WEIGHT=	Specifies the weight variable for the contributions of each classification effect
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial

Table 17.4 *continued*

Option	Description
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect with multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots starting at the variables' maximum and ending at the KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots starting at the KNOTMIN= value and ending at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect

ESTIMATE Statement

ESTIMATE '*label*' *contrast-specification* < **(***divisor***=***n***)** >
< , '*label*' *contrast-specification* < **(***divisor***=***n***)** > > < , . . . > < / *options* > **;**

The ESTIMATE statement provides a mechanism for obtaining custom linear estimate of the fixed and/or random effects. As in the CONTRAST statement, the basic element of the ESTIMATE statement is the *contrast-specification*, which consists of MODEL and RANDOM effects and their coefficients. Specifically, a *contrast-specification* takes the form

< *fixed-effect values* . . . > < | *random-effect values* . . . >

Based on the *contrast-specifications* in your ESTIMATE statement, PROC LMIXED constructs the matrix $\mathbf{L}' = [\mathbf{K}' \ \mathbf{M}']$, as in the CONTRAST statement, where $\mathbf{K}$ is associated with the fixed effects and $\mathbf{M}$ is associated with the G-side random effects. Each *contrast-specification* is referred to as a row in the $\mathbf{L}'$ matrix.

PROC LMIXED then produces for each row $\mathbf{l}$ of $\mathbf{L}'$ an approximate t test of the hypothesis $H: \mathbf{l}\boldsymbol{\phi} = 0$, where $\boldsymbol{\phi} = [\boldsymbol{\beta}' \ \boldsymbol{\gamma}']'$.

Note that multiple-row estimates are permitted. Unlike the CONTRAST statement, you need to specify a '*label*' for every row of the multiple-row estimate, because PROC LMIXED produces one test per row.

PROC LMIXED checks the estimability of the fixed-effects portion in each row of the multiple-row estimate.

If one row is found to be nonestimable (see the SINGULAR= option on page 886), then the procedure displays missing values for that row.

PROC LMIXED uses the residual degrees of freedom that you define by specifying the DDFM=RESIDUAL option. You can modify the degrees of freedom by using the DF= option. If you select DDFM=NONE and do not modify the degrees of freedom by using the DF= option, PROC LMIXED uses infinite degrees of freedom, essentially computing approximate z tests.

If PROC LMIXED finds the fixed-effects portion of the specified estimate to be nonestimable, then it displays "Non-est" for the estimate entry.

The construction of the **L** matrix for an ESTIMATE statement follows the same rules that are listed for the CONTRAST statement.

Table 17.5 summarizes the *options* available in the ESTIMATE statement.

Table 17.5 ESTIMATE Statement Options

Option	Description
ADJUST=	Specifies the method to use for multiple comparison adjustment of estimates
ALPHA=	Specifies the confidence level
CL	Constructs t-type confidence limits
DF=	Specifies the degrees of freedom
DIVISOR=	Specifies values to divide the coefficients
E	Displays the matrix coefficients
GROUP	Sets up random-effect contrasts between groups
LOWER	Performs one-sided, lower-tailed inference
SINGULAR=	Tunes the estimability checking
SUBJECT	Sets up random-effect estimates between subjects
UPPER	Performs one-sided, upper-tailed inference

Results from all ESTIMATE statements are displayed together in the Estimates ODS table.

You can specify the following *options* in the ESTIMATE statement after a slash (/):

ADJUST=BON | SCHEFFE | SIDAK | SIMULATE< (*simoptions*) > | T
performs a multiple comparison adjustment of the p-values and confidence limits for the estimates. The adjusted quantities are produced in addition to the unadjusted quantities. Adjusted confidence limits are produced if you specify the CL or ALPHA= option. For a description of the adjustments, see the ADJUST= option in the LSMEANS statement.

ALPHA=*number*
constructs a t-type confidence interval with confidence level $1 - number$. The value of *number* must be between 0 and 1, exclusive; the default is 0.05. If DDFM=NONE and you do not specify degrees of freedom by using the DF= option, PROC LMIXED uses infinite degrees of freedom, essentially computing a z interval.

CL

constructs *t*-type confidence limits. If DDFM=NONE and you do not specify degrees of freedom by using the DF= option, PROC LMIXED uses infinite degrees of freedom, essentially computing a *z* interval. By default, the confidence level is 0.95.

DF=*number*

specifies the degrees of freedom for the *t* test. The default is the residual degrees of freedom that you define by specifying the DDFM=RESIDUAL option.

DIVISOR=*value-list*

specifies a list of values by which to divide the coefficients so that fractional coefficients can be entered as integer numerators. If you do not specify a *value-list*, a default value of 1.0 is assumed. Missing values in the *value-list* are converted to 1.0.

If the number of elements in the *value-list* exceeds the number of rows of the estimate, the extra values are ignored. If the number of elements in the *value-list* is less than the number of rows of the estimate, the last value in the *value-list* is carried forward.

If you specify a row-specific divisor as part of the specification of the estimate row, this value multiplies the corresponding divisor implied by the *value-list*. For example, the following statement divides the coefficients in the first row by 8 and divides the coefficients in the third and fourth rows by 3:

```
estimate 'One vs. two'   A [2 1] [-2 2] (divisor=2),
         'One vs. three' A [1 1] [-1 3]            ,
         'One vs. four'  A [3 1] [-3 4]            ,
         'One vs. five'  A [1 1] [-1 5] / divisor=4,.,3;
```

E

displays the matrix coefficients. In the ODS output, the name of this "L Matrix Coefficients" table is Coef.

GROUP *coeffs*

sets up random-effect contrasts between different groups when a GROUP= variable appears in the RANDOM statement. By default, ESTIMATE statement coefficients about random effects are distributed equally across groups. You can enter a multiple-row estimate, but you can enter only one row for the GROUP coefficients. For example, the following ESTIMATE statement has a GROUP option with two sets of brackets; these two sets of brackets apply to each row of the estimate.

```
estimate 'Trt 1 vs 2 @ x=0.4' trt [1 1] [-1 2] | x [0.4 1],
         'Trt 1 vs 3 @ x=0.4' trt [1 1] [-1 3] | x [0.4 1],
         'Trt 1 vs 2 @ x=0.5' trt [1 1] [-1 2] | x [0.5 1],
         'Trt 1 vs 3 @ x=0.5' trt [1 1] [-1 3] | x [0.5 1] /
                              group [1 1] [-1 2];
```

If the GROUP effect has two levels and random effect 'x' has one level, then the specified coefficient 0.4 in the first contrast row is expanded across two levels of the GROUP effect weighted by the GROUP coefficients. The resulting coefficients are

```
0.4 -0.4
```

LOWER

LOWERTAILED

bases the *p*-value for the *t* test only on values less than the test statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

SINGULAR=*number*

tunes the estimability checking as documented for the SINGULAR= option in the CONTRAST statement.

