An Overview of the SQL Query Window

Introduction

Structured Query Language (SQL) is a language that retrieves and updates data in relational tables and databases. SAS implements SQL through the SQL procedure.

The SQL Query Window is an interactive interface that enables you to build, save, and run queries (requests to retrieve data) without being familiar with SQL or with the SAS SQL procedure. The query that you build in the SQL Query Window is passed to the SQL procedure or to the REPORT procedure for processing when you run the query.

The SQL Query Window also provides you with the following capabilities:

- You can create PROC SQL tables (SAS data files) and views.
- If you have SAS/ACCESS software installed for your database management system (DBMS), then you can query DBMS data by using PROC SQL Pass-Through. Some SAS/ACCESS interfaces enable you to access data using a library engine. Library engine technology enables you to assign a libref to DBMS data and work with the data in the same way that you would with data in a SAS library. For more information, refer to the SAS/ACCESS documentation for your DBMS.
- If SAS/CONNECT software is licensed at your site, then you can use the SQL Query Window to access data that is stored on remote hosts.
- You can use PROC REPORT to design a report from your query output without exiting the SQL Query Window.
After exiting the SQL Query Window, you can use your query output with other SAS procedures and SAS/ASSIST software to perform various other functions such as analyzing your data or producing graphics.

For more information about the SQL and REPORT procedures, refer to the Base SAS Procedures Guide.

## Invoking the SQL Query Window

You can invoke the SQL Query Window in one of the following ways:

- In the SAS command window or at the `Command ==>` prompt, issue the `QUERY` command.

You can also specify these optional arguments:

- **profile=**
  - the name of a user-defined profile that you want to use for your SQL Query Window session. You can specify a profile by using the following syntax: `profile=libref.catalog.profile`

- **access=**
  - the access mode (source of the data that you are going to use) for the SQL Query Window session.

- **active=** or **data=**
  - the name of the table (active SAS data set) that you want to use in your initial query.

  You can select more than one table by using the following syntax: `data='table1, table2'`

  where `table1` and `table2` are the names of the tables that you want to use in your initial query.

  If you use this argument, then the SQL Query Window is invoked with the table or tables already selected, and you go directly to the SQL QUERY COLUMNS window.

- **include=**
  - the name of a stored query that you want to include in your SQL Query Window session. You can include a stored query by using the following syntax: `include=libref.catalog.query`

  where `libref` is the library reference, `catalog` is the catalog in which the query is stored, and `query` is the query name.

  If you use this argument, then the SQL Query Window is invoked with the query components already selected, and you go directly to the SQL QUERY COLUMNS window.

- From any SAS window, select **Tools ➤ Query**.

- If SAS/ASSIST software is installed at your site, then you can follow this selection path: **Tasks ➤ Data Management ➤ Query ➤ SQL Query**.

- From a SAS/AF application, the method that you use depends on whether the application has a frame or program screen.
If the application has a frame or program screen, then you can invoke it with this command:

```
SUBMIT COMMAND CONTINUE;
QUERY
ENDF SUBMIT;
```

Following the `QUERY` statement, you can specify any of the optional arguments that were described earlier for the command window or `Command ===>` prompt.

If the application has no frame or program screen, then you can invoke it with a `CALL EXECCMD` statement:

```
CALL EXECCMD ('QUERY');
```

Optional arguments can follow the word `QUERY` and must precede the closing quotation mark.

---

**Query Window Menus**

**Overview of Query Window Menus**

The SQL Query Window has **File**, **Tools**, **View**, and **Profile** items on the menu bar.

Some items in a menu might appear dimmed, which means that they cannot be selected until you have performed some other action.

**Note:** The items that are described here are specific to the SQL Query Window. Other items that are on the menus are related to general SAS functionality. See the SAS System Help for more information about these items.

**File Menu**

**Save Query**

This item displays a menu from which you can select these options:

**Save as QUERY to include later**

saves your query as a QUERY catalog entry. You can include the saved query during your current SQL Query Window session or during a later session. Other users who have access to the catalog in which the query is stored can also include the query in their sessions.

**Save as SOURCE entry**

saves your query as a SOURCE catalog entry. A query that is saved as a .SOURCE entry can be used in SAS/AF and SAS/EIS applications, and it can be included in the SAS Program Editor, but it cannot be included in the SQL Query Window.
Save as External file

saves your query as a PROC SQL statement in an external file.

For all of these ways to save a query, the query is stored on the local host even if you are connected to a remote session through SAS/CONNECT software.

List/Include Saved Queries

This item displays a list of the queries that you have previously saved in the Profile catalog with which the SQL Query Window was invoked. You can also display a list of queries that were saved in other catalogs. If the SQL Query Window was invoked without a profile, then the default Profile catalog is SASUSER.PROFILE.

Create Table from Query Results

This item enables you to create a PROC SQL table, which is a SAS data set, and to save the results of your query into it. If SAS/CONNECT software is licensed at your site and you select this item when you are connected to a remote session, then you can choose to download the results of your query into a local SAS data set. You can also create the table on the remote system.

Create View of Query

This item enables you to create a PROC SQL view that contains the SQL syntax of your query. The PROC SQL view can be read by any SAS procedure as if the view were a SAS data set. When you specify the view in a PROC or DATA step, the query is processed and returns current data from the queried table or tables to your report. If SAS/CONNECT software is licensed at your site and you select this item when you are connected to a remote session, then the view will be created on the remote system.

View Menu

Columns

This item enables you to perform the following actions:

- select the columns that you want to include in your query
- set summary functions for columns
- build new computed columns to include in your query

Where Conditions for Subset

This item enables you to use a WHERE expression to read a subset of the data in a table or tables by specifying the conditions that the selected data must meet.

Distinct

This item removes duplicate rows from your query output.
Order By
This item enables you to select columns or column expressions to specify the order by which you want the output sorted.

Group(s) for Summary Functions
This item enables you to specify groups of column values to which a function is to be applied.

Having Condition for Group
This item enables you to build or modify a HAVING expression. A HAVING expression specifies a condition (or conditions) for each group that is included in the query. You specify the group in a Group By clause. If no Group By clause is specified, then the rows in a table or a subset of the table are evaluated as one group.

Tables
This item enables you to select the table or tables from which you want to retrieve data. This is the first step in the query-building process. If you have already started building your query, then you can use the Tables item to perform the following actions:
- select an additional table or tables for your query
- remove a table or tables from the current query
- select a table or tables for a new query

Join Type
This item enables you to use inner joins or outer joins to join tables when you have selected two tables for the query.

Tools Menu

Run Query
This item displays a menu from which you can select these options:

- Run Immediate
  immediately submits the query to the SQL procedure for processing. The output appears in the Output window. If SAS/CONNECT software is licensed at your site and you select this item when you are connected to a remote session, then the query is submitted to the remote session for processing.

- Design a Report
  uses the REPORT procedure to design a report for your query output. Another menu appears with the following options:
Begin with default report
Invokes PROC REPORT with the default settings for the query. You can then design a report within PROC REPORT.

Name a predefined report
Lists any report definitions that have been stored in the catalog from which you invoked your SQL Query Window session or in other catalogs.

Use definition from last report
Invokes PROC REPORT and uses the report definition that you designed when you selected Design a Report for your current query.

Show Query
This item displays the PROC SQL syntax for your query. You can choose this item at any time during the query-building process.

Preview Window
This item displays your query in a PREVIEW window. You can edit the query syntax in this window and save it to a file. Changes that you make in the PREVIEW window are not reflected in the current query in the SQL Query Window.

Switch Access Mode
This item enables you to specify whether you are going to query SAS data files (including SAS data sets and SAS data views) or tables from a database management system (DBMS). You can change the access mode at any time during an SQL Query Window session. Changing access modes resets the query and displays the tables that are available for that access mode.
Depending on your operating environment and the SAS/ACCESS products that have been installed at your site, you can select one of the following access modes:

- SAS
- DB2
- ODBC
- ORACLE
- Sybase
- SQLDS
- RDB
- DB2/2
- INGRES
- INFORMIX
- DB2/6000

Switch to New Profile
This item resets the query and enables you to change to a profile that was previously created and stored.
Reset
This item deletes your current query from the SQL Query Window and returns you to the Tables window to begin a new query.

Report Options
This item enables you to specify the beginning page number, title, and subtitles for the report.

Profile Menu

Set Preferences
This item enables you to create a profile entry.

Show Current Preferences
This item displays the preference settings that are in effect for your current SQL Query Window session.

Update Preferences
This item enables you to update the preference settings for any SQL Query Window profile.
If your system supports the use of a mouse, you can also display the most frequently used **Tools** and **View** items from the pop-up menu. To invoke the pop-up menu, click the right mouse button anywhere in the SQL Query Window.

- Run Query
- Show Query...
- Where Conditions for Subset...
- Order By...
- Group(s) for Summary Functions
- Having Condition for Group...
- Columns...
- Tables...
- Reset
- Join Type...

