "/mybucket/
bar.txt";
  get enckey="foo" "/mybucket/foo.txt" "/home/demouser/foo-get.txt";

  putdir enckey="foo2" "/home/demouser/s3" "/mybucket/enctest";

  getdir enckey="foo2" "/mybucket/enctest" "/home/demouser/enctest";

run;
```

Program Description

In a separate program, s3data.sas, you can specify the encryptions to use while you work with data from an S3 environment.

Include encryption key definitions so that they are accessible to the s3data.sas program. Use the %INCLUDE statement to retrieve encryption key definitions and their associated names.

```
/* s3data.sas */
%include "keys.sas";
```

List available encryption keys. Use the LIST option with the ENCKEY statement to see the currently defined encryption keys.

```
proc s3;
  enckey list;
```

Manipulate the encryptions for files. The PUT statement uses the foo encryption key from keys.sas to encrypt the local foo.txt file that is copied to an S3 bucket called Mybucket. The COPY statement copies the foo.txt file in Mybucket to a file called bar.txt that is encrypted using the bar encryption key. The GET statement copies the file foo.txt from Mybucket to your local directory and renames the file foo-get.txt. The file is encrypted using the foo encryption key.

```
  put enckey="foo" "/home/demouser/s3/foo.txt" "/mybucket/foo.txt";
  copy srckey="foo" "/mybucket/foo.txt" enckey="bar" "/mybucket/
bar.txt";
  get enckey="foo" "/mybucket/foo.txt" "/home/demouser/foo-get.txt";
```

Create a subdirectory in an S3 bucket and encrypt it. Use the PUTDIR statement to create a subdirectory, Enctest, in Mybucket. This location is a copy of your local directory `/home/demouser/s3`. The Enctest location is encrypted using the foo2 encryption key. In keys.sas, the foo2 encryption key is represented by a hexadecimal value, because that encryption key replaced the original encryption key for foo2.

```
  putdir enckey="foo2" "/home/demouser/s3" "/mybucket/enctest";
```

Create a decrypted local directory that is a copy of an encrypted S3 location. Use the GETDIR statement to create a decrypted copy of an S3 location, Enctest. The encryption key name is provided to enable decryption of the data. Data is encrypted by default during data transfer. The new local directory is `/home/demouser/enctest`.

```
  getdir enckey="foo2" "/mybucket/enctest" "/home/demouser/enctest";

run;
```

```
1          /* s3data.sas */
2          %include "keys.sas";

NOTE:  Created the S3 encryption key "foo".
NOTE:  Created the S3 encryption key "bar".
NOTE:  Created the S3 encryption key "foo2".
NOTE:  Created the S3 encryption key "bar2".
NOTE:  The value for S3 encryption key "foo2" was redefined.
NOTE:  The value for S3 encryption key "bar2" was redefined.

Example 4: Define a Custom Region with PROC S3

Features: REGION statement

Details

This example shows how to define a custom region using PROC S3.

Program

```
proc s3;

   region add host="s3.us-west-004.backblazeb2.com"
      name="us-west-002"
      sslrequired replace;
run;
```

Program Description

Connect to S3 using the default configuration file. Use the PROC S3 statement to connect to S3 with connection options that are specified in the .tks3.conf file in your home directory. This is the default configuration file location.

```
proc s3;
```

Define a new custom region. Use the REGION statement to create a custom region, us-west-002. The SSLREQUIRED argument indicates that SSL is required when communicating with the S3 environment. The REPLACE argument specifies that if the custom region is already defined, then the definition should be overwritten.

```
   region add host="s3.us-west-004.backblazeb2.com"
      name="us-west-002"
      sslrequired replace;
run;
```

61

SCAPROC Procedure

Overview: SCAPROC Procedure

What Does the SCAPROC Procedure Do?

The SCAPROC procedure implements the SAS Code Analyzer, which captures information about input, output, and the use of macro symbols from a SAS job while it is running. The SAS Code Analyzer can write this information and the information that is in the original SAS file to a file that you specify. The SCAPROC procedure can also generate a grid-enabled job that can concurrently run independent pieces of the job. You can issue the SCAPROC procedure on your operating system's command line or in SAS code in the SAS Editor window.

The following command runs your SAS job with the SAS Code Analyzer from your operating system's command line:

```
sas yourjob.sas -initstmt "proc scaproc;  record 'yourjob.txt' ; run;"
```

sas
is the command used at your site to start SAS.

yourjob.sas
is the name of the SAS job that you want to analyze.

yourjob.txt
is the name of the file that will contain a copy of your SAS code. The file will also contain the comments that are inserted to show input and output information, macro symbol usage, and other aspects of your job. For information about issuing PROC SCAPROC in SAS code, see the examples.

Special Considerations

Some tasks of grid-enabled jobs can have dependencies on previous tasks. PROC SCAPROC combines and reorders these tasks based on their dependencies to the preceding tasks. Combining the tasks and submitting them in the same work unit enables faster processing of the tasks. The NOOPTIMIZE argument of the GRID option disables the combining and reordering of tasks of grid-enabled jobs.

For the GRID statement to work, your site has to license SAS Grid Manager or SAS/CONNECT. SAS Grid Manager enables your generated grid job to run on a grid of distributed machines. SAS/CONNECT enables your generated grid job to run on parallel SAS sessions on one symmetric multiprocessing (SMP) machine.

Concepts: SCAPROC Procedure

Handling Global Statements

You can mark a set of statements that you want to submit to each remote session in the generated grid job. Include an `/* SCAPROC GLOBAL BEGIN */` comment on the line before the set of statements, and include an `/* SCAPROC GLOBAL END */` comment on the line after the statements. PROC SCAPROC submits the statements in the marked session to each of the remote sessions before any of the job's steps are submitted.

In the following example, PROC SCAPROC submits the statements between the /* SCAPROC GLOBAL BEGIN */ and /* SCAPROC GLOBAL END */ comments with each of the PROC SUMMARY statements.

```
/* SCAPROC GLOBAL BEGIN */;
    libname one "SAS-library-1";
    libname two "SAS-library-1";
   %let year=2018;
/* SCAPROC GLOBAL END */;

Proc summary data=one.sales;
   where year=&year
   class month;
   var sales;
   output out=sasuser.sales;
run;
Proc summary data=two.expenses;
   where year=&year
   class month;
   var expenses;
   output out=sasuser.expenses;
run;
```

You can include any SAS statement that is valid with the generated grid job. You can use text that is all uppercase, all lowercase, or mixed case.

Syntax: SCAPROC Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC SCAPROC;

RECORD *filespec* <ATTR> <OPENTIMES> <INTCON> <EXPANDMACROS> <GRID *filespec* <RESOURCE *"resource name"*> <INHERITLIB> <NOOPTIMIZE> >;

WRITE;

Statement	Task	Example
PROC SCAPROC	Implement the SAS Code Analyzer	Ex. 1, Ex. 2
RECORD	Specify a filename or a fileref to contain the output of the SAS Code Analyzer	Ex. 1, Ex. 2
WRITE	Output information to the record file	Ex. 1

PROC SCAPROC Statement

Specifies that SAS will run the SAS Code Analyzer with your SAS job.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Examples: "Example 1: Specifying a Record File" on page 2300
"Example 2: Specifying the Grid Job Generator" on page 2301

Syntax

PROC SCAPROC;

RECORD Statement

Specifies a filename or a fileref to contain the output of the SAS Code Analyzer.

Examples: "Example 1: Specifying a Record File" on page 2300
"Example 2: Specifying the Grid Job Generator" on page 2301

Syntax

RECORD *filespec* <ATTR> <OPENTIMES> <INTCON> <EXPANDMACROS> <GRID *filespec* <RESOURCE *"resource name"*> <INHERITLIB> <NOOPTIMIZE> >;

Required Argument

filespec
specifies a physical filename in quotation marks, or a fileref, that indicates a file to contain the output of the SAS Code Analyzer. The output is the original SAS source and comments that contain information about the job. For more information about the output comments, see "Results" on page 2296.

Optional Arguments

ATTR
writes additional information about the variables in the input data sets and views.

OPENTIMES
writes the open time, size, and physical filename of the input data sets.

INTCON
outputs information about table integrity constraints.

EXPANDMACROS
expands macro invocations into separate tasks.

GRID

filespec
specifies a physical filename in quotation marks, or a fileref, that points to a file that will contain the output of the Grid Job Generator.

RESOURCE "*resource name*"
specifies the resource to use in the `grdsvs_enable` function call. The default is SASApp.

INHERITLIB
adds INHERITLIB=(USER) to the SIGNON statements in the grid-enabled job. By default, the user library (if one is specified) is assigned in each remote session.

Note: INHERITLIB should be used only when the USER library is not globally accessible to all remote sessions.

NOOPTIMIZE
disables the combining and reordering of tasks for grid-enabled jobs.

WRITE Statement

Specifies output information to the record file.

Example: "Example 1: Specifying a Record File" on page 2300

Syntax

WRITE;

Without Arguments

The WRITE statement specifies that the SAS Code Analyzer writes information to the record file, if a file has been specified with the RECORD statement. The Grid Job Generator will also run at this time if it has been specified. Termination of SAS also causes the SAS Code Analyzer to write information to the specified record file.

Results: SCAPROC Procedure

Results

The following list contains explanations of the comments that the SAS Code Analyzer writes to the record file that you specify with PROC SCAPROC. The output comments are bounded by **/*** and ***/** comment tags in the record file. That format is represented here to enhance clarity when the user reads a record file.

`/* JOBSPLIT: DATASET INPUT|OUTPUT|UPDATE SEQ|MULTI` *name* `*/`
specifies that a data set was opened for reading, writing, or updating.

INPUT
specifies that SAS read the data set.

OUTPUT
specifies that SAS wrote the data set.

UPDATE
specifies that SAS updated the data set.

SEQ
specifies that SAS opened the data set for sequential access.

MULTI
specifies that SAS opened the data set for multipass access.

name
specifies the name of the data set.

`/* JOBSPLIT: CATALOG INPUT|OUTPUT|UPDATE` *name* `*/`
specifies that a catalog was opened for reading, writing, or updating.

INPUT
specifies that SAS read the catalog.

OUTPUT
specifies that SAS wrote the catalog.

UPDATE
specifies that SAS updated the catalog.

name
specifies the name of the catalog.

`/* JOBSPLIT: FILE INPUT|OUTPUT|UPDATE` *name* `*/`
specifies that an external file was opened for reading, writing, or updating.

INPUT
specifies that SAS read the file.

OUTPUT
specifies that SAS wrote the file.

UPDATE
specifies that SAS updated the file.

name
specifies the name of the file.

`/* JOBSPLIT: ITEMSTOR INPUT|OUTPUT|UPDATE name */`
specifies that an ITEMSTOR was opened for reading, writing, or updating.

INPUT
specifies that SAS read the ITEMSTOR.

OUTPUT
specifies that SAS wrote the ITEMSTOR.

UPDATE
specifies that SAS updated the ITEMSTOR.

name
specifies the name of the ITEMSTOR.

`/* JOBSPLIT: OPENTIME name DATE:date PHYS:phys SIZE:size */`
specifies that a data set was opened for input. SAS writes the OPENTIME and the SIZE of the file.

name
specifies the name of the data set.

DATE
specifies the date and time that the data set was opened. The value that is returned for DATE is not the creation time of the file.

PHYS
specifies the complete physical name of the data set that was opened.

SIZE
specifies the size of the data set in bytes.

`/* JOBSPLIT: ATTR name INPUT|OUTPUT VARIABLE:variable name TYPE:CHARACTER|NUMERIC LENGTH:length LABEL:label FORMAT:format INFORMAT:informat */`
specifies that when a data set is closed, SAS reopens it and writes the attributes of each variable. One ATTR line is produced for each variable.

name
specifies the name of the data set.

INPUT
specifies that SAS read the data set.

OUTPUT
specifies that SAS wrote the data set.

VARIABLE
specifies the name of the current variable.

TYPE
specifies whether the variable is character or numeric.

LENGTH
specifies the length of the variable in bytes.

LABEL
specifies the variable label if it has one.

FORMAT
specifies the variable format if it has one.

INFORMAT
specifies the variable informat if it has one.

`/* JOBSPLIT: SYMBOL SET|GET` *name* `*/`
specifies that a macro symbol was accessed.

SET
specifies that SAS set the symbol. For example, SAS set the symbol **sym1** in the following code: `%let sym1=sym2`

GET
specifies that SAS retrieved the symbol. For example, SAS retrieved the symbol **sym** in the following code: `a="&sym"`

name
specifies the name of the symbol.

`/* JOBSPLIT: ELAPSED` *number* `*/`
specifies a number for you to use to determine the relative run times of tasks.

number
specifies a number for you to use to determine the relative run times of tasks.

`/* JOBSPLIT: USER` *useroption* `*/`
specifies that SAS uses the USER option with the grid job code to enable single-level data set names to reside in the Work library.

useroption
specifies the value that is to be used while the code is running.

`/* JOBSPLIT: _DATA_ */`
specifies that SAS is to use the reserved data set name _DATA_.

`/* JOBSPLIT: _LAST_ */`
specifies that SAS is to use the reserved data set name _LAST_ .

`/* JOBSPLIT: PROCNAME procname|DATASTEP */`
specifies the name of the SAS procedure or DATA step for this step.

`/* JOBSPLIT: LIBNAME <libname options> */`
specifies the LIBNAME options that were provided in a LIBNAME statement or were set internally.

`/* JOBSPLIT: SYSSCP <sysscp> */`
specifies the value of the SYSSCP automatic macro variable when the SAS job was run.

`/* JOBSPLIT: JOBSTARTTIME <datetime> */`
records the date and time that a job started.

`/* JOBSPLIT: JOBENDTIME <datetime> */`
records the date and time that a job ended.

```
/* JOBSPLIT: TASKSTARTTIME <datetime> */
```
records the date and time that a task started.

```
/* JOBSPLIT: INTCON <table name> <INPUT | OUTPUT> NAME:<name>
TYPE:<UNIQUE|CHECK|NOTNULL|PRIMARY|FOREIGN|REFERENTIAL>
VARIABLES:<names> WHERE:<where clause> REFERENCE: ONDELETE: ONUPDATE:
MESSAGE:<msg> MESSAGETYPE:<USER> */
```
table name
specifies the name of the table.

INPUT
specifies that the table was opened for input.

OUTPUT
specifies that the table was opened for output.

NAME
specifies the name of the integrity constraint.

TYPE
specifies the type of integrity constraint:

Table 61.1 *Integrity Constraint for Each Type*

Type	Integrity Constraint
UNIQUE	unique
CHECK	check
NOTNULL	not null
PRIMARY	primary key
FOREIGN	foreign key
REFERENTIAL	a FOREIGN integrity constraint in another table that references this table

VARIABLES
specifies the variables involved with this integrity constraint. Otherwise, it is empty.

WHERE
specifies the WHERE expression for CHECK integrity constraints. Otherwise, it is empty.

REFERENCE
specifies one of the following integrity constraints:

- For FOREIGN integrity constraints, it specifies the table the foreign key references.
- For REFERENTIAL integrity constraints, it specifies the table containing the foreign key.

- Otherwise, it is empty.

ONDELETE
specifies the ON DELETE referential action for FOREIGN and REFERENTIAL integrity constraints. Otherwise, it is empty.

ONUPDATE
specifies the ON UPDATE referential action for FOREIGN and REFERENTIAL integrity constraints. Otherwise, it is empty.

MESSAGE
specifies the text of the error message, if there is any.

MESSAGETYPE
specifies USER if MESSAGETYPE=USER was specified. Otherwise, it is empty.

Examples: SCAPROC Procedure

Example 1: Specifying a Record File

Features: RECORD statement
WRITE statement

This example specifies the record file **'record.txt'** and writes information from the SAS Code Analyzer to the file.

Program

```
proc scaproc;
   record 'record.txt';
run;

data a;
   do i = 1 to 100000;
      j = cos(i);
      output;
   end;
run;

proc print data=a(obs=25);
run;
```

```
proc means data=a;
run;

proc scaproc;
   write;
run;
```

Output

Output 61.1 *Contents of the record.txt File*

```
/* JOBSPLIT: DATASET OUTPUT SEQ WORK.A.DATA */
/* JOBSPLIT: LIBNAME WORK ENGINE V9 PHYS C:\DOCUME~1\userid\LOCALS~1\Temp\SAS
Temporary Files\_TD1252 */
/* JOBSPLIT: ELAPSED 3984  */
/* JOBSPLIT: PROCNAME DATASTEP */
/* JOBSPLIT: STEP SOURCE FOLLOWS */

data a;
    do i = 1 to 1000000;
        j = cos(i);
        output;
    end;
run;

/* JOBSPLIT: ITEMSTOR INPUT SASUSER.TEMPLAT */
/* JOBSPLIT: ITEMSTOR INPUT SASHELP.TMPLMST */
/* JOBSPLIT: DATASET INPUT SEQ WORK.A.DATA */
/* JOBSPLIT: LIBNAME WORK ENGINE V9 PHYS C:\DOCUME~1\userid\LOCALS~1\Temp\SAS
Temporary Files\_TD1252 */
/* JOBSPLIT: ELAPSED 5187  */
/* JOBSPLIT: PROCNAME PRINT */
/* JOBSPLIT: STEP SOURCE FOLLOWS */
proc print data=a(obs=25);
run;

/* JOBSPLIT: DATASET INPUT SEQ WORK.A.DATA */
/* JOBSPLIT: LIBNAME WORK ENGINE V9 PHYS C:\DOCUME~1\userid\LOCALS~1\Temp\SAS
Temporary Files\_TD1252 */
/* JOBSPLIT: FILE OUTPUT C:\winnt\profiles\userid\record.txt */
/* JOBSPLIT: SYMBOL GET SYSSUMTRACE */
/* JOBSPLIT: ELAPSED 2750  */
/* JOBSPLIT: PROCNAME MEANS */
/* JOBSPLIT: STEP SOURCE FOLLOWS */
proc means data=a;
run;

/* JOBSPLIT: END */
```

Example 2: Specifying the Grid Job Generator

Features: RECORD statement

GRID statement

Details

This example writes information from the SAS Code Analyzer to the file that is named `1.txt`. The example code also runs the Grid Job Generator, and writes that information to the file that is named `1.grid`. Notice that this example does not have an ending statement that contains this code:

```
proc scaproc;
   write;
run;
```

When SAS terminates, PROC SCAPROC automatically runs any pending RECORD or GRID statements.

For the GRID statement to work, your site has to license SAS Grid Manager or SAS/CONNECT. SAS Grid Manager enables your generated grid job to run on a grid of distributed machines. SAS/CONNECT enables your generated grid job to run on parallel SAS sessions on one symmetric multiprocessing (SMP) machine.

Program

```
proc scaproc;
   record '1.txt' grid '1.grid';
run;

data a;
   do i = 1 to 100000;
      j = cos(i);
      output;
   end;
run;

proc print data=a(obs=25);
run;

proc means data=a;
run;
```

Output

Output 61.2 *Contents of the 1.txt File*

```
/* JOBSPLIT: DATASET OUTPUT SEQ WORK.A.DATA */
/* JOBSPLIT: LIBNAME WORK ENGINE V9 PHYS C:\DOCUME~1\userid\LOCALS~1\Temp\SAS
Temporary Files\_TD1252 */
/* JOBSPLIT: ELAPSED 375  */
/* JOBSPLIT: PROCNAME DATASTEP */
/* JOBSPLIT: STEP SOURCE FOLLOWS */

data a;
    do i = 1 to 1000000;
        j = cos(i);
        output;
    end;
run;

/* JOBSPLIT: DATASET INPUT SEQ WORK.A.DATA */
/* JOBSPLIT: LIBNAME WORK ENGINE V9 PHYS C:\DOCUME~1\userid\LOCALS~1\Temp\SAS
Temporary Files\_TD1252 */
/* JOBSPLIT: ELAPSED 46  */
/* JOBSPLIT: PROCNAME PRINT */
/* JOBSPLIT: STEP SOURCE FOLLOWS */
proc print data=a(obs=25);
run;

/* JOBSPLIT: DATASET INPUT SEQ WORK.A.DATA */
/* JOBSPLIT: LIBNAME WORK ENGINE V9 PHYS C:\DOCUME~1\userid\LOCALS~1\Temp\SAS
Temporary Files\_TD1252 */
/* JOBSPLIT: FILE OUTPUT C:\WINNT\Profiles\userid\1.txt */
/* JOBSPLIT: SYMBOL GET SYSSUMTRACE */
/* JOBSPLIT: ELAPSED 81453  */
/* JOBSPLIT: PROCNAME MEANS */
/* JOBSPLIT: STEP SOURCE FOLLOWS */
proc means data=a;
run;

/* JOBSPLIT: END */
```

62

SCOREACCEL Procedure

Overview: SCOREACCEL Procedure

What Does the SCOREACCEL Procedure Do?

PROC SCOREACCEL is an interactive procedure that provides an interface to the CAS server and external data sources for model publishing and scoring.

- Models are supported in the form of DATA step code, DS2 code, or analytic stores.
- Model code can be published to a session-local or global CAS table and executed in CAS. Session-local means it is accessible only to the current CAS session that is executing PROC SCOREACCEL. Publishing to a global CAS table is supported in SAS Viya 3.5.
- Alternatively, models can be published to Teradata or Hadoop. After a model is published to an external data source, it can be executed there. Running a model invokes the SAS Embedded Process (EP). To operate in these environments, you need to license SAS In-Database Technologies for Hadoop (on SAS Viya) or SAS In-Database Technologies for Teradata (on SAS Viya).
- As of SAS Viya 3.4 and SAS 9.4M6, models can be removed from CAS and from external databases using the PROC SCOREACCEL DELETEMODEL statement.
- PROC SCOREACCEL calls CAS actions to complete the tasks. For more information about the actions, see "Using DS2 Actions to Publish, Run, and Delete Models in CAS" in *SAS DS2 Programmer's Guide*.
- When publishing DATA step model code, PROC SCOREACCEL translates DATA step code into DS2 code on the SAS client.

Concepts: SCOREACCEL Procedure

Publishing Models to a Model Table on the CAS Server

Publishing a model to CAS involves adding or replacing a row in a model table. In order to publish a model to an existing model table, the model table must first be loaded on the CAS server. If the specified model table has been loaded on the CAS server, then the model table is updated. Otherwise, a new model table is created.

Prior to SAS Viya 3.5, a model could be published only to a model table local to the current CAS session. The local session table could then be promoted to global scope using the PUBLISHMODEL PROMOTETABLE= parameter.

Beginning in SAS Viya 3.5, a model can be published directly to a global model table in CAS. A model is published to a global model table in CAS when the PUBLISHMODEL PUBLISHGLOBAL= parameter is set to YES.

Syntax: SCOREACCEL Procedure

PROC SCOREACCEL *session-name* | *session-uuid*;
PUBLISHMODEL *required-arguments* <*publish-model-options*>;
RUNMODEL *required-arguments* <*run-model-options*>;
DELETEMODEL *required-arguments* <*delete-model-options*>;

Statement	Task	Example
PROC SCOREACCEL	Publish, execute, and delete models in CAS or an external database	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7
PUBLISHMODEL	Publish models in CAS or an external database	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 7
RUNMODEL	Run models in CAS or an external database	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7
DELETEMODEL	Delete models from CAS or an external database	Ex. 1, Ex. 2

PROC SCOREACCEL Statement

Publishes, executes, or deletes a model in CAS or an external data source.

Examples:

"Example 1: Publishing, Running, and Deleting a DATA Step Model in CAS" on page 2329
"Example 2: Publishing, Running, and Deleting a DS2 Model in Teradata" on page 2331
"Example 3: Publishing and Running a DATA Step Model in Teradata Using a CASLIB" on page 2334
"Example 4: Publishing and Running a Model in Hadoop" on page 2336
"Example 5: Publishing and Running a Model in Hadoop (Hive)" on page 2337

Syntax

PROC SCOREACCEL SESSREF=*session-name* | SESSUUID="*session-uuid*";

Arguments

SESSREF=*session-name* | SESSUUID="*session-uuid*"
specifies the name of a CAS session or the universally unique identifier (UUID) of an existing CAS session to which you want to connect. If no option is specified, the automatic CAS session, CASAUTO, is used.

SESSREF=*session-name*
specifies the name of a CAS session to which you want to connect.

SESSUUID="*session-uuid*"
specifies the universally unique identifier (UUID) of an existing CAS session. You must obtain the SESSUUID from the existing session before you can specify it in this option. The engine connects to the session that is identified in the UUID.

DELETEMODEL Statement

Deletes a model from CAS or an external database.

Restriction: This statement is available as of SAS Viya 3.4 and SAS 9.4M6.

Examples: "Example 1: Publishing, Running, and Deleting a DATA Step Model in CAS" on page 2329

"Example 2: Publishing, Running, and Deleting a DS2 Model in Teradata" on page 2331

Syntax

DELETEMODEL
MODELNAME="*model-name*"
MODELTABLE="*model-table*" | "*caslib.model-table*" | "*schema.model-table*"
<*delete-model-options*>;

Required Arguments

MODELNAME="*model-name*"
specifies the name of the model to be deleted.

Alias MODEL=

Applies to CAS

Hadoop

Teradata

MODELTABLE="*model-table*" | "*caslib.model-table*" | "*schema.model-table*"
specifies the name of the table that contains the model to be deleted.

Applies to CAS

Teradata

Restriction This parameter is required when deleting a model from CAS or Teradata. It does not apply when deleting a model from Hadoop.

Requirement Deleting a model from CAS involves removing a row from a model table. In order to remove the model, the model table must first be loaded to the CAS server.

Note The model table can be specified as a one-part or a two-part name. When deleting a model from CAS, the first part of a two-part name is interpreted as the name of the caslib that contains the model table. When deleting a model from Teradata, the first part of a two-part name is interpreted as the name of the database schema that contains the model table.

Delete Model Options

AUTHDOMAIN = "*authentication-domain*"
specifies the name of the authentication domain that contains the credentials (user name and password) that are used to access Teradata.

Applies to Teradata

CASLIB="*caslib*"
specifies the name of the caslib associated with the model table when deleting a model from CAS. When deleting models in Teradata or Hadoop, this is the name of the caslib whose associated data source is used to obtain options that are specific to the external database. This includes any user credentials that are specified in the data source definition.

Applies to CAS

Hadoop

Teradata

Requirement The caslib that is specified as the first part of a two-part model table name takes precedence over the caslib that is specified with the CASLIB option.

CLASSPATH="*classpath*"
specifies the class path used in the Hadoop call context. The class path can be a folder or individual JAR files. The Hadoop configuration folder must be included in the class path.

Applies to Hadoop

DATABASE="*database-name*"
specifies the name of the Teradata database.

Default "" (a zero-length string)

Applies to Teradata

Note This option provides the connection option that names the Teradata database to be accessed.

DELETEGLOBAL=YES | NO
specifies whether the model is deleted from a global model table in CAS. If DELETEGLOBAL=YES, then the model is deleted from the global model table. If DELETEGLOBAL=NO, then the model is deleted from the model table in the local CAS session, leaving the global table unaltered.

Default NO

Applies to CAS

Restriction This option is available as of SAS Viya 3.5.

JOBMANAGEMENTURL="*rest-url*"
specifies the URL used to submit execution requests over a REST interface to services such as Apache Livy.

Alias RESTURL=

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

MODELDIR="*model-directory*"
specifies the root HDFS folder containing the model directory from which the model is to be deleted.

Applies to Hadoop

PASSWORD="*password*"
is the password for the user ID on the Hadoop or Teradata server.

Aliases PASS=

PASSWD=

PWD=

Applies to Hadoop

Teradata

PERSISTTABLE=YES | NO
specifies whether the updated model table, that results from deleting a model, should be saved to the caslib data source associated with the table.

Default NO

Applies to CAS

Requirement If the model table already exists in the caslib data source, you must also specify REPLACETABLE=YES to save the table.

See REPLACETABLE= option

PROMOTETABLE=YES | NO
specifies whether the updated model table, that results from deleting a model, should be promoted to global scope on the CAS server.

Default NO

Applies to CAS

REPLACETABLE=YES | NO
specifies whether to allow an existing model table, that results from deleting a model, to be replaced when the updated model table is saved to the caslib data source.

Default YES

Applies to CAS

Requirement You must also specify PERSISTTABLE=YES to save the model table to the caslib data source.

See PERSISTTABLE= option

SCHEMA="*schema-name*"
specifies the name of the Teradata schema.

Applies to Teradata

Note This option provides the connection option that the Teradata database uses to qualify the Teradata tables.

SERVER="*server*"
specifies the name of the Teradata server.

Applies to Teradata

TARGET=CAS | HADOOP | TERADATA
specifies the target environment to which the model is to be deleted.

CAS
specifies to delete the model from a model table in CAS.

HADOOP
specifies to delete the model from the Hadoop server.

TERADATA
specifies to delete the model from a model table in the Teradata database.

Default CAS

Applies to CAS

Hadoop

Teradata

USERNAME='*id*'
is an authorized user ID on the Hadoop or Teradata server.

Aliases USER=

USERID=

UID=

Applies to Hadoop

Teradata

WEBHDFSURL="*webhdfs-url*"
specifies the URL used to access the Hadoop distributed file system through the REST API.

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

Note Use this argument when you delete, publish, or run a model in a platform that is configured to access the distributed file system through the REST API.

PUBLISHMODEL Statement

Publishes a model in CAS or an external database.

Examples:
"Example 1: Publishing, Running, and Deleting a DATA Step Model in CAS" on page 2329
"Example 2: Publishing, Running, and Deleting a DS2 Model in Teradata" on page 2331
"Example 3: Publishing and Running a DATA Step Model in Teradata Using a CASLIB" on page 2334
"Example 4: Publishing and Running a Model in Hadoop" on page 2336
"Example 5: Publishing and Running a Model in Hadoop (Hive)" on page 2337

Syntax

PUBLISHMODEL
MODELNAME ="*model-name*"
MODELTABLE="*model-table*" | "*caslib.model-table*" | "*schema.model-table*"
PROGRAMFILE="*file-path*" | *fileref*
< *publish-model-options*> ;

Required Arguments

MODELNAME="*model-name*"
specifies the name of the model to be published.

Alias MODEL=

Applies to CAS

Hadoop

Teradata

MODELTABLE="*model-table*" | "*caslib.model-table*" | "*schema.model-table*"
specifies the name of the table to which the model is published.

Applies to CAS

Teradata

Interaction The caslib that is specified as the first part of a two-part model table name takes precedence over the caslib that is specified with the CASLIB option.

Notes The model table can be specified as a one-part or a two-part name. When you publish a model to CAS, the first part of a two-part name is interpreted as the name of the caslib that contains the model table. When you publish a model to Teradata, the first part of a two-part name is interpreted as the name of the database schema that contains the model table.

Publishing a model to CAS involves adding or replacing a row in a model table. In order to publish a model to an existing model table, the model table must first be loaded onto the CAS server. If the specified model table has been loaded onto the CAS server, then the model table is updated. Otherwise, a new model table is created.

PROGRAMFILE="*file-path*" | *fileref*
specifies the file that contains the model program to be published.

Applies to CAS

Hadoop

Teradata

Interaction This argument is not required if a single analytic store is provided using the STOREFILES or the STORETABLES option.

Publish Model Options

AUTHDOMAIN = "*authentication-domain*"
specifies the name of the authentication domain that contains the credentials (user name and password) that will be used to access the specified Teradata database.

Applies to Teradata

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

CASLIB="*caslib*"
specifies name of the caslib in which the model table is created or to which the updated model table is written, when publishing a model to CAS.

Applies to CAS

Hadoop

Teradata

Interaction The caslib that is specified as the first part of a two-part model table name takes precedence over the caslib that is specified with the CASLIB option.

Note When you publish a model to Teradata or Hadoop, this argument specifies the name of the caslib whose associated data source is used to obtain options specific to the external database. This includes any user credentials that are specified in the data source definition.

CLASSPATH="*class_path*"
specifies the class path used in the Hadoop call. The class path must include the Hadoop configuration folder and it must also include either a folder containing the JAR files or the individual JAR files.

Applies to Hadoop

DATABASE="*database-name*"
specifies the name of the Teradata database.

Default "" (a zero-length string)

Applies to Teradata

Note This option provides the connection option that names the Teradata database to be accessed.

FORMATFILE=*file-path* | *fileref*
specifies the file that contains the user-defined format XML definition to be published.

Applies to CAS

Hadoop

Teradata

FORMATITEMSTOREFILE=*file-path* | *fileref*
specifies the file containing the format item store to be published.

Applies to CAS

Hadoop

Teradata

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

JOBMANAGEMENTURL="*rest-url*"
specifies the URL used to submit execution requests over a REST interface to services such as Apache Livy.

Alias RESTURL=

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

KEEPLIST=YES | NO
specifies whether to include a KEEP statement in the DS2 model program that was automatically generated from an analytic store model.

Default NO

Applies to CAS

Hadoop

Teradata

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

Interaction KEEPLIST can be specified when the STOREFILES or the STORETABLES option contains a single analytic store model, and an accompanying DS2 model program is not specified.

MODELDIR="*model-directory*"
specifies the root HDFS folder where the model directory is created.

Applies to Hadoop

MODELNOTES="*model-notes*"
specifies the model notes to be written to the model table.

Applies to CAS

Teradata

MODELTYPE=DATASTEP | DS2
specifies the type of the input model program.

DATASTEP
specifies that the input model program is DATA step code.

Alias DS

DS2
specifies that the input model program is DS2 code.

Default DS2

Applies to CAS

Hadoop

Teradata

Note The DATA step code is converted to DS2 code before being bundled into an item store.

MODELUUID="*model-uuid*"
specifies that the Model UUID is written to the model table.

Applies to CAS

Teradata

OUTDIR="*work-directory*"
specifies the local output directory that contains the program file that was converted from DATA step to DS2.

Applies to CAS

Hadoop

Teradata

PASSWORD="*password*"
is the password for the user ID on the Hadoop or Teradata server.

Aliases PASS=

PASSWD=

PWD=

Applies to Hadoop

Teradata

PERSISTTABLE=YES | NO
specifies whether the updated model table should be saved to the caslib data source associated with the table.

Default NO

Applies to CAS

Requirement If the model table already exists in the caslib data source, you must also specify REPLACETABLE=YES to save the table.

See REPLACETABLE= option

PROMOTETABLE=YES | NO
specifies whether the updated model table should be promoted to global scope on the CAS server.

Default NO

Applies to CAS

PUBLISHGLOBAL=YES | NO
specifies whether the model is published to a global model table in CAS. If PUBLISHGLOBAL=YES, then the model is published to a global model table. If PUBLISHGLOBAL=NO, then the model is published to the model table in the local CAS session, leaving the global model table unaltered.

Default NO

Applies to CAS

Restriction This option is available as of SAS Viya 3.5.

REPLACEMODEL=YES | NO
specifies whether to allow an existing model in the model table to be replaced by the model being published.

Default YES

Applies to CAS

Hadoop

Teradata

REPLACETABLE=YES | NO
specifies whether to allow an existing model table to be replaced when the updated model table is saved to the caslib data source.

Default YES

Applies to CAS

Requirement You must also specify PERSISTTABLE=YES to save the model table to the caslib data source.

See PERSISTTABLE= option

SCHEMA="*schema-name*"
specifies the name of the Teradata schema.

Applies to Teradata

Note This option provides the connection option that the Teradata database uses to qualify the Teradata tables.

SERVER="*server-name*"
specifies the name of the Teradata or Hive server.

Applies to Hadoop

Teradata

STOREFILES="*file-path*" <, "*file-path*"> | *fileref* <, *fileref*>
specifies a list of files, one for each analytic store to be published.

Alias STOREFILE=

Applies to CAS

Hadoop

Teradata

Interaction As of SAS Viya 3.4 and SAS 9.4M6, if a single analytic store model is specified without an accompanying DS2 program, the KEEPLIST option can also be specified.

Tip The list of files can be a mixture of file pathnames and file references.

STORETABLES= ("*store-table-1*" | "*caslib.store-table-1*" <, "*store-table-n*" | "*caslib.store-table-n*">
specifies one or more CAS blob table names that contain the analytic stores to be published. Each table must include a VARBINARY column named "_state_" that contains the analytic store blob.

Applies to CAS

Hadoop

Teradata

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

Interaction If a single analytic store model is specified without an accompanying DS2 program, then the KEEPLIST option can also be specified.

TARGET=CAS | HADOOP | TERADATA
specifies the target environment to which the model is published.

CAS
specifies to publish to a model table in CAS.

HADOOP
specifies to publish to the Hadoop server.

TERADATA
specifies to publish to a model table in the Teradata database.

Default CAS

Applies to CAS

Hadoop

Teradata

USERNAME='*ID*'
is an authorized user ID on the Hadoop or Teradata server.

Aliases USER=

USERID=

UID=

Applies to Hadoop

Teradata

VARXMLFILE=*file-path* | *fileref*
specifies the file that contains the variable metadata XML to be used during translation of an input DATA step model program to DS2.

Alias XMLFILE=

Applies to CAS

Hadoop

Teradata

WEBHDFSURL="*webhdfs-url*"
specifies the URL used to access the Hadoop distributed file system through the REST API.

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

Note Use this argument when you delete, publish, or run a model in a platform that is configured to access the distributed file system through the REST API.

RUNMODEL Statement

Runs a model in CAS or an external database.

Examples:
"Example 1: Publishing, Running, and Deleting a DATA Step Model in CAS" on page 2329
"Example 2: Publishing, Running, and Deleting a DS2 Model in Teradata" on page 2331
"Example 3: Publishing and Running a DATA Step Model in Teradata Using a CASLIB" on page 2334
"Example 4: Publishing and Running a Model in Hadoop" on page 2336
"Example 5: Publishing and Running a Model in Hadoop (Hive)" on page 2337

Syntax

RUNMODEL
MODELNAME ="*model-name*"
MODELTABLE="*model-table*" | "*caslib.model-table*" | "*schema.model-table*"
<*run-model-options*>;

Required Arguments

MODELNAME="*model-name*"
specifies the name of the model to run.

Alias: MODEL=

Applies to: CAS, Hadoop, Teradata

MODELTABLE="*model-table*" | "*caslib.model-table*" | "*schema.model-table*"
specifies the name of the table that contains the model to run.

Applies to: CAS, Teradata

Requirement: The caslib that is specified as the first part of a two-part model table name takes precedence over the caslib that is specified with the CASLIB option.

Note: The model table can be specified as a one-part or a two-part name. When running a model in CAS, the first part of a two-part name is interpreted as the name of the caslib that contains the

model table. When running a model in Teradata, the first part of a two-part name is interpreted as the name of the database schema that contains the model table.

Run Model Options

AUTHDOMAIN = "*authentication-domain*"
specifies the name of the authentication domain that contains the credentials (user name and password) that will be used to access Teradata.

Applies to Teradata

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

CASLIB="*caslib*"
specifies the name of the caslib associated with the model table, input table, and output table, when running a model in CAS. When running models in Teradata or Hadoop, the name of the caslib whose associated data source is used to obtain options that are specific to the external database. This includes any user credentials that are specified in the data source definition.

Applies to CAS

Hadoop

Teradata

Requirement The caslib that is specified as the first part of a two-part model table name takes precedence over the caslib that is specified with the CASLIB option.

CLASSPATH="*class_path*"
specifies the class path used in the Hadoop call context. The class path contains a folder or individual JAR files. The Hadoop configuration folder must be included in the class path if you are not specifying the CONFIGPATH option. If you are using Spark, Hadoop JAR files and Spark JAR files must be located in separate folders, and the Spark JAR folder must be specified as the last entry in the class path.

Applies to Hadoop

CONFIGPATH="*configuration-path*"
specifies a single folder where all the Hadoop and Spark configuration files reside.

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

Interactions This option is required if PLATFORM= is set to SPARK.

When the CONFIGPATH option is specified, the configuration folder does not need to be added to the CLASSPATH option.

CUSTOMJAR="*file-path*"
specifies the local JAR file that contains the user-provided custom reader. The custom JAR file is automatically copied to the Hadoop cluster during job submission.

Applies to Hadoop

DATABASE="*database-name*"
specifies the name of the Teradata database.

Default "" (a zero-length string)

Applies to Teradata

Note This option provides the connection option that names the Teradata database to be accessed.

DBMAXTEXT=*number-of-bytes*
specifies the maximum number of bytes to allocate for STRING data type columns. This option does not apply to CHAR or VARCHAR columns.

Default 32767

Range 1–32767

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

EPOPTIONS="*options-string*"
specifies the options that are passed to the SAS_SCORE_EP stored procedure that invokes the SAS Embedded Process for Teradata.

Applies to Teradata

Note The string specified by this parameter is passed directly to the SAS_SCORE_EP stored procedure via the stored procedure's OPTIONS parameter.

FORCEOVERWRITE=YES | NO
specifies whether to force deletion of the output data directory before running the Hadoop MapReduce job.

Applies to Hadoop

HIVEPORT=*integer*
specifies the Hive server port number.

Applies to Hadoop

INDATASET="*input-dataset*"
specifies the name of the Spark dataset passed as input to the SAS Embedded Process.

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

Requirement When running a model in Hadoop, either INDATASET, INHDMD, or INTABLE must be specified.

See INHDMD= option

INTABLE= option

INHDMD="*file-path*"
specifies the name of the input Hadoop metadata file on HDFS.

Applies to Hadoop

Requirement When running a model in Hadoop, either INDATASET, INHDMD, or INTABLE must be specified.

See INDATASET= option

INTABLE= option

INQUERY="*sql-query*"
specifies an SQL SELECT statement that defines the inputs to the SAS Embedded Process for Teradata.

Applies to Teradata

Requirement When running a model in Teradata, either INTABLE or INQUERY must be specified.

See INTABLE= option

INTABLE="*input-table*" | "*caslib.input-table*" | "*schema.input-table*"
specifies the name of the input table.

Alias INPUTTABLE=

Applies to CAS

Hadoop

Teradata

Requirement When running a model in Hadoop, either INDATASET, INHDMD, or INTABLE must be specified. When running a model in Teradata, either INTABLE or INQUERY must be specified.

Note The input table can be specified as a one-part or a two-part name. When running a model in CAS, the first part of a two-part name is interpreted as the name of the caslib that contains the input table. When running a model in Teradata, the first part of a two-part name is interpreted as the name of the database schema that contains the input table.

See INDATASET= option

INHDMD= option

INQUERY= option

JOBMANAGEMENTURL="*rest-url*"
specifies the URL used to submit execution requests over a REST interface to services such as Apache Livy.

Alias RESTURL=

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

KEEPLISTCOLUMNS="*column-1* <*column-2* ... >"
KEEPLISTCOLUMNS=(*column-1* <*column-2* ... >)
KEEPLISTCOLUMNS=("*column-1*" <"*column-2*" ... >)
specifies the name of the column (or columns) to be kept by the DS2 program.

Alias KEEPLISTCOLS=

Applies to Hadoop

Interaction The parameters KEEPLISTFILE and KEEPLISTCOLUMNS are mutually exclusive.

KEEPLISTFILE="*file-path*"
specifies the name of the file that contains a list of columns to be kept by the DS2 program.

Applies to Hadoop

Interaction The parameters KEEPLISTFILE and KEEPLISTCOLUMNS are mutually exclusive.

MODELDIR="*model-directory*"
specifies the root HDFS folder where the model directory is created.

Applies to Hadoop

OUTDATASET="*output-dataset*"
specifies the name of the output Spark dataset to be created by the SAS Embedded Process.

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

Requirement When running a model in Hadoop, either OUTDATASET, OUTHDMD, or OUTTABLE must be specified.

See OUTHDMD= option

OUTTABLE= option

OUTHDMD="*file-path*"
specifies the name of the output Hadoop metadata file that is created by the SAS Embedded Process.

Applies to Hadoop

Requirement When running a model in Hadoop, either OUTDATASET, OUTHDMD, or OUTTABLE must be specified.

See OUTDATASET= option

OUTTABLE= option

OUTKEY=(*column*, ..., *column*)
specifies the name of one or more columns used for the primary index of the output table that is created by the SAS Embedded Process for Teradata.

Applies to Teradata

OUTPUTFOLDER="*directory-path*"
specifies the name of the directory where the output files are stored.

Applies to Hadoop

OUTPUTFORMATCLASS="*class-name*"
specifies the name of the output format class in dot notation that is used to write the output records.

Applies to Hadoop

OUTRECORDFORMAT=BINARY | DELIMITED
specifies the format of the output record that is produced by the SAS Embedded Process for Hadoop.

BINARY
specifies that the output record is binary.

DELIMITED
specifies that the output record is delimited.

Default DELIMITED

Applies to Hadoop

OUTSCHEMA="*output-schema*"
specifies the Hive output database schema name when running a model in Hadoop.

Applies to Hadoop

OUTTABLE="*output-table*" | "*caslib.output-table*" | "*schema.output-table*"
specifies the name of the output table.

Alias OUTPUTTABLE=

Applies to CAS

Hadoop

Teradata

Requirement When running a model in Hadoop, either OUTDATASET, OUTHDMD, or OUTTABLE must be specified.

Note The output table can be specified as a one-part or a two-part name. When running a model in CAS, the first part of a two-part name is interpreted as the name of the caslib that contains the output table. When running a model in Teradata, the first part of a two-part name is interpreted as the name of the database schema that contains the output table.

See OUTDATASET= option

OUTHDMD= option

OUTTABLEOPTIONS="*options-string*"
provides user-specified options that are appended to the Hive CREATE TABLE statement.

Applies to Hadoop

PASSWORD="*password*"
is the password for the user ID on the Hadoop or Teradata server.

Aliases PASS=

PASSWD=

PWD=

Applies to Hadoop

Teradata

PLATFORM=MAPRED | SPARK
specifies the platform where the Hadoop Embedded Process is to be executed.

MAPRED
specifies to run the model in MapReduce.

SPARK
specifies to run the model in Spark.

Interaction If PLATFORM is set to SPARK, you must specify the CONFIGPATH option.

Default MAPRED

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.4 and SAS 9.4M6.

PROPERTIES="*name1=value*" <PROPERTIES="*name2=value*"> | PROPERTIES=("*name=value*"<, "*name=value*", ...>)

specifies a Hadoop configuration property as a name-value pair. For multiple properties, specify multiple PROPERTIES arguments or specify a single argument containing a comma-separated list of name-value pairs enclosed in parentheses. Any Hadoop configuration property can be assigned using this option.

If multiple properties are required, then the PROPERTIES parameter can also be specified multiple times, once for each property.

Applies to Hadoop

Requirement If your output is to a Hive table and the Hive database folder is under an HDFS encrypted zone, you must set the SAS Embedded Process temporary folder to a location that is under the same encrypted zone. To do this, set the sas.ep.tempdir configuration property. Here is an example:

```
properties="sas.ep.tempdir=yourSASEPTemporaryFolder"
```

SCHEMA="*schema-name*"

specifies the name of the Teradata schema.

Applies to Teradata

Note This option provides the connection option that the Teradata database uses to qualify the Teradata tables.

SENDPROGRAM=YES | NO

specifies whether the model program source code should be sent back to the client and displayed for the user.

Applies to CAS

SERVER="*server*"

specifies the name of the Teradata or Hive server.

Applies to Hadoop

Teradata

TARGET=CAS | HADOOP | TERADATA

specifies the target environment to which the model is published.

CAS

specifies to publish to a model table in CAS.

HADOOP

specifies to publish to the Hadoop server.

TERADATA

specifies to publish to a model table in the Teradata database.

Default CAS

Applies to CAS

Hadoop

Teradata

TRACE
runs the SAS Embedded Process for Hadoop with traces on.

Applies to Hadoop

USERNAME='*id*'
is an authorized user ID on the Hadoop or Teradata server.

Aliases USER=

USERID=

UID=

Applies to Hadoop

Teradata

VERBOSE
specifies that the SAS Embedded Process for Hadoop provide additional logging information.

Applies to Hadoop

WEBHDFSURL="*webhdfs-url*"
specifies the URL used to access the Hadoop distributed file system through the REST API.

Applies to Hadoop

Restriction This option is available as of SAS Viya 3.5 (August 2021 release, or earlier if you apply a hot fix).

Note Use this argument when you delete, publish, or run a model in a platform that is configured to access the distributed file system through the REST API.

Examples: SCOREACCEL Procedure

Example 1: Publishing, Running, and Deleting a DATA Step Model in CAS

Features:
PROC SCOREACCEL statement
PUBLISHMODEL statement
RUNMODEL statement
DELETEMODEL statement
CASLIB LIBNAME statement

Details

In this PROC SCOREACCEL example, a DATA step model is published and run in CAS. The model is then deleted.

PROC SCOREACCEL translates DATA step code into DS2 code on the SAS client.

Program

```
cas mysess1;
libname mycaslib cas casref=mysess1;

proc delete data=mycaslib.model01_score_data; run;
libname eminput "/mydir/scoring/model01";
data mycaslib.model01_score_data;
   set eminput.traindata;
   id=_n_; run;
quit;

proc scoreaccel sessref=mysess1;
   publishmodel
      modelname="model01"
      modeltype=datastep
      modeltable="modeltable1"
      programfile="/mydir/scoring/model01/score.sas"
      xmlfile="/mydir/scoring/model01/score.xml"
```

```
      outdir="/user1/score/work/"
      modelnotes="Simple model01 test model"
      replacemodel=yes
      promotetable=no
      persisttable=no
      ;
quit;

proc delete data=mycaslib.model01out_data run;
proc scoreaccel sessref=mysess1;
   runModel
      modelname="model01"
      modeltable="modeltable1"
      intable="model01_score_data"
      outtable="model01_out_data"
      ;
quit;

proc scoreaccel sessref=mysess1;
   deletemodel
      modelname="model01"
      modeltable="modeltable1"
      ;
quit;
```

Program Description

Assign a CAS LIBNAME. The CAS LIBNAME is passed to the DATA step in PROC DELETE.

```
cas mysess1;
libname mycaslib cas casref=mysess1;
```

Create an input scoring table in CAS. The DELETE procedure removes an existing input scoring table.

```
proc delete data=mycaslib.model01_score_data; run;
libname eminput "/mydir/scoring/model01";
data mycaslib.model01_score_data;
   set eminput.traindata;
   id=_n_; run;
quit;
```

Publish a model in CAS. The DATA step model is converted to DS2 in this step and is published in CAS.

```
proc scoreaccel sessref=mysess1;
   publishmodel
      modelname="model01"
      modeltype=datastep
      modeltable="modeltable1"
      programfile="/mydir/scoring/model01/score.sas"
      xmlfile="/mydir/scoring/model01/score.xml"
      outdir="/user1/score/work/"
      modelnotes="Simple model01 test model"
      replacemodel=yes
      promotetable=no
```

```
      persisttable=no
      ;
quit;
```

Run the model in CAS. The DELETE procedure removes an existing CAS table before running the model.

```
proc delete data=mycaslib.model01out_data run;
proc scoreaccel sessref=mysess1;
   runModel
      modelname="model01"
      modeltable="modeltable1"
      intable="model01_score_data"
      outtable="model01_out_data"
      ;
quit;
```

Delete the model from the model table in CAS. T

```
proc scoreaccel sessref=mysess1;
   deletemodel
      modelname="model01"
      modeltable="modeltable1"
      ;
quit;
```

Example 2: Publishing, Running, and Deleting a DS2 Model in Teradata

Features:

PROC SCOREACCEL statement

PUBLISHMODEL statement

RUNMODEL statement

DELETEMODEL statement

Details

This PROC SCOREACCEL example publishes and runs a DS2 Model in Teradata. PROC SCOREACCEL invokes the Model publishing or DS2 actions in CAS to delete a model, publish a model, or run a model.

Program

```
libname mytdlib teradata server=mytdserver user=model password=XXXXX
   database=model;

proc delete data=mytdlib.model01_score_data; run;
```

```
libname eminput "/mydir/scoring/model01";
data mytdlib.model01_score_data;
   set eminput.traindata;
   id=_n_; run;
quit;

proc scoreaccel sessref=mysess1;
   publishmodel
      target=teradata
      modelname="model01"
      modeltype=DS2
      modeltable="modeltable1"
      programfile="/mydir/scoring/model01/score.ds2"
      modelnotes="Simple model01 test model"
      username="model"
      password="XXXXX"
      server="mytdserver"
      database="model"
      replacemodel=yes
   ;
quit;

proc scoreaccel sessref=mysess1;
   runmodel
      target=teradata
      modelname="model01"
      modeltable="modeltable1"
      intable="model01_score_data"
      outtable="model01_out_data"
      outkey="id"
      username="model"
      password="XXXXX"
      server="mytdserver"
      database="model"
      ;
   quit;

proc scoreaccel sessref=mysess1;
   deletemodel
      target=teradata
      modelname="model01"
      modeltable="modeltable1"
      authdomain="indb"
      server="mytdserver"
      database="model"
      ;
   quit;
```

Program Description

Create the Teradata LIBNAME reference. The Teradata libref is needed for PROC DELETE and the DATA step program.

```
libname mytdlib teradata server=mytdserver user=model password=XXXXX
   database=model;
```

Create an input scoring table in CAS. The DELETE procedure removes an existing input scoring table.

```
proc delete data=mytdlib.model01_score_data; run;
libname eminput "/mydir/scoring/model01";
data mytdlib.model01_score_data;
   set eminput.traindata;
   id=_n_; run;
quit;
```

Publish a DS2 model to Teradata. The PROGRAMFILE statement contains the DS2 model.

```
proc scoreaccel sessref=mysess1;
   publishmodel
      target=teradata
      modelname="model01"
      modeltype=DS2
      modeltable="modeltable1"
      programfile="/mydir/scoring/model01/score.ds2"
      modelnotes="Simple model01 test model"
      username="model"
      password="XXXXX"
      server="mytdserver"
      database="model"
      replacemodel=yes
   ;
quit;
```

Run the DS2 model in Teradata.

```
proc scoreaccel sessref=mysess1;
   runmodel
      target=teradata
      modelname="model01"
      modeltable="modeltable1"
      intable="model01_score_data"
      outtable="model01_out_data"
      outkey="id"
      username="model"
      password="XXXXX"
      server="mytdserver"
      database="model"
      ;
   quit;
```

Delete the model from the model table in Teradata.

```
proc scoreaccel sessref=mysess1;
   deletemodel
      target=teradata
      modelname="model01"
      modeltable="modeltable1"
      authdomain="indb"
      server="mytdserver"
      database="model"
      ;
   quit;
```

Example 3: Publishing and Running a DATA Step Model in Teradata Using a CASLIB

Features: PROC SCOREACCEL statement
PUBLISHMODEL statement
RUNMODEL statement
CASLIB LIBNAME statement
CAS procedure

Details

In this PROC SCOREACCEL example, a DATA step model is published and run in CAS. PROC SCOREACCEL translates DATA step code into DS2 code on the SAS client. Here, the user credentials and other database connection information is pulled from the specified CASLIB.

Program

```
libname mytdlib teradata server=mytdserver user=model password=XXXXX
   database=model;

proc delete data=mytdlib.model01_score_data; run;

libname eminput "/mydir/scoring/model01";
data mytdlib.model01_score_data;
   set eminput.traindata;
   id=_n_; run;
quit;

proc cas;
   session mysess1;
   action addCaslib /
       caslib="tdlib1"
       datasource={
       srcType="teradata",
       dataTransferMode="parallel",
       server="mytdserver",
       username="model",
       password="XXXXX",
       database="model"
   };
run;

proc scoreaccel sessref=mysess1;
```

```
   publishmodel
      target=teradata
      modelname="model01"
      modeltype=datastep
      modeltable="modeltable1"
      programfile="/mydir/scoring/model01/score.sas"
      xmlfile="/mydir/scoring/model01/score.xml"
      outdir="/score/work/"
      modelnotes="Simple model01 test model"
      replacemodel=yes
      ;
   runmodel
      target=teradata
      caslib="tdlib1"
      modelname="model01"
      modeltable="modeltable1"
      intable="model01_score_data"
      outtable="model01_out_data"
      outkey="id"
      ;
   quit;
```

Program Description

Create the Teradata connection options and LIBNAME reference.

```
libname mytdlib teradata server=mytdserver user=model password=XXXXX
   database=model;
```

Create an input scoring table in Teradata. PROC DELETE removes an existing input scoring table.

```
proc delete data=mytdlib.model01_score_data; run;

libname eminput "/mydir/scoring/model01";
data mytdlib.model01_score_data;
   set eminput.traindata;
   id=_n_; run;
quit;
```

Define a Teradata caslib. The addCaslib action adds a CAS library to the current mysess1 session.

```
proc cas;
   session mysess1;
   action addCaslib /
       caslib="tdlib1"
       datasource={
       srcType="teradata",
       dataTransferMode="parallel",
       server="mytdserver",
       username="model",
       password="XXXXX",
       database="model"
   };
run;
```

Publish and run the DATA step model in Teradata.

```
proc scoreaccel sessref=mysess1;
   publishmodel
      target=teradata
      modelname="model01"
      modeltype=datastep
      modeltable="modeltable1"
      programfile="/mydir/scoring/model01/score.sas"
      xmlfile="/mydir/scoring/model01/score.xml"
      outdir="/score/work/"
      modelnotes="Simple model01 test model"
      replacemodel=yes
      ;
   runmodel
      target=teradata
      caslib="tdlib1"
      modelname="model01"
      modeltable="modeltable1"
      intable="model01_score_data"
      outtable="model01_out_data"
      outkey="id"
      ;
   quit;
```

Example 4: Publishing and Running a Model in Hadoop

Features: PROC SCOREACCEL statement
PUBLISHMODEL statement
RUNMODEL statement

Details

In this PROC SCOREACCEL example, a simple DS2 model is published and run in Hadoop.

Program

The CLASSPATH option specifies a link to the Hadoop cluster.

```
proc scoreaccel sessref=mysess1;
   publishmodel
      target=hadoop
      modelname="simple01"
```

```
      modeltype=DS2
      programfile="/score/simple/simple.ds2"
      username="test"
      password="XXXXX"
      modeldir="/data/model/dlm/ds2"
      classpath="/server/sdm/hadoopjars/cdh58/prod:
                 /server/sdm/hadoopcfg/cdh58/prod";
   ;
quit;
proc scoreaccel sessref=mysess1;
   runmodel
      target=hadoop
      modelname="simple01"
      username="test"
      password="XXXXX"
      modeldir="/data/model/dlm/ds2"
      server="server1.com"
      inhdmd="/data/model/dlm/meta/simple01sashdmd"
      outhdmd="/data/model/dlm/meta/simple01_out.sashdmd"
      outputfolder="/data/model/dlm/temp/simple01"
      forceoverwrite=yes
      classpath="/server/sdm/hadoopjars/cdh58/prod:
                 /user1/server/sdm/hadoopcfg/cdh58/prod";
      ;
quit;
```

Example 5: Publishing and Running a Model in Hadoop (Hive)

Features: PROC SCOREACCEL statement
PUBLISHMODEL statement
RUNMODEL statement

Details

In this PROC SCOREACCEL example, a simple DS2 model is published to Hadoop and executed there with Hive.

Program

The classpath statement specifies a link to the Hadoop cluster. The input and output tables, *carsorc* and *carsout*, already exist on the Hadoop cluster.

```
proc scoreaccel sessref=mysess1;
```

```
   publishmodel
      target=hadoop
      modelname="simple01"
      modeltype=DS2
      filelocation=local
      programfile="/user1/score/simple/simple.ds2"
      username="test"
      modeldir="/user/user1/cas/models"
      classpath="/server/sdm/hadoopjars/cdh58/prod:
                 /user1/server/sdm/hadoopcfg/cdh58/prod";
      ;
   runmodel
      target=hadoop
      modelname="simple01"
      username="test"
      modeldir="/user/user1/cas/models"
      server="server2.com"
      intable="carsorc"
      outtable="carsout"
      outtableoptions="stored as ORC"
      forceoverwrite=yes
      classpath="/server/sdm/hadoopjars/cdh58/prod:
                 /user1/server/sdm/hadoopcfg/cdh58/prod";
      ;
quit;
```

Example 6: Running a Model in Spark

Features: PROC SCOREACCEL statement
RUNMODEL statement

Details

In this PROC SCOREACCEL example, a DS2 model is run in Spark with the SAS Embedded Process.

Program

To run in Spark, the cluster must have Spark installed and configured. When the Hadoop tracer script is run to collect JAR files, the **spark** folder is created along with the required Spark JAR files. During this process, the Spark configuration file is placed into the user's configuration folder. To run the model in Spark, specify the PLATFORM=SPARK option in the RUNMODEL statement. To run the model, the folder containing the client-side Spark JAR files must be specified last in the

CLASSPATH option. In this example, the input and output tables, *carsorc* and *carsout*, already exist on the Hadoop cluster.

```
proc scoreaccel sessref=mysess1;
runmodel
    target=hadoop
    modelname="cars"
    username="test"
    modeldir="/user1/cas/models"
    server="server2.com"
    intable="carsorc"
    outtable="carsout"
    forceoverwrite=yes
    classpath="/nfs/hadoop/jars"
    configpath="/nfs/hadoop/cfg"
    platform=SPARK
    ;
  quit;
```

Example 7: Running a Model in Spark by Using the Apache Livy REST Interface

Features:

CASLIB statement
CAS procedure
PROC SCOREACCEL statement
PUBLISHMODEL statement
RUNMODEL statement

Details

In this example, PROC SCOREACCEL publishes and runs a model in Spark. The request to run the model is submitted by using the Apache Livy REST service.

Create a CAS session, and assign a caslib to Spark. A best practice is to specify all the connection properties in the caslib, so that you do not have to remember which connection properties are required by the different actions and statements.

```
cas mysess;

caslib myspark datasource=(srctype='spark',
       schema="model",
       username="myuser",
       password="mypwd",
       jobmanagementurl="https://nnnnn.cloud.company.com/cdp-proxy-api/
livy/",
       server="cloud.company.com",
```

```
      hadoopJarPath="path-to-hadoop-jar-files",
      hadoopConfigDir="path-to-hadoop-configuration",
      dbmaxtext=512);
```

Start the SAS Embedded Process for Spark continuous session. Most customers choose to use a continuous session for better performance.

```
proc cas;
   sparkEmbeddedProcess.startSparkEP
   caslib="myspark";
run;
quit;
```

Publish a model to Spark.

```
proc scoreaccel sessref=mysess;
   publishmodel
      target=hadoop
      caslib="myspark"
      modelname="mymodel"
      programfile="/mydir/myscorefile.ds2"
      modeldir="/user/dir"
      replacemodel=yes;
run;
quit;
```

Run the model in Spark. The INTABLE= option specifies the input Spark table that contains the data to run the model against.

```
proc scoreaccel sessref=mysess;
   runmodel
      target=hadoop
      caslib="myspark"
      modelname="mymodel"
      modeldir="/user/dir"
      intable="mytable"
      outtable="mytable_out"
      forceoverwrite=yes;
run;
quit;
```

63

SOAP Procedure

Overview: SOAP Procedure

What Does the SOAP Procedure Do?

The Simple Object Access Protocol (SOAP) procedure reads XML input from a file that has a fileref and writes XML output to another file that has a fileref. The message component, an XML document that corresponds to a service request, is part of the content of the fileref. It is defined in the IN option of PROC SOAP. The input XML is either a SOAPEnvelope element, or an element inside the SOAPEnvelope that is required to invoke the web service.

For information about using PROC SOAP to invoke web services, see *SAS BI Web Services: Developer's Guide*.

Concepts: SOAP Procedure

Concepts: SOAP Procedure

With PROC SOAP, you can include an optional SOAPEnvelope element in your XML file. Do this if you want to include custom information in the SOAPHeader element. A SOAP envelope wraps the message, which has an application-specific message vocabulary. The SOAPHeader content is added to the actual SAS registered web service request. This addition occurs because there could be additional SOAPHeader elements that were not included in the XML file that was passed to PROC SOAP. The XML code that is transmitted might not exactly match the XML code provided in this case.

Examples of additional elements that might be included are those for WS-Security or WS-Addressing. Web Services Security (WS-Security) is a specification that defines how security measures are implemented in web services to protect them from external attacks. It is a set of protocols that ensure security for SOAP-based messages by implementing the principles of confidentiality, integrity, and authentication. WS-Addressing is a standard for adding addressing information to SOAP messages. For more information, see Overview of Security for Web Services.

A request does not need to be contained in a SOAP envelope. An envelope is added if you do not specify an envelope. If an envelope is specified, it is incorporated into the envelope that is sent. A response is returned within an envelope only if the envelope property is set. The default behavior is to return only the contents of the envelope.

You can set the amount of time to wait for a response from the web service by using the CONFIGFILE option. The default time to wait is 60 seconds.

Requests must not include an encoding declaration even if the envelope is included. If the request is being read from a file, the file must be encoded in the same encoding as the session encoding. Requests are encoded as UTF-8 before being sent to the web service.

z/OS Specifics: Calling SAS registered services is not available in the z/OS operating environment. SAS registered web services require WS-Security with Password Digest, and Password Digest is not supported on z/OS.

Syntax: SOAP Procedure

Restrictions: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

When SAS is in a locked-down state, the SOAP procedure is not available. Your server administrator can re-enable this procedure so that it is accessible in the lockdown state. When the FILENAME URL access method is re-enabled by using the LOCKDOWN ENABLE_AMS = statement, the SOAP procedure is automatically re-enabled. For more information, see "SAS Processing Restrictions for Servers in a Locked-Down State" in *SAS Programmer's Guide: Essentials*.

See: "LOCKDOWN Statement" in *SAS Intelligence Platform: Application Server Administration Guide*

Locked-Down Servers

PROC SOAP *options* <*properties*>;

Statement	Task	Example
PROC SOAP	Invoke a Web Service By Using a Proxy and Using PROC SOAP with a SOAPEnvelope Element	Ex. 1
	Invoke a Web Service By Using a Proxy and Using PROC SOAP without a SOAPEnvelope Element	Ex. 2
	Add numbers using Online Calculator	Ex. 3

PROC SOAP Statement

Invokes a web service through Java Native Interface (JNI).

Syntax

PROC SOAP *options* <*properties*>;

Summary of Optional Arguments

CONFIGFILE
: sets the time-out limit for web service calls.

DEBUG
: specifies an output log file.

ENVFILE
: specifies the location of the SAS environments file.

ENVIRONMENT
: specifies that you use the environment that is defined in the SAS environments file.

MUSTUNDERSTAND
: specifies the setting for the mustUnderstand attribute.

OUT=*fileref 'your-output-file'*
: specifies a fileref for response output.

PROXYDOMAIN
: specifies an HTTP proxy server domain.

PROXYHOST
: specifies an HTTP proxy server host name.

PROXYPASSWORD
: specifies an HTTP proxy server password.

PROXYPORT
: specifies an HTTP proxy server port.

PROXYUSERNAME
: specifies an HTTP proxy server user name.

SOAPACTION
: specifies a SOAPAction element.

SRSURL
: specifies the URL of the System Registry Service.

WEBAUTHDOMAIN
: specifies user name and password retrieval from metadata.

WEBDOMAIN
: specifies the domain or realm for a user name and password.

WEBPASSWORD
: specifies a password for web service authentication.

WEBUSERNAME
: specifies a user name for web service authentication.

WSSAUTHDOMAIN
: specifies that the active connection to the SAS Metadata Server is used to retrieve credentials.

WSSPASSWORD
: specifies a WS-Security password.

WSSUSERNAME
: specifies a WS-Security user name.

Required Arguments

IN=*fileref* '*your-input-file*'
specifies the fileref that is used to input XML data that contains a PROC SOAP request.

The fileref might have SOAPEnvelope and SOAPHeader elements as part of its content, but they are not required unless you have specific header information to provide.

SERVICE
specifies the SAS registered web service that you want to call.

Tip If you use the SERVICE option, then do not use the URL option.

URL
specifies the URL of the web service endpoint.

Tip If you use the URL option, then do not use the SERVICE option.