SUBJECT *coeffs*

sets up random-effect estimates between different subjects when a SUBJECT= variable appears in the RANDOM statement. By default, ESTIMATE statement coefficients about random effects are distributed equally across subjects. The rules for listing subject coefficients for an ESTIMATE statement with multiple rows are the same as the rules for listing GROUP coefficients.

UPPER

UPPERTAILED

bases the *p*-value for the *t* test only on values greater than the test statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the data set. PROC LMIXED treats each observation as if it appears f times, where f is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If the frequency value is less than 1 or missing, the observation is not used in the analysis. When the FREQ statement is omitted, each observation is assigned a frequency of 1.

The analysis that you produce by using a FREQ statement reflects the expanded number of observations. For example, PROC LMIXED produces the same results for the following two data sets if variable count is used in the FREQ statement:

```
data one;
input p$ a$ b y count;
datalines;
P1 A1 1 8  2
P1 A1 2 10 1
P2 A2 1 7  3
P2 A1 2 8  2
P3 A1 1 12 2
P3 A2 2 9  1
P1 A2 1 7  3
P1 A2 2 8  2
```

```
P2 A2 1 7  3
P2 A2 2 9  2
;

data one;
input p$ a$ b y;
datalines;
P1 A1 1 8
P1 A1 1 8
P1 A1 2 10
P2 A2 1 7
P2 A2 1 7
P2 A2 1 7
P2 A1 2 8
P2 A1 2 8
P3 A1 1 12
P3 A1 1 12
P3 A2 2 9
P1 A2 1 7
P1 A2 1 7
P1 A2 1 7
P1 A2 2 8
P1 A2 2 8
P2 A2 1 7
P2 A2 1 7
P2 A2 1 7
P2 A2 2 9
P2 A2 2 9
;
```

LSMEANS Statement

LSMEANS *fixed-effects* < / *options* > **;**

The LSMEANS statement computes least squares means (LS-means) of classification fixed effects. As in the GLM procedure, LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as classification and subclassification arithmetic means are to balanced designs. The **L** matrix constructed to compute them is the same as the **L** matrix formed in PROC GLM; however, the standard errors are adjusted for the covariance parameters in the model.

Each LS-mean is computed as $\mathbf{L}'\widehat{\boldsymbol{\beta}}$, where $\mathbf{L}$ is the coefficient matrix associated with the least squares mean and $\widehat{\boldsymbol{\beta}}$ is the estimate of the fixed-effects parameter vector. The approximate standard errors for the LS-mean is computed as the square root of $\mathbf{L}'(\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-}\mathbf{L}$.

LS-means can be computed for any effect in the MODEL statement that involves CLASS variables. You can specify multiple effects in one LSMEANS statement or in multiple LSMEANS statements, and all LSMEANS statements must appear after the MODEL statement. As in the ESTIMATE statement, the **L** matrix is tested for estimability, and if this test fails, PROC LMIXED displays "Non-est" for the LS-means entries.

Assuming the LS-mean is estimable, PROC LMIXED constructs an approximate t test to test the null hypothesis that the associated population quantity equals zero. By default, the denominator degrees of freedom for this test are the residual degrees of freedom.

Table 17.6 summarizes the *options* available in the LSMEANS statement.

Table 17.6 LSMEANS Statement Options

Option	Description
ADJUST=	Determines the method of multiple comparison adjustment of LS-means differences
ALPHA=	Specifies the confidence level
AT=	Modifies covariate values in computing LS-means
CL	Constructs *t*-type confidence limits
CORR	Displays the estimated correlation matrix
COV	Displays the estimated covariance matrix
DF=	Specifies the degrees of freedom
DIFF	Displays the differences of the LS-means
E	Displays the matrix coefficients for LSMEANS effects
SINGULAR=	Tunes the estimability checking
SLICE=	Partitions interaction LSMEANS effects
STEPDOWN	Adjusts multiple comparison *p*-values further through a step-down adjustment process

You can specify the following *options* in the LSMEANS statement after a slash (/).

ADJUST=*method*
requests a multiple comparison adjustment for the *p*-values and confidence limits for the differences of LS-means. The adjusted quantities are produced along with the unadjusted quantities. The ADJUST= option works together with the DIFF option. If you omit the DIFF option, then the ADJUST= option implies the DIFF option except for ADJUST=T.

You can specify the following *methods* for the ADJUST= option:

BON performs Bonferroni *t* tests of differences between LS-means. The method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

DUNNETT performs Dunnett's *t* test, testing whether any treatments are significantly different from a single control for the effects in the LSMEANS statement. If the LS-means are correlated, PROC LMIXED uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment as "Dunnett-Hsu" in the results. The approximation derives approximate "effective sample sizes" for which exact critical values are computed.

NELSON performs Nelson's *t* test of each LS-mean against an average of the LS-means (Ott 1967; Nelson 1982, 1991, 1993). When the LS-means are correlated, PROC LMIXED uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment as "Nelson-Hsu" in the results. The approximation derives approximate "effective sample sizes" for which exact critical values are computed.

SCHEFFE performs Scheffé's multiple comparison procedure.

SIDAK performs pairwise t tests on differences between LS-means with levels adjusted according to Šidák's inequality. The method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

SIMULATE < (*simoptions*) > performs the simulation-based multiple comparison procedure. This method computes adjusted p-values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate t random vector. All covariance parameters, except the residual scale parameter, are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates q, the true $(1-\alpha)$ quantile, where $1-\alpha$ is the confidence coefficient. The default value of α is 0.05; you can change this value by specifying the ALPHA= option in the LSMEANS statement.

The number of samples is set so that the tail area for the simulated q is within γ of $1-\alpha$ with $100(1-\epsilon)\%$ confidence. In equation form,

$$\Pr(|F(\widehat{q}) - (1-\alpha)| \leq \gamma) = 1-\epsilon$$

where $\hat{q}$ is the simulated q and F is the true distribution function of the maximum; see Edwards and Berry (1987) for details. By default, $\gamma = 0.005$ and $\epsilon = 0.01$, placing the tail area of $\hat{q}$ within 0.005 of 0.95 with 99% confidence.

You can specify the following *simoptions* in parentheses after the ADJUST=SIMULATE option:

ACC=*value* specifies the target accuracy radius γ of a $100(1-\epsilon)\%$ confidence interval for the true probability content of the estimated $(1-\alpha)$ quantile. By default, ACC=0.005. Note that, if you also specify the CVADJUST *simoption*, then the actual accuracy radius will probably be substantially less than this target.

CVADJUST specifies that the quantile be estimated by the control variate adjustment method of Hsu and Nelson (1998) instead of simply as the quantile of the simulated sample. Specifying this option usually has the effect of significantly reducing the accuracy radius γ of a $100 \times (1-\epsilon)\%$ confidence interval for the true probability content of the estimated $(1-\alpha)$ quantile. The control-variate-adjusted quantile estimate takes approximately twice as long to compute, but it is typically much more accurate than the sample quantile.