Setting Up the Environment

Query Window Sample Data Library

To practice with the examples in this chapter, you will need to use the sample data library that is provided with the SQL Query Window.

Submit the following statement in the Program Editor to assign the SAMPLE libref to the sample library:
libname sample 'sample library';

Consult your on-site SAS support personnel for the location of the sample library. Some of the examples require that you save files to the sample library. If you do not have Write access to the sample library, you can save the files to another library of your choice, such as the SASUSER library.

Invoking the Query Window

For these examples, invoke the SQL Query Window by selecting Tools ⇒ Query or by entering query in the command window or at the command ==> prompt.

The SQL QUERY TABLES window appears. By default, the SASUSER libref is selected and the tables from that libref appear in the Available Tables list.

Changing Your Profile

In order to include the tables that are in the sample library in the Available Tables list, you must set your SQL Query Window profile to include the tables in the SAMPLE library. Select Profile ⇒ Set Preferences.

Select the right arrow next to Data Restrictions to display the Data Restrictions for Profile window.
Select SAMPLE from the Table Source list. Select Add entire Table Source to preferences from the pop-up menu that appears.

Select WORK from the Table Source list. Select Add entire Table Source to preferences from the pop-up menu.

Note: If you do not have Write access to the SAMPLE library, then repeat the previous step for the SASUSER library.

Select OK to return to the Preference Settings for Profile window.

Select Save to save your new profile setting.
Type **SAMPLE** in the **Entry Name** field of the Name Catalog Entry for Profile window. Select **OK**.

Select **Close** in the Preference Settings for Profile window.

From the SQL QUERY TABLES window, select **Tools ⇄ Switch to New Profile**.

Select the right arrow next to the **Profile Name** field to display a list of profiles.

In the Preference Profiles in Catalog window, select **SASUSER** from the **Libraries** list. Next, select **PROFILE** from the **Catalogs** list, and then select **SAMPLE** from the **Profiles** list. Select **OK**.

Select **OK** to return to the SQL QUERY TABLES window and to complete the switch to the new profile. The new profile displays only the tables that are in the sample library.

See “Setting Your Profile” on page 76 for more information about the SQL Query Window user profile.
Performing Simple Queries

Selecting a Table

First, you will analyze the relation between salary level, position, and hire date. Select `SAMPLE.SALARY` from the Available Tables list.

Select the right arrow to add your selection to the Selected Tables list. For mouse-enabled operating environments, you can also double-click on `SAMPLE.SALARY` to move it to the Selected Tables list. Select OK to display the SQL QUERY COLUMNS window.

Select the right arrow to add your selection to the Selected Tables list. For mouse-enabled operating environments, you can also double-click on `SAMPLE.SALARY` to move it to the Selected Tables list. Select OK to display the SQL QUERY COLUMNS window.
Selecting Columns

Select Salary, BEGDATE, and JOBCODE from the Available Columns list. Select the right arrow to add your selections to the Selected Columns list.

Alias Names and Labels

To create more descriptive labels for JOBCODE and BEGDATE, select JOBCODE from the Selected Columns list. Select Column Alias/Label to assign a new label to the JOBCODE column.

Alias Name

specifies an alias for the column. The alias is used in place of the column name both in the query and in any table or view that is created from the query. Aliases make a result table clearer or easier to read. You can also use an alias to name a column expression.

Label

associates a label with a column heading.

Type Job Code in the Label field. Select OK to return to the SQL QUERY COLUMNS window. The assigned label is displayed next to JOBCODE in the Selected Columns List.
Select **BEGDATE** from the **Selected Columns** list. Select **Column Alias/Label**. Type **Beginning Date** in the **Label** field. Select **OK**.

---

**Column Format**

To modify the format of the **BEGDATE** column, select **BEGDATE** from the **Selected Columns** list. Select **Column Formats** to specify the format in which the beginning dates are presented.

- **Format** specifies the form in which the column data is displayed. You can enter a format, or select the right arrow to see a list of valid formats. When you select a format, a formatted example appears, along with its width range, default width, default decimal, and name. You can either accept the default width and decimal values, or you can specify your own values in the **Width** field.

- **Informat** specifies the form in which the column data is read by other SAS procedures if you create a table or view from the query. You can enter an informat, or you can select the right arrow to see a list of valid informats. When you select an
informat, a formatted example appears, along with its width range, default width, default decimal, and name. You can either accept the default width and decimal values, or specify your own values.

Select the right arrow next to the Format field to display a list of formats.

Select date from the Format Names list. Type 9 in the Width field. Select OK.
Select OK to return to the SQL QUERY COLUMNS window.

Creating a WHERE Expression

Overview of Creating a WHERE Expression

A WHERE expression returns a subset of data that meets conditions that you specify. In this example, you create a WHERE expression that displays the range of job codes for employees who were hired after October 1991 and whose salaries are less than $18,000.00.

Select View ➔ Where Conditions for Subset. The WHERE EXPRESSION window appears.
Available Columns

The Available Columns list contains all columns from the selected tables, in addition to the following choices:

<CONSTANT enter value>
   enables you to enter a constant value for the WHERE expression.

<PROMPT at run-time>
   enables you to enter a value for the WHERE expression when you run the query or create a table or view.

Comparison Operators

Select Salary from the Available Columns list. A list of numeric comparison operators appears.

The list of operators is specific to the data type.

EQ
   is equal to

NE
   is not equal to

GT
   is greater than

LT
   is less than
GE
  is greater than or equal to
LE
  is less than or equal to
*  multiplies by
/  divides by
+  adds
-  subtracts
**  raises to a power

The OTHER operators are:
Is Missing
  selects rows in which a column value is missing or null.
Is Not Missing
  selects rows in which a column value is not missing or is not null.
Between
  searches for values that lie within the specified parameters.
Not Between
  searches for values that lie outside the specified parameters.
In
  tests if the column value is a member of a set.
Not In
  tests if the column value is not a member of a set.

Select **LT** from the list of comparison operators.

Constant Values

Select **<CONSTANT enter value>**. Enter 10000 in the **Numeric** field.
Select **OK**. The **WHERE** expression is built for you as you select new operators and values.

**Undo**

You can delete the last operator or operand that you added to the **WHERE** statement by selecting **Undo**. For this example, select **Undo** to remove **10000** from the **WHERE** statement.

**Lookup Distinct Values**

Select `<LOOKUP distinct values>` to view all the unique values that exist in the **SALARY** column.

Select **$18,000** from the list of values. Because the LT comparison operator requires only one value, the **WHERE EXPRESSION** window automatically reappears.

**Logical Operators**

Select **Operators** to display the list of operators. Note that the list of comparison operators has changed to a list of logical operators. Select **AND** from the list of operators.
Select **BEGDATE** from the **Available Columns** list. Select **GT** from the list of comparison operators.

**Run-Time Prompt**

Select **<PROMPT at run-time>** to display the Prompt String dialog box. Type **Beginning Date:** in the **Prompt String** field.

Select **OK**. **&PROMPT1** in the **WHERE** expression indicates that you will supply a value for this variable when you run the query.

Select **OK** from the **WHERE EXPRESSION** window to return to the **SQL QUERY COLUMNS** window.

**Running Your Query**

To run your query, select **Tools ➪ Run Query ➪ Run Immediate**.

The **Prompt at Run Time** window appears, with the **Beginning Date:** prompt that you specified in the **WHERE** expression.

Select **Lookup** to display a list of values for the **BEGDATE** column.
Select 13OCT1991 from the list of values; the Prompt at Run Time window is displayed with the value that you selected. Select OK to continue to run the query and to view your output in the Output window.

Sorting Your Output

Order by Columns

You can specify the order in which you want the output sorted. In this example, you use the query from the last example and change the ordering sequence of the columns in the Output window. From the SQL QUERY COLUMNS window, select View \(\Rightarrow\) Order By.
Move Before
displays all columns in the Order By Columns list except the currently chosen one. The currently chosen column will be inserted before the column that you select.

Move After
displays all the columns in the Order By Columns list except the currently chosen one. The currently chosen column will be inserted following the column that you select.

Ascending Order
changes the ordering sequence of the selected column's values to ascending (lowest value to highest value).

Descending Order
changes the ordering sequence of the selected column's values to descending.

Build a Column
displays the Build a Column Expression window, which enables you to create a calculated column for use in sorting your output. Use the Build a Column Expression window to create new columns by performing calculations on existing (numeric) columns.

Select BEGDATE from the Available Columns list. Select the right arrow to move the column to the Order By Columns list. By default, columns are sorted in ascending order, so the abbreviation ASC appears next to the column name in the Order By Columns list. Select BEGDATE ASC and Descending Order to change the ordering sequence.
Select **Salary** and **JOBCODE**, and move them to the **Order By Columns** list.

### Move Columns

Select **Salary ASC** from the **Order By Columns** list and select **Move Before**. The Move Columns window appears.