Optional Arguments

CONFIGFILE
enables you to set the time-out limit for web service calls. The default time-out is 60 seconds.

DEBUG
enables you to specify an output log file. The debug option turns on wire logging for httpclient and writes the output to the specified file. The value of this option is the path or filename to the desired output.

ENVFILE
specifies the location of the SAS environments file.

ENVIRONMENT
specifies to use the environment that is defined in the SAS environments file.

MUSTUNDERSTAND
specifies the setting for the mustUnderstand attribute in the PROC SOAP header.

OUT=*fileref* '*your-output-file*'
specifies the fileref where the PROC SOAP XML response output is written.

PROXYDOMAIN
specifies an HTTP proxy server domain.

Tip This option is required only if your proxy server requires domain- or realm-qualified credentials.

PROXYHOST
specifies an HTTP proxy server host name.

PROXYPASSWORD
specifies an HTTP proxy server password. Encodings that are produced by PROC PWENCODE are supported.

Tip This option is required only if your proxy server requires credentials.

PROXYPORT
specifies an HTTP proxy server port.

PROXYUSERNAME
specifies an HTTP proxy server user name.

Tip This option is required only if your proxy server requires credentials.

SOAPACTION
specifies a SOAPAction element to invoke on the web service.

SRSURL
specifies the URL of the System Registry Service.

WEBAUTHDOMAIN
specifies that a user name and password be retrieved from metadata for the specified authentication domain.

WEBDOMAIN
specifies the domain or realm for the user name and password.

WEBPASSWORD
specifies a password for basic web service authentication. Encodings that are produced by PROC PWENCODE are supported.

WEBUSERNAME
specifies a user name for basic web service authentication.

WSSAUTHDOMAIN
specifies that the active connection to the SAS Metadata Server is used to retrieve credentials in the specified authentication domain.

If credentials are found, they are used as the credentials for a WS-Security UsernameToken.

WSSUSERNAME
specifies a WS-Security user name. If a value is set, then WS-Security is used and a UsernameToken is sent with the web service request for user authentication, security, and encryption.

WSSPASSWORD
specifies a WS-Security password that is the password for WSSUSERNAME. Encodings that are produced by PROC PWENCODE are supported.

Properties

ENVELOPE
specifies that a SOAP envelope is to be included in the response.

Usage: SOAP Procedure

Using PROC SOAP with Transport Layer Security (TLS)

TLS and Data Encryption

Transport Layer Security (TLS) enables web browsers and web servers to communicate over a secured connection by encrypting data. Both browsers and servers encrypt data before the data is transmitted. The receiving browser or server then decrypts the data before it is processed. Because PROC SOAP invokes a web service using the Java Native Interface, JREOPTIONS need to be specified either on the command line or in a configuration file to configure a TLS connection.

Note: All discussion of TLS is also applicable to the predecessor protocol, Secure Sockets Layer (SSL).

When you require client authentication, TLS has a renegotiation feature that prevents unauthorized text from being added to the beginning or end of an encrypted data stream. This feature is specifically used by certificate-based client authentication. This feature disables TLS renegotiation in the Java Secure Sockets Extension (JSSE) by default. As a result, when you attempt to access a web resource that requires certificate-based client authentication through the interception proxy, the following Java TLS error message is generated:

```
(javax.net.ssl.SSLException): HelloRequest followed by
an unexpected handshake message
```

However, it is still possible to enable the TLS renegotiation in Java by setting the following system property to true before the JSSE library is initialized.

```
sun.security.ssl.allowUnsafeRenegotiation
```

Making PROC SOAP Calls By Using the HTTPS Protocol

In order to make PROC SOAP calls using the HTTPS protocol, you must have a truststore that contains the certificates for the services that you trust. This truststore must be provided to the SAS session by setting Java system option Djavax.net.ssl.trustStore.

Clients must ensure that the CA that signed the certificate has been added to their truststore. You can provide the path to the truststore on the SAS command line or in a SAS configuration file using JREOPTIONS.

```
-jreoptions (-Djavax.net.ssl.trustStore=full-path-to-the-trust-store)
```

Note: As a best practice, anytime that you are using passwords in configuration files, use file system permissions that allow write only access by the owner of the SAS or SAS Viya deployment. By default, the owner is "sas".

Here is an example using the SAS command line. The example uses the Windows operating environment.

Note: Add the following entry on one line.

```
"C:\Program Files\SAS\SASFoundation\9.4\sas.exe" -CONFIG "C:\Program
Files\SAS\SASFoundation\9.4\nls\en\SASV9.CFG" -jreoptions
(-Djavax.net.ssl.trustStore=C:\Documents and Settings\mydir\.keystore)
```

Here is an example of how to specify the JREOPTIONS in the sasv9.cfg file.

Note: Add the system option and value on one line.

```
-JREOPTIONS (-Djavax.net.ssl.trustStore=
!SASHOME/../config/etc/SASSecurityCertificateFramework/
cacerts/trustedcerts.jks)
```

Methods of Calling SAS Registered Web Services

You can use two methods to call SAS registered web services. The first method requires that you know the URL of the Service Registry Service and the URL of the endpoint of the service that you are calling. You must set the URL of the Service Registry Service on the SRSURL option. The URL option indicates the endpoint of the service that you are calling.

The second method that is used to call SAS registered web services uses the SAS environments file to specify the endpoint of the service that you are calling. Using

this method, you can indicate the location of the SAS environments file in one of two ways:

- use the ENVFILE option in PROC SOAP
- define the Java property **env.definition.location** in JREOPTIONS on the SAS command line or in the SAS configuration file

Use the following –JREOPTIONS syntax:

```
-jreoptions (-Denv.definition.location=http://your-SAS-environment.xml)
```

You must also specify the desired environment within that file using the ENVIRONMENT option, and specify the name of the service that you are calling using the SERVICE option.

In both cases, the WSUSERNAME and WSPASSWORD options are set to the user name and password that are required to contact the Security Token Service.

Calling a SAS Secured Service without Providing Credentials

You can use the SRSURL, ENVFILE, or ENVIRONMENT options to call a SAS secured service without having to supply a set of credentials. In this case, you do not need to use the WSSUSERNAME, WSSPASSWORD, or WSSAUTHDOMAIN options. This functionality eliminates the need to store user credentials in metadata and reduces the flow of credentials across the network. A connection to the metadata server is required. Credentials that are valid for a single use are generated for the user that is connected to the metadata server.

Specifying an Output Log File

The log file contains HTTP headers and data that are transmitted to and from servers when transmitting the HTTP request in PROC SOAP. You use the log file that is created with the DEBUG option to log debug output.

PROC SOAP uses log4j for logging requests and responses so that you can trace them. To create a log file that contains the request issued and the response received, create a file that has the following contents:

```
log4j.appender.FILE=org.apache.log4j.FileAppender
log4j.appender.FILE.File=wire.log
log4j.appender.FILE.layout=org.apache.log4j.PatternLayout
log4j.appender.FILE.layout.ConversionPattern =%d %5p [%c] %m%n

log4j.logger.httpclient.wire=DEBUG, FILE
```

To turn on logging to see the SOAP request and response for an entire SAS session, you must restart SAS with the –jreoptions command line option. Enable logging by setting a Java system option using –jreoptions on the SAS command line or in a SAS configuration file. The following syntax shows how to set the system option:

```
-jreoptions (-Dlog4j.configuration=path-to-log4j-config-file)
```

The following example shows how to use the entry on the SAS command line. The example uses the Windows operating environment.

Note: Add entry on one line.

```
"C:\Program Files\SAS\SASFoundation\9.2\sas.exe" -CONFIG
"C:\ProgramFiles\SAS\SASFoundation\9.2\nls\en\SASV9.CFG"
-jreoptions(- Dlog4j.configuration=file:/c:/public/log4j.properties)
```

Using the configuration file and JREOPTIONS method described above turns on logging for the entire SAS session. To turn on httpclient.wire for an individual PROC SOAP call, use the DEBUG option.

You can use the DEBUG option to turn on wire logging for the duration of a PROC SOAP call. The value of the DEBUG option is the path or filename to the output file.

Examples: SOAP Procedure

Example 1: Using a Proxy and PROC SOAP with a SOAPEnvelope Element

Details

This example uses a proxy and a SOAPEnvelope element.

Program

```
filename REQUEST temp;
filename RESPONSE temp;
data _null_;
   file request;
   input;
   put _infile_;
   datalines4;
```

```
<soapenv:Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xmlns:xsd="http://www.w3.org/2001/XMLSchema"
         xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
         xmlns:soap="http://www.SoapClient.com/xml/SoapResponder.xsd">
<soapenv:Header/>
<soapenv:Body>
   <soap:Method1
         soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/
encoding/">
         <bstrParam1 xsi:type="xsd:string">apple</bstrParam1>
         <bstrParam2 xsi:type="xsd:string">zebra3</bstrParam2>
   </soap:Method1>
</soapenv:Body>
</soapenv:Envelope>
;;;;

run;

proc soap in= request
          out= response
          url="http://soapclient.com/xml/soapresponder.wsdl"
          soapaction="http://www.SoapClient.com/SoapObject"
          proxyhost="proxygw.unx.sas.com"
          proxyusername="soaptest"
          proxypassword="testpw"
          proxyport=80;
run;
```

Example 2: Using a Proxy and PROC SOAP without a SOAPEnvelope Element

Details

This example uses a proxy and does not use a SOAPEnvelope element.

Program

```
filename REQUEST temp;
filename RESPONSE temp;
data _null_;
   file request;
   input;
   put _infile_;
   datalines4;
```

```
<soap:Method1 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:xsd="http://www.w3.org/2001/XMLSchema"
      xmlns:soap="http://www.SoapClient.com/xml/SoapResponder.xsd"
      encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
      <bstrParam1 xsi:type="xsd:string">apple</bstrParam1>
      <bstrParam2 xsi:type="xsd:string">zebra3</bstrParam2>
</soap:Method1>
;;;;

run;

proc soap in=request
          out=response
          url="http://soapclient.com/xml/soapresponder.wsdl"
          soapaction="http://www.SoapClient.com/SoapObject"
          proxyhost="proxygw.unx.sas.com"
          proxyusername="soaptest"
          proxypassword="testpw"
          proxyport=80;
run;
```

Example 3: Add Numbers Using Online Calculator

Details

This example uses the DNEONLINE Calculator to add 7 and 4.

Program

```
/*Set up filename statements to create temporary REQUEST and RESPONSE
*/
/* files. */
filename request temp;
filename response temp;

/*Create a soap request to submit to the URL (writing to filename*/
/* request above).*/
/* This request is specific to each application (ie url)in this case,
*/
/* the calculator application in DNEONLINE requires two integers that
*/
/* are added together. */
data _null_;
   file request;
```

```
   input;
   put _infile_;
   datalines4;
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/
envelope/"
                  xmlns:tem="http://tempuri.org/">
   <soapenv:Header/>
   <soapenv:Body>
      <tem:Add>
         <tem:intA>7</tem:intA>
         <tem:intB>4</tem:intB>
      </tem:Add>
   </soapenv:Body>
</soapenv:Envelope>
;;;;

/*submit the request to the url:*/
/*a response is returned via OUT=*/
proc soap
   in=request
   out=response
   url="http://www.dneonline.com/calculator.asmx"
   soapaction="http://tempuri.org/Add";
   run;
```

After running the program in SAS 9.4M6, the RESPONSE in the SAS log file shows the following result:

```
<AddResponse xmls="http://tempuri.org"><AddResult>11</AddResult></AddResponse>
```

64

SORT Procedure

Overview: SORT Procedure

What Does the SORT Procedure Do?

The SORT procedure orders SAS data set observations by the values of one or more character or numeric variables. The SORT procedure either replaces the original data set or creates a new data set. PROC SORT produces only an output data set. For more information, see "Procedure Output" on page 2390.

Note: If extended attributes are defined on the input data set, PROC SORT propagates the extended attributes to the output data set. For information about extended attributes, see "Extended Attributes" on page 567.

Operating Environment Information: The sorting capabilities that are described in this chapter are available for all operating environments. In addition, if you use the HOST value of the SAS system option SORTPGM=, you might be able to use other sorting options that are available for your operating environment. For more information about other sorting capabilities, see the SAS documentation for your operating environment.

Sorting SAS Data Sets

In the following example, the original data set was in alphabetical order by last name. PROC SORT replaces the original data set with a data set that is sorted by employee identification number. The following log shows the results from running this PROC SORT step. Output 64.331 on page 2357 shows the results of the PROC PRINT step. The statements that produce the output follow:

```
proc sort data=employee;
   by idnumber;
run;

proc print data=employee;
run;
```

Example Code 64.1 SAS Log Generated by PROC SORT

```
NOTE: There were six observations read from the data set WORK.EMPLOYEE.
NOTE: The data set WORK.EMPLOYEE has six observations and three variables.
NOTE: PROCEDURE SORT used:
      real time           0.01 seconds
      cpu time            0.01 seconds
```

Output 64.1 Observations Sorted by the Values of One Variable

```
                          The SAS System                          1

                 Obs     Name          IDnumber

                  1      Belloit         1988
                  2      Wesley          2092
                  3      Lemeux          4210
                  4      Arnsbarger      5466
                  5      Pierce          5779
                  6      Capshaw         7338
```

The following output shows the results of a more complicated sort by three variables. The businesses in this example are sorted by town, then by debt from highest amount to lowest amount, then by account number. For an explanation of the program that produces this output, see "Example 2: Sorting in Descending Order" on page 2394.

Output 64.2 Observations Sorted by the Values of Three Variables

```
                    Customers with Past-Due Accounts                     1
                 Listed by Town, Amount, Account Number

                                                                Account
     Obs    Company                   Town               Debt     Number

       1    Paul's Pizza              Apex              83.00      1019
       2    Peter's Auto Parts        Apex              65.79      7288
       3    Watson Tabor Travel       Apex              37.95      3131
       4    Tina's Pet Shop           Apex              37.95      5108
       5    Apex Catering             Apex              37.95      9923
       6    Deluxe Hardware           Garner           467.12      8941
       7    Boyd & Sons Accounting    Garner           312.49      4762
       8    World Wide Electronics    Garner           119.95      1122
       9    Elway Piano and Organ     Garner            65.79      5217
      10    Ice Cream Delight         Holly Springs    299.98      2310
      11    Tim's Burger Stand        Holly Springs    119.95      6335
      12    Strickland Industries     Morrisville      657.22      1675
      13    Pauline's Antiques        Morrisville      302.05      9112
      14    Bob's Beds                Morrisville      119.95      4998
```

Concepts: SORT Procedure

Threaded Sorting

The THREADS system option enables threaded sorting. Threaded sorting achieves a degree of parallelism in the sorting operations. This parallelism is intended to reduce the real time to completion for a given operation and therefore limit the cost of additional CPU resources. For more information, see "Support for Parallel Processing" in *SAS Language Reference: Concepts*.

The multi-threaded SAS sort can also be invoked when you specify the THREADS option in the PROC SORT statement. The multi-threaded sort stores all temporary data in a single utility file within one of the locations that are specified by the UTILLOC= system option. The size of this utility file is proportional to the amount of data that is read from the input data set. A second utility file of the same size can be created in another of these locations when the amount of data that is read from the input data set is large or the amount of memory that is available to the SORT procedure is small. For more information, refer to "UTILLOC= System Option" in *SAS System Options: Reference*.

Note: The TAGSORT option on page 2383 does not support threaded sorting.

The multi-threaded SAS sort can be invoked when the THREAD system option is specified and the value of the CPUCOUNT= system option is greater than 1. The value of the SAS system option CPUCOUNT= affects the performance of the threaded sort. CPUCOUNT= suggests how many system CPUs are available for use by the threaded procedures.

Calculated statistics can vary slightly, depending on the order in which observations are processed. Such variations are due to numerical errors that are introduced by floating–point arithmetic, the results of which should be considered approximate and not exact. The order of observation processing can be affected by nondeterministic effects of multithreaded or parallel processing. The order of processing can also be affected by inconsistent or nondeterministic ordering of observations that are produced by a data source, such as a DBMS that delivers query results through an ACCESS engine. For more information, see "Numerical Accuracy in SAS Software" in *SAS Language Reference: Concepts* and "Threading in Base SAS" in *SAS Language Reference: Concepts*.

For more information, see the "THREADS System Option" in *SAS System Options: Reference* and the "CPUCOUNT= System Option" in *SAS System Options: Reference*.

Sorting Orders for Numeric Variables

For numeric variables, the following is the smallest-to-largest comparison sequence:

1. SAS missing values (shown as a period or special missing value)
2. negative numeric values
3. zero
4. positive numeric values

Sorting Orders for Character Variables

Default Collating Sequence

The order in which alphanumeric characters are sorted is known as the collating sequence. This sort order is determined by the session encoding.

By default, PROC SORT uses either the EBCDIC or the ASCII collating sequence when it compares character values, depending on the environment under which the procedure is running.

For more information about the various collating sequences and when they are used, see "Collating Sequence" in *SAS National Language Support (NLS): Reference Guide*.

Note: ASCII and EBCDIC represent the family names of the session encodings. The sort order can be determined by referring to the encoding.

EBCDIC Order

The z/OS operating environment uses the EBCDIC collating sequence.

The sorting order of the English-language EBCDIC sequence is consistent with the following sort order example.

Table 64.1 EBCDIC Sort Order Example

blank . < (+ | & ! $ *) ; ¬ - / , % _ > ? : # @ ' = "
a b c d e f g h i j k l m n o p q r ~ s t u v w x y z
{ A B C D E F G H I } J K L M N O P Q R \ S T
U V W X Y Z
0 1 2 3 4 5 6 7 8 9

The main features of the EBCDIC sequence are that lowercase letters are sorted before uppercase letters, and uppercase letters are sorted before digits. Note also that some special characters interrupt the alphabetic sequences. The blank is the smallest character that you can display.

ASCII Order

The operating environments that use the ASCII collating sequence include the following:

- UNIX and its derivatives
- Windows
- OpenVMS

From the smallest to the largest character that you can display, the English-language ASCII sequence is consistent with the order shown in the following table.

Table 64.2 ASCII Sort Order Example

blank ! " # $ % & ' ( ) * + , - . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ? @
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z [\ ] ◦ _
a b c d e f g h i j k l m n o p q r s t u v w x y z { } ~

The main features of the ASCII sequence are that digits are sorted before uppercase letters, and uppercase letters are sorted before lowercase letters. The blank is the smallest character that you can display.

Specifying Sorting Orders for Character Variables

The options ASCII, EBCDIC, DANISH, NATIONAL, SWEDISH, and REVERSE specify collating sequences that are stored in the HOST catalog.

If you want to provide your own collating sequences or change a collating sequence provided for you, then use the TRANTAB procedure to create or modify translation tables. When you create your own translation tables, they are stored in your PROFILE catalog, and they override any translation tables that have the same name in the HOST catalog. For complete details, see "TRANTAB Procedure" in *SAS National Language Support (NLS): Reference Guide*.

Note: System managers can modify the HOST catalog by copying newly created tables from the PROFILE catalog to the HOST catalog. Then all users can access the new or modified translation table.

Linguistic Collation sorts data according to rules of language. For detailed information about Linguistic Collation, see "Collating Sequence" in *SAS National Language Support (NLS): Reference Guide*.

Stored Sort Information

PROC SORT records the BY variables, collating sequence, and character set that it uses to sort the data set. This information is stored with the data set to help avoid unnecessary sorts.

Before PROC SORT sorts a data set, it checks the stored sort information. If you try to sort a data set how it is currently sorted, then PROC SORT does not perform the sort and writes a message to the log to that effect. To override this behavior, use the FORCE option. If you try to sort a data set the same way it is currently sorted and you specify an OUT= data set, then PROC SORT simply makes a copy of the DATA= data set.

To override the sort information that PROC SORT stores, use the _NULL_ value with the SORTEDBY= data set option. Refer to the "SORTEDBY= Data Set Option" in *SAS Data Set Options: Reference*.

If you want to change the sort information for an existing data set, then use the SORTEDBY= data set option in the MODIFY statement in the DATASETS procedure. For more information, see "MODIFY Statement" on page 644.

To access the sort information that is stored with a data set, use the CONTENTS statement in PROC DATASETS. For more information, see "CONTENTS Statement" on page 603.

The number of variables by which you can sort a data set with PROC SORT is limited only by available memory. The number of columns by which you can order the rows of a result set using PROC SQL, is also limited only by available memory. The sort indicator, whether stored in the metadata of a Base data set or represented in memory, is limited to 127 variables. For this reason, up to 127 variables can be stored in the sort indicator or listed on the SORTEDBY= data set option. If you are sorting by more than 127 variables, then only the first 127 are recorded in the sort indicator. If you sort the data set again by the entire list of BY variables, the data set is not recognized as being sorted, because the additional variables (beyond 127) are not found within the sort indicator. For a detailed

explanation, refer to "What Is a Sort Indicator?" in *SAS Language Reference: Concepts*.

Presorted Input Data Sets

Specifying the "PRESORTED" on page 2381 option prevents SAS from sorting an already sorted data set. Before sorting, SAS checks the sequence of observations within the input data set to determine whether the observations are in order. Use the PRESORTED option when you know or strongly suspect that a data set is already in order according to the key variables specified in the BY statement. The sequence of observations within the data set is checked by reading the data set and comparing the BY variables of each observation read to the BY variables of the preceding observation. This process continues until either the entire data set has been read or an out-of-sequence observation is detected.

If the entire data set has been read and no out-of-sequence observations have been found, then one of two actions is taken. If no output data set has been specified, the sort order metadata of the input data set is updated to indicate that the sequence has been verified. This verification notes that the data set is validly sorted according to the specified BY variables. Otherwise, the data set is considered sorted and either the input data set metadata is updated or, if OUT= has been specified, the data is copied to an output data set.

If observations within the data set are not in sequence, then the data set is sorted.

If the "NODUPKEY" on page 2378 option has been specified, then the sequence checking determines whether observations with duplicate keys are present in the data set. If observations with duplicate keys are found, then the data set is considered unsorted and a sort is performed. Otherwise, the data set is considered sorted and actions are taken where either the metadata of the input data set is updated or, if OUT= has been specified, data is copied to the output data set. The actions taken are described in more detail in the previous paragraphs.

If the metadata of the input data set indicates that the data is already sorted according to the key variables listed in the BY statement and the input data set has been validated, then neither sequence checking nor sorting is performed.

See "Sorted Data Sets" in *SAS Language Reference: Concepts* and interactions with the "SORTVALIDATE System Option" in *SAS System Options: Reference*.

Linguistic Sorting of Data Sets and ICU

Linguistic collation sorts characters in a culturally sensitive manner according to rules that are associated with a language and locale. The rules and default collating sequence are based on the language specified in the current locale setting. The implementation is provided by the International Components for Unicode (ICU) library. It produces results that are largely compatible with the Unicode Collation Algorithms (UCA).

SAS provides ICU collation when the linguistic option (SORTSEQ=LINGUISTIC) is specified on the Base SAS procedure, PROC SORT. Starting in the third maintenance release of SAS 9.4, you can specify linguistic collation using the SORTSEQ= option in the SQL procedure and by specifying the SORTSEQ=LINGUISTIC system option.

Note: Only PROC SORT and PROC SQL are affected when the SORTSEQ=LINGUISTIC system option is specified.

When the SORTSEQ=LINGUISTIC option is specified, SAS relies on the ICU libraries as the reference implementation of the Unicode Collation Algorithm (UCA) and as a de facto standard.

In SAS 9.4, the ICU library incorporated by SAS and used by PROC SORT is ICU version 4.8.1. This ICU version uses locale data from version 2.0 of the Unicode Common Locale Data Repository (CLDR). For in-depth information about the UCA algorithm or the International Components for Unicode (ICU) library implementation, see Download the ICU 4.8 Release and find the CLDR 2.0 Release Note at CLDR Releases/Downloads.

In SAS Viya, the ICU library version incorporated by SAS and used by PROC SORT is ICU 56. This ICU version uses locale data from version 28 of the Unicode Common Locale Data Repository (CLDR). For in-depth information, see Download ICU 56 and CLDR 28 Release Note.

A change in the version of the ICU that is used by PROC SORT for linguistic collation, can affect the interpretation of data sets sorted by another version of SAS. If a data set is linguistically sorted by one or more character variables in one version of SAS, the data set is recognized as being sorted when accessed in another version of SAS if the two SAS versions use different versions of the ICU. Because collation rules can change between ICU versions, variations in the rules can cause the order of observations produced by PROC SORT to be different. If the ordering differences are ignored, unexpected results can be seen during processing.

When sorting linguistically, the ICU version used by SAS is recorded in the sort indicator that is stored in the data set header. The ICU version is examined when determining if a data set is considered sorted. A difference between the ICU version in use and the ICU version recorded in the sort indicator of a data set causes the SAS system to ignore the indicated sort order and assume that the data set is unsorted.

Note: The PROC CONTENTS output shows the ICU version in use. See "Example 5: Linguistic Sorting Using ALTERNATE_HANDLING=" on page 2401.

If a sort indicator on a permanent data set is ignored, to facilitate processing, it can be desirable to reassert the order and reestablish the sort indicator on the data set. This can be done using PROC SORT with the PRESORTED option. Most often, because the order of observations within the data set has not been disturbed and is likely correct, the SORT procedure probably only needs to sequentially read the data set to reestablish the indicator instead of performing a complete sort. If the order of observations is not correct, then the SORT procedure reorders the observations as necessary.

For both the COPY and MIGRATE procedures, if the ICU version recorded on an input data set is different from the version in use by the SAS system, then the sort indicator on the input data set is ignored, the output data set is not marked as sorted, and a message is written to the SAS log. However, both procedures write observations to an output data set in the same order as they are read from the input. This order is preserved if a physical order is supported by the engine used for the OUT= destination library. For these reasons, when migrating to a new release of SAS, consider re-establishing the sort order of permanent data sets using PROC SORT with the PRESORTED option.

Additional information about how linguistic collation is used by SAS can be found in the following documents, as well as in the PROC SORT SORTSEQ=LINGUISTIC system option.

- See "SORTSEQ=sort-table | LINGUISTIC" in *SAS SQL Procedure User's Guide*.
- See PROC SORT option" LINGUISTIC<*(collating-options)*>" on page 2370.
- See "Specifying Linguistic Collation" in *SAS National Language Support (NLS): Reference Guide*.
- See Chapter 14, "CONTENTS Procedure," on page 489.
- See Chapter 15, "COPY Procedure," on page 521.
- See Chapter 41, "MIGRATE Procedure," on page 1559
- See the Appendix 4, "ICU License," on page 2825.

The following are SAS papers that provide detailed information about Linguistic Collation.

- Creating Order out of Character Chaos: Collation Capabilities of the SAS System
- Linguistic Collation: Everyone Can Get What They Expect
- Processing Multilingual Data with the SAS 9.2 Unicode Server
- New Language Features in SAS 9.2 for the Global Enterprise

Here is a list of third-party documentation that should be read for in-depth information about Linguistic Collation.

- See the Unicode Collation Algorithm (UCA) Specification.
- See the Collation section of the ICU User Guide

Force SAS to Sort Data Sets Using System Option SORTPGM

You can force data sets to be sorted by SAS by setting system option SORTPGM=SAS. This system option must be set prior to using PROC SORT. Setting system option SORTPGM=SAS ensures that your data set is sorted in the order in which SAS expects.

By default, SORTPGM defaults to BEST, what SAS determines is probably the best performance choice. When SORTPGM is set to BEST, sorting might be performed by the following:

- a system or third-party host sorting utility program, if one is installed and available.
- a DBMS if the input data resides in a database and a SAS/ACCESS engine is used to read it.

To work properly, the host sort or DBMS and the SAS system must be configured for compatible operation. The host sort or the DBMS can be configured to order data differently from SAS. When the observations returned to SAS are not ordered as SAS expects, the SORTPGM= system option can be set to SAS to instruct SAS to sort the data in the order needed by SAS.

See "SORTPGM: Windows" in *SAS Companion for Windows*, "SORTPGM System Option: UNIX" in *SAS Companion for UNIX Environments*, , "SORTPGM= System Option: z/OS" in *SAS Companion for z/OS*and "In-Database Processing: PROC SORT" on page 2387.

Syntax: SORT Procedure

Requirement: BY statement

Notes: Some SAS statements and options are not supported when running in CAS and might result in an error when PROC SORT is deciding whether to run in CAS.

Some SAS statements and options are not supported when running in CAS but will not prevent operation in CAS. A note will be printed for such options when PROC SORT decides to run in CAS.

Most PROC SORT specific options do not have any effect and do not prevent running in CAS.

Tips: You can use the ATTRIB, FORMAT, LABEL, and WHERE statements with the PROC SORT procedure. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

For in-database processing to occur, your data must reside within a supported version of a DBMS that has been properly configured for SAS in-database processing. For more information, see "In-Database Processing: PROC SORT" on page 2387.

See: "SORT Procedure: Windows" in *SAS Companion for Windows*, "SORT Procedure Statement: z/OS" in *SAS Companion for z/OS*, "SORT Procedure: UNIX" in *SAS Companion for UNIX Environments*.

PROC SORT <*collating-sequence-option*> <*other options*>;

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...>;

KEY *variable(s)* </ *option*>;

Statement	Task	Example
PROC SORT	Order SAS data set observations by the values of one or more character or numeric variables	Ex. 1, Ex. 3, Ex. 4
BY	Specify the sorting variables	Ex. 1, Ex. 2, Ex. 4
KEY	Specify sorting keys and variables	

PROC SORT Statement

Orders SAS data set observations by the values of one or more character or numeric variables.

Examples:
"Example 1: Sorting by the Values of Multiple Variables" on page 2391
"Example 3: Maintaining the Relative Order of Observations in Each BY Group" on page 2396
"Example 4: Retaining the First Observation of Each BY Group" on page 2399
"Example 7: Eliminate All Duplicate Observations Using NODUPKEY" on page 2408

Syntax

PROC SORT <*collating-sequence-option*> <*other options*>;

Summary of Optional Arguments

DATA= *SAS-data-set*
: specifies the input data set.

DATECOPY
: sorts a SAS data set without changing the created and modified dates.

FORCE
: forces redundant sorting.

OVERWRITE
: deletes the input data set before the replacement output data set is populated.

PRESORTED
: specifies whether the data set is likely already sorted.

SORTSIZE=*memory-specification*
: specifies the available memory.

TAGSORT
: reduces temporary disk usage.

Create output data sets

DUPOUT= *SAS-data-set*
specifies the output data set to which duplicate observations are written.

OUT= *SAS-data-set*
specifies the output data set.

UNIQUEOUT= *SAS-data-set*
specifies the output data set for eliminated observations.

Eliminate duplicate observations

NODUPKEY
deletes observations with duplicate BY values.

Eliminate unique observations

NOUNIQUEKEY
eliminates observations from the output data set that have a unique sort key.

Override SAS system option THREADS

NOTHREADS
prevents threaded sorting.

THREADS

NOTHREADS
enables or prevents the activation of threaded sorting.

Specify the collating sequence

ASCII
specifies ASCII.

DANISH
specifies Danish.

EBCDIC
specifies EBCDIC.

FINNISH
specifies Finnish.

NATIONAL
specifies a customized sequence.

NORWEGIAN
specifies Norwegian.

REVERSE
reverses the collation order for character variables.

SORTSEQ= *collating-sequence*
specifies the collating sequence.

SWEDISH
specifies Swedish.

Specify the output order

EQUALS

NOEQUALS
specifies the relative order within BY groups.

NOEQUALS

does not maintain relative order within BY groups.

Collating-Sequence-Options

Operating Environment Information: For information about behavior specific to your operating environment for the DANISH, FINNISH, NORWEGIAN, or SWEDISH *collating-sequence-option*, see the SAS documentation for your operating environment.

You can specify only one *collating-sequence-option* and multiple *other options* in a PROC SORT step. The order of the two types of options does not matter and both types are not necessary in the same PROC SORT step.

ASCII
sorts character variables using the ASCII collating sequence. You need this option only when you want to achieve an ASCII ordering on a system where EBCDIC is the native collating sequence.

See "ASCII Order" on page 2360

DANISH
sorts characters according to the Danish and Norwegian convention.

The Danish and Norwegian collating sequence is shown in Figure 64.87 on page 2369.

EBCDIC
sorts character variables using the EBCDIC collating sequence. You need this option only when you want to achieve an EBCDIC ordering on a system where ASCII is the native collating sequence.

See "EBCDIC Order" on page 2359

FINNISH
sorts characters according to the Finnish and Swedish convention.

The Finnish and Swedish collating sequence is shown in Figure 64.87 on page 2369.

NATIONAL
sorts character variables using an alternate collating sequence, as defined by your installation, to reflect a country's National Use Differences. To use this option, your site must define a customized national sort sequence. Check with the SAS Installation Representative at your site to determine whether a customized national sort sequence is available.

NORWEGIAN
sorts characters according to the Danish and Norwegian convention.

The Norwegian collating sequence is shown in Figure 64.87 on page 2369.

REVERSE
sorts character variables using a collating sequence that is reversed from the normal collating sequence.

Operating Environment Information: For information about the normal collating sequence for your operating environment, see "EBCDIC Order" on page

2359, "ASCII Order" on page 2360, and the SAS documentation for your operating environment.

Restriction Only one collating-sequence-option can be specified.

Interaction Using REVERSE with the DESCENDING option in the BY statement restores the sequence to the normal order.

See The "DESCENDING" on page 2385 option in the BY statement. The difference is that the DESCENDING option can be used with both character and numeric variables.

SWEDISH
sorts characters according to the Finnish and Swedish convention.

The Finnish and Swedish collating sequence is shown in Figure 64.87 on page 2369.

SORTSEQ= *collating-sequence*
The *collating-sequence* can be one of the following:

- collating-sequence-option on page 2369
- translation_table on page 2369
- encoding-value on page 2370
- LINGUISTIC on page 2370

For detailed information, refer to "Collating Sequence" in *SAS National Language Support (NLS): Reference Guide*.

Figure 64.1 *National Collating Sequences of Alphanumeric Characters*

```
Danish:     0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZÆØÅabcdefghijklmnopqrstuvwxyzæøå
Finnish:    0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZÅÄÖabcdefghijklmnopqrstuvwxyzåäö
Italian:    0123456789AÀBCÇDEÉÈFGHIÌJKLMNOÒPQRSTUÙVWXYZaàbcçdeéèfghiìjklmnoòpqrstuùvwxyz
Norwegian:  0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZÆØÅabcdefghijklmnopqrstuvwxyzæøå
Spanish:    0123456789AÁaáBbCcDdEÉeéFfGgHhIÍiíJjKkLlMmNnÑñOÓoóPpQqRrSsTtUÚuúÜüVvWwXxYyZz
Swedish:    0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZÅÄÖabcdefghijklmnopqrstuvwxyzåäö
```

Here are descriptions of the types of collating sequences:

collating-sequence-option
translation_table
specifies one of the PROC SORT statement *collating-sequence-options* (ASCII, DANISH, EBCDIC, FINNISH, NORWEGIAN, REVERSE, SWEDISH) or a translation table, which can be one that SAS provides or any user-defined translation table. Translation tables provided by SAS are: ASCII, DANISH, EBCDIC, FINNISH, ITALIAN, NORWEGIAN, POLISH, REVERSE, SPANISH, and SWEDISH.

Restriction You can specify only one *collating-sequence-option* or one translation table for the SORTSEQ= option.

Interaction In-database processing will not occur when the SORTSEQ= option is specified.

Tip The SORTSEQ= collating-sequence options are specified without parenthesis and there are no arguments associated with them.

See For a more detailed description of each *collating-sequence-option*, see "Collating-Sequence-Options" on page 2368.

To see the Sorting Order of Character variables, see "EBCDIC Order" on page 2359, "ASCII Order" on page 2360, and Figure 64.87 on page 2369 for all others.

Example
```
proc sort data=mydata SORTSEQ=ASCII;
```

Example For an example of using PROC TRANTAB and PROC SORT with SORTSEQ=, see "Using Different Translation Tables for Sorting" in *SAS National Language Support (NLS): Reference Guide*.

encoding-value

specifies an encoding value. The result is the same as a binary collation of the character data represented in the specified encoding. See the supported encoding value in the *SAS National Language Support (NLS): Reference Guide*.

Restriction PROC SORT is the only procedure or part of the SAS system that recognizes an encoding specified for the SORTSEQ= option.

Tip When the encoding value contains a character other than an alphanumeric character or underscore, the value needs to be enclosed in quotation marks.

See The list of the encodings that can be specified in the *SAS National Language Support (NLS): Reference Guide*.

LINGUISTIC<*(collating-options)*>

specifies linguistic collation, which sorts characters in a culturally sensitive manner according to rules that are associated with a language and locale. The rules and default *collating-sequence* options are based on the language that is specified in the current locale setting. The implementation is provided by the International Components for Unicode (ICU) library. It produces results that are largely compatible with the Unicode Collation Algorithms (UCA). For more information, see " Linguistic Sorting of Data Sets and ICU" on page 2362.

Note: Only PROC SORT and PROC SQL are affected when the linguistic collation system option is specified.

The following are options that can be used when specifying SORTSEQ=LINGUISTIC. These options modify the linguistic collating sequence:

ALTERNATE_HANDLING=SHIFTED
controls the handling of variable characters like spaces, punctuation, and symbols. When this option is not specified (using the default value Non-Ignorable), differences among these variable characters are of the same importance as differences among letters. If the ALTERNATE_HANDLING option is specified, these variable characters are of minor importance.

Default NON_IGNORABLE

Tip The SHIFTED value is often used in combination with STRENGTH= set to Quaternary. In such a case, spaces, punctuation, and symbols are considered when comparing strings, but only if all other aspects of the strings (base letters, accents, and case) are identical.

See "Example 5: Linguistic Sorting Using ALTERNATE_HANDLING=" on page 2401 and "Example 6: Linguistic Sorting Using ALTERNATE_HANDLING= and STRENGTH=" on page 2405.

CASE_FIRST=
specifies the order of uppercase and lowercase letters. This argument is valid for only TERTIARY, QUATERNARY, or IDENTICAL levels. The following table provides the values and information for the CASE_FIRST argument:

Table 64.3 *Arguments for CASE_FIRST=*

Value	Description
UPPER	Sorts uppercase letters first, then the lowercase letters.
LOWER	Sorts lowercase letters first, then the uppercase letters.

COLLATION=
specifies character ordering. The following table lists the available COLLATION= values.

Note: If you do not select a collation value, then the user's locale-default collation is selected.

Table 64.4 *Values for COLLATION=*

Value	Description
BIG5HAN	Specifies Pinyin ordering for Latin and specifies bug5 charset ordering for Chinese, Japanese, and Korean characters.
DIRECT	Specifies a Hindi variant.

Value	Description
GB21312HAN	Specifies Pinyin ordering for Latin and specifies gb2312han charset ordering for Chinese, Japanese, and Korean characters.
PHONEBOOK	Specifies a telephone-book style for ordering of characters. Select PHONEBOOK only with the German language.
PINYIN	Specifies an ordering for Chinese, Japanese, and Korean characters based on character-by-character transliteration into Pinyin. This ordering is typically used with simplified Chinese.
POSIX	Portable Operating System Interface. This option specifies a "C" locale ordering of characters.
STROKE	Specifies a nonalphabetic writing style ordering of characters. Select STROKE with Chinese, Japanese, Korean, or Vietnamese languages. This ordering is typically used with Traditional Chinese.
TRADITIONAL	Specifies a traditional style for ordering of characters. For example, select TRADITIONAL with the Spanish Language.

LOCALE= ***locale_name***
specifies the locale name in the form of a POSIX name (for example, ja_JP). For a list of locale and POSIX values supported by PROC SORT, see "LOCALE= Values for PAPERSIZE and DFLANG, Options" in *SAS National Language Support (NLS): Reference Guide*.

Restriction The following Locales are not supported by PROC SORT:

- Afrikaans_SouthAfrica, af_ZA
- Cornish_UnitedKingdom, kw_GB
- ManxGaelic_UnitedKingdom, gv_GB

NUMERIC_COLLATION=
orders integer values within the text by the numeric value instead of characters used to represent the numbers.

Table 64.5 *Values for NUMERIC_COLLATION*

Value	Description
ON	Order numbers by the numeric value. For example, "8 Main St." would sort before "45 Main St.".

Value	Description
OFF	Order numbers by the character value. For example, "45 Main St." would sort before "8 Main St.".

Default OFF

STRENGTH=
The value of strength is related to the collation level. There are five collation-level values. The following table provides information about the five levels. The default value for strength is related to the locale.

Table 64.6 *Values for STRENGTH=*

Value	Type of Collation	Description
PRIMARY or 1	PRIMARY specifies differences between base characters (for example, "a" < "b").	It is the strongest difference. For example, dictionaries are divided into different sections by base character.
SECONDARY or 2	Accents in the characters are considered secondary differences (for example, "as" < "às" < "at").	A secondary difference is ignored when there is a primary difference anywhere in the strings. Other differences between letters can also be considered secondary differences, depending on the language.
TERTIARY or 3	Upper and lowercase differences in characters are distinguished at the tertiary level (for example, "ao" < "Ao" < "aò"). For an example, see "Example 5: Linguistic Sorting Using ALTERNATE_HANDLING=" on page 2401.	A tertiary difference is ignored when there is a primary or secondary difference

Value	Type of Collation	Description
		anywhere in the strings. Another example is the difference between large and small Kana.
QUATERNARY or 4	When punctuation is ignored at level 1-3, an additional level can be used to distinguish words with and without punctuation (for example, "a-b" < "ab" < "aB"). For an example, see "Example 6: Linguistic Sorting Using ALTERNATE_HANDLING= and STRENGTH=" on page 2405.	The quaternary level should be used if ignoring punctuation is required or when processing Japanese text. This difference is ignored when there is a primary, secondary, or tertiary difference.
IDENTICAL or 5	When all other levels are equal, the identical level is used as a tiebreaker. The Unicode code point values of the Normalization Form D (NFD) form of each string are compared at this level, just in case there is no difference at levels 1-4.	This level should be used sparingly, because code-point value differences between two strings rarely occur. For example, only Hebrew cantillation marks are distinguished at this level.

Alias LEVEL=

Alias UCA

Restrictions The SORTSEQ=LINGUISTIC option is available only on the PROC SORT SORTSEQ= option and is not available for the system option SORTSEQ.

Linguistic collation is not supported on platforms VMS on Itanium (VMI) or 64-bit Windows on Itanium (W64).

Interaction The ICU version can change in a new SAS release. The order of observations produced when sorting a data set linguistically, using one release of SAS, can be different from the order produced by another release if the two releases use different versions of the ICU. When migrating to a new release of SAS, consider re-establishing the sort order of permanent data sets using PROC SORT with the PRESORTED option. For more details, see " Linguistic Sorting of Data Sets and ICU" on page 2362.

Tips The CONTENTS procedure or CONTENTS statement output shows the ICU version number of a data set that is linguistically sorted.

The *collating-options* must be enclosed in parentheses. More than one collating option can be specified.

When BY processing is performed on data sets that are sorted with linguistic collation, the NOBYSORTED system option might need to be specified in order for the data set to be treated properly. BY processing is performed differently than collating sequence processing.

See For ICU License Agreement, see Appendix 4, "ICU License," on page 2825.

For more information, see "Specifying Linguistic Collation" in *SAS National Language Support (NLS): Reference Guide*. For more information, see " Linguistic Sorting of Data Sets and ICU" on page 2362.

CAUTION

If you use a host sort utility to sort your data, then specifying a translation-table-based collating sequence with the SORTSEQ= option might corrupt the character BY variables. For more information, see the PROC SORT documentation for your operating environment.

Interaction In-database processing does not occur when the SORTSEQ= option is specified.

Tip The SORTSEQ= *collating-sequence* options are specified without parenthesis and no arguments are associated with them. Here is an example of how to specify a collating sequence: `proc sort data=mydata SORTSEQ=ASCII;`

Other Options

Options can include one *collating-sequence-option* and multiple other options. The order of the two types of options does not matter and both types are not necessary in the same PROC SORT step.

DATA= *SAS-data-set*
identifies the input SAS data set.

Restrictions For in-database processing to occur, the data set must refer to a table residing on the DBMS.

SAS data set options DROP=, KEEP=, RENAME= are not supported in CAS. When these options are specfied on the data set, CAS operations will not occur.

Notes PROC SORT supports extended attributes by copying the attributes from the input data set to the output data set.

When options NODUPKEY or NOUNIKEY are specified and the DATA= option refers to a CAS table, and the OUT=, DUPOUT=, or UNIOUT= options refer to a CAS table, PROC SORT invokes the CAS deduplicate action on a CAS server. For more information, see the deduplicate Action .

See "Input Data Sets" on page 26

SAS Data Set Options: Reference

DATECOPY
copies the SAS internal date and time at which the SAS data set was created and the date and time at which it was last modified before the sort to the resulting sorted data set. Note that the operating environment date and time are not preserved.

Restriction DATECOPY can be used only when the resulting data set uses the V8 or V9 engine.

Tip You can alter the file creation date and time with the DTC= option in the MODIFY statement in PROC DATASETS. For more information, see "MODIFY Statement" on page 644.

DUPOUT= *SAS-data-set*
specifies the output data set to which duplicate observations are written.

Interactions In-database processing does not occur when the DUPOUT= option is specified.

The DUPOUT= and UNIQUEOUT= options are not compatible and cannot be specified simultaneously.

Note When options NODUPKEY or NOUNIKEY are specified and the DATA= option refers to a CAS table, and the OUT=, DUPOUT=, or UNIOUT= options refer to a CAS table, PROC SORT invokes the

CAS deduplicate action on a CAS server. For more information, see the deduplicate Action .

Tips The DUPOUT= option can be used only with the NODUPKEY option. It cannot be combined with the NOUNIQUEKEY option.

If the DUPOUT= data set name that is specified is the same as the INPUT data set name, SAS does not sort or overwrite the INPUT data set. Instead, SAS generates an error message. The FORCE option must be specified in order to overwrite the INPUT data set with the DUPOUT= data set of the same name.

See *SAS Data Set Options: Reference*

EQUALS | NOEQUALS

specifies the order of the observations in the output data set. For observations with identical BY-variable values, EQUALS maintains the relative order of the observations within the input data set in the output data set. NOEQUALS does not necessarily preserve this order in the output data set.

Default EQUALS

Interactions When you use NODUPKEY to remove observations in the output data set, the choice of EQUALS or NOEQUALS can affect which observations are removed.

The EQUALS | NOEQUALS procedure option overrides the default sort stability behavior that is established with the SORTEQUALS | NOSORTEQUALS system option.

The EQUALS option is supported by the threaded sort. However, I/O performance might be reduced when using the EQUALS option with the threaded sort because partitioned data sets are processed as if they consist of a single partition.

The NOEQUALS option is supported by the threaded sort. The order of observations within BY groups that are returned by the threaded sort might not be consistent between runs.

Tip Using NOEQUALS can save CPU time and memory.

FORCE

sorts and replaces an indexed data set when the OUT= option is not specified. Without the FORCE option, PROC SORT does not sort and replace an indexed data set because sorting destroys user-created indexes for the data set. When you specify FORCE, PROC SORT sorts and replaces the data set and destroys all user-created indexes for the data set. Indexes that were created or required by integrity constraints are preserved.

Restriction If you use PROC SORT with the FORCE option on data sets that were created with the Version 5 compatibility engine or with a sequential engine such as a tape format engine, you must also specify the OUT= option.

Tip PROC SORT checks for the sort indicator before it sorts a data set so that data is not sorted again unnecessarily. By default, PROC SORT does not sort a data set if the sort information matches the requested sort. You can use FORCE to override this behavior. You might need to use FORCE if SAS cannot verify the sort specification in the data set option SORTEDBY=. For more information about SORTEDBY= , see the chapter on SAS data set options in *SAS Data Set Options: Reference*.

NODUPKEY

checks for and eliminates observations with duplicate BY values. If you specify this option, PROC SORT compares all BY values for each observation to the ones for the previous observation that is written to the output data set. If an exact match is found, the observation is not written to the output data set.

Sorting causes observations that have equal BY variable values to be grouped together for output. Normally, PROC SORT writes all observations for each BY group that it assembles to the output data set. The NODUPKEY option instructs the SORT procedure to write only the first observation of each BY group to the output data set and to discard any additional observations that are contained within that BY group.

Several factors dictate whether an observation occurs first within a BY group that PROC SORT has assembled for output. These factors include the order in which observations are read from the input data set, the sort program being used, and whether stability is provided by the sorting algorithm.

When the SORT procedure's input is a Base SAS engine data set and the sorting is done by SAS, then the order of observations within an output BY group is predictable. The order of the observations within the group is the same as the order in which they were written to the data set when it was created. Because the Base SAS engine maintains observations in the order that they were written to the data set, they are read by PROC SORT in the same order. While processing, PROC SORT maintains the order of the observations because it uses a stable sorting algorithm. The stable sorting algorithm is used because the EQUALS option is set by default. Therefore, the observation that is selected by PROC SORT to be written to the output data set for a given BY group is the first observation in the data set having the BY variable values that define the group.

If the SORT procedure reads its input from an engine that does not provide a predictable observation order or an alternative sorting program (when a host sort performs the sort), the observations that are eliminated and the one that is written to the output data set might not be well defined. For example, determining which observations are kept and which observations are discarded might be unpredictable if data is being read into SAS from a DBMS that presents query results in a nondeterministic order due to parallel processing.

Operating Environment Information: If you use the VMS operating environment and are using the VMS host sort, the observation that is written to the output data set is not always the first observation of the BY group.

To ensure that each observation in the output data set is unique, you can use the NODUPKEY option with PROC SORT and sort by _ALL_ variables in the input data set. An observation in a data set is unique when no other observation in the data set has the same combination of variable values. See example

program "Example 7: Eliminate All Duplicate Observations Using NODUPKEY" on page 2408.

Note: If you drop one or more BY variables from the output data set when using NODUPKEY, you void (eliminate) the guarantee that each observation has a unique set of BY variable values. Similarly, when you use NODUPKEY and sort by _ALL_ variables to produce unique observations, if you drop one or more variables from the output data set, observations in the output data set are no longer guaranteed to be unique.

Another way to ensure that observations in an output data set are unique is to use PROC SQL with the DISTINCT keyword. Here is a simple example using PROC SQL:

```
PROC SQL;
 CREATE TABLE DL (keep division league) AS SELECT DISTINCT *
 FROM SASHELP.BASEBALL;
QUIT;
```

Interactions

The Base SAS engine provides a consistent ordering where the first observation (the first observation that was written and stored) is generally the first one that is read by PROC SORT. The sorted data set contains only the first observation of each BY group that PROC SORT reads.

When you are removing observations with duplicate BY values with NODUPKEY, the choice of EQUALS or NOEQUALS can have an effect on which observations are removed. Use the EQUALS option (the default value) with the NODUPKEY option for consistent results in your output data sets.

In-database sorting occurs when the NODUPKEY option is specified and the system option SQLGENERATION= is assigned a DBMS and the system option SORTPGM=BEST.

The options NODUPKEY and NOUNIQUEKEY are not compatible. If these options are specified together, an error is printed to the SAS log.

Note

When options NODUPKEY or NOUNIKEY are specified and the DATA= option refers to a CAS table, and the OUT=, DUPOUT=, or UNIOUT= options refer to a CAS table, PROC SORT invokes the CAS deduplicate action on a CAS server. For more information, see the deduplicate Action .

Tip

The DUPOUT= option can be used with the NODUPKEY option. However, it cannot be used with the NOUNIQUEKEY option.

Examples

"Example 4: Retaining the First Observation of Each BY Group" on page 2399

"Example 7: Eliminate All Duplicate Observations Using NODUPKEY" on page 2408

NOEQUALS
See "EQUALS|NOEQUALS" on page 2377.

NOTHREADS
See "THREADS|NOTHREADS" on page 2383.

NOUNIQUEKEY
checks for and eliminates observations from the output data set that have a unique sort key. A sort key is unique when the observation containing the key is the only observation within a BY group.

Note: Unlike NODUPKEY, which writes one observation of a BY group to the output data set and discards all other observations from the BY group, the NOUNIQUEKEY maintains BY group integrity. Either all observations of a BY group are written to the output data set when the BY group consists of two or more observations, or all observations of the BY group are discarded when the BY group consists of a single observation.

Alias	NOUNIKEY | NOUNIKEYS | NOUNIQUEKEYS
Interaction	Options NODUPKEY and NOUNIQUEKEY are not compatible. If NODUPKEY and NOUNIQUEKEY are specified together, an error is printed to the SAS log.
Note	When options NODUPKEY or NOUNIKEY are specified and the DATA= option refers to a CAS table, and the OUT=, DUPOUT=, or UNIOUT= options refer to a CAS table, PROC SORT invokes the CAS deduplicate action on a CAS server. For more information, see the deduplicate Action .
Tip	The UNIQUEOUT= option can be used with the NOUNIQUEKEY option. It cannot be combined with the NODUPKEY option.
See	UNIQUEOUT= to direct the observations that have been eliminated to an output data set.

OUT= *SAS-data-set*
names the output data set. If *SAS-data-set* does not exist, then PROC SORT creates it.

CAUTION
Use care when you use PROC SORT without OUT=. Without the OUT= option, PROC SORT replaces the original data set with the sorted observations when the procedure executes without errors.

Default	Without OUT=, PROC SORT overwrites the original data set.
Note	When options NODUPKEY or NOUNIKEY are specified and the DATA= option refers to a CAS table, and the OUT=, DUPOUT=, or UNIOUT= options refer to a CAS table, PROC SORT invokes the CAS deduplicate action on a CAS server. For more information, see the deduplicate Action .

Tips With in-database sorts, the output data set cannot refer to the input table on the DBMS.

You can use data set options with OUT=.

See *SAS Data Set Options: Reference*

Example "Example 1: Sorting by the Values of Multiple Variables" on page 2391

OVERWRITE
enables the input data set to be deleted before the replacement output data set of the same name is populated with observations.

CAUTION
Use the OVERWRITE option only with a data set that is backed up or with a data set that you can reconstruct. Because the input data set is deleted, data is lost if a failure occurs while the output data set is being written.

Restrictions If the OVERWRITE and OUT= options are specified and the OUT= data set name is not the same as the INPUT data set name, SAS does not overwrite the INPUT data set.

The OVERWRITE option has no effect if you also specify the TAGSORT option. You cannot overwrite the input data set because TAGSORT must reread the input data set while populating the output data set.

The OVERWRITE option is supported by the SAS sort and SAS threaded sort only. The option has no effect if you are using a host sort.

Tip Using the OVERWRITE option can reduce disk space requirements.

PRESORTED
before sorting, checks within the input data set to determine whether the sequence of observations is in order. Use the PRESORTED option when you know or strongly suspect that a data set is already in order according to the key variables that are specified in the BY statement. By specifying this option, you avoid the cost of sorting the data set.

Interaction Sequence checking is not performed when the "FORCE" on page 2377 option is specified.

Tips You can use the DATA step to import data, from external text files, in a sequence compatible with SAS processing and according to the sort order specified by the combination of SORT options and key variables listed in the BY statement. You can then specify the PRESORTED option if you know or highly suspect that the data is sorted accordingly.

Using the PRESORTED option with ACCESS engines and DBMS data is not recommended. These external databases are not guaranteed to return observations in sorted order unless an ORDER BY clause is

specified in a query. Generally, physical ordering is not a concept that external databases use. Therefore, these databases are not guaranteed to return observations in the same order when executing a query multiple times. Physical order can be important for producing consistent, repeatable results when processing data. Without a repeatable data retrieval order, PROC SORT does not guarantee the return of observations in the same order from one PROC SORT execution to another, even when the "EQUALS| NOEQUALS" on page 2377 option is used to request sort stability. Without a repeatable retrieval order, the detection and elimination of adjacent duplicate records by PROC SORT can also vary from one PROC SORT execution to another.

See System option "SORTVALIDATE System Option" in *SAS System Options: Reference*.

SORTSIZE=*memory-specification*
specifies the maximum amount of memory that is available to PROC SORT. Valid values for *memory-specification* are as follows:

MAX
specifies that all available memory can be used.

n
specifies the amount of memory in bytes, where *n* is a real number.

***n*K**
specifies the amount of memory in kilobytes, where *n* is a real number.

***n*M**
specifies the amount of memory in megabytes, where *n* is a real number.

***n*G**
specifies the amount of memory in gigabytes, where *n* is a real number.

Specifying the SORTSIZE= option in the PROC SORT statement temporarily overrides the SAS system option. For more information, see "SORTSIZE= System Option" in *SAS System Options: Reference*.

Operating Environment Information: Some system sort utilities might treat this option differently. Refer to the SAS documentation for your operating environment.

Alias SIZE=

Default the value of the SAS system option SORTSIZE=

Tips Setting the SORTSIZE= option in the PROC SORT statement to MAX or 0, or not setting the SORTSIZE= option, limits the PROC SORT to the available physical memory based on the settings of the SAS system options REALMEMSIZE and MEMSIZE.

For information about the SAS system options REALMEMSIZE and MEMSIZE, see the SAS documentation for your operating environment.

TAGSORT

stores only the BY variables and the observation numbers in temporary files. The BY variables and the observation numbers are called *tags*. At the completion of the sorting process, PROC SORT uses the tags to retrieve records from the input data set in sorted order.

Note: The utility file created is much smaller than it would be if the TAGSORT option were not specified.

Restriction The TAGSORT option is not compatible with the OVERWRITE option.

Interaction The TAGSORT option is not supported by the threaded sort.

Tip When the total length of BY variables is small compared with the record length, TAGSORT reduces temporary disk usage considerably. However, processing time might be much higher.

THREADS | NOTHREADS

enables or prevents the activation of threaded sorting.

Default The value of the THREADS | NOTHREADS SAS system option. Note that the default can be overridden using the SORT procedure THREADS | NOTHREADS option.

Restrictions Your site administrator can create a restricted options table. A restricted options table specifies SAS system option values that are established at start-up and cannot be overridden. If the THREADS | NOTHREADS system option is listed in the restricted options table, any attempt to set these system options is ignored and a warning message is written to the SAS log.

If a failure occurs when adding the THREADS | NOTHREADS procedure option using the SPD engine, PROC SORT stops processing and writes a message to the SAS log.

Interactions The PROC SORT THREADS | NOTHREADS options override the SAS system THREADS | NOTHREADS options unless the system option is restricted. (See Restriction.) For more information, see "THREADS System Option" in *SAS System Options: Reference*.

The THREADS system option is honored if PROC SORT determines that threaded processing is deemed to be beneficial. If the value of the SAS system option CPUCOUNT=1, then threaded processing is not beneficial. However, you can specify the PROC SORT THREADS option to force threaded processing when the system option is set to NOTHREADS or when the system option is THREADS and the procedure option is NOTHREADS. This option combination prevents threaded processing and overrides the actions taken that are based on the system options. Note that when threaded sorting is in effect and NOEQUALS is specified,

observations within BY groups might be returned in an unpredictable order.

If threaded SAS sort is being used, the UTILLOC= system option affects the placement of utility files. Thread-enabled SAS applications are able to create temporary files that can be accessed in parallel by separate threads. For more information, see "UTILLOC= System Option" in *SAS System Options: Reference*.

The page size of the utility file used by PROC SORT is influenced by the new STRIPESIZE= system option. For more information, see "STRIPESIZE= System Option" in *SAS System Options: Reference*.

The TAGSORT option is not supported by the threaded sort. Specifying the TAGSORT option prevents threaded processing.

See "Threaded Sorting" on page 2358 and "Support for Parallel Processing" in *SAS Language Reference: Concepts*.

UNIQUEOUT= *SAS-data-set*

specifies the output data set for observations eliminated by the NOUNIQUEKEY option.

Alias UNIOUT=

Interaction The DUPOUT= and UNIOUT= options are not compatible and cannot be specified simultaneously.

Note When options NODUPKEY or NOUNIKEY are specified and the DATA= option refers to a CAS table, and the OUT=, DUPOUT=, or UNIOUT= options refer to a CAS table, PROC SORT invokes the CAS deduplicate action on a CAS server. For more information, see the deduplicate Action .

Tip The UNIQUEOUT= option can be used with the NOUNIQUEKEY option. It cannot be combined with the NODUPKEY option.

See "NOUNIQUEKEY" on page 2380

SAS Data Set Options: Reference

BY Statement

Specifies the sorting variables.

Examples: "Example 1: Sorting by the Values of Multiple Variables" on page 2391
"Example 2: Sorting in Descending Order" on page 2394
"Example 4: Retaining the First Observation of Each BY Group" on page 2399

Syntax

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...>;

Required Argument

variable
specifies the variable by which PROC SORT sorts the observations. PROC SORT first arranges the data set by the values in ascending order, by default, of the first BY variable. PROC SORT then arranges any observations that have the same value of the first BY variable by the values of the second BY variable in ascending order. This sorting continues for every specified BY variable.

Tip When using the Google BigQuery data source, columns in the BY statement in PROC SORT cannot be of data type FLOAT64 for in-database processing.

Optional Argument

DESCENDING
reverses the sort order for the variable that immediately follows in the statement so that observations are sorted from the largest value to the smallest value. The DESCENDING keyword modifies the variable that follows it.

Tips In a PROC SORT BY statement, the DESCENDING keyword modifies the variable that follows it.

The THREADS SAS system option is the default as long as the PROC SORT THREADS | NOTHREADS option is unspecified.

Example "Example 2: Sorting in Descending Order" on page 2394

KEY Statement

Specifies sorting keys and variables. The KEY statement is an alternative to the BY statement. The KEY statement syntax allows for the future possibility of specifying different collation options for each KEY variable. Currently, the only options allowed are ASCENDING and DESCENDING.

Restriction: The BY statement cannot be used with the KEY statement.

Tip: Multiple KEY statements can be specified.

Syntax

KEY *variable(s)* </ *option*> ;

Required Argument

variable(s)

specifies the variable by which PROC SORT orders the observations. Multiple variables can be specified. Each of these variables must be separated by a space. A range of variables can also be specified. For example, the following code shows how to specify multiple variables and a range of variables:

```
data sortKeys;
   input x1 x2 x3 x4 ;
cards;
   7 8 9 8
   0 0 0 0
   1 2 3 4 ;
run;
proc sort data=sortKeys out=sortedOutput;
   key x1 x2-x4;
run;
```

Multiple KEY statements can also be specified. The first sort key encountered from among all sort keys is considered the primary sort key. Sorting continues for every specified KEY statement and its variables. For example, the following code shows how to specify multiple KEY statements:

```
proc sort data=sortKeys out=sortedOutput;
   key x2;
   key x3;
run;
```

The following code example uses the BY statement to accomplish the same type of sort as the previous example:

```
proc sort data=sortKeys out=sortedOutput;
   by x2 x3;
run;
```

Optional Arguments

ASCENDING

sorts in ascending order the variable or variables that it follows. Observations are sorted from the smallest value to the largest value. The ASCENDING keyword modifies all the variables that precede it in the KEY statement.

Alias ASC

Default ASCENDING is the default sort order.

Tip In a PROC SORT KEY statement, the ASCENDING option modifies all the variables that it follows. The option must follow the /. In the following example, the x1 variable in the input data set is sorted in ascending order.

```
proc sort data=sortVar out=sortedOutput;
   key x1 / ascending;
```

```
run;
```

DESCENDING

reverses the sort order for the variable that it follows in the statement so that observations are sorted from the largest value to the smallest value. The DESCENDING keyword modifies all the variables that it precedes in the KEY statement.

Alias DESC

Default ASCENDING (ASC) is the default sort order.

Tip In a PROC SORT KEY statement, the DESCENDING option modifies the variables that follows it. The option must follow the /. In the following example, the x1 and x2 variables in the input data set is sorted in descending order:

```
proc sort data=sortVar out=sortedOutput;
   key x1 x2 / descending;
run;
```

The following example uses the BY statement to accomplish the same type of sort as the previous example:

```
proc sort data=sortVar out=sortedOutput;
   by descending x1 descending x2 ;
run;
```

Usage: SORT Procedure

In-Database Processing: PROC SORT

In-database processing has several advantages over processing within SAS. These advantages include increased security, reduced network traffic, and the potential for faster processing. Increased security is possible because sensitive data does not have to be extracted from the DBMS. Faster processing is possible because data is manipulated locally, on the DBMS, using high-speed secondary storage devices instead of being transported across a relatively slow network connection, because the DBMS might have more processing resources at its disposal, and because the DBMS might be capable of optimizing a query for execution in a highly parallel and scalable fashion.

When the DATA= input data set is stored as a table or view in a database management system (DBMS), the PROC SORT procedure can use in-database processing to sort the data. In-database processing can provide the advantages of

faster processing and reduced data transfer between the database and SAS software.

In-database processing for PROC SORT supports the following database management systems:

- Amazon Redshift
- Aster
- DB2
- Google BigQuery
- Greenplum
- Hadoop
- HAWQ
- Impala
- Microsoft SQL Server
- Netezza
- Oracle
- PostgreSQL
- SAP HANA
- Snowflake
- Teradata
- Vertica
- Yellowbrick

Note: When using the Google BigQuery data source, columns in the BY statement in PROC SORT cannot be of data type FLOAT64 for in-database processing.

PROC SORT performs in-database processing using SQL explicit pass-through. The pass-through facility uses SAS/ACCESS to connect to a DBMS and to send statements directly to the DBMS for execution. This facility lets you use the SQL syntax of your DBMS. For details, see "Pass-Through Facility for Relational Databases" in *SAS/ACCESS for Relational Databases: Reference*.

In-database processing is used by PROC SORT when a combination of procedure and system options are properly set. When system option SORTPGM=BEST, system option SQLGENERATION= is set to cause in-database processing, and when the PROC SORT NODUPKEY option is specified, PROC SORT generates a DBMS SQL query that sorts the data. The sorted results can either remain as a new table within the DBMS or can be returned to SAS. To view the SQL queries generated, set the SASTRACE= option.

The SAS system option SORTPGM= can also be used without setting the SQLGENERATION option to instruct PROC SORT to use either the DBMS, SAS, or the HOST to perform the sort. If SORTPGM=BEST is specified, then either the DBMS, SAS, or HOST performs the sort. The observation ordering that is produced by PROC SORT depends on whether the DBMS or SAS performs the sorting.

If the DBMS performs the sort, then the configuration and characteristics of the DBMS sorting program affects the resulting data order. The DBMS configuration settings and characteristics that can affect data order include character collation, ordering of NULL values, and sort stability. Most database management systems do not guarantee sort stability, and the sort might be performed by the DBMS regardless of the state of the SORTEQUALS/NOSORTEQUALS system option and EQUALS/NOEQUALS procedure option.

If you set the SAS system option SORTPGM= to SAS, then unordered data is delivered from the DBMS to SAS and SAS performs the sorting. However, consistency in the delivery order of observations from a DBMS is not guaranteed. Therefore, even though SAS can perform a stable sort on the DBMS data, SAS cannot guarantee that the ordering of observations within output BY groups is the same from one PROC SORT execution to the next. To achieve consistency in the ordering of observations within BY groups, first populate a SAS data set with the DBMS data, and then use the EQUALS or SORTEQUALS option to perform a stable sort.

In-database processing is affected by the following circumstances:

- When PROC SORT options, SORTSEQ=, or DUPOUT=, are specified, no in-database processing occurs.
- For in-database processing, the OUT= procedure option must be specified and the output data set cannot refer to the input table on the DBMS.
- LIBNAME options and data set options can also affect whether in-database processing occurs and what type of query is generated. See "In-Database Procedures" in *SAS/ACCESS for Relational Databases: Reference* for a complete list of these options. The user can also set OPTIONS MSGLEVEL=I in SAS to see which options prevent or affect in-database processing.