EPS=*value* specifies the value ϵ for a $100 \times (1-\epsilon)\%$ confidence interval for the true probability content of the estimated $(1-\alpha)$ quantile. The default value of the accuracy confidence is 99%, corresponding to EPS=0.01.

NSAMP=*n* specifies the sample size for the simulation. By default, *n* is set by a formula that is based on the values of the target accuracy radius γ and accuracy confidence $100 \times (1-\epsilon)\%$ for an interval

for the true probability content of the estimated $(1-\alpha)$ quantile. When the default values are used for γ, ϵ, and α (0.005, 0.01, and 0.05, respectively), NSAMP=12605.

REPORT — specifies that a report on the simulation be displayed, including a listing of the parameters, such as γ, ϵ, and α, as well as an analysis of various methods of estimating or approximating the quantile.

SEED=*number* — specifies an integer to be used to start the pseudorandom number generator for the simulation. If you do not specify a seed, or if you specify a *number* less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

SMM | GT2 performs pairwise comparisons based on the studentized maximum modulus and Šidák's uncorrelated-*t* inequality, yielding Hochberg's GT2 method when sample sizes are unequal.

T | NONE performs no adjustment for multiple comparisons.

TUKEY performs Tukey's studentized range test on LS-means. When your data are unbalanced, PROC LMIXED uses the approximation described in Kramer (1956) and identifies the adjustment as "Tukey-Kramer" in the results.

By default, ADJUST=T | NONE.

If you specify ADJUST=DUNNETT, the procedure analyzes all differences with the first control level unless you have specified different control level. If you specify ADJUST=NELSON, then DIFF=ANOM is assumed.

If you specify ADJUST=TUKEY, then DIFF=ALL is assumed. If you specify other *methods*, then the procedure performs all pairwise differences unless you specify the DIFF option.

Note that computing the exact adjusted *p*-values and critical values for unbalanced designs can be computationally intensive, especially for ADJUST=NELSON.

ALPHA=*number*

requests that a *t*-type confidence interval be constructed for each of the LS-means with confidence level $1-$ *number*. The value of *number* must be between 0 and 1; the default is 0.05.

AT *at-specification*

enables you to modify the values of the covariates that are used in computing LS-means. By default, all covariates are set equal to their mean values for computing standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

You can specify the following *at-specifications*:

MEANS sets covariates equal to their mean values (as with standard LS-means) and applies this adjustment to crossproducts of covariates.

variable=*value* sets the covariate *variable* equal to *value*.

(*variable-list*)=(*value-list*) sets covariates in the *variable-list* equal to values in the *value-list*.

As an example, consider the following invocation of PROC LMIXED:

```
proc lmixed;
   class A B;
   model Y = A*B x1 x2 x1*x2;
   LSMEANS A*B;
   LSMEANS A*B / at means;
   LSMEANS A*B / at x1=1.2;
   LSMEANS A*B / at (x1 x2)=(1.2 0.3);
run;
```

For the first two LSMEANS statements, the LS-means coefficient of x1 is $\overline{x}_1$ (the mean of x1) and of x2 is $\overline{x}_2$ (the mean of x2). For the first LSMEANS statement, the coefficient of x1*x2 is $\overline{x_1 x_2}$. However, for the second LSMEANS statement, the coefficient is $\overline{x}_1 \times \overline{x}_2$. The third LSMEANS statement sets the coefficient of x1 equal to 1.2 and leaves it at $\overline{x}_2$ for x2, and the final LSMEANS statement sets these values to 1.2 and 0.3, respectively.

Even if you specify a WEIGHT variable, the unweighted covariate means are used for the covariate coefficients if you omit the AT option. If you specify the AT option, then WEIGHT or FREQ variables are taken into account as follows. The weighted covariate means are used for the covariate coefficients for which no explicit AT option values are given, or if you specify the AT MEANS option. Observations that do not contribute to the analysis because of a missing dependent variable are used in computing the covariate means. You should use the E option in conjunction with the AT option to verify that the modified LS-means coefficients are the ones that you want.

CL

requests that *t*-type confidence limits be constructed for each of the LS-means. If DDFM=NONE, then PROC LMIXED uses infinite degrees of freedom for this test, essentially computing a *z* interval. The confidence level is 0.95 by default; this can be changed with the ALPHA= option. If you specify an ADJUST= option, then the confidence limits are adjusted for multiplicity. If you also specify the STEPDOWN option, then only *p*-values, not the confidence limits, are step-down-adjusted.

CORR

displays the estimated correlation matrix of the least squares means as part of the "Least Squares Means" table.

COV

displays the estimated covariance matrix of the least squares means as part of the "Least Squares Means" table.

DF=*number*

specifies the degrees of freedom for the *t* test and confidence limits. The default is the residual degrees of freedom that you define by specifying the DDFM=RESIDUAL option.

DIFF<=*difftype***>**

PDIFF<=*difftype***>**

requests that differences of the LS-means be displayed. You can specify the following values for the optional *difftype*.

ALL requests all pairwise differences.

ANOM requests differences between each LS-mean and the average LS-mean, as in the analysis of means (Ott 1967). The average is computed as a weighted mean of the LS-means, with the weights being inversely proportional to the diagonal entries of the $\mathbf{L}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{L}'$ matrix. When a WEIGHT statement is specified, then the preceding matrix is replaced with $\mathbf{L}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{L}'$ where $\mathbf{W}$ is the diagonal matrix that contains the weights. If LS-means are nonestimable, this design-based weighted mean is replaced with an equally weighted mean. Note that the ANOM procedure in SAS/QC software implements both tables and graphics for the analysis of means with a variety of response types. For one-way designs and normally distributed data, the DIFF=ANOM computations are equivalent to the results of PROC ANOM.

CONTROL requests differences with a control; by default, the control is the first level of each of the specified LSMEANS effects. To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the CONTROL keyword. For example, if the effects A, B, and C are classification variables, each having two levels, 1 and 2, the following LSMEANS statement specifies the (1,2) level of A*B and the (2,1) level of B*C as controls:

```
lsmeans A*B B*C / diff=control('1' '2', '2' '1');
```

For multiple effects, the results depend upon the order of the list, and so you should check the output to make sure that the controls are correct.

CONTROL produces two-tailed tests and confidence limits.

CONTROLL requests one-tailed results and tests whether the noncontrol levels are significantly smaller than the control. The upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing.

CONTROLU requests one-tailed results and tests whether the noncontrol levels are significantly larger than the control. The upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

The differences of the LS-means are displayed in a table titled "Differences of Least Squares Means." The table name is "Diffs."