Select **BEGDATE** and **OK**. The ORDER BY COLUMNS window appears with **Salary** first in the **Order By Columns** list.
Select **OK** to return to the SQL QUERY COLUMNS window.

Select **View** ⇒ **Where Conditions for Subset**.

The WHERE EXPRESSION window appears. Select **Undo** four times, until only **SALARY LT $18,000** is displayed.

Select **OK**.

---

**Viewing Your Output**

To run your query and view the output in the Output window, select **Tools** ⇒ **Run Query** ⇒ **Run Immediate**.
Building Calculated Columns

Build a Column Expression

Using the query from the last example, you can create a new column that computes the hourly wage for each salary.

Select **Build a Column** from the SQL QUERY COLUMNS window to display the BUILD A COLUMN EXPRESSION window.

Select **Salary** from the **Available Columns** list. Select the division operator (/) from the list of operators.
Select `<CONSTANT enter value>` from the **Available Columns** list. Enter **50** in the Numeric Constant dialog box. Select **OK** to return to the BUILD A COLUMN EXPRESSION window.

Select the division operator again from the list of operators. Select `<CONSTANT enter value>` and enter **40** to divide the number of weeks by the number of hours in each week. Select **OK**. Select outside the list of operators to dismiss it.

### Correcting Your Mistakes

You realize that you have made a mistake and that you want to divide Salary by **52**, the number of weeks in a year. Select **50** in the **Column Expression** field. A pop-up menu displays a list of choices.
Select Replace from the pop-up menu. The BUILD A COLUMN EXPRESSION window displays Select from Available Columns to replace this value.

Select `<CONSTANT enter value>` from the Available Columns list. Enter 52 as the new constant and select OK.

Defining the Column Format and Label

Select Column Attributes to define the format and label for your new column.

Enter hourly as the alias name. Select the right arrow next to the Format field to choose the format in which the new column will appear.
Select dollar from the Format Names list. Enter 2 in the Decimal field so that the hourly wage will be displayed to two decimal places. Select OK.

Enter Hourly Rate in the Label field for the column. Select OK.

The complete calculated column is displayed in the BUILD A COLUMN EXPRESSION window.

Select OK to return to the SQL QUERY COLUMNS window. Note that the new column has automatically been added to the Selected Columns list.

Viewing Your Output

To run your query and view the output in the Output window, select Tools → Run Query → Run Immediate.
Building and Adding Tables

Creating a Table from Query Results

Using the query from the last example, you can build a new table from the results.

In the SQL QUERY COLUMNS window, select View ➔ Tables to return to the SQL QUERY TABLES window.

From the SQL QUERY TABLES window, select File ➔ Create Table from Query Results.

Select the right arrow next to the Library field to display a list of available libraries.
You can also enter the library name in the **Library** field.

Select **SAMPLE** to include your new table in the SAMPLE library.

**Note:** If you do not have Write access to the SAMPLE library, then select **SASUSER** instead.

Select **OK**.

Type **WAGE** in the **Table** field.

Type **Hourly Wages** in the **Label** field.

Select **OK** to return to the SQL QUERY TABLES window.

Select **Tools** ⇒ **Reset** to reset your query. Select **OK** from the dialog box that appears. Note that SAMPLE.WAGE is now in the **Available Tables** list.
Joining Matching Data

Choosing a Join Type

The data that you need for a report could be located in more than one table. In order to select the data from the tables, you join the tables in a query. Joining tables enables you to select data from multiple tables as if the data were contained in one table. Joins do not alter the original tables.

The SQL Query window supports two types of joins:

- Inner Joins return a result table for all the rows in a table that have one or more matching rows in the other table or tables that are listed in the Selected Tables list.
- Outer Joins are inner joins that are augmented with rows that do not match any row from the other table in the join. See “Creating and Using Outer Joins” on page 68 for more information about outer joins.

For this example, you use an inner join to display the hourly wage for each employee identification number.

In the previous example, you added SAMPLE.WAGE to the Available Tables list. Select SAMPLE.SALARY and SAMPLE.WAGE from the Available Tables list and add them to the Selected Tables list. Select OK to display the SQL QUERY COLUMNS window.

Select Identification Number, JOBCODE, and Hourly Rate from the Available Columns list and move them to the Selected Columns list.

Select View ➔ Join Type to display the Join Types window.

Select Matched Join and OK.

Setting Join Criteria

In the Columns for Setting Join Criteria window, select Salary from both the SAMPLE.SALARY Columns list and the SAMPLE.WAGE Columns list. Select
JOBCODE from the SAMPLE.SALARY Columns list and select Job Code from the SAMPLE.WAGE Columns list.

Select OK to return to the SQL QUERY COLUMNS window.

Viewing Your Output

To run your query and view the output in the Output window, select Tools ⇒ Run Query ⇒ Run Immediate.

Saving Queries

Saving a Query to Include Later

To save the query that you created in the previous example in SASUSER.PROFILE, select Tools ⇒ Show Query to display the SQL QUERY window.
Select **Save Query** ⇒ **Save as QUERY to Include later** to save your query to SASUSER.PROFILE or another catalog of your choosing.

Type IDWAGE in the **Entry Name** field. Type ID number and hourly wage in the description field. Select **OK** to save your query as an entry in SASUSER.PROFILE and to return to the SQL QUERY window. Select **Goback** to return to the SQL QUERY COLUMNS window.

---

**Saving Several Queries**

You can save more than one query and then select from a list of queries that you have saved in the current Query Window session or in a previous Query Window session. In this example, you create and save several queries for later selection from a list of the saved queries.

From the SQL QUERY COLUMNS window, select **View** ⇒ **Tables** to return to the SQL QUERY TABLES window.

Remove SAMPLE.WAGE from the **Selected Tables** list. Select **OK** to display the SQL QUERY COLUMNS window.
Select **Salary** from the **Available Columns** list and add it to the **Selected Columns** list. Select **View ⇒ Where Conditions for Subset** to display the **WHERE** **EXPRESSION** window.

Select **Salary** from the **Available Columns** list. Select **GT** (greater than) from the list of operators. Select `<LOOKUP distinct values>` from the **Available Columns** list. Select **$25,000** from the Lookup Values window. Select **OK** to save your **WHERE** expression.

Select **View ⇒ Order By** to display the **ORDER BY COLUMNS** window. Select **Salary** from the **Available Columns** list and add it to the **Selected Columns** list. Select **OK** to return to the SQL QUERY COLUMNS window.

In addition to the method of saving queries that was described earlier, you can also select **File ⇒ Save Query ⇒ Save as Query to Include later**. Type **ABOVE25** in the **Entry Name** field. Type **Salaries above $25,000** in the description field. Select **OK**.

You can also save queries that will be processed against different tables. To create the next query that you will save, select **View ⇒ Tables** to return to the SQL QUERY TABLES window. Remove **SAMPLE.SALARY** from the **Selected Tables** list. If a dialog box appears, then select **OK** to clear the **WHERE** expression.

Select **SAMPLE.EMPINFO** from the **Available Tables** list and add it to the **Selected Tables** list. Select **OK** to display the SQL QUERY COLUMNS window.

Add **NAME**, **DIVISION**, and **Education Level** to the **Selected Columns** list. Select **View ⇒ Where Conditions for Subset**.

Select **Education level** from the **Available Columns** list. Select **GE** (greater than or equal to) from the list of operators. Select `<LOOKUP distinct values>`, and select **20** from the **Lookup Values** list. Select **OK** to return to the SQL QUERY COLUMNS window.

Select **File ⇒ Save Query ⇒ Save as Query to Include later**.

Type **EDU20** in the **Entry Name** field. Type **Education level above 20 years** in the description field. Select **OK** to save the query.

---

**Listing Saved Queries**

You can now display a list of the queries that you have saved, and include one of the queries. Select **File ⇒ List/Include Saved Queries**. The queries that you have created are listed in the Saved Queries window.
Including a Saved Query

Select `SASUSER.PROFILE.EDU20` and select **OK**. A dialog box asks whether you want to clear the previous query or include the previous query with the new one. Select **OK**.

Viewing Your Output

You can run `SASUSER.PROFILE.EDU20` by selecting **Tools** ⇒ **Run Query** ⇒ **Run Immediate**. The results are displayed in the Output window.
Using Parentheses and Other Operators

Changing a WHERE Expression

You can use operators other than the comparison operators to subset your data for querying; you can easily change a WHERE condition that has been previously set.

You can change the WHERE expression in SASUSER.PROFILE.EDU20 from the previous example. In the SQL QUERY TABLES window, select View → Where Conditions for Subset.

Select Operators to display the list of valid operators.

AND

Select AND from the list.

Select Operators. Select ( from the list. Select Birth date from the Available Columns list. Select OTHER Operators from the list of operators to display a second menu of operators.
Between

Select **Between** from the list of other operators.

Select <LOOKUP distinct values> from the Available Columns list.