SAS Cloud Analytic Services Processing for PROC SORT

Starting in SAS Viya 3.5, PROC SORT supports the ability to run the duplicate detection and manipulation options (NODUPKEY, NOUNIKEY, DUPOUT=, UNIOUT=) in CAS. This functionality is provided to facilitate the migration of code for users of SAS Viya. PROC SORT provides the capability to eliminate duplicate entries in data sets when running in SAS 9. CAS also needs the ability to eliminate duplicate entries in data sets. This task is performed by using the deduplicate action available in SAS Viya 3.5.

When the input data set references the CAS view or an in-memory table, the SORT procedure uses the CAS deduplicate action to perform the equivalent functionality of the NODUPKEY or NOUNIKEY options of PROC SORT. When options NODUPKEY or NOUNIKEY are specified in the PROC SORT statement and input to PROC SORT is read by CAS, and all output from PROC SORT (including the optional DUPOUT= and UNIOUT= data sets) is written to a CAS table, PROC SORT invokes the CAS deduplicate action on the CAS server. Under these conditions, the

action is invoked and the work is performed in CAS with no data moved into or out of the CAS server.

See the deduplicate Action for information about the CAS aAction.

For conceptual information about procedures that run in CAS, see Chapter 5, "CAS Processing of Base Procedures," on page 93.

Integrity Constraints: SORT Procedure

Sorting the input data set and replacing it with the sorted data set preserves both referential and general integrity constraints, as well as any indexes that they might require. A sort that creates a new data set does not preserve any integrity constraints or indexes. For more information about implicit replacement, explicit replacement, and no replacement with and without the OUT= option, see "Output Data Set" on page 2390. For more information about integrity constraints, see the chapter on "SAS Data Files" in *SAS Language Reference: Concepts*.

Results: SORT Procedure

Procedure Output

PROC SORT produces only an output data set. To see the output data set, you can use PROC PRINT, PROC REPORT, or another of the many available methods of printing in SAS.

Output Data Set

Without the OUT= option, PROC SORT replaces the original data set with the sorted observations when the procedure executes without errors. When you specify the OUT= option using a new data set name, PROC SORT creates a new data set that contains the sorted observations.

Table 64.7 *Data Set Replacement Options*

Task	Options
implicit replacement of input data set	proc sort data=names;

Task	Options
explicit replacement of input data set	proc sort data=names out=names;
no replacement of input data set	proc sort data=names out=namesbyid;

With all three replacement options (implicit replacement, explicit replacement, and no replacement) there must be at least enough space in the output library for a copy of the original data set.

You can also sort compressed data sets. If you specify a compressed data set as the input data set and omit the OUT= option, then the input data set is sorted and remains compressed. If you specify an OUT= data set, then the resulting data set is compressed only if you choose a compression method with the COMPRESS= data set option. For more information, see "COMPRESS= Data Set Option" in *SAS Data Set Options: Reference* .

Also note that PROC SORT manipulates the uncompressed observation in memory and, if there is insufficient memory to complete the sort, stores the uncompressed data in a utility file. For these reasons, sorting compressed data sets might be intensive and require more storage than anticipated. Consider using the TAGSORT option when sorting compressed data sets.

Note: If the SAS system option NOREPLACE is in effect, then you cannot replace an original permanent data set with a sorted version. You must either use the OUT= option or specify the SAS system option REPLACE in an OPTIONS statement. The SAS system option NOREPLACE does not affect temporary SAS data sets.

Examples: SORT Procedure

Example 1: Sorting by the Values of Multiple Variables

Features:

PROC SORT statement option
OUT=

BY statement

PROC PRINT

Details

This example does the following:

- sorts the observations by the values of two variables
- creates an output data set for the sorted observations
- prints the results

Program

```

14	Strickland Industries	Morrisville	657.22	1675

Example 2: Sorting in Descending Order

Features: This example BY statement option
DESCENDING
PROC PRINT

Data set: Account

Details

This example does the following:

- sorts the observations by the values of three variables
- sorts one of the variables in descending order

- prints the results

Program

```
proc sort data=account out=sorted;
   by town descending debt accountnumber;
run;
proc print data=sorted;
   var company town debt accountnumber;
   title  'Customers with Past-Due Accounts';
   title2 'Listed by Town, Amount, Account Number';
run;
```

Program Description

Create the output data set SORTED. OUT= creates a new data set for the sorted observations.

```
proc sort data=account out=sorted;
```

Sort by three variables with one in descending order. The BY statement specifies that observations should be first ordered alphabetically by town, then by descending value of amount owed, then by ascending value of the account number.

```
   by town descending debt accountnumber;
run;
```

Print the output data set SORTED. PROC PRINT prints the data set SORTED.

```
proc print data=sorted;
```

Specify the variables to be printed. The VAR statement specifies the variables to be printed and their column order in the output.

```
   var company town debt accountnumber;
```

Specify the titles.

```
   title  'Customers with Past-Due Accounts';
   title2 'Listed by Town, Amount, Account Number';
run;
```

Output: HTML

Note that sorting last by AccountNumber puts the businesses in Apex with a debt of $37.95 in order of account number.

Output 64.4 *Sorting in Descending Order*

Customers with Past-Due Accounts
Listed by Town, Amount, Account Number

Obs	Company	Town	Debt	AccountNumber
1	Paul's Pizza	Apex	83.00	1019
2	Peter's Auto Parts	Apex	65.79	7288

11	Tim's Burger Stand	Holly Springs	119.95	6335
12	Strickland Industries	Morrisville	657.22	1675
13	Pauline's Antiques	Morrisville	302.05	9112
14	Bob's Beds	Morrisville	119.95	4998

Example 3: Maintaining the Relative Order of Observations in Each BY Group

Features: PROC SORT statement option
EQUALS | NOEQUALS
PROC PRINT

Details

This example does the following:

- sorts the observations by the value of the first variable
- maintains the relative order with the EQUALS option
- does not maintain the relative order with the NOEQUALS option

Program

```
data insurance;
   input YearsWorked 1 InsuranceID 3-5;
   datalines;
5 421
5 336
1 209
1 564
3 711
3 343
4 212
4 616
;

proc sort data=insurance out=byyears1 equals;

   by yearsworked;
run;

proc print data=byyears1;

   var yearsworked insuranceid;

   title 'Sort with EQUALS';
run;

proc sort data=insurance out=byyears2 noequals;

   by yearsworked;
run;

proc print data=byyears2;

   var yearsworked insuranceid;

   title 'Sort with NOEQUALS';
run;
```

Program Description

Create the input data set INSURANCE. INSURANCE contains the number of years worked by all insured employees and their insurance IDs.

```
data insurance;
   input YearsWorked 1 InsuranceID 3-5;
   datalines;
5 421
5 336
1 209
1 564
3 711
3 343
4 212
4 616
;
```

Create the output data set BYYEARS1 with the EQUALS option. OUT= creates a new data set for the sorted observations. The EQUALS option maintains the order of the observations relative to each other.

```
proc sort data=insurance out=byyears1 equals;
```

Sort by the first variable. The BY statement specifies that the observations should be ordered numerically by the number of years worked.

```
   by yearsworked;
run;
```

Print the output data set BYYEARS1. PROC PRINT prints the data set BYYEARS1.

```
proc print data=byyears1;
```

Specify the variables to be printed. The VAR statement specifies the variables to be printed and their column order in the output.

```
   var yearsworked insuranceid;
```

Specify the title.

```
   title 'Sort with EQUALS';
run;
```

Create the output data set BYYEARS2. OUT= creates a new data set for the sorted observations. The NOEQUALS option does not maintain the order of the observations relative to each other.

```
proc sort data=insurance out=byyears2 noequals;
```

Sort by the first variable. The BY statement specifies that the observations should be ordered numerically by the number of years worked.

```
   by yearsworked;
run;
```

Print the output data set BYYEARS2. PROC PRINT prints the data set BYYEARS2.

```
proc print data=byyears2;
```

Specify the variables to be printed. The VAR statement specifies the variables to be printed and their column order in the output.

```
   var yearsworked insuranceid;
```

Specify the title.

```
   title 'Sort with NOEQUALS';
run;
```

Output: HTML

Note that sorting with the EQUALS option versus sorting with the NOEQUALS option causes a different sort order for the observations where YearsWorked=3.

Output 64.5 *Sorting with the EQUALS Option*

Sort with EQUALS

Obs	YearsWorked	InsuranceID
1	1	209
2	1	564
3	3	711
4	3	343
5	4	212
6	4	616
7	5	421
8	5	336

Output 64.6 *Sorting with the NOEQUALS Option*

Sort with NOEQUALS

Obs	YearsWorked	InsuranceID
1	1	209
2	1	564
3	3	343
4	3	711
5	4	212
6	4	616
7	5	421
8	5	336

Example 4: Retaining the First Observation of Each BY Group

Features: PROC SORT statement option
NODUPKEY

BY statement

PROC PRINT

Data set: Account

Note: The EQUALS option must be in effect to ensure that the first observation for each BY group is the one that is retained by the NODUPKEY option. The EQUALS option is the default. If the NOEQUALS option has been specified, then one observation for each BY group is retained by the NODUPKEY option, but not necessarily the first observation.

Details

For this example, we are assuming that the Base SAS engine is being used. The Base SAS engine provides a consistent ordering where the first observation (the first observation that was written and stored) is generally the first one that is read by PROC SORT. The sorted data set contains only the first observation of each BY group.

Sorting causes observations that have equal BY variable values to be grouped together for output. Normally, PROC SORT writes all observations for each BY group that it assembles to the output data set. The NODUPKEY option instructs the SORT procedure to write only the first observation of each BY group to the output data set and discard any additional observations contained within that BY group. The resulting report in this example contains one observation for each town where the businesses are located.

Program

```
proc sort data=account out=towns nodupkey;
   by town;
run;
proc print data=towns;
   var town company debt accountnumber;
   title 'Towns of Customers with Past-Due Accounts';
run;
```

Program Description

Create the output data set TOWNS but include only the first observation of each BY group. NODUPKEY writes only the first observation of each BY group to the new data set TOWNS.

```
proc sort data=account out=towns nodupkey;
```

Sort by one variable. The BY statement specifies that observations should be ordered by town.

```
   by town;
run;
```

Print the output data set TOWNS. PROC PRINT prints the data set TOWNS.

```
proc print data=towns;
```

Specify the variables to be printed. The VAR statement specifies the variables to be printed and their column order in the output.

```
   var town company debt accountnumber;
```

Specify the title.

```
   title 'Towns of Customers with Past-Due Accounts';
run;
```

Output: HTML

The output data set contains only four observations, one for each town in the input data set.

Output 64.7 *Retaining the First Observation of Each BY Group*

Towns of Customers with Past-Due Accounts

Obs	Town	Company	Debt	AccountNumber
1	Apex	Paul's Pizza	83.00	1019
2	Garner	World Wide Electronics	119.95	1122
3	Holly Springs	Ice Cream Delight	299.98	2310
4	Morrisville	Strickland Industries	657.22	1675

Example 5: Linguistic Sorting Using ALTERNATE_HANDLING=

Features:

PROC SORT statement option
sortseq=linguistic
ALTERNATE_HANDLING=SHIFTED
STRENGTH=3

BY statement

VAR statement

PROC PRINT

PROC CONTENTS

Note: For more information about strengthening the linguistic sort of strings, see "Example 6: Linguistic Sorting Using ALTERNATE_HANDLING= and STRENGTH=" on page 2405.

Details

In this example, PROC SORT creates an output data set that contains only the first observation of each BY group. You have specified ALTERNATE_HANDLING=SHIFTED because you want "a-b" to sort close to "ab" and "aB". That is, you do not want "a-b" to appear somewhere far away from "ab" and "aB" by virtue of its hyphen.

Note: In this example, the default STRENGTH for this locale is 3.

Notice how "a-b" and "ab" are treated equivalently in the following example. To order them beyond the first three levels of comparison (alphabetic, diacritic, and case), you can use the fourth level of comparison and specify STRENGTH=4. "Example 6: Linguistic Sorting Using ALTERNATE_HANDLING= and STRENGTH=" on page 2405 shows how to distinguish the strings further.

PROC CONTENTS shows a Sort Information section in the output. The ICU version is also shown in the sort information. In SAS 9.4, the ICU library incorporated by SAS and used by PROC SORT is ICU version 4.8.1. In SAS Viya, the ICU library version incorporated by SAS and used by PROC SORT is ICU 56.

Program

```
data a;
   length x $ 10;
   x='a-b'; output;
   x='ab'; output;
   x='a-b'; output;
   x='aB'; output;
run;

proc sort data=a sortseq=linguistic( ALTERNATE_HANDLING=SHIFTED );
   by x;
run;

title1 "Linguistic Collation with ALTERNATE_HANDLING=SHIFTED";
proc print data=a;
run;

title1 "Linguistic Collation with ALTERNATE_HANDLING=SHIFTED and BY
Processing";
proc print data=a;
   var x;
   by x;
run;
```

```
proc contents data=a;
run;
```

Program Description

Create the data set.

```
data a;
   length x $ 10;
   x='a-b'; output;
   x='ab'; output;
   x='a-b'; output;
   x='aB'; output;
run;
```

Sort the data set using linguistic sorting. Use linguistic sorting and the ALTERNATE_HANDLING=SHIFTED option to sort the data set. Note that the default STRENGTH for this locale is 3. Also use the BY statement to order observations by x.

```
proc sort data=a sortseq=linguistic( ALTERNATE_HANDLING=SHIFTED );
   by x;
run;
```

Print data set A. The TITLE1 statement tells the PRINT procedure the title to use for the output. PROC PRINT then prints data set A.

```
title1 "Linguistic Collation with ALTERNATE_HANDLING=SHIFTED";
proc print data=a;
run;
```

Print data set A using By processing. The TITLE1 statement tells the PRINT procedure the title to use for the output. PROC PRINT then prints data set A using By processing.

```
title1 "Linguistic Collation with ALTERNATE_HANDLING=SHIFTED and BY
Processing";
proc print data=a;
   var x;
   by x;
run;
```

Print the Sort Information when linguistic sorting is being used. The PROC CONTENTS output contains a Sort Information section when PROC SORT is used with linguistic collation. This sort information also includes the ICU version being used.

```
proc contents data=a;
run;
```

Output: HTML

The first PROC PRINT shows that the order of "a-b" and "ab" is not well defined. The second PROC PRINT uses BY processing to show that these values are considered

equivalent. “Example 6: Linguistic Sorting Using ALTERNATE_HANDLING= and STRENGTH=” on page 2405 shows how to distinguish the strings more.

Output 64.8 *Linguistic Sorting Using the ALTERNATE_HANDLING Option*

Linguistic Collation with ALTERNATE_HANDLING=SHIFTED

Obs	x
1	a-b
2	ab
3	a-b
4	aB

Linguistic Collation with ALTERNATE_HANDLING=SHIFTED and BY Processing

x=a-b

Obs	x
1	a-b
2	ab
3	a-b

x=aB

Obs	x
4	aB

PROC CONTENTS prints out sort information when linguistic sorting is used. Information about the ICU version that is being used is also provided.

Sort Information	
Sortedby	x
Validated	YES
Character Set	ANSI
Collating Sequence	LINGUISTIC
Locale	en_US
Strength	3
Alternate Handling	SHIFTED
ICU Version Number	48

Example 6: Linguistic Sorting Using ALTERNATE_HANDLING= and STRENGTH=

Features:

PROC SORT statement option
sortseq=linguistic
ALTERNATE_HANDLING=SHIFTED
STRENGTH=4

BY statement

VAR statement

PROC PRINT

Details

In this example, PROC SORT creates an output data set that contains only the first observation of each BY group. In this example, ALTERNATE_HANDLING=SHIFTED is specified because you want "a-b" to sort close to "ab" and "aB" regardless of the hyphen.

Notice how "a-b" and "ab" are treated equivalently in the following example. However, if you want to further distinguish between them and have them appear in two separate BY groups, you must order the strings further. To order them beyond the first three levels of comparison (alphabetic, diacritic, and case), use the fourth level of comparison, STRENGTH=4.

Program

```
data a;
   length x $ 10;
   x='a-b'; output;
   x='ab'; output;
   x='a-b'; output;
   x='aB'; output;
run;

proc sort data=a sortseq=linguistic( ALTERNATE_HANDLING=SHIFTED
STRENGTH=4);
   by x;
run;

title1 "Linguistic Collation with STRENGTH=4";
proc print data=a;
run;

Title1 "Linguistic Collation with STRENGTH=4 and BY Processing";
proc print data=a;
   var x;
   by x;
run;
```

Program Description

Create the data set.

```
data a;
   length x $ 10;
   x='a-b'; output;
   x='ab'; output;
   x='a-b'; output;
   x='aB'; output;
run;
```

Sort the data set using linguistic sorting. Use linguistic sorting and the ALTERNATE_HANDLING=SHIFTED option to sort the data set. Note that the default STRENGTH for this locale is 4. The BY statement specifies that observations should be ordered by x.

```
proc sort data=a sortseq=linguistic( ALTERNATE_HANDLING=SHIFTED
STRENGTH=4);
   by x;
run;
```

Print the output data set A. The TITLE1 statement tells the PRINT procedure the title to use for the output. PROC PRINT then prints data set A.

```
title1 "Linguistic Collation with STRENGTH=4";
proc print data=a;
run;
```

Print the output data set A using By processing. The TITLE statement tells the PRINT procedure what title to use for this output. PROC PRINT then prints data set A using By processing.

```
Title1 "Linguistic Collation with STRENGTH=4 and BY Processing";
proc print data=a;
   var x;
   by x;
run;
```

Output: HTML

The first PROC PRINT shows that the order of "a-b" and "ab" is not well defined. Differentiate between the two by setting STRENGTH=4. The second PROC PRINT uses BY processing to show the order of precedence and how they are differentiated.

Output 64.9 *Linguistic Sorting Using the ALTERNATE_HANDLING and STRENGTH Options*

Linguistic Collation with STRENGTH=4

Obs	x
1	a-b
2	a-b
3	ab
4	aB

Linguistic Collation with STRENGTH=4 and BY Processing

x=a-b

Obs	x
1	a-b
2	a-b

x=ab

Obs	x
3	ab

x=aB

Obs	x
4	aB

Example 7: Eliminate All Duplicate Observations Using NODUPKEY

Features:

PROC SORT statement option
- NODUPKEY
- OUT=

BY statement

PROC PRINT

KEEP= data set option

Details

In this example, PROC SORT with NODUPKEY creates an output data set that has no duplicate observations. Each of these observations is unique. There is only one observation in the output data set for a given set of variable values. The BY _ALL_ variable sorts by the kept variables (KEEP= option), DIVISION and LEAGUE.

Program

```
proc sort data=sashelp.baseball(keep=division league)out=DL NODUPKEY;
   by _ALL_;
run;
```

```
proc print data=DL;
title 'Baseball Leagues and Divisions';
run;
```

Program Description

Processing only the division and league variables from the input data set (KEEP=), create the DL output data set and remove all duplicate entries.

```
proc sort data=sashelp.baseball(keep=division league)out=DL NODUPKEY;
```

Sort by all variables.

```
   by _ALL_;
run;
```

Print the output data set DL.

```
proc print data=DL;
title 'Baseball Leagues and Divisions';
run;
```

Output: HTML

The output data set contains only four observations, one for each unique division and league in baseball. No duplicate entries for Division and League are kept.

Output 64.10 *Remove all Duplicate observations from a Data Set*

Baseball Leagues and Divisions

Obs	League	Division
1	American	East
2	American	West
3	National	East
4	National	West

65

SQL Procedure

A Brief Overview

The SQL procedure is the Base SAS implementation of Structured Query Language. PROC SQL is part of Base SAS software, and you can use it with any SAS data set (table). Often, PROC SQL can be an alternative to other SAS procedures or the DATA step. You can use SAS language elements such as global statements, data set options, functions, informats, and formats with PROC SQL just as you can with other SAS procedures. PROC SQL enables you to perform the following tasks:

- generate reports
- generate summary statistics
- retrieve data from tables or views
- combine data from tables or views
- create tables, views, and indexes
- update the data values in PROC SQL tables
- update and retrieve data from database management system (DBMS) tables
- modify a PROC SQL table by adding, modifying, or dropping columns

For more information, see *SAS SQL Procedure User's Guide*

Example: Using the SQL Procedure

The following example selects all rows where Type="Sports" and the MSRP is greater than 100,000 from the Cars data set.

```
proc sql;
   select * from sashelp.cars
      where Type='Sports' and MSRP>100000;
quit;
```

Output 65.1 *SQL Procedure Result*

Make	Model	Type	Origin	DriveTrain	MSRP	Invoice	Engine Size (L)	Cylinders	Horsepower	MPG (City)	MPG (Highway)	Weight (LBS)	Wheelbase (IN)	Length (IN)
Mercedes-Benz	SL55 AMG 2dr	Sports	Europe	Rear	$121,770	$113,388	5.5	8	493	14	21	4235	101	179
Mercedes-Benz	SL600 convertible 2dr	Sports	Europe	Rear	$126,670	$117,854	5.5	12	493	13	19	4429	101	179
Porsche	911 GT2 2dr	Sports	Europe	Rear	$192,465	$173,560	3.6	6	477	17	24	3131	93	175

66

SQOOP Procedure

Overview: SQOOP Procedure

What Does the SQOOP Procedure Do?

You can use Apache Sqoop (pronounced *scoop*) to transfer data between Hadoop and relational database management systems (RDBMSs). You can use the SQOOP procedure to access Apache Sqoop from a SAS session to transfer data between a database and HDFS. It lets you submit Sqoop commands from within your SAS application to your Hadoop cluster.

Sqoop commands are passed to the cluster using the Apache Oozie Workflow Scheduler for Hadoop. PROC SQOOP defines an Oozie workflow for your Sqoop task, which is then submitted to an Oozie server using a RESTful API.

PROC SQOOP works similarly to the Apache Sqoop command-line interface (CLI). Using the same syntax, a user who has licensed SAS/ACCESS Interface to Hadoop can transfer data between a database and HDFS. The user can submit Sqoop CLI

commands in the COMMAND statement for the SQOOP procedure. The procedure provides feedback as to whether the job completed successfully and where to get more details from your Hadoop cluster if the Sqoop task failed.

Some Hadoop distributions support different versions of the Sqoop command. Refer to the documentation for your distribution for specific Sqoop command syntax.

For more information about Apache Sqoop, see the online documentation at http://sqoop.apache.org and http://sqoop.apache.org/docs/1.4.5/index.html.

For Sqoop considerations and usage, refer to the *Apache Sqoop Cookbook*.

You can find more information about Oozie at http://oozie.apache.org.

Syntax: SQOOP Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Requirements: To use this procedure requires a separate license to SAS/ACCESS Interface to Hadoop.

Specify the --username or --password options separately with the DBUSER= and DBPWD= options in the PROC SQOOP statement rather than in the Sqoop command.

Supports: Kerberos only on Linux

Notes: By default, the SQOOP procedure uses the hive-site.xml file to locate the Zookeeper service discovery. If the Zookeeper service discovery is not available, in the SQOOP procedure you can set a server name and port with the HIVE_SERVER= option or a JDBC URI with the HIVE_URI= option.

Support for HIVE_SERVER= and HIVE_URI= options was added in SAS Viya 3.5

See: SERVER= LIBNAME connection option, URI= LIBNAME connection option

Example: Importing from Teradata to HDFS Using an SQL Query

PROC SQOOP <*sqoop-options*>;

Statement	Task	Example
PROC SQOOP	Allow access to Apache Sqoop for data transfer	Ex. 1

PROC SQOOP Statement

Allows access to Apache Sqoop using options to allow data transfer between a database and HDFS.

Syntax

PROC SQOOP
COMMAND='*command-to-sqoop*'
DBPWD='*database-password*'
DBUSER='*database-user-name*'
<DELETEWF>
HADOOPUSER='*hadoop-user-name*'
HADOOPPWD='*hadoop-password*'
<HIVE_SERVER='*server-name-and-port*'>
<HIVE_URI='*JDBC-URI*'>
<JOBTRACKER='*job-tracker-URL*'>
<NAMENODE='*name-node-URL*'>
OOZIEURL='*oozie-URL*'
<PASSWORDFILE='*password-file*'>
<WFHDFSPATH='*Oozie-workflow-path*'>;

run;

Required Arguments

COMMAND='*command-to-sqoop*'
specifies the Apache Sqoop command. Here is how you must specify the command:

```
SQOOP-command --option … --option
```

Restriction Do not use the `sqoop` invocation command.

Note The escape character, a forward slash (\), in $CONDITIONS is not required when you submit Sqoop commands using the SQOOP procedure.

Tip For more information about Apache Sqoop commands, see the online documentation at http://sqoop.apache.org.

DBPWD='*database-password*'
specifies the database password that is associated with the DBUSER option. Because this option is mutually exclusive with the PASSWORDFILE option, you must specifiy only one or the other.

DBUSER='*database-user-name*'
specifies the database user name to use for import or export.

HADOOPPWD='*hadoop-password*'
specifies the Hadoop password that is associated with the HADOOPUSER= option.

Restriction Do not provide this option when connecting to a cluster that is enabled for Kerberos.

HADOOPUSER='*hadoop-user-name*'
specifies the Hadoop user name to use for import or export.

Restriction Do not provide this option when connecting to a cluster that is enabled for Kerberos.

OOZIEURL='*oozie-URL*'
specifies the URL to the Oozie server.

Optional Arguments

DELETEWF
specifies that, if an Oozie workflow file exists as specified by the location in WFHDFSPATH, it should be deleted. The SQOOP procedure then creates a new workflow file at that location.

HIVE_SERVER='*server-name-and-port*'
specifies the Hive server name that runs the Hive service and the port number to use to connect to the specified Hive service.

Restriction You can specify only one option at a time: HIVE_SERVER= or HIVE_URI=.

Requirements If the server name contains spaces or nonalphanumeric characters, you must enclose it in quotation marks.

This option is required when connecting to a Kerberized HDP 3.1 cluster when the hive-site.xml file does not contain the Zookeeper service.

HIVE_URI=jdbc:hive2://*HiveServerHost*:*HiveServerPort*</Schema:*Property1=Value*;...><*PropertyN=Value*;>
specifies the JDBC URI.

Restriction You can specify only one option at a time: HIVE_SERVER= or HIVE_URI=.

Requirement This option is required when connecting to a Kerberized HDP 3.1 cluster when the hive-site.xml file does not contain the Zookeeper service.

Example `jdbc:hive2://MyHiveServer:10000`

JOBTRACKER='*job-tracker-URL*'
specifies the URL to the JobTracker or ResourceManager services.

Default SAS_HADOOP_CONFIG_PATH determines the value for this option if you do not specify one.

NAMENODE='*name-node-URL*'
specifies the URL to the NameNode services.

Default SAS_HADOOP_CONFIG_PATH determines the value for this option if you do not specify one.

PASSWORDFILE='*password-file*'
specifies the name of the file that is located in HDFS that contains the database password for import or export. This separate password file must exist before you can run this procedure, and care should be taken to keep this file secure.

WFHDFSPATH='*Oozie-workflow-path-and-filename*'
specifies the path and filename for where to upload the Oozie workflow, as shown below.

```
/user/myID/mydir/myfile.xml
```

Default A generated path is used if you do not provide a value.

Tip You can use hdfs://server syntax, although it is not required.

Usage: SQOOP Procedure

General Usage

Because the Oracle JDBC Connector requires it, you must specify the value to be used for the --table option in Sqoop in uppercase letters. For details about case sensitivity for tables, see the documentation for your specific DBMS.

Connection strings should include the character set option that is appropriate for the data to be imported. For details, refer to your connector documentation.

Using Workflows

Workflows are created only when they are required. Some SQOOP jobs can use Oozie proxy submission, which generates no workflow file. Proxy submission is selected if you are running Oozie 4.1 or later and are not using a Hive table as the destination. The SAS log contains a note if PROC SQOOP uses proxy submission.

Requirements for Using the SQOOP Procedure

Here is what you need before you can begin using the SQOOP procedure.

What You Need	PROC SQOOP Option	Where to Find It
database connector	COMMAND: Sqoop syntax requires a --connection option that is specific to your database.	Refer to the documentation for your Hadoop distribution.
database user ID	DBUSER	Contact your database administrator.
database password	DBPWD	
HDFS file that contains the database password	PASSWORDFILE	Contact your database administrator and your Hadoop cluster administrator.
Hadoop user ID	HADOOPUSER	Contact your Hadoop cluster administrator.
Hadoop password	HADOOPPWD	
Oozie URL	OOZIEURL	
name node	NAMENODE	
Job Tracker (MR1) or Resource Manager (MR2)	JOBTRACKER	
Oozie workflow output path	WFHDFSPATH	Contact your Hadoop cluster administrator. Generally, the Oozie workflow can be written to your user directory in HDFS.
Sqoop Command	COMMN	Refer to the Sqoop documentation for your Hadoop distribution.

Example: Importing from Teradata to HDFS Using an SQL Query

In this example, DELETEWF is included to replace an existing workflow with a new workflow for this task.

Note: For proper default NAMENODE and JOBTRACKER port values for your environment, check the configuration for your particular distribution or refer to your Hadoop documentation.

```
proc sqoop dbuser='mydbusr1' dbpwd='mydbpwd1'
   hadoopuser='sashdpusr1' hadooppwd='sashdppwd1'
   oozieurl='http://myoozie-04:55000/oozie'
   namenode='hdfs://myoozie-04.unx.srvr.com:8020'
   jobtracker='myoozie-04.unx.srvr.com:8032'
   wfhdfspath='hdfs://myoozie-04.unx.srvr.com:8020/user/mydbusr1/
myworkflow.xml'
   deletewf
   command='import
      --connection-manager
com.cloudera.connector.teradata.TeradataManager
      --connect jdbc:teradata://myconnecti/Database=sqoop
      --query "SELECT * FROM sales where ($CONDITIONS and I < 25)" -m 1
      --split-by i --delete-target-dir
      --target-dir /user/mydbusr1/sales2';
run;
```

67

STANDARD Procedure

Overview: STANDARD Procedure

What Does the STANDARD Procedure Do?

The STANDARD procedure standardizes variables in a SAS data set to a given mean and standard deviation, and it creates a new SAS data set containing the standardized values.

Standardizing Data

The following output shows a simple standardization where the output data set contains standardized student exam scores. The statements that produce the output follow:

```
proc standard data=score mean=75 std=5
              out=stndtest;
run;

proc print data=stndtest;
run;
```

Output 67.1 *Standardized Test Scores Using PROC STANDARD*

```
                        The SAS System                          1

                Obs    Student       Test1

                  1    Capalleti    80.5388
                  2    Dubose       64.3918
                  3    Engles       80.9143
                  4    Grant        68.8980
                  5    Krupski      75.2816
                  6    Lundsford    79.7877
                  7    McBane       73.4041
                  8    Mullen       78.6612
                  9    Nguyen       74.9061
                 10    Patel        71.9020
                 11    Si           73.4041
                 12    Tanaka       77.9102
```

The following output shows a more complex example that uses BY-group processing. PROC STANDARD computes Z scores separately for two BY groups by standardizing life-expectancy data to a mean of 0 and a standard deviation of 1. The data are 1950 and 1993 life expectancies at birth for 16 countries. The birth rates for each country, classified as stable or rapid, form the two BY groups. The statements that produce the analysis also do the following:

- print statistics for each variable to standardize
- replace missing values with the given mean
- calculate standardized values using a given mean and standard deviation
- print the data set with the standardized values

For an explanation of the program that produces this output, see "Example 2: Standardizing BY Groups and Replacing Missing Values" on page 2435.

Output 67.2 *Z Scores for Each BY Group Using PROC STANDARD*

```
               Life Expectancies by Birth Rate                2

-------------------- PopulationRate=Stable ---------------------

                    The STANDARD Procedure

       Rapid       Philippines        1.19208     0.59572
       Rapid       Turkey             0.39736     0.83888
```

Syntax: STANDARD Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Tip: You can use the ATTRIB, FORMAT, LABEL, and WHERE statements. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

PROC STANDARD <*options*>;

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...> <NOTSORTED>;

FREQ *variable*;

VAR *variable(s)*;

WEIGHT *variable*;

Statement	Task	Example
PROC STANDARD	Standardize variables to a given mean and standard deviation	Ex. 1, Ex. 2
BY	Calculate separate standardized values for each BY group	Ex. 2
FREQ	Identify a variable whose values represent the frequency of each observation	
VAR	Select the variables to standardize and determine the order in which they appear in the printed output	Ex. 1
WEIGHT	Identify a variable whose values weight each observation in the statistical calculations	

PROC STANDARD Statement

Standardizes variables in a SAS data set to a given mean and standard deviation, and it creates a new SAS data set containing the standardized values.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Examples: "Example 2: Standardizing BY Groups and Replacing Missing Values" on page 2435

"Example 1: Standardizing to a Given Mean and Standard Deviation" on page 2432

Syntax

PROC STANDARD <*options*>;

Summary of Optional Arguments

DATA=*SAS-data-set*
: specifies the input data set.

EXCLNPWGT
: excludes observations with nonpositive weights.

MEAN=*mean-value*
: specifies the mean value.

OUT=*SAS-data-set*
: specifies the output data set.

REPLACE
: replace missing values with a variable mean or MEAN= value.

STD=*std-value*
: specifies the standard deviation value.

VARDEF=*divisor*
: specifies the divisor for variance calculations.

Control printed output

NOPRINT
: suppresses all printed output.

PRINT
: prints statistics for each variable to standardize.

Preserve values

PRESERVERAWBYVALUES
: preserves raw by values.

Without Arguments

If you do not specify MEAN=, REPLACE, or STD=, the output data set is an identical copy of the input data set.

Optional Arguments

DATA=*SAS-data-set*
: specifies the input SAS data set.

Restriction: You cannot use PROC STANDARD with an engine that supports concurrent access if another user is updating the data set at the same time.

See: "Input Data Sets" on page 26

EXCLNPWGT
excludes observations with nonpositive weight values (zero or negative). The procedure does not use the observation to calculate the mean and standard deviation, but the observation is still standardized. By default, the procedure treats observations with negative weights like those with zero weights and counts them in the total number of observations.

Alias EXCLNPWGTS

MEAN=*mean-value*
standardizes variables to a mean of *mean-value*.

Default mean of the input values

Example "Example 1: Standardizing to a Given Mean and Standard Deviation" on page 2432

NOPRINT
suppresses the printing of the procedure output. NOPRINT is the default value.

OUT=*SAS-data-set*
specifies the output data set. If *SAS-data-set* does not exist, PROC STANDARD creates it. If you omit OUT=, the data set is named Data*n*, where *n* is the smallest integer that makes the name unique.

Default Data*n*

Example "Example 1: Standardizing to a Given Mean and Standard Deviation" on page 2432

PRESERVERAWBYVALUES
preserves raw by values. of all BY variables when those variables are propagated to the output data set.

PRINT
prints the original frequency, mean, and standard deviation for each variable to standardize.

Example "Example 2: Standardizing BY Groups and Replacing Missing Values" on page 2435

REPLACE
replaces missing values with the variable mean.

Interaction If you use MEAN=, PROC STANDARD replaces missing values with the given mean.

Example "Example 2: Standardizing BY Groups and Replacing Missing Values" on page 2435

STD=*std-value*
standardizes variables to a standard deviation of *std-value*.

Default standard deviation of the input values

Example "Example 1: Standardizing to a Given Mean and Standard Deviation" on page 2432

VARDEF=*divisor*

specifies the divisor to use in the calculation of variances and standard deviation. The following table shows the possible values for *divisor* and the associated divisors.

Table 67.1 *Possible Values for VARDEF=*

Value	Divisor	Formula for Divisor
DF	Degrees of freedom	$n - 1$
N	Number of observations	n
WDF	Sum of weights minus one	$(\Sigma_i w_i) - 1$
WEIGHT|WGT	Sum of weights	$\Sigma_i w_i$

The procedure computes the variance as $CSS/divisor$, where CSS is the corrected sums of squares and equals $\Sigma (x_i - \overline{x})^2$. When you weight the analysis variables, CSS equals $\Sigma w_i(x_i - \overline{x}_w)^2$ where $\overline{x}_w$ is the weighted mean.

Default DF

Tips When you use the WEIGHT statement and VARDEF=DF, the variance is an estimate of σ^2 , where the variance of the *i*th observation is $var(x_i) = \sigma^2/w_i$ and w_i is the weight for the *i*th observation. This yields an estimate of the variance of an observation with unit weight.

When you use the WEIGHT statement and VARDEF=WGT, the computed variance is asymptotically (for large *n*) an estimate of $\sigma^2/\overline{w}$, where $\overline{w}$ is the average weight. This yields an asymptotic estimate of the variance of an observation with average weight.

See "WEIGHT" on page 82

"Keywords and Formulas" on page 2700

BY Statement

Calculates standardized values separately for each BY group.

See: "BY" on page 74

Example: "Example 2: Standardizing BY Groups and Replacing Missing Values" on page 2435

Syntax

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...> <NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then the observations in the data set must either be sorted by all the variables that you specify. Otherwise, they must be indexed appropriately. These variables are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the data set is sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The data are grouped in another way, such as chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, the procedure treats each contiguous set as a separate BY group.

FREQ Statement

Specifies a numeric variable whose values represent the frequency of the observation.

Tip: The effects of the FREQ and WEIGHT statements are similar except when calculating degrees of freedom.

See: For an example that uses the FREQ statement, see "FREQ" on page 79

Syntax

FREQ *variable*;

Required Argument

variable
specifies a numeric variable whose value represents the frequency of the observation. If you use the FREQ statement, the procedure assumes that each observation represents *n* observations, where *n* is the value of *variable*. If *n* is not an integer, SAS truncates it. If *n* is less than 1 or is missing, the procedure does not use that observation to calculate statistics but the observation is still standardized.

The sum of the frequency variable represents the total number of observations.

VAR Statement

Specifies the variables to standardize and their order in the printed output.

Default: If you omit the VAR statement, PROC STANDARD standardizes all numeric variables not listed in the other statements.

Example: "Example 1: Standardizing to a Given Mean and Standard Deviation" on page 2432

Syntax

VAR *variable(s)*;

Required Argument

variable(s)
identifies one or more variables to standardize.

WEIGHT Statement

Specifies weights for analysis variables in the statistical calculations.

See: For information about calculating weighted statistics and for an example that uses the WEIGHT statement, see "WEIGHT" on page 82.

Syntax

WEIGHT *variable*;

Required Argument

variable

specifies a numeric variable whose values weight the values of the analysis variables. The values of the variable do not have to be integers. The table below shows what the action will be based on the weight value.

Table 67.2 *WEIGHT Statement Value and PROC STANDARD Action*

Weight Value	PROC STANDARD Action
0	Counts the observation in the total number of observations
Less than 0	Converts the weight value to zero and counts the observation in the total number of observations
Missing	Excludes the observation from the calculation of mean and standard deviation

To exclude observations that contain negative and zero weights from the calculation of mean and standard deviation, use EXCLNPWGT. Note that most SAS/STAT procedures, such as PROC GLM, exclude negative and zero weights by default.

Tip When you use the WEIGHT statement, consider which value of the VARDEF= option is appropriate. For more information, see "VARDEF=*divisor* " on page 2427 and the calculation of weighted statistics in "Keywords and Formulas" on page 2700.

Details

Note: Prior to Version 7 of SAS, the procedure did not exclude the observations with missing weights from the count of observations.

Usage: STANDARD Procedure

Statistical Computations: STANDARD Procedure

Standardizing values removes the location and scale attributes from a set of data. The formula to compute standardized values is

$$x_i' = \frac{S * (x_i - \overline{x})}{s_x} + M$$

where

x_i'
is a new standardized value.

S
is the value of STD=.

M
is the value of MEAN=.

x_i
is an observation's value.

$\overline{x}$
is a variable's mean.

s_x
is a variable's standard deviation.

PROC STANDARD calculates the mean ($\overline{x}$) and standard deviation (s_x) from the input data set. The resulting standardized variable has a mean of **M** and a standard deviation of **S**.

If the data are normally distributed, standardizing is also studentizing since the resulting data have a Student's **t** distribution.

Results: STANDARD Procedure

Missing Values

By default, PROC STANDARD excludes missing values for the analysis variables from the standardization process, and the values remain missing in the output data set. When you specify the REPLACE option, the procedure replaces missing values with the variable's mean or the MEAN= value.

If the value of the WEIGHT variable or the FREQ variable is missing, then the procedure does not use the observation to calculate the mean and the standard deviation. However, the observation is standardized.

Output Data Set

PROC STANDARD always creates an output data set that stores the standardized values in the VAR statement variables, regardless of whether you specify the OUT= option. The output data set contains all the input data set variables, including those not standardized. PROC STANDARD does not print the output data set. Use PROC PRINT, PROC REPORT, or another SAS reporting tool to print the output data set.

Examples: STANDARD Procedure

Example 1: Standardizing to a Given Mean and Standard Deviation

Features: PROC STANDARD statement options
- MEAN=
- OUT=
- STD=

VAR statement
PRINT procedure

Details

This example does the following:

- standardizes two variables to a mean of 75 and a standard deviation of 5
- specifies the output data set
- combines standardized variables with original variables
- prints the output data set

Program

```
options nodate pageno=1 linesize=80 pagesize=60;

          old.test1, new.test1 as StdTest1,
          old.test2, new.test2 as StdTest2,
          old.final
   from score as old, stndtest as new
   where old.student=new.student;

proc print data=combined noobs round;
   title 'Standardized Test Scores for a College Course';
run;
```

Program Description

Set the SAS system options. The NODATE option specifies to omit the date and time at which the SAS job began. The PAGENO= option specifies the page number for the next page of output that SAS produces. The LINESIZE= option specifies the line size. The PAGESIZE= option specifies the number of lines for a page of SAS output.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Create the Score data set. This data set contains test scores for students who took two tests and a final exam. The FORMAT statement assigns the Z*w.d* format to StudentNumber. This format pads right-justified output with 0s instead of blanks. The LENGTH statement specifies the number of bytes to use to store values of Student.

```
data score;
   length Student $ 9;
   input Student $ StudentNumber Section $
         Test1 Test2 Final @@;
   format studentnumber z4.;
   datalines;
Capalleti 0545 1 94 91 87  Dubose    1252 2 51 65 91
Engles    1167 1 95 97 97  Grant     1230 2 63 75 80
Krupski   2527 2 80 69 71  Lundsford 4860 1 92 40 86
McBane    0674 1 75 78 72  Mullen    6445 2 89 82 93
Nguyen    0886 1 79 76 80  Patel     9164 2 71 77 83
Si        4915 1 75 71 73  Tanaka    8534 2 87 73 76
;
```

Generate the standardized data and create the Stndtest output data set. PROC STANDARD uses a mean of 75 and a standard deviation of 5 to standardize the values. OUT= identifies Stndtest as the data set to contain the standardized values.

```
proc standard data=score mean=75 std=5 out=stndtest;
```

Specify the variables to standardize. The VAR statement specifies the variables to standardize and their order in the output.

```
   var test1 test2;
run;
```

Create a data set that combines the original values with the standardized values. PROC SQL joins Score and Stndtest to create the Combined data set (table) that contains standardized and original test scores for each student. Using AS to rename the standardized variables NEW.TEST1 to StdTest1 and NEW.TEST2 to StdTest2 makes the variable names unique.

```
proc sql;
   create table combined as
   select old.student, old.studentnumber,
          old.section,
          old.test1, new.test1 as StdTest1,
          old.test2, new.test2 as StdTest2,
          old.final
   from score as old, stndtest as new
   where old.student=new.student;
```

Print the data set. PROC PRINT prints the Combined data set. ROUND rounds the standardized values to two decimal places. The TITLE statement specifies a title.

```
proc print data=combined noobs round;
   title 'Standardized Test Scores for a College Course';
run;
```

Output: Listing

The following data set contains variables with both standardized and original values. StdTest1 and StdTest2 store the standardized test scores that PROC STANDARD computes.

Output 67.3 *Standardized Test Scores for a College Course*

Standardized Test Scores for a College Course 1

Student	Student Number	Section	Test1	Std Test1	Test2	Std Test2	Final
Capalleti	0545	1	94	80.54	91	80.86	87

Program Description

Set the SAS system options. The NODATE option specifies to omit the date and time at which the SAS job began. The PAGENO= option specifies the page number for the next page of output that SAS produces. The LINESIZE= option specifies the line size. The PAGESIZE= option specifies the number of lines for a page of SAS output.

```
options nodate pageno=1 linesize=80 pagesize=60;
```

Assign a character string format to a numeric value. PROC FORMAT creates the format POPFMT to identify birth rates with a character value.

```
proc format;
   value popfmt 1='Stable'
                2='Rapid';
run;
```

Create the Lifeexp data set. Each observation in this data set contains information about 1950 and 1993 life expectancies at birth for 16 nations. The birth rate for each nation is classified as stable (1) or rapid (2). The nations with missing data obtained independent status after 1950. Data are from Vital Signs 1994: The Trends That Are Shaping Our Future, Lester R. Brown, Hal Kane, and David Malin Roodman, eds. Copyright © 1994 by Worldwatch Institute. Reprinted by permission of W.W. Norton & Company, Inc.

```
data lifexp;
   input PopulationRate Country $char14. Life50 Life93 @@;
   label life50='1950 life expectancy'
         life93='1993 life expectancy';
   datalines;
2 Bangladesh     .  53 2 Brazil         51 67
2 China          41 70 2 Egypt          42 60

1 Russia          . 65 2 Turkey         44 66
1 United Kingdom 69 76 1 United States  69 75
;
```

Sort the Lifeexp data set. PROC SORT sorts the observations by the birth rate.

```
proc sort data=lifexp;
   by populationrate;
run;
```

Generate the standardized data for all numeric variables and create the Z-score output data set. PROC STANDARD standardizes all numeric variables to a mean of 1 and a standard deviation of 0. REPLACE replaces missing values. PRINT prints statistics.

```
proc standard data=lifexp mean=0 std=1 replace
              print out=zscore;
```

Create the standardized values for each BY group. The BY statement standardizes the values separately by birth rate.

```
   by populationrate;
```

Assign a format to a variable and specify a title for the report. The FORMAT statement assigns a format to PopulationRate. The output data set contains formatted values. The TITLE statement specifies a title.

```
   format populationrate popfmt.;
   title1 'Life Expectancies by Birth Rate';
run;
```

Print the data set. PROC PRINT prints the ZSCORE data set with the standardized values. The TITLE statements specify two titles to be printed.

```
proc print data=zscore noobs;
   title 'Standardized Life Expectancies at Birth';
   title2 'by a Country''s Birth Rate';
run;
```

Output: Listing

PROC STANDARD prints the variable name, mean, standard deviation, input frequency, and label of each variable to standardize for each BY group. Life expectancies for Bangladesh, Mozambique, and Russia are no longer missing. The missing values are replaced with the given mean (0).

Output 67.4 *Life Expectancies by Birth Rate*

Life Expectancies by Birth Rate 1

PopulationRate=Stable

Name	Mean	Standard Deviation	N	Label
Life50	67.400000	1.854724	5	1950 life expectancy

STREAM Procedure

Overview: STREAM Procedure

What Does the STREAM Procedure Do?

The STREAM procedure enables you to process an input stream that consists of arbitrary text that can contain SAS macro specifications. The macros are executed and expanded while the other text in the input stream is preserved. The text stream is not validated as SAS syntax. The output stream is sent to an external file that is referenced by a fileref and that can be defined to use any traditional SAS output destination.

The STREAM procedure is valid in SAS Viya. Support for the STREAM procedure with SAS Viya was added in SAS 9.4M5.

Concepts: STREAM Procedure

How Text and Macro Code Are Interpreted

The following example uses a macro called %DOIT to produce an HTML stream that contains a table:

```
%macro doit(nrows,ncols);
<table>
%do i=1 %to &nrows;
<tr>
%do j=1 %to &ncols;
<td>&j</td>
%end;
</tr>
%end;
</table>
%mend doit;
```

If this macro is executed within a SAS code stream, then HTML output will be produced but the output will be syntactically invalid because it is not valid SAS syntax. However, if this macro is executed through PROC STREAM, the HTML output will instead be written to a file and not validated as SAS syntax. The following is an example:

```
proc stream outfile=myfile; begin
%doit(2,3)
;;;;
```

The following output is written to *myfile*:

```
<table> <tr> <td>1</td> <td>2</td> <td>3</td> </tr> <tr> <td>1</td> <td>2</td> <td>3</td> </tr>
</table>
```

You can use the %INCLUDE statement in the input stream. The types of input files that you can use include HTML files, RTF files, or any other type of text-based file. Note that you would not likely use %INCLUDE to include actual SAS code except for macro definitions and invocations. Any actual SAS code beyond macros is not executed, but is treated like any other text.

Text that follows a % and that is recognized by a macro is executed. Examples include %LET, %INCLUDE, and %SYSFUNC. Any other macros, such as user-defined macros, are also executed.

All macro variable references are resolved, but warnings are issued if the macro name is not recognized. Macro statements such as %PUT and %LIST send output to the log and do not produce tokens. You should avoid using these statements in an input stream, although they are allowed.

Tokenizer Limitations

The SAS tokenizer or word-scanner has a number of limitations that can be a problem for correctly processing syntax input streams other than SAS syntax input streams. These limitations are described in the following list.

- Input records that come from the %INCLUDE statement cannot exceed a record size of 32,767 bytes, which is the default value.
- The tokenizer does not provide accurate information about record size to PROC STREAM if the input record from %INCLUDE exceeds 32,767 bytes.
- %INCLUDE and %LET statements must begin on a statement boundary. That is, a semicolon must precede the statements, and the statements must end with a semicolon. Macro invocations do not have this requirement.
- Macro statements are completely consumed and executed by the tokenizer, and PROC STREAM is not aware of them. For example, `%let xyz=2;` is completely consumed. This behavior also holds true for macro statements that are not global in scope, such as %IF and %GOTO. These macro statements are flagged as errors but PROC STREAM is not aware of the error.
- Any token that starts with the letters a-z (uppercase or lowercase), or an underscore that is preceded by an &, is assessed by the macro processor to determine whether it is a macro variable to be resolved. If it is not a macro variable, a warning is issued. Currently, this warning cannot be suppressed.
- PL/I programming language comments (/* *comment* */) are typically completely absorbed by the tokenizer and are not seen by PROC STREAM. You can use the NOABSSCMT option in the PROC STREAM statement so that all text between and including the /* and */ are seen. This option is also needed if the input stream can contain occurrences of /* that are not enclosed in quotation marks. An example of this is `/tmp/xyz/*`, which is a UNIX wildcard specification.
- No single token can exceed 32,767 characters.
- If the last token in a record is followed by a line feed that is preceded by an optional carriage return, and the first token in the next record begins in column 1, then the tokenizer introduces an artificial blank between these tokens. The blank allows for valid SAS syntax, because these tokens are not concatenated unless they are part of a string that is enclosed in quotation marks. For example, a record is 80 characters long. The string *abc*, preceded by a blank, is located in columns 78–80. In the next record, the string *def* , followed by a blank, appears in columns 1–3. In this case, PROC STREAM receives *abc* followed by *def*, which has a leading blank, even though a leading blank did not appear in the token

stream. If, instead, *'abc*, preceded by a blank, appears in columns 77-80, and *def'*, followed by a blank, appears in columns 1-4, then PROC STREAM receives *'abcdef'*.

- Non-printable characters (except for carriage return (CR) and line feed (LF)) cannot be properly tokenized.
- The input stream cannot be a binary stream such as a PDF or a JPG file.
- The normal behavior for the tokenizer is to provide a string, either with single or double quotation marks, as a single token. This is a problem if text, such as *don't do this*, is not enclosed in quotation marks, or if text has an escape sequence, as in *don''t do this*. The QUOTING= option can be used to allow for quotation marks to be treated like any other special character, such a hyphen or a slash.
- A single macro variable can expand into no more than 64,000 characters. However, there is no limit to what a macro can return as model text, apart from resource limitations such as memory and disk space.

Syntax: STREAM Procedure

PROC STREAM OUTFILE=*fileref* <*options*>; BEGIN
text-1
<*text-n*>
;;;;

Statement	Task
PROC STREAM	Process an input stream that consists of arbitrary text that can contain SAS macro specifications

PROC STREAM Statement

Enables you to process an input stream that consists of arbitrary text that can contain SAS macro specifications.

Syntax

PROC STREAM OUTFILE= *fileref* <*options*>; BEGIN
text-1
<*text-n*>
;;;;

Summary of Optional Arguments

MOD
: Specifies that the output file is appended to instead of being overwritten.

NOABSSCMT
: Specifies whether comments are written to the output stream.

PRESCOL
: Indicates that an attempt is made to preserve the columns of the original input file.

QUOTING=SINGLE | DOUBLE | BOTH
: Specifies how quotation marks are handled.

RESETDELIM='*label*'
: Indicates a special marker token.

Required Arguments

OUTFILE=*fileref*
specifies the file where all tokens are written.

The LRECL specification for the fileref is used. If no LRECL is given, then the default value for the global LRECL= option, which is 32,767 bytes, is used. Unless you use the PRESCOL option, all tokens are streamed out with the proper number of intervening blanks between tokens. No token is broken between records. Also, no stream of tokens is broken between records unless there is at least one blank within them. For example, <table>X</table> will not be broken between records, but <table> X </table> can be broken where you see the blanks (before and after the X).

text
specifies the SAS statements or macros to use with PROC STREAM.

Optional Arguments

MOD
specifies that the output file is appended to instead of being overwritten.

NOABSSCMT
specifies whether comments are written to the output stream.

If PL/I programming language style comments appear (`/* comments */`), all text between the comment characters (/* and */) appears in the output stream. If this option is omitted, the PL/I-style comments do not appear in the output stream. Note that if NOABSSCMT is set, it is strongly suggested that QUOTING= also be set, because single quotation marks (such as in the word don't) can commonly appear in comments.

PRESCOL
indicates that an attempt is made to preserve the columns of the original input file.

Using this option is not as successful if there is macro substitution or if the record size exceeds 32,767 bytes. In this case, macro expansion might affect column location.

The PRESCOL option improves the validity of RTF files that are included with the %INCLUDE macro.

QUOTING=SINGLE | DOUBLE | BOTH
specifies how quotation marks are handled.

SINGLE
specifies that single quotation marks are treated like any other character. If you use the SINGLE option and macro references occur within single quotation marks, such as '&hello', the macro references are expanded.

DOUBLE
specifies that double quotation marks are treated like any other character.

BOTH
specifies that both SINGLE and DOUBLE options are used.

RESETDELIM='*label*'
indicates a special marker token.

This option is used when there is a need for statements to be expanded, such as the %INCLUDE and %LET statements. These statements must begin on a statement boundary. If your syntax does not allow for a statement boundary, then the given label, followed by a semicolon, can be introduced in the input stream to satisfy the tokenizer requirements. The label and semicolon are not sent to the output file.

In the following example, %INCLUDE is not preceded by a semicolon, and the code is not correct:

```
x y %include myfile; z
```

However, if you use the RESETDELIM= option, the expansion occurs as expected:

```
resetdelim='mylabel'
x y mylabel;
%include myfile; z
```

Mylabel; is not seen in the output file.

Mylabel must be a valid SAS name, that is, it must begin with a letter or underscore, and all subsequent characters must be letters, underscores, or digits. The length of *mylabel* must not exceed 32 characters.

The specification and usage is not case-sensitive. There is no default value for RESETDELIM=.

PROC STREAM checks for the existence of a macro variable called &STREAMDELIM. If that macro variable exists, it is used as is. If it does not exist, PROC STREAM verifies whether the RESETDELIM= option was given. If this is the case, the macro variable &STREAMDELIM is set to the value of the RESETDELIM= option. If the RESETDELIM= option is not given, PROC STREAM constructs a unique value for the &STREAMDELIM macro variable based on the current datetime value.

With this consideration, you can add &STREAMDELIM into the input for PROC STREAM. When this macro variable is seen, it is assumed that optional keywords will follow. A closing semicolon is then expected. All tokens from the

&STREAMDELIM value up to and including the semicolon are not emitted to the output stream, but are instead special control information items for PROC STREAM.

If you need to provide a %INCLUDE statement in your input, but a semicolon does not precede it, then you must add the following statement before the %INCLUDE statement:

```
&STREAMDELIM;
```

This statement forces a semicolon to be seen by the tokenizer, but it is absorbed by PROC STREAM.

The following optional keywords can follow &STREAMDELIM:

NEWLINE
specifies that a new line is emitted to the output file.

READFILE *filename*
specifies that the given filename is opened, and its contents are read as is and written to the output file. There is no macro expansion of the contents of this file, and new lines are preserved. This differs from %INCLUDE, where macro expansion occurs and new lines are ignored. For an example of how to use the READFILE keyword, see "Using the READFILE Keyword" on page 2450.

Usage: STREAM Procedure

Using Macro-Based Code in the Input Stream

Any macro-based code in the input stream is expanded, as shown in this example:

```
%let abc=123;
proc stream outfile=out; begin
<title>Run &abc</title>
<table>
<tr> <td>1<td>2</tr>
<tr> <td>3<td>4</tr>
</table>
;;;;
```

The output file contains the following results:

```
<title>Run 123</title> <table> <tr> <td>1<td>2</tr> <tr> <td>3<td>4</tr> </table>
```

Note that there are no line breaks, but blanks are preserved, and a blank is inserted for each line break.

The fact that the occurrence of % and & in the input stream are not enclosed in quotation marks and are not escape sequences can cause problems. For example, *&* appears in HTML streams as an escape sequence for an ampersand. If you have a macro variable called *&AMP*, then its value is substituted for *&amp*. If this type of macro variable is not present, then SAS issues a warning. You can avoid these problems by using the & as an escape character, as in %STR(&), as the following example shows:

```
<title>A %str(&)amp; B</title>
```

The following output is written to the output stream:

```
<title>A &amp; B</title>
```

Likewise, for %, any occurrence that is not to be misinterpreted by a macro should appear as `%STR(%)`, as the following example shows:

```
<a href="www.sas.com/x%str(%20y)">the link</a>
```

The following output is written to the output stream:

```
<a href="www.sas.com/x%20y">the link</a>
```

If the escape sequence for %STR occurs within single quotation marks, then either use the QUOTING= option, or use the escape sequence with a single quotation mark, %STR(%').

Beginning an Input Stream with Brackets or Parentheses

When you start your input stream with brackets or parentheses, specifically {, [, or (, this causes the BEGIN keyword to be treated as a name. This is true even when the first input character is on the line after BEGIN in your code. For example, the following code would treat BEGIN as a name rather than as the keyword that identifies the start of an input stream:

```
filename dheader "c:\temp\dheader.txt";
proc stream outfile=dheader; begin
[SAS version 9.4]
;;;;
```

To prevent this, use the &STREAMDELIM; statement. You can always use the &STREAMDELIM; statement after BEGIN to indicate the beginning of any input stream.

When you include this statement, the starting point of the input stream is interpreted correctly:

```
filename dheader "c:\temp\dheader.txt"
proc stream outfile=dheader; begin &streamdelim;
[SAS version 9.4]
;;;;
```

Executing SAS Code

As described in a previous section, any SAS code that is encountered is not executed. The tokens are streamed out like any other tokens. An exception to this occurs when the %SYSFUNC or %SYSCALL macro functions are encountered. These macro functions do execute the specified function, as shown in the following example:

```
%let abc=%sysfunc(getoption(obs));
&abc
```

This statement causes the GETOPTION function to be called, which obtains the value of the OBS option. GETOPTION returns the value as a character string to be placed into the ABC macro variable. That value is then written to the output stream.

It is possible to execute a stream of SAS code by using the DOSUB function in %SYSFUNC. The DOSUB function is provided a fileref, and all of the SAS code within that file is executed.

In this example, the fileref MYCODE points to the following SAS code:

```
filename myhtml "c:\temp\temp.txt";

data _null_;
   file myhtml;
   put '<table>';
   put '<tr><td>1</td></tr>';
   put '<tr><td>2</td></tr>';
   put '</table>';
run;
```

If you then execute the following STREAM procedure, you can see that PROC STREAM uses *mycode* as an argument to DOSUB in the %SYSFUNC function:

```
filename myhtml "c:\temp\temp.txt";
filename new "c:\temp\new.html";

proc stream outfile=new; begin
%let abc=%sysfunc(dosub(mycode));
%include myhtml;
;;;;
```

The output stream contains the following results:

```
<table><tr><td>1</td></tr><tr><td>2</td></tr></table>
```

Note: The DOSUB function is similar to the DOSUBL function, but DOSUB is passed a fileref for a file that contains SAS code. DOSUBL is passed a text string and executes the value as SAS code. For more information, see "DOSUBL Function" in *SAS Functions and CALL Routines: Reference*.

Rich Text Format (RTF) File Output

You can use Microsoft Word to input data and create RTF output. If you enter `Today is &sysdate..` and `My name is &name..`, Microsoft Word saves the data as an RTF file called Mytest.rtf. This file is approximately 30K in size, and contains a large amount of markup data. A section of that data contains the actual text that was entered, as seen here:

```
\fs20\lang1033\langfe1033\cgrid\langnp1033\langfenp1033 {\rtlch\fcs1 \af0 \ltrch\fcs0
\insrsid8922096
Today is &sysdate.. }{\rtlch\fcs1 \af0 \ltrch\fcs0 \insrsid14092174
\par }{\rtlch\fcs1 \af0 \ltrch\fcs0 \insrsid8922096
\par My name is &name..
\par
```

Note that the text as entered has macro substitutions.

When you execute this SAS program, a new RTF file is created called Newrtf.rtf. The difference in this output file is that the macro substitutions have taken place, but the markup language remains intact:

```
%let name=John;
filename oldrtf 'mytest.rtf' recfm=v lrecl=32767;
filename newrtf 'newrtf.rtf' recfm=v lrecl=32767;
proc stream outfile=newrtf quoting=both asis; begin
&streamdelim;
%include oldrtf;
;;;;
```

Then when the Newrtf.rtf file is read by Microsoft Word, this is what is displayed:

```
Today is 30NOV12.

My name is John.
```

Using the READFILE Keyword

In HTML, the <PRE> ... </PRE> tags encapsulate a stream of text that has been pre-formatted, and is displayed as is, honoring new lines and spacing. You can read the contents of a file and have it preserved as is by using the READFILE keyword. The READFILE keyword follows the &STREAMDELIM macro variable:

```
filename fixed temp;
data _null_; file fixed;
     input; put _infile_;
     datalines4;
This is the first line of fixed text.
This is another line to be fixed.
This is the last line of fixed text.
```

```
;;;;

%macro doit(nrows,ncols);
<table>
%do i=1 %to &nrows;
<tr>
%do j=1 %to &ncols;
<td>&j</td>
%end;
</tr>
%end;
%mend;

filename new temp;
proc stream outfile=new; begin
<PRE>
&streamdelim readfile fixed;
</PRE>
%doit(2,3)
;;;;

data _null_; infile new; input; put _infile_; run;
filename fixed temp;
data _null_; file fixed;
     input; put _infile_;
     datalines4;
This is the first line of fixed text.
This is another line to be fixed.
This is the last line of fixed text.
;;;;

%macro doit(nrows,ncols);
<table>
%do i=1 %to &nrows;
<tr>
%do j=1 %to &ncols;
<td>&j</td>
%end;
</tr>
%end;
%mend;

filename new temp;
proc stream outfile=new; begin
<PRE>
&streamdelim readfile fixed;
</PRE>
%doit(2,3)
;;;;

data _null_; infile new; input; put _infile_; run;
```

This is the resulting file:

```
<PRE>
This is the first line of fixed text.
This is another line to be fixed.
This is the last line of fixed text.
</PRE> <table> <tr> <td>1</td> <td>2</td> <td>3</dt> </tr>
<tr> <td>1</td> <td>2</td> <td>3</dt> </tr> </table>
```

Using %INCLUDE to Include a File in PROC STREAM

To stream complex HTML and Javascript code, you can create the code in a separate file. Then use the %INCLUDE statement to include the file in your program.

The following example shows this approach.

```
filename temp1 temp;

data _null_;
   infile datalines;
   file temp1;
   input;
   l=length(_infile_);
   put @1 _infile_ $varying200. l;
   datalines4;
<table>
<tr>
<td>abc</td><td>def</td>
</tr>
<tr>
<td>ghi</td><td>jkl</td>
</tr>
</table>
;;;;

filename myfile "c:\temp\test1.html";

proc stream outfile=myfile prescol resetdelim='label'; begin
<html>
<h2>Test Example</h2>
label;
%include temp1;
</html>
;;;;
```

Inserting a New Line into the Output Stream

To insert a new line into the output stream, add the keyword NEWLINE after the delimiter and before the semicolon, as shown in the following example:

```
proc stream outfile=abc resetdelim='mylabel'; begin
my item here;
mylabel newline;
my next item here
;;;;
```

This example produces the following output:

```
my item here;
my next item here
```

There is no other way to ensure a predictable new line.

Ending the STREAM Procedure

The end of the PROC STREAM step is indicated by four semicolons with no blanks between them, written as the last line of the procedure. If the last item in the input stream ends with a semicolon, use the label that is specified in RESETDELIM=, followed by a semicolon, immediately after the last item.

The following example is not coded correctly because the semicolon after `here` is not recognized:

```
proc stream outfile=abc; begin
my item here;
;;;;
```

The following example is coded correctly:

```
proc stream outfile=abc resetdelim='mylabel'; begin
my item here;
mylabel;
;;;;
```

RESETDELIM= is used in this example because it recognizes the semicolon after `here`.

69

SUMMARY Procedure

Overview: SUMMARY Procedure

What Does the SUMMARY Procedure Do?

The SUMMARY procedure provides data summarization tools that compute descriptive statistics for variables across all observations or within groups of observations. The SUMMARY procedure is very similar to the MEANS procedure; for full syntax details, see Chapter 40, “MEANS Procedure,” on page 1463. Except for the differences that are discussed here, all the PROC MEANS information also applies to PROC SUMMARY.

PROC SUMMARY can be used in SAS Cloud Analytic Services (CAS). Running PROC SUMMARY with CAS actions has several advantages over processing within SAS. See Chapter 40, “MEANS Procedure,” on page 1463 for information about running PROC MEANS and PROC SUMMARY in CAS.

Calculated statistics can vary slightly, depending on the order in which observations are processed. Such variations are due to numerical errors that are introduced by floating–point arithmetic, the results of which should be considered approximate and not exact. The order of observation processing can be affected by nondeterministic effects of multithreaded or parallel processing. The order of processing can also be affected by inconsistent or nondeterministic ordering of

observations that are produced by a data source, such as a DBMS that delivers query results through an ACCESS engine. For more information, see "Numerical Accuracy in SAS Software" in *SAS Language Reference: Concepts* and "Threading in Base SAS" in *SAS Language Reference: Concepts*.

Syntax: SUMMARY Procedure

Tips:

Supports the Output Delivery System. For details, see "Output Delivery System: Basic Concepts" in *SAS Output Delivery System: User's Guide*.

You can use the ATTRIB, FORMAT, LABEL, and WHERE statements.

Full syntax descriptions are in "Syntax" on page 1475.

PROC SUMMARY <*options*> <*statistic-keyword(s)*>;

BY <DESCENDING> *variable-1*<<DESCENDING> *variable-2* ...> <NOTSORTED>;

CLASS *variable(s)* </ *options*>;

FREQ *variable*;

ID *variable(s)*;

OUTPUT <OUT=*SAS-data-set*> <*output-statistic-specification(s)*> <*id-group-specification(s)*> <*maximum-id-specification(s)*> <*minimum-id-specification(s)*> </ *options*> ;

TYPES *request(s)*;

VAR *variable(s)* </ WEIGHT=*weight-variable*>;

WAYS *list*;

WEIGHT *variable*;

Statement	Task
PROC SUMMARY	Compute descriptive statistics for variables across all observations or within groups of observations
BY	Calculate separate statistics for each BY group
CLASS	Identify variables whose values define subgroups for the analysis
FREQ	Identify a variable whose values represent the frequency of each observation
ID	Include additional identification variables in the output data set
OUTPUT	Create an output data set that contains specified statistics and identification variables

Statement	Task
TYPES	Identify specific combinations of class variables to use to subdivide the data
VAR	Identify the analysis variables and their order in the results
WAYS	Specify the number of ways to make unique combinations of class variables
WEIGHT	Identify a variable whose values weight each observation in the statistical calculations

PROC SUMMARY Statement

Computes descriptive statistics for variables across all observations or within groups of observations.

See: For full syntax details, see "PROC MEANS Statement" on page 1476.

Details

PRINT | NOPRINT
specifies whether PROC SUMMARY displays the descriptive statistics. By default, PROC SUMMARY does not display output, but PROC MEANS does display output.

Default NOPRINT

VAR Statement

Identifies the analysis variables and their order in the results.

Default: If you omit the VAR statement, then PROC SUMMARY produces a simple count of observations, whereas PROC MEANS tries to analyze all the numeric variables that are not listed in the other statements.

Interaction: If you specify statistics in the PROC SUMMARY statement and the VAR statement is omitted or if a numeric variable is not associated with a statistic in the OUTPUT statement , then PROC SUMMARY stops processing and an error message is written to the SAS log.

Note: See the VAR Statement in PROC MEANS for a full description of the VAR statement.

See: For complete syntax, see “VAR Statement” on page 1507.

70

TABULATE Procedure

Overview: TABULATE Procedure

What Does the TABULATE Procedure Do?

The TABULATE procedure displays descriptive statistics in tabular format, using some or all of the variables in a data set. You can create a variety of tables ranging from simple to highly customized.

PROC TABULATE computes many of the same statistics that are computed by other descriptive statistical procedures such as MEANS, FREQ, and REPORT. PROC TABULATE provides the following features:

- simple but powerful methods to create tabular reports
- flexibility in classifying the values of variables and establishing hierarchical relationships between the variables
- mechanisms for labeling and formatting variables and procedure-generated statistics
- the ability to create accessible output tables when used with the ACCESSIBLETABLE system option. PROC TABULATE also provides the ability to add captions to tables.

  For more information about creating accessible tables with PROC TABULATE, see "Overview of Table Accessibility " in *Creating Accessible SAS Output Using ODS and ODS Graphics* . This feature applies to SAS 9.4M6 and to later releases.

Simple Tables

The following output shows a simple table that was produced by PROC TABULATE. The data set "ENERGY" on page 2788 contains data on expenditures of energy by two types of customers, residential and business, in individual states in the Northeast (1) and West (4) regions of the United States. The table sums expenditures for states within a geographic division. The RTS option provides enough space to display the column headings without hyphenating them.