E

requests that the matrix coefficients for all LSMEANS effects be displayed. The name of this "Matrix Coefficients" table is "Coef."

PDIFF

is the same as the DIFF option. See the description of the DIFF option on page 891.

SINGULAR=*number*

tunes the estimability checking as documented for the SINGULAR= in the CONTRAST statement.

SLICE=*fixed-effect* | **(***fixed-effects***)**

SLICEBY=*fixed-effect* | **(***fixed-effects***)**

specifies effects by which to partition interaction LSMEANS effects. This can produce what are known as tests of simple effects (Winer 1971). For example, suppose that A*B is significant, and you want to test the effect of A for each level of B. The appropriate LSMEANS statement is

```
lsmeans A*B / slice=B;
```

This statement tests for the simple main effects of A for B, which are calculated by extracting the appropriate rows from the coefficient matrix for the A*B LS-means and by using them to form an *F* test.

The SLICE= option produces *F* tests that test the simultaneous equality of cell means at a fixed level of the slice effect (Schabenberger, Gregoire, and Kong 2000).

The SLICE= option produces a table titled "Tests of Effect Slices." The table name is "Slices."

STEPDOWN< (*step-down-options*) >
performs a further step-down adjustment to the multiple-comparison-adjusted *p*-values for differences of LS-means. Specifically, the ADJUST= option in the LSMEANS statement performs a multiple comparison adjustment for the *p*-values and confidence limits that are associated with differences of LS-means. When you specify the STEPDOWN option, PROC LMIXED applies an additional adjustment to these multiple-comparison-adjusted *p*-values. Step-down methods increase the power of multiple comparisons by taking advantage of the fact that a *p*-value will never be declared significant unless all smaller *p*-values are also declared significant.

You must specify the ADJUST= option when you specify the STEPDOWN option in the LSMEANS statement.

The STEPDOWN option affects only *p*-values, not confidence limits.

You can specify the following *step-down-options* in parentheses:

MAXTIME=*n*
specifies an upper limit of *n* seconds to compute the maximal logically consistent sequential subsets of equality hypotheses when you specify the TYPE=LOGICAL option. The default is 60 seconds. Step-down adjustments require substantial computation time when you have a large number of LS-means comparisons, such as all pairwise comparisons when the number of groups exceeds 10. In such cases, it is recommended that you use the TYPE=FREE or TYPE=LOGICAL(*n*) option with a small value of *n*.

REPORT
displays the report of the step-down adjustment, including a list of the sequential subsets (Westfall 1997). When you specify the STEPDOWN option along with the ADJUST=SIMULATE option, the report also includes the step-down simulation results.

TYPE=LOGICAL< (*n*) > | FREE
specifies the type of step-down adjustment method. By default, TYPE=FREE. You can specify the following method types:

TYPE=FREE performs step-down adjustments in which sequential subsets are computed without considering the logical constraints.

TYPE=LOGICAL(*n*) performs step-down adjustments on the basis of maximal logically consistent sequential subsets of equality hypotheses (Shaffer 1986; Westfall 1997). Because considering all logical constraints can be computationally intensive, you can limit the depth of the search tree by specifying a nonnegative integer *n*. If you omit *n* or if $n = -1$, the full search tree is used.

The TYPE=FREE option results are more conservative than the TYPE=LOGICAL option results, but they are generally more efficient in computing step-down adjustments when you have a large number of comparisons. For example, it is not feasible to take logical constraints between all pairwise comparisons when the number of groups exceeds 10. As with TYPE=FREE, results for TYPE=LOGICAL(*n*) are more conservative than the true TYPE=LOGICAL results, but even for TYPE=LOGICAL(0) they can be appreciably less conservative than the TYPE=FREE results, and they are computationally feasible for much larger numbers of comparisons.

When you specify the STEPDOWN option along with the ADJUST=BON option, the method of Holm (1979) is used if TYPE=FREE, and "Method 2" of Shaffer (1986) is used if TYPE=LOGICAL.

When you specify the STEPDOWN option along with the ADJUST=SIMULATE option, the method of Westfall (1997) is used, where the generalized least squares hybrid approach is used to increase Monte Carlo accuracy.

LSMESTIMATE Statement

LSMESTIMATE *fixed-effect* < '*label*' > *values* < *divisor*=*n* >
< , < '*label*' > *values* < *divisor*=*n* > > < , . . . >
< / *options* > ;

The LSMESTIMATE statement provides a mechanism for performing custom hypothesis tests among the least squares means (LS-means). In contrast to the hypotheses that are tested using the ESTIMATE or CONTRAST statement, the LSMESTIMATE statement enables you to form linear combinations of the LS-means rather than linear combination of fixed-effects parameter estimates and/or random-effects solutions. Multiple-row sets of coefficients are permitted.

Computing an LS-means estimate involves two coefficient matrices. Suppose that the *fixed-effect* has n_l levels. Then the LS-means are formed as $\mathbf{L}_1\widehat{\boldsymbol{\beta}}$, where $\mathbf{L}_1$ is an $(n_l \times p)$ coefficient matrix. The $(k \times n_l)$ coefficient matrix $\mathbf{K}$ is formed from the *values* that you supply in the k rows of the LSMESTIMATE statement. The LS-means estimates then represent the $(k \times 1)$ vector

$$\mathbf{K}\mathbf{L}_1\boldsymbol{\beta} = \mathbf{L}\boldsymbol{\beta}$$

You can use the ELSM option to display the coefficient matrix $\mathbf{K}$ and use the E option to display the coefficient matrix $\mathbf{L}$.

The LSMESTIMATE statement produces a t test for each row of coefficients that you specify. You can adjust p-values and confidence intervals for multiplicity by specifying the ADJUST= option. You can obtain an F test of single-row or multiple-row LS-means estimates by specifying the FTEST option.

Note that you specify only a single fixed effect in the LSMESTIMATE statement. The row labels are optional and follow the effects specification. For example, the following statements fit a split-plot design and compare the average of the third and fourth LS-mean of the whole-plot factor A to the first LS-mean of the factor:

```
proc lmixed;
   class a b block;
   model y = a b a*b /  s;
   random int a / sub=block;
   lsmestimate A 'a1 vs avg(a3,a4)' [2, 1] [-1, 3] [-1, 4] divisor=2;
```

```
run;
```

The order in which coefficients are assigned to the LS-means corresponds to the order in which they are displayed in the "Least Squares Means" table. You can use the ELSM option to see how coefficients are matched to levels of the *fixed-effect*.

The *DIVISOR=n* specification enables you to assign a separate divisor to each row of the LS-means estimate. You can also use the DIVISOR= option in this statement after a slash (/).

Table 17.7 summarizes the *options* available in the LSMESTIMATE statement.