Select 17OCT1945 from the **Lookup Values** list. Because the Between operator requires a second value, the Lookup Distinct Values window appears again after you select a value. Select 18DEC1948 from the Lookup Values list.

In the WHERE EXPRESSION window, select **Operators**. Select ) from the list of operators to complete the expression that will be evaluated first when the query is run.
Select **OK** to return to the SQL QUERY COLUMNS window.

### Viewing Your Output

Select **Tools** ⇔ **Run Query** ⇔ **Run Immediate** to display the output of your query.

From the SQL QUERY COLUMNS window, select **Tools** ⇔ **Reset** to reset your query.

### Designing and Saving a Report

When you run your query, you can use the REPORT procedure to modify your output.

### Sample Tables for Designing and Saving a Report

You will need two of the sample tables to practice using the examples in this section.
If there is an active query in the SQL Query Window, then select **Tools ⇒ Reset** to clear the query. Select **OK** in the dialog box that appears.

In the SQL QUERY TABLES window, select **SAMPLE.EMPINFO** and **SAMPLE.SALARY** from the Available Tables list and add them to the Selected Tables list.

Select **OK** to display the SQL QUERY COLUMNS window. Add **Identification Number**, **DIVISION**, **Education level**, and **Salary** to the Selected Columns list.

Select **View ⇒ Join Type**. Select **Matched Join** from the Join Types window to create an inner join. Select **OK**.

Select **Identification Number** from both lists in the Columns for Setting Join Criteria window.
Producing Output with the REPORT Procedure

Select Tools \(\rightarrow\) Run Query \(\rightarrow\) Design a Report \(\rightarrow\) Begin with default report.

The output from your query appears in a PROC REPORT window.

Modifying the Format of Your Report

Set Report Options

You can now modify your report. In the REPORT window, select Tools \(\rightarrow\) Options \(\rightarrow\) Report.

In the ROPTIONS window, type 80 in the Linesize field to set the width of the output. Type 60 in the Pagesize field. Select the HEADLINE and HEADSKIP check boxes.
Select OK.

Define Selected Item

Select the Identification Number heading. Select Edit \(\Rightarrow\) Define.

Select NOPRINT in the DEFINITION window to prevent the identification number from being displayed.

Select OK.

Move Selected Item

In the REPORT window, select the Education level heading. Select Edit \(\Rightarrow\) Move \(\Rightarrow\) Left of the Next Selected Item.

Select the DIVISION heading in the REPORT window. Education Level appears as the first column in the window.

Select the Education level heading in the REPORT window. Select Edit \(\Rightarrow\) Define.

In the DEFINITION window, select ORDER. Type 2 in the Format field. Type 15 in the Width field. Type CENTER in the Justify field.
Select OK.

Select the **Salary** heading in the REPORT window. Select **Edit** ⇒ **Move** ⇒ **Left of the Next Selected Item**.

Select the **Division** heading. Salary will appear as the second column in the window.

Select the **Salary** heading. Select **Edit** ⇒ **Define**.

In the DEFINITION window, type **DOLLAR8** in the **Format** field. Type **8** in the **Width** field.

Select OK.

Select the **DIVISION** heading in the REPORT window. Select **Edit** ⇒ **Define**.

Type **$30** in the **Format** field of the DEFINITION window. Type **30** in the **Width** field.
The Formatted Report

Your completed report compares the salaries of employees from different divisions who have the same education level.

<table>

Viewing the Report Statements

You can view your report statements in the SOURCE window by selecting Tools ⇒ REPORT Statements.

Select File ⇒ Close to close the SOURCE window and return to the REPORT window.

Saving Your Report

You can save your customized report to a catalog entry for use with later queries by selecting File ⇒ Save Report to display the SAVE DEFINITION window. Type SAMPLE in the Libname field. Type SQL in the Catalog field. Type SALARY in the Report name field. Type Salaries and Divisions in the Description field.
Select OK. A dialog box appears that notifies you of the creation of a new catalog. Select OK.

Select File ⇒ Close to exit the REPORT window. Select OK in the dialog box that appears.

You can also save your report definition in the SQL Query Window when you save the query.

**Use Definition from Last Report**

You can use your customized report definition. In the SQL QUERY COLUMNS window, select Tools ⇒ Run Query ⇒ Design a Report ⇒ Use definition from last Report.

The results of the query are presented using your predefined report. Select File ⇒ Close to exit the REPORT window. Select OK in the dialog box that appears.

**Creating Summary Reports**

You can use the SQL Query window in conjunction with the REPORT Procedure to create a summary report with totals.

**Using a Saved Report Definition**

For this example you will modify the report that you created in the previous example to display the total salaries for each division. In the SQL QUERY COLUMNS window, select Tools ⇒ Run Query ⇒ Design a Report ⇒ Name a predefined report. When the dialog box appears, select SAMPLE from the Libraries list. The libraries and catalogs that are listed in your display might differ from the ones in the example.
Select SQL from the Catalogs list. Select the SALARY report definition. Select OK.

Deleting a Heading
You do not need to display education level for this report. In the REPORT window, select the Education level heading. Select Edit ⇒ Delete to delete the Education Level column from the report. You are not deleting EDUCATION LEVEL from the query.

Summarizing Information
Select the DIVISION heading. Select Edit ⇒ Summarize Information ⇒ After Item to display the BREAK window. Select the Double overline summary check box to print a double line over the summary total. Select the Skip line after break and Summarize analysis columns check boxes.
Select **OK** to return to the REPORT window and display the total salaries for each division.

![Image of the REPORT window showing salaries by division](image)

Select **File ➔ Close**.

Select **OK** in the dialog box that appears. The SQL QUERY COLUMNS window reappears.

Select **Tools ➔ Reset** to reset the query and return to the SQL QUERY TABLES window.

---

## Counting and Grouping Data Automatically

### Overview of Counting and Grouping Data

You can count and report the total number of rows that have the same value for one or more columns. You can use the automatic group-by feature to group the values according to their columns.

The following query displays the number of employees in each division.
In the SQL QUERY TABLES window, select `SAMPLE.EMPINFO` from the Available Tables list and add it to the Selected Tables list. Select OK.

In the SQL QUERY COLUMNS window, select `DIVISION` and `< COUNT(*) >` from the Available Columns list and add them to the Selected Columns list.

**Count**

Select `COUNT(*)` from the Selected Columns List. Select Move After to move the column. Reselect `COUNT(*)`. Select Column Alias/Label. Type Count of Employees for Each Division in the Label field of the Column Alias and Label window.

Select OK.

**Grouping Columns Automatically**

Select Tools ⇒ Run Query ⇒ Run Immediate. A dialog box appears.
Select **AUTOGROUP** to automatically select the correct columns. Selected columns that do not have summary functions applied to them will be the group or groups that the summary functions are computed for.

A second dialog box appears.

Select **No**. The automatic Group By clause will be part of the query syntax while the query runs, but it will not be retained. You can select or remove columns after the query is executed and use **AUTOGROUP** to automatically select the columns again.

The count of employees for each division is displayed in the Output window.
In the SQL QUERY COLUMNS window, select Tools ⇒ Reset to reset your query. Select OK from the dialog box that appears.

Automatic Group By with More Than One Table

The next query joins two tables to display the number of employees for each job title. The JOBCODES table contains the job title for each job code.

Select SAMPLE.JOBCODES and SAMPLE.EMPINFO from the Available Tables list and add them to the Selected Tables list.

Select OK.

In the SQL QUERY COLUMNS window, select TITLE and < COUNT(*) > from the Available Columns list and add them to the Selected Columns list.

Select View ⇒ Where Conditions for Subset.

In the WHERE EXPRESSION window, select EMPINFO.JOBCODE from the Available Columns list. Select EQ from the list of comparison operators.

Select JOBCODES.JOBCODE from the Available Columns list.
Select OK to return to the SQL QUERY COLUMNS window.

Select COUNT(*) from the Selected Columns List. Select Move After to move the column. Reselect COUNT(*). Select Column Alias/Label. Type Count of Employees for Each Title in the Label field of the Column Alias and Label window.

Select OK.

Retaining an Automatic Group By as Part of a Query

Select Tools ➪ Run Query ➪ Run Immediate. A dialog box appears. Select AUTOGROUP in the dialog box to use JOBCODES.TITLE as the Group By column. A second dialog box appears. Select Yes in the second dialog box to retain the Group By column as part of the query.
The Output window displays the number of employees for each job title.

![Output window](image)

In the SQL QUERY COLUMNS window, select Tools ⇒ Show Query.

![SQL Query window](image)

The automatic Group By will be retained as part of the query syntax when the query is run again, saved, or used to create a table or view. Select Goback to return to the SQL QUERY COLUMNS window.

In the SQL QUERY COLUMNS window, select File ⇒ Save Query ⇒ Save as QUERY to Include later.

In the Entry Name field, type COUNTS as the name of the query. In the description field, type Count of EMPNO by TITLE. Select OK to save the query and return to the SQL QUERY COLUMNS window.