```
proc tabulate data=energy;
   class region division type;
   var expenditures;
   table region*division, type*expenditures /
         rts=20;
run;
```

Output 70.1 *Simple Table Produced by PROC TABULATE*

The SAS System

		Type	
		1	2
		Expenditures	Expenditures
		Sum	Sum
Region	Division		
1	1	7477.00	5129.00
	2	19379.00	15078.00
4	3	5476.00	4729.00
	4	13959.00	12619.00

Complex Tables

The following output is a more complicated table using the same data set that was used to create Output 70.346 on page 2461. The statements that create this report do the following:

- customize column and row headings
- apply a format to all table cells
- sum expenditures for residential and business customers
- compute subtotals for each division
- compute totals for all regions

For an explanation of the program that produces this report, see "Example 6: Summarizing Information with the Universal Class Variable ALL" on page 2566.

Output 70.2 *Complex Table Produced by PROC TABULATE*

Energy Expenditures for Each Region
(millions of dollars)

		Customer Base		All Customers
		Residential Customers	Business Customers	
Region	Division			
Northeast	New England	7,477	5,129	12,606
	Middle Atlantic	19,379	15,078	34,457
	Subtotal	26,856	20,207	47,063
West	Division			
	Mountain	5,476	4,729	10,205
	Pacific	13,959	12,619	26,578
	Subtotal	19,435	17,348	36,783
Total for All Regions		$46,291	$37,555	$83,846

PROC TABULATE and the Output Delivery System

The following output shows a table that is created in Hypertext Markup Language (HTML). You can use the Output Delivery System with PROC TABULATE to create customized output in HTML, Rich Text Format (RTF), Portable Document Format (PDF), and other output formats. For an explanation of the program that produces this table, see "Example 14: Specifying Style Overrides for ODS Output" on page 2607.

Output 70.3 *HTML Table Produced by PROC TABULATE*

Energy Expenditures
(millions of dollars)

Region=Northeast

Region by Division by Type		Type		Total
		Residential Customers	Business Customers	
		Expenditures	Expenditures	Expenditures
		Sum	Sum	Sum
Region	Division			
Northeast	New England	$7,477	$5,129	$12,606
	Middle Atlantic	$19,379	$15,078	$34,457
	Total	$26,856	$20,207	$47,063
Total	Division			
	New England	$7,477	$5,129	$12,606
	Middle Atlantic	$19,379	$15,078	$34,457
	Total	$26,856	$20,207	$47,063

Concepts: TABULATE Procedure

Terminology: TABULATE Procedure

The following figures illustrate some of the terms that are commonly used in discussions of PROC TABULATE.

Figure 70.1 *Parts of a PROC TABULATE Table*

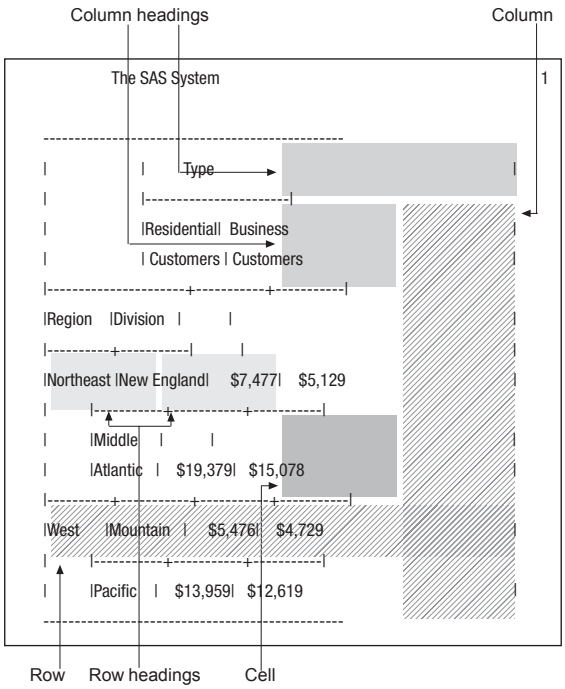

Figure 70.2 *PROC TABULATE Table Dimensions*

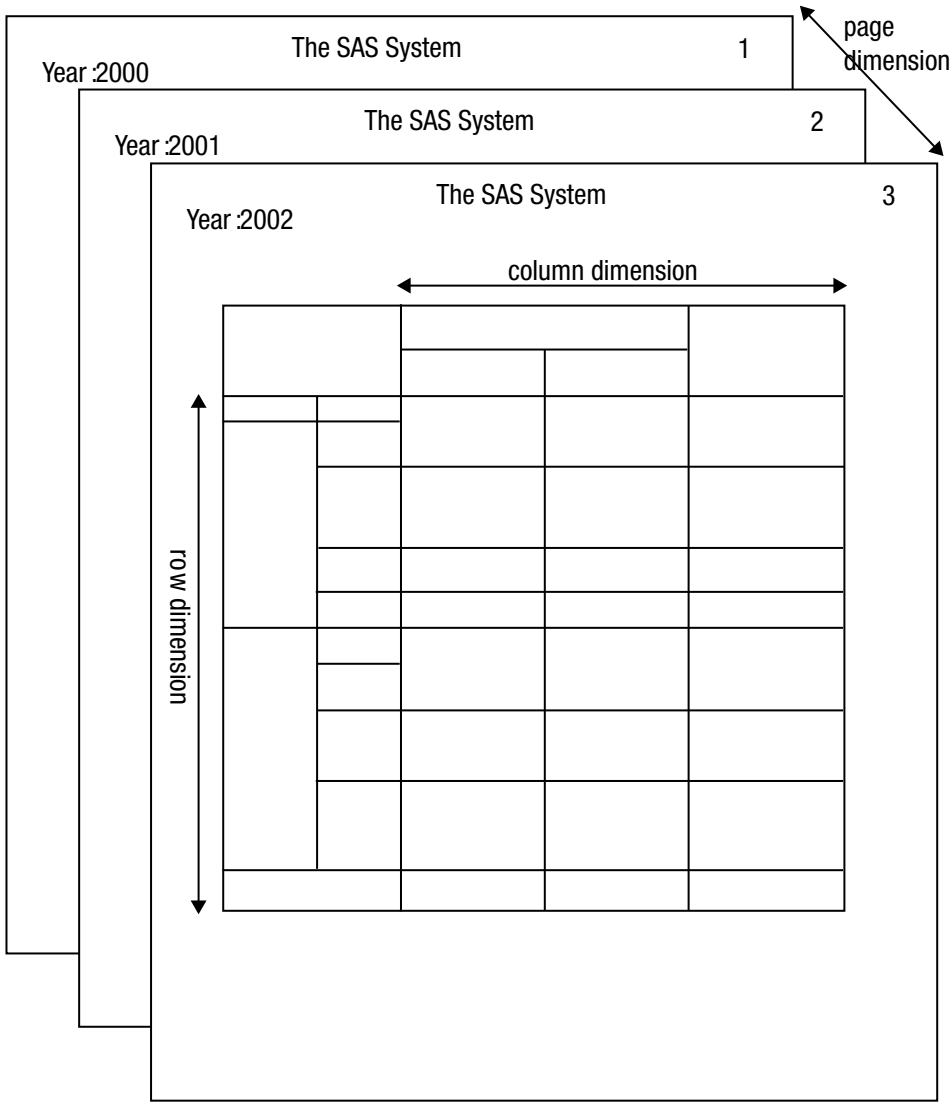


In addition, the following terms frequently appear in discussions of PROC TABULATE:

category
: the combination of unique values of class variables. The TABULATE procedure creates a separate category for each unique combination of values that exists in the observations of the data set. Each category that is created by PROC TABULATE is represented by one or more cells in the table where the pages, rows, and columns that describe the category intersect.

  The table in Figure 70.88 on page 2464 contains three class variables: Region, Division, and Type. These class variables form the eight categories listed in the following table. (For convenience, the categories are described in terms of their formatted values.)

Table 70.1 *Categories Created from Three Class Variables*

Region	Division	Type
Northeast	New England	Residential Customers
Northeast	New England	Business Customers
Northeast	Middle Atlantic	Residential Customers
Northeast	Middle Atlantic	Business Customers
West	Mountain	Residential Customers
West	Mountain	Business Customers
West	Pacific	Residential Customers
West	Pacific	Business Customers

continuation message
: the text that appears below the table if it spans multiple physical pages.

nested variable
: a variable whose values appear in the table with each value of another variable.

  In Figure 70.88 on page 2464, Division is nested under Region.

page dimension text
: the text that appears above the table if the table has a page dimension. However, if you specify BOX=_PAGE_ in the TABLE statement, then the text that would appear above the table appears in the box. In Figure 70.89 on page 2465, the word **`Year:`**, followed by the value, is the page dimension text.

  Page dimension text has a style. The default style is *Beforecaption*. For more information about using styles, see "Using ODS Styles with PROC TABULATE" on page 2522.

subtable
: the group of cells that is produced by crossing a single element from each dimension of the TABLE statement when one or more dimensions contain concatenated elements.

  Figure 70.88 on page 2464 contains no subtables. For an illustration of a table that consists of multiple subtables, see "Example 13: Using Denominator Definitions to Display Basic Frequency Counts and Percentages" on page 2593.

Threaded Processing of Input DATA Sets

The THREADED option enables or disables parallel processing of the input data set. Threaded processing achieves a degree of parallelism in the processing operations. This parallelism is intended to reduce the real time to completion for a given operation and therefore limit the cost of additional CPU resources. For more information, see "Support for Parallel Processing" in *SAS Language Reference: Concepts*.

The value of the SAS system option CPUCOUNT= affects the performance of the threaded sort. CPUCOUNT= suggests how many system CPUs are available for use by the threaded procedures.

For more information, see the "THREADS System Option" in *SAS System Options: Reference* and the "CPUCOUNT= System Option" in *SAS System Options: Reference*.

Calculated statistics can vary slightly, depending on the order in which observations are processed. Such variations are due to numerical errors that are introduced by floating–point arithmetic, the results of which should be considered approximate and not exact. The order of observation processing can be affected by nondeterministic effects of multithreaded or parallel processing. The order of processing can also be affected by inconsistent or nondeterministic ordering of observations that are produced by a data source, such as a DBMS that delivers query results through an ACCESS engine. For more information, see "Numerical Accuracy in SAS Software" in *SAS Language Reference: Concepts* and "Threading in Base SAS" in *SAS Language Reference: Concepts*.

Syntax: TABULATE Procedure

Requirements: At least one TABLE statement is required in a PROC TABULATE procedure step.

Depending on the variables that appear in the TABLE statement, a CLASS statement, a VAR statement, or both are required.

Accessibility note: Starting with SAS 9.4M6, you can use the ACCESSIBLECHECK and ACCESSIBLETABLE system options to check for and create accessible tables. For information about creating accessible PROC TABULATE tables, see "Overview of Table Accessibility " in *Creating Accessible SAS Output Using ODS and ODS Graphics*. in *Creating Accessible SAS Output Using ODS and ODS Graphics*.

Tips: You can use the ATTRIB, FORMAT, LABEL, and WHERE statements with the PROC TABULATE procedure. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73.

For in-database processing to occur, your data must reside within a supported version of a DBMS that has been properly configured for SAS in-database processing. For more information, see "In-Database Processing for PROC TABULATE" on page 2537.

PROC TABULATE <*options*> <STYLE=*style-override(s)*>;

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...> <NOTSORTED>;

CLASS *variable(s)* </ *options*> <STYLE=*style-override(s)* >;

CLASSLEV *variable(s)* </ STYLE=*style-override(s)*>;

FREQ *variable*;

KEYLABEL *keyword-1*='*description-1*' <*keyword-2*='*description-2*' ...>;

KEYWORD *keyword(s)* </ STYLE=*style-override(s)*>;

TABLE <<*page-expression*,> *row-expression*,>
column-expression </ *table-options*>;

VAR *analysis-variable(s)* </ *options*> <STYLE=*style-override(s)*>;

WEIGHT *variable*;

Statement	Task	Example
PROC TABULATE	Display descriptive statistics in tabular format	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 6, Ex. 8, Ex. 12, Ex. 14, Ex. 15
BY	Create a separate table for each BY group	
CLASS	Identify variables in the input data set as class variables	Ex. 3, Ex. 4
CLASSLEV	Specify a style for class variable level value headings	Ex. 14, Ex. 15
FREQ	Identify a variable in the input data set whose values represent the frequency of each observation	
KEYLABEL	Specify a label for a keyword	
KEYWORD	Specify a style for keyword headings	Ex. 14
TABLE	Describe the table to create	Ex. 1, Ex. 3, Ex. 4, Ex. 5, Ex. 6, Ex. 7, Ex. 8, Ex. 9, Ex. 10, Ex. 11, Ex. 12, Ex. 13, Ex. 14, Ex. 15
VAR	Identify variables in the input data set as analysis variables	Ex. 14
WEIGHT	Identify a variable in the input data set whose values weight each observation in the statistical calculations	

PROC TABULATE Statement

Displays descriptive statistics in tabular format.

Syntax

PROC TABULATE <*options*>;

Summary of Optional Arguments

CONTENTS=*link-text* <#BYLINE> <#BYVAL> < #BYVAR>
: specifies the text for the entries in the table of contents.

DATA=*SAS-data-set*
: specifies the input data set.

NOTHREADS
: disables parallel processing of the input data set.

OUT=*SAS-data-set*
: specifies the output data set.

THREADS

NOTHREADS
: overrides the SAS system option THREADS | NOTHREADS.

TRAP
: enables floating point exception recovery.

Control the statistical analysis

ALPHA=*value*
: specifies the confidence level for the confidence limits.

EXCLNPWGT
: excludes observations with nonpositive weights.

QMARKERS=*number*
: specifies the sample size to use for the P^2 quantile estimation method.

QMETHOD=OS | P2
: specifies the quantile estimation method.

QNTLDEF=1 | 2 | 3 | 4 | 5
: specifies the mathematical definition to calculate quantiles.

VARDEF=*divisor*
: specifies the variance divisor.

Customize the appearance of the table

FORMAT=*format-name*
: specifies a default format for each cell in the table.

FORMCHAR <(*position(s)*)>='*formatting-character(s)*'
: defines the characters to use to construct the table outlines and dividers.

NOSEPS
: eliminates horizontal separator lines from the row titles and the body of the table.

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
: orders the values of a class variable according to the specified order.

STYLE=*style-override(s)*
: specifies one or more style overrides to use for specific areas of the table.

Identify categories of data that are of interest

CLASSDATA=*SAS-data-set*
: specifies a secondary data set that contains the combinations of values of class variables to include in tables and output data sets.

EXCLUSIVE
: excludes from tables and output data sets all combinations of class variable values that are not in the CLASSDATA= data set.

MISSING
: considers missing values as valid values for class variables.

Optional Arguments

ALPHA=*value*
specifies the confidence level to compute the confidence limits for the mean. The percentage for the confidence limits is (1–*value*)×100. For example, `ALPHA=.05` results in a 95% confidence limit.

Default .05

Range 0-1

Interaction To compute confidence limits specify the *statistic-keyword* LCLM or UCLM.

CLASSDATA=*SAS-data-set*
specifies a data set that contains the combinations of values of the class variables that must be present in the output. Any combination of values of the class variables appear in each table or output data set and have a frequency of zero if they meet the following criteria:

1. occur in the CLASSDATA= data set
2. but not in the input data set

Restriction The CLASSDATA= data set must contain all class variables. Their data type and format must match the corresponding class variables in the input data set.

Interaction If you use the EXCLUSIVE option, then PROC TABULATE excludes any observations in the input data set whose combinations of values of class variables are not in the CLASSDATA= data set.

Tip Use the CLASSDATA= data set to filter or supplement the input data set.

Example "Example 2: Specifying Class Variable Combinations to Appear in a Table" on page 2553

CONTENTS=*link-text* <#BYLINE> <#BYVAL> < #BYVAR>
specifies the text for the entries in the table of contents created by default or by options settings in ODS destinations that support the STYLE= option.

Starting with SAS 9.4M6, these options are available if a BY statement is in effect:

#BYLINE
substitutes the entire BY line without leading or trailing blanks for #BYLINE in the text string. The BY line uses the format *variable-name=value*.

#BYVAL*n*
#BYVAL(*BY-variable-name*)
substitutes the current value of the specified BY variable for #BYVAL in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAL2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAL(YEAR) specifies the BY variable, YEAR. *Variable-name* is not case sensitive.

#BYVAR*n*
#BYVAR(*BY-variable-name*)
substitutes the name of the BY-variable or the label associated with the variable (whatever the BY line would normally display) for #BYVAR in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAR2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAR(SITES) specifies the BY variable, SITES. *Variable-name* is not case sensitive.

See "Substituting BY Line Values in a Text String" on page 2538

DATA=*SAS-data-set*
specifies the input data set.

See "Input Data Sets" on page 26

EXCLNPWGT
excludes observations with nonpositive weight values (zero or negative) from the analysis. By default, PROC TABULATE treats observations with negative weights like observations with zero weights and counts them in the total number of observations.

Alias EXCLNPWGTS

See "WEIGHT=*weight-variable*" on page 2513 and "WEIGHT Statement" on page 2514

EXCLUSIVE
excludes from the tables and the output data sets all combinations of the class variable that are not found in the CLASSDATA= data set.

Requirement If a CLASSDATA= data set is not specified, then the EXCLUSIVE option is ignored.

Example "Example 2: Specifying Class Variable Combinations to Appear in a Table" on page 2553

FORMAT=*format-name*
specifies a default format for the value in each table cell. You can use any SAS or user-defined format.

Alias F=

Default If you omit FORMAT=, then PROC TABULATE uses BEST12.2 as the default format.

Interaction Formats that are specified in a TABLE statement override the format that is specified with FORMAT=.

Tip The FORMAT= option is especially useful for controlling the number of print positions that are used to print a table.

Examples "Example 1: Creating a Basic Two-Dimensional Table" on page 2550

"Example 6: Summarizing Information with the Universal Class Variable ALL" on page 2566

FORMCHAR <(*position(s)*)>='*formatting-character(s)*'
defines the characters to use for constructing the table outlines and dividers.

position(s)
identifies the position of one or more characters in the SAS formatting-character string. A space or a comma separates the positions.

Default Omitting *position(s)* is the same as specifying all 20 possible SAS formatting characters, in order.

formatting-character(s)
lists the characters to use for the specified positions.

PROC TABULATE assigns characters in *formatting-character(s)* to *position(s)*, in the order in which they are listed. For example, the following

option assigns the asterisk (*) to the third formatting character, the number sign (#) to the seventh character, and does not alter the remaining characters:

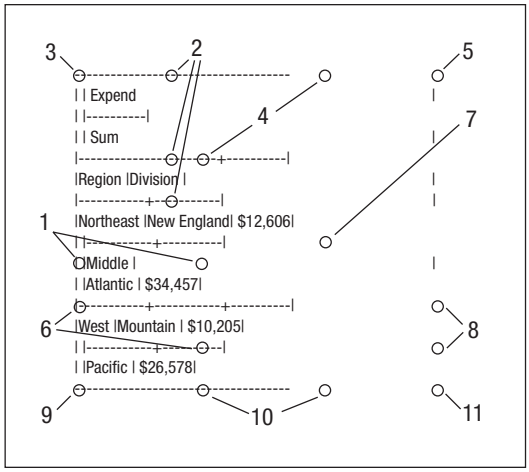
```
formchar(3,7)='*#'
```

PROC TABULATE uses 11 of the 20 formatting characters that SAS provides. Table 70.128 on page 2473 shows the formatting characters that PROC TABULATE uses. Figure 70.90 on page 2474 illustrates the use of each formatting character in the output from PROC TABULATE.

Table 70.2 *Formatting Characters Used by PROC TABULATE*

Position	Default	Used to Draw
1	|	Right and left borders and the vertical separators between columns
2	-	Top and bottom borders and the horizontal separators between rows
3	-	Top character in the left border
4	-	Top character in a line of characters that separate columns
5	-	Top character in the right border
6	|	Leftmost character in a row of horizontal separators
7	+	Intersection of a column of vertical characters and a row of horizontal characters
8	|	Rightmost character in a row of horizontal separators
9	-	Bottom character in the left border
10	-	Bottom character in a line of characters that separate columns
11	-	Bottom character in the right border

Figure 70.3 *Formatting Characters in PROC TABULATE Output*



Restriction The FORMCHAR= option affects only the traditional SAS monospace output destination.

Interaction The SAS system option FORMCHAR= specifies the default formatting characters. The system option defines the entire string of formatting characters. The FORMCHAR= option in a procedure can redefine selected characters.

Tips You can use any character in *formatting-characters*, including hexadecimal characters. If you use hexadecimal characters, then you must put `x` after the closing quotation mark. For example, the following option assigns the hexadecimal character 2-D to the third formatting character, assigns the hexadecimal character 7C to the seventh character, and does not alter the remaining characters:

```
formchar(3,7)='2D7C'x
```

Specifying all blanks for *formatting-character(s)* produces tables with no outlines or dividers.

```
formchar(1,2,3,4,5,6,7,8,9,10,11)          ='           '
```

(11 blanks)

See For more examples using formatting output, see *PROC TABULATE by Example, Second Edition*.

For information about which hexadecimal codes to use for which characters, consult the documentation for your hardware.

MISSING

considers missing values as valid values to create the combinations of class variables. Special missing values that are used to represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a separate value. A heading for each missing value appears in the table.

Default If you omit MISSING, then PROC TABULATE does not include observations with a missing value for any class variable in the report.

See "Including Observations with Missing Class Variables" on page 2543

"Creating Special Missing Values" in *SAS Language Reference: Concepts* for a discussion of missing values that have special meaning.

NOSEPS
eliminates horizontal separator lines from the row titles and the body of the table. Horizontal separator lines remain between nested column headings.

Restriction The NOSEPS option affects only the traditional SAS monospace output destination.

Tip If you want to replace the separator lines with blanks rather than remove them, then use option "FORMCHAR <(*position(s)*)>='*formatting-character(s)*' " on page 2472.

Example "Example 8: Indenting Row Headings and Eliminating Horizontal Separators" on page 2571

NOTHREADS
disables parallel processing of the input data set. See "THREADS | NOTHREADS" on page 2480.

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
specifies the sort order to create the unique combinations of the values of the class variables, which form the headings of the table, according to the specified order.

DATA
orders values according to their order in the input data set.

Interaction If you use PRELOADFMT in the CLASS statement, then the order for the values of each class variable matches the order that PROC FORMAT uses to store the values of the associated user-defined format. If you use the CLASSDATA= option, then PROC TABULATE uses the order of the unique values of each class variable in the CLASSDATA= data set to order the output levels. If you use both options, then PROC TABULATE first uses the user-defined formats to order the output. If you omit EXCLUSIVE, then PROC TABULATE appends after the user-defined format and the CLASSDATA= values the unique values of the class variables in the input data set in the same order in which they are encountered.

Tips By default, PROC FORMAT stores a format definition in sorted order. Use the NOTSORTED option to store the values or ranges of a user-defined format in the order in which you define them.

When you are using in-database procedures with the ORDER=DATA option, the results can vary. DBMS tables have no inherent order for the rows. The order of rows written to a database table from a SAS procedure is not likely to be preserved.

FORMATTED
orders values by their ascending formatted values. If no format has been assigned to a numeric class variable, then the default format, BEST12., is used. This order depends on your operating environment.

Aliases FMT

EXTERNAL

FREQ
orders values by descending frequency count.

Interaction Use the ASCENDING option in the CLASS statement to order values by ascending frequency count.

UNFORMATTED
orders values by their unformatted values. This order depends on your operating environment. This sort sequence is particularly useful for displaying dates chronologically.

Specifying ORDER=UNFORMATTED usually, but not always, produces the same results as PROC SORT. For more information about ordering data, see "Controlling the Order of Data Values" on page 27.

Aliases UNFMT

INTERNAL

Default UNFORMATTED

Interaction If you use the PRELOADFMT option in the CLASS statement, then PROC TABULATE orders the levels by the order of the values in the user-defined format.

Example "Understanding the Order of Headings with ORDER=DATA" on page 2548

OUT=*SAS-data-set*
names the output data set. If *SAS-data-set* does not exist, then PROC TABULATE creates it.

The number of observations in the output data set depends on the number of categories of data that are used in the tables and the number of subtables that are generated. The output data set contains these variables (in the following order):

by variables	variables that are listed in the BY statement.
class variables	variables that are listed in the CLASS statement.
TYPE	a character variable that shows which combination of class variables produced the summary statistics in that observation. Each position in _TYPE_ represents one variable in the CLASS statement. If that variable is in the category

that produced the statistic, then the position contains a 1. Otherwise, the position contains a 0. In simple PROC TABULATE steps that do not use the universal class variable ALL, all values of _TYPE_ contain only 1s because the only categories that are being considered involve all class variables. If you use the variable ALL, then your tables will contain data for categories that do not include all the class variables, and positions of _TYPE_ will, therefore, include both 1s and 0s.

PAGE The logical page that contains the observation.

TABLE The number of the table that contains the observation.

statistics statistics that are calculated for each observation in the data set.

Example "Example 3: Using Preloaded Formats with Class Variables" on page 2556

QMARKERS=*number*

specifies the default number of markers to use for the P^2 quantile estimation method. The number of markers controls the size of fixed memory space.

Default The default value depends on which quantiles you request. For the median (P50), *number* is 7. For the quartiles (P25 and P75), *number* is 25. For the quantiles P1, P5, P10, P90, P95, or P99, *number* is 105. If you request several quantiles, then PROC TABULATE uses the largest default value of *number*.

Range any odd integer greater than 3

Tip Increase the number of markers above the default settings to improve the accuracy of the estimates; reduce the number of markers to conserve memory and computing time.

See "Quantiles" on page 1512

QMETHOD=OS | P2

specifies the method PROC TABULATE uses to process the input data when it computes quantiles. If the number of observations is less than or equal to the QMARKERS= value and QNTLDEF=5, then both methods produce the same results.

OS

uses order statistics. PROC UNIVARIATE uses this technique.

Note: This technique can be very memory-intensive.

P2

uses the P^2 method to approximate the quantile.

Alias HIST

Default OS

Restriction When QMETHOD=P2, PROC TABULATE will not compute MODE or weighted quantiles.

Tip When QMETHOD=P2, reliable estimates of some quantiles (P1, P5, P95, P99) might not be possible for some types of data.

See "Quantiles" on page 1512

QNTLDEF=1 | 2 | 3 | 4 | 5
specifies the mathematical definition that the procedure uses to calculate quantiles when QMETHOD=OS is specified. When QMETHOD=P2, you must use QNTLDEF=5.

Alias PCTLDEF=

Default 5

See "Quantile and Related Statistics" on page 2706

STYLE=*style-override(s)*
specifies one or more style overrides to use for the data cells of a table. For example, the following statement specifies that the background color for data cells is red:

```
proc tabulate data=one style=[backgroundcolor=red];
```

style-override
specifies one or more style attributes or style elements to override the default style element and attributes in a specific area of a report.

You can specify a style override in three ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.
- Specify the PARENT value. The PARENT value specifies that the data cell use the style element of its parent heading.

style-override has the following form:

PARENT | *style-element-name* | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

<PARENT>
specifies that the data cell use the style element of its parent heading.

The parent style element of a data cell is one of the following:

- the style element of the leaf heading above the column that contains the data cell, if the table specifies no row dimension, or if the table specifies the style element in the column dimension expression

- the style element of the leaf heading above the row that contains the cell, if the table specifies the style element in the row dimension expression
- the Beforecaption style element, if the table specifies the style element in the page dimension expression
- undefined, otherwise

Note: In this usage, the angle brackets around the word PARENT are required. Braces or square brackets cannot be substituted in the syntax.

Note: The parent of a heading (not applicable to STYLE= in the PROC TABULATE statement) is the heading under which the current heading is nested.

style-attribute-name
specifies the attribute to change.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-attribute-value
specifies a value for the attribute. Each attribute has a different set of valid values. A SAS format can also be used as an attribute value for conditional formatting.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For information about using SAS formats as style attribute values, see "Using a Format to Assign a Style Attribute" on page 2534.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-element-name
is the name of a style element that is part of an ODS style template.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

Alias S=

Tips The STYLE= option can be used in other statements, or in dimension expressions, to specify style elements for other parts of a table.

To specify a style element for data cells with missing values, use STYLE= in the TABLE statement MISSTEXT= option.

You can use braces ({ and }) instead of square brackets ([and]).

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

Example "Example 14: Specifying Style Overrides for ODS Output" on page 2607

THREADS | NOTHREADS

enables or disables parallel processing of the input data set. This option overrides the SAS system option THREADS | NOTHREADS unless the system option is restricted. (For more information, see "Support for Parallel Processing" in *SAS Language Reference: Concepts*.)

Default value of SAS system option THREADS | NOTHREADS.

Restriction Your site administrator can create a restricted options table. A restricted options table specifies SAS system option values that are established at start-up and cannot be overridden. If the THREADS | NOTHREADS system option is listed in the restricted options table, any attempt to set these system options is ignored and a warning message is written to the SAS log.

Interaction PROC TABULATE uses the value of the SAS system option THREADS except when a BY statement is specified or the value of the SAS system option CPUCOUNT is less than 2. In those cases, you can specify the THREADS option in the PROC TABULATE statement to force PROC TABULATE to use parallel processing. When multi-threaded processing, also known as parallel processing, is in effect, observations might be returned in an unpredictable order. However, the observations are sorted correctly if a BY statement is specified.

TRAP

enables floating point exception (FPE) recovery during data processing beyond the recovery that is provided by normal SAS FPE handling. Note that without the TRAP option, normal SAS FPE handling is still in effect so that PROC TABULATE terminates in the case of math exceptions.

VARDEF=*divisor*

specifies the divisor to use in the calculation of the variance and standard deviation. The following table shows the possible values for *divisor* and the associated divisors.

Table 70.3 Possible Values for VARDEF=

Value	Divisor	Formula for Divisor
DF	Degrees of freedom	$n - 1$
N	Number of observations	n
WDF	Sum of weights minus one	$(\Sigma_i w_i) - 1$
WEIGHT | WGT	Sum of weights	$\Sigma_i w_i$

The procedure computes the variance as $CSS/divisor$, where CSS is the corrected sums of squares and equals $\Sigma (x_i - \overline{x})^2$. When you weight the analysis variables, CSS equals $\Sigma w_i(x_i - \overline{x}_w)^2$ where $\overline{x}_w$ is the weighted mean.

Default DF

Requirement To compute standard error of the mean, use the default value of VARDEF=.

Tips When you use the WEIGHT statement and VARDEF=DF, the variance is an estimate of σ^2, where the variance of the *i*th observation is $var(x_i) = \sigma^2/w_i$, and w_i is the weight for the *i*th observation. This yields an estimate of the variance of an observation with unit weight.

When you use the WEIGHT statement and VARDEF=WGT, the computed variance is asymptotically (for large *n*) an estimate of $\sigma^2/\overline{w}$, where $\overline{w}$ is the average weight. This yields an asymptotic estimate of the variance of an observation with average weight.

See "Weighted Statistics Example" on page 84

BY Statement

Creates a separate table for each BY group.

Accessibility note: When BY statements are specified, default labels for the BY group tables are displayed in the table of contents in PDF and RTF output, the contents file in HTML output, the trace record created by the ODS TRACE statement, and the entry list created by the LIST statement in PROC DOCUMENT. The labels are based on the values of the BY variable. For an example of creating a table with default BY group labels, see "Overview of Table Accessibility " in *Creating Accessible SAS Output Using ODS and ODS Graphics* .

See: "BY" on page 74

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...> <NOTSORTED>;

Required Argument

variable
You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then the observations in the data set must either be sorted by all the variables that you specify, or they must be indexed appropriately. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the observations are sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. For example, the observations are grouped in chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

CLASS Statement

Identifies class variables for the table. Class variables determine the categories that PROC TABULATE uses to calculate statistics.

Note: CLASS statements without options use the internal default or the value specified by an option in the PROC TABULATE statement. For example, in the following code, variables c and d would use the internal default. If an ORDER= option had been specified in the PROC TABULATE statement, then variables c and d would use the value specified by the ORDER= option in the PROC TABULATE statement.

```
class a b / order=data;
class c d;
```

Tips: You can use multiple CLASS statements.

Some CLASS statement options are also available in the PROC TABULATE statement. They affect all CLASS variables rather than just the ones that you specify in a CLASS statement.

Examples: "Example 3: Using Preloaded Formats with Class Variables" on page 2556
"Example 4: Using Multilabel Formats" on page 2560

Syntax

CLASS *variable(s)* </ *options*>;

Summary of Optional Arguments

ASCENDING
: specifies to sort the class variable values in ascending order.

DESCENDING
: specifies to sort the class variable values in descending order.

EXCLUSIVE
: excludes from tables and output data sets all combinations of class variables that are not found in the preloaded range of user-defined formats.

GROUPINTERNAL
: specifies not to apply formats to the class variables when PROC TABULATE groups the values to create combinations of class variables.

MISSING
: considers missing values as valid class variable levels. Special missing values that represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a separate value.

MLF
: enables PROC TABULATE to use the format label or labels for a given range or overlapping ranges to create subgroup combinations when a multilabel format is assigned to a class variable.

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
: specifies the order to group the levels of the class variables in the output.

PRELOADFMT
: specifies that all formats are preloaded for the class variables.

STYLE=*style-override*
: specifies one or more style overrides to use for page dimension text and class variable name headings.

Required Argument

variable(s)
: specifies one or more variables that the procedure uses to group the data. Variables in a CLASS statement are referred to as *class variables*. Class variables can be numeric or character. Class variables can have continuous

values, but they typically have a few discrete values that define the classifications of the variable. You do not have to sort the data by class variables.

Interaction If a variable name and a statistic name are the same, enclose the statistic name in single or double quotation marks.

Optional Arguments

ASCENDING
specifies to sort the class variable values in ascending order.

Alias ASCEND

Interaction PROC TABULATE issues a warning message if you specify both ASCENDING and DESCENDING and ignores both options.

DESCENDING
specifies to sort the class variable values in descending order.

Alias DESCEND

Default ASCENDING

Interaction PROC TABULATE issues a warning message if you specify both ASCENDING and DESCENDING and ignores both options.

EXCLUSIVE
excludes from tables and output data sets all combinations of class variables that are not found in the preloaded range of user-defined formats.

Requirement You must specify the PRELOADFMT option in the CLASS statement to preload the class variable formats.

Example "Example 3: Using Preloaded Formats with Class Variables" on page 2556

GROUPINTERNAL
specifies not to apply formats to the class variables when PROC TABULATE groups the values to create combinations of class variables.

Interactions If you specify the PRELOADFMT option in the CLASS statement, then PROC TABULATE ignores the GROUPINTERNAL option and uses the formatted values.

If you specify the ORDER=FORMATTED option, then PROC TABULATE ignores the GROUPINTERNAL option and uses the formatted values.

Tip The GROUPINTERNAL option saves computer resources when the class variables contain discrete numeric values.

MISSING
considers missing values as valid class variable levels. Special missing values that represent numeric values (the letters A through Z and the underscore (_) character) are each considered as a separate value.

Default If you omit the MISSING option, then PROC TABULATE excludes the observations with any missing CLASS variable values from tables and output data sets.

See "Creating Special Missing Values" in *SAS Language Reference: Concepts* for a discussion of missing values with special meanings.

MLF
enables PROC TABULATE to use the format label or labels for a given range or overlapping ranges to create subgroup combinations when a multilabel format is assigned to a class variable.

Note: When the formatted values overlap, one internal class variable value maps to more than one class variable subgroup combination. Therefore, the sum of the N statistics for all subgroups is greater than the number of observations in the data set (the overall N statistic).

Requirement You must use PROC FORMAT and the MULTILABEL option in the VALUE statement to create a multilabel format.

Interactions Using MLF with ORDER=FREQ might not produce the order that you expect for the formatted values.

When you specify MLF, the formatted values of the class variable become internal values. Therefore, specifying ORDER=FORMATTED produces the same results as specifying ORDER=UNFORMATTED.

Tip If you omit MLF, then PROC TABULATE uses the primary format labels, which correspond to the first external format value, to determine the subgroup combinations.

See "MULTILABEL" on page 1124 in the VALUE statement of the FORMAT procedure.

Example "Example 4: Using Multilabel Formats" on page 2560

ORDER=DATA | FORMATTED | FREQ | UNFORMATTED
specifies the order to group the levels of the class variables in the output.

DATA
orders values according to their order in the input data set.

Interaction If you use PRELOADFMT, then the order for the values of each class variable matches the order that PROC FORMAT uses to store the values of the associated user-defined format. If you use the CLASSDATA= option in the PROC statement, then PROC TABULATE uses the order of the unique values of each class variable in the CLASSDATA= data set to order the output levels.

If you use both options, then PROC TABULATE first uses the user-defined formats to order the output. If you omit EXCLUSIVE in the PROC statement, then PROC TABULATE places, in the order in which they are encountered, the unique values of the class variables that are in the input data set after the user-defined format and the CLASSDATA= values.

Tip By default, PROC FORMAT stores a format definition in sorted order. Use the NOTSORTED option to store the values or ranges of a user-defined format in the order in which you define them.

FORMATTED
orders values by their ascending formatted values. This order depends on your operating environment.

Aliases FMT

EXTERNAL

FREQ
orders values by descending frequency count.

Interaction Use the ASCENDING option to order values by ascending frequency count.

UNFORMATTED
orders values by their unformatted values. This order depends on your operating environment. This sort sequence is particularly useful for displaying dates chronologically.

Specifying ORDER=UNFORMATTED usually, but not always, produces the same results as PROC SORT. For more information about ordering data, see "Controlling the Order of Data Values" on page 27.

Aliases UNFMT

INTERNAL

Default UNFORMATTED

Interaction If you use the PRELOADFMT option in the CLASS statement, then PROC TABULATE orders the levels by the order of the values in the user-defined format.

Tip By default, all orders except FREQ are ascending. For descending orders, use the DESCENDING option.

Example "Understanding the Order of Headings with ORDER=DATA" on page 2548

PRELOADFMT
specifies that all formats are preloaded for the class variables.

Requirement PRELOADFMT has no effect unless you specify EXCLUSIVE, ORDER=DATA, or PRINTMISS and you assign formats to the class

variables. If you specify PRELOADFMT without also specifying EXCLUSIVE, ORDER=DATA, or PRINTMISS, then SAS writes a warning message to the SAS log.

Interactions To limit PROC TABULATE output to the combinations of formatted class variable values present in the input data set, use the EXCLUSIVE option in the CLASS statement.

To include all ranges and values of the user-defined formats in the output, use the PRINTMISS option in the TABLE statement. Use care when you use PRELOADFMT with PRINTMISS. This feature creates all possible combinations of formatted class variables. Some of these combinations might not make sense.

Note When preloading a character format, there must be at least one representative raw value that produces the label. If a range does not have any raw values, the range is considered unreachable and an error is generated. For example, you cannot preload a multi-label character format with both Other= and Low-High ranges. Other is a special keyword that refers to values or ranges that remain after all labels have been defined. For character formats, missing values are included in the low range so that there are no raw values left to occupy the Other range.

Example "Example 3: Using Preloaded Formats with Class Variables" on page 2556

STYLE=*style-override*

specifies one or more style overrides to use for page dimension text and class variable name headings. For example, the following statement specifies that the background color for page dimension text and class variable name headings is light green:

```
class region division prodtype / style=[background=lightgreen];
```

style-override

specifies one or more style attributes or style elements to override the default style element and attributes in a specific area of a report.

You can specify a style override in three ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.
- Specify the PARENT value. The PARENT value specifies that the data cell use the style element of its parent heading.

style-override has the following form:

PARENT | *style-element-name* | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

<PARENT>
specifies that the data cell use the style element of its parent heading.

The parent style element of a data cell is one of the following:

- the style element of the leaf heading above the column that contains the data cell, if the table specifies no row dimension, or if the table specifies the style element in the column dimension expression
- the style element of the leaf heading above the row that contains the cell, if the table specifies the style element in the row dimension expression
- the Beforecaption style element, if the table specifies the style element in the page dimension expression
- undefined, otherwise

Note: In this usage, the angle brackets around the word PARENT are required. Braces or square brackets cannot be substituted in the syntax.

Note: The parent of a heading (not applicable to STYLE= in the PROC TABULATE statement) is the heading under which the current heading is nested.

style-attribute-name
specifies the attribute to change.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-attribute-value
specifies a value for the attribute. Each attribute has a different set of valid values. A SAS format can also be used as an attribute value for conditional formatting.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For information about using SAS formats as style attribute values, see "Using a Format to Assign a Style Attribute" on page 2534.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-element-name
is the name of a style element that is part of an ODS style template.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

Alias S=

Tips To override a style element that is specified for page dimension text in the CLASS statement, you can specify a style element in the TABLE statement page dimension expression.

To override a style element that is specified for a class variable name heading in the CLASS statement, you can specify a style element in the related TABLE statement dimension expression.

If a page dimension expression contains multiple nested elements, then the Beforecaption style element is the style element of the first element in the nesting.

The use of STYLE= in the CLASS statement differs slightly from its use in the PROC TABULATE statement. In the CLASS statement, inheritance is different for rows and columns. For rows, the parent heading is located to the left of the current heading. For columns, the parent heading is located above the current heading.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

Example "Example 14: Specifying Style Overrides for ODS Output" on page 2607

Details

How PROC TABULATE Handles Missing Values for Class Variables

By default, if an observation contains a missing value for any class variable, then PROC TABULATE excludes that observation from all tables that it creates. CLASS statements apply to all TABLE statements in the PROC TABULATE step. Therefore, if you define a variable as a class variable, then PROC TABULATE omits observations that have missing values for that variable from every table even if the variable does not appear in the TABLE statement for one or more tables.

If you specify the MISSING option in the PROC TABULATE statement, then the procedure considers missing values as valid levels for all class variables. If you specify the MISSING option in a CLASS statement, then PROC TABULATE considers missing values as valid levels for the class variables that are specified in that CLASS statement.

CLASSLEV Statement

Specifies a style element for class variable level value headings.

Examples: "Example 14: Specifying Style Overrides for ODS Output" on page 2607
"Example 15: Style Precedence" on page 2612

Syntax

CLASSLEV *variable(s)* </ STYLE=*style-override(s)*>;

Required Argument

variable(s)
specifies one or more class variables from the CLASS statement for which you want to specify a style element.

Optional Argument

STYLE=*style-override*
specifies one or more style overrides for class variable level value headings. For example, the following statement specifies that the background color for class variable level name headings is yellow:

```
classlev region division prodtype  / style=[background=yellow];
```

style-override
specifies one or more style attributes or style elements to override the default style element and attributes in a specific area of a report.

You can specify a style override in three ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.
- Specify the PARENT value. The PARENT value specifies that the data cell use the style element of its parent heading.

style-override has the following form:

PARENT | *style-element-name* | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

<PARENT>
specifies that the data cell use the style element of its parent heading.

The parent style element of a data cell is one of the following:

- the style element of the leaf heading above the column that contains the data cell, if the table specifies no row dimension, or if the table specifies the style element in the column dimension expression
- the style element of the leaf heading above the row that contains the cell, if the table specifies the style element in the row dimension expression
- the Beforecaption style element, if the table specifies the style element in the page dimension expression
- undefined, otherwise

Note: In this usage, the angle brackets around the word PARENT are required. Braces or square brackets cannot be substituted in the syntax.

Note: The parent of a heading (not applicable to STYLE= in the PROC TABULATE statement) is the heading under which the current heading is nested.

style-attribute-name
specifies the attribute to change.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-attribute-value
specifies a value for the attribute. Each attribute has a different set of valid values. A SAS format can also be used as an attribute value for conditional formatting.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For information about using SAS formats as style attribute values, see "Using a Format to Assign a Style Attribute" on page 2534.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-element-name
is the name of a style element that is part of an ODS style template.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

Alias S=

Tips The use of STYLE= in the CLASSLEV statement differs slightly from its use in the PROC TABULATE statement. In the CLASSLEV statement, inheritance is different for rows and columns. For rows, the parent heading is located to the left of the current heading. For columns, the parent heading is located above the current heading.

To override a style element that is specified in the CLASSLEV statement, you can specify a style element in the related TABLE statement dimension expression.

You can use braces ({ and }) instead of square brackets ([and]).

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

Example "Example 14: Specifying Style Overrides for ODS Output" on page 2607

FREQ Statement

Specifies a numeric variable that contains the frequency of each observation.

Tip: The effects of the FREQ and WEIGHT statements are similar except when calculating degrees of freedom.

Example: "FREQ" on page 79

Syntax

FREQ *variable*;

Required Argument

variable
specifies a numeric variable whose value represents the frequency of the observation.

If you use the FREQ statement, then the procedure assumes that each observation represents *n* observations, where *n* is the value of *variable*. If *n* is not an integer, then SAS truncates it. If *n* is less than 1 or is missing, then the procedure does not use that observation to calculate statistics.

The sum of the frequency variable represents the total number of observations.

KEYLABEL Statement

Labels a keyword for the duration of the PROC TABULATE step. PROC TABULATE uses the label anywhere that the specified keyword would otherwise appear.

Syntax

KEYLABEL *keyword-1*='*description-1*' <*keyword-2*='*description-2*' ...>;

Required Arguments

keyword
specifies a statistic keyword.

keyword can be one of the keywords for statistics that is discussed in "Statistics That Are Available in PROC TABULATE" on page 2515 or is the universal class variable ALL. (See "Elements That You Can Use in a Dimension Expression" on page 2507.)

description
specifies the keyword label.

Length	256 characters
Restriction	Each keyword can have only one label in a particular PROC TABULATE step. If you request multiple labels for the same keyword, then PROC TABULATE uses the last one that is specified in the step.
Requirement	You must enclose *description* in quotation marks

KEYWORD Statement

Specifies a style element for keyword headings.

Example: "Example 14: Specifying Style Overrides for ODS Output" on page 2607

Syntax

KEYWORD *keyword(s)* </ STYLE=*style-override(s)*>;

Required Argument

keyword
specifies the keyword statistic.

keyword can be one of the keywords for statistics that is discussed in "Statistics That Are Available in PROC TABULATE" on page 2515 or is the universal class variable ALL. (See "Elements That You Can Use in a Dimension Expression" on page 2507.)

Optional Argument

STYLE=*style-override*
specifies one or more style overrides for the keyword headings.

For example, the following statement specifies that the background color for keyword headings is linen:

```
keyword all sum / style=[background=linen];
```

style-override
specifies one or more style attributes or style elements to override the default style element and attributes in a specific area of a report.

You can specify a style override in three ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.
- Specify the PARENT value. The PARENT value specifies that the data cell use the style element of its parent heading.

style-override has the following form:

PARENT | *style-element-name* | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

<PARENT>
specifies that the data cell use the style element of its parent heading.

The parent style element of a data cell is one of the following:

- the style element of the leaf heading above the column that contains the data cell, if the table specifies no row dimension, or if the table specifies the style element in the column dimension expression
- the style element of the leaf heading above the row that contains the cell, if the table specifies the style element in the row dimension expression
- the Beforecaption style element, if the table specifies the style element in the page dimension expression
- undefined, otherwise

Note: In this usage, the angle brackets around the word PARENT are required. Braces or square brackets cannot be substituted in the syntax.

Note: The parent of a heading (not applicable to STYLE= in the PROC TABULATE statement) is the heading under which the current heading is nested.

style-attribute-name
specifies the attribute to change.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-attribute-value
specifies a value for the attribute. Each attribute has a different set of valid values. A SAS format can also be used as an attribute value for conditional formatting.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For information about using SAS formats as style attribute values, see "Using a Format to Assign a Style Attribute" on page 2534.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-element-name
is the name of a style element that is part of an ODS style template.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

Alias S=

Tips The use of STYLE= in the KEYWORD statement differs slightly from its use in the PROC TABULATE statement. In the KEYWORD statement, inheritance is different for rows and columns. For rows, the parent heading is located to the left of the current heading. For columns, the parent heading is located above the current heading.

To override a style element that is specified in the KEYWORD statement, you can specify a style element in the related TABLE statement dimension expression.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

Example "Example 14: Specifying Style Overrides for ODS Output" on page 2607

TABLE Statement

Describes a table to be printed.

Requirement: All variables in the TABLE statement must appear in either the VAR statement or the CLASS statement.

Tips: To create several tables use multiple TABLE statements.

Use of variable name list shortcuts is now supported within the TABLE statement. For more information, see "Shortcuts for Specifying Lists of Variable Names" on page 62.

Syntax

TABLE <<*page-expression*,> *row-expression*,>
column-expression </ *table-options*>;

Summary of Optional Arguments

BOX={<*label=value*> <**STYLE=*style-override(s)***>}
: specifies text and a style override for the empty box above the row titles.

BOX=*value*
: specifies text for the empty box above the row titles.

CAPTION= *text*<#BYLINE> <#BYVAL><#BYVAR>
: specifies a caption text string to add before each table.

CONDENSE
: prints as many complete logical pages as possible on a single printed page or, if possible, prints multiple pages of tables that are too wide to fit on a page one below the other on a single page, instead of on separate pages.

CONTENTS=*link-text* <#BYLINE> <#BYVAL> <#BYVAR>
: enables you to name the link in the HTML table of contents that points to the ODS output of the table that is produced by using the TABLE statement.

FORMAT_PRECEDENCE=PAGE | ROW | COLUMN
: specifies whether the format that is specified for the page dimension (PAGE), row dimension (ROW), or column dimension (COLUMN) is applied to the contents of the table cells.

FUZZ=*number*
: supplies a numeric value against which analysis variable values and table cell values other than frequency counts are compared to eliminate trivial values (absolute values less than the FUZZ= value) from computation and printing.

INDENT=*number-of-spaces*
: specifies the number of spaces to indent nested row headings, and suppresses the row headings for class variables.

MISSTEXT='*text*'
: supplies up to 256 characters of text to be printed for table cells that contain missing values.

MISSTEXT={<*label*='*text*'> <STYLE=*style-override(s)*>}
: supplies up to 256 characters of text to be printed and specifies a style override for table cells that contain missing values.

NOCELLMERGE
: specifies that data cells are not merged with other data cells in the table.

NOCONTINUED
: suppresses the continuation message, **continued**, that is displayed at the bottom of tables that span multiple pages.

page-expression
: defines the pages in a table.

PRINTMISS
: prints all values that occur for a class variable each time headings for that variable are printed, even if there are no data for some of the cells that these headings create.

ROW=CONSTANT | FLOAT
: specifies whether all title elements in a row crossing are allotted space even when they are blank.

row-expression
: defines the rows in the table.

RTSPACE=*number*
: specifies the number of print positions to allot to all of the headings in the row dimension, including spaces that are used to print outlining characters for the row headings.

STYLE_PRECEDENCE=PAGE | ROW | COLUMN
: specifies whether the style that is specified for the page dimension (PAGE), row dimension (ROW), or column dimension (COLUMN or COL) is applied to the contents of the table cells.

STYLE=*style-override*
: specifies one or more style overrides to use for parts of the table other than table cells.

Required Argument

column-expression
defines the columns in the table. For information about constructing dimension expressions, see "Details" on page 2507.

Restriction A column dimension is the last dimension in a TABLE statement. A row dimension or a row dimension and a page dimension can precede a column dimension.

Optional Arguments

page-expression
defines the pages in a table. For information about constructing dimension expressions, see "Details" on page 2507.

Restrictions A page dimension is the first dimension in a table statement. Both a row dimension and a column dimension must follow a page dimension.

If the ACCESSIBLETABLE=ON system option is specified and the TABULATE table has page dimension text, then that text is the accessible caption. Otherwise use the CAPTION=/ CONTENTS= text.

Accessibility note Starting with SAS 9.4M6, you can use the ACCESSIBLECHECK and ACCESSIBLETABLE system options to check for and create accessible tables. For information about creating accessible PROC TABULATE tables, see "Overview of Table Accessibility " in *Creating Accessible SAS Output Using ODS and ODS Graphics* . If the ACCESSIBLETABLE=ON system option is specified and the TABULATE table has page dimension text, then that text is the accessible caption.

Example "Example 9: Creating Multipage Tables" on page 2574

row-expression
defines the rows in the table. For information about constructing dimension expressions, see "Details" on page 2507.

Restriction A row dimension is the next to last dimension in a table statement. A column dimension must follow a row dimension. A page dimension can precede a row dimension.

Table Options

BOX=*value*
specifies text for the empty box above the row titles.

Value can be one of the following:

PAGE
writes the page-dimension text in the box. If the page-dimension text does not fit, then it is placed in its default position above the box, and the box remains empty.

BOX={<*label*=*value*> <STYLE=*style-override(s)*>}
specifies text and a style override for the empty box above the row titles.

Value can be one of the following:

PAGE
writes the page-dimension text in the box. If the page-dimension text does not fit, then it is placed in its default position above the box, and the box remains empty.

'string'
writes the quoted string in the box. Any string that does not fit in the box is truncated.

variable
writes the name (or label, if the variable has one) of a variable in the box. Any name or label that does not fit in the box is truncated.

For details about the arguments of the STYLE= option and how it is used, see STYLE= on page 2504 in the TABLE statement.

Examples "Example 9: Creating Multipage Tables" on page 2574

"Example 14: Specifying Style Overrides for ODS Output" on page 2607

CAPTION= *text*<#BYLINE> <#BYVAL><#BYVAR>
specifies a caption text string to add before each table. If no string is specified, then the caption defaults to the text specified by the CONTENTS= option in the TABLE statement.

This option makes table captions both visual and accessible if the ACCESSIBLETABLE system option is specified.

If the NOACCESSIBLETABLE system option is specified, then no caption is displayed, however the caption text is still accessible.

Starting with SAS 9.4M6, these options are available if a BY statement is in effect:

#BYLINE
substitutes the entire BY line without leading or trailing blanks for #BYLINE in the text string. The BY line uses the format *variable-name=value*.

#BYVAL*n*
#BYVAL(*BY-variable-name*)
substitutes the current value of the specified BY variable for #BYVAL in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAL2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAL(YEAR) specifies the BY variable, YEAR. *Variable-name* is not case sensitive.

#BYVAR*n*
#BYVAR(*BY-variable-name*)
substitutes the name of the BY-variable or the label associated with the variable (whatever the BY line would normally display) for #BYVAR in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAR2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAR(SITES) specifies the BY variable, SITES. *Variable-name* is not case sensitive.

Restrictions The ACCESSIBLETABLE system option must be specified to enable captions.

The CAPTION= option is not valid in the LISTING destination.

Note This feature applies to SAS 9.4M6 and to later releases.

Tip You can use the PROC DOCUMENT OBBNOTE option to display or edit the caption.

See Creating Accessible Tables with the TABULATE Procedure in *Creating Accessible SAS Output Using ODS and ODS Graphics*

CONDENSE
prints as many complete logical pages as possible on a single printed page or, if possible, prints multiple pages of tables that are too wide to fit on a page one below the other on a single page, instead of on separate pages. A *logical page* is all the rows and columns that fall within one of the following:

- a page-dimension category (with no BY-group processing)
- a BY group with no page dimension
- a page-dimension category within a single BY group

Restriction The CONDENSE option has no effect on the pages that are generated by the BY statement. The first table for a BY group always begins on a new page.

Example “Example 9: Creating Multipage Tables” on page 2574

CONTENTS=*link-text* <#BYLINE> <#BYVAL> <#BYVAR>
enables you to name the link in the HTML table of contents that points to the ODS output of the table that is produced by using the TABLE statement.

Starting with SAS 9.4M6, these options are available if a BY statement is in effect:

#BYLINE
substitutes the entire BY line without leading or trailing blanks for #BYLINE in the text string. The BY line uses the format *variable-name=value*.

#BYVAL*n*
#BYVAL(*BY-variable-name*)
substitutes the current value of the specified BY variable for #BYVAL in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAL2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAL(YEAR) specifies the BY variable, YEAR. *Variable-name* is not case sensitive.

#BYVAR*n*
#BYVAR(*BY-variable-name*)
substitutes the name of the BY-variable or the label associated with the variable (whatever the BY line would normally display) for #BYVAR in the text string.

Specify the variable with one of the following:

n
specifies a variable by its position in the BY statement. For example, #BYVAR2 specifies the second variable in the BY statement.

BY-variable-name
specifies a variable from the BY statement by its name. For example, #BYVAR(SITES) specifies the BY variable, SITES. *Variable-name* is not case sensitive.

See "Substituting BY Line Values in a Text String" on page 2538

Creating Accessible Tables with the TABULATE Procedure in *Creating Accessible SAS Output Using ODS and ODS Graphics*

FORMAT_PRECEDENCE=PAGE | ROW | COLUMN
specifies whether the format that is specified for the page dimension (PAGE), row dimension (ROW), or column dimension (COLUMN) is applied to the contents of the table cells.

PAGE
specifies that the format that is specified for the page dimension is applied to the contents of the table cells.

ROW
specifies that the format that is specified for the row dimension is applied to the contents of the table cells.

COLUMN
specifies that the format that is specified for the column dimension is applied to the contents of the table cells.

Alias COL

Default COLUMN

FUZZ=*number*
supplies a numeric value against which analysis variable values and table cell values other than frequency counts are compared to eliminate trivial values (absolute values less than the FUZZ= value) from computation and printing. A number whose absolute value is less than the FUZZ= value is treated as zero in computations and printing. The default value is the smallest representable floating-point number on the computer that you are using.

INDENT=*number-of-spaces*
specifies the number of spaces to indent nested row headings, and suppresses the row headings for class variables.

Restriction In the HTML, RTF, and Printer destinations, the INDENT= option suppresses the row headings for class variables but does not indent nested row headings.

Tip When there are no crossings in the row dimension, there is nothing to indent, so the value of *number-of-spaces* has no effect. However, in such cases INDENT= still suppresses the row headings for class variables.

See "Example 8: Indenting Row Headings and Eliminating Horizontal Separators" on page 2571 (with crossings) "Example 9: Creating Multipage Tables" on page 2574 (without crossings)

MISSTEXT='*text*'
supplies up to 256 characters of text to be printed for table cells that contain missing values.

MISSTEXT={<*label*='*text*'> <STYLE=*style-override(s)*>}
supplies up to 256 characters of text to be printed and specifies a style override for table cells that contain missing values. For details about the arguments of the STYLE= option and how it is used, see STYLE= on page 2504 in the TABLE statement.

Interaction A style element that is specified in a dimension expression overrides a style element that is specified in the MISSTEXT= option for any given cells.

Examples "Providing Text for Cells That Contain Missing Values" on page 2546

"Example 14: Specifying Style Overrides for ODS Output" on page 2607

NOCELLMERGE
specifies that data cells are not merged with other data cells in the table.

Note: The NOCELLMERGE option works with the ODS formatted destinations. These include the ODS MARKUP family, ODS RTF, and the ODS PRINTER family destinations.

Restriction The NOCELLMERGE option does not work with the traditional monospace output.

Interactions If you specify ROW=FLOAT or INDENT=0, PROC TABULATE produces single unmerged data rows. The NOCELLMERGE option is then ignored because there are no rows that need to be merged.

If the NOCELLMERGE option is in effect, the style of the empty data cells will be the default style of the data cell. The style of the empty data cells might not be the same style as the style of the formatted data cells.

Example "Example 16: Using the NOCELLMERGE Option" on page 2616

NOCONTINUED

suppresses the continuation message, **`continued`**, that is displayed at the bottom of tables that span multiple pages. The text is rendered with the AFTERCAPTION style element.

Note: Because HTML browsers do not break pages, NOCONTINUED has no effect on the HTML destination.

PRINTMISS

prints all values that occur for a class variable each time headings for that variable are printed, even if there are no data for some of the cells that these headings create. Consequently, PRINTMISS creates row and column headings that are the same for all logical pages of the table, within a single BY group.

Default If you omit the PRINTMISS option, then PROC TABULATE suppresses a row or column for which there are no data, unless you use the CLASSDATA= option in the PROC TABULATE statement.

Restriction If an entire logical page contains only missing values, then that page is not printed regardless of the PRINTMISS option.

See "CLASSDATA=*SAS-data-set*" on page 2470

Example "Providing Headings for All Categories" on page 2545

ROW=CONSTANT | FLOAT

specifies whether all title elements in a row crossing are allotted space even when they are blank.

CONSTANT

allots space to all row titles even if the title has been blanked out. (For example, N=' '.)

Alias CONST

FLOAT
divides the row title space equally among the nonblank row titles in the crossing.

Default CONSTANT

Example "Example 7: Eliminating Row Headings" on page 2569

RTSPACE=*number*
specifies the number of print positions to allot to all of the headings in the row dimension, including spaces that are used to print outlining characters for the row headings. PROC TABULATE divides this space equally among all levels of row headings.

Alias RTS=

Default one-fourth of the value of the SAS system option LINESIZE=

Restriction The RTSPACE= option affects only the traditional SAS monospace output destination.

Interaction By default, PROC TABULATE allots space to row titles that are blank. Use ROW=FLOAT in the TABLE statement to divide the space among only nonblank titles.

See For more examples of controlling the space for row titles, see *PROC TABULATE by Example, Second Edition*.

Example "Example 1: Creating a Basic Two-Dimensional Table" on page 2550

STYLE=*style-override*
specifies one or more style overrides to use for parts of the table other than table cells. For example, the following statement specifies that the background color for missing values is red and the background color the box is orange:

```
table (region all)*(division all),
         (prodtype all)*(actual*f=dollar10.) /
         misstext=[label='Missing' style=[background=red]]
         box=[label='Region by Division and Type'  style=[backgroundcolor=orange]];
```

style-override
specifies one or more style attributes or style elements to override the default style element and attributes in a specific area of a report.

You can specify a style override in three ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.
- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.
- Specify the PARENT value. The PARENT value specifies that the data cell use the style element of its parent heading.

style-override has the following form:

PARENT | *style-element-name* | [*style-attribute-name-1=style-attribute-value-1*

<style-attribute-name-2=style-attribute-value-2 ...>]

<PARENT>
specifies that the data cell use the style element of its parent heading.

The parent style element of a data cell is one of the following:

- the style element of the leaf heading above the column that contains the data cell, if the table specifies no row dimension, or if the table specifies the style element in the column dimension expression
- the style element of the leaf heading above the row that contains the cell, if the table specifies the style element in the row dimension expression
- the Beforecaption style element, if the table specifies the style element in the page dimension expression
- undefined, otherwise

Note: In this usage, the angle brackets around the word PARENT are required. Braces or square brackets cannot be substituted in the syntax.

Note: The parent of a heading (not applicable to STYLE= in the PROC TABULATE statement) is the heading under which the current heading is nested.

style-attribute-name
specifies the attribute to change.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-attribute-value
specifies a value for the attribute. Each attribute has a different set of valid values. A SAS format can also be used as an attribute value for conditional formatting.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For information about using SAS formats as style attribute values, see "Using a Format to Assign a Style Attribute" on page 2534.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-element-name
is the name of a style element that is part of an ODS style template.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

Alias S=

Tips To override a style element specification that is made as an option in the TABLE statement, specify STYLE= in a dimension expression of the TABLE statement.

You can use braces ({ and }) instead of square brackets ([and]).

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

Example "Example 14: Specifying Style Overrides for ODS Output" on page 2607

STYLE_PRECEDENCE=PAGE | ROW | COLUMN
specifies whether the style that is specified for the page dimension (PAGE), row dimension (ROW), or column dimension (COLUMN or COL) is applied to the contents of the table cells.

PAGE
specifies that the style that is specified for the page dimension is applied to the contents of the table cells.

ROW
specifies that the style that is specified for the row dimension is applied to the contents of the table cells.

COLUMN
specifies that the style that is specified for the column dimension is applied to the contents of the table cells.

Alias COL

Default COLUMN

Example "Example 15: Style Precedence" on page 2612

Details

What Are Dimension Expressions?

A dimension expression defines the content and appearance of a dimension (the columns, rows, or pages in the table) by specifying the combination of variables, variable values, and statistics that make up that dimension. A TABLE statement consists of from one to three dimension expressions separated by commas. Options can follow the dimension expressions.

If all three dimensions are specified, then the leftmost dimension expression defines pages, the middle dimension expression defines rows, and the rightmost dimension expression defines columns. If two dimensions are specified, then the left dimension expression defines rows, and the right dimension expression defines columns. If a single dimension is specified, then the dimension expression defines columns.

A dimension expression consists of one or more elements and operators.

Elements That You Can Use in a Dimension Expression

analysis variables
(See the VAR statement on page 2511.)

class variables
(See the CLASS statement on page 2482.)

the universal class variable ALL
summarizes all of the categories for class variables in the same parenthetical group or dimension (if the variable ALL is not contained in a parenthetical group).

Note: If the input data set contains a variable named ALL, then enclose the name of the universal class variable in quotation marks.

Examples
"Example 6: Summarizing Information with the Universal Class Variable ALL" on page 2566

"Example 9: Creating Multipage Tables" on page 2574

"Example 13: Using Denominator Definitions to Display Basic Frequency Counts and Percentages" on page 2593

keywords for statistics
See "Statistics That Are Available in PROC TABULATE" on page 2515 for a list of available statistics. Use the asterisk (*) operator to associate a statistic keyword with a variable. The N statistic (number of nonmissing values) can be specified in a dimension expression without associating it with a variable.

Default
For analysis variables, the default statistic is SUM. Otherwise, the default statistic is N.

Restriction Statistic keywords other than N must be associated with an analysis variable.

Interaction Statistical keywords should be enclosed by single or double quotation marks to ensure that the keyword element is treated as a statistical keyword and not treated as a variable. By default, SAS treats these keywords as variables.

Example
```
n
Region*n
Sales*max
```

Examples "Example 10: Reporting on Multiple-Response Survey Data" on page 2577

"Example 13: Using Denominator Definitions to Display Basic Frequency Counts and Percentages" on page 2593

format modifiers

define how to format values in cells. Use the asterisk (*) operator to associate a format modifier with the element (an analysis variable or a statistic) that produces the cells that you want to format. Format modifiers have the form

`f=format`

Tip Format modifiers have no effect on CLASS variables.

See For more information about specifying formats in tables, see "Formatting Values in Tables" on page 2518.

Example `Sales*f=dollar8.2`

Example "Example 6: Summarizing Information with the Universal Class Variable ALL" on page 2566

labels

temporarily replace the names of variables and statistics. Labels affect only the variable or statistic that immediately precedes the label. Labels have the form

`statistic-keyword-or-variable-name='label-text'`

Tip PROC TABULATE eliminates the space for blank column headings from a table but by default does not eliminate the space for blank row headings unless all row headings are blank. Use ROW=FLOAT in the TABLE statement to remove the space for blank row headings.

Example
```
Region='Geographical Region'
Sales*max='Largest Sale'
```

Examples "Example 5: Customizing Row and Column Headings" on page 2564

"Example 7: Eliminating Row Headings" on page 2569

style specifications
specify style elements and style attributes for page dimension text, headings, or data cells. For details, see " Specifying Style Attributes and Style Elements in Dimension Expressions" on page 2510.

Operators That You Can Use in a Dimension Expression

asterisk *
creates categories from the combination of values of the class variables and constructs the appropriate headings for the dimension. If one of the elements is an analysis variable, then the statistics for the analysis variable are calculated for the categories that are created by the class variables. This process is called crossing.

Example
```
Region*Division
Quarter*Sales*f=dollar8.2
```

Example "Example 1: Creating a Basic Two-Dimensional Table" on page 2550

(blank)
places the output for each element immediately after the output for the preceding element. This process is called concatenation.

Example
```
n Region*Sales ALL
```

Example "Example 6: Summarizing Information with the Universal Class Variable ALL" on page 2566

parentheses ()
group elements and associate an operator with each concatenated element in the group.

Example
```
Division*(Sales*max Sales*min)
(Region ALL)*Sales
```

Example "Example 6: Summarizing Information with the Universal Class Variable ALL" on page 2566

angle brackets <>
specify denominator definitions, which determine the value of the denominator in the calculation of a percentage. For a discussion of how to construct denominator definitions, see "Calculating Percentages " on page 2519.

Examples "Example 10: Reporting on Multiple-Response Survey Data" on page 2577

"Example 13: Using Denominator Definitions to Display Basic Frequency Counts and Percentages" on page 2593

Specifying Style Attributes and Style Elements in Dimension Expressions

You can specify one or more style elements or style attributes in a dimension expression to control the appearance of non-LISTING output. You can modify the appearance of the following areas:

- analysis variable name headings
- class variable name headings
- class variable level value headings
- data cells
- keyword headings
- page dimension text

Specifying a style attribute or style element in a dimension expression is useful when you want to override a style attribute or style element that you have specified in another statement, such as the PROC TABULATE, CLASS, CLASSLEV, KEYWORD, TABLE, or VAR statements.

The syntax for specifying style elements and style attributes in a dimension expression is

[STYLE<(CLASSLEV)>=<*style-element-name* | PARENT>

[*style-attribute-name-1=style-attribute-value-1< style-attribute-name-2=style-attribute-value-2 ...*>]]

These are some examples of style attributes in dimension expressions:

-
```
dept={label='Department'
      style=[color=red]}, N
```
- `dept*[style=MyDataStyle], N`
- `dept*[format=12.2 style=MyDataStyle], N`

Note: When used in a dimension expression, the STYLE= option must be enclosed within square brackets ([and]) or braces ({ and }).

(CLASSLEV)
assigns a style element to a class variable level value heading. For example, the following TABLE statement specifies that the level value heading for the class variable, DEPT, has a foreground color of yellow:

```
table dept=[style(classlev)=
            [color=yellow]]*sales;
```

Note: The CLASSLEV option is used only in dimension expressions.

For an example that shows how to specify style elements within dimension expressions, see "Example 14: Specifying Style Overrides for ODS Output" on page

2607. For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

VAR Statement

Identifies numeric variables to use as analysis variables.

Alias: VARIABLES

Tip: You can use multiple VAR statements.

Example: "Example 14: Specifying Style Overrides for ODS Output" on page 2607

Syntax

VAR *analysis-variable(s)* </ *options*>;

Required Argument

analysis-variable(s);
identifies the analysis variables in the table. Analysis variables are numeric variables for which PROC TABULATE calculates statistics. The values of an analysis variable can be continuous or discrete.

If an observation contains a missing value for an analysis variable, then PROC TABULATE omits that value from calculations of all statistics except N (the number of observations with nonmissing variable values) and NMISS (the number of observations with missing variable values). For example, the missing value does not increase the SUM, and it is not counted when you are calculating statistics such as the MEAN.

Interaction If a variable name and a statistic name are the same, enclose the statistic name in single or double quotation marks.

Optional Arguments

STYLE=*style-override(s)*
specifies one or more style overrides for analysis variable name headings. For example, the following statement specifies that the background color for analysis variable name headings is tan:

```
var actual  / style=[background=tan];
```

style-override
specifies one or more style attributes or style elements to override the default style element and attributes in a specific area of a report.

You can specify a style override in three ways:

- Specify a style element. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program.

- Specify a style attribute. A style attribute is a name-value pair that describes a single behavioral or visual aspect of a piece of output. This is the most specific method of changing the appearance of your output.
- Specify the PARENT value. The PARENT value specifies that the data cell use the style element of its parent heading.

style-override has the following form:

PARENT | *style-element-name* | [*style-attribute-name-1=style-attribute-value-1*

<*style-attribute-name-2=style-attribute-value-2* ...>]

<PARENT>
specifies that the data cell use the style element of its parent heading.

The parent style element of a data cell is one of the following:

- the style element of the leaf heading above the column that contains the data cell, if the table specifies no row dimension, or if the table specifies the style element in the column dimension expression
- the style element of the leaf heading above the row that contains the cell, if the table specifies the style element in the row dimension expression
- the Beforecaption style element, if the table specifies the style element in the page dimension expression
- undefined, otherwise

Note: In this usage, the angle brackets around the word PARENT are required. Braces or square brackets cannot be substituted in the syntax.

Note: The parent of a heading (not applicable to STYLE= in the PROC TABULATE statement) is the heading under which the current heading is nested.

style-attribute-name
specifies the attribute to change.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-attribute-value
specifies a value for the attribute. Each attribute has a different set of valid values. A SAS format can also be used as an attribute value for conditional formatting.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For information about using SAS formats as style attribute values, see "Using a Format to Assign a Style Attribute" on page 2534.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

style-element-name
is the name of a style element that is part of an ODS style template.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

For a table of default style attributes and style elements for each ODS destination, see "Style Elements and Style Attributes for Table Regions" on page 2530.

Alias S=

Tips To override a style element that is specified in the VAR statement, you can specify a style element in the related TABLE statement dimension expression.

The use of STYLE= in the VAR statement differs slightly from its use in the PROC TABULATE statement. In the VAR statement, inheritance is different for rows and columns. For rows, the parent heading is located to the left of the current heading. For columns, the parent heading is located above the current heading.

See For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

Example "Example 14: Specifying Style Overrides for ODS Output" on page 2607

WEIGHT=*weight-variable*
specifies a numeric variable whose values weight the values of the variables that are specified in the VAR statement. The variable does not have to be an integer. If the value of the weight variable is

Weight Value	PROC TABULATE Response
0	Counts the observation in the total number of observations
Less than 0	Converts the value to zero and counts the observation in the total number of observations
Missing	Excludes the observation

To exclude observations that contain negative and zero weights from the analysis, use EXCLNPWGT. Note that most SAS/STAT procedures, such as PROC GLM, exclude negative and zero weights by default.

Restriction To compute weighted quantiles, use QMETHOD=OS in the PROC statement.

Note Prior to Version 7 of SAS, the procedure did not exclude the observations with missing weights from the count of observations.

Tips When you use the WEIGHT= option, consider which value of the VARDEF= option is appropriate. See the discussion of "VARDEF=*divisor* " on page 2480.

Use the WEIGHT option in multiple VAR statements to specify different weights for the analysis variables.

WEIGHT Statement

Specifies weights for analysis variables in the statistical calculations.

See: For information about calculating weighted statistics and for an example that uses the WEIGHT statement, see "Calculating Weighted Statistics" on page 83.

Syntax

WEIGHT *variable*;

Required Argument

variable
specifies a numeric variable whose values weight the values of the analysis variables. The values of the variable do not have to be integers. PROC TABULATE responds to weight values in accordance with the following table.

Weight Value	PROC TABULATE Response
0	Counts the observation in the total number of observations
Less than 0	Converts the value to zero and counts the observation in the total number of observations
Missing	Excludes the observation

To exclude observations that contain negative and zero weights from the analysis, use EXCLNPWGT. Note that most SAS/STAT procedures, such as PROC GLM, exclude negative and zero weights by default.

Note: Prior to Version 7 of SAS, the procedure did not exclude the observations with missing weights from the count of observations.

Restrictions To compute weighted quantiles, use QMETHOD=OS in the PROC statement.

PROC TABULATE will not compute MODE when a weight variable is active. Instead, try using PROC UNIVARIATE when MODE needs to be computed and a weight variable is active.

Interaction If you use the WEIGHT= option in a VAR statement to specify a weight variable, then PROC TABULATE uses this variable instead to weight those VAR statement variables.

Tip When you use the WEIGHT statement, consider which value of the VARDEF= option is appropriate. See the discussion of "VARDEF=*divisor* " on page 2480 and the calculation of weighted statistics in the "Keywords and Formulas" on page 2700 section of this document.

Usage: TABULATE Procedure

Statistics That Are Available in PROC TABULATE

Use the following keywords to request statistics in the TABLE statement or to specify statistic keywords in the KEYWORD or KEYLABEL statement.

Note: If a variable name (class or analysis) and a statistic name are the same, then enclose the statistic name in single quotation marks (for example, `'MAX'`).

Descriptive statistic keywords	
COLPCTN	PCTSUM
COLPCTSUM	RANGE

CSS	REPPCTN
CV	REPPCTSUM
KURTOSIS | KURT	ROWPCTN
LCLM	ROWPCTSUM
MAX	SKEWNESS | SKEW
MEAN	STDDEV | STD
MIN	STDERR
MODE	SUM
N	SUMWGT
NMISS	UCLM
PAGEPCTN	USS
PAGEPCTSUM	VAR
PCTN	
Quantile statistic keywords	
MEDIAN | P50	Q3 | P75
P1	P70
P5	P80
P10	P90
P20	P95
P30	P99
P40	
P60	
Q1|P25	QRANGE
Hypothesis testing keywords	

PROBT | PRT	T

These statistics, the formulas that are used to calculate them, and their data requirements are discussed in the "Keywords and Formulas" on page 2700 section of this document.

To compute standard error of the mean (STDERR) or Student's *t*-test, you must use the default value of the VARDEF= option, which is DF. The VARDEF= option is specified in the PROC TABULATE statement.

To compute weighted quantiles, you must use QMETHOD=OS in the PROC TABULATE statement.

Use both LCLM and UCLM to compute a two-sided confidence limit for the mean. Use only LCLM or UCLM to compute a one-sided confidence limit. Use the ALPHA= option in the PROC TABULATE statement to specify a confidence level.

Formatting Class Variables

Use the FORMAT statement to assign a format to a class variable for the duration of a PROC TABULATE step. When you assign a format to a class variable, PROC TABULATE uses the formatted values to create categories, and it uses the formatted values in headings. If you do not specify a format for a class variable, and the variable does not have any other format assigned to it, then the default format, BEST12., is used, unless the GROUPINTERNAL option is specified.

User-defined formats are particularly useful for grouping values into fewer categories. For example, if you have a class variable, Age, with values that range from 1 to 99, then you could create a user-defined format that groups the ages so that your tables contain a manageable number of categories. The following PROC FORMAT step creates a format that condenses all possible values of age into six groups of values.

```
proc format;
   value agefmt  0-29='Under 30'
                 30-39='30-39'
                 40-49='40-49'
                 50-59='50-59'
                 60-69='60-69'
                 other='70 or over';
run;
```

For information about creating user-defined formats, see Chapter 30, "FORMAT Procedure," on page 1075.

By default, PROC TABULATE includes in a table only those formats for which the frequency count is not zero and for which values are not missing. To include missing values for all class variables in the output, use the MISSING option in the PROC TABULATE statement, and to include missing values for selected class variables, use the MISSING option in a CLASS statement. To include formats for which the frequency count is zero, use the PRELOADFMT option in a CLASS statement and

the PRINTMISS option in the TABLE statement, or use the CLASSDATA= option in the PROC TABULATE statement.

Formatting Values in Tables

The formats for data in table cells serve two purposes. They determine how PROC TABULATE displays the values, and they determine the width of the columns. The default format for values in table cells is 12.2. You can modify the format for printing values in table cells by doing the following:

- changing the default format with the FORMAT= option in the PROC TABULATE statement
- crossing elements in the TABLE statement with the F= format modifier

Note: You cannot modify the format for printing values in table cells by using the FORMAT or the ATTRIB statement. If you use these statements, the analysis variable formats that they contain will be ignored.

PROC TABULATE determines the format to use for a particular cell from the following default order of precedence for formats:

1. If no other formats are specified, then PROC TABULATE uses the default format (12.2).
2. The FORMAT= option in the PROC TABULATE statement changes the default format. If no format modifiers affect a cell, then PROC TABULATE uses this format for the value in that cell.
3. A format modifier in the page dimension applies to the values in all the table cells on the logical page unless you specify another format modifier for a cell in the row or column dimension.
4. A format modifier in the row dimension applies to the values in all the table cells in the row unless you specify another format modifier for a cell in the column dimension.
5. A format modifier in the column dimension applies to the values in all the table cells in the column.

You can change this order of precedence by using the FORMAT_PRECEDENCE= option in the TABLE statement. For more information, see “TABLE Statement” on page 2496. For example, if you specify FORMAT_PRECEDENCE=ROW and specify a format modifier in the row dimension, then that format overrides all other specified formats for the table cells.

Calculating Percentages

Calculating the Percentage of the Value in a Single Table Cell

The following statistics print the percentage of the value in a single table cell in relation to the total of the values in a group of cells. No denominator definitions are required. However, an analysis variable can be used as a denominator definition for percentage sum statistics.

- REPPCTN and REPPCTSUM statistics—print the percentage of the value in a single table cell in relation to the total of the values in the report.
- COLPCTN and COLPCTSUM statistics—print the percentage of the value in a single table cell in relation to the total of the values in the column.
- ROWPCTN and ROWPCTSUM statistics—print the percentage of the value in a single table cell in relation to the total of the values in the row.
- PAGEPCTN and PAGEPCTSUM statistics—print the percentage of the value in a single table cell in relation to the total of the values in the page.

These statistics calculate the most commonly used percentages. See "Example 12: Calculating Various Percentage Statistics" on page 2589 for an example.

Using PCTN and PCTSUM

PCTN and PCTSUM statistics can be used to calculate these same percentages. They enable you to manually define denominators. PCTN and PCTSUM statistics print the percentage of the value in a single table cell in relation to the value (used in the denominator of the calculation of the percentage) in another table cell or to the total of the values in a group of cells. By default, PROC TABULATE summarizes the values in all N cells (for PCTN) or all SUM cells (for PCTSUM) and uses the summarized value for the denominator. You can control the value that PROC TABULATE uses for the denominator with a denominator definition.

You place a denominator definition in angle brackets (< and >) next to the PCTN or PCTSUM statistic. The denominator definition specifies which categories to sum for the denominator.

This section illustrates how to specify denominator definitions in a simple table. "Example 13: Using Denominator Definitions to Display Basic Frequency Counts and Percentages" on page 2593 illustrates how to specify denominator definitions in a table that consists of multiple subtables. For more examples of denominator definitions, see *PROC TABULATE by Example, Second Edition*.

Specifying a Denominator for the PCTN Statistic

The following PROC TABULATE step calculates the N statistic and three different versions of PCTN using the data set "ENERGY" on page 2788.

```
proc tabulate data=energy;
   class division type;
   table division*
           (n='Number of customers'
            pctn<type>='% of row' 1
            pctn<division>='% of column' 2
            pctn='% of all customers'), 3
          type/rts=50;
   title 'Number of Users in Each Division';
run;
```

The TABLE statement creates a row for each value of Division and a column for each value of Type. Within each row, the TABLE statement nests four statistics: N and three different calculations of PCTN. (See the following figure.) Each occurrence of PCTN uses a different denominator definition.

Figure 70.4 *Three Different Uses of the PCTN Statistic with Frequency Counts Highlighted*

Number of Users in Each Division

		Type	
		1	2
Division			
1	Number of customers	6.00	6.00
	% of row 1	50.00	50.00
	% of column 2	27.27	27.27
	% of all customers 3	13.64	13.64
2	Number of customers	3.00	3.00
	% of row	50.00	50.00
	% of column	13.64	13.64
	% of all customers	6.82	6.82
3	Number of customers	8.00	8.00
	% of row	50.00	50.00
	% of column	36.36	36.36
	% of all customers	18.18	18.18
4	Number of customers	5.00	5.00
	% of row	50.00	50.00
	% of column	22.73	22.73
	% of all customers	11.36	11.36

1 `<type>` sums the frequency counts for all occurrences of Type within the same value of Division. Thus, for Division=1, the denominator is 6 + 6, or 12.

2 `<division>` sums the frequency counts for all occurrences of Division within the same value of Type. Thus, for Type=1, the denominator is 6 + 3 + 8 + 5, or 22.

3 The third use of PCTN has no denominator definition. Omitting a denominator definition is the same as including all class variables in the denominator

definition. Thus, for all cells, the denominator is 6 + 3 + 8 + 5 + 6 + 3 + 8 + 5, or 44.

Specifying a Denominator for the PCTSUM Statistic

The following PROC TABULATE step sums expenditures for each combination of Type and Division and calculates three different versions of PCTSUM.

```
proc tabulate data=energy format=8.2;
   class division type;
   var expenditures;
   table division*
           (sum='Expenditures'*f=dollar10.2
            pctsum<type>='% of row' 1
            pctsum<division>='% of column' 2
            pctsum='% of all customers'), 3
         type*expenditures/rts=40;
   title 'Expenditures in Each Division';
run;
```

The TABLE statement creates a row for each value of Division and a column for each value of Type. Because Type is crossed with Expenditures, the value in each cell is the sum of the values of Expenditures for all observations that contribute to the cell. Within each row, the TABLE statement nests four statistics: SUM and three different calculations of PCTSUM. (See the following figure.) Each occurrence of PCTSUM uses a different denominator definition.

Figure 70.5 *Three Different Uses of the PCTSUM Statistic with Sums Highlighted*

Expenditures in Each Division

		Type	
		1	2
		Expenditures	Expenditures
Division			
1	Expenditures	$7,477.00	$5,129.00
	% of row 1	59.31	40.69
	% of column 2	16.15	13.66
	% of all customers 3	8.92	6.12
2	Expenditures	$19,379.00	$15,078.00
	% of row	56.24	43.76
	% of column	41.86	40.15
	% of all customers	23.11	17.98
3	Expenditures	$5,476.00	$4,729.00
	% of row	53.66	46.34
	% of column	11.83	12.59
	% of all customers	6.53	5.64
4	Expenditures	$13,959.00	$12,619.00
	% of row	52.52	47.48
	% of column	30.15	33.60
	% of all customers	16.65	15.05

1 `<type>` sums the values of Expenditures for all occurrences of Type within the same value of Division. Thus, for Division=1, the denominator is $7,477 + $5,129.

2 `<division>` sums the frequency counts for all occurrences of Division within the same value of Type. Thus, for Type=1, the denominator is $7,477 + $19,379 + $5,476 + $13,959.

3 The third use of PCTN has no denominator definition. Omitting a denominator definition is the same as including all class variables in the denominator definition. Thus, for all cells, the denominator is $7,477 + $19,379 + $5,476 + $13,959 + $5,129 + $15,078 + $4,729 + $12,619.

Using ODS Styles with PROC TABULATE

Using Styles with Base SAS Procedures

Most Base SAS procedures that support ODS use one or more table templates to produce output objects. These table templates include templates for table

elements: columns, headers, and footers. Each table element can specify the use of one or more style elements for various parts of the output. These style elements cannot be specified within the syntax of the procedure, but you can use customized styles for the ODS destinations that you use. For more information about customizing tables and styles, see "TEMPLATE Procedure: Creating a Style Template" in *SAS Output Delivery System: Procedures Guide*.

The Base SAS reporting procedures, PROC PRINT, PROC REPORT, and PROC TABULATE, enable you to quickly analyze your data and organize it into easy-to-read tables. You can use the STYLE= option with these procedure statements to modify the appearance of your report. The STYLE= option enables you to make changes in sections of output without changing the default style for all of the output. You can customize specific sections of procedure output by specifying the STYLE= option in specific statements within the procedure.

The following program uses the STYLE= option to create the colors in the PROC TABULATE output below:

```
proc sort data=sashelp.prdsale out=prdsale;
    by Country;
run;

proc tabulate data=prdsale;
   class region division prodtype / style=[background=lightgreen];
   classlev region division prodtype  / style=[background=yellow];
   var actual  / style=[background=tan];
   keyword all sum / style=[background=linen color=blue];
   keylabel all='Total';
   table (region all)*(division all),
         (prodtype all)*(actual*f=dollar10.) /
         box=[label='Region by Division and Type'
style=[backgroundcolor=orange]];

title 'Actual Product Sales';
title2 '(millions of dollars)';
run;
```

Output 70.4 *Enhanced PROC TABULATE Output*

Actual Product Sales
(millions of dollars)

Region by Division and Type		Product type		Total
		FURNITURE	OFFICE	
		Actual Sales	Actual Sales	Actual Sales
		Sum	Sum	Sum
Region	Division			
EAST	CONSUMER	$72,570	$108,686	$181,256
	EDUCATION	$73,901	$115,104	$189,005
	Total	$146,471	$223,790	$370,261
WEST	Division			
	CONSUMER	$76,209	$105,020	$181,229
	EDUCATION	$67,945	$110,902	$178,847

	Total	$290,625	$439,712	$730,337

Styles, Style Elements, and Style Attributes

Understanding Styles, Style Elements, and Style Attributes

The appearance of SAS output is controlled by ODS style templates (ODS styles). ODS styles are produced from compiled STYLE templates written in PROC TEMPLATE style syntax. An ODS style template is a collection of style elements that provides specific visual attributes for your SAS output.

- A style element is a named collection of style attributes that apply to a particular part of the output. Each area of ODS output has a style element name that is associated with it. The style element name specifies where the style attributes are applied. For example, a style element might contain instructions for the presentation of column headings or for the presentation of the data inside the cells. Style elements might also specify default colors and fonts for output that uses the style.
- A style attribute is a visual property, such as color, font properties, and line characteristics, that is defined in ODS with a reserved name and value. Style attributes are collectively referenced by a style element within a style template.

Each *style attribute* specifies a value for one aspect of the presentation. For example, the BACKGROUNDCOLOR= attribute specifies the color for the background of an HTML table or for a colored table in printed output. The FONTSTYLE= attribute specifies whether to use a Roman font or an italic font.

Note: Because styles control the presentation of the data, they have no effect on output objects that go to the LISTING, DOCUMENT, or OUTPUT destination.

Available styles are in the SASHELP.TMPLMST item store. In SAS Enterprise Guide, the list of style sheets is shown by the Style Wizard. In batch mode or SAS Studio, you can display the list of available style templates by using the LIST statement in PROC TEMPLATE:

```
proc template;
   list styles / store=sashelp.tmplmst;
run;
```

For complete information about viewing ODS styles, see "Viewing ODS Styles Supplied by SAS" in *SAS Output Delivery System: Advanced Topics*.

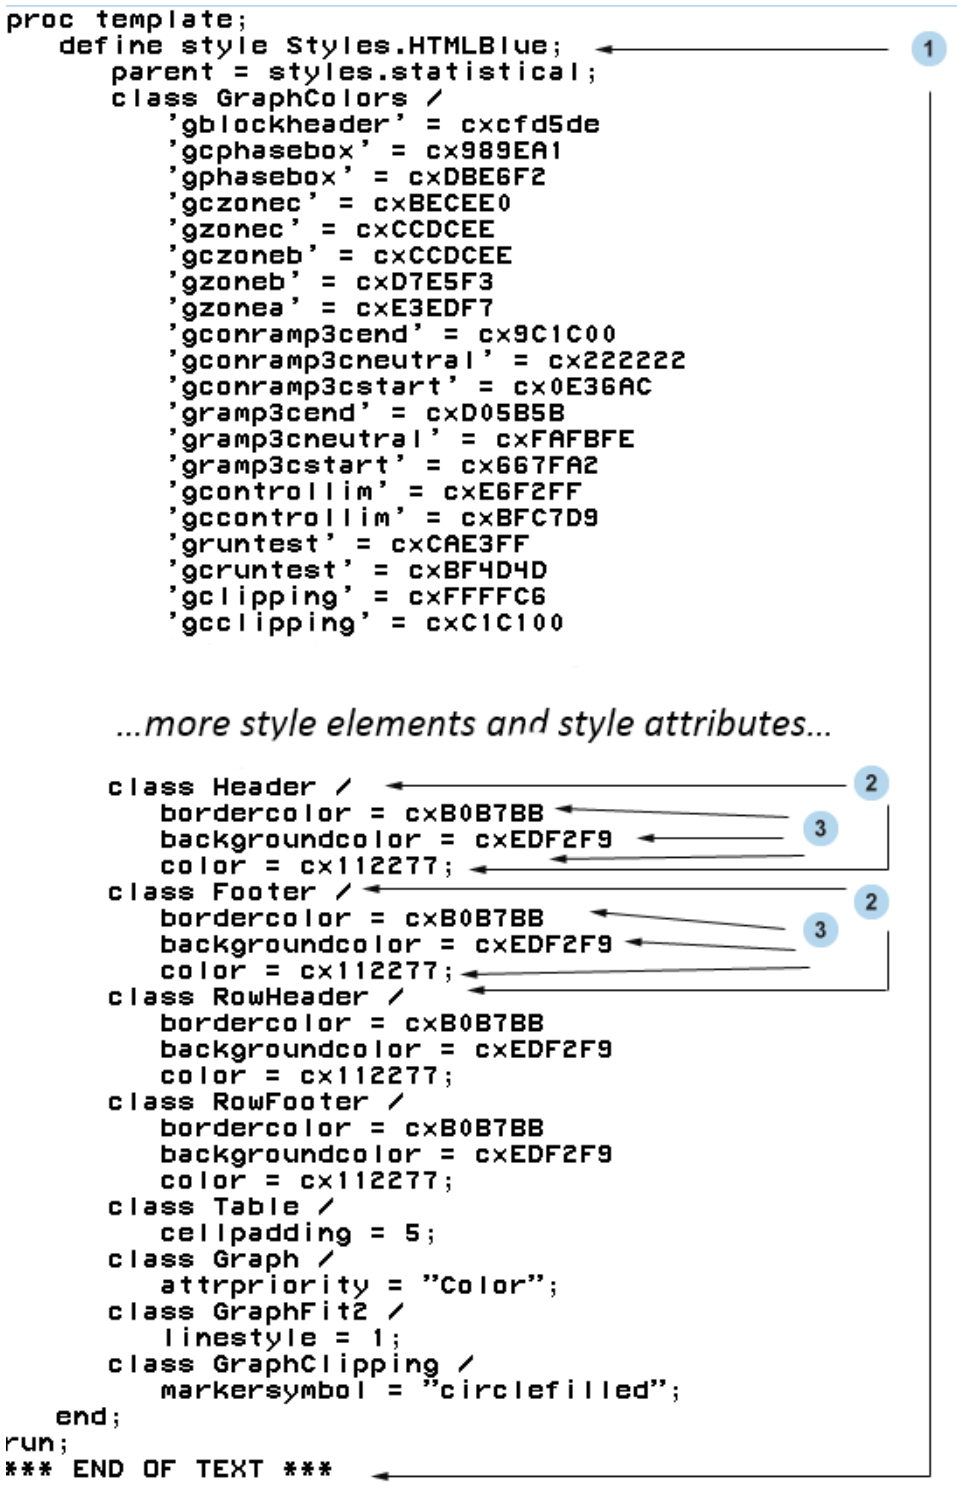
By default, HTML 4 output uses the HTMLBlue style template and HTML 5 output uses the HTMLEncore style template. To help you become familiar with styles, style elements, and style attributes, look at the relationship between them.

You can use the SOURCE statement in PROC TEMPLATE to display the structure of a style template. The following code prints the structure of the HTMLBlue style template to the SAS log:

```
proc template;
   source styles.HTMLBlue;
run;
```

The following figure illustrates the structure of a style. The figure shows the relationship between the style, the style elements, and the style attributes.

Figure 70.6 Diagram of the HtmlBlue Style



The following list corresponds to the numbered items in the preceding figure:

1 Styles.HtmlBlue is the *style*. Styles describe how to display presentation aspects (color, font, font size, and so on) of the SAS output. A style determines the overall appearance of the ODS documents that use it. The default style for HTML output is HtmlBlue. Each style consists of style elements.

You can create new styles with the "DEFINE STYLE Statement" in *SAS Output Delivery System: Procedures Guide*. New styles can be created independently or from an existing style. You can use "PARENT= Statement" in *SAS Output Delivery System: Procedures Guide* to create a new style from an existing style. For complete documentation about ODS styles, see "Style Templates" in *SAS Output Delivery System: Advanced Topics*.

2 Header and Footer are examples of *style elements*. A style element is a collection of style attributes that apply to a particular part of the output for a SAS program. For example, a style element might contain instructions for the presentation of column headings or for the presentation of the data inside table cells. Style elements might also specify default colors and fonts for output that uses the style. Style elements exist inside styles and consist of one or more style attributes. Style elements can be user-defined or supplied by SAS. User-defined style elements can be created by the "STYLE Statement" in *SAS Output Delivery System: Procedures Guide*.

Note: For a list of the default style elements used for HTML and markup languages and their inheritance, see "Style Elements" in *SAS Output Delivery System: Advanced Topics*.

3 BORDERCOLOR=, BACKGROUNDCOLOR=, and COLOR= are examples of *style attributes*. Style attributes specify a value for one aspect of the area of the output that its style element applies to. For example, the COLOR= attribute specifies the value `cx112277` for the font color. For a list of style attributes supplied by SAS, see "Style Attributes" in *SAS Output Delivery System: Advanced Topics*.

Style attributes can be referenced with style references. See "style-reference" in *SAS Output Delivery System: Advanced Topics* for more information about style references.

The following table shows commonly used style attributes that you can set with the STYLE= option in PROC PRINT, PROC TABULATE, and PROC REPORT. Most of these attributes apply to parts of the table other than cells (for example, table borders and the lines between columns and rows). Note that not all attributes are valid in all destinations. For more information about these style attributes, their valid values, and their applicable destinations, see "Style Attributes Tables" in *SAS Output Delivery System: Advanced Topics*.

Table 70.4 *Style Attributes for PROC REPORT, PROC TABULATE, and PROC PRINT*

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE

CELLSPACING=	X		X		X	
CELLWIDTH=	X	X	X	X		X
CLASS=	X	X	X	X	X	X
COLOR=	X	X	X			
FLYOVER=	X	X		X		X
FONT=	X	X	X	X	X	X
FONTFAMILY=	X	X	X	X	X	X
FONTSIZE=	X	X	X	X	X	X
FONTSTYLE=	X	X	X	X	X	X
FONTWEIGHT=	X	X	X	X	X	X
FONTWIDTH=	X	X	X	X		X
FRAME=	X		X		X	
HEIGHT=	X	X		X	X	X
HREFTARGET=		X		X		X
HTMLSTYLE=	X	X	X	X	X	
NOBREAKSPACE=[2]	X	X		X		X
OUTPUTWIDTH=	X	X	X	X	X	
POSTHTML=[1]	X	X	X	X	X	X

Attribute	PROC REPORT STATEMENT REPORT Area	PROC REPORT Areas: CALLDEF, COLUMN, HEADER, LINES, SUMMARY	PROC TABULATE STATEMENT TABLE	PROC TABULATE STATEMENTS VAR, CLASS, BOX, CLASSLEV, KEYWORD	PROC PRINT TABLE location	PROC PRINT: all locations other than TABLE
POSTIMAGE=	X	X	X	X	X	X
POSTTEXT=[1]	X	X	X	X	X	X
PREHTML=[1]	X	X	X	X	X	X
PREIMAGE=	X	X	X	X	X	X
PRETEXT=[1]	X	X	X	X	X	X
PROTECTSPECIALCHARS=		X		X	X	X
RULES=	X		X		X	
TAGATTR=	X	X	X	X	X	X
TEXTALIGN=	X	X	X	X	X	X
URL=		X		X		X
VERTICALALIGN=		X		X		X
WIDTH=	X	X	X	X	X	

1 When you use these attributes in this location, they affect only the text that is specified with the PRETEXT=, POSTTEXT=, PREHTML=, and POSTHTML= attributes. To alter the foreground color or the font for the text that appears in the table, you must set the corresponding attribute in a location that affects the cells rather than the table. For complete documentation about style attributes and their values, see "Style Attributes" in *SAS Output Delivery System: Advanced Topics*.

2 To help prevent unexpected wrapping of long text strings when using PROC REPORT with the ODS RTF destination, set NOBREAKSPACE=OFF in a location that affects the LINE statement. The NOBREAKSPACE=OFF attribute must be set in the PROC REPORT code either on the LINE statement or on the PROC REPORT statement where style(lines) is specified.

Style Elements and Style Attributes for Table Regions

The following table lists the default style elements and style attributes for various regions of a PROC TABULATE table. The table lists defaults for the most commonly used ODS destinations: HTML, PDF, and RTF. Each destination has a default style template that is applied to all output that is written to the destination.

- The default style for HTML output is HTMLBlue.

- The default style for PRINTER output is Pearl.
- The default style for RTF output is RTF.

For complete documentation about the ODS destinations and their default styles, see "Style Templates" in *SAS Output Delivery System: Advanced Topics*.

Table 70.5 *Default Style Elements and Style Attributes for Table Regions*

Region	Style Element	HTML Style Attributes	PDF Style Attributes	RTF Style Attributes
Column headings and Box	Header	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = bold FONTSTYLE = roman COLOR = cx112277 BACKGROUNDCOLOR = cxedf2f9	FONTFAMILY = "Arial, 'Albany AMT'" FONTSIZE = 8pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxffffff BORDERWIDTH = NaN	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 11pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxbbbbbb
Page dimension text	Beforecaption	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = bold FONTSTYLE = roman COLOR = cx112277 BACKGROUNDCOLOR = cxfafbfe	FONTFAMILY = "Arial, 'Albany AMT'" FONTSIZE = 8pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxffffff	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 11pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000
Row headings	Rowheader	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = bold FONTSTYLE = roman COLOR = cx112277 BACKGROUNDCOLOR = cxedf2f9	FONTFAMILY = "Arial, 'Albany AMT'" FONTSIZE = 8pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxffffff BORDERWIDTH = NaN	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 11pt FONTWEIGHT = bold FONTSTYLE = roman COLOR =cx000000 BACKGROUNDCOLOR = cxbbbbbb

Region	Style Element	HTML Style Attributes	PDF Style Attributes	RTF Style Attributes
Data cells	Data	FONTFAMILY = "Arial, 'Albany AMT', Helvetica, Helv" FONTSIZE = 2 FONTWEIGHT = medium FONTSTYLE = roman BACKGROUNDCOLOR = cxffffff	FONTFAMILY ="'Albany AMT', Albany" FONTSIZE = 8pt FONTWEIGHT = medium FONTSTYLE = roman COLOR = cx000000 BORDERWIDTH = NaN COLOR = cx000000	FONTFAMILY ="'Times New Roman', 'Times Roman'" FONTSIZE = 10pt FONTWEIGHT = medium FONTSTYLE = roman COLOR = cx000000

Using the STYLE= Option with PROC TABULATE Statements

PROC TABULATE style overrides are applied to a table based on the statements that create the table. With the STYLE= option, you can make changes to either the style element or style attributes that control the appearance of an area of the output by specifying the STYLE= option in the statement that controls the area that you want to modify. The following table shows the areas of a table that can be modified and their corresponding statements.

Specifications in the TABLE statement override the same specification in the PROC TABULATE, CLASS, CLASSLEV, VAR, and KEYWORD statements. This enables you to have different style behavior with multiple TABLE statements. However, any style attributes that you specify in the PROC TABULATE statement and that you do not override in the TABLE statement are inherited. For example, if you specify a blue background and a white foreground for all data cells in the PROC TABULATE statement, and you specify a gray background for the data cells of a particular crossing in the TABLE statement, then the background for those data cells is gray, and the foreground is white (as specified in the PROC TABULATE statement).

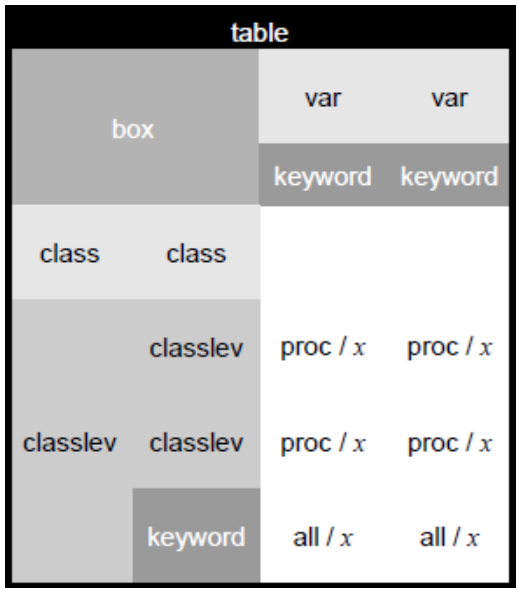
Detailed information about the STYLE= option is provided in the documentation for individual statements.

Table 70.6 *Using the STYLE= Option in PROC TABULATE*

Area To Be Modified	STYLE Option To Use
Data cells	PROC TABULATE statement or dimension expression(s) (p. 2469)

Area To Be Modified	STYLE Option To Use
Page dimension text and class variable name headings	"CLASS Statement" (p. 2482)
Class level value headings	"CLASSLEV Statement" (p. 2490)
Keyword headings	"KEYWORD Statement" (p. 2493)
Table borders, rules, and other parts that are not specified elsewhere	"TABLE Statement" (p. 2496)
Box text	BOX= option of the TABLE statement (p. 2496)
Missing values	MISSTEXT= option of the TABLE statement (p. 2496)
Analysis variable name headings	"VAR Statement" (p. 2511)

Figure 70.7 *PROC TABULATE Areas and Corresponding Statements*



Applying Style Attributes to Table Cells

PROC TABULATE determines the style attributes to use for a particular cell from the following default order of precedence for styles:

1 If no other style attributes are specified, then PROC TABULATE uses the default style attributes from the default style (Data).

2 The STYLE= option in the PROC TABULATE statement changes the default style attributes. If no other STYLE= option specifications affect a cell, then PROC TABULATE uses these style attributes for that cell.

3 A STYLE= option that is specified in the page dimension applies to all the table cells on the logical page unless you specify another STYLE= option for a cell in the row or column dimension.

4 A STYLE= option that is specified in the row dimension applies to all the table cells in the row unless you specify another STYLE= option for a cell in the column dimension.

5 A STYLE= option that is specified in the column dimension applies to all the table cells in the column.

You can change this order of precedence by using the STYLE_PRECEDENCE= option in the TABLE statement on page 2506. For example, if you specify STYLE_PRECEDENCE=ROW and specify a STYLE= option in the row dimension, then those style attribute values override all others that are specified for the table cells.

Using a Format to Assign a Style Attribute

You can use a format to assign a style attribute value to any cell whose content is determined by values of a class or analysis variable. For example, the following code assigns a red background to cells whose values are less than 10,000, a yellow background to cells whose values are at least 10,000 but less than 20,000, and a green background to cells whose values are at least 20,000:

```
proc format;
   value expfmt low-<10000='red'
                    10000-<20000='yellow'
                    20000-high='green';
run;

ods html body='external-HTML-file';
proc tabulate data=energy style=[backgroundcolor=expfmt.];
   class region division type;
   var expenditures;
   table (region all)*(division all),
           type*expenditures;
run;
ods html close;
```

Specifying Style Attributes and Style Elements in Dimension Expressions

You can specify one or more style elements or style attributes in a dimension expression to control the appearance of non-LISTING output. You can modify the appearance of the following areas:

- analysis variable name headings
- class variable name headings
- class variable level value headings
- data cells
- keyword headings
- page dimension text

Specifying a style attribute or style element in a dimension expression is useful when you want to override a style attribute or style element that you have specified in another statement, such as the PROC TABULATE, CLASS, CLASSLEV, KEYWORD, TABLE, or VAR statements.

The syntax for specifying style elements and style attributes in a dimension expression is

[STYLE<(CLASSLEV)>=<*style-element-name* | PARENT>

[*style-attribute-name-1=style-attribute-value-1< style-attribute-name-2=style-attribute-value-2 ...*>]]

These are some examples of style attributes in dimension expressions:

-
```
dept={label='Department'
      style=[color=red]}, N
```
- `dept*[style=MyDataStyle], N`
- `dept*[format=12.2 style=MyDataStyle], N`

Note: When used in a dimension expression, the STYLE= option must be enclosed within square brackets ([and]) or braces ({ and }).

(CLASSLEV)
assigns a style element to a class variable level value heading. For example, the following TABLE statement specifies that the level value heading for the class variable, DEPT, has a foreground color of yellow:

```
table dept=[style(classlev)=
            [color=yellow]]*sales;
```

Note: The CLASSLEV option is used only in dimension expressions.

For an example that shows how to specify style elements within dimension expressions, see "Example 14: Specifying Style Overrides for ODS Output" on page 2607. For information about using styles with PROC TABULATE, see "Using ODS Styles with PROC TABULATE" on page 2522.

SAS Cloud Analytic Services Processing for PROC TABULATE

If your input data set originates from SAS Cloud Analytic Services (CAS), some of the PROC TABULATE analysis can be performed by the CAS server. Reports that require significant summarization of data can benefit from CAS processing. Running PROC TABULATE with CAS actions has several advantages over processing within SAS. These advantages include reduced network traffic, and the potential for faster processing. Faster processing is possible because in-memory tables are manipulated locally on the server instead of being transferred across a relatively slow network connection. CAS is used because it might have more processing resources at its disposal.

When the DATA= input data set references an in-memory table or view in CAS, the TABULATE procedure can use CAS actions to perform a significant portion of its work within the server. To reference an in-memory table or view, you must specify the CAS engine LIBNAME statement and use the CAS engine libref with the input table name.

By default, PROC TABULATE uses CAS processing whenever a CAS engine libref is specified on the input table name.

In the following example, the LIBNAME statement assigns a CAS engine libref named mycas that you use to connect to the CAS session casauto.

```
option casport=5570 cashost="cloud.example.com";
cas casauto ;
libname mycas cas;
data mycas.class;
   set sashelp.class;
run;

proc tabulate data=mycas.class;
   class sex age;
   var height weight;
   table sex,age*(height weight)*(sum mean);
run;
```

The following statistics are supported for CAS processing:

CSS	RANGE
CV	STDERR
LCLM	SUM
MAX	SUMWGT
MEAN	STD
MIN	UCLM
N	USS
NMISS	VAR

When SAS format definitions reside in CAS, formatting of class variables occurs in CAS. If the SAS format definitions do not reside on the CAS server, the CAS aggregation occurs on the raw values, and the relevant formats are applied by SAS as the results set is merged into the PROC TABULATE internal structure. User-defined formats that are created in SAS must be copied into CAS for them to work as expected. It is a best practice to keep formats consistent between SAS and CAS. For complete documentation about using user-defined formats with CAS, see *SAS Cloud Analytic Services: User-Defined Formats*.

For information about how to use the CAS LIBNAME statement, see "CAS LIBNAME Statement" in *SAS Cloud Analytic Services: User's Guide*. For more information about how procedures work with CAS processing, see Chapter 5, "CAS Processing of Base Procedures," on page 93.

In-Database Processing for PROC TABULATE

In-database processing has several advantages over processing within SAS. These advantages include increased security, reduced network traffic, and the potential for faster processing. Increased security is possible because sensitive data does not have to be extracted from the database management system (DBMS). Faster processing is possible because data is manipulated locally, on the DBMS, using high-speed secondary storage devices instead of being transported across a relatively slow network connection, because the DBMS might have more processing resources at its disposal, and because the DBMS might be capable of optimizing a query for execution in a highly parallel and scalable fashion.

When the DATA= input data set is stored as a table or view in a DBMS, the PROC TABULATE procedure can use in-database processing to perform most of its work within the database. In-database processing can provide the advantages of faster processing and reduced data transfer between the database and SAS software.

PROC TABULATE performs in-database processing by using SQL implicit pass-through. The procedure generates SQL queries that are based on the classifications and the statistics that you specify in the TABLE statement. The database executes these SQL queries to construct initial summary tables, which are then transmitted to PROC TABULATE.

If class variables are specified, the procedure creates an SQL GROUP BY clause that represents the n-way type. Only the n-way class tree is generated on the DBMS. The result set that is created when the aggregation query executes in the database is read by SAS into the internal PROC TABULATE data structure.

When SAS format definitions have been deployed in the database, formatting of class variables occurs in the database. If the SAS format definitions have not been deployed in the database, the in-database aggregation occurs on the raw values, and the relevant formats are applied by SAS as the results' set is merged into the PROC TABULATE internal structures. Multi-label formatting is always done by SAS using the initially aggregated result set that is returned by the database.

The following statistics are supported for in-database processing:

CSS RANGE

CV	STDERR
LCLM	SUM
MAX	SUMWGT
MEAN	STD
MIN	UCLM
N	USS
NMISS	VAR

The SQLGENERATION system option or LIBNAME statement option controls whether and how in-database procedures are run inside the database. By default, the in-database procedures are run inside the database when possible. There are many data set options that will prevent in-database processing. For a complete listing, see “In-Database Procedures” in *SAS/ACCESS for Relational Databases: Reference*.

PROC TABULATE is supported by the following databases:

- Amazon Redshift
- Aster
- DB2
- Google BigQuery
- Greenplum
- Hadoop
- HAWQ
- IMPALA
- Microsoft SQL Server
- Netezza
- Oracle
- PostgreSQL
- SAP HANA
- Snowflake
- Teradata
- Vertica
- Yellowbrick

Substituting BY Line Values in a Text String

Starting with SAS 9.4M6, #BYLINE, #BYVAR, and #BYVAL substitutions are available in the following options:

- The CONTENTS= option in the TABLE statement and the PROC TABULATE statement.

- The CAPTION= option in the TABLE statement

To use the #BYVAR and #BYVAL substitutions, insert the item in the text string at the position where you want the substitution text to appear. Both #BYVAR and #BYVAL specifications must be followed by a delimiting character. The character can be either a space or other non-alphanumeric character, such as a quotation mark. If no delimiting character is provided, then the specification is ignored and its text remains intact and is displayed with the rest of the string. To allow a #BYVAR or #BYVAL substitution to be followed immediately by other text, with no delimiter, use a trailing dot (as with macro variables). The trailing dot is not displayed in the resolved text. If you want a period to be displayed as the last character in the resolved text, use two dots after the #BYVAR or #BYVAL substitution.

The substitution for #BYVAR or #BYVAL does not occur in the following cases:

- if you use a #BYVAR or #BYVAL specification for a variable that is not named in the BY statement. For example, you might use #BYVAL2 when there is only one BY-variable or #BYVAL(ABC) when ABC is non-existent or is not a BY-variable.
- if there is no BY statement

Results: TABULATE Procedure

Missing Values

How PROC TABULATE Treats Missing Values

How a missing value for a variable in the input data set affects your output depends on how you use the variable in the PROC TABULATE step. The following table summarizes how the procedure treats missing values.

Table 70.7 *Summary of How PROC TABULATE Treats Missing Values*

Condition	PROC TABULATE Default	To Override Default
An observation contains a missing value for an analysis variable	Excludes that observation from the calculation of statistics (except N and NMISS) for that particular variable	No alternative

Condition	PROC TABULATE Default	To Override Default
An observation contains a missing value for a class variable	Excludes that observation from the table[1]	Use MISSING in the PROC TABULATE statement, or MISSING in the CLASS statement
There are no data for a category	Does not show the category in the table	Use PRINTMISS in the TABLE statement, or use CLASSDATA= in the PROC TABULATE statement
Every observation that contributes to a table cell contains a missing value for an analysis variable	Displays a missing value for any statistics (except N and NMISS) in that cell	Use MISSTEXT= in the TABLE statement
There are no data for a formatted value	Does not display that formatted value in the table	Use PRELOADFMT in the CLASS statement with PRINTMISS in the TABLE statement, or use CLASSDATA= in the PROC TABULATE statement, or add dummy observations to the input data set so that it contains data for each formatted value
A FREQ variable value is missing or is less than 1	Does not use that observation to calculate statistics	No alternative
A WEIGHT variable value is missing or 0	Uses a value of 0	No alternative

This section presents a series of PROC TABULATE steps that illustrate how PROC TABULATE treats missing values. The following program creates the data set and formats that are used in this section and prints the data set. The data set COMPREV contains no missing values. (See the output below.)

```
proc format;
   value cntryfmt 1='United States'
                  2='Japan';
   value compfmt  1='Supercomputer'
                  2='Mainframe'
                  3='Midrange'
                  4='Workstation'
                  5='Personal Computer'
                  6='Laptop';
run;
```

1. The CLASS statement applies to all TABLE statements in a PROC TABULATE step. Therefore, if you define a variable as a class variable, PROC TABULATE omits observations that have missing values for that variable even if you do not use the variable in a TABLE statement.

United States	Personal Computer	18660.9	18428.0	23531.1
Japan	Supercomputer	469.9	495.6	448.4
Japan	Mainframe	5697.6	6242.4	5382.3
Japan	Midrange	5392.1	5668.3	4845.9
Japan	Workstation	1511.6	1875.5	1924.5
Japan	Personal Computer	4746.0	4600.8	4363.7

No Missing Values

The following PROC TABULATE step produces the following output:

```
proc tabulate data=comprev;
   class country computer;
   var rev90 rev91 rev92;
   table computer*country,rev90 rev91 rev92 /
         rts=32;
   format country cntryfmt. computer compfmt.;
   title 'Revenues from Computer Sales';
   title2 'for 1990 to 1992';
run;
```

Because the data set contains no missing values, the table includes all observations. All headings and cells contain nonmissing values.

Output 70.6 *Computer Sales Data: No Missing Values*

Revenues from Computer Sales
for 1990 to 1992

		Rev90	Rev91	Rev92
		Sum	Sum	Sum
Computer	Country			
Supercomputer	United States	788.80	877.60	944.90
	Japan	469.90	495.60	448.40
Mainframe	United States	12538.10	9855.60	8527.90
	Japan	5697.60	6242.40	5382.30
Midrange	United States	9815.80	6340.30	8680.30
	Japan	5392.10	5668.30	4845.90
Workstation	United States	3147.20	3474.10	3722.40
	Japan	1511.60	1875.50	1924.50
Personal Computer	United States	18660.90	18428.00	23531.10
	Japan	4746.00	4600.80	4363.70

A Missing Class Variable

The next program copies COMPREV and alters the data so that the eighth observation has a missing value for Computer. Except for specifying this new data set, the program that produces the output “Computer Sales Data: Midrange, Japan, Deleted” below, is the same as the program that produces the output “Computer Sales Data: No Missing Values”, above. PROC TABULATE ignores observations with missing values for a class variable.

```
data compmiss;
   set comprev;
   if _n_=8 then computer=.;
run;

proc tabulate data=compmiss;
   class country computer;
   var rev90 rev91 rev92;
   table computer*country,rev90 rev91 rev92 /
         rts=32;
   format country cntryfmt. computer compfmt.;
   title 'Revenues from Computer Sales';
   title2 'for 1990 to 1992';
run;
```

The observation with a missing value for Computer was the category **`Midrange, Japan`**. This category no longer exists. By default, PROC TABULATE ignores

observations with missing values for a class variable, so this table contains one less row than the output “Computer Sales Data: No Missing Values”.

Output 70.7 *Computer Sales Data: Midrange, Japan, Deleted*

Revenues from Computer Sales
for 1990 to 1992

		Rev90	Rev91	Rev92
		Sum	Sum	Sum
Computer	Country			
Supercomputer	United States	788.80	877.60	944.90
	Japan	469.90	495.60	448.40
Mainframe	United States	12538.10	9855.60	8527.90
	Japan	5697.60	6242.40	5382.30
Midrange	United States	9815.80	6340.30	8680.30
Workstation	United States	3147.20	3474.10	3722.40
	Japan	1511.60	1875.50	1924.50
Personal Computer	United States	18660.90	18428.00	23531.10
	Japan	4746.00	4600.80	4363.70

Including Observations with Missing Class Variables

This program adds the MISSING option to the previous program. MISSING is available either in the PROC TABULATE statement or in the CLASS statement. If you want MISSING to apply only to selected class variables, but not to others, then specify MISSING in a separate CLASS statement with the selected variables. The MISSING option includes observations with missing values of a class variable in the report. (See the following output.)

```
proc tabulate data=compmiss missing;
   class country computer;
   var rev90 rev91 rev92;
   table computer*country,rev90 rev91 rev92 /
         rts=32;
   format country cntryfmt. computer compfmt.;
   title 'Revenues from Computer Sales';
   title2 'for 1990 to 1992';
run;
```

This table includes a category with missing values of Computer. This category makes up the first row of data in the table.

Output 70.8 *Computer Sales Data: Missing Values for Computer*

Revenues from Computer Sales for 1990 to 1992

		Rev90	Rev91	Rev92
		Sum	Sum	Sum
Computer	Country			
.	Japan	5392.10	5668.30	4845.90
Supercomputer	United States	788.80	877.60	944.90
	Japan	469.90	495.60	448.40
Mainframe	United States	12538.10	9855.60	8527.90
	Japan	5697.60	6242.40	5382.30
Midrange	United States	9815.80	6340.30	8680.30
Workstation	United States	3147.20	3474.10	3722.40
	Japan	1511.60	1875.50	1924.50
Personal Computer	United States	18660.90	18428.00	23531.10
	Japan	4746.00	4600.80	4363.70

Formatting Headings for Observations with Missing Class Variables

By default, as shown in the output "Computer Sales Data: Missing Values for Computer", PROC TABULATE displays missing values of a class variable as one of the standard SAS characters for missing values (a period, a blank, an underscore, or one of the letters A through Z). If you want to display something else instead, then you must assign a format to the class variable that has missing values, as shown in the following program. (See the following output.)

```
proc format;
   value misscomp 1='Supercomputer'
                  2='Mainframe'
                  3='Midrange'
                  4='Workstation'
                  5='Personal Computer'
                  6='Laptop'
                  .='No type given';
run;

proc tabulate data=compmiss missing;
   class country computer;
   var rev90 rev91 rev92;
   table computer*country,rev90 rev91 rev92 /
         rts=32;
   format country cntryfmt. computer misscomp.;
   title 'Revenues for Computer Sales';
   title2 'for 1990 to 1992';
```

```
run;
```

In this table, the missing value appears as the text that the MISSCOMP. format specifies.

Output 70.9 *Computer Sales Data: Text Supplied for Missing Computer Value*

Revenues for Computer Sales for 1990 to 1992

		Rev90	Rev91	Rev92
		Sum	Sum	Sum
Computer	Country			
No type given	Japan	5392.10	5668.30	4845.90
Supercomputer	United States	788.80	877.60	944.90
	Japan	469.90	495.60	448.40
Mainframe	United States	12538.10	9855.60	8527.90
	Japan	5697.60	6242.40	5382.30
Midrange	United States	9815.80	6340.30	8680.30
Workstation	United States	3147.20	3474.10	3722.40
	Japan	1511.60	1875.50	1924.50
Personal Computer	United States	18660.90	18428.00	23531.10
	Japan	4746.00	4600.80	4363.70

Providing Headings for All Categories

By default, PROC TABULATE evaluates each page that it prints and omits columns and rows for categories that do not exist. For example, “Computer Sales Data: Text Supplied for Missing Computer Value ” does not include a row for `No type given` and for `United States` or for `Midrange` and for `Japan` because there are no data in these categories. If you want the table to represent all possible categories, then use the PRINTMISS option in the TABLE statement, as shown in the following program. (See the following output.)

```
proc tabulate data=compmiss missing;
   class country computer;
   var rev90 rev91 rev92;
   table computer*country,rev90 rev91 rev92 /
         rts=32 printmiss;
   format country cntryfmt. computer misscomp.;
   title 'Revenues for Computer Sales';
   title2 'for 1990 to 1992';
run;
```

This table contains a row for the category **`No type given`**, **`United States`** and the category **`Midrange, Japan`**. Because there are no data in these categories, the values for the statistics are all missing.

Output 70.10 *Computer Sales Data: Missing Statistics Values*

Revenues for Computer Sales for 1990 to 1992

		Rev90	Rev91	Rev92
		Sum	Sum	Sum
Computer	Country			
No type given	United States	.	.	.
	Japan	5392.10	5668.30	4845.90
Supercomputer	United States	788.80	877.60	944.90
	Japan	469.90	495.60	448.40
Mainframe	United States	12538.10	9855.60	8527.90
	Japan	5697.60	6242.40	5382.30
Midrange	United States	9815.80	6340.30	8680.30
	Japan	.	.	.
Workstation	United States	3147.20	3474.10	3722.40
	Japan	1511.60	1875.50	1924.50
Personal Computer	United States	18660.90	18428.00	23531.10
	Japan	4746.00	4600.80	4363.70

Providing Text for Cells That Contain Missing Values

If some observations in a category contain missing values for analysis variables, then PROC TABULATE does not use those observations to calculate statistics (except N and NMISS). However, if each observation in a category contains a missing value, then PROC TABULATE displays a missing value for the value of the statistic. To replace missing values for analysis variables with text, use the MISSTEXT= option in the TABLE statement to specify the text to use, as shown in the following program. (See the following output.)

```
proc tabulate data=compmiss missing;
   class country computer;
   var rev90 rev91 rev92;
   table computer*country,rev90 rev91 rev92 /
         rts=32 printmiss misstext='NO DATA!';
   format country cntryfmt. computer misscomp.;
   title 'Revenues for Computer Sales';
   title2 'for 1990 to 1992';
run;
```

This table replaces the period normally used to display missing values with the text of the MISSTEXT= option.

Output 70.11 *Computer Sales Data: Text Supplied for Missing Statistics Values*

Revenues for Computer Sales for 1990 to 1992

		Rev90	Rev91	Rev92
		Sum	Sum	Sum
Computer	Country			
No type given	United States	NO DATA!	NO DATA!	NO DATA!
	Japan	5392.10	5668.30	4845.90

	Japan	469.90	495.60	448.40
Mainframe	United States	12538.10	9855.60	8527.90
	Japan	5697.60	6242.40	5382.30
Midrange	United States	9815.80	6340.30	8680.30
	Japan	NO DATA!	NO DATA!	NO DATA!
Workstation	United States	3147.20	3474.10	3722.40
	Japan	1511.60	1875.50	1924.50
Personal Computer	United States	18660.90	18428.00	23531.10
	Japan	4746.00	4600.80	4363.70

Providing Headings for All Values of a Format

PROC TABULATE prints headings only for values that appear in the input data set. For example, the format COMPFMT. provides for six possible values of Computer. Only five of these values occur in the data set COMPREV. The data set contains no data for laptop computers.

If you want to include headings for all possible values of Computer (perhaps to make it easier to compare the output with tables that are created later when you do have data for laptops), then you have three different ways to create such a table:

- Use the PRELOADFMT option in the CLASS statement with the PRINTMISS option in the TABLE statement. See "Example 3: Using Preloaded Formats with Class Variables" on page 2556 for another example that uses PRELOADFMT.
- Use the CLASSDATA= option in the PROC TABULATE statement. See "Example 2: Specifying Class Variable Combinations to Appear in a Table" on page 2553 for an example that uses the CLASSDATA= option.
- Add dummy values to the input data set so that each value that the format handles appears at least once in the data set.

The following program adds the PRELOADFMT option to a CLASS statement that contains the relevant variable.

The results are shown in the following output.

```
proc tabulate data=compmiss missing;
   class country;
   class computer / preloadfmt;
   var rev90 rev91 rev92;
   table computer*country,rev90 rev91 rev92 /
         rts=32 printmiss misstext='NO DATA!';
   format country cntryfmt. computer compfmt.;
   title 'Revenues for Computer Sales';
   title2 'for 1990 to 1992';
run;
```

This table contains a heading for each possible value of Computer.

Output 70.12 *Computer Sales Data: All Possible Computer Values Included*

Revenues for Computer Sales
for 1990 to 1992

		Rev90	Rev91	Rev92
		Sum	Sum	Sum

	Japan	NO DATA!	NO DATA!	NO DATA!

Understanding the Order of Headings with ORDER=DATA

The ORDER= option applies to all class variables. Occasionally, you want to order the headings for different variables differently. One method for reordering the headings is to group the data as you want them to appear and to specify ORDER=DATA.

For this technique to work, the first value of the first class variable must occur in the data with all possible values of all the other class variables. If this criterion is not met, then the order of the headings might surprise you.

The following program creates a simple data set in which the observations are ordered first by the values of Animal, then by the values of Food. The ORDER= option in the PROC TABULATE statement orders the heading for the class variables by the order of their appearance in the data set. (See the following output.) Although `bones` is the first value for Food in the group of observations where Animal=`dog`, all other values for Food appear before `bones` in the data set because `bones` never appears when Animal=`cat`. Therefore, the heading for `bones` in the table in the following output is not in alphabetical order.

In other words, PROC TABULATE maintains for subsequent categories the order that was established by earlier categories. If you want to re-establish the order of Food for each value of Animal, then use BY-group processing. PROC TABULATE creates a separate table for each BY group, so that the ordering can differ from one BY group to the next.

```
data foodpref;
   input Animal $ Food $;
   datalines;
cat fish
cat meat
cat milk
dog bones
dog fish
dog meat
;

proc tabulate data=foodpref format=9.
              order=data;
   class animal food;
   table animal*food;
run;
```

Output 70.13 *Ordering the Headings of Class Variables*

Animal Food Preference

Animal					
cat			dog		
Food			Food		
fish	meat	milk	fish	meat	bones
N	N	N	N	N	N
1	1	1	1	1	1

Portability of ODS Output with PROC TABULATE

Under certain circumstances, using PROC TABULATE with the Output Delivery System produces files that are not portable. If the SAS system option FORMCHAR= in your SAS session uses nonstandard line-drawing characters, then the output might include strange characters instead of lines in operating environments in which the SAS Monospace font is not installed. To avoid this problem, specify the following OPTIONS statement before executing PROC TABULATE:

```
options formchar="|----|+|---+=|-/\<>*";
```

Examples: TABULATE Procedure

Example 1: Creating a Basic Two-Dimensional Table

Features:

CLASS statement

PROC TABULATE statement options
- DATA=
- FORMAT=

TABLE statement options
- crossing (*) operator
- RTS=

VAR statement

DATA step

FORMAT procedure

FORMAT statement

TITLE statement

Data set: ENERGY

Details

The following example program does the following:

- creates a category for each type of user (residential or business) in each division of each region

- applies the same format to all cells in the table
- applies a format to each class variable
- extends the space for row headings

Program

```
data energy;
   length State $2;
   input Region Division state $ Type Expenditures;
   datalines;
1 1 ME 1 708
1 1 ME 2 379

 ... more data lines ...

4 4 HI 1 273
4 4 HI 2 298
;
proc format;
   value regfmt 1='Northeast'
                2='South'
                3='Midwest'
                4='West';
   value divfmt 1='New England'
                2='Middle Atlantic'
                3='Mountain'
                4='Pacific';
   value usetype 1='Residential Customers'
                 2='Business Customers';
run;
proc tabulate data=energy format=dollar12.;
   class region division type;

   var expenditures;
   table region*division,
         type*expenditures
          / rts=25;
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
```

Program Description

Create the ENERGY data set. ENERGY contains data on expenditures of energy for business and residential customers in individual states in the Northeast and West regions of the United States. A DATA step on page 2788 creates the data set.

```
data energy;
   length State $2;
   input Region Division state $ Type Expenditures;
   datalines;
1 1 ME 1 708
1 1 ME 2 379

 ... more data lines ...

4 4 HI 1 273
4 4 HI 2 298
;
```

Create the REGFMT., DIVFMT., and USETYPE. formats. PROC FORMAT creates formats for Region, Division, and Type.

```
proc format;
   value regfmt 1='Northeast'
                2='South'
                3='Midwest'
                4='West';
   value divfmt 1='New England'
                2='Middle Atlantic'
                3='Mountain'
                4='Pacific';
   value usetype 1='Residential Customers'
                 2='Business Customers';
run;
```

Specify the table options. The FORMAT= option specifies DOLLAR12. as the default format for the value in each table cell.

```
proc tabulate data=energy format=dollar12.;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Region, Division, and Type.

```
   class region division type;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
   var expenditures;
```

Define the table rows and columns. The TABLE statement creates a row for each formatted value of Region. Nested within each row are rows for each formatted value of Division. The TABLE statement also creates a column for each formatted value of Type. Each cell that is created by these rows and columns contains the sum of the analysis variable Expenditures for all observations that contribute to that cell.

```
   table region*division,
         type*expenditures
```

Specify the row title space. RTS= provides 25 characters per line for row headings.

```
    / rts=25;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
    format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
    title 'Energy Expenditures for Each Region';
    title2 '(millions of dollars)';
run;
```

Output

Output 70.14 *Basic Two-Dimensional Table*

Energy Expenditures for Each Region
(millions of dollars)

		Type	
		Residential Customers	Business Customers
		Expenditures	Expenditures
		Sum	Sum
Region	Division		
Northeast	New England	$7,477	$5,129
	Middle Atlantic	$19,379	$15,078
West	Mountain	$5,476	$4,729
	Pacific	$13,959	$12,619

Example 2: Specifying Class Variable Combinations to Appear in a Table

Features:

CLASS statement

PROC TABULATE Statement options
- DATA=
- CLASSDATA=
- EXCLUSIVE
- FORMAT=

TABLE statement options
- crossing (*) operator
- RTS=

VAR statement

DATA step
FORMAT statement
TITLE statement

Data set: ENERGY

Details

This example does the following:

- uses the CLASSDATA= option to specify combinations of class variables to appear in a table.
- uses the EXCLUSIVE option to restrict the output to only the combinations specified in the CLASSDATA= data set. Without the EXCLUSIVE option, the output would be the same as in "Example 1: Creating a Basic Two-Dimensional Table" on page 2550.

Program

```
data classes;
   input region division type;
   datalines;
1 1 1
1 1 2
4 4 1
4 4 2
;

proc tabulate data=energy format=dollar12.
              classdata=classes exclusive;

   class region division type;

   var expenditures;

   table region*division,
         type*expenditures

        / rts=25;

   format region regfmt. division divfmt. type usetype.;

   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
```

Program Description

Create the CLASSES data set. CLASSES contains the combinations of class variable values that PROC TABULATE uses to create the table.

```
data classes;
   input region division type;
   datalines;
1 1 1
1 1 2
4 4 1
4 4 2
;
```

Specify the table options. CLASSDATA= and EXCLUSIVE restrict the class level combinations to those that are specified in the CLASSES data set.

```
proc tabulate data=energy format=dollar12.
              classdata=classes exclusive;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Region, Division, and Type.