Table 17.7 LSMESTIMATE Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values in computing LS-means
DIVISOR=	Specifies a list of values to divide the coefficients
SINGULAR=	Tunes the singular criterion for estimability checking
Tests, Adjustment, and *p*-Values	
ADJUST=	Determines the method of multiple comparison adjustment of LS-means estimate differences
ALPHA=α	Determines the confidence level $(1-\alpha)$
CHISQ	Requests a chi-square test in addition to the F test
DF=	Assigns a specific value to degrees of freedom for tests and confidence limits
FTEST	Produces an F test
LOWER	Performs one-sided, lower-tailed inference
UPPER	Performs one-sided, upper-tailed inference
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means estimates
COV	Displays the covariance matrix of LS-means estimates
E	Displays the **L** matrix
ELSM	Displays the **K** matrix

You can specify the following *options* in the LSMESTIMATE statement after a slash (/):

ADJUST=*method*

performs a multiple comparison adjustment for the p-values and confidence limits for the differences of LS-means estimates. The adjusted quantities are produced in addition to the unadjusted p-values and confidence limits. Adjusted confidence limits are produced if you specify the CL or ALPHA= option. For a description of the adjustments, see the ADJUST= option in the LSMEANS statement.

You can specify the following *methods*:

BON

performs Bonferroni t tests of differences between LS-means. The method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The

MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

SCHEFFE performs Scheffé's multiple comparison procedure.

SIDAK performs pairwise t tests on differences between LS-means with levels adjusted according to Šidák's inequality. The method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

SIMULATE<(*simoptions***)>** performs the simulation-based multiple comparison procedure. This method computes adjusted p-values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate t random vector. All covariance parameters, except the residual scale parameter, are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates q, the true $(1-\alpha)$ quantile, where $1-\alpha$ is the confidence coefficient. For a description of the *simoptions* (except for the CVADJUST option, which you cannot use in the MARGINS statement), see the ADJUST= option in the LSMEANS statement.

ALPHA=*number*

constructs a t-type confidence interval for each of the LS-means with confidence level 1 – *number*. The value of *number* must be between 0 and 1; the default is 0.05.

AT *at-specification*

enables you to modify the values of the covariates that are used in computing LS-means. By default, all covariate effects are set equal to their mean values for computing standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

You can specify the following *at-specifications*:

MEANS sets covariates equal to their mean values (as with standard LS-means) and applies this adjustment to crossproducts of covariates.

*variable***=***value* sets the covariate *variable* equal to *value*.

(*variable-list***)=(***value-list***)** sets covariates in the *variable-list* equal to values in the *value-list*.

As an example, consider the following invocation of PROC LMIXED:

```
proc lmixed;
   class A;
   model Y = A x1 x2 x1*x2;
   lsmestimate A 'a1 vs a2' [1, 1] [-1, 2];
   lsmestimate A 'a1 vs a2' [1, 1] [-1, 2] / at means;
   lsmestimate A 'a1 vs a2' [1, 1] [-1, 2] / at x1=1.2;
   lsmestimate A 'a1 vs a2' [1, 1] [-1, 2] / at (x1 x2)=(1.2 0.3);
run;
```

For the first two LSMESTIMATE statements, the LS-means coefficient of x1 is $\overline{x}_1$ (the mean of x1) and of x2 is $\overline{x}_2$ (the mean of x2). For the first LSMESTIMATE statement, the coefficient of x1*x2 is $\overline{x_1 x_2}$. However, for the second LSMESTIMATE statement, the coefficient is $\overline{x}_1 \times \overline{x}_2$. The third LSMESTIMATE statement sets the coefficient of x1 equal to 1.2 and leaves it at $\overline{x}_2$ for x2, and the final LSMESTIMATE statement sets these values to 1.2 and 0.3, respectively.

Even if you specify a WEIGHT variable, the unweighted covariate means are used for the covariate coefficients if you omit the AT option. If you specify the AT option, WEIGHT or FREQ variables are taken into account as follows. The weighted covariate means are used for the covariate coefficients for which no explicit AT option values are given, or if you specify the AT MEANS option. Observations that do not contribute to the analysis because of a missing dependent variable are used in computing the covariate means. You should use the E option in conjunction with the AT option to check that the modified LS-means coefficients are the ones that you want.

CHISQ
performs chi-square tests in addition to *F* tests, when you specify the FTEST option.

CL
constructs the *t*-type confidence limits for each of the LS-means. If DDFM=NONE, then PROC LMIXED uses infinite degrees of freedom for this test, essentially computing a *z* interval. The confidence level is 95% by default, corresponding to the default ALPHA=0.05 option. You can change this by specifying the ALPHA= option.

CORR
displays the estimated correlation matrix of the linear combination of the LS-means.

COV
displays the estimated covariance matrix of the linear combination of the LS-means.

DF=*number*
specifies the degrees of freedom for the *t* test and confidence limits. The default is the residual degrees of freedom that you define by specifying the DDFM=RESIDUAL option.

DIVISOR=*value-list*
specifies a list of values by which to divide the coefficients so that fractional coefficients can be entered as integer numerators. If you do not specify a *value-list*, a default value of 1.0 is assumed. Missing values in the *value-list* are converted to 1.0.

If the number of elements in the *value-list* exceeds the number of rows of the estimate, the extra values are ignored. If the number of elements in the *value-list* is less than the number of rows of the estimate, the last value in the *value-list* is carried forward.

If you specify a row-specific divisor as part of the specification of the estimate row, this value multiplies the corresponding value in the *value-list*. For example, the following statement divides the coefficients in the first row by 8 and the coefficients in the third and fourth rows by 3:

```
lsmestimate A 'One vs. two'   [8, 1] [-8, 2] divisor=2,
              'One vs. three' [1, 1] [-1, 3]          ,
              'One vs. four'  [3, 1] [-3, 4]          ,
              'One vs. five'  [3, 1] [-3, 5]           / divisor=4,.,3;
```

Coefficients in the second row are not altered.

E

displays the **L** coefficients of the estimable function. These are the coefficients that apply to the fixed-effects parameter estimates. The E option displays the coefficients that you would need to enter in an equivalent ESTIMATE statement.

ELSM

displays the **K** matrix coefficients. These are the coefficients that apply to the LS-means. This option is useful to ensure that you assigned the coefficients correctly to the LS-means.

FTEST

JOINT

produces an *F* test that jointly tests the rows of the LSMESTIMATE against zero. If you specify the LOWER or UPPER options, the LMIXED procedure computes a simulation-based *p*-value for the constrained joint test.

LOWER

LOWERTAILED

requests that the *p*-value for the *t* test be based only on values that are less than the test statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

Note that for ADJUST=SCHEFFE the one-sided adjusted confidence intervals and one-sided adjusted *p*-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the *F* distribution.

If you specify the FTEST option, then a one-sided left-tailed order restriction is applied to all estimable functions.

SINGULAR=*number*

tunes the singular criterion for estimability checking.