Select View ⇒ Tables to return to the SQL QUERY TABLES window. Remove SALARY.JOBCODES from the Selected Tables list. Select OK in the dialog box that appears.
Summarizing Groups of Data

Summary Functions

Summary functions produce a statistical summary of a table or groups of data. The following example displays the minimum, average, and maximum level of employee education within each division. Use the Group By clause and a summary function to summarize information about a group of data. If you omit a Group By, then one summary value is produced for the entire table.

The Selected Tables list in the SQL QUERY TABLES window contains SAMPLE.EMPINFO from the previous example. Select OK.

In the SQL QUERY COLUMNS window, remove COUNT(*) from the Selected Columns list. Select DIVISION and Education level from the Available Columns list and add them to the Selected Columns list.

Select Education level a second time from the Available Columns List and add it to the Selected Columns list.

Select Education level a third time from the Available Columns list and add it to the Selected Columns list.

Select the first Education level from the Selected Columns list. Select Summary Functions.
Select **MIN** from the list of summary functions. A summary function is applied to the selected column and a default unique column alias is automatically generated. The summary function and the selected column name are automatically set as the label. You can use this default label in the report, or you can set a new alias or label.

Select the second **Education level** from the **Selected Columns** list. Select **Summary Functions**. Select **AVG** from the list of summary functions.

Select the third **Education level** from the **Selected Columns** list. Select **Summary Functions**. Select **MAX** from the list of summary functions.

Select the first **Education level** from the **Selected Columns** list. Select **Column Alias/Label**. Type **Minimum Years of Education** in the **Label** field of the Column Alias and Label window.
Select OK.

Select the second Education level from the Selected Columns list. Select Column Alias/Label. Type Average Years of Education in the Label field of the Column Alias and Label window.

Select OK.

Select the third Education level from the Selected Columns list. Select Column Alias/Label. Type Maximum Years of Education in the Label field of the Column Alias and Label window.

Select OK.

Select the second Education level from the Selected Columns list. Select Column Formats.

Type comma4.0 in the Format field. Select OK.

Select Tools ⇒ Run Query ⇒ Run Immediate. A dialog box appears.
Group By Columns

Select **GROUPBY** to display the GROUP BY COLUMNS window.

Select **DIVISION** from the **Available Columns** list and add it to the **Group By Columns** list. Select **OK**.

The minimum, average, and maximum education levels of the employees for each division are displayed in the Output window.

In the SQL QUERY COLUMNS window, select **Tools ⇒ Reset** to reset your query and return to the SQL QUERY TABLES window. Select **OK** from the dialog box that appears.
Removing Duplicate Rows

You can remove duplicate rows from your query output. To display each distinct division and location, select `SAMPLE.EMPINFO` and add it to the `Selected Tables` list. Select `OK`.

In the SQL QUERY COLUMNS window, select `DIVISION` and `LOCATION` and add them to the `Selected Columns` list.

Select `View` ⇒ `Distinct`.

Select `Tools` ⇒ `Run Query` ⇒ `Run Immediate`. Lines in the Output window that contain the same division and location are not repeated.

In the SQL QUERY COLUMNS window, select `Tools` ⇒ `Reset` to reset your query and return to the SQL QUERY TABLES window. Select `OK` from the dialog box that appears.

Subsetting Groups of Data with the HAVING Condition

How to Subset Groups of Data with the HAVING Condition

The HAVING condition specifies the condition or conditions that each group must satisfy in order to be included in the query output. You can use a HAVING condition to subset grouped data by using HAVING in the same query with a `GROUPBY` and a summary function.

Which divisions in the previous example have a minimum employee education level that is greater than 15 years? To find out, select `SAMPLE.EMPINFO` and add it to the `Selected Tables` list. Select `OK`.

In the SQL QUERY COLUMNS window, select **DIVISION** and add it to the **Selected Columns** list. Remove duplicate values by selecting **View > Distinct**.

**HAVING EXPRESSION Window**

To create a condition that each output group must satisfy, select **View > Having Condition for Group** to display the **HAVING EXPRESSION** window.

Select **Summary Functions**. Select **MIN** from the list of summary functions.

Select **Education level** from the Available Columns list.

Select **GT** from the list of operators that appears.

Select **<CONSTANT enter value>** from the Available Columns list. The Numeric Values dialog box appears.

Type 15 in the **Numeric** field and select **OK**.
In the HAVING EXPRESSION window, select OK to return to the SQL QUERY COLUMNS window.

Viewing the Results of the HAVING Condition

Select View ➔ Group(s) for Summary Functions to display the GROUP BY COLUMNS window.

Select DIVISION from the Available Columns list and add it to the Group By Columns list.

Select OK.

Select Tools ➔ Run Query ➔ Run Immediate to display the divisions whose minimum employee education level is greater than 15.

In the SQL QUERY COLUMNS window, select Tools ➔ Reset to reset the query and return to the SQL QUERY TABLES window. Select OK from the dialog box that appears.
Using the Automatic Lookup Feature

How to Implement the Automatic Lookup Feature

You can implement automatic lookup for any column in a table that can be accessed from the SQL Query window. Automatic lookup causes an action, that varies according to the lookup strategy, to automatically occur when that column and an operator are selected from the WHERE EXPRESSION window.

In this example, you implement automatic lookup by creating a SAS data set called a lookup table. You then insert a set of values into the lookup table for each column for which you want a Lookup Values window to be displayed.

Lookup Strategies

You can specify any one of five lookup strategies for each column:

V (Value)  
automatically retrieves the distinct values of the column that has been specified in the lookup table. The distinct values appear in a Lookup Values window in the WHERE EXPRESSION window when you have selected both the specified column from the Available Columns window and an operator from the menu that subsequently appears. When you select one or more values, these values are inserted into the WHERE expression. The EQ operator is converted to the IN operator to allow multiple selections.

T (Table)  
reads a table and displays the values of all the columns in the Lookup Values window. The first column in the table must contain the values that are needed in the WHERE expression. You can use other columns to provide descriptive information.

If the first column contains a small number of distinct rows in comparison to the number of rows in the table, then the distinct values and their descriptions can be stored in a separate table. This table can be used to display automatic lookup values for the subset conditions.

L (List)  
 enables you to select specific columns from a table for display in the Lookup Values window. The first column that you specify must contain the values that are needed for the WHERE expression. You can use other columns to provide descriptive data values.

F (Format)  
displays column data values and their corresponding formatted values that have been created with the FORMAT procedure.
P (Program) invokes a user-written SAS/AF program. A list that contains the currently pending WHERE expression is passed to the program, where it can be either used or ignored.

Creating an Empty Lookup Table

Submit the following PROC SQL statements in the Program Editor to create an empty lookup table.

```sql
proc sql;
create table sasuser.lookup
  (lookltc char(100) label='library.table.column',
   lookinfo char(200) label='varies depending on strategy',
   strategy char(8) label='lookup strategy to use');
```

SASUSER.LOOKUP is the default name of the lookup table. The SQL Query Window looks for this table to determine whether any automatic lookup is to be performed.

Adding a Row to the Lookup Table

After you create the empty lookup table, you can submit additional PROC SQL statements to insert values into the table’s LOOKLTC, LOOKINFO, and STRATEGY columns. You can also invoke PROC FSEDIT to add this information. The syntax for inserting values into the table is

```sql
proc sql;
insert into lookup.table
  values('lookltc-value','lookinfo-value','strategy-value');
```

Add a row to the SASUSER.LOOKUP data set by submitting the following code in the Program Editor:

```sql
proc sql;
insert into sasuser.lookup
  values('sample.empinfo.location','sample.program.region.frame','P');
quit;
```

This row contains information that the SQL Query Window uses to perform automatic lookup. Whenever the LOCATION column is selected from the SAMPLE.EMPINFO table in the WHERE EXPRESSION window for any query, the FRAME entry that is defined in SAMPLE.PROGRAM.REGION.FRAME is executed. The lookup strategy value of P indicates that the action that is to take place is a program execution.
Using the Lookup Table

Before you can use the lookup table, you do either of the following in order for the SQL Query Window to read the lookup table:

- exit and restart the SQL Query Window
- switch to a profile that uses SASUSER.LOOKUP as the automatic lookup table.

For this example, select **Tools ⇄ Switch to New Profile**. Select the SASUSER.PROFILE.QUERY profile and select **OK**. The SASUSER.PROFILE.QUERY profile uses SASUSER.LOOKUP as the automatic lookup table.

To display the number of employees in each division within a specific geographic region, from the SQL QUERY TABLES window, select **File ⇄ List/Include Saved Queries** to display the Saved Queries window.

Select **SASUSER.PROFILE.COUNTS**, which you created in “Counting and Grouping Data Automatically” on page 47. Select **OK** to include the query and to return to the SQL QUERY TABLES window.

Select **View ⇄ Where Conditions for Subset** to display the WHERE EXPRESSION window.
Select **Operators**. Select **AND** from the list of operators.