```
   class region division type;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
   var expenditures;
```

Define the table rows and columns. The TABLE statement creates a row for each formatted value of Region. Nested within each row are rows for each formatted value of Division. The TABLE statement also creates a column for each formatted value of Type. Each cell that is created by these rows and columns contains the sum of the analysis variable Expenditures for all observations that contribute to that cell.

```
   table region*division,
         type*expenditures
```

Specify the row title space. RTS= provides 25 characters per line for row headings.

```
        / rts=25;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
   format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
```

Output

Output 70.15 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

		Type	
		Residential Customers	Business Customers
		Expenditures	Expenditures
		Sum	Sum
Region	Division		
Northeast	New England	$7,477	$5,129
West	Pacific	$13,959	$12,619

Example 3: Using Preloaded Formats with Class Variables

Features:

CLASS statement options
- EXCLUSIVE
- PRELOADFMT

PROC TABULATE statement options
- DATA=
- FORMAT=
- OUT=

TABLE statement options
- crossing (*) operator
- PRINTMISS
- RTS

VAR statement

FORMAT statement

PRINT procedure

TITLE statement

Data set: ENERGY

Details

This example does the following:

- creates a table that includes all possible combinations of formatted class variable values (PRELOADFMT with PRINTMISS), even if those combinations have a zero frequency and even if they do not make sense
- uses only the preloaded range of user-defined formats as the levels of class variables (PRELOADFMT with EXCLUSIVE)
- writes the output to an output data set, and prints that data set

Program

```
proc tabulate data=energy format=dollar12.;
   class region division type / preloadfmt;
   var expenditures;
   table region*division,
         type*expenditures / rts=25 printmiss;
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
proc tabulate data=energy format=dollar12. out=tabdata;
   class region division type / preloadfmt exclusive;
   var expenditures;
   table region*division,
         type*expenditures / rts=25;
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
proc print data=tabdata;
run;
```

Program Description

Specify the table options. The FORMAT= option specifies DOLLAR12. as the default format for the value in each table cell.

```
proc tabulate data=energy format=dollar12.;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Region, Division, and Type. PRELOADFMT specifies that PROC TABULATE use the preloaded values of the user-defined formats for the class variables.

```
   class region division type / preloadfmt;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
var expenditures;
```

Define the table rows and columns, and specify row and column options. PRINTMISS specifies that all possible combinations of user-defined formats be used as the levels of the class variables.

```
table region*division,
      type*expenditures / rts=25 printmiss;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
title 'Energy Expenditures for Each Region';
title2 '(millions of dollars)';
run;
```

Specify the table options and the output data set. The OUT= option specifies the name of the output data set to which PROC TABULATE writes the data.

```
proc tabulate data=energy format=dollar12. out=tabdata;
```

Specify subgroups for the analysis. The EXCLUSIVE option, when used with PRELOADFMT, uses only the preloaded range of user-defined formats as the levels of class variables.

```
class region division type / preloadfmt exclusive;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
var expenditures;
```

Define the table rows and columns, and specify row and column options. The PRINTMISS option is not specified in this case. If it were, then it would override the EXCLUSIVE option in the CLASS statement.

```
table region*division,
      type*expenditures / rts=25;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
title 'Energy Expenditures for Each Region';
title2 '(millions of dollars)';
run;
```

Print the output data set WORK.TABDATA.

```
proc print data=tabdata;
run;
```

Output

This output, created with the PRELOADFMT and PRINTMISS options, contains all possible combinations of preloaded user-defined formats for the class variable values. It includes combinations with zero frequencies, and combinations that make no sense, such as **Northeast** and **Pacific**.

Output 70.16 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

		Type	
		Residential Customers	Business Customers
		Expenditures	Expenditures
		Sum	Sum
Region	Division		
Northeast	New England	$7,477	$5,129
	Middle Atlantic	$19,379	$15,078
	Mountain	.	.
	Pacific	.	.
South	New England	.	.
	Middle Atlantic	.	.
	Mountain	.	.
	Pacific	.	.
Midwest	New England	.	.
	Middle Atlantic	.	.
	Mountain	.	.
	Pacific	.	.
West	New England	.	.
	Middle Atlantic	.	.
	Mountain	$5,476	$4,729
	Pacific	$13,959	$12,619

This output, created with the PRELOADFMT and EXCLUSIVE options, contains only those combinations of preloaded user-defined formats for the class variable values that appear in the input data set. This output is identical to the output from "Example 1: Creating a Basic Two-Dimensional Table" on page 2550.

Output 70.17 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

		Type	
		Residential Customers	Business Customers
		Expenditures	Expenditures
		Sum	Sum
Region	Division		
Northeast	New England	$7,477	$5,129
	Middle Atlantic	$19,379	$15,078
West	Mountain	$5,476	$4,729
	Pacific	$13,959	$12,619

This output shows the output data set TABDATA, which was created by the OUT= option in the PROC TABULATE statement. TABDATA contains the data that is created by having the PRELOADFMT and EXCLUSIVE options specified.

Output 70.18 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

Obs	Region	Division	Type	_TYPE_	_PAGE_	_TABLE_	Expenditures_Sum
1	Northeast	New England	Residential Customers	111	1	1	7477
2	Northeast	New England	Business Customers	111	1	1	5129
3	Northeast	Middle Atlantic	Residential Customers	111	1	1	19379
4	Northeast	Middle Atlantic	Business Customers	111	1	1	15078
5	West	Mountain	Residential Customers	111	1	1	5476
6	West	Mountain	Business Customers	111	1	1	4729
7	West	Pacific	Residential Customers	111	1	1	13959
8	West	Pacific	Business Customers	111	1	1	12619

Example 4: Using Multilabel Formats

Features:

CLASS statement options
- MLF

PROC TABULATE statement options
- DATA=
- FORMAT=

TABLE statement

ALL class variable
concatenation (blank) operator
crossing (*) operator
grouping elements (parentheses) operator
label
variable list

VAR statement

DATA step

FORMAT procedure

FORMAT statement

TITLE statement

Data set: CARSURVEY

Details

This example does the following:

- shows how to specify a multilabel format in the VALUE statement of PROC FORMAT
- shows how to activate multilabel format processing using the MLF option with the CLASS statement
- demonstrates the behavior of the N statistic when multilabel format processing is activated

Program

```
data carsurvey;
   input Rater Age Progressa Remark Jupiter Dynamo;
   datalines;
1   38  94  98  84  80
2   49  96  84  80  77
3   16  64  78  76  73
4   27  89  73  90  92

 ... more data lines ...

77   61  92  88  77  85
78   24  87  88  88  91
79   18  54  50  62  74
80   62  90  91  90  86
;

proc format;
   value agefmt (multilabel notsorted)
         15 - 29 = 'Below 30 years'
         30 - 50 = 'Between 30 and 50'
```

```
        51 - high = 'Over 50 years'
          15 - 19 = '15 to 19'
          20 - 25 = '20 to 25'
          25 - 39 = '25 to 39'
          40 - 55 = '40 to 55'
        56 - high = '56 and above';
run;

proc tabulate data=carsurvey format=10.;

   class age / mlf;

   var progressa remark jupiter dynamo;

   table age all, n all='Potential Car Names'*(progressa remark
      jupiter dynamo)*mean;

   title1 "Rating Four Potential Car Names";
   title2 "Rating Scale 0-100 (100 is the highest rating)";

   format age agefmt.;
run;
```

Program Description

Create the CARSURVEY data set. CARSURVEY contains data from a survey that was distributed by a car manufacturer to a focus group of potential customers who were brought together to evaluate new car names. Each observation in the data set contains an identification number, the participant's age, and the participant's ratings of four car names. A DATA step creates the data set.

```
data carsurvey;
   input Rater Age Progressa Remark Jupiter Dynamo;
   datalines;
1   38  94  98  84  80
2   49  96  84  80  77
3   16  64  78  76  73
4   27  89  73  90  92

 ... more data lines ...

77   61  92  88  77  85
78   24  87  88  88  91
79   18  54  50  62  74
80   62  90  91  90  86
;
```

Create the AGEFMT. format. The FORMAT procedure creates a multilabel format for ages by using the "MULTILABEL" on page 1124. A multilabel format is one in which multiple labels can be assigned to the same value, in this case because of overlapping ranges. Each value is represented in the table for each range in which it occurs. The NOTSORTED option stores the ranges in the order in which they are defined.

```
proc format;
   value agefmt (multilabel notsorted)
```

```
          15 - 29 = 'Below 30 years'
          30 - 50 = 'Between 30 and 50'
        51 - high = 'Over 50 years'
          15 - 19 = '15 to 19'
          20 - 25 = '20 to 25'
          25 - 39 = '25 to 39'
          40 - 55 = '40 to 55'
        56 - high = '56 and above';
run;
```

Specify the table options. The FORMAT= option specifies up to 10 digits as the default format for the value in each table cell.

```
proc tabulate data=carsurvey format=10.;
```

Specify subgroups for the analysis. The CLASS statement identifies Age as the class variable and uses the MLF option to activate multilabel format processing.

```
   class age / mlf;
```

Specify the analysis variables. The VAR statement specifies that PROC TABULATE calculate statistics on the Progressa, Remark, Jupiter, and Dynamo variables.

```
   var progressa remark jupiter dynamo;
```

Define the table rows and columns. The row dimension of the TABLE statement creates a row for each formatted value of Age. Multilabel formatting allows an observation to be included in multiple rows or age categories. The row dimension uses the ALL class variable to summarize information for all rows. The column dimension uses the N statistic to calculate the number of observations for each age group. Notice that the result of the N statistic crossed with the ALL class variable in the row dimension is the total number of observations instead of the sum of the N statistics for the rows. The column dimension uses the ALL class variable at the beginning of a crossing to assign a label, `Potential Car Names`. The four nested columns calculate the mean ratings of the car names for each age group.

```
   table age all, n all='Potential Car Names'*(progressa remark
      jupiter dynamo)*mean;
```

Specify the titles.

```
   title1 "Rating Four Potential Car Names";
   title2 "Rating Scale 0-100 (100 is the highest rating)";
```

Format the output. The FORMAT statement assigns the user-defined format AGEFMT. to Age for this analysis.

```
   format age agefmt.;
run;
```

Output

Output 70.19 *Rating Four Potential Car Names*

Rating Four Potential Car Names
Rating Scale 0-100 (100 is the highest rating)

	N	Potential Car Names			
		Progressa	Remark	Jupiter	Dynamo
		Mean	Mean	Mean	Mean
Age					
15 to 19	14	75	78	81	73
20 to 25	11	89	88	84	89
25 to 39	26	84	90	82	72
40 to 55	14	85	87	80	68
56 and above	15	84	82	81	75
Below 30 years	36	82	84	82	75
Between 30 and 50	25	86	89	81	73
Over 50 years	19	82	84	80	76
All	80	83	86	81	74

Example 5: Customizing Row and Column Headings

Features:
CLASS statement
PROC TABULATE statement options
- DATA=
- FORMAT=

TABLE statement options
- crossing (*) operator
- labels
- RTS=

VAR statement
FORMAT statement
TITLE statement

Data set: ENERGY
Format: REGFMT.
Format: DIVFMT.
Format: USETYPE.

Details

This example shows how to customize row and column headings. A label specifies text for a heading. A blank label creates a blank heading. PROC TABULATE removes the space for blank column headings from the table.

Program

```
proc tabulate data=energy format=dollar12.;
   class region division type;
   var expenditures;
   table region*division,
        type='Customer Base'*expenditures=' '*sum=' '
         / rts=25;
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
```

Program Description

Specify the table options. The FORMAT= option specifies DOLLAR12. as the default format for the value in each table cell.

```
proc tabulate data=energy format=dollar12.;
```

Specify subgroups for the analysis. The CLASS statement identifies Region, Division, and Type as class variables.

```
   class region division type;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
   var expenditures;
```

Define the table rows and columns. The TABLE statement creates a row for each formatted value of Region. Nested within each row are rows for each formatted value of Division. The TABLE statement also creates a column for each formatted value of Type. Each cell that is created by these rows and columns contains the sum of the analysis variable Expenditures for all observations that contribute to that cell. Text in quotation marks specifies headings for the corresponding variable or statistic. Although Sum is the default statistic, it is specified here so that you can specify a blank for its heading.

```
   table region*division,
```

```
          type='Customer Base'*expenditures=' '*sum=' '
```

Specify the row title space. RTS= provides 25 characters per line for row headings.

```
           / rts=25;
```

Format the output. The FORMAT statement assigns formats to Region, Division, and Type.

```
     format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
     title 'Energy Expenditures for Each Region';
     title2 '(millions of dollars)';
run;
```

Output

The heading for Type contains text that is specified in the TABLE statement. The TABLE statement eliminated the headings for Expenditures and Sum.

Output 70.20 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

		Customer Base	
		Residential Customers	Business Customers
Region	Division		
Northeast	New England	$7,477	$5,129
	Middle Atlantic	$19,379	$15,078
West	Mountain	$5,476	$4,729
	Pacific	$13,959	$12,619

Example 6: Summarizing Information with the Universal Class Variable ALL

Features:

CLASS statement

PROC TABULATE statement options
- DATA=
- FORMAT=

TABLE statement
- ALL class variable
- concatenation (blank operator)
- format modifiers

grouping elements (parentheses operator)
RTS=

VAR statement

FORMAT statement

TITLE statement

Data set:	ENERGY
Format:	REGFMT.
Format:	DIVFMT.
Format:	USETYPE.

Details

This example shows how to use the universal class variable ALL to summarize information from multiple categories.

Program

```
proc tabulate data=energy format=comma12.;
   class region division type;
   var expenditures;
   table region*(division all='Subtotal')
      all='Total for All Regions'*f=dollar12.,
      type='Customer Base'*expenditures=' '*sum=' '
         all='All Customers'*expenditures=' '*sum=' '
      / rts=25;
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
```

Program Description

Specify the table options. The FORMAT= option specifies COMMA12. as the default format for the value in each table cell.

```
proc tabulate data=energy format=comma12.;
```

Specify subgroups for the analysis. The CLASS statement identifies Region, Division, and Type as class variables.

```
   class region division type;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
var expenditures;

table region*(division all='Subtotal')
   all='Total for All Regions'*f=dollar12.,

   type='Customer Base'*expenditures=' '*sum=' '
      all='All Customers'*expenditures=' '*sum=' '
```

Specify the row title space. RTS= provides 25 characters per line for row headings.

```
   / rts=25;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
```

Output

The universal class variable ALL provides subtotals and totals in this table.

Output 70.21 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

		Customer Base		All Customers
		Residential Customers	Business Customers	
Region	Division			
Northeast	New England	7,477	5,129	12,606
	Middle Atlantic	19,379	15,078	34,457
	Subtotal	26,856	20,207	47,063
West	Division			
	Mountain	5,476	4,729	10,205
	Pacific	13,959	12,619	26,578
	Subtotal	19,435	17,348	36,783
Total for All Regions		$46,291	$37,555	$83,846

Example 7: Eliminating Row Headings

Features:
CLASS statement
PROC TABULATE statement options
DATA=
FORMAT=
TABLE statement options
crossing (*) operator
labels
ROW=FLOAT
RTS=
VAR statement
FORMAT statement
TITLE statement

Data set: ENERGY

Format: REGFMT.

Format: DIVFMT.

Format: USETYPE.

Details

This example shows how to eliminate blank row headings from a table. To do so, you must both provide blank labels for the row headings and specify ROW=FLOAT in the TABLE statement.

Program

```
proc tabulate data=energy format=dollar12.;
   class region division type;
   var expenditures;
   table region*division*expenditures=' '*sum=' ',
         type='Customer Base'
         / rts=25 row=float;
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;
```

Program Description

Specify the table options. The FORMAT= option specifies DOLLAR12. as the default format for the value in each table cell.

```
proc tabulate data=energy format=dollar12.;
```

Specify subgroups for the analysis. The CLASS statement identifies Region, Division, and Type as class variables.

```
    class region division type;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
    var expenditures;
```

Define the table rows. The row dimension of the TABLE statement creates a row for each formatted value of Region. Nested within these rows is a row for each formatted value of Division. The analysis variable Expenditures and the Sum statistic are also included in the row dimension, so PROC TABULATE creates row headings for them as well. The text in quotation marks specifies the headings for the corresponding variable or statistic. Although Sum is the default statistic, it is specified here so that you can specify a blank for its heading.

```
    table region*division*expenditures=' '*sum=' ',
```

Define the table columns. The column dimension of the TABLE statement creates a column for each formatted value of Type.

```
          type='Customer Base'
```

Specify the row title space and eliminate blank row headings. RTS= provides 25 characters per line for row headings. ROW=FLOAT eliminates blank row headings.

```
          / rts=25 row=float;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
    format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
    title 'Energy Expenditures for Each Region';
    title2 '(millions of dollars)';
run;
```

Output

Compare this table with the output in "Example 5: Customizing Row and Column Headings" on page 2564. The two tables are identical, but the program that creates this table uses Expenditures and Sum in the row dimension. PROC TABULATE automatically eliminates blank headings from the column dimension, whereas you must specify ROW=FLOAT to eliminate blank headings from the row dimension.

Output 70.22 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

		Customer Base	
		Residential Customers	Business Customers
Region	Division		
Northeast	New England	$7,477	$5,129
	Middle Atlantic	$19,379	$15,078
West	Mountain	$5,476	$4,729
	Pacific	$13,959	$12,619

Example 8: Indenting Row Headings and Eliminating Horizontal Separators

Features:

CLASS statement

PROC TABULATE statement options
- DATA=
- FORMAT=
- NOSEPS

TABLE statement options
- crossing (*) operator
- labels
- INDENT=
- RTS=

VAR statement

FORMAT statement

ODS LISTING statement

ODS LISTING CLOSE statement

OPTIONS statement

TITLE statement

Data set: ENERGY

Format: REGFMT.

Format: DIVFMT.

Format: USETYPE.

Details

This example shows how to condense the structure of a table by doing the following:

- removing row headings for class variables
- indenting nested rows underneath parent rows instead of placing them next to each other
- eliminating horizontal separator lines from the row titles and the body of the table

Program

```
options nodate nonumber;
ods listing;

proc tabulate data=energy format=dollar12. noseps;

   class region division type;

   var expenditures;

    table region*division,
          type='Customer Base'*expenditures=' '*sum=' '

         / rts=25 indent=4;

   format region regfmt. division divfmt. type usetype.;

   title 'Energy Expenditures for Each Region';
   title2 '(millions of dollars)';
run;

ods listing close;
```

Program Description

Open the LISTING destination. The INDENT argument does not indent nested row headings for HTML output. The output will be captured as a listing with page numbering and date turned off.

```
options nodate nonumber;
ods listing;
```

Specify the table options. The FORMAT= option specifies DOLLAR12. as the default format for the value in each table cell. NOSEPS eliminates horizontal separator lines from row titles and from the body of the table.

```
proc tabulate data=energy format=dollar12. noseps;
```

Specify subgroups for the analysis. The CLASS statement identifies Region, Division, and Type as class variables.

```
class region division type;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
var expenditures;
```

Define the table rows and columns. The TABLE statement creates a row for each formatted value of Region. Nested within each row are rows for each formatted value of Division. The TABLE statement also creates a column for each formatted value of Type. Each cell that is created by these rows and columns contains the sum of the analysis variable Expenditures for all observations that contribute to that cell. Text in quotation marks in all dimensions specifies headings for the corresponding variable or statistic. Although Sum is the default statistic, it is specified here so that you can specify a blank for its heading.

```
 table region*division,
       type='Customer Base'*expenditures=' '*sum=' '
```

Specify the row title space and indention value. RTS= provides 25 characters per line for row headings. INDENT= removes row headings for class variables, places values for Division beneath values for Region rather than beside them, and indents values for Division four spaces.

```
      / rts=25 indent=4;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
    title 'Energy Expenditures for Each Region';
    title2 '(millions of dollars)';
run;
```

Close the LISTING destination.

```
ods listing close;
```

Output

NOSEPS removes the separator lines from the row titles and the body of the table. INDENT= eliminates the row headings for Region and Division and indents values for Division underneath values for Region.

Output 70.23 *Energy Expenditures for Each Region*

Energy Expenditures for Each Region
(millions of dollars)

	Customer Base	
	Residential Customers	Business Customers
Northeast		
New England	$7,477	$5,129
Middle Atlantic	$19,379	$15,078
West		
Mountain	$5,476	$4,729
Pacific	$13,959	$12,619

Example 9: Creating Multipage Tables

Features:
- CLASS statement
- PROC TABULATE statement options
  - DATA=
  - FORMAT=
- TABLE statement options
  - ALL class variable
  - BOX=
  - CONDENSE
  - INDENT=
  - page expression
  - RTS=
- VAR statement
- FORMAT statement
- TITLE statement

Data set: ENERGY

Format: REGFMT.

Format: DIVFMT.

Format: USETYPE.

Details

This example creates a separate table for each region and one table for all regions. By default, PROC TABULATE creates each table on a separate page, but the CONDENSE option places them all on the same page.

Program

```
proc tabulate data=energy format=dollar12.;
   class region division type;
   var expenditures;
   table region='Region: ' all='All Regions',
   division all='All Divisions',
         type='Customer Base'*expenditures=' '*sum=' '
         / rts=25 box=_page_ condense indent=1;
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures for Each Region and All Regions';
   title2 '(millions of dollars)';
run;
```

Program Description

Specify the table options. The FORMAT= option specifies DOLLAR12. as the default format for the value in each table cell.

```
proc tabulate data=energy format=dollar12.;
```

Specify subgroups for the analysis. The CLASS statement identifies Region, Division, and Type as class variables.

```
   class region division type;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Expenditures variable.

```
   var expenditures;
```

Define the table pages. The page dimension of the TABLE statement creates one table for each formatted value of Region and one table for all regions. Text in quotation marks provides the heading for each page.

```
   table region='Region: ' all='All Regions',
```

Define the table rows. The row dimension creates a row for each formatted value of Division and a row for all divisions. Text in quotation marks provides the row headings.

```
   division all='All Divisions',
```

Define the table columns. The column dimension of the TABLE statement creates a column for each formatted value of Type. Each cell that is created by these pages, rows, and columns contains the sum of the analysis variable Expenditures for all observations that contribute to that cell. Text in quotation marks specifies headings for the corresponding variable or statistic. Although Sum is the default statistic, it is specified here so that you can specify a blank for its heading.

```
         type='Customer Base'*expenditures=' '*sum=' '
```

Specify additional table options. RTS= provides 25 characters per line for row headings. BOX= places the page heading inside the box above the row headings. CONDENSE places as many tables as possible on one physical page. INDENT= eliminates the row heading for Division. (Because there is no nesting in the row dimension, there is nothing to indent.)

```
/ rts=25 box=_page_ condense indent=1;
```

Format the output. The FORMAT statement assigns formats to the variables Region, Division, and Type.

```
format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
title 'Energy Expenditures for Each Region and All Regions';
title2 '(millions of dollars)';
run;
```

Output

Output 70.24 *Energy Expenditures for Each Region and All Regions*

Energy Expenditures for Each Region and All Regions
(millions of dollars)

Region: Northeast	Customer Base	
	Residential Customers	Business Customers
New England	$7,477	$5,129
Middle Atlantic	$19,379	$15,078
All Divisions	$26,856	$20,207

Region: West	Customer Base	
	Residential Customers	Business Customers
Mountain	$5,476	$4,729
Pacific	$13,959	$12,619
All Divisions	$19,435	$17,348

All Regions	Customer Base	
	Residential Customers	Business Customers
New England	$7,477	$5,129
Middle Atlantic	$19,379	$15,078
Mountain	$5,476	$4,729
Pacific	$13,959	$12,619
All Divisions	$46,291	$37,555

Data set: CUSTOMER_RESPONSE

Details

The two tables in this example show the following:

- which factors most influenced customers' decisions to buy products
- where customers heard of the company

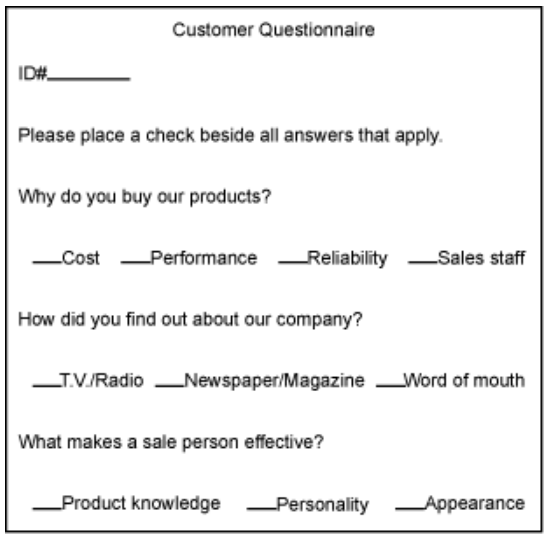
The reports appear on one physical page with only one page number. By default, they would appear on separate pages.

In addition to showing how to create these tables, this example shows how to do the following:

- use a DATA step to count the number of observations in a data set
- store that value in a macro variable
- access that value later in the SAS session

The following figure shows the survey form that is used to collect data.

Figure 70.8 *Completed Survey Form*



Customer Questionnaire

ID#_____

Please place a check beside all answers that apply.

Why do you buy our products?

___Cost ___Performance ___Reliability ___Sales staff

How did you find out about our company?

___T.V./Radio ___Newspaper/Magazine ___Word of mouth

What makes a sale person effective?

___Product knowledge ___Personality ___Appearance

         source2='Newspaper'
         source3='Word of Mouth',
         (n='Count'*f=7. pctn<customer>='Percent'*f=pctfmt9.) ;

   title 'Source of Company Name';
   footnote "Number of Respondents: &num";
run;

options formdlim='' number;
```

Program Description

Create the CUSTOMER_RESPONSE data set. CUSTOMER_RESPONSE contains data from a customer survey. Each observation in the data set contains information about factors that influence one respondent's decisions to buy products. A DATA step on page 2782 creates the data set. Using missing values rather than 0s is crucial for calculating frequency counts in PROC TABULATE.

```
data customer_response;
   input Customer Factor1-Factor4 Source1-Source3
         Quality1-Quality3;
   datalines;
1 . . 1 1 1 1 . 1 . .
2 1 1 . 1 1 1 . 1 1 .
3 . . 1 1 1 1 . . . .

. . . more data lines . . .

119 . . . 1 . . . 1 . .
120 1 1 . 1 . . . . 1 .
;
```

Store the number of observations in a macro variable. The SET statement reads the descriptor portion of CUSTOMER_RESPONSE at compile time and stores the number of observations (the number of respondents) in COUNT. The SYMPUT routine stores the value of COUNT in the macro variable NUM. This variable is available for use by other procedures and DATA steps for the remainder of the SAS session. The IF 0 condition, which is always false, ensures that the SET statement, which reads the observations, never executes. (Reading observations is unnecessary.) The STOP statement ensures that the DATA step executes only once.

```
data _null_;
   if 0 then set customer_response nobs=count;
   call symput('num',left(put(count,4.)));
   stop;
run;
```

Create the PCTFMT. format. The FORMAT procedure creates a format for percentages. The PCTFMT. format writes all values with at least one digit to the left of the decimal point and with one digit to the right of the decimal point. A blank and a percent sign follow the digits.

```
proc format;
   picture pctfmt low-high='009.9 %';
run;
```

Create the report and use the default table options.

```
proc tabulate data=customer_response;
```

Specify the analysis variables. The VAR statement specifies that PROC TABULATE calculate statistics on the Factor1, Factor2, Factor3, Factor4, and Customer variables. The variable Customer must be listed because it is used to calculate the Percent column that is defined in the TABLE statement.

```
   var factor1-factor4 customer;
```

Define the table rows and columns. The TABLE statement creates a row for each factor, a column for frequency counts, and a column for the percentages. Text in quotation marks supplies headings for the corresponding row or column. The

format modifiers F=7. and F=PCTFMT9. provide formats for values in the associated cells and extend the column widths to accommodate the column headings.

```
      table factor1='Cost'
            factor2='Performance'
            factor3='Reliability'
            factor4='Sales Staff',
            (n='Count'*f=7. pctn<customer>='Percent'*f=pctfmt9.) ;
```

Specify the titles.

```
      title 'Customer Survey Results: Spring 1996';
      title3 'Factors Influencing the Decision to Buy';
   run;
```

Create the report and use the default table options.

```
   proc tabulate
   data=customer_response;
```

Specify the analysis variables. The VAR statement specifies that PROC TABULATE calculate statistics on the Source1, Source2, Source3, and Customer variables. The variable Customer must be in the variable list because it appears in the denominator definition.

```
      var source1-source3 customer;
```

Define the table rows and columns. The TABLE statement creates a row for each source of the company name, a column for frequency counts, and a column for the percentages. Text in quotation marks supplies a heading for the corresponding row or column.

```
      table source1='TV/Radio'
            source2='Newspaper'
            source3='Word of Mouth',
            (n='Count'*f=7. pctn<customer>='Percent'*f=pctfmt9.) ;
```

Specify the title and footnote. The macro variable NUM resolves to the number of respondents. The FOOTNOTE statement uses double rather than single quotation marks so that the macro variable will resolve.

```
      title 'Source of Company Name';
      footnote "Number of Respondents: &num";
   run;
```

Reset the SAS system options. The FORMDLIM= option resets the page delimiter to a page eject. The NUMBER option resumes the display of page numbers on subsequent pages.

```
   options formdlim='' number;
```

Data set: RADIO

Details

This report of listener preferences shows how many listeners select each type of programming during each of seven time periods on a typical weekday. The data was collected by a survey, and the results were stored in a SAS data set. Although this data set contains all the information needed for this report, the information is not arranged in a way that PROC TABULATE can use.

To make this crosstabulation of time of day and choice of radio programming, you must have a data set that contains a variable for time of day and a variable for programming preference. PROC TRANSPOSE reshapes the data into a new data set that contains these variables. Once the data are in the appropriate form, PROC TABULATE creates the report.

The following figure shows the survey form that is used to collect data.

Figure 70.9 *Completed Survey Form*

                      '8'='Other'
                    other='*** Data Entry Error ***';
run;

proc transpose data=radio
               out=radio_transposed(rename=(col1=Choice))
               name=Timespan;
   by listener;
   var time1-time7;
run;

proc tabulate data=radio_transposed format=12.;

format timespan $timefmt. choice $pgmfmt.;

   class timespan choice;

   table timespan='Time of Day',
         choice='Choice of Radio Program'*n='Number of Listeners';
```

```
   title 'Listening Preferences on Weekdays';
run;
```

Program Description

Create the RADIO data set and specify the input file. RADIO contains data from a survey of 336 listeners. The data set contains information about listeners and their preferences in radio programming. The INFILE statement specifies the external file that contains the data. MISSOVER prevents the input pointer from going to the next record if it fails to find values in the current line for all variables that are listed in the INPUT statement.

```
data radio;
   infile 'input-file' missover;

   input /(Time1-Time7) ($1. +1);
   listener=_n_;
run;
```

Create the $TIMEFMT. and $PGMFMT. formats. PROC FORMAT creates formats for the time of day and the choice of programming.

```
proc format;
   value $timefmt 'Time1'='6-9 a.m.'
                  'Time2'='9 a.m. to noon'
                  'Time3'='noon to 1 p.m.'
                  'Time4'='1-4 p.m.'
                  'Time5'='4-6 p.m.'
                  'Time6'='6-10 p.m.'
                  'Time7'='10 p.m. to 2 a.m.'
                    other='*** Data Entry Error ***';
   value $pgmfmt      '0'="Don't Listen"
                  '1','2'='Rock and Top 40'
                     '3'='Country'
              '4','5','6'='Jazz, Classical, and Easy Listening'
                     '7'='News/ Information /Talk'
                     '8'='Other'
                    other='*** Data Entry Error ***';
run;
```

Reshape the data by transposing the RADIO data set. PROC TRANSPOSE creates RADIO_TRANSPOSED. This data set contains the variable Listener from the original data set. It also contains two transposed variables: Timespan and Choice. Timespan contains the names of the variables (Time1-Time7) from the input data set that are transposed to form observations in the output data set. Choice contains the values of these variables. (See "Details" on page 2587 for a complete explanation of the PROC TRANSPOSE step.)

```
proc transpose data=radio
               out=radio_transposed(rename=(col1=Choice))
               name=Timespan;
   by listener;
   var time1-time7;
run;
```

Create the report and specify the table options. The FORMAT= option specifies the default format for the values in each table cell.

```
proc tabulate data=radio_transposed format=12.;
```

Format the transposed variables. The FORMAT statement permanently associates these formats with the variables in the output data set.

```
format timespan $timefmt. choice $pgmfmt.;
```

Specify subgroups for the analysis. The CLASS statement identifies Timespan and Choice as class variables.

```
class timespan choice;
```

Define the table rows and columns. The TABLE statement creates a row for each formatted value of Timespan and a column for each formatted value of Choice. In each column are values for the N statistic. Text in quotation marks supplies headings for the corresponding rows or columns.

```
table timespan='Time of Day',
      choice='Choice of Radio Program'*n='Number of Listeners';
```

Specify the title.

```
title 'Listening Preferences on Weekdays';
run;
```

Output

Output 70.26 *Listening Preferences on Weekdays*

Listening Preferences on Weekdays

Details

Reshape the Data

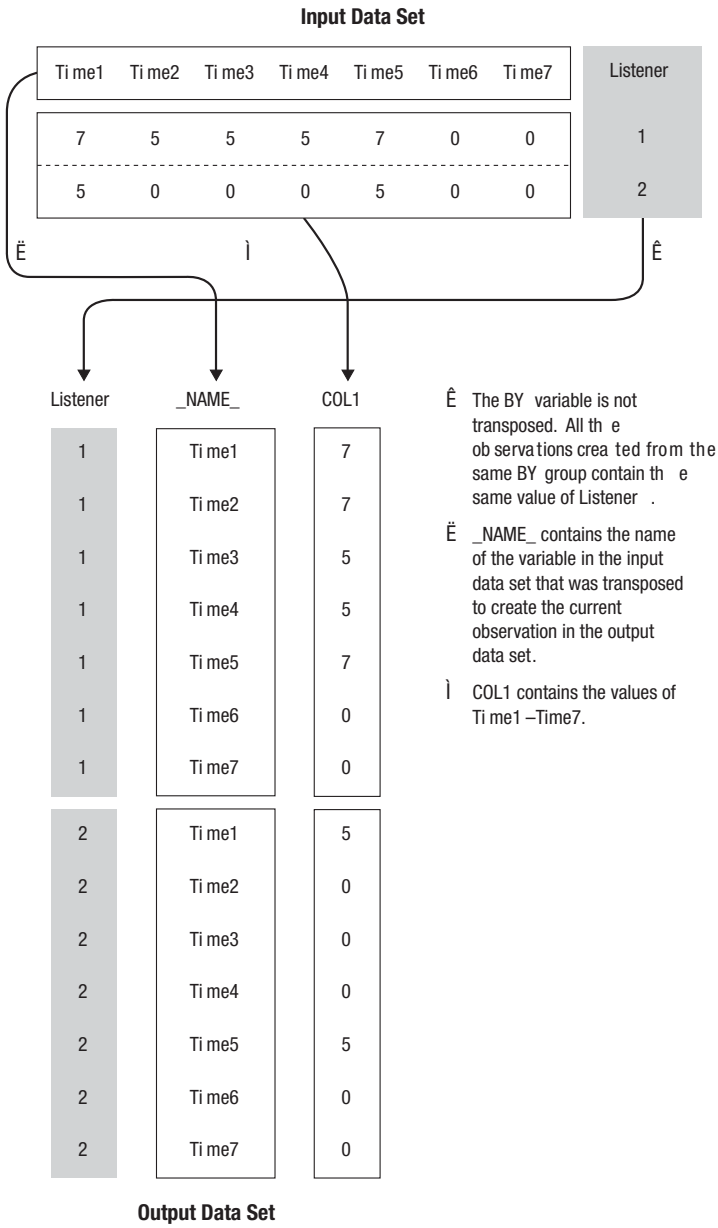
The original input data set has all the information that you need to make the crosstabular report, but PROC TABULATE cannot use the information in that form. PROC TRANSPOSE rearranges the data so that each observation in the new data set contains the variable Listener, a variable for time of day, and a variable for programming preference. The following figure illustrates the transposition. PROC TABULATE uses this new data set to create the crosstabular report.

PROC TRANSPOSE restructures data so that values that were stored in one observation are written to one variable. You can specify which variables you want to transpose.

When you transpose with BY processing, as this example does, you create from each BY group one observation for each variable that you transpose. In this example, Listener is the BY variable. Each observation in the input data set is a BY group because the value of Listener is unique for each observation.

This example transposes seven variables, Time1 through Time7. Therefore, the output data set has seven observations from each BY group (each observation) in the input data set.

Figure 70.10 Transposing Two Observations



Understanding the PROC TRANSPOSE Step

Here is a detailed explanation of the PROC TRANSPOSE step that reshapes the data:

```
proc transpose data=radio    1
               out=radio_transposed(rename=(col1=Choice))    2

               name=Timespan;    3
   by listener;    4
   var time1-time7;    5
   format timespan $timefmt. choice $pgmfmt.;    6
```

```
run;
```

1 The DATA= option specifies the input data set.

2 The OUT= option specifies the output data set. The RENAME= data set option renames the transposed variable from COL1 (the default name) to Choice.

3 The NAME= option specifies the name for the variable in the output data set that contains the name of the variable that is being transposed to create the current observation. By default, the name of this variable is _NAME_.

4 The BY statement identifies Listener as the BY variable.

5 The VAR statement identifies Time1 through Time7 as the variables to transpose.

6 The FORMAT statement assigns formats to Timespan and Choice. The PROC TABULATE step that creates the report does not need to format Timespan and Choice because the formats are stored with these variables.

;
```

Create the PCTFMT. format. The FORMAT procedure creates a format for percentages. The PCTFMT. format writes all values with at least one digit, a blank, and a percent sign.

```
proc format;
   picture pctfmt low-high='009 %';
run;
```

Specify the title.

```
title "Fundraiser Sales";
```

Create the report and specify the table options. The FORMAT= option specifies up to seven digits as the default format for the value in each table cell.

```
proc tabulate format=7.;
```

Specify subgroups for the analysis. The CLASS statement identifies Team and Classrm as class variables.

```
   class team classrm;
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Sales variable.

```
   var sales;
```

Define the table rows. The row dimension of the TABLE statement creates a row for each formatted value of Team. The last row of the report summarizes sales for all teams.

```
      table (team all),
```

Define the table columns. The column dimension of the TABLE statement creates a column for each formatted value of Classrm. Crossed within each value of Classrm is the analysis variable (`sales`) with a blank label. Nested within each column are columns that summarize sales for the class. The first nested column, labeled `sum`, is the sum of sales for the row for the classroom. The second nested column, labeled `ColPctSum`, is the percentage of the sum of sales for the row for the classroom in relation to the sum of sales for all teams in the classroom. The third nested column, labeled `RowPctSum`, is the percentage of the sum of sales for the row for the classroom in relation to the sum of sales for the row for all classrooms. The fourth nested column, labeled `RepPctSum`, is the percentage of the sum of sales for the row for the classroom in relation to the sum of sales for all teams for all classrooms. The last column of the report summarizes sales for the row for all classrooms.

```
            classrm='Classroom'*sales=' '*(sum
            colpctsum*f=pctfmt9.
            rowpctsum*f=pctfmt9.
            reppctsum*f=pctfmt9.)
            all*sales*sum=' '
```

Specify the row title space and eliminate blank row headings. RTS= provides 20 characters per line for row headings.

```
            /rts=20;
run;
```

Output

Output 70.27 *Fundraiser Sales*

Fundraiser Sales

	Classroom								All
	A				B				
	Sum	ColPctSum	RowPctSum	RepPctSum	Sum	ColPctSum	RowPctSum	RepPctSum	sales
team									
BLUE	31	34 %	46 %	15 %	36	31 %	53 %	17 %	67
GREEN	18	19 %	31 %	8 %	39	34 %	68 %	19 %	57
RED	42	46 %	52 %	20 %	38	33 %	47 %	18 %	80
All	91	100 %	44 %	44 %	113	100 %	55 %	55 %	204

Details

Here are the percentage sum statistic calculations used to produce the output for the Blue Team in Classroom A:

- COLPCTSUM=31/91*100=34%
- ROWPCTSUM=31/67*100=46%
- REPPCTSUM=31/204*100=15%

Similar calculations were used to produce the output for the remaining teams and classrooms.

Example 13: Using Denominator Definitions to Display Basic Frequency Counts and Percentages

Details

Crosstabulation tables (also called contingency tables or stub-and-banner reports) show combined frequency distributions for two or more variables. This table shows frequency counts for females and males within each of four job classes. The table also shows the percentage that each frequency count represents the following:

- the total women and men in that job class (row percentage)
- the total for that gender in all job classes (column percentage)
- the total for all employees

Program

```
data jobclass;
   input Gender Occupation @@;
```

1 4  1 4  1 4  1 1  1 1  1 1  1 1
1 1  1 2  1 2  1 2  1 2  1 2  1 2
1 2  1 3  1 3  1 3  1 3  1 4  1 4
1 4  1 4  1 4  1 1  1 3  2 1  2 1
2 1  2 1  2 1  2 1  2 1  2 2  2 2
2 2  2 2  2 2  2 3  2 3  2 3  2 4
2 4  2 4  2 4  2 4  2 4  2 1  2 3
2 3  2 3  2 3  2 3  2 4  2 4  2 4
2 4  2 4  2 1  2 1  2 1  2 1  2 1
2 2  2 2  2 2  2 2  2 2  2 2  2 2
2 3  2 3  2 4  2 4  2 4  2 1  2 1
2 1  2 1  2 1  2 2  2 2  2 2  2 3
2 3  2 3  2 3  2 4
;
```

Create the GENDFMT. and OCCUPFMT. formats. PROC FORMAT creates formats for the variables Gender and Occupation.

```
proc format;
   value gendfmt 1='Female'
                 2='Male'
              other='*** Data Entry Error ***';
   value occupfmt 1='Technical'
                  2='Manager/Supervisor'
                  3='Clerical'
                  4='Administrative'
               other='*** Data Entry Error ***';
run;
```

Create the report and specify the table options. The FORMAT= option specifies the 8.2 format as the default format for the value in each table cell.

```
proc tabulate data=jobclass format=8.2;
```

Specify subgroups for the analysis. The CLASS statement identifies Gender and Occupation as class variables.

```
   class gender occupation;

    table (occupation='Job Class' all='All Jobs')
              *(n='Number of employees'*f=9.
              pctn<gender all>='Percent of row total'
              pctn<occupation all>='Percent of column total'
              pctn='Percent of total'),
```

Define the table columns and specify the amount of space for row headings. The column dimension creates a column for each formatted value of Gender and for all employees. Text in quotation marks supplies the heading for the corresponding column. The RTS= option provides 50 characters per line for row headings.

```
    gender='Gender' all='All Employees'/ rts=50;
```

Format the output. The FORMAT statement assigns formats to the variables Gender and Occupation.

```
   format gender gendfmt. occupation occupfmt.;
```

Specify the titles.

```
   title 'Gender Distribution';
   title2 'within Job Classes';
run;
```

Output

Output 70.28 *Gender Distribution within Job Classes*

	Percent of total	49.59	50.41	100.00

Details

Overview

The part of the TABLE statement that defines the rows of the table uses the PCTN statistic to calculate three different percentages.

In all calculations of PCTN, the numerator is N, the frequency count for one cell of the table. The denominator for each occurrence of PCTN is determined by the denominator definition. The denominator definition appears in angle brackets after the keyword PCTN. It is a list of one or more expressions. The list tells PROC TABULATE which frequency counts to sum for the denominator.

Analyzing the Structure of the Table

Taking a close look at the structure of the table helps you understand how PROC TABULATE uses the denominator definitions. The following simplified version of the TABLE statement clarifies the basic structure of the table:

```
table occupation='Job Class' all='All Jobs',
      gender='Gender' all='All Employees';
```

The table is a concatenation of four subtables. In this report, each subtable is a crossing of one class variable in the row dimension and one class variable in the column dimension. Each crossing establishes one or more categories. A category is a combination of unique values of class variables, such as `female, technical` or `all, clerical`

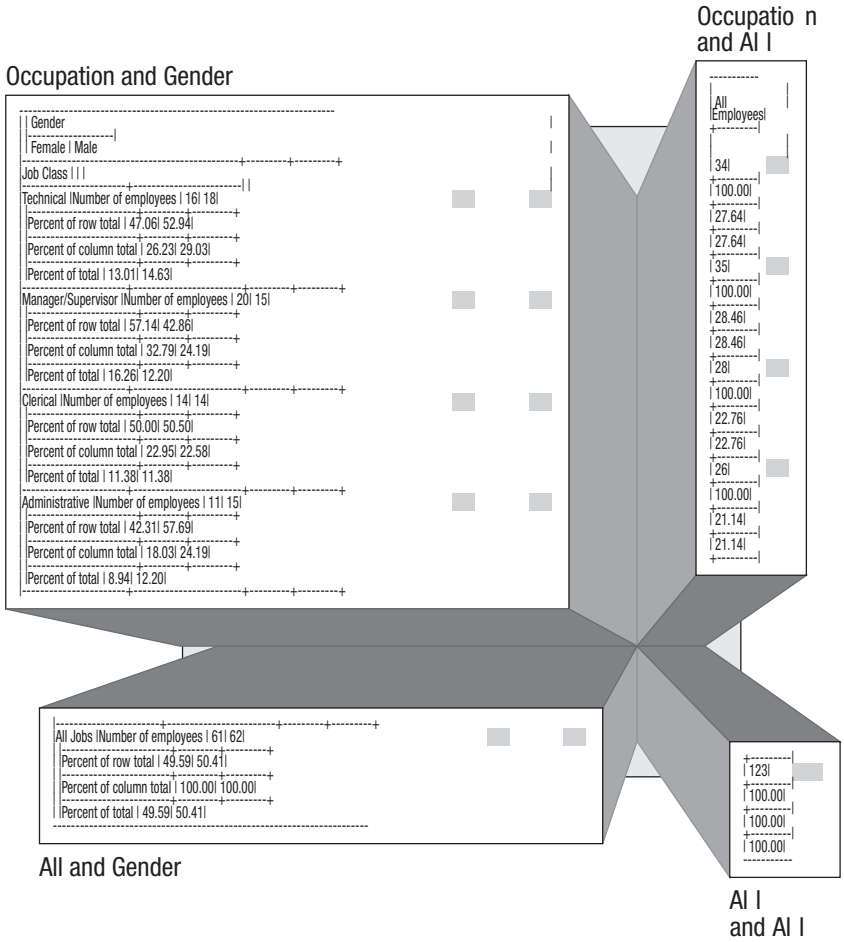
The following table describes each subtable:

Table 70.8 *Contents of Subtables*

Class Variables Contributing to the Subtable	Description of Frequency Counts	Number of Categories
Occupation and Gender	Number of females in each job or number of males in each job	8
All and Gender	Number of females or number of males	2
Occupation and All	Number of people in each job	4
All and All	Number of people in all jobs	1

The following figure highlights these subtables and the frequency counts for each category.

Figure 70.11 *Illustration of the Four Subtables*



Interpreting Denominator Definitions

The following fragment of the TABLE statement defines the denominator definitions for this report. The PCTN keyword and the denominator definitions are highlighted.

```
table (occupation='Job Class' all='All Jobs')
            *(n='Number of employees'*f=5.
              pctn<gender all>='Row percent'
              pctn<occupation all>='Column percent'
              pctn='Percent of total'),
```

Each use of PCTN nests a row of statistics within each value of Occupation and All. Each denominator definition tells PROC TABULATE which frequency counts to sum for the denominators in that row. This section explains how PROC TABULATE interprets these denominator definitions.

Row Percentages

The part of the TABLE statement that calculates the row percentages and that labels the row is

```
pctn<gender all>='Row percent'
```

Consider how PROC TABULATE interprets this denominator definition for each subtable.

Output 70.29 *Subtable 1: Occupation and Gender*

Gender Distribution within Job Classes

		Gender		All Employees
		Female	Male	
Job Class				
Technical	Number of employees	16	18	34
	Percent of row total	47.06	52.94	100.00
	Percent of column total	26.23	29.03	27.64
	Percent of total	13.01	14.63	27.64
Manager/Supervisor	Number of employees	20	15	35
	Percent of row total	57.14	42.86	100.00
	Percent of column total	32.79	24.19	28.46
	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Gender, and asks whether Gender contributes to the subtable. Because Gender does contribute to the subtable, PROC TABULATE uses it as the denominator definition. This denominator definition tells PROC TABULATE to sum the frequency counts for all occurrences of Gender within the same value of Occupation.

For example, the denominator for the category `female, technical` is the sum of all frequency counts for all categories in this subtable for which the value of Occupation is `technical`. There are two such categories: `female, technical` and `male, technical`. The corresponding frequency counts are 16 and 18. Therefore, the denominator for this category is 16+18, or 34.

Output 70.30 *Subtable 2: All and Gender*

Gender Distribution
within Job Classes

		Gender		All Employees
		Female	Male	
Job Class				
Technical	Number of employees	16	18	34
	Percent of row total	47.06	52.94	100.00
	Percent of column total	26.23	29.03	27.64
	Percent of total	13.01	14.63	27.64
Manager/Supervisor	Number of employees	20	15	35
	Percent of row total	57.14	42.86	100.00
	Percent of column total	32.79	24.19	28.46
	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Gender, and asks whether Gender contributes to the subtable. Because Gender does contribute to the subtable, PROC TABULATE uses it as the denominator definition. This denominator definition tells PROC TABULATE to sum the frequency counts for all occurrences of Gender in the subtable.

For example, the denominator for the category `all, female` is the sum of the frequency counts for `all, female` and `all, male`. The corresponding frequency counts are 61 and 62. Therefore, the denominator for cells in this subtable is 61+62, or 123.

Output 70.31 *Subtable 3: Occupation and All*

Gender Distribution within Job Classes

		Gender		All Employees
		Female	Male	
Job Class				
Technical	Number of employees	16	18	34
	Percent of row total	47.06	52.94	100.00
	Percent of column total	26.23	29.03	27.64
	Percent of total	13.01	14.63	27.64
Manager/Supervisor	Number of employees	20	15	35
	Percent of row total	57.14	42.86	100.00
	Percent of column total	32.79	24.19	28.46
	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Gender, and asks whether Gender contributes to the subtable. Because Gender does not contribute to the subtable, PROC TABULATE looks at the next element in the denominator definition, which is All. The variable All does contribute to this subtable, so PROC TABULATE uses it as the denominator definition. All is a reserved class variable with only one category. Therefore, this denominator definition tells PROC TABULATE to use the frequency count of All as the denominator.

For example, the denominator for the category `clerical, all` is the frequency count for that category, 28.

Note: In these table cells, because the numerator and the denominator are the same, the row percentages in this subtable are all 100.

Output 70.32 *Subtable 4: All and All*

Gender Distribution
within Job Classes

		Gender		All Employees
		Female	Male	
Job Class				
Technical	Number of employees	16	18	34
	Percent of row total	47.06	52.94	100.00
	Percent of column total	26.23	29.03	27.64
	Percent of total	13.01	14.63	27.64
Manager/Supervisor	Number of employees	20	15	35
	Percent of row total	57.14	42.86	100.00
	Percent of column total	32.79	24.19	28.46
	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Gender, and asks whether Gender contributes to the subtable. Because Gender does not contribute to the subtable, PROC TABULATE looks at the next element in the denominator definition, which is All. The variable All does contribute to this subtable, so PROC TABULATE uses it as the denominator definition. All is a reserved class variable with only one category. Therefore, this denominator definition tells PROC TABULATE to use the frequency count of All as the denominator.

There is only one category in this subtable: `all, all`. The denominator for this category is 123.

Note: In this table cell, because the numerator and denominator are the same, the row percentage in this subtable is 100.

Column Percentages

The part of the TABLE statement that calculates the column percentages and labels the row is

```
pctn<occupation all>='Column percent'
```

Consider how PROC TABULATE interprets this denominator definition for each subtable.

Output 70.33 *Subtable 1: Occupation and Gender*

Gender Distribution within Job Classes

		Gender		All Employees
		Female	Male	
Job Class				
Technical	Number of employees	16	18	34
	Percent of row total	47.06	52.94	100.00
	Percent of column total	26.23	29.03	27.64
	Percent of total	13.01	14.63	27.64
Manager/Supervisor	Number of employees	20	15	35
	Percent of row total	57.14	42.86	100.00
	Percent of column total	32.79	24.19	28.46
	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Occupation, and asks whether Occupation contributes to the subtable. Because Occupation does contribute to the subtable, PROC TABULATE uses it as the denominator definition. This denominator definition tells PROC TABULATE to sum the frequency counts for all occurrences of Occupation within the same value of Gender.

For example, the denominator for the category `manager/supervisor, male` is the sum of all frequency counts for all categories in this subtable for which the value of Gender is `male`. There are four such categories: `technical, male`; `manager/supervisor, male`; `clerical, male`; and `administrative, male`. The corresponding frequency counts are 18, 15, 14, and 15. Therefore, the denominator for this category is 18+15+14+15, or 62.

Output 70.34 *Subtable 2: All and Gender*

Gender Distribution within Job Classes

	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Occupation, and asks whether Occupation contributes to the subtable. Because Occupation does not contribute to the subtable, PROC TABULATE looks at the next element in the denominator definition, which is All. Because the variable All does contribute to this subtable, PROC TABULATE uses it as the denominator definition. All is a reserved class variable with only one category. Therefore, this denominator definition tells PROC TABULATE to use the frequency count for All as the denominator.

For example, the denominator for the category `all, female` is the frequency count for that category, 61.

Note: In these table cells, because the numerator and denominator are the same, the column percentages in this subtable are all 100.

Output 70.35 *Subtable 3: Occupation and All*

Gender Distribution within Job Classes

		Gender		All Employees
		Female	Male	
Job Class				
Technical	Number of employees	16	18	34
	Percent of row total	47.06	52.94	100.00
	Percent of column total	26.23	29.03	27.64
	Percent of total	13.01	14.63	27.64
Manager/Supervisor	Number of employees	20	15	35
	Percent of row total	57.14	42.86	100.00
	Percent of column total	32.79	24.19	28.46
	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Occupation, and asks whether Occupation contributes to the subtable. Because Occupation does contribute to the subtable, PROC TABULATE uses it as the denominator definition. This denominator definition tells PROC TABULATE to sum the frequency counts for all occurrences of Occupation in the subtable.

For example, the denominator for the category `technical, all` is the sum of the frequency counts for `technical, all`; `manager/supervisor, all`; `clerical, all`; and `administrative, all`. The corresponding frequency counts are 34, 35, 28, and 26. Therefore, the denominator for this category is 34+35+28+26, or 123.

Output 70.36 *Subtable 4: All and All*

Gender Distribution
within Job Classes

		Gender		All Employees
		Female	Male	
Job Class				
Technical	Number of employees	16	18	34
	Percent of row total	47.06	52.94	100.00
	Percent of column total	26.23	29.03	27.64
	Percent of total	13.01	14.63	27.64
Manager/Supervisor	Number of employees	20	15	35
	Percent of row total	57.14	42.86	100.00
	Percent of column total	32.79	24.19	28.46
	Percent of total	16.26	12.20	28.46
Clerical	Number of employees	14	14	28
	Percent of row total	50.00	50.00	100.00
	Percent of column total	22.95	22.58	22.76
	Percent of total	11.38	11.38	22.76
Administrative	Number of employees	11	15	26
	Percent of row total	42.31	57.69	100.00
	Percent of column total	18.03	24.19	21.14
	Percent of total	8.94	12.20	21.14
All Jobs	Number of employees	61	62	123
	Percent of row total	49.59	50.41	100.00
	Percent of column total	100.00	100.00	100.00
	Percent of total	49.59	50.41	100.00

PROC TABULATE looks at the first element in the denominator definition, Occupation, and asks whether Occupation contributes to the subtable. Because Occupation does not contribute to the subtable, PROC TABULATE looks at the next element in the denominator definition, which is All. Because the variable All does contribute to this subtable, PROC TABULATE uses it as the denominator definition. All is a reserved class variable with only one category. Therefore, this denominator definition tells PROC TABULATE to use the frequency count of All as the denominator.

There is only one category in this subtable: `all, all`. The frequency count for this category is 123.

Note: In this calculation, because the numerator and denominator are the same, the column percentage in this subtable is 100.

Total Percentages

The part of the TABLE statement that calculates the total percentages and labels the row is:

```
pctn='Total percent'
```

If you do not specify a denominator definition, then PROC TABULATE obtains the denominator for a cell by totaling all the frequency counts in the subtable. The following table summarizes the process for all subtables in this example.

Table 70.9 *Denominators for Total Percentages*

Class Variables Contributing to the Subtable	Frequency Counts	Total
Occupant and Gender	16, 18, 20, 15 14, 14, 11, 15	123
Occupant and All	34, 35, 28, 26	123
Gender and All	61, 62	123
All and All	123	123

Consequently, the denominator for total percentages is always 123.

Example 14: Specifying Style Overrides for ODS Output

Features:

CLASS statement option
    STYLE=

CLASSLEV statement option
    STYLE=

KEYLABEL statement

KEYWORD statement option
    STYLE=

PROC TABULATE statement options
    DATA=
    STYLE=

TABLE statement options
    STYLE=
    MISSTEXT=
    BOX=

ODS HTML statement
ODS HTML CLOSE statement
ODS PDF statement
ODS PDF CLOSE statement
ODS RTF statement
ODS RTF CLOSE statement
OPTIONS statement
TITLE statement

Data set: ENERGY
Format: REGFMT.
Format: DIVFMT.
Format: USETYPE.

Details

This example creates HTML, RTF, and PDF files and specifies style overrides for various table regions.

Program

```
options nodate pageno=1;

proc sort data=energy;
   by region;
run;

ods html5 path='path' body='filename.htm';
ods pdf file='filename.pdf' contents=yes;
ods rtf file='filename.rtf' contents=yes;

proc tabulate data=energy style=[fontweight=bold];

by region;

   class region division type / style=[textalign=center];

   classlev region division type / style=[textalign=left];

   var expenditures / style=[fontsize=3];

   keyword all sum / style=[fontwidth=wide];
   keylabel all="Total";

   table (region all)*(division all*[style=[backgroundcolor=yellow]]),
         (type all)*(expenditures*f=dollar10.) /
         style=[bordercolor=blue]

         misstext=[label="Missing" style=[fontweight=light]]

         box=[label="Region by Division by Type"
```

```
            style=[fontstyle=italic]];
   format region regfmt. division divfmt. type usetype.;
   title 'Energy Expenditures';
   title2 '(millions of dollars)';
run;
ods _all_ close;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number.

```
options nodate pageno=1;
```

Sort the data set.

```
proc sort data=energy;
   by region;
run;
```

Specify the ODS output filenames. By opening multiple ODS destinations, you can produce multiple output files in a single execution. The ODS HTML5 statement produces output that is written in HTML 5.0. The ODS PDF statement produces output in Portable Document Format (PDF). The ODS RTF statement produces output in Rich Text Format (RTF). The output from PROC TABULATE goes to each of these files.

In the ODS PDF and ODS RTF statements, the CONTENTS= option creates a table of contents.

```
ods html5 path='path' body='filename.htm';
ods pdf file='filename.pdf' contents=yes;
ods rtf file='filename.rtf' contents=yes;
```

Customize the data cells. The STYLE= option in the PROC TABULATE statement specifies the style override for the data cells of the table.

```
proc tabulate data=energy style=[fontweight=bold];
```

Specify the BY-group. When BY statements are specified, labels for the BY group tables are displayed in the table of contents. The labels are based on the values of the BY variable.

```
by region;
```

Customize the class variable name headings. The STYLE= option in the CLASS statement specifies the style override for the class variable name headings.

```
   class region division type / style=[textalign=center];
```

Customize the class variable value headings. The STYLE= option in the CLASSLEV statement specifies the style override for the class variable level value headings.

```
   classlev region division type / style=[textalign=left];
```

Customize the analysis variable name headings. The STYLE= option in the VAR statement specifies a style element for the variable name headings.

```
      var expenditures / style=[fontsize=3];
```

Specify the style attributes for keywords, and label the "all" keyword. The STYLE= option in the KEYWORD statement specifies a style element for keywords. The KEYLABEL statement assigns a label to the keyword.

```
      keyword all sum / style=[fontwidth=wide];
      keylabel all="Total";
```

Define and customize the table rows and columns. The STYLE= option in the dimension expression overrides any other STYLE= specifications in PROC TABULATE that specify overrides for table cells. The STYLE= option after the slash (/) specifies style overrides for parts of the table other than table cells.

```
      table (region all)*(division all*[style=[backgroundcolor=yellow]]),
            (type all)*(expenditures*f=dollar10.) /
            style=[bordercolor=blue]
```

Customize missing values. The STYLE= option in the MISSTEXT option of the TABLE statement specifies a style element to use for the text in table cells that contain missing values.

```
            misstext=[label="Missing" style=[fontweight=light]]
```

Customize the box above the row titles. The STYLE= option in the BOX option of the TABLE statement specifies a style override for text in the box above the row titles.

```
            box=[label="Region by Division by Type"
               style=[fontstyle=italic]];
```

Format the class variable values.

```
      format region regfmt. division divfmt. type usetype.;
```

Specify the titles.

```
      title 'Energy Expenditures';
      title2 '(millions of dollars)';
   run;
```

Close all of the ODS destinations.

```
   ods _all_ close;
```

Output

Output 70.37 *HTML Output*

Energy Expenditures

Example 15: Style Precedence

Features:

CLASS statement0

CLASSLEV statement option
- STYLE=

KEYLABEL statement

LABEL statement

PROC TABULATE statement options
- DATA=
- FORMAT=

TABLE statement
- crossing (*) operator
- STYLE=
- STYLE_PRECEDENCE= option

VAR statement

ODS HTML statement

FORMAT procedure

FORMAT statement

TITLE statement

Data set: SALES

Details

This example does the following:

- creates a category for each sales type, retail or wholesale, in each region
- applies the dollar format to all cells in the table
- applies an italic font style for each region and sales type
- applies a style (background = red, yellow, or orange) color based on the STYLE_PRECEDENCE = option
- generates ODS HTML output

Program

```
proc format;
      value $saletypefmt 'R'='Retail'
                         'W'='WholeSale';
run;

ods html file="stylePrecedence.html";

title "Style Precedence";
title2 "First Table: no precedence, Orange";
title3 "Second Table: style_precedence=page, Yello";

proc tabulate data=sales format=dollar10.;

class product region saletype;

classlev region saletype / style={font_style=italic};

var netsales;

label netsales="Net Sales";

keylabel all="Total";

table product *{style={background=#edf8b1}},
region*{style={background=yellow}},
saletype*{style={background=orange}};

table product *{style={background=#edf8b1}},
region*{style={background=yellow}},
saletype*{style={background=orange}} / style_precedence=page;

format saletype $saletypefmt.;

run;
```

Program Description

Create the SALETYPEFMT. formats. PROC FORMAT creates formats for SALETYPE.

```
proc format;
      value $saletypefmt 'R'='Retail'
                         'W'='WholeSale';
run;
```

Specify the ODS output filename. The ODS HTML statement produces output that is written in HTML.

```
ods html file="stylePrecedence.html";
```

Specify the titles of the tables to be produced. Two tables will be generated. The First Table will show no style precedence whereas the Second Table will show that the color that takes precedence is based on what is specified by the STYLE_PRECEDENCE option.

```
title "Style Precedence";
title2 "First Table: no precedence, Orange";
title3 "Second Table: style_precedence=page, Yello";
```

Specify the table options. The FORMAT= option specifies DOLLAR10. as the default format for the value in each table cell.

```
proc tabulate data=sales format=dollar10.;
```

Specify subgroups for the analysis. The CLASS statement separates the analysis by values of Product, Region, and SaleType.

```
class product region saletype;
```

Specify styles for the subgroups. The CLASSLEV statement specifies a style for the Region and Saletype elements.

```
classlev region saletype / style={font_style=italic};
```

Specify the analysis variable. The VAR statement specifies that PROC TABULATE calculate statistics on the Netsales variable.

```
var netsales;
```

Specify labels. The LABEL statement renames the Netsales variable to Net Sales.

```
label netsales="Net Sales";
```

Specify Keylabel. The KEYLABEL statement labels the universal class variable ALL to Total.

```
keylabel all="Total";
```

Define the table rows and columns. The TABLE statement creates a table per product per page. In this example, there is one product, A100. The TABLE statement also creates a row for each formatted value of Region and creates a column for each formatted value of SaleType. Each cell that is created by these rows and columns contains the sum of the analysis variable Net Sales for all

observations that contribute to that cell. The STYLE= option in the dimension expression overrides any other STYLE= specifications in PROC TABULATE that specify attributes for the table cells. In this first table, the column expression is the default and the style associated with column takes precedence. Therefore, orange will be the default color of the background.

```
table product *{style={background=#edf8b1}},
region*{style={background=yellow}},
saletype*{style={background=orange}};
```

Define the table rows and columns using the STYLE_PRECEDENCE option. The TABLE statement creates a table per product per page, A100. The TABLE statement also creates a row for each formatted value of Region and creates a column for each formatted value of SaleType. Each cell that is created by these rows and columns contains the sum of the analysis variable Net Sales for all observations that contribute to that cell. The STYLE= option in the dimension expression overrides any other STYLE= specifications in PROC TABULATE that specify attributes for the table cells. In this second table, the STYLE_PRECEDENCE option is specified on the page expression. Therefore, the style that applies to the background is red.

```
table product *{style={background=#edf8b1}},
region*{style={background=yellow}},
saletype*{style={background=orange}} / style_precedence=page;
```

Format the output. The FORMAT statement assigns formats to the SaleType variable.

```
format saletype $saletypefmt.;
```

Run the program.

```
run;
```

Output

Output 70.40 *Table with No Style Precedence*

Style Precedence
First Table: no precedence, orange
Second Table: style_precedence=page, Yellow

Product A100

	SaleType	
	Retail	*WholeSale*
	N	N
Region		
NC	$3	$3
TX	.	$2

Output 70.41 *Table Style Precedence*

Style Precedence
First Table: no precedence, orange
Second Table: style_precedence=page, Yellow

Product A100

	SaleType	
	Retail	*WholeSale*

Example 16: Using the NOCELLMERGE Option

Features:

CLASS statement

PROC TABULATE statement options
- DATA=
- STYLE=

CLASS statement

TABLE statement
- crossing (*) operator
- STYLE= option
- NOCELLMERGE= option

ODS HTML statement

ODS HTML CLOSE statement

TITLE statement

Details

This example does the following:

- creates a table with merged cells style behavior
- creates a second table without merged cells
- shows how cells styles are affected when empty data cells and the formatted data cells use different styles

Program

```
ods html file="tabstyle.html";
proc tabulate data=sashelp.class style={background=#edf8b1};
class sex age;

table sex*{style={background=#7fcdbb}} all, age;
title 'Data Cell Styles in Merged Cells';
run;

proc tabulate data=sashelp.class style={background=#edf8b1};
class sex age;

table sex*{style={background=#7fcdbb}} all, age/nocellmerge;
title1 'Data Cell Styles with NOCELLMERGE Option';
run;

ODS html close;
ods html;
```

Program Description

Specify the ODS output filename. The ODS HTML statement produces output that is written in HTML.

```
ods html file="tabstyle.html";
```

Specify the PROC TABULATE options. The STYLE= option sets the background color for the cells in the table to red.

```
proc tabulate data=sashelp.class style={background=#edf8b1};
```

Specify subgroups. The CLASS statement separates the data by sex and age.

```
class sex age;
```

Define the table rows and columns. The TABLE statement creates a table. The STYLE= option in the dimension expression overrides the STYLE= setting from the PROC TABULATE statement for table cells attributes.

```
table sex*{style={background=#7fcdbb}} all, age;
```

Specify the title of the table to be produced. This table shows how changing the style color affects the merged cells.