UPPER

UPPERTAILED

requests that the *p*-value for the *t* test be based only on values that are greater than the test statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the CL or ALPHA= option.

Note that for ADJUST=SCHEFFE the one-sided adjusted confidence intervals and one-sided adjusted *p*-values are the same as the corresponding two-sided statistics, because this adjustment is based on only the right tail of the *F* distribution.

If you specify the FTEST option, then a one-sided right-tailed order restriction is applied to all estimable functions.

MARGINS Statement

MARGINS *fixed-effects* < / *options* > **;**

The MARGINS statement computes predictive margins of fixed effects. You can compute predictive margins for any effect in the MODEL statement that involves only classification variables.

The predictive margin for a specific level (group) of a fixed effect represents the average predicted response if all the observations in the data set were in that group (Lane and Nelder 1982; Chang, Gelman, and Pagano 1982). You compute the predictive margin by fixing this effect at the specified level for all observations and averaging the predicted responses. The standard error of the predictive margin is computed by using the delta method. The weighted average predicted response is the weighted predictive margins.

For example, consider the simple regression $y_{ij} = \alpha_i + \beta x_{ij}$, where α_i is the effect of the ith level of the classification effect α, $i = 1, \ldots, R$, and x_{ij} is the covariate for the jth observation in the ith level of the effect α, $j = 1, \ldots, n_i$. Then the predictive margin for level r of effect α is

$$\frac{1}{N}\left(\sum_{i=1}^{R}\sum_{j=1}^{n_i}\hat{\alpha}_r + \hat{\beta}x_{ij}\right)$$

where $N = \sum_{i=1}^{R} n_i$.

For a more complex example, consider the following linear model with an interaction effect:

```
data mylib.bal;
input sex$ group rep y yname$;
cards;
boy    2    1   12  y1
boy    2    2    8  y2
boy    3    1   14  y3
boy    3    2    9  y4
girl   1    1   10  y5
girl   1    2   23  y6
girl   2    1   14  y7
girl   2    2   13  y8
girl   3    1   13  y9
girl   3    2   12  y10
;

proc lmixed data=mylib.bal;
   class sex group;
   model y = sex group sex*group;
   margins sex;
run;
```

The model fits the data that have ten observations: four of them are for the variable boy, and six of them are for the variable girl. Notice that group 1 has no data for boy. The predictive margin for boy is the average of the predicted values of these ten response variables, assuming that all responses are observed from boys. However, you cannot compute the predicted values for y5 and y6 for boy because y5 and y6 are in group 1, which is a group level that is absent from the data for boys. Thus, the predictive margin for boy is not predictable. This nonpredictability is caused by the lack of estimated parameters for boy interacting with group 1, which is due to the missing information in the interaction effect.

You can specify multiple effects in one or multiple MARGINS statements. Predictive margin computations are not supported for constructed effects.

PROC LMIXED constructs an approximate t test to determine whether the null hypothesis that the associated population quantity equals zero is valid. By default, the denominator degrees of freedom for this test are the same as those displayed for the effect in the "Type III Tests of Fixed Effects" table.

Table 17.8 summarizes the options available in the MARGINS statement. All these options are discussed in alphabetical order after the table.

Table 17.8 MARGINS Statement Options

Option	Description
Construction and Computation of Predictive Margins	
AT	Modifies the covariate value in computing predictive margins
DIFF	Computes differences of predictive margins
SLICEBY=	Partitions F tests
SLICEDIFF	Computes differences of sliced predictive margins and determines the types of differences
WEIGHT	Computes the weighted predictive margins
Degrees of Freedom and *p*-Values	
ADJUST=	Specifies the method of multiple comparison adjustment of predictive margin differences
ALPHA=α	Specifies the confidence level $(1 - \alpha)$
DF=	Assigns specific value to degrees of freedom for tests and confidence limits
Statistical Output	
CL	Constructs confidence limits for predictive margins and/or predictive margin differences

You can specify the following *options* in the MARGINS statement after a slash (/).

ADJUST=*method*

performs a multiple comparison adjustment of the p-values and confidence limits for the differences of predictive margins. The adjusted quantities are produced in addition to the unadjusted quantities. By default, PROC LMIXED performs all pairwise differences. If you specify ADJUST=DUNNETT, the procedure analyzes all differences with a control level. The ADJUST= option does not imply the DIFF option.

Adjusted confidence limits are produced if you specify the CL or ALPHA=α option. For a description of the adjustments, see the ADJUST= option in the LSMEANS statement.

You can specify the following *methods*:

BON performs Bonferroni t tests of differences between margins. This method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

DUNNETT performs Dunnett's *t* test, which determines whether any treatments are significantly different from a single control for the effects in the MARGINS statement.

SCHEFFE performs Scheffé's multiple comparison procedure.

SIDAK performs pairwise *t* tests on differences between LS-means with levels adjusted according to Šidák's inequality. This method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

SIMULATE<(*simoptions***)>** performs the simulation-based multiple comparison procedure. This method computes adjusted *p*-values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate *t* random vector. All covariance parameters, except the residual scale parameter, are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates q, the true $(1-\alpha)$ quantile, where $1-\alpha$ is the confidence coefficient. For a description of the *simoptions* (except for the CVADJUST option, which you cannot use in the MARGINS statement), see the ADJUST= option in the LSMEANS statement.

TUKEY performs Tukey's studentized range test on the predictive margins.

ALPHA=*number*

constructs a *t*-type confidence interval for each of the predictive margins with confidence level is $1-$ *number*. The value of *number* must be between 0 and 1, exclusive; by default, ALPHA=0.05.

AT *at-specification*

enables you to modify the values of the covariates that are used in computing predictive margins. By default, all covariate effects are set equal to their mean values for computing standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

You can specify the following *at-specifications*:

MEANS sets covariates equal to their mean values (as with standard LS-means) and applies this adjustment to crossproducts of covariates.

*variable***=***value* sets the covariate *variable* equal to *value*.

(*variable-list***)=(***value-list***)** sets covariates in the *variable-list* equal to values in the *value-list*.

As an example, consider the following invocation of PROC LMIXED:

```
proc lmixed;
   class A;
   model Y = A x1 x2 x1*x2;
   margins A;
   margins A / at means;
   margins A / at x1=1.2;
```

```
   margins A / at (x1 x2)=(1.2 0.3);
run;
```

The first MARGINS statement sets x1 and x2 to their observed values for each observation. For the second MARGINS statement, x1 is set to $\overline{x}_1$ (the mean of x1) and x2 is set to $\overline{x}_2$ (the mean of x2). Their interaction is set to $\overline{x}_1 \times \overline{x}_2$. The third MARGINS statement sets x1 to 1.2, and the final MARGINS statement sets these variables to 1.2 and 0.3, respectively.