Select **EMPINFO.LOCATION** from the **Available Columns** list. Select **EQ** from the list of comparison operators that appears. Because you have defined **EMPINFO.LOCATION** with an automatic lookup, the Company Locations window automatically appears.

The Company Locations window is the FRAME entry that is defined in **SAMPLE.PROGRAM.REGION.FRAME**. Select the westernmost site to complete the **WHERE** clause.
Select **OK**.

### Viewing Your Output

Select **Tools ➔ Run Query ➔ Run Immediate** to display the results of your query.

In the SQL QUERY TABLES window, select **Tools ➔ Reset** to reset your query. Select **OK** from the dialog box that appears.

### Using a Slider Bar to Indicate a Range

#### Overview of Using a Slider Bar to Indicate a Range

You can use a slider bar to select a range of lookup values in a query.

In this example, you associate the slider with the EMPINFO.SALARY column. Because you might not want to permanently associate these lookup values with the EMPINFO.SALARY column, you can insert the lookup table into a different profile and switch to that profile when you want to use the slider bar.
Creating a New Lookup Table

Submit the following PROC SQL statements in the Program Editor to create an empty lookup table in the SAMPLE library.

```sql
proc sql;
cREATE TABLE sample.lookup
    (lookltc  char(100) label='library.table.column',
     lookinfo char(200) label='varies depending on strategy',
     strategy char(8) label='lookup strategy to use');
```

Add a row to the SAMPLE.LOOKUP data set by submitting the following code in the Program Editor:

```sql
proc sql;
INSERT INTO sample.lookup
    VALUES('sample.salary.salary','sample.program.salrange.frame','P');
quit;
```

SAMPLE.PROGRAM.SALRANGE.FRAME is a FRAME entry that defines the slider bar.

Creating a New Profile

Create an SQL Query Window profile that specifies SAMPLE.LOOKUP as the automatic lookup table as follows. Select Profile → Set Preferences.

Select the right arrow next to Automatic Lookup to display the Set Lookup SAS Data Set for Preferences window.

Select the right arrow next to the Library field. Select SAMPLE from the Libraries list and select OK. Select OK to return to the Preference Settings for Profile window.

Select the right arrow next to Data Restrictions to display the Data Restrictions for Profile window. Select SAMPLE from the Table Sources list. Select Add entire Table Source to preferences from the pop-up menu that appears. Select WORK from the Table Sources list. Select Add entire Table Source to preferences from the pop-up menu that appears.

Note: If you do not have Write access to the SAMPLE library, then repeat the previous step for the SASUSER library.
Select **OK** to return to the Preference Settings for Profile window.

Select **Save** to save your new profile setting. Type **LOOKUP** in the **Entry Name** field of the Name Catalog Entry for Profile window. Type **Slider Bar for Salary Range** in the description field.

Select **OK** to return to the Preference Settings for Profile window. Select **Close**.

From the SQL QUERY TABLES window, select **Tools ^= Switch to New Profile**. The Preference Profiles in Catalog window appears.

Select the right arrow next to the **Profile Name** field to display a list of profiles.

Select the **SASUSER.PROFILE.LOOKUP** profile.

Select **OK** to return to the SQL QUERY TABLES window and to complete the switch to the new profile.

See “Setting Your Profile” on page 76 for more information about the SQL Query Window user profile.

A Demonstration of the Slider Bar

To show how the slider works, you can construct a simple WHERE expression that displays the range of salaries. In the SQL QUERY TABLES window, select **SAMPLE.SALARY** from the **Available Tables** list and add it to the **Selected Tables** list. Select **OK** to display the SQL QUERY COLUMNS window.

In the SQL QUERY COLUMNS window, select **Salary** and **Identification Number** from the **Available Columns** list and add them to the **Selected Columns** list.

Select **View ^= Where Conditions for Subset**.

In the WHERE EXPRESSION window, select **Salary** from the **Available Columns** list. Select **Between** from the **OTHER Operators** list. Because the lookup table is associated with the Salary column, the slider bar that is the FRAME entry appears.

Select **OK** to accept the value of **12000**. The slider bar appears again because the Between operator requires a second value. Move the slider to the right until **51000** is displayed. Select **OK** to complete the WHERE expression.
Select OK to return to the SQL QUERY COLUMNS window. Select Tools ⇒ Run Query ⇒ Run Immediate to display the employee identification numbers whose salaries are between $12,000 and $51,000.

Select Tools ⇒ Reset to reset the query and return to the SQL QUERY TABLES window.

Using SCL to Call a FRAME Entry

If your site is licensed to use SAS/AF software, then you can use SAS Component Language (SCL) to create a lookup table that uses the SAMPLE.PROGRAM.SALRANGE.FRAME entry or another FRAME entry that you design. The following SCL program is associated with the SAMPLE.PROGRAM.SALRANGE.FRAME entry:

```
entry
looklst 8 lkuptype $1 rc 8 msg $40 wherelst 8;

init:
   salrange =12000;
   lkuptype = 'N';
   return;

main:
   return;

term:
   return;
```
Creating and Using Outer Joins

Overview of Outer Joins

An outer join combines rows of data from two tables. There are three types of outer joins:

- left join
  returns all matching rows in both tables, in addition to rows in the left table that have no matching rows in the right table.

- right join
  returns all matching rows in both tables, in addition to rows in the right table that have no matching rows in the left table.

- full join
  returns all matching and nonmatching rows from both tables.

In all three types of outer joins, the columns in the result row that are from the unmatched row are set to missing values.

In this example, you first create an inner join that relates employee identification number and salary. Then, you create an outer join that combines this data with data from another table to compute the gross monthly pay for employees who have taken leave.

Creating a Query View

You can create an SQL view that contains the syntax of your query. For this example, you use a view to create an outer join query.

In the SQL QUERY TABLES window, select SAMPLE.EMPINFO and SAMPLE.SALARY from the Available Tables list and add them to the Selected Tables list. Select OK.
In the SQL QUERY COLUMNS window, select NAME, the two ADDRESS items, Identification Number, Employee number, Salary, BEGDATE, and ENDDATE and add them to the Selected Columns list.

Select View ⇒ Where Conditions for Subset to display the WHERE EXPRESSION window.

Select EMPINFO.Identification Number from the Available Columns list. Select EQ from the list of operators. Select Salary.Identification Number from the Available Columns list. Select OK.

This WHERE expression creates an inner join of EMPINFO and Salary based on Identification Number. To save the query as a view, select Tools ⇒ Show Query to display the SQL QUERY window. Select Create View.

Select the right arrow next to the Library field to display a list of SAS libraries.

The list of libraries displayed at your site might be different from the ones in the illustration. Select SAMPLE from the Libraries list. Select OK.

Type MYVIEW in the View field. Select OK to return to the SQL QUERY window. Select Goback to return to the SQL QUERY COLUMNS window.
Creating an Outer Join

Select Tools ⇒ Reset to reset the query. Select OK in the dialog box that appears.

Select SAMPLE.MYVIEW and SAMPLE.LEAVE from the Available Tables list and add them to the Selected Tables list. Select OK to display the SQL QUERY COLUMNS window.

Select View ⇒ Join Type.

Select Matched Join and Unmatched Rows (Outer Join). Select OK to display the Columns for Setting Join Criteria window.

Select Identification Number from the SAMPLE.MYVIEW Columns (Left) list. Select Identification Number from the SAMPLE.LEAVE Columns (Right) list. Select the down arrow next to Join Type. Select Left from the pop-up menu. Select OK to return to the SQL QUERY COLUMNS window.

Select View ⇒ Distinct to eliminate duplicate values from your output.

Select NAME, Identification Number, and Employee number from the Available Columns list and add them to the Selected Columns list.
Building a Column Expression

Select **Build a Column** to display the BUILD A COLUMN EXPRESSION window.

Select **MYVIEW.Salary** from the Available Columns list. Select `/` from the list of operators. Select `<CONSTANT enter value>` from the Available Columns list. Type 12 in the Numeric field. Select **OK**. Select outside the list of operators to dismiss it.

Select **Column Attributes** to display the Expression Column Attributes window. Enter **monthpay** in the Alias Name field. Enter `dollar12.2` in the Format field. Enter Employee’s Monthly Pay in the Label field.

Select **OK** to return to the BUILD A COLUMN EXPRESSION window. Select **OK** to return to the SQL QUERY COLUMNS window.
In the SQL QUERY COLUMNS window, select Build a Column to display the BUILD A COLUMN EXPRESSION window. Select Operators. Select ( from the list of operators.

Select monthpay from the Available Columns list. Select * from the list of operators. Select LEAVE.Payroll percentage from the Available Columns list. Select ) from the list of operators. Select outside the list of operators to dismiss it.

Select Column Attributes to display the Expression Column Attributes window. Enter adjstpay in the Alias Name field. Enter dollar12.2 in the Format field. Enter Employee’s Gross Pay in the Label field. Select OK to return to the BUILD A COLUMN EXPRESSION window. Select OK to return to the SQL QUERY COLUMNS window.