```
title 'Data Cell Styles in Merged Cells';
```

Run the program.

```
run;
```

Specify the PROC TABULATE options. The STYLE= option sets the background color for the cells in the table to red.

```
proc tabulate data=sashelp.class style={background=#edf8b1};
```

Specify subgroups. The CLASS statement separates the data by sex and age.

```
class sex age;
```

Define the table rows and columns. The TABLE statement creates a table. The STYLE= option in the dimension expression overrides the STYLE= setting from the PROC TABULATE statement, but only for the formatted data cells.

```
table sex*{style={background=#7fcdbb}} all, age/nocellmerge;
```

Specify the title of the table to be produced. This table shows how changing the style color affects the formatted cells that are not merged.

```
title1 'Data Cell Styles with NOCELLMERGE Option';
```

Run the program.

```
run;
```

Close the ODS HTML output destination.

```
ODS html close;
ods html;
```

Output

Output 70.42 *Data Cell Styles in Merged Cells*

Data Cell Styles in Merged Cells

TIMEPLOT Procedure

Overview: TIMEPLOT Procedure

What Does the TIMEPLOT Procedure Do?

The TIMEPLOT procedure plots one or more variables over time intervals. A listing of variable values accompanies the plot. Although the plot and the listing are

similar to the ones produced by the PLOT and PRINT procedures, PROC TIMEPLOT output has these distinctive features:

- The vertical axis always represents the sequence of observations in the data set. Thus, if the observations are in order of date or time, then the vertical axis represents the passage of time.
- The horizontal axis represents the values of the variable that you are examining. Like PROC PLOT, PROC TIMEPLOT can overlay multiple plots on one set of axes so that each line of the plot can contain values for more than one variable.
- A plot produced by PROC TIMEPLOT can occupy more than one page.
- Each observation appears sequentially on a separate line of the plot; PROC TIMEPLOT does not hide observations as PROC PLOT sometimes does.
- The listing of the plotted values can include variables that do not appear in the plot.

The following output illustrates a simple report that you can produce with PROC TIMEPLOT. This report shows sales of refrigerators for two sales representatives during the first six weeks of the year. The statements that produce the output follow. A DATA step in "Example 1: Plotting a Single Variable" on page 2637 creates the data set Sales.

```
title 'The SAS System';
options source;

options linesize=64 pagesize=60 nodate
        pageno=1;

proc timeplot data=sales;
   plot icebox;
   id month week;
   title 'Weekly Sales of Refrigerators';
   title2 'for the';
   title3 'First Six Weeks of the Year';
run;
```

Output 71.1 Simple Report Created with PROC TIMEPLOT

```
                Weekly Sales of Refrigerators
                          for the
                First Six Weeks of the Year

Month     Week     Icebox    min                           max
                             2520.04                   3550.43
                             *-------------------------------*
    1        1    3450.94    |                            I  |

    1        4    3400.24    |                          I    |
    1        4    2870.61    |           I                   |
    2        1    3550.43    |                              I|
    2        1    2730.09    |      I                        |
    2        2    3385.74    |                          I    |
    2        2    2670.93    |     I                         |
                             *-------------------------------*
```

The following output is a more complicated report of the same data set that is used to create Output 71.389 on page 2623. The statements that create this report do the following:

- create one plot for the sale of refrigerators and one for the sale of stoves
- plot sales for both sales representatives on the same line
- identify points on the plots by the first letter of the sales representative's last name
- control the size of the horizontal axis
- control formats and labels

For an explanation of the program that produces this report, see "Example 5: Showing Multiple Observations on One Line of a Plot" on page 2648.

Output 71.2 *More Complex Report Created with PROC TIMEPLOT*

Weekly Appliance Sales for the First Quarter

Month	Week	Kreitz Icebox	LeGrange Icebox	min $2,520.04 — max $3,550.43
January	1	$3,450.94	$2,520.04	|L K |
January	2	$3,240.67	$2,675.42	| L K |
January	3	$3,160.45	$2,805.35	| L K |
January	4	$3,400.24	$2,870.61	| L K |
February	1	$3,550.43	$2,730.09	| L K|
February	2	$3,385.74	$2,670.93	| L K |

Weekly Appliance Sales for the First Quarter

Month	Week	Seller :Kreitz Stove	Seller :LeGrange Stove	min $184.24 — max $2,910.37
January	1	$1,312.61	$728.13	| L K |
January	2	$222.35	$184.24	|! |
January	3	$2,263.33	$267.35	| L K |
January	4	$1,787.45	$274.51	| L K |
February	1	$2,910.37	$397.98	| L K|
February	2	$819.69	$2,242.24	| K L |

Syntax: TIMEPLOT Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Requirement: At least one PLOT statement is required.

Tip: You can use the ATTRIB, FORMAT, LABEL, and WHERE statements with PROC TIMEPLOT.

PROC TIMEPLOT <*options*>;

BY <DESCENDING> *variable-1* <<DESCENDING> *variable-2* ...> <NOTSORTED>;

CLASS *variable(s)*;

ID *variable(s)*;

PLOT *plot-request(s)* </*options*>;

Statement	Task	Example
PROC TIMEPLOT	Request that the plots be produced	Ex. 4
BY	Produce a separate plot for each BY group	
CLASS	Group data according to the values of the class variables	Ex. 5
ID	Print in the listing the values of the variables that you identify	Ex. 1, Ex. 2, Ex. 3
PLOT	Specify the plots to produce	Ex. 1, Ex. 2, Ex. 3, Ex. 4, Ex. 5

PROC TIMEPLOT Statement

Requests that the plots be produced.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Example: "Example 4: Superimposing Two Plots" on page 2646

Syntax

PROC TIMEPLOT <*options*>;

Optional Arguments

DATA=*SAS-data-set*
identifies the input data set.

ENCRYPTKEY=*key-value*
specifies the key value needed for plotting an AES-encrypted data set. If the input data set was created with ENCRYPT=AES, then you must specify the ENCRYPTKEY= value to plot its data. For example, if a data set named secretPlot is created using the DATA statement.

```
data secretPlot(encrypt=AES encryptkey=Ib007)
```

Then, you must specify the following PROC statement to plot the data in secretPlot:

```
proc timeplot data=secretPlot(encryptkey=Ib007);
```

See "ENCRYPTKEY= Data Set Option" in *SAS Data Set Options: Reference* for more information about the ENCRYPTKEY= data set option.

MAXDEC=*number*
specifies the maximum number of decimal places to be printed in the listing.

Default 2

Range 0-12

Interaction A decimal specification in a format overrides a MAXDEC= specification.

Example "Example 4: Superimposing Two Plots" on page 2646

SPLIT='*split-character*'
specifies a split character, which controls line breaks in column headings. It also specifies that labels be used as column headings. PROC TIMEPLOT breaks a column heading when it reaches the split character and continues the heading on the next line. Unless the split character is a blank, it is not part of the column heading. Each occurrence of the split character counts toward the 256-character maximum for a label.

Alias S=

Default blank (' ')

Note Column headings can occupy up to three lines. If the column label can be split into more lines than this fixed number, then the split character is used only as a recommendation on how to split the label.

UNIFORM
uniformly scales the horizontal axis across all BY groups. By default, PROC TIMEPLOT separately determines the scale of the axis for each BY group.

Interaction UNIFORM also affects the calculation of means for reference lines. For more information, see "REF=*reference-value(s)* " on page 2634.

BY Statement

Produces a separate plot for each BY group.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

See: "BY" on page 74

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2* ...>
<NOTSORTED>;

Required Argument

variable
specifies the variable that the procedure uses to form BY groups. You can specify more than one variable. Unless you use the NOTSORTED option in the BY statement, the data must either be sorted by variables or indexed. These variables are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the data set is sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The data is grouped in another way, such as chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. In fact, the procedure does not use an index if you specify NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations that have the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

CLASS Statement

Groups data according to the values of the class variables.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Tip: PROC TIMEPLOT uses the formatted values of the CLASS variables to form classes. Thus, if a format groups the values, then the procedure uses those groups.

Example: "Example 5: Showing Multiple Observations on One Line of a Plot" on page 2648

Syntax

CLASS *variable(s)*;

Required Argument

variable(s)
specifies one or more variables that the procedure uses to group the data. Variables in a CLASS statement are called *class variables*. Class variables can be numeric or character. Class variables can have continuous values, but they

typically have a few discrete values that define the classifications of the variable. You do not have to sort the data by class variables.

The values of the class variables appear in the listing. PROC TIMEPLOT prints and plots one line each time the combination of values of the class variables changes. Therefore, the output typically is more meaningful if you sort or group the data according to values of the class variables.

Details

Using Multiple CLASS Statements

You can use any number of CLASS statements. If you use more than one CLASS statement, then PROC TIMEPLOT simply concatenates all variables from all of the CLASS statements. The following form of the CLASS statement includes three variables:

CLASS *variable-1 variable-2 variable-3*;

It has the same effect as this form:

CLASS *variable-1*;

CLASS *variable-2*;

CLASS *variable-3*;

Using a Symbol Variable

Normally, you use the CLASS statement with a symbol variable. In this case, the listing of the plot variable contains a column for each value of the symbol variable. Each row of the plot contains a point for each value of the symbol variable. The plotting symbol is the first character of the formatted value of the symbol variable. But, if more than one observation within a class has the same symbol value, then PROC TIMEPLOT plots and prints only the first occurrence of that symbol. SAS prints a warning in the log describing this behavior.

For more information about plotting symbols and the CLASS statement, see plot requests on page 2630.

ID Statement

Prints in the listing the values of the variables that you identify.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Examples: “Example 1: Plotting a Single Variable” on page 2637

“Example 2: Customizing an Axis and a Plotting Symbol” on page 2640

“Example 3: Using a Variable for a Plotting Symbol” on page 2643

Syntax

ID *variable(s)*;

Required Argument

variable(s)
identifies one or more *ID variables* to be printed in the listing.

PLOT Statement

Specifies the plots to produce.

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

Tip: Each PLOT statement produces a separate plot.

Examples:
"Example 1: Plotting a Single Variable" on page 2637
"Example 2: Customizing an Axis and a Plotting Symbol" on page 2640
"Example 3: Using a Variable for a Plotting Symbol" on page 2643
"Example 4: Superimposing Two Plots" on page 2646
"Example 5: Showing Multiple Observations on One Line of a Plot" on page 2648

Syntax

PLOT *plot-request(s)* </*options*>;

Summary of Optional Arguments

Control the appearance of the plot

HILOC
connects the leftmost plotting symbol to the rightmost plotting symbol with a line of hyphens (-).

JOINREF
connects the leftmost and rightmost symbols on each line of the plot with a line of hyphens (-) regardless of whether the symbols are reference symbols or plotting symbols.

NOSYMNAME
suppresses the name of the symbol variable in column headings when you use a CLASS statement.

NPP
suppresses the listing of the values of the variables that appear in the PLOT statement.

POS=*print-positions-for-plot*
specifies the number of print positions to use for the horizontal axis.

Create and customize a reference line

REF=*reference-value(s)*
draws lines on the plot that are perpendicular to the specified values on the horizontal axis.

REFCHAR=*'character'*
specifies the character for drawing reference lines.

Customize the axis

AXIS=*axis-specification*
specifies the range of values to plot on the horizontal axis, as well as the interval represented by each print position on the horizontal axis.

REVERSE
orders the values on the horizontal axis with the largest value in the leftmost position.

Display multiple plots on the same set of axes

OVERLAY
plots all requests in one PLOT statement on one set of axes.

OVPCHAR=*'character'*
specifies the character to be printed if multiple plotting symbols coincide.

Required Argument

plot-request(s)
specifies the variable or variables to plot. (Optional) Also specifies the plotting symbol to use. By default, each plot request produces a separate plot.

You can mix different forms of requests in one PLOT statement. For an example of mixing forms, see "Example 4: Superimposing Two Plots" on page 2646.

variable(s)
identifies one or more numeric variables to plot. PROC TIMEPLOT uses the first character of the variable name as the plotting symbol.

Example "Example 1: Plotting a Single Variable" on page 2637

(variable(s))='plotting-symbol'
identifies one or more numeric variables to plot and specifies the plotting symbol to use for all variables in the list. You can omit the parentheses if you use only one variable.

Example "Example 2: Customizing an Axis and a Plotting Symbol" on page 2640

(variable(s))=symbol-variable
identifies one or more numeric variables to plot and specifies a *symbol variable*. PROC TIMEPLOT uses the first nonblank character of the formatted value of the symbol variable as the plotting symbol for all variables in the list. The plotting symbol changes from one observation to the next if the

value of the symbol variable changes. You can omit the parentheses if you use only one variable.

Example "Example 3: Using a Variable for a Plotting Symbol" on page 2643

Optional Arguments

AXIS=*axis-specification*

specifies the range of values to plot on the horizontal axis, as well as the interval represented by each print position on the axis. PROC TIMEPLOT labels the first and last ends of the axis, if space permits.

For numeric values, *axis-specification* can be one of the following or a combination of both:

n< ...*n*>

n **TO** *n* <BY *increment*>

The values must be in either ascending or descending order. Use a negative value for *increment* to specify descending order. The specified values are spaced evenly along the horizontal axis even if the values are not uniformly distributed. Numeric values can be specified in the following ways:

Table 71.1 *Specifying AXIS= Values*

Specification	Comments
`axis=1 2 10`	Values are 1, 2, and 10.
`axis=10 to 100 by 5`	Values appear in increments of 5, starting at 10 and ending at 100.
`axis=12 10 to 100 by 5`	A combination of the two previous forms of specification.

For axis variables that contain datetime values, *axis-specification* is either an explicit list of values or a starting value and an ending value with an increment specified:

'*date-time-value*'*i* < ...'*date-time-value*'*i*>

'*date-time-value*'*i* **TO** '*date-time-value*'*i*
<BY *increment*>

'date-time-value'i

any SAS date, time, or datetime value described for the SAS functions INTCK and INTNX. The suffix *i* is one of the following:

D date

T time

DT datetime

increment
one of the valid arguments for the INTCK or INTNX functions. For dates, *increment* can be one of the following:

- DAY
- WEEK
- MONTH
- QTR
- YEAR

For datetimes, *increment* can be one of the following:

- DTDAY
- DTWEEK
- DTMONTH
- DTQTR
- DTYEAR

For times, *increment* can be one of the following:

- HOUR
- MINUTE
- SECOND

The following statement is an example of using the day increment:

```
axis='01JAN95'd to '01JAN96'd by month
axis='01JAN95'd to '01JAN96'd by qtr
```

For descriptions of individual intervals, see *SAS Language Reference: Concepts*.

Note: You must use a FORMAT statement to print the tick-mark values in an understandable form.

Interaction The value of POS= (see "POS=*print-positions-for-plot*" on page 2633) overrides an interval set with AXIS=.

Tip It is possible for your data to be out of range and fall outside the axis area of the plot. When this happens, PROC TIMEPLOT places angle brackets, (<) or (>), on the sides of the plot to indicate that there is data not being represented.

Example "Example 2: Customizing an Axis and a Plotting Symbol" on page 2640

HILOC
connects the leftmost plotting symbol to the rightmost plotting symbol with a line of hyphens (-).

Interaction If you specify JOINREF, then PROC TIMEPLOT ignores HILOC.

JOINREF
connects the leftmost and rightmost symbols on each line of the plot with a line of hyphens (-), regardless of whether the symbols are reference symbols or plotting symbols. However, if a line contains only reference symbols, then PROC TIMEPLOT does not connect the symbols.

Example "Example 3: Using a Variable for a Plotting Symbol" on page 2643

NOSYMNAME
suppresses the name of the symbol variable in column headings when you use a CLASS statement. If you use NOSYMNAME, then only the value of the symbol variable appears in the column heading.

Example "Example 5: Showing Multiple Observations on One Line of a Plot" on page 2648

NPP
suppresses the listing of the values of the variables that appear in the PLOT statement.

Example "Example 3: Using a Variable for a Plotting Symbol" on page 2643

OVERLAY
plots all requests in one PLOT statement on one set of axes. Otherwise, PROC TIMEPLOT produces a separate plot for each plot request.

Example "Example 4: Superimposing Two Plots" on page 2646

OVPCHAR='*character*'
specifies the character to be printed if multiple plotting symbols coincide. If a plotting symbol and a character in a reference line coincide, then PROC TIMEPLOT prints the plotting symbol.

Default at sign (@)

Example "Example 5: Showing Multiple Observations on One Line of a Plot" on page 2648

POS=*print-positions-for-plot*
specifies the number of print positions to use for the horizontal axis.

Default If you omit both POS= and AXIS=, then PROC TIMEPLOT initially assumes that POS=20. However, if space permits, then this value increases so that the plot fills the available space.

Interaction If you specify POS=0 and AXIS=, then the plot fills the available space. POS= overrides an interval set with AXIS= . See the discussion of "AXIS=*axis-specification*" on page 2631.

See "Page Layout" on page 2635

Example "Example 1: Plotting a Single Variable" on page 2637

REF=*reference-value(s)*
draws lines on the plot that are perpendicular to the specified values on the horizontal axis. The values for *reference-value(s)* can be constants, or you can use the form

MEAN(*variable(s)*)

If you use this form of REF=, then PROC TIMEPLOT evaluates the mean for each variable that you list and draws a reference line for each mean.

Interactions If you use the UNIFORM option in the PROC TIMEPLOT statement, then the procedure calculates the mean values for the variables over all observations for all BY groups. If you do not use UNIFORM, then the procedure calculates the mean for each variable for each BY group.

If a plotting symbol and a reference character coincide, then PROC TIMEPLOT prints the plotting symbol.

Examples "Example 3: Using a Variable for a Plotting Symbol" on page 2643

"Example 4: Superimposing Two Plots" on page 2646

REFCHAR=*'character'*
specifies the character for drawing reference lines.

Default vertical bar (|)

Interaction If you are using the JOINREF or HILOC option, then do not specify a value for REFCHAR= that is the same as a plotting symbol. If you do this, then PROC TIMEPLOT will interpret the plotting symbols as reference characters and will not connect the symbols as you expect.

Example "Example 3: Using a Variable for a Plotting Symbol" on page 2643

REVERSE
orders the values on the horizontal axis with the largest value in the leftmost position.

Example "Example 4: Superimposing Two Plots" on page 2646

Results: TIMEPLOT Procedure

Data Considerations

The input data set usually contains a date variable to use as either a class or ID variable. Although PROC TIMEPLOT does not require an input data set sorted by date, the output is usually more meaningful if the observations are in chronological order. In addition, if you use a CLASS statement, then the output is more meaningful if the input data set groups observations according to combinations of class variable values. For more information, see "CLASS Statement" on page 2627.

Procedure Output

Page Layout

For each plot request, PROC TIMEPLOT prints a listing and a plot. PROC TIMEPLOT determines the arrangement of the page as follows:

- If you use POS=, then the procedure does the following:
  - determines the size of the plot from the POS= value
  - determines the space for the listing from the width of the columns of printed values, equally spaced and with a maximum of five positions between columns
  - centers the output on the page
- If you omit POS=, then the procedure does the following:
  - determines the width of the plot from the value of the AXIS= option
  - expands the listing to fill the rest of the page

If there is not enough space to print the listing and the plot, then PROC TIMEPLOT produces no output and writes the following error message to the SAS log:

```
ERROR:  Too many variables/symbol values
        to print.
```

The error does not affect other plot requests.

Contents of the Listing

The listing in the output contains different information depending on whether you use a CLASS statement. If you do not use a CLASS statement, then PROC TIMEPLOT prints (and plots) each observation on a separate line. For an example of the output without the CLASS statement, see "Example 1: Plotting a Single Variable" on page 2637.

If you do use a CLASS statement, then the form of the output varies depending on whether you specify a symbol variable. For more information about using a symbol variable with the CLASS statement, see "Using a Symbol Variable" on page 2628.

ODS Table Names

The TIMEPLOT procedure assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. For more information, see *SAS Output Delivery System: User's Guide*.

Table 71.2 *ODS Tables Produced by the TIMEPLOT Procedure*

Table Name	Description	Conditions When Table Is Generated
Plot	A single plot	If you do not specify the OVERLAY option
OverlaidPlot	Two or more plots on a single set of axes	If you specify the OVERLAY option

Missing Values

Four types of variables can appear in the listing from PROC TIMEPLOT:

- plot variables
- ID variables
- class variables
- symbol variables (as part of some column headings)

Plot variables and symbol variables can also appear in the plot.

Observations with missing values of a class variable form a class of observations.

In the listing, missing values appear as a period (.), a blank, or a special missing value (the letters A through Z and the underscore (_) character).

In the plot, PROC TIMEPLOT handles different variables in different ways:

- An observation or class of observations with a missing value does not appear in the plot.
- If you use a symbol variable, then PROC TIMEPLOT uses a period (.) as the symbol variable on the plot for all observations that have a missing value for the symbol variable. For more information about using symbol variables, see plot requests on page 2630.

Examples: TIMEPLOT Procedure

Example 1: Plotting a Single Variable

Features:

PROC TIMEPLOT statement options
DATA=

ID statement

PLOT statement

PLOT statement option
POS=

DATA step

Details

This example demonstrates the following tasks:

- uses a DATA step to create the data set Sales
- uses a single PLOT statement to plot sales of refrigerators
- specifies the number of print positions to use for the horizontal axis of the plot
- provides context for the points in the plot by printing in the listing the values of two variables that are not in the plot

Program

```
options formchar="|----|+|---+=|-/\<>*";

data sales;
   input Month Week Seller $ Icebox Stove;
   datalines;
1 1 Kreitz   3450.94 1312.61
1 1 LeGrange 2520.04  728.13
1 2 Kreitz   3240.67  222.35
1 2 LeGrange 2675.42  184.24
1 3 Kreitz   3160.45 2263.33
1 3 LeGrange 2805.35  267.35
1 4 Kreitz   3400.24 1787.45
1 4 LeGrange 2870.61  274.51
2 1 Kreitz   3550.43 2910.37
2 1 LeGrange 2730.09  397.98
2 2 Kreitz   3385.74  819.69
2 2 LeGrange 2670.93 2242.24
;

proc timeplot data=sales;
   plot icebox / pos=50;

   id month week;

   title 'Weekly Sales of Iceboxes';
   title2 'for the';
   title3 'First Six Weeks of the Year';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create the Sales data set. Sales contains weekly information about the sales of refrigerators and stoves by two sales representatives.

```
data sales;
   input Month Week Seller $ Icebox Stove;
   datalines;
1 1 Kreitz   3450.94 1312.61
1 1 LeGrange 2520.04  728.13
1 2 Kreitz   3240.67  222.35
1 2 LeGrange 2675.42  184.24
1 3 Kreitz   3160.45 2263.33
1 3 LeGrange 2805.35  267.35
1 4 Kreitz   3400.24 1787.45
1 4 LeGrange 2870.61  274.51
2 1 Kreitz   3550.43 2910.37
2 1 LeGrange 2730.09  397.98
2 2 Kreitz   3385.74  819.69
```

```
2 2 LeGrange 2670.93 2242.24
;
```

Plot sales of refrigerators. The plot variable, Icebox, appears in both the listing and the output. POS= provides 50 print positions for the horizontal axis.

```
proc timeplot data=sales;
   plot icebox / pos=50;
```

Label the rows in the plot listing. The values of the ID variables, Month and Week, are used to uniquely identify each row of the listing section of the plot.

```
   id month week;
```

Specify the titles.

```
   title 'Weekly Sales of Iceboxes';
   title2 'for the';
   title3 'First Six Weeks of the Year';
run;
```

Output

The column headings in the listing are the variables' names. The plot uses the default plotting symbol, which is the first character of the plot variable's name.

Output 71.3 *Plot for a Single Variable*

Weekly Sales of Refrigerators
for the
First Six Weeks of the Year

Month	Week	Icebox	min 2520.04 … max 3550.43
1	1	3450.94	I
1	1	2520.04	I
1	2	3240.67	I
1	2	2675.42	I
1	3	3160.45	I
1	3	2805.35	I
1	4	3400.24	I
1	4	2870.61	I
2	1	3550.43	I
2	1	2730.09	I
2	2	3385.74	I
2	2	2670.93	I

Example 2: Customizing an Axis and a Plotting Symbol

Features:
- PROC PLOT statement option AXIS=
- ID statement
- PLOT statement
- LABEL statement
- PROC FORMAT
- LIBNAME statement
- FMTSEARCH= system option

Data set: Sales

Details

This example demonstrates the following tasks:

- specifies the character to use as the plotting symbol
- specifies the minimum and maximum values for the horizontal axis as well as the interval represented by each print position
- provides context for the points in the plot by printing in the listing the values of two variables that are not in the plot
- uses a variable's label as a column heading in the listing
- creates and uses a permanent format

Program

```
libname proclib  'SAS-library';

options formchar="|----|+|---+=|-/\<>*";

proc format library=proclib;
   value monthfmt 1='January'
                  2='February';
run;

proc timeplot data=sales;
   plot icebox='R' / axis=2500 to 3600 by 25;

   id month week;

   label icebox='Refrigerator';

   format month monthfmt.;

title 'Weekly Refrigerator Sales';
title2 'for the First Six Weeks of the Year';
run;
```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib  'SAS-library';
```

Set the SAS system options. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Create a format for the Month variable. PROC FORMAT creates a permanent format for Month. The LIBRARY= option specifies a permanent storage location so

that the formats are available in subsequent SAS sessions. This format is used for examples throughout this chapter.

```
proc format library=proclib;
   value monthfmt 1='January'
                  2='February';
run;
```

Plot sales of refrigerators. The plot variable, Icebox, appears in both the listing and the output. The plotting symbol is 'R'. AXIS= sets the minimum value of the axis to 2500 and the maximum value to 3600. BY 25 specifies that each print position on the axis represents 25 units (in this case, dollars).

```
proc timeplot data=sales;
   plot icebox='R' / axis=2500 to 3600 by 25;
```

Label the rows in the listing. The values of the ID variables, Month and Week, are used to uniquely identify each row of the listing.

```
   id month week;
```

Apply a label to the sales column in the listing. The LABEL statement associates a label with the variable Icebox for the duration of the PROC TIMEPLOT step. PROC TIMEPLOT uses the label as the column heading in the listing.

```
   label icebox='Refrigerator';
```

Apply the MONTHFMT. format to the Month variable. The FORMAT statement assigns a format to use for Month in the report.

```
   format month monthfmt.;
```

Specify the titles.

```
title 'Weekly Refrigerator Sales';
title2 'for the First Six Weeks of the Year';
run;
```

Output

There are three column headings in the listing: the variables Month and Week, which have no labels, and the label Refrigerator, which is the label for the variable Icebox. The plotting symbol is `R`, which represents the variable label Refrigerator).

Output 71.4 *Plot with Customized Axis and Plotting Symbol*

Refrigerator Sales
for the First Six Weeks of the Year

Month	Week	Refrigerator	min 2500 ... max 3600
January	1	3450.94	R
January	1	2520.04	R
January	2	3240.67	R
January	2	2675.42	R
January	3	3160.45	R
January	3	2805.35	R
January	4	3400.24	R
January	4	2870.61	R
February	1	3550.43	R
February	1	2730.09	R
February	2	3385.74	R
February	2	2670.93	R

Example 3: Using a Variable for a Plotting Symbol

Features: ID statement
PLOT statement
PLOT statement options
JOINREF
NPP
REF=
REFCHAR=

Data set: Sales

Format: MONTHFMT.

Details

This example demonstrates the following:

- specifies a variable to use as the plotting symbol to distinguish between points for each of two sales representatives
- suppresses the printing of the values of the plot variable in the listing
- draws a reference line to a specified value on the axis and specifies the character to use to draw the line
- connects the leftmost and rightmost symbols on each line of the plot

Program

```
libname proclib
'SAS-library';

options formchar="|----|+|---+=|-/\<>*" fmtsearch=(proclib);

proc timeplot data=sales;
   plot stove=seller /

                      npp

                      ref=1500 refchar=':'

                      joinref

                      axis=100 to 3000 by 50;

   id month week;

   format month monthfmt.;

   title 'Weekly Sales of Stoves';
   title2 'Compared to Target Sales of $1500';
   title3 'K for Kreitz; L for LeGrange';
run;
```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib
'SAS-library';
```

Set the SAS system options. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available. FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options formchar="|----|+|---+=|-/\<>*" fmtsearch=(proclib);
```

Plot sales of stoves. The PLOT statement specifies both the plotting variable, Stove, and a symbol variable, Seller. The plotting symbol is the first letter of the formatted value of the Seller (in this case, **L** or **K**).

```
proc timeplot data=sales;
   plot stove=seller /
```

Suppress the appearance of the plotting variable in the listing. The values of the Stove variable will not appear in the listing.

```
                      npp
```

Create a reference line on the plot. REF= and REFCHAR= draw a line of colons at the sales target of $1500.

```
                      ref=1500 refchar=':'
```

Draw a line between the symbols on each line of the plot. In this plot, JOINREF connects each plotting symbol to the reference line.

```
joinref
```

Customize the horizontal axis. AXIS= sets the minimum value of the horizontal axis to 100 and the maximum value to 3000. BY 50 specifies that each print position on the axis represents 50 units (in this case, dollars).

```
axis=100 to 3000 by 50;
```

Label the rows in the listing. The values of the ID variables, Month and Week, are used to identify each row of the listing.

```
id month week;
```

Apply the MONTHFMT. format to the Month variable. The FORMAT statement assigns a format to use for Month in the report.

```
format month monthfmt.;
```

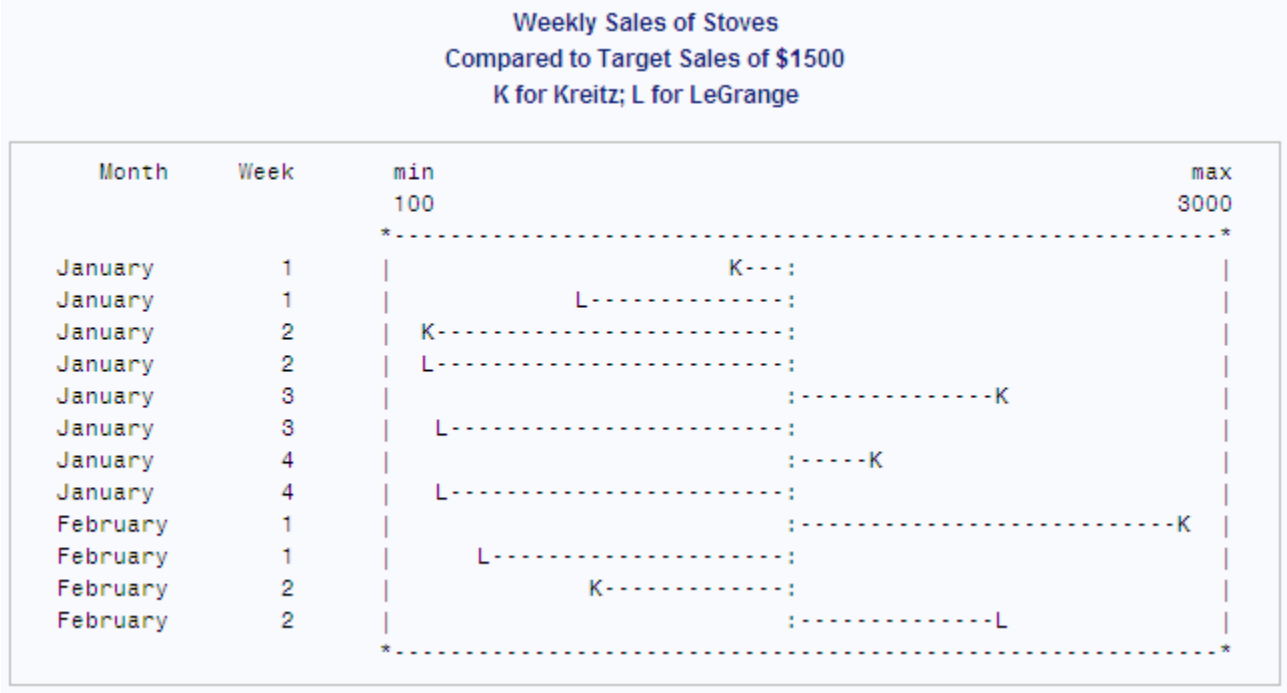
Specify the titles.

```
title 'Weekly Sales of Stoves';
title2 'Compared to Target Sales of $1500';
title3 'K for Kreitz; L for LeGrange';
run;
```

Output

The plot uses the first letter of the value of Seller as the plotting symbol.

Output 71.5 *Plot with Variable for Plotting Symbol*



Example 4: Superimposing Two Plots

Features:
PROC TIMEPLOT statement option
MAXDEC=
PLOT statement
PLOT statement options
OVERLAY
REF=MEAN(*variable(s)*)
REVERSE

Data set: Sales

Details

This example demonstrates the following:

- superimposes two plots on one set of axes
- specifies a variable to use as the plotting symbol for one plot and a character to use as the plotting symbol for the other plot
- draws a reference line to the mean value of each of the two variables plotted
- reverses the labeling of the axis so that the largest value is at the far left of the plot

Program

```
options formchar="|----|+|---+=|-/\<>*";
proc timeplot data=sales maxdec=0;
   plot stove=seller icebox='R' /
          overlay
            ref=mean(stove icebox)

reverse;
   label icebox='Refrigerators';
   title 'Weekly Sales of Stoves and Refrigerators';
   title2 'for the';
   title3 'First Six Weeks of the Year';
run;
```

Program Description

Set the FORMCHAR option. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available.

```
options formchar="|----|+|---+=|-/\<>*";
```

Specify the number of decimal places to display. MAXDEC= specifies the number of decimal places to display in the listing.

```
proc timeplot data=sales maxdec=0;
```

Plot sales of both stoves and refrigerators. The PLOT statement requests two plots. One plot uses the first letter of the formatted value of Seller to plot the values of Stove. The other uses the letter **R** (to match the label Refrigerators) to plot the value of Icebox.

```
    plot stove=seller icebox='R' /
```

Print both plots on the same set of axes.

```
          overlay
```

Create two reference lines on the plot. REF= draws two reference lines: one perpendicular to the mean of Stove, the other perpendicular to the mean of Icebox.

```
            ref=mean(stove icebox)
```

Order the values on the horizontal axis from largest to smallest.

```
reverse;
```

Apply a label to the sales column in the listing. The LABEL statement associates a label with the variable Icebox for the duration of the PROC TIMEPLOT step. PROC TIMEPLOT uses the label as the column heading in the listing.

```
    label icebox='Refrigerators';
```

Specify the titles.

```
    title 'Weekly Sales of Stoves and Refrigerators';
    title2 'for the';
    title3 'First Six Weeks of the Year';
run;
```

Output

The column heading for the variable Icebox in the listing is the variable's label (Refrigerators). One plot uses the first letter of the value of Seller as the plotting symbol. The other plot uses the letter `R`.

Output 71.6 Two Plots Superimposed Using Different Plotting Symbols

Weekly Sales of Stoves and Refrigerators
for the
First Six Weeks of the Year

```
Stove     Refrigerators      max                                           min
                             3550.43                                    184.24
                            *-------------------------------------------------*
 1313              3451     |R     |                        K   |             |
  728              2520     |      |       R                    |    L        |
  222              3241     |   R  |                            |           K |
  184              2675     |      |    R                       |            L|
 2263              3160     |     R|          K                 |             |
  267              2805     |      |   R                        |           L |
 1787              3400     | R    |                  K         |             |
  275              2871     |      |  R                         |           L |
 2910              3550     |R     | K                          |             |
  398              2730     |      |    R                       |         L   |
  820              3386     | R    |                            |   K         |
 2242              2671     |      |     R     L                |             |
                            *-------------------------------------------------*
```

Example 5: Showing Multiple Observations on One Line of a Plot

Features: CLASS statement
PLOT statement
PLOT statement options
NOSYMNAME
OVPCHAR=
POS=

Data set: Sales

Format: MONTHFMT.

Details

This example demonstrates the following tasks:

- groups observations for the same month and week so that sales for the two sales representatives appear on the same line of the plot
- specifies a variable to use as the plotting symbol

- suppresses the name of the plotting variable in one plot
- specifies a size for the plots so that they both occupy the same amount of space

Program

```
libname proclib
'SAS-library';

options formchar="|----|+|---+=|-/\<>*" fmtsearch=(proclib);

proc timeplot data=sales;
   class month week;

   plot stove=seller  / pos=25 ovpchar='!';
   plot icebox=seller / pos=25 ovpchar='!' nosymname;

   format stove icebox dollar10.2 month monthfmt.;

   title 'Weekly Appliance Sales for the First Quarter';
run;
```

Program Description

Declare the PROCLIB SAS library.

```
libname proclib
'SAS-library';
```

Set the SAS system options. Setting FORMCHAR to this exact string renders better HTML output when it is viewed outside of the SAS environment where SAS Monospace fonts are not available. FMTSEARCH= adds the SAS library PROCLIB to the search path that is used to locate formats.

```
options formchar="|----|+|---+=|-/\<>*" fmtsearch=(proclib);
```

Specify subgroups for the analysis. The CLASS statement groups all observations with the same values of Month and Week into one line in the output. Using the CLASS statement with a symbol variable produces in the listing one column of the plot variable for each value of the symbol variable.

```
proc timeplot data=sales;
   class month week;
```

Plot sales of stoves and refrigerators. Each PLOT statement produces a separate plot. The plotting symbol is the first character of the formatted value of the symbol variable: `K` for Kreitz; `L` for LeGrange. POS= specifies that each plot uses 25 print positions for the horizontal axis. OVPCHAR= designates the exclamation point as the plotting symbol when the plotting symbols coincide. NOSYMNAME suppresses the name of the symbol variable Seller from the second listing.

```
   plot stove=seller  / pos=25 ovpchar='!';
   plot icebox=seller / pos=25 ovpchar='!' nosymname;
```

Apply formats to values in the listing. The FORMAT statement assigns formats to use for Stove, Icebox, and Month in the report. The TITLE statement specifies a title.

```
format stove icebox dollar10.2 month monthfmt.;
```

Specify the title.

```
title 'Weekly Appliance Sales for the First Quarter';
run;
```

Output

Output 71.7 *Weekly Icebox Sales by Seller*

Weekly Appliance Sales for the First Quarter

Month	Week	Kreitz Icebox	LeGrange Icebox	min $2,520.04 … max $3,550.43
January	1	$3,450.94	$2,520.04	L … K
January	2	$3,240.67	$2,675.42	L … K
January	3	$3,160.45	$2,805.35	L … K
January	4	$3,400.24	$2,870.61	L … K
February	1	$3,550.43	$2,730.09	L … K
February	2	$3,385.74	$2,670.93	L … K

Output 71.8 *Weekly Stove Sales by Seller*

Weekly Appliance Sales for the First Quarter

Month	Week	Seller :Kreitz Stove	Seller :LeGrange Stove	min $184.24 … max $2,910.37
January	1	$1,312.61	$728.13	L K
January	2	$222.35	$184.24	!
January	3	$2,263.33	$267.35	L … K
January	4	$1,787.45	$274.51	L … K
February	1	$2,910.37	$397.98	L … K
February	2	$819.69	$2,242.24	K … L

TRANSPOSE Procedure

Overview: TRANSPOSE Procedure

What Does the TRANSPOSE Procedure Do?

The TRANSPOSE procedure creates an output data set by restructuring the values in a SAS data set, transposing selected variables into observations. The TRANSPOSE procedure can often eliminate the need to write a lengthy DATA step to achieve the same result. Further, the output data set can be used in subsequent DATA or PROC steps for analysis, reporting, or further data manipulation.

PROC TRANSPOSE does not produce printed output. To print the output data set from the PROC TRANSPOSE step, use PROC PRINT, PROC REPORT, or another SAS reporting tool.

To create a transposed variable, the procedure transposes the values of an observation in the input data set into values of a variable in the output data set.

What Types of Transpositions Can PROC TRANSPOSE Perform?

Simple Transposition

The following example illustrates a simple transposition. In the input data set, each variable represents the scores from one tester. In the output data set, each observation now represents the scores from one tester. Each value of _NAME_ is the name of a variable in the input data set that the procedure transposed. Thus, the value of _NAME_ identifies the source of each observation in the output data set. For example, the values in the first observation in the output data set come from the values of the variable Tester1 in the input data set. The statements that produce the output follow.

```
proc print data=proclib.product noobs;
   title 'The Input Data Set';
run;

proc transpose data=proclib.product
               out=proclib.product_transposed;
```

```
run;

proc print data=proclib.product_transposed noobs;
   title 'The Output Data Set';
run;
```

Output 72.1 *A Simple Transposition*

The Input Data Set 1

Tester1	Tester2	Tester3	Tester4
22	25	21	21
15	19	18	17
17	19	19	19
20	19	16	19
14	15	13	13
15	17	18	19
10	11	9	10
22	24	23	21

The Output Data Set 2

NAME	COL1	COL2	COL3	COL4	COL5	COL6	COL7	COL8
Tester1	22	15	17	20	14	15	10	22
Tester2	25	19	19	19	15	17	11	24
Tester3	21	18	19	16	13	18	9	23
Tester4	21	17	19	19	13	19	10	21

Complex Transposition Using BY Groups

The next example, which uses BY groups, is more complex. The input data set represents measurements of the weight and length of fish at two lakes. The statements that create the output data set do the following:

- transpose only the variables that contain the length measurements
- create six BY groups, one for each lake and date
- use a data set option to name the transposed variable

Output 72.2 *A Transposition with BY Groups*

Input Data Set 1

Location	Date	Length1	Width1	Length2	Width2	Length3	Width3	Length4	Width4
Cole Pond	02JUN95	31	0.25	32	0.30	32	0.25	33	0.30
Cole Pond	03JUL95	33	0.32	34	0.41	37	0.48	32	0.28
Cole Pond	04AUG95	29	0.23	30	0.25	34	0.47	32	0.30
Eagle Lake	02JUN95	32	0.35	32	0.25	33	0.30	.	.
Eagle Lake	03JUL95	30	0.20	36	0.45	.	.	.	.
Eagle Lake	04AUG95	33	0.30	33	0.28	34	0.42	.	

.

Fish Length Data for Each Location and Date 2

Location	Date	_NAME_	Measurement
Cole Pond	02JUN95	Length1	31
Cole Pond	02JUN95	Length2	32
Cole Pond	02JUN95	Length3	32
Cole Pond	02JUN95	Length4	33
Cole Pond	03JUL95	Length1	33
Cole Pond	03JUL95	Length2	34
Cole Pond	03JUL95	Length3	37
Cole Pond	03JUL95	Length4	32
Cole Pond	04AUG95	Length1	29
Cole Pond	04AUG95	Length2	30

Eagle Lake	02JUN95	Length2	32
Eagle Lake	02JUN95	Length3	33
Eagle Lake	02JUN95	Length4	.
Eagle Lake	03JUL95	Length1	30
Eagle Lake	03JUL95	Length2	36
Eagle Lake	03JUL95	Length3	.
Eagle Lake	03JUL95	Length4	.
Eagle Lake	04AUG95	Length1	33
Eagle Lake	04AUG95	Length2	33
Eagle Lake	04AUG95	Length3	34
Eagle Lake	04AUG95	Length4	.

For a complete explanation of the SAS program that produces these results, see "Example 4: Transposing BY Groups" on page 2673.

In-Database Processing for PROC TRANSPOSE

In-database processing has several advantages over processing within SAS. These advantages include increased security, reduced network traffic, and the potential for faster processing. Increased security is possible because sensitive data does not have to be extracted from the data source. Faster processing is possible because data is manipulated locally, on the data source, using high-speed secondary storage devices instead of being transported across a relatively slow network connection. The data source is used because it might have more processing resources at its disposal, and it might be capable of optimizing a query for execution in a highly parallel and scalable fashion.

Note: In-database processing of PROC TRANSPOSE is not supported in SAS Viya.

When the DATA= input table is stored as a table or view in a database, PROC TRANSPOSE can use in-database processing to perform most of its work within the database. In-database processing can provide the advantages of faster processing and reduced data transfer between the database and SAS software.

In-database processing for PROC TRANSPOSE supports the following data providers:

- Hadoop
- Teradata

Note: A valid license for SAS Code Accelerator for Hadoop or SAS Code Accelerator for Teradata is required.

The TRANSPOSE procedure performs a dynamic transformation of the data in which the characteristics of the output table, specifically the number and names of the variables, as well as their types, are determined from the variable values, as well as the characteristics of the input table. This dynamic behavior is achieved by a two-pass process in which rows of the input table are examined to determine the characteristics of the output table, during the first pass, and in which the work of transposing the data is performed during the second pass. Parallel operation within the massively parallel processing (MPP) database speeds up both the first and second pass. The MPP performs a set of coordinated computations in parallel with the use of a large number of processors or separate computers. In the first pass, rows are examined in parallel and in place, according to the manner in which they are already partitioned across the nodes of a cluster. In the second pass, rows are repartitioned to form BY groups that are then processed independently and in parallel.

Both the first and second passes of the in-database processing are performed by executing a DS2 program within the SAS Embedded Process that resides within the nodes of the cluster. The DBMS provides the SAS Embedded Process with the ability to read data from and write data to tables. The SAS Embedded Process provides an execution context for the DS2 program. Because the two passes of

work are expressed in the DS2 language, columns of the tables are cast to variables that have DS2 data types. Data type support within DS2 is more extensive than that provided by the traditional SAS system so, when executing inside the database, the ability of the TRANSPOSE procedure to preserve data types and value of input data within the transposed output data is enhanced.

The SQLGENERATION system option or LIBNAME statement option controls whether and how in-database procedures are run inside the database. PROC TRANSPOSE runs inside the database when you specify INDB=YES. There are many programming considerations that can prevent in-database processing. For a complete listing, see "Procedure Considerations and Limitations" in *SAS In-Database Products: User's Guide*.

CAS Processing for PROC TRANSPOSE

If your input originates from SAS Cloud Analytic Services (CAS) and your output is directed back to the CAS server, then the transposition might be performed entirely on the server. Running PROC TRANSPOSE with CAS actions has several advantages over processing within SAS. These advantages include reduced network traffic, and the potential for faster processing. Faster processing is possible because in-memory tables are manipulated locally on the server instead of being transferred across a relatively slow network connection. CAS is used because it might have more processing resources at its disposal.

See the "Transpose Action Set" in *SAS Viya: System Programming Guide* for information about the Transpose action that runs in CAS.

When the DATA= input data set references an in-memory table or view in CAS, the TRANSPOSE procedure can use CAS actions to perform all of its work within the server.

The CAS LIBNAME statement option controls whether and how CAS procedures are run inside CAS. By default, the CAS procedures are run inside CAS when possible. There are many data set options that prevent CAS processing.

CAS is the analytic server and associated cloud services in SAS Viya. The CAS LIBNAME engine can connect a SAS 9.4 session to an existing SAS Cloud Analytic Services session through the CAS session name or the CAS session UUID. The libref then becomes your handle to communicate from SAS with the specific session. See The Future of Transpose for more information about PROC TRANSPOSE and examples.

For conceptual information about procedures that run in CAS, see Chapter 5, "CAS Processing of Base Procedures," on page 93.

Syntax: TRANSPOSE Procedure

Restriction: If the DATA= and OUT= options point to CAS, the transpose is performed within CAS by invoking the CAS TRANSPOSE action.

Tips: Does not support the Output Delivery System

For in-database processing to occur, your data must reside within a supported version of a DBMS that has been properly configured for SAS in-database processing. For more information, see "In-Database Processing for PROC TRANSPOSE " on page 2655.

You can use the ATTRIB, FORMAT, LABEL, and WHERE statements. For more information, see "Statements with the Same Function in Multiple Procedures" on page 73. You can also use any global statement. For a list, see "Dictionary of SAS Global Statements" in *SAS Global Statements: Reference*.

PROC TRANSPOSE <DATA=*input-data-set*> <DELIMITER=*delimiter*>
<LABEL=*label*>
<LET> <NAME=*name*> <OUT=*output-data-set*> <PREFIX=*prefix*>
<SUFFIX=*suffix*>;

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-2 ...*>
<NOTSORTED>;

COPY *variable(s)*;

ID *variable*;

IDLABEL *variable*;

VAR *variable(s)*;

Statement	Task	Example
PROC TRANSPOSE	Create an output data set by restructuring the values in a SAS data set, transposing selected variables into observations	Ex. 1, Ex. 2, Ex. 3, Ex. 5
BY	Transpose each BY group	Ex. 4
COPY	Copy variables directly without transposing them	Ex. 6
ID	Specify a variable whose values name the transposed variables	Ex. 2
IDLABEL	Create labels for the transposed variables	Ex. 3
VAR	List the variables to transpose	Ex. 4, Ex. 6

PROC TRANSPOSE Statement

Creates an output data set by restructuring the values in a SAS data set, transposing selected variables into observations.

Tip: You can use data set options with the DATA= and OUT= options. For more information, see Chapter 3, "Statements with the Same Function in Multiple Procedures," on page 73. You can also use any global statement. For a list, see "Dictionary of SAS Global Statements" in *SAS Global Statements: Reference*.

Examples:
"Example 1: Performing a Simple Transposition" on page 2668
"Example 2: Naming Transposed Variables" on page 2669
"Example 3: Labeling Transposed Variables" on page 2671
"Example 4: Transposing BY Groups" on page 2673
"Example 5: Naming Transposed Variables When the ID Variable Has Duplicate Values" on page 2676
"Example 6: Transposing Data for Statistical Analysis" on page 2678

Syntax

PROC TRANSPOSE <DATA=*input-data-set*> <DELIMITER=*delimiter*> <INDB=YES|NO><LABEL=*label*> <LET> <NAME=*name*> <OUT=*output-data-set*> <PREFIX=*prefix*> <SUFFIX=*suffix*>;

Optional Arguments

DATA= *input-data-set*
names the SAS data set to transpose.

Default most recently created SAS data set

DELIMITER= *delimiter*
specifies a delimiter to use in constructing names for transposed variables in the output data set. If specified, the delimiter is inserted between variable values if more than one variable has been specified in the ID statement.

Alias DELIM=

Tip You can use name literals (n-literals) for the value of DELIMITER. Name literals are helpful when specifying typographical or foreign characters, especially when VALIDVARNAME=ANY.

See "ID Statement" on page 2662

INDB=YES | NO
specifies if in-database processing is active.

YES
specifies that INDB is active.

Default YES

NO
specifies that INDB is not active.

LABEL= *label*
specifies a name for the variable in the output data set that contains the label of the variable that is being transposed to create the current observation.

Default _LABEL_

Tip You can use name literals (n-literals) for the value of LABEL. Name literals are helpful when specifying typographical or foreign characters, especially when VALIDVARNAME=ANY.

LET
allows duplicate values of an ID variable. PROC TRANSPOSE transposes the observation that contains the last occurrence of a particular ID value within the data set or BY group.

See "Example 5: Naming Transposed Variables When the ID Variable Has Duplicate Values" on page 2676

NAME= *name*
specifies the name for the variable in the output data set that contains the name of the variable that is being transposed to create the current observation.

Default _NAME_

See "Example 2: Naming Transposed Variables" on page 2669

OUT= *output-data-set*
names the output data set. If *output-data-set* does not exist, then PROC TRANSPOSE creates it by using the DATA*n* naming convention.

Default DATA*n*

See "Example 1: Performing a Simple Transposition" on page 2668

PREFIX= *prefix*
specifies a prefix to use in constructing names for transposed variables in the output data set. For example, if PREFIX=VAR, then the names of the variables are VAR1, VAR2, ...,VAR*n*.

Interaction When you use PREFIX= with an ID statement, the variable name begins with the prefix value followed by the ID value.

Tip You can use name literals (n-literals) for the value of PREFIX. Name literals are helpful when specifying typographical or foreign characters, especially when VALIDVARNAME=ANY.

See "Example 2: Naming Transposed Variables" on page 2669

SUFFIX= ***suffix***
specifies a suffix to use in constructing names for transposed variables in the output data set.

Interaction When you use SUFFIX= with an ID statement, the value is appended to the ID value.

Tip You can use name literals (n-literals) for the value of SUFFIX. Name literals are helpful when specifying typographical or foreign characters, especially when VALIDVARNAME=ANY.

BY Statement

Defines BY groups.

Restriction: Do not use PROC TRANSPOSE with a BY statement or an ID statement if another user is updating the data set at the same time.

Example: "Example 4: Transposing BY Groups" on page 2673

Syntax

BY <DESCENDING> *variable-1*
<<DESCENDING> *variable-1* ...>
<NOTSORTED>;

Required Argument

variable
specifies the variable that PROC TRANSPOSE uses to form BY groups. You can specify more than one variable. If you do not use the NOTSORTED option in the BY statement, then either the observations must be sorted by all the variables that you specify, or they must be indexed appropriately. Variables in a BY statement are called *BY variables*.

Optional Arguments

DESCENDING
specifies that the data set is sorted in descending order by the variable that immediately follows the word DESCENDING in the BY statement.

NOTSORTED
specifies that observations are not necessarily sorted in alphabetic or numeric order. The data is grouped in another way, such as chronological order.

The requirement for ordering or indexing observations according to the values of BY variables is suspended for BY-group processing when you use the NOTSORTED option. The procedure does not use an index if you specify

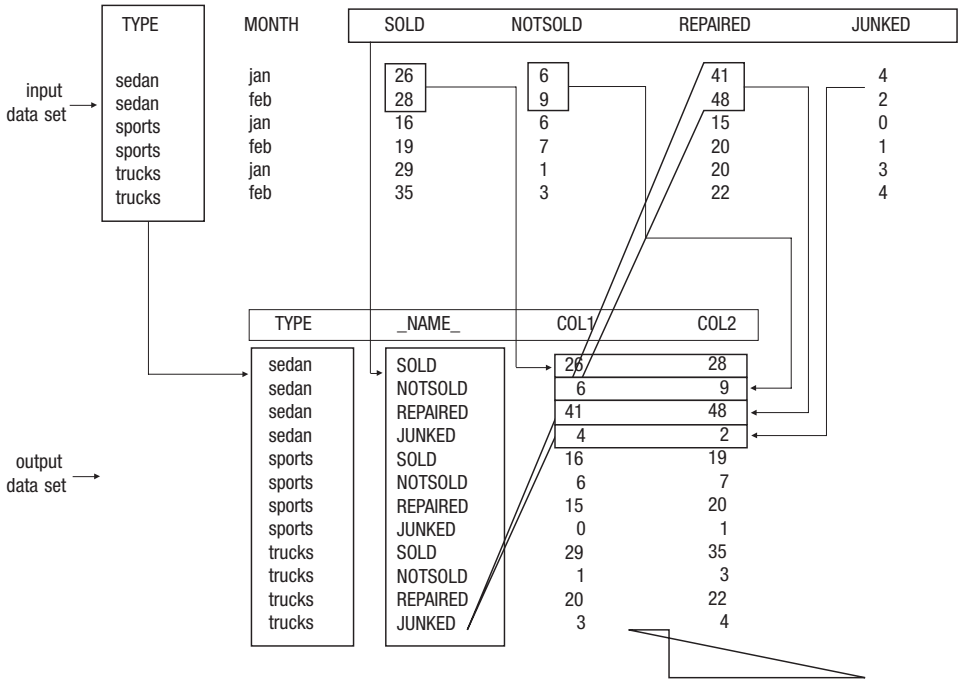
NOTSORTED. The procedure defines a BY group as a set of contiguous observations that have the same values for all BY variables. If observations with the same values for the BY variables are not contiguous, then the procedure treats each contiguous set as a separate BY group.

The NOBYSORTED system option disables observation sequence checking system-wide and applies to all procedures and BY statements. See the "BYSORTED System Option" in *SAS System Options: Reference*.

Details

The following figure shows what happens when you transpose a data set with BY groups. TYPE is the BY variable, and SOLD, NOTSOLD, REPAIRED, and JUNKED are the variables to transpose.

Figure 72.1 *Transposition with BY Groups*



- The number of observations in the output data set (12) is the number of BY groups (3) multiplied by the number of variables that are transposed (4).
- The BY variable is not transposed.
- _NAME_ contains the name of the variable in the input data set that was transposed to create the current observation in the output data set. You can use the NAME= option to specify another name for the _NAME_ variable.
- The maximum number of observations in any BY group in the input data set is two. Therefore, the output data set contains two variables, COL1 and COL2. COL1 and COL2 contain the values of SOLD, NOTSOLD, REPAIRED, and JUNKED.

Note: If a BY group in the input data set has more observations than other BY groups, then PROC TRANSPOSE assigns missing values in the output data set to the variables that have no corresponding input observations.

COPY Statement

Copies variables directly from the input data set to the output data set without transposing them.

Example: "Example 6: Transposing Data for Statistical Analysis" on page 2678

Syntax

COPY *variable(s)*;

Required Argument

variable(s)
names one or more variables that the COPY statement copies directly from the input data set to the output data set without transposing them.

Details

Because the COPY statement copies variables directly to the output data set, the number of observations in the output data set is equal to the number of observations in the input data set.

The procedure pads the output data set with missing values if the number of observations in the input data set is not equal to the number of variables that it transposes.

ID Statement

Specifies one or more variables in the input data set whose nonmissing formatted values name the transposed variables in the output data set. When a variable name is being formed in the transposed (output) data set, the formatted values of all listed ID variables are concatenated in the same order that the variables are listed in the ID statement. The PREFIX=, DELIMITER=, and SUFFIX= options can be used to modify the formed variable name. The PREFIX= option specifies a common character or character string to appear at the beginning of the formed variable names. The DELIMITER= option specifies a common character or character string to be inserted between the values of the ID variables. The SUFFIX= option specifies a common character or character string to be appended to the end of each formed variable name.

Restriction: You cannot use PROC TRANSPOSE with an ID statement or a BY statement with an engine that supports concurrent access if another user is updating the data set at the same time.

Tip: If the value of any ID variable is missing, then PROC TRANSPOSE writes a warning message to the log. The procedure does not transpose observations that have a missing value for any ID variable.

Example: "Example 2: Naming Transposed Variables" on page 2669

Syntax

ID *variable(s)*;

Required Argument

variable(s)
names one or more variables whose formatted values are used to form the names of the variables in the output data set.

Details

Duplicate Output Data Set Variable Names

A variable name formed from the input data set ID variable values, combined with the PREFIX, DELIMITER, and SUFFIX option values, should be unique within the output data set. An output data set variable name that occurs more than once indicates that two or more observations from the input data set are transposed to a single variable in the output data set and the result is data loss. This situation occurs when, in the case of a single ID variable, duplicate formatted values occur within the input data set or, if you use a BY statement, within a BY group. Similarly, this situation occurs in the case of multiple ID variables when the combination of formatted values of the ID variables occurs more than once within the input data set or BY group. To prevent data loss, if duplicate output data set variable names are formed, PROC TRANSPOSE issues an error message about duplicate ID values and stop processing. However, if the LET option is specified in the PROC TRANSPOSE statement then the procedure issues a warning message and continue processing, transposing the observation containing the last occurrence of the duplicate formatted variable values.

Note: The character substitutions and truncation required to ensure that the variable name formed from the ID variables is a valid SAS variable name, according to the VALIDVARNAME option setting, can result in duplicate output data set variable names even though the formatted value of the ID variable or combination of ID variables is unique within the input data set.

Making Variable Names Out of Numeric Values

When you use a numeric variable as an ID variable, PROC TRANSPOSE changes the formatted ID value into a valid SAS name.

SAS variable names cannot begin with a number unless you have set VALIDVARNAME=ANY. When the first character of the formatted value is numeric, the procedure prefixes an underscore to the value, this action truncates the last character of a 32-character value. Remaining invalid characters are replaced by underscores. The procedure truncates to 32 characters any ID value that is longer than 32 characters when the procedure uses that value to name a transposed variable.

If the formatted value looks like a numeric constant, then PROC TRANSPOSE changes the characters +, −, and . to P, N, and D, respectively. If the formatted value has characters that are not numeric, then PROC TRANSPOSE changes the characters +, −, and . to underscores.

Note: If the value of the VALIDVARNAME system option is V6, then PROC TRANSPOSE truncates transposed variable names to 8 characters.

Making Variable Names Out of Multiple ID Variables

When you specify a single ID variable, in forming an output data set variable name, the formatted values of the variable are made to conform with the SAS variable naming conventions imposed by the VALIDVARNAME option. The name formed by combining the ID variable values with the value of the PREFIX and SUFFIX options are also made to conform with the SAS variable naming convention. For both the formatted ID variable values and their combination with the PREFIX and SUFFIX options, invalid characters are replaced with underscores or, if the name appears to be a numeric constant, an underscore is used as a prefix and the characters +, -, and . are changed to P, N, and D. The resulting name is truncated to the maximum name length allowed by the VALIDVARNAME option setting. When you specify multiple ID variables, conformance to the SAS variable naming convention is imposed on the components of the variable name, using the formatted value of each ID variable, and also on the name composed from the ID variable values and the PREFIX, DELIMITER, and SUFFIX options. The resulting name is truncated to a length appropriate for the VALIDVARNAME option setting.

IDLABEL Statement

Creates labels for the transposed variables.

Restriction: Must appear after an ID statement.

Example: “Example 3: Labeling Transposed Variables” on page 2671

Syntax

IDLABEL *variable*;

Required Argument

variable
names the variable whose values the procedure uses to label the variables that the ID statement names. *variable* can be character or numeric.

Note: To see the effect of the IDLABEL statement, print the output data set with the PRINT procedure by using the LABEL option. You can also print the contents of the output data set by using the CONTENTS statement in the DATASETS procedure.

VAR Statement

Lists the variables to transpose.

Note: Add the special SAS variable list name _CHARACTER_ to the VAR statement to include all character variables in the transposition. See Special SAS Name Lists.

Examples: "Example 4: Transposing BY Groups" on page 2673
"Example 6: Transposing Data for Statistical Analysis" on page 2678

Syntax

VAR *variable(s)*;

Required Argument

variable(s)
names one or more variables to transpose.

Details

- If you omit the VAR statement, then the TRANSPOSE procedure transposes all numeric variables in the input data set that are not listed in another statement.
- You must list character variables in a VAR statement if you want to transpose them.

Note: If the procedure is transposing any character variable, then all transposed variables are character variables.

Results: TRANSPOSE Procedure

Output Data Set

The TRANSPOSE procedure always produces an output data set, regardless of whether you specify the OUT= option in the PROC TRANSPOSE statement. PROC TRANSPOSE does not print the output data set. Use PROC PRINT, PROC REPORT, or some other SAS reporting tool to print the output data set.

Output Data Set Variables

The output data set contains the following variables:

- variables that result from transposing the values of each variable into an observation.
- a variable that PROC TRANSPOSE creates to identify the source of the values in each observation in the output data set. This variable is a character variable whose values are the names of the variables that are transposed from the input data set. By default, PROC TRANSPOSE names this variable _NAME_. To override the default name, use the NAME= option. The label for the _NAME_ variable is **NAME OF FORMER VARIABLE**.
- variables that PROC TRANSPOSE copies from the input data set when you use either the BY or COPY statement. These variables have the same names and values as they do in the input data set. These variables also have the same attributes (for example: type, length, label, informat, and format).
- a character variable whose values are the variable labels of the variables that are being transposed (if any of the variables that the procedure is transposing have labels). Specify the name of the variable by using the LABEL= option. The default is `_LABEL_`.

Note: If the value of the LABEL= option or the NAME= option is the same as a variable that appears in a BY or COPY statement, then the output data set does not contain a variable whose values are the names or labels of the transposed variables.

Attributes of Transposed Variables

- All transposed variables are the same type and length.
- If all variables that the procedure is transposing are numeric, then the transposed variables are numeric. Thus, if the numeric variable has a character string as a formatted value, then its unformatted numeric value is transposed.
- If any variable that the procedure is transposing is character, then all transposed variables are character. If you are transposing a numeric variable that has a character string as a formatted value, then the formatted value is transposed.
- The length of the transposed variables is equal to the length of the longest variable that is being transposed.

Names of Transposed Variables

PROC TRANSPOSE uses the following rules to name transposed variables:

1. An ID statement specifies a variable or variables in the input data set whose formatted values become names for the transposed variables. If multiple ID variables are specified, the name of the transposed variable is the concatenation of the values of the ID variables. If the DELMITER= option is specified, its value is inserted between the formatted values of the ID variables when the names of the transposed variables are formed.
2. The PREFIX= option specifies a prefix to use in constructing the names of transposed variables. The SUFFIX= option also specifies a suffix to append to the names of the transposed variables.
3. If you do not use an ID statement, PREFIX= option, or the SUFFIX= option, then PROC TRANSPOSE looks for an input variable called _NAME_ to get the names of the transposed variables.
4. If you do not use an ID statement or the PREFIX= option, and if the input data set does not contain a variable named _NAME_, then PROC TRANSPOSE assigns the names COL1, COL2, ..., COL*n* to the transposed variables.

Examples: TRANSPOSE Procedure

Example 1: Performing a Simple Transposition

Features: PROC TRANSPOSE statement option
OUT=

This example performs a default transposition and uses no subordinate statements.

Program

```
options nodate pageno=1 linesize=80 pagesize=40;

data score;
   input Student $9. +1 StudentID $ Section $ Test1 Test2 Final;
   datalines;
Capalleti 0545 1  94 91 87
Dubose    1252 2  51 65 91
Engles    1167 1  95 97 97
Grant     1230 2  63 75 80
Krupski   2527 2  80 76 71
Lundsford 4860 1  92 40 86
McBane    0674 1  75 78 72
;

proc transpose data=score out=score_transposed;
run;

proc print data=score_transposed noobs;
    title 'Student Test Scores in Variables';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Create the SCORE data set. Set SCORE contains students' names, their identification numbers, and their grades on two tests and a final exam.

```
data score;
   input Student $9. +1 StudentID $ Section $ Test1 Test2 Final;
   datalines;
Capalleti 0545 1  94 91 87
Dubose    1252 2  51 65 91
Engles    1167 1  95 97 97
Grant     1230 2  63 75 80
Krupski   2527 2  80 76 71
Lundsford 4860 1  92 40 86
McBane    0674 1  75 78 72
;
```

Transpose the data set. PROC TRANSPOSE transposes only the numeric variables, Test1, Test2, and Final, because no VAR statement appears and none of the numeric variables appear in another statement. OUT= puts the result of the transposition in the data set SCORE_TRANSPOSED.

```
proc transpose data=score out=score_transposed;
run;
```

Print the SCORE_TRANSPOSED data set. The NOOBS option suppresses the printing of observation numbers

```
proc print data=score_transposed noobs;
    title 'Student Test Scores in Variables';
run;
```

Output

In the output data set SCORE_TRANSPOSED, the variables COL1 through COL7 contain the individual scores for the students. Each observation contains all the scores for one test. The variable _NAME_ contains the names of the variables from the input data set that were transposed.

Output 72.3 *Student Test Scores in Variables*

Student Test Scores in Variables

NAME	COL1	COL2	COL3	COL4	COL5	COL6	COL7
Test1	94	51	95	63	80	92	75
Test2	91	65	97	75	76	40	78
Final	87	91	97	80	71	86	72

Example 2: Naming Transposed Variables

Features: PROC TRANSPOSE statement options

NAME=
PREFIX=

ID statement

Data set: SCORE

This example uses the values of a variable and a user-supplied value to name transposed variables.

Program

```
options nodate pageno=1 linesize=80 pagesize=40;

proc transpose data=score out=idnumber name=Test
     prefix=sn;
    id studentid;
run;

proc print data=idnumber noobs;
   title 'Student Test Scores';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Transpose the data set. PROC TRANSPOSE transposes only the numeric variables, Test1, Test2, and Final, because no VAR statement appears. OUT= puts the result of the transposition in the IDNUMBER data set. NAME= specifies Test as the name for the variable that contains the names of the variables in the input data set that the procedure transposes. The procedure names the transposed variables by using the value from PREFIX=, sn, and the value of the ID variable StudentID.

```
proc transpose data=score out=idnumber name=Test
     prefix=sn;
    id studentid;
run;
```

Print the IDNUMBER data set. The NOOBS option suppresses the printing of observation numbers.