Even if you specify a weight variable in the WEIGHT statement, the unweighted covariate means are used for the covariate coefficients if you omit the AT option. If you specify the AT option, the weight variable in the WEIGHT statement or the frequency variable in the FREQ statement is taken into account as follows. The weighted covariate means are used for the covariate coefficients for which no explicit AT option values are given, or if you specify the AT MEANS option. Observations that do not contribute to the analysis because of a missing dependent variable are used in computing the covariate means.

CL

constructs *t*-type confidence limits for each of the predictive margins. If DDFM=NONE, then PROC LMIXED uses infinite degrees of freedom for this test, essentially computing a z interval. The confidence level is 0.95 by default; you can change this by specifying the ALPHA=α option. If you specify an ADJUST= option, then the confidence limits are adjusted for multiplicity.

DF=*number*

specifies the degrees of freedom for the *t* test and confidence limits. The default is the denominator degrees of freedom from the "Type III Tests of Fixed Effects" table corresponding to the margins effect.

DIFF<=*difftype***>**

PDIFF<=*difftype***>**

displays differences of the predictive margins. The optional *difftype* specifies which differences to produce; the *difftype* values are ALL, CONTROL, CONTROLL, and CONTROLU. The ALL *difftype* displays all pairwise differences; it is the default. The CONTROL *difftype* displays differences between each margin and a control, which, by default, is the first level of each effect that you specify in the MARGINS statement.

To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the CONTROL keyword. For example, for the classification variables A, B, and C, each having two levels, 1 and 2, the following MARGINS statement specifies the (1,2) level of A*B and the (2,1) level of B*C as controls:

```
margins A*B B*C / diff=control('1' '2', '2' '1');
```

For an effect that has multiple classification variables, the quoted formatted values are assigned to these variables in the order in which they appear in the CLASS statement.

Two-tailed tests and confidence limits are associated with the CONTROL *difftype*. For one-tailed results, use either the CONTROLL or CONTROLU *difftype*. The CONTROLL *difftype* tests whether the noncontrol levels are significantly smaller than the control level; the upper confidence limits for the control level minus the noncontrol levels are considered to be infinity and are displayed as missing. Conversely, the CONTROLU *difftype* tests whether the noncontrol levels are significantly larger than

the control level; the upper confidence limits for the noncontrol levels minus the control level are considered to be infinity and are displayed as missing.

If you want to perform multiple comparison adjustments on the differences of predictive margins, you must specify the ADJUST= option.

SLICEBY=*fixed-effect* | **(***fixed-effects***)**

SLICE=*fixed-effect* | **(***fixed-effects***)**

specifies effects by which to partition interaction effects that you specify in the MARGINS statement. This option produces tests of margins for each level of the specified slice effect.

For example, suppose that the effect specified in the MARGINS statement is A*B. To test the margins of A*B for each level of A, you can specify the following statement:

```
margins A*B / sliceby=A;
```

The SLICEBY= option produces an F test that performs a test of the simultaneous equality of the margins at a fixed level of the slice effect A. You can compute differences of the margins while holding one or more factors at a fixed level by specifying the SLICEDIFF option.

SLICEDIFF< =*difftype* **>**

constructs the specified type of differences for the sliced margins and tests them against zero. The *difftype* values are ALL, CONTROL, CONTROLL, and CONTROLU. The ALL *difftype* computes all pairwise differences; it is the default. The CONTROL, CONTROLL, and CONTROLU *difftypes* compute the differences between each margin and a control. Whereas the SLICEBY= option tests the simultaneous equality of the margins at a fixed level of the slice effect, the SLICEDIFF option tests pairwise differences of these margins. This enables you to perform multiple comparisons among the levels of one factor at a fixed level of the other factor.

For example, assume that, in a certain design, factors A and B have $a = 4$ and $b = 3$ levels, respectively. Consider the following statements:

```
proc lmixed;
   class A B;
   model y = A B A*B;
   margins A*B / sliceby=A;
   margins A*B / sliceby=A slicediff=all;
run;
```

The first MARGINS statement produces four F tests, one per level of A. Denote the three margins that correspond to the first level of A as $\mathbf{m}_{a1}^{(1)}$, $\mathbf{m}_{a1}^{(2)}$, and $\mathbf{m}_{a1}^{(3)}$. Then the first F test determines whether the two-degrees-of-freedom hypothesis is valid:

$$H: \begin{cases} \mathbf{m}_{a1}^{(1)} - \mathbf{m}_{a1}^{(2)} = 0 \\ \mathbf{m}_{a1}^{(1)} - \mathbf{m}_{a1}^{(3)} = 0 \end{cases}$$

The SLICEDIFF option performs tests of the differences between all pairs of these three margins. In the example, this corresponds to tests of the following form:

$$H: \mathbf{m}_{a1}^{(1)} - \mathbf{m}_{a1}^{(2)} = 0$$
$$H: \mathbf{m}_{a1}^{(1)} - \mathbf{m}_{a1}^{(3)} = 0$$
$$H: \mathbf{m}_{a1}^{(2)} - \mathbf{m}_{a1}^{(3)} = 0$$

In the example, where $a = 4$ and $b = 3$, the second MARGINS statement produces four sets of predictive margin differences. Within each set, factor A is held fixed at a particular level, and each set consists of three comparisons.

For differences between each margin and a control, the default control is the first level of each effect that you specify in the MARGINS statement. To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the keyword CONTROL.

For example, if the effects A, B, and C are classification variables, each having three levels (1, 2, and 3), the following MARGINS statement specifies the (1,3) level of A*B as the control:

```
margins A*B / sliceby=(A B)
              slicediff=control('1' '3');
```

This MARGINS statement first produces predictive margin differences while holding the levels of A fixed, and then it produces predictive margin differences while holding the levels of B fixed. In the former case, level '3' of B serves as the control level. In the latter case, level '1' of A serves as the control.

For an effect that has multiple classification variables, the quoted formatted values are assigned to these variables in the order in which they appear in the CLASS statement.

Two-tailed tests and confidence limits are associated with the CONTROL *difftype*. For one-tailed results, use either the CONTROLL or CONTROLU *difftype*. The CONTROLL *difftype* tests whether the noncontrol levels are significantly smaller than the control level; the upper confidence limits for the control level minus the noncontrol levels are considered to be infinity and are displayed as missing. Conversely, the CONTROLU *difftype* tests whether the noncontrol levels are significantly larger than the control level; the upper confidence limits for the noncontrol levels minus the control level are considered to be infinity and are displayed as missing.

When you specify the ADJUST= option, the LMIXED procedure also adjusts the tests for multiplicity. The adjustment is based on the number of comparisons within each level of the SLICEBY= effect.

WEIGHT

computes the weighted predictive margins. The weight values are provided by the WEIGHT statement. By default, the unweighted predictive margins are computed even if you specify the WEIGHT statement.