Order by Columns

In the SQL QUERY COLUMNS window, select View Æ Order By to display the ORDER BY COLUMNS window.
Select the second **Identification Number** from the **Available Columns** list and add it to the **Order By Columns** list. Select **OK** to return to the SQL QUERY COLUMNS window.

### Viewing Your Output

Select **Tools → Run Query → Run Immediate** to display the results of the query in the Output window.

Using SAS Data Sets to Store System Tables Information

Handling Embedded Blanks in Column Names

Including Saved Queries
Setting Your Profile

Create a Profile

You can customize your SQL Query Window sessions by specifying your own default settings and storing them in a profile. When you invoke the SQL Query Window with the profile, your own preferences are automatically in effect. Your user-defined default settings are called preference settings. You can set up customized profiles for yourself or for a group of users. For example, you can define a profile to specify which table sources and tables are available in an SQL Query Window session.

Create a profile entry by selecting, from the SQL Query Window, Profile → Set Preferences.

Configure Remote Session

How to Configure a Remote Session

Installations that license SAS/CONNECT software can use the SQL Query Window to query tables or databases that are stored on remote systems. To connect to a remote system you must first create an SQL Query Window profile that contains information about the remote configuration.

Select the right arrow next to Configure Remote Session in the Preference Settings for Profile window.
Fill in the fields in this window with values that are appropriate for your site.

Use the **Description** field to describe the remote configuration.

Select the right arrow next to **Setup SAS Library Librefs for Remote Session** to enter the values that will be used to submit SAS statements remotely.

To query DBMS data through a SAS/ACCESS library engine, enter the name of the libref that you want to create in the **Libref** field. Enter the name of the SAS/ACCESS library engine that you want to use (usually the DBMS name) in the **Engine** field. Enter the LIBNAME options that are required for the libref in the **Options** field. In most cases, the **SAS Library Name** field can remain empty. For more information about library engines, see the SAS/ACCESS software documentation for your DBMS.

When you have entered your values, select **OK** to return to the Configure Remote Session window. Select **OK** to return to the Profile Preference Settings window.

Use the other items in the Profile Preference Settings window to specify any other preference settings that you want to include in your profile.

Select **Save** to save the profile.
Signing On to the Remote Host

You can sign on to the remote host either when you invoke the SQL Query Window, or during an SQL Query Window session.

- To sign on to the remote host when you invoke the SQL Query Window, specify the profile that contains the remote configuration information. The connection to the remote host is made automatically.

- To sign on to the remote host during an SQL Query Window session, select Tools -> Switch to New Profile. In the Switch to New Profile window, specify the library, catalog name, and profile name for the profile that contains your remote configuration information. Select OK to make the connection to the remote host.

- To remain signed on after exiting the SQL Query Window, select Remain signed on after exit Query Window in the Configure Remote Session window. If the remote host that is specified in your profile has already been signed on to during your SAS session, then the SQL Query Window uses that connection to the remote host. You are not signed off from the remote host when you exit the SQL Query Window session.

Access Mode

Access Mode Options

Access Mode specifies the source of the data that you will access. The source can be either SAS (for SAS data files and views), or most of the database management systems (DBMSs) for which the PROC SQL Pass-Through Facility is available if you have SAS/ACCESS software installed. If you are using a SAS/ACCESS library engine to query DBMS data, then set the access mode to SAS. This mode enables you to access the DBMS data via the libraries that are defined in your SAS session. The default access mode is SAS.
For some DBMSs, such as Sybase and ORACLE, you must specify access mode options such as the user name, password, and server. When you select one of these DBMSs that require options from the Access Mode window, an Access Mode Options window appears.

For access modes such as DB2 that do not require any options, you can select Access Mode Options to set additional options.
Automatic Join

Creating an Automatic Join Data Set

An automatic join (or “autojoin”) data set contains the table names and column links that are required to join tables automatically in an SQL Query Window session. When tables that are defined in the automatic join data set are selected together, the corresponding column links are used to automatically start the query’s WHERE expression. An autojoin data set can be shared by many users.

The following example illustrates the creation of an automatic join data set. Select the right arrow next to the **Automatic Join** field, and then select **Create an Automatic Join Data Set** from the pop-up menu that appears.

Select **SAMPLE** from the **Table Source** list to populate the **Available Tables** list. Select **SAMPLE.EMPINFO** and **SAMPLE.LEAVE**. Select **OK**. The Automatic Join Column Links window is displayed.

Select **SAMPLE** from the **Table Source** list to populate the **Available Tables** list. Select **SAMPLE.EMPINFO** and **SAMPLE.LEAVE**. Select **OK**. The Automatic Join Column Links window is displayed.
These two tables have the NAME column in common. Select NAME from both the SAMPLE.EMPINFO Columns list and the SAMPLE.LEAVE Columns list. Select OK. If the two tables had any other columns in common, then you would be able to select these columns as well and store the column links in the automatic join data set.

Select Goback to return to the Available Tables list.

Select Show Links to display the link that you have created between the two data sets.

Select Goback. You can repeat the previous procedure for as many pairs of tables as you want.

When you are finished defining column links, select Save to save your automatic join data set.
If desired, enter an appropriate label in the **Label** field. Select **OK**.

**Note:** For this example, the default SASUSER.AUTOJOIN data set is used. However, by specifying a different library or table name, you can save the autojoin data set to a different location.

Select **Goback** to return to the Preference Settings for Profile window. Select **Save** and then **OK** to save the changes to the profile. Select **Close** to return to the SQL QUERY TABLES window.

When you start the SQL Query Window, the software looks for the automatic join data set that is specified in the default profile, whether the automatic join data set is the default SASUSER.AUTOJOIN or some other data set that you have specified. If an autojoin data set is not found, then no automatic joins are performed.

Select **File** ⇒ **Close** to end your SQL Query Window session. Select **OK** in the dialog box that appears in order to return to the Program Editor.

Invoke another SQL Query Window session. Select SAMPLE.EMPINFO and SAMPLE.LEAVE from the **Available Tables** list and add them to the **Selected Tables** list. Select **OK** to display the SQL QUERY COLUMNS window.

Select DIVISION from the **Available Columns** list and add it to the **Selected Columns** list.

Select **View** ⇒ **Where Conditions for Subset** to display the WHERE EXPRESSION window.
The WHERE expression begins with the column link that you specified in your autojoin table.

Updating Your Automatic Join Data Set

You can update an automatic join data set with PROC FSEDIT or PROC SQL. Automatic join data sets contain two columns, AUTOCOL1 and AUTOCOL2. Each column contains the library name, table name, and column name, in the format `libname.table-name.column-name`, for one of the column links.

Selecting a Different Automatic Join Data Set

You can select a different automatic join data set for a given profile. In the Preference Settings for Profile window, select the right arrow next to the Automatic Join field, and then select Set Name for Automatic Join Data Set from the pop-up menu that appears. Select the library and table name of the desired autojoin data set and select OK.

Automatic Lookup

Automatic Lookup specifies a lookup table. See “Using the Automatic Lookup Feature” on page 60 for information about the automatic lookup feature.

Data Restrictions

Data Restrictions specifies the table sources, tables, and columns that will be available in an SQL Window session that is invoked with this profile. Data Restrictions also shows you which table sources, tables, and columns that you have made available for the profile.

Password Protect

Password Protect enables you to specify a password for your profile. After you enter the password, you are prompted to re-enter it for verification. Thereafter, users can invoke the SQL Query Window with this profile without knowing the password. However, a user cannot update the profile without supplying the password.

Restrict Input Rows to Query

Restrict Input Rows to Query imposes a limit on the number of rows (observations) that the SQL Query Window will process from any single table. This item is useful for debugging queries on large tables, or for preventing the excessive expenditure of computer resources that would result from running queries on large tables.
Set SQL Options

Set SQL Options enables you to set SQL options for the execution of the query.

**INOBS=**
restricts the number of rows that are processed from any single source.

**OUTOBS=**
restricts the number of rows that are processed as the target.

**LOOPS=**
limits the number of iterations in the inner loop.

**FLOW=**
specifies the limit beyond which character columns are to be flowed to multiple lines.

**SORTSEQ=**
specifies the collating sequence to be used with an ORDER BY clause. Use this option to specify a collating sequence other than the default.

---

Keep Profile in Menu

Keep Profile in Menu enables you to remove or retain the Profile item on the SQL Query Window menu bar and to turn on or off the ability to switch to a new profile from the Tools menu.
Exit Confirmation

Exit Confirmation enables you to turn off the dialog box that asks you if you want to end the query session. The dialog box appears when you select Close from the File menu.

Switching to Another Profile

To change to a different profile during an SQL Query Window session, select Tools ➔ Switch to New Profile.

In the dialog box that appears, select the library, catalog, and profile name for the desired profile. Select OK when you are finished making selections.