```
proc print data=idnumber noobs;
   title 'Student Test Scores';
run;
```

Output

The following data set is the output data set, IDNUMBER.

Output 72.4 *Student Test Scores*

Student Test Scores

Test	sn0545	sn1252	sn1167	sn1230	sn2527	sn4860	sn0674
Test1	94	51	95	63	80	92	75
Test2	91	65	97	75	76	40	78
Final	87	91	97	80	71	86	72

Example 3: Labeling Transposed Variables

Features: PROC TRANSPOSE statement option
PREFIX=
IDLABEL statement

Data set: SCORE

This example uses the values of the variable in the IDLABEL statement to label transposed variables.

Program 1

```
options nodate pageno=1 linesize=80 pagesize=40;

proc transpose data=score out=idlabel name=Test
     prefix=sn;
   id studentid;

     idlabel student;
run;

  proc print data=idlabel label noobs;
     title 'Student Test Scores';
  run;

proc contents data=idlabel;
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number.

LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Transpose the data set. PROC TRANSPOSE transposes only the numeric variables, Test1, Test2, and Final, because no VAR statement appears. OUT= puts the result of the transposition in the IDLABEL data set. NAME= specifies Test as the name for the variable that contains the names of the variables in the input data set that the procedure transposes. The procedure names the transposed variables by using the value from PREFIX=, sn, and the value of the ID variable StudentID.

```
proc transpose data=score out=idlabel name=Test
     prefix=sn;
   id studentid;
```

Assign labels to the output variables. PROC TRANSPOSE uses the values of the variable Student to label the transposed variables. The procedure provides the following as the label for the _NAME_ variable:NAME OF FORMER VARIABLE

```
      idlabel student;
run;
```

Print the IDLABEL data set. The LABEL option causes PROC PRINT to print variable labels for column headings. The NOOBS option suppresses the printing of observation numbers.

```
  proc print data=idlabel label noobs;
     title 'Student Test Scores';
  run;
```

Display the IDLABEL variable names and label. PROC CONTENTS displays the variable names and labels.

```
proc contents data=idlabel;
run;
```

Output 1

This data set is the output data set, IDLABEL.

Output 72.5 *Student Test Scores, IDLABEL*

Student Test Scores

NAME OF FORMER VARIABLE	Capalleti	Dubose	Engles	Grant	Krupski	Lundsford	McBane
Test1	94	51	95	63	80	92	75
Test2	91	65	97	75	76	40	78
Final	87	91	97	80	71	86	72

Program 2

Display the variable and label names. PROC CONTENTS displays the variable names and the labels used in the first program.

```
proc contents data=idlabel;
run;
```

Output 2

In the following output, PROC CONTENTS displays the variables and labels.

Output 72.6 *The Contents Procedure*

Alphabetic List of Variables and Attributes				
#	Variable	Type	Len	Label
1	Test	Char	8	NAME OF FORMER VARIABLE
2	sn0545	Num	8	Capalleti
8	sn0674	Num	8	McBane
4	sn1167	Num	8	Engles
5	sn1230	Num	8	Grant
3	sn1252	Num	8	Dubose
6	sn2527	Num	8	Krupski
7	sn4860	Num	8	Lundsford

Example 4: Transposing BY Groups

Features:

BY statement

VAR statement

Data set option
RENAME=

This example illustrates transposing BY groups and selecting variables to transpose.

Program

```
options nodate pageno=1 linesize=80 pagesize=40;
data fishdata;
   infile datalines missover;
   input Location & $10. Date date7.
```

```
         Length1 Weight1 Length2 Weight2 Length3 Weight3
         Length4 Weight4;
   format date date7.;
   datalines;
Cole Pond   2JUN95 31 .25 32 .3  32 .25 33 .3
Cole Pond   3JUL95 33 .32 34 .41 37 .48 32 .28
Cole Pond   4AUG95 29 .23 30 .25 34 .47 32 .3
Eagle Lake  2JUN95 32 .35 32 .25 33 .30
Eagle Lake  3JUL95 30 .20 36 .45
Eagle Lake  4AUG95 33 .30 33 .28 34 .42
;

proc transpose data=fishdata
     out=fishlength(rename=(col1=Measurement));

   var length1-length4;

   by location date;
run;

proc print data=fishlength noobs;
   title 'Fish Length Data for Each Location and Date';
run;
```

Program Description

Create the FISHDATA data set and set the SAS system options. The data in FISHDATA represents length and weight measurements of fish that were caught at two ponds on three separate days. The raw data is sorted by Location and Date. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=80 pagesize=40;
data fishdata;
   infile datalines missover;
   input Location & $10. Date date7.
         Length1 Weight1 Length2 Weight2 Length3 Weight3
         Length4 Weight4;
   format date date7.;
   datalines;
Cole Pond   2JUN95 31 .25 32 .3  32 .25 33 .3
Cole Pond   3JUL95 33 .32 34 .41 37 .48 32 .28
Cole Pond   4AUG95 29 .23 30 .25 34 .47 32 .3
Eagle Lake  2JUN95 32 .35 32 .25 33 .30
Eagle Lake  3JUL95 30 .20 36 .45
Eagle Lake  4AUG95 33 .30 33 .28 34 .42
;
```

Transpose the data set. OUT= puts the result of the transposition in the FISHLENGTH data set. RENAME= renames COL1 in the output data set to Measurement.

```
proc transpose data=fishdata
     out=fishlength(rename=(col1=Measurement));
```

Specify the variables to transpose. The VAR statement limits the variables that PROC TRANSPOSE transposes.

```
   var length1-length4;
```

Organize the output data set into BY groups. The BY statement creates BY groups for each unique combination of values of Location and Date. The procedure does not transpose the BY variables.

```
   by location date;
run;
```

Print the FISHLENGTH data set. The NOOBS option suppresses the printing of observation numbers.

```
proc print data=fishlength noobs;
   title 'Fish Length Data for Each Location and Date';
run;
```

Output

The following data set is the output data set, FISHLENGTH. For each BY group in the original data set, PROC TRANSPOSE creates four observations, one for each variable that it is transposing. Missing values appear for the variable Measurement (renamed from COL1) when the variables that are being transposed have no value in the input data set for that BY group. Several observations have a missing value for Measurement. For example, in the last observation, a missing value appears because the input data contained no value for Length4 on 04AUG95 at Eagle Lake.

Output 72.7 *Fish Length Data*

Fish Length Data for Each Location and Date

Location	Date	_NAME_	Measurement
Cole Pond	02JUN95	Length1	31
Cole Pond	02JUN95	Length2	32
Cole Pond	02JUN95	Length3	32
Cole Pond	02JUN95	Length4	33
Cole Pond	03JUL95	Length1	33
Cole Pond	03JUL95	Length2	34
Cole Pond	03JUL95	Length3	37
Cole Pond	03JUL95	Length4	32
Cole Pond	04AUG95	Length1	29
Cole Pond	04AUG95	Length2	30
Cole Pond	04AUG95	Length3	34
Cole Pond	04AUG95	Length4	32
Eagle Lake	02JUN95	Length1	32
Eagle Lake	02JUN95	Length2	32
Eagle Lake	02JUN95	Length3	33
Eagle Lake	02JUN95	Length4	.
Eagle Lake	03JUL95	Length1	30
Eagle Lake	03JUL95	Length2	36
Eagle Lake	03JUL95	Length3	.
Eagle Lake	03JUL95	Length4	.
Eagle Lake	04AUG95	Length1	33
Eagle Lake	04AUG95	Length2	33
Eagle Lake	04AUG95	Length3	34
Eagle Lake	04AUG95	Length4	.

Example 5: Naming Transposed Variables When the ID Variable Has Duplicate Values

Features: PROC TRANSPOSE statement option
LET

This example shows how to use values of a variable (ID) to name transposed variables even when the ID variable has duplicate values.

Program

```
options nodate pageno=1 linesize=64 pagesize=40;

data stocks;
    input Company $14. Date $ Time $ Price;
    datalines;
Horizon Kites jun11 opening 29
Horizon Kites jun11 noon    27
Horizon Kites jun11 closing 27
Horizon Kites jun12 opening 27
Horizon Kites jun12 noon    28
Horizon Kites jun12 closing 30
SkyHi Kites   jun11 opening 43
SkyHi Kites   jun11 noon    43
SkyHi Kites   jun11 closing 44
SkyHi Kites   jun12 opening 44
SkyHi Kites   jun12 noon    45
SkyHi Kites   jun12 closing 45
;

proc transpose data=stocks out=close let;

   by company;

   id date;
 run;

proc print data=close noobs;
   title 'Closing Prices for Horizon Kites and SkyHi Kites';
run;
```

Program Description

Set the SAS system options. The NODATE option suppresses the display of the date and time in the output. PAGENO= specifies the starting page number. LINESIZE= specifies the output line length, and PAGESIZE= specifies the number of lines on an output page.

```
options nodate pageno=1 linesize=64 pagesize=40;
```

Create the STOCKS data set. STOCKS contains stock prices for two competing kite manufacturers. The prices are recorded for two days, three times a day: at opening, at noon, and at closing. Notice that the input data set contains duplicate values for the Date variable.

```
data stocks;
    input Company $14. Date $ Time $ Price;
    datalines;
Horizon Kites jun11 opening 29
Horizon Kites jun11 noon    27
Horizon Kites jun11 closing 27
Horizon Kites jun12 opening 27
Horizon Kites jun12 noon    28
Horizon Kites jun12 closing 30
SkyHi Kites   jun11 opening 43
```

```
SkyHi Kites   jun11 noon    43
SkyHi Kites   jun11 closing 44
SkyHi Kites   jun12 opening 44
SkyHi Kites   jun12 noon    45
SkyHi Kites   jun12 closing 45
;
```

Transpose the data set. LET transposes only the last observation for each BY group. PROC TRANSPOSE transposes only the Price variable. OUT= puts the result of the transposition in the CLOSE data set.

```
proc transpose data=stocks out=close let;
```

Organize the output data set into BY groups. The BY statement creates two BY groups, one for each company.

```
   by company;
```

Name the transposed variables. The values of Date are used as names for the transposed variables.

```
   id date;
run;
```

Print the CLOSE data set. The NOOBS option suppresses the printing of observation numbers..

```
proc print data=close noobs;
   title 'Closing Prices for Horizon Kites and SkyHi Kites';
run;
```

Output

The following data set is the output data set, CLOSE.

Output 72.8 *Closing Prices*

Closing Prices for Horizon Kites and SkyHi Kites

Company	_NAME_	jun11	jun12
Horizon Kites	Price	27	30
SkyHi Kites	Price	44	45

Example 6: Transposing Data for Statistical Analysis

Features: COPY statement
VAR statement

This example arranges data to make it suitable for either a multivariate or a univariate repeated-measures analysis.

The data is from Chapter 8, “Repeated-Measures Analysis of Variance,” in SAS System for Linear Models, Third Edition.

Program 1

```

WI    82 83 84 85 84 85 86
;
```

Create the SPLIT data set. This DATA step rearranges WEIGHTS to create the data set SPLIT. The DATA step transposes the strength values and creates two new variables: Time and Subject. SPLIT contains one observation for each repeated measure. SPLIT can be used in a PROC GLM step for a univariate repeated-measures analysis.

```
data split;
   set weights;
   array s{7} s1-s7;
   Subject + 1;
   do Time=1 to 7;
      Strength=s{time};
      output;
   end;
   drop s1-s7;
run;
```

Print the SPLIT data set. The NOOBS options suppresses the printing of observation numbers. The OBS= data set option limits the printing to the first 15 observations. SPLIT has 105 observations.

```
proc print data=split(obs=15) noobs;
   title 'SPLIT Data Set';
   title2 'First 15 Observations Only';
run;
```

Output 1

Output 72.9 *Split Data Set*

SPLIT Data Set
First 15 Observations Only

Program	Subject	Time	Strength
CONT	1	1	85
CONT	1	2	85
CONT	1	3	86
CONT	1	4	85
CONT	1	5	87
CONT	1	6	86
CONT	1	7	87
CONT	2	1	80
CONT	2	2	79
CONT	2	3	79
CONT	2	4	78
CONT	2	5	78
CONT	2	6	79
CONT	2	7	78
CONT	3	1	78

Program 2

```
options nodate pageno=1 linesize=80 pagesize=40;

proc transpose data=split out=totsplit prefix=Str;

   by program subject;
   copy time strength;

   var strength;
run;

proc print data=totsplit(obs=15) noobs;
   title  'TOTSPLIT Data Set';
   title2 'First 15 Observations Only';
run;
```

Program Description

Set the SAS system options.

```
options nodate pageno=1 linesize=80 pagesize=40;
```

Transpose the SPLIT data set. PROC TRANSPOSE transposes SPLIT to create TOTSPLIT. The TOTSPLIT data set contains the same variables as SPLIT and a variable for each strength measurement (Str1-Str7). TOTSPLIT can be used for either a multivariate repeated-measures analysis or a univariate repeated-measures analysis.

```
proc transpose data=split out=totsplit prefix=Str;
```

Organize the output data set into BY groups, and populate each BY group with untransposed values. The variables in the BY and COPY statements are not transposed. TOTSPLIT contains the variables Program, Subject, Time, and Strength with the same values that are in SPLIT. The BY statement creates the first observation in each BY group, which contains the transposed values of Strength. The COPY statement creates the other observations in each BY group by copying the values of Time and Strength without transposing them.

```
   by program subject;
   copy time strength;
```

Specify the variable to transpose. The VAR statement specifies the Strength variable as the only variable to be transposed.

```
   var strength;
run;
```

Print the TOTSPLIT data set. The NOOBS options suppresses the printing of observation numbers. The OBS= data set option limits the printing to the first 15 observations. SPLIT has 105 observations.

```
proc print data=totsplit(obs=15) noobs;
   title  'TOTSPLIT Data Set';
   title2 'First 15 Observations Only';
run;
```

Output 2

In the following output, the variables in TOTSPLIT with missing values are used only in a multivariate repeated-measures analysis. The missing values do not preclude this data set from being used in a repeated-measures analysis because the MODEL statement in PROC GLM ignores observations with missing values.

Output 72.10 *TOTSPLIT Data Set*

TOTSPLIT Data Set
First 15 Observations Only

Program	Subject	Time	Strength	_NAME_	Str1	Str2	Str3	Str4	Str5	Str6	Str7

XSL Procedure

Overview: XSL Procedure

What Does the Extensible Style Sheet Language (XSL) Procedure Do?

The XSL procedure transforms an XML document into another format, such as HTML, text, or another XML document type. PROC XSL reads an input XML document, transforms it by using an XSL style sheet, and then writes the output.

To transform the XML document, PROC XSL uses the Saxon-EE version 9.3 software application from Saxonica, which is a collection of tools for processing XML documents. The XSLT processor implements the XSLT 2.0 standard. For information about Saxon, see the website About Saxon.

Understanding XSL

XSL is a family of transformation languages that enables you to describe how to convert files that are encoded in XML. The languages include the following:

- XSL Transformations (XSLT) for transforming an XML document
- XML Path Language (XPath), which is used by XSLT, for selecting parts of an XML document

For information about XSLT standards, see the website XSL Transformations (XSLT) Version 2.0.

Syntax: XSL Procedure

Restriction: This procedure is not available in SAS Viya orders that include only SAS Visual Analytics.

PROC XSL IN=*fileref* | '*external-file*' OUT=*fileref* | '*external-file*' XSL=*fileref* | '*external-file*';

PARAMETER '*parameter*'='*value*';

Statement	Task	Example
PROC XSL	Transform an XML document	Ex. 1, Ex. 2, Ex. 3
PARAMETER	Pass a parameter to the XSL style sheet to set a value	Ex. 2, Ex. 3

PROC XSL Statement

Transforms an XML document.

Example: "Example 1: Transforming an XML Document into Another XML Document" on page 2688

Syntax

PROC XSL IN=*fileref* | *'external-file'* OUT=*fileref* | *'external-file'* XSL=*fileref* | *'external-file'*;

Required Arguments

IN=*fileref* | *'external-file'*
specifies the input file. The file must be a well-formed XML document.

fileref
specifies the SAS fileref that is assigned to the input XML document. To assign a fileref, use the FILENAME statement.

'external-file'
is the physical location of the input XML document. Include the complete pathname and the filename. Enclose the physical name in single or double quotation marks. The maximum length is 200 characters.

Interaction When the LOCKDOWN option or NOXCMD option is set on a session, any operating system commands that are specified in the XSL file fail with an ERROR.

Example "Example 1: Transforming an XML Document into Another XML Document" on page 2688

OUT=*fileref* | *'external-file'*
specifies the output file.

fileref
specifies the SAS fileref that is assigned to the output file. To assign a fileref, use the FILENAME statement.

'external-file'
is the physical location of the output file. Include the complete pathname and the filename. Enclose the physical name in single or double quotation marks. The maximum length is 200 characters.

Example "Example 1: Transforming an XML Document into Another XML Document" on page 2688

XSL=*fileref* | *'external-file'*
specifies the XSL style sheet to transform the XML document. The XSL style sheet is a file that describes how to transform the XML document by using the XSLT language. The XSL style sheet must be a well-formed XML document.

fileref
specifies the SAS fileref that is assigned to the XSL style sheet. To assign a fileref, use the FILENAME statement.

'external-file'
is the physical location of the XSL style sheet. Include the complete pathname and the filename. Enclose the physical name in single or double quotation marks. The maximum length is 200 characters.

Alias XSLT=

Example "Example 1: Transforming an XML Document into Another XML Document" on page 2688

PARAMETER Statement

Changes instances of a parameter in an XSL style sheet to a specified value.

Examples: "Example 2: Passing a Character String Parameter Value to the XSL Style Sheet" on page 2690
"Example 3: Passing a Numeric Parameter Value to the XSL Style Sheet" on page 2693

Syntax

PARAMETER '*parameter*'='*value*';

Required Argument

'parameter'='value'
specifies the parameter name and a value to be passed to the XSL style sheet. PROC XSL changes instances of the parameter in the style sheet to the specified value. The specified parameter must exist in the XSL style sheet. Enclose the parameter name in single or double quotation marks. The specified value can be a character string or a numeric value. Enclose the value in single or double quotation marks if the value is a character string.

Examples: XSL Procedure

Example 1: Transforming an XML Document into Another XML Document

Features: PROC XSL statement

Details

The following PROC XSL example transforms an XML document into another XML document.

This is the input XML document named XMLInput.xml, which contains data about vehicles. Each second-level repeating element describes a particular car, with the nested elements that contain information about the model and year. The make information is an attribute on the second-level repeating element.

```
<?xml version="1.0" ?>
<vehicles>
  <car make="Ford">
    <model>Mustang</model>
    <year>1965</year>
  </car>
  <car make="Chevrolet">
    <model>Nova</model>
    <year>1967</year>
  </car>
</vehicles>
```

This is the XSL style sheet named XSLTransform.xsl that describes how to transform the XML. The conversion creates <root> as the root-enclosing element and <model> as the second-level repeating element. Each <model> element in the output XML document will include the values from the <car> element and the make= attribute from the input XML document.

```
<?xml version="1.0" ?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
<xsl:output method="xml" indent="yes"/>

<xsl:template match="/vehicles">
       <root> <xsl:apply-templates select="car"/> </root>
</xsl:template>

<xsl:template match="car">
    <model make="{@make}">
       <xsl:value-of select="model" />
    </model>
</xsl:template>

</xsl:stylesheet>
```

Program

Execute the PROC XSL statement. The PROC XSL statement specifies the input XML document, the XSL style sheet, and the output XML document.

```
proc xsl
   in='C:\XmlInput.xml'
   xsl='C:\XslTransform.xsl'
   out='C:\XmlOutput.xml';
run;
```

Output: Transforming an XML Document into Another XML Document

Output 73.1 *PROC XSL Output of Transformed XML Document*

```
<?xml version="1.0" encoding="UTF-8"?>
<root>
<model make="Ford">Mustang</model>
<model make="Chevrolet">Nova</model>
</root>
```

Example 2: Passing a Character String Parameter Value to the XSL Style Sheet

Features: PROC XSL statement
PARAMETER statement

Details

This example shows how to use PROC XSL to pass a character string value to a parameter in an XSL style sheet. A parameter, which is a named variable in the style sheet for which you can set a value, is an easy way to customize generated output.

This is the XSL style sheet named Format.xsl. The XSL style sheet extracts elements and attributes from an input XML document to generate HTML output. The style sheet contains the declared parameter DateVar.

```
<?xml version="1.0" encoding="UTF-8"?>
  <xsl:stylesheet version="1.0"
     xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
    <xsl:param name="DateVar"/>
    <xsl:template match="TABLE">
     <html>
     <head/>
     <body>
```

```
  <h2><xsl:value-of select="$DateVar"/></h2>
  <table border="1" rules="all">
  <tr>
     <td>Name</td>
     <td>Sex</td>
     <td>Age</td>
     <td>Height</td>
     <td>Weight</td>
  </tr>
  <xsl:apply-templates/>
  </table>
  </body>
 </html>
 </xsl:template>
 <xsl:template match="CLASS">
  <tr>
      <td><xsl:value-of select="Name"/></td>
      <td><xsl:value-of select="Sex"/></td>
      <td><xsl:value-of select="Age"/></td>
      <td><xsl:value-of select="Height"/></td>
      <td><xsl:value-of select="Weight"/></td>
  </tr>
 </xsl:template>
</xsl:stylesheet>
```

The input XML document named Class.xml contains classroom data.

```
<?xml version="1.0" encoding="windows-1252" ?>
<TABLE>
   <CLASS>
      <Name> Alfred </Name>
      <Sex> M </Sex>
      <Age> 14 </Age>
      <Height> 69 </Height>
      <Weight> 112.5 </Weight>
   </CLASS>
   <CLASS>
      <Name> Alice </Name>
      <Sex> F </Sex>
      <Age> 13 </Age>
      <Height> 56.5 </Height>
      <Weight> 84 </Weight>
   </CLASS>
   <CLASS>
      <Name> Barbara </Name>
      <Sex> F </Sex>
      <Age> 13 </Age>
      <Height> 65.3 </Height>
      <Weight> 98 </Weight>
   </CLASS>
   .
   .
   .
   <CLASS>
      <Name> Thomas </Name>
      <Sex> M </Sex>
      <Age> 11 </Age>
```

```
      <Height> 57.5 </Height>
      <Weight> 85 </Weight>
   </CLASS>
   <CLASS>
      <Name> William </Name>
      <Sex> M </Sex>
      <Age> 15 </Age>
      <Height> 66.5 </Height>
      <Weight> 112 </Weight>
   </CLASS>
</TABLE>
```

Program

```
proc xsl
   in='C:\XSL\Class.xml'
   xsl='C:\XSL\Format.xsl'
   out='C:\XSL\Class.html';

   parameter 'DateVar'="Report Date: &sysdate";
run;
```

Program Description

Execute the PROC XSL statement. The PROC XSL statement specifies the input XML document, the XSL style sheet, and the output HTML file.

```
proc xsl
   in='C:\XSL\Class.xml'
   xsl='C:\XSL\Format.xsl'
   out='C:\XSL\Class.html';
```

Pass the parameter value to the XSL style sheet. The PARAMETER statement passes a character string value for the parameter DateVar to the XSL style sheet. Note that because the value includes a macro variable reference, the value must be in double quotation marks.

```
   parameter 'DateVar'="Report Date: &sysdate";
run;
```

Output: Passing a Character String Parameter Value to the XSL Style Sheet

Output 73.2 *PROC XSL Output Class.html*

Report Date: 15NOV12

Name	Sex	Age	Height	Weight
Alfred	M	14	69	112.5
Alice	F	13	56.5	84

Thomas	M	11	57.5	85
William	M	15	66.5	112

Example 3: Passing a Numeric Parameter Value to the XSL Style Sheet

Features: PROC XSL statement
PARAMETER statement

Details

This example shows how to use PROC XSL to pass a numeric value to a parameter in an XSL style sheet.

This is the XSL style sheet named Discount.xsl. The XSL style sheet extracts elements and attributes from an input XML document to generate XML output. The style sheet contains the declared parameter DiscountPct. PROC XSL passes in a numeric value to the parameter, and a discount amount is calculated.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
  <xsl:output method="xml" indent="yes" />
  <xsl:param name="DiscountPct" />

  <xsl:template match="table">
    <xsl:copy>
      <xsl:apply-templates select="product" />
    </xsl:copy>
  </xsl:template>

  <xsl:template match="product">
    <xsl:copy>
      <xsl:copy-of select="category|type|size|gender|price" />
      <discount>
        <xsl:value-of select="$DiscountPct" />
      </discount>
      <discountAmount>
        <xsl:value-of select="(price * $DiscountPct)" />
      </discountAmount>
      <xsl:copy-of select="in_stock|ship_type" />
    </xsl:copy>
  </xsl:template>

</xsl:stylesheet>
```

The input XML document named Product.xml contains product data:

```
<?xml version="1.0"?>
<table>
 <product>
   <category>shoe</category>
   <type>Nike Air</type>
   <size>12</size>
   <gender>male</gender>
   <price>99</price>
   <in_stock>yes</in_stock>
   <ship_type>overnight</ship_type>
 </product>
</table>
```

Program

```
proc xsl
   in='C:\XSL\Product.xml'
   xsl='C:\XSL\Discount.xsl'
   out='C:\XSL\Calculated.xml';

   parameter 'DiscountPct'=.20;
run;
```

Program Description

Execute the PROC XSL statement. The PROC XSL statement specifies the input XML document, the XSL style sheet, and the output XML document.

```
proc xsl
   in='C:\XSL\Product.xml'
   xsl='C:\XSL\Discount.xsl'
   out='C:\XSL\Calculated.xml';
```

Pass the parameter to the XSL style sheet. The PARAMETER statement passes a numeric value for the parameter DiscountPct to the XSL style sheet. The output XML document will contain the discount value and a calculated discount amount.

```
   parameter 'DiscountPct'=.20;
run;
```

Output: Passing a Numeric Parameter Value to the XSL Style Sheet

Output 73.3 *PROC XSL Output Calculated.xml*

```
<?xml version="1.0" encoding="UTF-8"?>
<table>
   <product>
      <category>shoe</category>
      <type>Nike Air</type>
      <size>12</size>
      <gender>male</gender>
      <price>99</price>
      <discount>0.2</discount>
      <discountAmount>19.8</discountAmount>
      <in_stock>yes</in_stock>
      <ship_type>overnight</ship_type>
   </product>
</table>
```

PART 3

Appendix 1

SAS Elementary Statistics Procedures

Overview of SAS Elementary Statistics Procedures

This appendix provides a brief description of some of the statistical concepts necessary for you to interpret the output of Base SAS procedures for elementary statistics. In addition, this appendix lists statistical notation, formulas, and standard keywords used for common statistics in Base SAS procedures. Brief examples illustrate the statistical concepts.

Table A1.1 on page 2701 lists the most common statistics and the procedures that compute them.

Keywords and Formulas

Simple Statistics

The Base SAS procedures use a standardized set of keywords to refer to statistics. You specify these keywords in SAS statements to request the statistics to be displayed or stored in an output data set.

In the following notation, summation is over observations that contain nonmissing values of the analyzed variable and, except where shown, over nonmissing weights and frequencies of one or more:

x_i
: is the nonmissing value of the analyzed variable for observation *i*.

f_i
: is the frequency that is associated with x_i if you use a FREQ statement. If you omit the FREQ statement, then $f_i = 1$ for all *i*.

w_i
: is the weight that is associated with x_i if you use a WEIGHT statement. The base procedures automatically exclude the values of x_i with missing weights from the analysis.

  By default, the base procedures treat a negative weight as if it is equal to zero. However, if you use the EXCLNPWGT option in the PROC statement, then the procedure also excludes those values of x_i with nonpositive weights. Note that

most SAS/STAT procedures, such as PROC TTEST and PROC GLM, exclude values with nonpositive weights by default.

If you omit the WEIGHT statement, then $w_i = 1$ for all *i*.

n

is the number of nonmissing values of x_i, Σf_i. If you use the EXCLNPWGT option and the WEIGHT statement, then n is the number of nonmissing values with positive weights.

$\overline{x}$

is the mean

$$\Sigma w_i x_i / \Sigma w_i$$

s^2

is the variance

$$\frac{1}{d} \Sigma w_i (x_i - \overline{x})^2$$

where d is the variance divisor (the VARDEF= option) that you specify in the PROC statement. Valid values are as follows:

When VARDEF=	d equals
N	n
DF	$n - 1$
WEIGHT	Σw_i
WDF	$\Sigma w_i - 1$

The default is DF.

z_i

is the standardized variable

$$(x_i - \overline{x})/s$$

The standard keywords and formulas for each statistic follow. Some formulas use keywords to designate the corresponding statistic.

Descriptive Statistics

The keywords for descriptive statistics are

CSS
is the sum of squares corrected for the mean, computed as

$$\Sigma\, w_i(x_i - \overline{x})^2$$

CV
is the percent coefficient of variation, computed as

$$(100s)/\overline{x}$$

KURTOSIS | KURT
is the kurtosis, which measures heaviness of tails. When VARDEF=DF, the kurtosis is computed as

$$c_{4_n}\, \Sigma\, z_i^4 - \frac{3(n-1)^2}{(n-2)(n-3)}$$

where c_{4_n} is $\frac{n(n+1)}{(n-1)(n-2)(n-3)}$. The weighted kurtosis is computed as

$$= c_{4_n} \Sigma \left((x_i - \bar{x})/\widehat{\sigma_i}\right)^4 - \frac{3(n-1)^2}{(n-2)(n-3)}$$

$$= c_{4_n} \Sigma\, w_i^2((x_i - \bar{x})/\widehat{\sigma})^4 - \frac{3(n-1)^2}{(n-2)(n-3)}$$

When VARDEF=N, the kurtosis is computed as

$$= \frac{1}{n} \Sigma\, z_i^4 - 3$$

and the weighted kurtosis is computed as

$$= \frac{1}{n} \Sigma \left((x_i - \bar{x})/\widehat{\sigma_i}\right)^4 - 3$$

$$= \frac{1}{n} \Sigma\, w_i^2((x_i - \bar{x})/\widehat{\sigma})^4 - 3$$

where σ_i^2 is σ^2/w_i. The formula is invariant under the transformation $w_i^* = zw_i,\ z > 0$. When you use VARDEF=WDF or VARDEF=WEIGHT, the kurtosis is set to missing.

Note: PROC MEANS and PROC TABULATE do not compute weighted kurtosis.

MAX
is the maximum value of x_i.

MEAN
is the arithmetic mean $\bar{x}$.

MIN
is the minimum value of x_i.

MODE
is the most frequent value of x_i.

Note: When QMETHOD=P2, PROC REPORT, PROC MEANS, and PROC TABULATE do not compute MODE.

N
is the number of x_i values that are not missing. Observations with f_i less than one and w_i equal to missing or $w_i \leq 0$ (when you use the EXCLNPWGT option) are excluded from the analysis and are not included in the calculation of N.

NMISS
is the number of x_i values that are missing. Observations with f_i less than one and w_i equal to missing or $w_i \leq 0$ (when you use the EXCLNPWGT option) are excluded from the analysis and are not included in the calculation of NMISS.

NOBS
is the total number of observations and is calculated as the sum of N and NMISS. However, if you use the WEIGHT statement, then NOBS is calculated as the sum of N, NMISS, and the number of observations excluded because of missing or nonpositive weights.

RANGE
is the range and is calculated as the difference between maximum value and minimum value.

SKEWNESS | SKEW
is skewness, which measures the tendency of the deviations to be larger in one direction than in the other. When VARDEF=DF, the skewness is computed as

$$c_{3_n} \Sigma z_i^3$$

where c_{3_n} is $\frac{n}{(n-1)(n-2)}$. The weighted skewness is computed as

$$= c_{3_n} \Sigma \left((x_i - \overline{x})/\widehat{\sigma_j}\right)^3$$
$$= c_{3_n} \Sigma w_i^{3/2}((x_i - \overline{x})/\widehat{\sigma})^3$$

When VARDEF=N, the skewness is computed as

$$= \frac{1}{n} \Sigma z_i^3$$

and the weighted skewness is computed as

$$= \frac{1}{n} \Sigma \left((x_i - \overline{x})/\widehat{\sigma_j}\right)^3$$
$$= \frac{1}{n} \Sigma w_i^{3/2}((x_i - \overline{x})/\widehat{\sigma})^3$$

The formula is invariant under the transformation $w_i^* = zw_i,\ z > 0$. When you use VARDEF=WDF or VARDEF=WEIGHT, the skewness is set to missing.

Note: PROC MEANS and PROC TABULATE do not compute weighted skewness.

STDDEV | STD
is the standard deviation *s* and is computed as the square root of the variance, s^2 .

STDERR | STDMEAN
is the standard error of the mean, computed as

$$s/\sqrt{\Sigma w_i}$$

when VARDEF=DF, which is the default. Otherwise, STDERR is set to missing.

SUM
is the sum, computed as

$$\Sigma w_i x_i$$

SUMWGT
is the sum of the weights, W , computed as

$$\Sigma w_i$$

USS
is the uncorrected sum of squares, computed as

$$\Sigma\, w_i x_i^2$$

VAR
is the variance s^2 .

Quantile and Related Statistics

The keywords for quantiles and related statistics are

MEDIAN
is the middle value.

P1
is the 1st percentile.

P5
is the 5th percentile.

P10
is the 10th percentile.

P90
is the 90th percentile.

P95
is the 95th percentile.

P99
is the 99th percentile.

Q1
is the lower quartile (25th percentile).

Q3
is the upper quartile (75th percentile).

QRANGE
is interquartile range and is calculated as

$$Q_3 - Q_1$$

You use the QNTLDEF= option (PCTLDEF= in PROC UNIVARIATE) to specify the method that the procedure uses to compute percentiles. Let n be the number of nonmissing values for a variable, and let $x_1, x_2, \ldots, x_n$ represent the ordered values of the variable such that x_1 is the smallest value, x_2 is next smallest value, and x_n is the largest value. For the tth percentile between 0 and 1, let $p = t/100$. Then specify j as the integer part of np and g as the fractional part of np or $(n+1)p$, so that

$$\begin{aligned} np &= j + g && \text{when QNTLDEF} = 1, 2, 3, \text{or } 5 \\ (n+1)p &= j + g && \text{when QNTLDEF} = 4 \end{aligned}$$

Here, QNTLDEF= specifies the method that the procedure uses to compute the *t*th percentile, as shown in the table that follows.

When you use the WEIGHT statement, the *t*th percentile is computed as

$$y = \begin{cases} \frac{1}{2}(x_i + x_{i+1}) & \text{if } \sum_{j=1}^{i} w_j = pW \\ x_{i+1} & \text{if } \sum_{j=1}^{i} w_j < pW < \sum_{j=1}^{i+1} w_j \end{cases}$$

where w_j is the weight associated with x_i and $W = \sum_{i=1}^{n} w_i$ is the sum of the weights.

When the observations have identical weights, the weighted percentiles are the same as the unweighted percentiles with QNTLDEF=5.

Table A66.2 *Methods for Computing Quantile Statistics*

QNTLDEF =	Description	Formula	
1	weighted average at x_{np}	$y = (1-g)x_j + gx_{j+1}$	
		where x_o is taken to be x_1	
2	observation numbered closest to np	$y = x_i$	if $g \neq \frac{1}{2}$
		$y = x_j$	if $g = \frac{1}{2}$ and j is even
		$y = x_{j+1}$	if $g = \frac{1}{2}$ and j is odd
		where *i* is the integer part of $np + \frac{1}{2}$	
3	empirical distribution function	$y = x_j$	if $g = 0$
		$y = x_{j+1}$	if $g > 0$
4	weighted average aimed at $x_{(n+1)p}$	$y = (1-g)x_j + gx_{j+1}$	
		where x_{n+1} is taken to be x_n	
5	empirical distribution function with averaging	$y = \frac{1}{2}(x_j + x_{j+1})$	if $g = 0$
		$y = x_{j+1}$	if $g > 0$

Hypothesis Testing Statistics

The keywords for hypothesis testing statistics are

T
is the Student's *t* statistic to test the null hypothesis that the population mean is equal to μ_0 and is calculated as

$$\frac{\overline{x} - \mu_0}{s/\sqrt{\Sigma\, w_i}}$$

By default, μ_0 is equal to zero. You can use the MU0= option in the PROC UNIVARIATE statement to specify μ_0 . You must use VARDEF=DF, which is the default variance divisor, otherwise T is set to missing.

By default, when you use a WEIGHT statement, the procedure counts the x_i values with nonpositive weights in the degrees of freedom. Use the EXCLNPWGT option in the PROC statement to exclude values with nonpositive weights. Most SAS/STAT procedures, such as PROC TTEST and PROC GLM automatically exclude values with nonpositive weights.

PROBT | PRT
is the two-tailed *p*-value for Student's *t* statistic, T, with $n - 1$ degrees of freedom. This value is the probability under the null hypothesis of obtaining a more extreme value of T than is observed in this sample.

Confidence Limits for the Mean

The keywords for confidence limits are

CLM
is the two-sided confidence limit for the mean. A two-sided $100(1 - \alpha)$ percent confidence interval for the mean has upper and lower limits

$$\overline{x} \pm t_{(1 - \alpha/2;\, n - 1)} \frac{s}{\sqrt{\Sigma\, w_i}}$$

where s is $\sqrt{\frac{1}{n-1}\,\Sigma\,(x_i - \overline{x})^2}$, $t_{(1 - \alpha/2;\, n - 1)}$ is the ($1 - \alpha/2$) critical value of the Student's *t* statistics with $n - 1$ degrees of freedom, and α is the value of the ALPHA= option which by default is 0.05. Unless you use VARDEF=DF, which is the default variance divisor, CLM is set to missing.

LCLM
is the one-sided confidence limit below the mean. The one-sided $100(1 - \alpha)$ percent confidence interval for the mean has the lower limit

$$\overline{x} - t_{(1 - \alpha;\, n - 1)} \frac{s}{\sqrt{\Sigma\, w_i}}$$

Unless you use VARDEF=DF, which is the default variance divisor, LCLM is set to missing.

UCLM
is the one-sided confidence limit above the mean. The one-sided $100(1-\alpha)$ percent confidence interval for the mean has the upper limit

$$\overline{x} + t_{(1-\alpha;n-1)}\frac{s}{\sqrt{\Sigma w_i}}$$

Unless you use VARDEF=DF, which is the default variance divisor, UCLM is set to missing.

Using Weights

For more information about using weights and an example, see "WEIGHT" on page 82.

Data Requirements for Summarization Procedures

Here are the minimal data requirements to compute unweighted statistics and do not describe recommended sample sizes. Statistics are reported as missing if VARDEF=DF (the default) and the following requirements are not met:

- N and NMISS are computed regardless of the number of missing or nonmissing observations.
- SUM, MEAN, MAX, MIN, RANGE, USS, and CSS require at least one nonmissing observation.
- VAR, STD, STDERR, CV, T, PRT, and PROBT require at least two nonmissing observations.
- SKEWNESS requires at least three nonmissing observations.
- KURTOSIS requires at least four nonmissing observations.
- SKEWNESS, KURTOSIS, T, PROBT, and PRT require that STD is greater than zero.
- CV requires that MEAN is not equal to zero.
- CLM, LCLM, UCLM, STDERR, T, PRT, and PROBT require that VARDEF=DF.

Statistical Background

Populations and Parameters

Usually, there is a clearly defined set of elements in which you are interested. This set of elements is called the *universe*, and a set of values associated with these elements is called a *population* of values. The statistical term *population* has nothing to do with people. A statistical population is a collection of values, not a collection of people. For example, a universe is all the students at a particular school, and there could be two populations of interest: one of height values and one of weight values. Or, a universe is the set of all widgets manufactured by a particular company, and the population of values could be the length of time each widget is used before it fails.

A population of values can be described in terms of its *cumulative distribution function*, which gives the proportion of the population less than or equal to each possible value. A discrete population can also be described by a *probability function*, which gives the proportion of the population equal to each possible value. A continuous population can often be described by a *density function*, which is the derivative of the cumulative distribution function. A density function can be approximated by a histogram that gives the proportion of the population lying within each of a series of intervals of values. A probability density function is like a histogram with an infinite number of infinitely small intervals.

In technical literature, when the term *distribution* is used without qualification, it generally refers to the cumulative distribution function. In informal writing, *distribution* sometimes means the density function instead. Often the word *distribution* is used simply to refer to an abstract population of values rather than some concrete population. Thus, the statistical literature refers to many types of abstract distributions, such as normal distributions, exponential distributions, Cauchy distributions, and so on. When a phrase such as *normal distribution* is used, it frequently does not matter whether the cumulative distribution function or the density function is intended.

It might be expedient to describe a population in terms of a few measures that summarize interesting features of the distribution. One such measure, computed from the population values, is called a *parameter*. Many different parameters can be specified to measure different aspects of a distribution.

The most commonly used parameter is the (arithmetic) *mean*. If the population contains a finite number of values, then the population mean is computed as the sum of all the values in the population divided by the number of elements in the population. For an infinite population, the concept of the mean is similar but requires more complicated mathematics.

E(x) denotes the mean of a population of values symbolized by x, such as height, where E stands for *expected value*. You can also consider expected values of derived functions of the original values. For example, if x represents height, then $\mathrm{E}(x^2)$ is the expected value of height squared, that is, the mean value of the population obtained by squaring every value in the population of heights.

Samples and Statistics

It is often impossible to measure all of the values in a population. A collection of measured values is called a *sample*. A mathematical function of a sample of values is called a *statistic*. A statistic is to a sample as a parameter is to a population. It is customary to denote statistics by Roman letters and parameters by Greek letters. For example, the population mean is often written as μ, whereas the sample mean is written as $\bar{x}$. The field of *statistics* is largely concerned with the study of the behavior of sample statistics.

Samples can be selected in a variety of ways. Most SAS procedures assume that the data constitute a *simple random sample*, which means that the sample was selected in such a way that all possible samples were equally likely to be selected.

Statistics from a sample can be used to make inferences, or reasonable guesses, about the parameters of a population. For example, if you take a random sample of 30 students from the high school, then the mean height for those 30 students is a reasonable guess, or *estimate*, of the mean height of all the students in the high school. Other statistics, such as the standard error, can provide information about how good an estimate is likely to be.

For any population parameter, several statistics can estimate it. Often, however, there is one particular statistic that is customarily used to estimate a given parameter. For example, the sample mean is the usual estimator of the population mean. In the case of the mean, the formulas for the parameter and the statistic are the same. In other cases, the formula for a parameter might be different from that of the most commonly used estimator. The most commonly used estimator is not necessarily the best estimator in all applications.

Measures of Location

Overview of Measures of Location

Measures of location include the mean, the median, and the mode. These measures describe the center of a distribution. In the definitions that follow, notice that if the entire sample changes by adding a fixed amount to each observation, then these measures of location are shifted by the same fixed amount.

The Mean

The population mean $\mu = \mathrm{E}(x)$ is usually estimated by the sample mean $\overline{x}$.

The Median

The population median is the central value, lying above and below half of the population values. The sample median is the middle value when the data are arranged in ascending or descending order. For an even number of observations, the midpoint between the two middle values is usually reported as the median.

The Mode

The mode is the value at which the density of the population is at a maximum. Some densities have more than one local maximum (peak) and are said to be *multimodal*. The sample mode is the value that occurs most often in the sample. By default, PROC UNIVARIATE reports the lowest such value if there is a tie for the most-often-occurring sample value. PROC UNIVARIATE lists all possible modes when you specify the MODES option in the PROC statement. If the population is continuous, then all sample values occur once, and the sample mode has little use.

Percentiles

Percentiles, including quantiles, quartiles, and the median, are useful for a detailed study of a distribution. For a set of measurements arranged in order of magnitude, the *p*th percentile is the value that has *p* percent of the measurements below it and (100–*p*) percent above it. The median is the 50th percentile. Because it might not be possible to divide your data so that you get exactly the desired percentile, the UNIVARIATE procedure uses a more precise definition.

The upper quartile of a distribution is the value below which 75% of the measurements fall (the 75th percentile). Twenty-five percent of the measurements fall below the lower quartile value.

Quantiles

In the following example, SAS artificially generates the data with a pseudorandom number function. The UNIVARIATE procedure computes a variety of quantiles and measures of location and writes the values to a SAS data set. A DATA step then

uses the SYMPUT routine to assign the values of the statistics to macro variables. The macro %FORMGEN uses these macro variables to produce value labels for the FORMAT procedure. PROC CHART uses the resulting format to display the values of the statistics on a histogram.

Measures of Variability

Overview of Measures of Variability

Another group of statistics is important in studying the distribution of a population. These statistics measure the *variability*, also called the spread, of values. In the definitions given in the sections that follow, notice that if the entire sample is changed by the addition of a fixed amount to each observation, then the values of these statistics are unchanged. If each observation in the sample is multiplied by a constant, however, then the values of these statistics are appropriately rescaled.

The Range

The sample range is the difference between the largest and smallest values in the sample. For many populations, at least in statistical theory, the range is infinite, so the sample range might not tell you much about the population. The sample range tends to increase as the sample size increases. If all sample values are multiplied by a constant, then the sample range is multiplied by the same constant.

The Interquartile Range

The interquartile range is the difference between the upper and lower quartiles. If all sample values are multiplied by a constant, then the sample interquartile range is multiplied by the same constant.

The Variance

The population variance, usually denoted by σ^2, is the expected value of the squared difference of the values from the population mean:

$$\sigma^2 = \mathrm{E}(x - \mu)^2$$

The sample variance is denoted by s^2. The difference between a value and the mean is called a *deviation from the mean*. Thus, the variance approximates the mean of the squared deviations.

When all the values lie close to the mean, the variance is small but never less than zero. When values are more scattered, the variance is larger. If all sample values are multiplied by a constant, then the sample variance is multiplied by the square of the constant.

Sometimes values other than $n - 1$ are used in the denominator. The VARDEF= option controls what divisor the procedure uses.

The Standard Deviation

The standard deviation is the square root of the variance, or root-mean-square deviation from the mean, in either a population or a sample. The usual symbols are σ for the population and *s* for a sample. The standard deviation is expressed in the same units as the observations, rather than in squared units. If all sample values are multiplied by a constant, then the sample standard deviation is multiplied by the same constant.

Coefficient of Variation

The coefficient of variation is a unitless measure of relative variability. It is defined as the ratio of the standard deviation to the mean expressed as a percentage. The coefficient of variation is meaningful only if the variable is measured on a ratio scale. If all sample values are multiplied by a constant, then the sample coefficient of variation remains unchanged.

Measures of Shape

Skewness

The variance is a measure of the overall size of the deviations from the mean. Since the formula for the variance squares the deviations, both positive and negative deviations contribute to the variance in the same way. In many distributions, positive deviations might tend to be larger in magnitude than negative deviations, or vice versa. *Skewness* is a measure of the tendency of the deviations to be larger in one direction than in the other. For example, the data in the last example are skewed to the right.

Population skewness is defined as

$$\mathrm{E}(x - \mu)^3/\sigma^3$$

Because the deviations are cubed rather than squared, the signs of the deviations are maintained. Cubing the deviations also emphasizes the effects of large deviations. The formula includes a divisor of σ^3 to remove the effect of scale, so multiplying all values by a constant does not change the skewness. Skewness can thus be interpreted as a tendency for one tail of the population to be heavier than the other. Skewness can be positive or negative and is unbounded.

Kurtosis

The heaviness of the tails of a distribution affects the behavior of many statistics. Therefore, it is useful to have a measure of tail heaviness. One such measure is *kurtosis*. The population kurtosis is usually defined as

$$\frac{\mathrm{E}(x-\mu)^4}{\sigma^4} - 3$$

Note: Some statisticians omit the subtraction of 3.

Because the deviations are raised to the fourth power, positive and negative deviations make the same contribution, and large deviations are strongly emphasized. Because of the divisor σ^4 , multiplying each value by a constant has no effect on kurtosis.

Population kurtosis must lie between -2 and $+\infty$, inclusive. If M_3 represents population skewness and M_4 represents population kurtosis, then

$$M_4 > (M_3)^2 - 2$$

Statistical literature sometimes reports that kurtosis measures the *peakedness* of a density. However, heavy tails have much more influence on kurtosis than does the shape of the distribution near the mean (Kaplansky 1945; Ali 1974; Johnson, et al. 1980).

Sample skewness and kurtosis are rather unreliable estimators of the corresponding parameters in small samples. They are better estimators when your sample is very large. However, large values of skewness or kurtosis might merit attention even in small samples because such values indicate that statistical methods that are based on normality assumptions might be inappropriate.

The Normal Distribution

One especially important family of theoretical distributions is the *normal* or *Gaussian* distribution. A normal distribution is a smooth symmetric function often referred to as "bell-shaped." Its skewness and kurtosis are both zero. A normal distribution can be completely specified by only two parameters: the mean and the standard deviation. Approximately 68% of the values in a normal population are within one standard deviation of the population mean; approximately 95% of the values are within two standard deviations of the mean; and about 99.7% are within three standard deviations. Use of the term *normal* to describe this particular type of distribution does not imply that other types of distributions are necessarily abnormal or pathological.

Many statistical methods are designed under the assumption that the population being sampled is normally distributed. Nevertheless, most real-life populations do

not have normal distributions. Before using any statistical method based on normality assumptions, you should consult the statistical literature to find out how sensitive the method is to nonnormality and, if necessary, check your sample for evidence of nonnormality.

In the following example, SAS generates a sample from a normal distribution with a mean of 50 and a standard deviation of 10. The UNIVARIATE procedure performs tests for location and normality. Because the data are from a normal distribution, all *p*-values from the tests for normality are greater than 0.15. The CHART procedure displays a histogram of the observations. The shape of the histogram is a bell-like, normal density.

Sampling Distribution of the Mean

If you repeatedly draw samples of size *n* from a population and compute the mean of each sample, then the sample means themselves have a distribution. Consider a new population consisting of the means of all the samples that could possibly be drawn from the original population. The distribution of this new population is called a *sampling distribution*.

It can be proven mathematically that if the original population has mean μ and standard deviation σ, then the sampling distribution of the mean also has mean μ,

but its standard deviation is $\sigma/\sqrt{n}$. The standard deviation of the sampling distribution of the mean is called the *standard error of the mean*. The standard error of the mean provides an indication of the accuracy of a sample mean as an estimator of the population mean.

If the original population has a normal distribution, then the sampling distribution of the mean is also normal. If the original distribution is not normal but does not have excessively long tails, then the sampling distribution of the mean can be approximated by a normal distribution for large sample sizes.

The following example consists of three separate programs that show how the sampling distribution of the mean can be approximated by a normal distribution as the sample size increases. The first DATA step uses the RANEXP function to create a sample of 1000 observations from an exponential distribution. The theoretical population mean is 1.00, and the sample mean is 1.01, to two decimal places. The population standard deviation is 1.00; the sample standard deviation is 1.04.

The following example is an example of a nonnormal distribution. The population skewness is 2.00, which is close to the sample skewness of 1.97. The population kurtosis is 6.00, but the sample kurtosis is only 4.80.

The next DATA step generates 1000 different samples from the same exponential distribution. Each sample contains ten observations. The MEANS procedure computes the mean of each sample. In the data set that is created by PROC MEANS, each observation represents the mean of a sample of ten observations from an exponential distribution. Thus, the data set is a sample from the sampling distribution of the mean for an exponential population.

PROC UNIVARIATE displays statistics for this sample of means. Notice that the mean of the sample of means is .99, almost the same as the mean of the original population. Theoretically, the standard deviation of the sampling distribution is $\sigma/\sqrt{n} = 1.00/\sqrt{10} = .32$, whereas the standard deviation of this sample from the sampling distribution is .30. The skewness (.55) and kurtosis (-.006) are closer to zero in the sample from the sampling distribution than in the original sample from the exponential distribution because the sampling distribution is closer to a normal distribution than is the original exponential distribution. The CHART procedure displays a histogram of the 1000-sample means. The shape of the histogram is much closer to a bell-like, normal density, but it is still distinctly lopsided.

In the following DATA step, the size of each sample from the exponential distribution is increased to 50. The standard deviation of the sampling distribution is smaller than in the previous example because the size of each sample is larger. Also, the sampling distribution is even closer to a normal distribution, as can be seen from the histogram and the skewness.

Testing Hypotheses

Defining a Hypothesis

The purpose of the statistical methods that have been discussed so far is to estimate a population parameter by means of a sample statistic. Another class of statistical methods is used for testing hypotheses about population parameters or for measuring the amount of evidence against a hypothesis.

Consider the universe of students in a college. Let the variable X be the number of pounds by which a student's weight deviates from the ideal weight for a person of the same sex, height, and build. You want to find out whether the population of students is, on the average, underweight or overweight. To this end, you have taken a random sample of X values from nine students, with results as given in the following DATA step:

```
title 'Deviations from Normal Weight';

data x;
   input X @@;
   datalines;
-7 -2 1 3 6 10 15 21 30
;
```

You can define several hypotheses of interest. One hypothesis is that, on the average, the students are of exactly ideal weight. If μ represents the population

mean of the X values, then you can write this hypothesis, called the *null* hypothesis, as $H_0: \mu = 0$. The other two hypotheses, called *alternative* hypotheses, are that the students are underweight on the average, $H_1: \mu < 0$, and that the students are overweight on the average, $H_2: \mu > 0$.

The null hypothesis is so called because it corresponds in many situations to the assumption of "no effect" or "no difference." However, this interpretation is not appropriate for all testing problems. The null hypothesis is like a straw man that can be toppled by statistical evidence. You decide between the alternative hypotheses according to which way the straw man falls.

A naive way to approach this problem would be to look at the sample mean $\bar{x}$ and decide among the three hypotheses according to the following rule:

- If $\bar{x} < 0$, then decide on $H_1: \mu < 0$.
- If $\bar{x} = 0$, then decide on $H_0: \mu = 0$.
- If $\bar{x} > 0$, then decide on $H_2: \mu > 0$.

The trouble with this approach is that there might be a high probability of making an incorrect decision. If H_0 is true, then you are nearly certain to make a wrong decision because the chances of $\bar{x}$ being exactly zero are almost nil. If μ is slightly less than zero, so that H_1 is true, then there might be nearly a 50% chance that $\bar{x}$ will be greater than zero in repeated sampling, so the chances of incorrectly choosing H_2 would also be nearly 50%. Thus, you have a high probability of making an error if $\bar{x}$ is near zero. In such cases, there is not enough evidence to make a confident decision, so the best response might be to reserve judgment until you can obtain more evidence.

The question is, how far from zero must $\bar{x}$ be for you to be able to make a confident decision? The answer can be obtained by considering the sampling distribution of $\bar{x}$. If X has an approximately normal distribution, then $\bar{x}$ has an approximately normal sampling distribution. The mean of the sampling distribution of $\bar{x}$ is μ. Assume temporarily that σ, the standard deviation of X, is known to be 12. Then the standard error of $\bar{x}$ for samples of nine observations is $\sigma/\sqrt{n} = 12/\sqrt{9} = 4$.

You know that about 95% of the values from a normal distribution are within two standard deviations of the mean, so about 95% of the possible samples of nine X values have a sample mean $\bar{x}$ between $0 - 2(4)$ and $0 + 2(4)$, or between −8 and 8. Consider the chances of making an error with the following decision rule:

- If $\bar{x} < -8$, then decide on $H_1: \mu < 0$.
- If $-8 \le \bar{x} \le 8$, then reserve judgment.
- If $\bar{x} > 8$, then decide on $H_2: \mu > 0$.

If H_0 is true, then in about 95% of the possible samples $\bar{x}$ will be between the *critical values* -8 and 8, so you will reserve judgment. In these cases the statistical evidence is not strong enough to fell the straw man. In the other 5% of the samples, you will make an error. In 2.5% of the samples, you will incorrectly choose H_1; in 2.5%, you will incorrectly choose H_2.

The price that you pay for controlling the chances of making an error is the necessity of reserving judgment when there is not sufficient statistical evidence to reject the null hypothesis.

Significance and Power

The probability of rejecting the null hypothesis, if it is true, is called the *Type I error rate* of the statistical test and is typically denoted as α. In this example, an $\overline{x}$ value less than -8 or greater than 8 is said to be *statistically significant* at the 5% level. You can adjust the type I error rate according to your needs by choosing different critical values. For example, critical values of −4 and 4 would produce a significance level of about 32%, and −12 and 12 would give a type I error rate of about 0.3%.

The decision rule is a *two-tailed test* because the alternative hypotheses allow for population means either smaller or larger than the value specified in the null hypothesis. If you were interested only in the possibility of the students being overweight on the average, then you could use a one-tailed test:

- If $\overline{x} \leq 8$, then reserve judgment.
- If $\overline{x} > 8$, then decide on $\mathrm{H}_2\colon\ \mu > 0$.

For this one-tailed test, the type I error rate is 2.5%, half that of the two-tailed test.

The probability of rejecting the null hypothesis, if it is false, is called the *power* of the statistical test and is typically denoted as $1 - \beta$. β is called the *Type II error rate*, which is the probability of not rejecting a false null hypothesis. The power depends on the true value of the parameter. In the example, assume that the population mean is 4. The power for detecting H_2 is the probability of getting a sample mean greater than 8. The critical value 8 is one standard error higher than the population mean 4. The chance of getting a value at least one standard deviation greater than the mean from a normal distribution is about 16%, so the power for detecting the alternative hypothesis H_2 is about 16%. If the population mean were 8, then the power for H_2 would be 50%, whereas a population mean of 12 would yield a power of about 84%.

The smaller the type I error rate is, the less the chance of making an incorrect decision, but the higher the chance of having to reserve judgment. In choosing a type I error rate, you should consider the resulting power for various alternatives of interest.

Student's t Distribution

In practice, you usually cannot use any decision rule that uses a critical value based on σ because you do not usually know the value of σ. However, you can use *s* as an estimate of σ. Consider the following statistic:

$$t = \frac{\overline{x} - \mu_0}{s/\sqrt{n}}$$

This *t* statistic is the difference between the sample mean and the hypothesized mean μ_0 divided by the estimated standard error of the mean.

If the null hypothesis is true and the population is normally distributed, then the *t* statistic has what is called a *Student's t distribution* with $n - 1$ degrees of freedom. This distribution looks very similar to a normal distribution, but the tails of the Student's *t* distribution are heavier. As the sample size gets larger, the sample standard deviation becomes a better estimator of the population standard deviation, and the *t* distribution gets closer to a normal distribution.

You can base a decision rule on the *t* statistic:

- If $t < -2.3$, then decide on $\mathrm{H}_1\colon \mu < 0$.
- If $-2.3 \leq t \leq 2.3$, then reserve judgment.
- If $t > 2.3$, then decide on $\mathrm{H}_0\colon \mu > 0$.

The value 2.3 was obtained from a table of Student's *t* distribution to give a type I error rate of 5% for 8 (that is, $9 - 1 = 8$) degrees of freedom. Most common statistics texts contain a table of Student's *t* distribution. If you do not have a statistics text handy, then you can use the DATA step and the TINV function to print any values from the *t* distribution.

By default, PROC UNIVARIATE computes a *t* statistic for the null hypothesis that $\mu_0 = 0$, along with related statistics. Use the MU0= option in the PROC statement to specify another value for the null hypothesis.

This example uses the data on deviations from normal weight, which consist of nine observations. First, PROC MEANS computes the *t* statistic for the null hypothesis that $\mu = 0$. Then, the TINV function in a DATA step computes the value of Student's *t* distribution for a two-tailed test at the 5% level of significance and eight degrees of freedom.

```
data devnorm;
   title 'Deviations from Normal Weight';
   input X @@;
   datalines;
-7 -2 1 3 6 10 15 21 30
;

proc means data=devnorm maxdec=3 n mean
           std stderr t probt;
run;

title 'Student''s t Critical Value';

data _null_;
   file print;
   t=tinv(.975,8);
   put t 5.3;
run;
```

Deviations from Normal Weight

The MEANS Procedure

Analysis Variable : X					
N	Mean	Std Dev	Std Error	t Value	Pr > |t|
9	8.556	11.759	3.920	2.18	0.0606

Student's t Critical Value

2.306

```
          Deviations from Normal Weight                1
                      The MEANS Procedure

                    Analysis Variable : X

 N           Mean        Std Dev      Std Error   t Value   Pr > |t|
 ------------------------------------------------------------------
 9          8.556         11.759          3.920      2.18     0.0606
 ------------------------------------------------------------------
```

```
                   Student's t Critical Value                  2
2.306
```

In the current example, the value of the *t* statistic is 2.18, which is less than the critical *t* value of 2.3 (for a 5% significance level and eight degrees of freedom). Thus, at a 5% significance level, you must reserve judgment. If you had chosen to use a 10% significance level, then the critical value of the *t* distribution would have been 1.86 and you could have rejected the null hypothesis. The sample size is so small, however, that the validity of your conclusion depends strongly on how close the distribution of the population is to a normal distribution.

Probability Values

Another way to report the results of a statistical test is to compute a *probability value* or *p-value*. A *p*-value gives the probability in repeated sampling of obtaining a statistic as far in the directions specified by the alternative hypothesis as is the value actually observed. A two-tailed *p*-value for a *t* statistic is the probability of obtaining an absolute *t* value that is greater than the observed absolute *t* value. A one-tailed *p*-value for a *t* statistic for the alternative hypothesis $\mu > \mu_0$ is the probability of obtaining a *t* value greater than the observed *t* value. Once the *p*-value is computed, you can perform a hypothesis test by comparing the *p*-value

with the desired significance level. If the *p*-value is less than or equal to the type I error rate of the test, then the null hypothesis can be rejected. The two-tailed *p*-value, labeled `Pr > |t|` in the PROC MEANS output, is .0606, so the null hypothesis could be rejected at the 10% significance level but not at the 5% level.

A *p*-value is a measure of the strength of the evidence against the null hypothesis. The smaller the *p*-value, the stronger the evidence for rejecting the null hypothesis.

Note: For a more thorough discussion, consult an introductory statistics textbook such as Mendenhall and Beaver (1998); Ott and Mendenhall (1994); or Snedecor and Cochran (1989).

Operating Environment-Specific Procedures

Descriptions of Operating Environment-Specific Procedures

The following table gives a brief description and the relevant releases for some common operating environment-specific procedures. All of these procedures are described in more detail in operating environment-companion documentation.

Table A67.1 *Host-Specific Procedures*

Procedure	Description	Releases
CONVERT	Converts BMDP, OSIRIS, and SPSS system files to SAS data sets.	All
C16PORT	Converts a 16-bit SAS library or catalog that was created in Release 6.08 to a transport file. You can then convert to a 32-bit format for use in the current release of SAS by using the CIMPORT procedure.	6.10 - 6.12
FSDEVICE	Creates, copies, modifies, deletes, or renames device descriptions in a catalog.	All

Procedure	Description	Releases
PDS	Lists, deletes, or renames the members of a partitioned data set.	6.09E
PDSCOPY	Copies partitioned data sets from disk to disk, disk to tape, tape to tape, or tape to disk.	6.09E
RELEASE	Releases unused space at the end of a disk data set.	6.09E
SOURCE	Provides an easy way to back up and process source library data sets.	6.09E
TAPECOPY	Copies an entire tape volume, or files from one or more tape volumes, to one output tape volume.	6.09E
TAPELABEL	Writes the label information of an IBM standard-labeled tape volume to the SAS procedure output file.	6.09E

Appendix 3

Raw Data and DATA Steps for Base SAS Procedures

Overview of Raw Data and DATA Steps for Base SAS Procedures

The following raw data examples and DATA step examples are for use with the Base SAS Procedures.

The programs for examples in this document generally show you how to create the data sets that are used. Some examples show only partial data. For these examples, the complete data is shown in this appendix.

RADIO

This DATA step uses an INFILE statement to read data that is stored in an external file.

```
data radio;
   infile 'input-file' missover;
   input /(time1-time7) ($1. +1);
   listener=_n_;
run;
```

Here is the data that is stored in the external file:

```

#    and Technology.  All Rights Reserved.
#
#    Use, reproduction, and distribution of this software is permitted.
#    Any copy of this software, whether in its original form or modified,
#    must include both the above copyright notice and the following
#    paragraphs.
#
#    Nara Institute of Science and Technology (NAIST),
#    the copyright holders, disclaims all warranties with regard to this
#    software, including all implied warranties of merchantability and
#    fitness, in no event shall NAIST be liable for
#    any special, indirect or consequential damages or any damages
#    whatsoever resulting from loss of use, data or profits, whether in an
#    action of contract, negligence or other tortuous action, arising out
#    of or in connection with the use or performance of this software.
#
#    A large portion of the dictionary entries
#    originate from ICOT Free Software.  The following conditions for ICOT
#    Free Software applies to the current dictionary as well.
#
```

```
#    Each User may also freely distribute the Program, whether in its
#    original form or modified, to any third party or parties, PROVIDED
#    that the provisions of Section 3 ("NO WARRANTY") will ALWAYS appear
#    on, or be attached to, the Program, which is distributed substantially
#    in the same form as set out herein and that such intended
#    distribution, if actually made, will neither violate or otherwise
#    contravene any of the laws and regulations of the countries having
#    jurisdiction over the User or the intended distribution itself.
#
#    NO WARRANTY
#
#    The program was produced on an experimental basis in the course of the
#    research and development conducted during the project and is provided
#    to users as so produced on an experimental basis.  Accordingly, the
#    program is provided without any warranty whatsoever, whether express,
#    implied, statutory or otherwise.  The term "warranty" used herein
#    includes, but is not limited to, any warranty of the quality,
#    performance, merchantability and fitness for a particular purpose of
#    the program and the nonexistence of any infringement or violation of
#    any right of any third party.
#
#    Each user of the program will agree and understand, and be deemed to
#    have agreed and understood, that there is no warranty whatsoever for
#    the program and, accordingly, the entire risk arising from or
#    otherwise connected with the program is assumed by the user.
#
#    Therefore, neither ICOT, the copyright holder, or any other
#    organization that participated in or was otherwise related to the
#    development of the program and their respective officials, directors,
#    officers and other employees shall be held liable for any and all
#    damages, including, without limitation, general, special, incidental
#    and consequential damages, arising out of or otherwise in connection
#    with the use or inability to use the program or any product, material
#    or result produced or otherwise obtained by using the program,
#    regardless of whether they have been advised of, or otherwise had
#    knowledge of, the possibility of such damages at any time during the
#    project or thereafter.  Each user will be deemed to have agreed to the
#    foregoing by his or her commencement of use of the program.  The term
#    "use" as used herein includes, but is not limited to, the use,
#    modification, copying and distribution of the program and the
#    production of secondary products from the program.
#
#    In the case where the program, whether in its original form or
#    modified, was distributed or delivered to or received by a user from
#    any person, organization or entity other than ICOT, unless it makes or
#    grants independently of ICOT any specific warranty to the user in
#    writing, such person, organization or entity, will also be exempted
#    from and not be held liable to the user for any such damages as noted
#    above as far as the program is concerned.

3. Time Zone Database

ICU uses the public domain data and code derived from Time Zone Database for its time zone support. The ownership of the TZ database is explained in BCP 175: Procedure for Maintaining the Time Zone Database section 7.

```
7.  Database Ownership

   The TZ database itself is not an IETF Contribution or an IETF
   document.  Rather it is a pre-existing and regularly updated work
   that is in the public domain, and is intended to remain in the
public
   domain.  Therefore, BCPs 78 [RFC5378] and 79 [RFC3979] do not apply
   to the TZ Database or contributions that individuals make to it.
   Should any claims be made and substantiated against the TZ Database,
   the organization that is providing the IANA Considerations defined
in
   this RFC, under the memorandum of understanding with the IETF,
   currently ICANN, may act in accordance with all competent court
   orders.  No ownership claims will be made by ICANN or the IETF Trust
   on the database or the code.  Any person making a contribution to
the
   database or code waives all rights to future claims in that
   contribution or in the TZ Database.
```