Handling Missing Values

You can use the SQL Query Window to test for missing values in a data set. This example generates a list of employees whose education level is not known.

From the SQL QUERY TABLES window, select SAMPLE.EMPINFO from the Available Tables list and add it to the Selected Tables list. Select OK.

In the SQL QUERY COLUMNS window, select NAME and Education level from the Available Columns list and add them to the Selected Columns list.

Select View ➔ Where Conditions for Subset.

In the WHERE EXPRESSION window, select Education level from the Available Columns list. Select Is Missing from the OTHER Operators list.
Select **OK** to return to the SQL QUERY COLUMNS window.

Select **Tools ⇒ Run Query ⇒ Run Immediate** to display a list of employees whose education level is missing from the data set.

---

Defining a Format outside the SQL Query Window

You can use the FORMAT procedure to define additional output formats. In this example, you define a format using the FORMAT procedure and then use that format to create a report with the SQL Query Window.

---

Creating the Format

In the Program Editor, submit the following SAS code:

```sas
proc format;
   value edlevel 1-12 = 'No High School Diploma'
                       12 = 'High School Diploma'
                       13 = 'Completing Associate'
                       14 = 'Associate'
                       15 = 'Completing Bachelors'
                       16 = 'Bachelors'
                       17 = 'Completing Masters'
                       18 = 'Masters'
                       19 = 'Completing PhD'
                       20-99 = 'PhD'
                              . = 'No Education Data';
run;
```

The previous procedure creates the EDLEVEL. format, which prints a text string that corresponds to the numeric education level value.

See *Base SAS Procedures Guide* for more information about the FORMAT procedure.
Selecting Your Format

Invoke the SQL Query Window. In the SQL QUERY TABLES window, select SAMPLE.EMPINFO from the Available Tables list and add it to the Selected Tables list. Select OK.

In the SQL QUERY COLUMNS window, select NAME and Education level from the Available Columns List and add them to the Selected Columns list.

Select Education level from the Selected Columns list. Select Column Formats to display the Column Formats dialog box.

Select the right arrow next to the Format field to display the Format Names list.

Select edlevel from the Format Names list. Select OK to return to the Column Formats window. Select OK to return to the SQL QUERY COLUMNS window.
Using Formatted Values in a WHERE Expression

Select View ⇒ Where Conditions for Subset to display the WHERE EXPRESSION window. Select Education level from the Available Columns list. Select EQ from the list of operators.

Select <LOOKUP distinct values> from the Available Columns list. The Lookup Values list contains the distinct values for the Education Level column using the EDLEVEL. format that you defined.

Select PhD from the list. Because the EQ operator can take only one value, the WHERE EXPRESSION window automatically reappears. Select OK to return to the SQL QUERY COLUMNS window.

Viewing Your Output

Select Tools ⇒ Run Query ⇒ Run Immediate to display a list of the employees whose education level is PhD.

In the SQL QUERY COLUMNS window, select Tools ⇒ Reset to reset the query. Select OK from the dialog box that appears.
Changing Access Modes

ORACLE Access Mode Options

If you have the SAS/ACCESS interface to ORACLE installed, then you can switch access modes and use the SQL Pass-Through Facility to query ORACLE tables.

From the SQL QUERY TABLES window, select Tools ⇒ Switch Access Mode ⇒ ORACLE to display the ORACLE Access Mode Options window.

Fill in the fields with the information appropriate for your site. Contact your ORACLE administrator for more information.

Select OK to return to the SQL QUERY TABLES window. The sample tables that are available with your ORACLE DBMS are listed in the Available Tables column.

Creating a WHERE Expression

This example shows that although the steps for creating a WHERE expression are the same regardless of access mode, the generated SQL code is specific to the DBMS. If you have the SAS/ACCESS interface to ORACLE installed, then you can follow this example using any ORACLE table.

Select an ORACLE table from the Available Tables list and move it to the Selected Tables list. For this example, ORDERS is used. Select OK to display the SQL QUERY COLUMNS window.
Select one or more columns from the Available Columns list and add them to the Selected Columns list. This example uses FABRICCHARGES, SHIPTO, DATEORDERED, TAKENBY, and PROCESSEDBY.

Select View ➔ Where Conditions for Subset to display the WHERE EXPRESSION window.

Create a WHERE expression. For this example, the expression SHIPPED Is Not Missing is created. Note that the Is Not Missing operator is selected from the OTHER Operators list.

Select OK to close the WHERE EXPRESSION window.
Viewing Your Query

From the SQL QUERY COLUMNS window, select **Tools ➔ Show Query** to view your query.

For this example, the query reports information for orders that have been shipped. ORACLE SQL is generated as the query is built.

The syntax that is enclosed by the parentheses that follow `from connection to oracle` is transported through the SQL Procedure Pass-Through Facility to the ORACLE DBMS for processing. The **Is Not Missing** operator from the WHERE expression is converted to the `is not null` ORACLE operator.

The syntax that is outside of the parentheses that follow `from connection to oracle` is processed by SAS.

---

Using SAS Data Sets to Store System Tables Information

For access modes other than SAS, the individual database management system (DBMS) tables are queried for the Available Tables and Available Columns lists. For DB2, DB2/2, DB2/6000, Sybase, and ODBC, the system tables information that fills the Available Tables and Available Columns can now be stored in SAS data sets. One data set contains Tables information. The other data set contains Columns information. When you use a remote session for querying, these SAS data sets can be stored locally for enhanced performance.

If you have Read authority to the system tables, then you can assign the DB2, DB2/2, or DB2/6000 system tables to be read to SAS tables that are mirror images
of the DB2 tables. If you are executing a remote session, then you can specify whether these SAS DB2 system tables are to be read locally or remotely.

You can create these mirror image tables by querying the DB2 system tables in an SQL Query Window session and creating SAS tables of the queries built. They can also be created with a PROC SQL program that queries the DB2 system tables. The PROC SQL statements can be saved and the SAS program can be run in batch whenever you need to update the mirror image tables.

SAS tables (data sets) that are created by automatic joins can also be created for any of the access modes that provide system tables and dictionaries with a PROC SQL program.

For ODBC, you can generate SAS data sets that contain system tables:

1. Select Profile ☰ Set Preferences.
2. In the Preference Settings for Profile window, set Access Mode to ODBC. Enter the data source, user name, and password, and select OK.
3. In the Preference Settings for Profile window, select the right arrow next to Access Mode Options.
4. In the Preference Settings for ODBC Access Mode window, enter the SAS data set names for system tables information.
5. If SAS data sets have not been created, then select Create Table and Create Column.

For Sybase, the system table information can be read from a SAS data set:

1. Select Profile ☰ Set Preferences.
2. In the Preference Settings for Profile window, set Access Mode to SYBASE.
3. In the Sybase Access Mode Options window, enter the parameters for the Sybase access mode.
4. Select SAS Data Sets.
5. In the Available Tables and Columns for Sybase window, enter the SAS library name and SAS data set name for Sybase system tables. If the Sybase system tables do not already exist, then select Create Table and Create Column.

**Handling Embedded Blanks in Column Names**

DB2, DB2/2, DB2/6000, ORACLE, and ODBC column names can contain blanks. The SQL Query Window encloses column names in double quotation marks for these access modes to support any blanks within the column name string. Some ODBC drivers might not support double-quoted column names. To avoid conflicts with ODBC drivers, follow these steps:

1. Select Profile ☰ Set Preferences.
2. In the Preference Settings for Profile window, set Access Mode to ODBC. Enter the data source, user name, and password, and select OK.
3 In the Preference Settings for ODBC Access Mode window, select **Exclude double quote around column names**.

---

**Including Saved Queries**

When you save a query, references in the query to tables are saved as two-level names (libref.filename). If you try to include a saved query that specifies a libref that is not currently assigned, or tables that have been moved or deleted, then the SQL Query Window will inform you that the tables cannot be found.

The tables in the query to be included are not available in the current Query window session. If you need to change the table names in the query to be included to table names that are available in this session and have the same column names as those in the query you are including, select Yes. Otherwise, select No.

If the tables are available in another library, or if you want to run the query against different tables, then select **Yes**. The Include Query Tablename Edit window appears (probably with different names than in this example).

If the tables exist in another library, then select that library from the **Table Sources** list, and then select the tables from the **Available Tables** list.

If you want to run the query against different tables, then select the library that contains the tables from the **Table Sources** list, then select the tables from the...
Available Tables list. The tables must have identical structures to the tables on which the query was built.

This feature enables you to create a query that can be used on any identically structured table. For example, you could create a query on a table containing March sales data, and then use that query on a table containing April sales data. Remember that, to be prompted for a new table for the query, the original table on which the query was created must not be available in the SQL Query Window session. For example, by moving the March table from the CUR_MON (Current Month) library, and moving the April table into the CUR_MON library, you would be prompted to supply the table for the query.

See “Saving Queries” on page 33 for more information about creating and saving queries.