MODEL Statement

MODEL *dependent* **=** < *fixed-effects* >< / *options* > **;**

The MODEL statement names a single dependent variable and the fixed effects, which determine the **X** matrix of the mixed model. The MODEL statement is required.

An intercept is included in the fixed-effects model by default. If no fixed effects are specified, only this intercept term is fit. You can remove the intercept by using the NOINT option. You cannot explicitly specify an intercept by using the keyword INTERCEPT as an effect in MODEL statement.

Table 17.9 summarizes options in the MODEL statement. These are subsequently discussed in detail in alphabetical order.

Table 17.9 Summary of Important MODEL Statement Options

Option	Description
Model Building	
NOINT	Excludes the fixed-effect intercept from the model
Statistical Computations	
ALPHA=α	Determines the confidence level $(1-\alpha)$ for fixed effects
DDF=	Specifies the denominator degrees of freedom
DDFM=	Specifies the method for computing the denominator degrees of freedom
Statistical Output	
CL	Displays confidence limits for fixed-effects parameter estimates
DENSESOL	Displays dense-type fixed-effects parameter estimates
SOLUTION	Displays fixed-effects parameter estimates

You can specify the following *options* in the MODEL statement after a slash (/):

ALPHA=α

sets the confidence level to be $1-\alpha$ for each confidence interval of the fixed-effects parameters, where α must be a number between 0 and 1. By default, ALPHA=0.05.

CL

constructs that t-type confidence limits for each of the fixed-effects parameter estimates. The confidence level is 0.95 by default; this can be changed by specifying the ALPHA= option.

DDF=*value-list*

enables you to specify your own denominator degrees of freedom for the fixed effects. The *value-list* is a list of numbers or missing values (.) separated by commas. The degrees of freedom should be listed in the order in which the effects appear in the MODEL statement. If you want to retain the default degrees of freedom for a particular effect, use a missing value for its location in the list. For example, the following statement assigns 3 denominator degrees of freedom to A and 4.7 to A*B, while those for B remain the same:

```
model Y = A B A*B / ddf=3,.,4.7;
```

DDFM=CONTAIN | NONE | RESIDUAL

specifies the method of computing the denominator degrees of freedom for the tests of fixed effects. You can specify the following methods:

CONTAIN invokes the *containment method* to compute denominator degrees of freedom (DDF). The containment method is carried out as follows: Denote the fixed effect in question A, and search the effect list that you specify in the RANDOM statement for the effects that *syntactically* contain A. For example, the random effect B(A) contains A, but the random effect C does not, even if it has the same levels as B(A).

Among the random effects that contain A, compute their rank contribution to the $(\mathbf{X}\ \mathbf{Z})$ matrix. The DDF that is assigned to A is the smallest of these rank contributions. If no effects are found, the DDF for A is set equal to the residual degrees of freedom, $N - \mathrm{rank}(\mathbf{X}\ \mathbf{Z})$. This choice of DDF matches the tests that are performed for balanced split-plot designs and should be adequate for moderately unbalanced designs.

The DDFM=CONTAIN option is supported only when DMMETHOD=DENSE.

CAUTION: If you have a $\mathbf{Z}$ matrix that contains a large number of columns, the overall memory requirements and the computing time after convergence can be substantial for the containment method. If they are too great, you might want to use the DDFM=RESIDUAL option instead.

NONE does not apply any denominator degrees of freedom. PROC LMIXED then essentially assumes that infinite degrees of freedom are available in the calculation of *p*-values. The *p*-values for *t* tests are then identical to *p*-values that are derived from the standard normal distribution.

RESIDUAL performs all tests by using the residual degrees of freedom, $n - \mathrm{rank}(\mathbf{X})$, where n is the number of observations that are used.

By default, DDFM=RESIDUAL.

DENSESOL

produces the solutions for the fixed-effects parameters that match the solutions when you specify DMMETHOD=DENSE in the PROC LMIXED statement. The DENSESOL option changes only the ODS table ParameterEstimates.

Note that this option consumes extra computer memory. The DENSESOL option is valid only when DMMETHOD=SPARSE. It is designed specifically for users who need a solution for the fixed-effects parameters to match the solutions when DMMETHOD=DENSE in the PROC LMIXED statement.

NOINT

requests that no intercept be included in the model. (An intercept is included by default.)

SOLUTION

S

produces a solution for the fixed-effects parameters. Using notation from the section "Linear Mixed Models Theory" on page 935, the fixed-effects parameter estimates are $\widehat{\boldsymbol{\beta}}$ and their approximate standard errors are the square roots of the diagonal elements of $(\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-}$.

Along with the estimates and their approximate standard errors, a t statistic is computed as the estimate divided by its standard error. The Pr > |t| column contains the two-tailed p-value that corresponds to the t statistic and associated degrees of freedom. You can use the CL option to request confidence intervals for all of the parameters; they are constructed around the estimate by using a radius that is the product of the standard error times a percentage point from the t distribution.

OPTIMIZATION Statement

OPTIMIZATION < *options* > **;**

The OPTIMIZATION statement specifies the technique and relevant specifications that are used in nonlinear optimization of REML and ML functions.

You can specify the following *options*. The effect of some *options* depends on the technique that is specified in the TECHNIQUE= option.

ABSCONV=*r*

specifies an absolute function convergence criterion. For minimization, termination requires $f(\boldsymbol{\psi}^{(k)}) \leq r$, where $\boldsymbol{\psi}$ is the vector of parameters in the optimization and $f(\cdot)$ is the objective function. The default value of r is the negative square root of the largest double-precision value, which serves only as a protection against overflows.

ABSFCONV=*r*

specifies an absolute function difference convergence criterion. For all techniques except Nelder-Mead simplex (TECHNIQUE=NMSIMP), termination requires a small change of the function value in successive iterations:

$$|f(\boldsymbol{\psi}^{(k-1)}) - f(\boldsymbol{\psi}^{(k)})| \leq r$$

Here, $\boldsymbol{\psi}$ denotes the vector of parameters that participate in the optimization and $f(\cdot)$ is the objective function. The same formula is used for the Nelder-Mead simplex technique, but $\boldsymbol{\psi}^{(k)}$ is defined as the vertex that has the lowest function value and $\boldsymbol{\psi}^{(k-1)}$ is defined as the vertex that has the highest function value in the simplex. By default, ABSFCONV=0.

ABSGCONV=*r*

specifies an absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\boldsymbol{\psi}^{(k)})| \leq r$$

Here, $\boldsymbol{\psi}$ denotes the vector of parameters that participate in the optimization and $g_j(\cdot)$ is the gradient of the objective function with respect to the j parameter. This criterion is not used by the Nelder-Mead simplex technique. By default, ABSGCONV=1E–5.

FCONV=*r*

specifies a relative function convergence criterion. For all techniques except the Nelder-Mead simplex technique, termination requires a small relative change of the function value in successive iterations:

$$\frac{|f(\boldsymbol{\psi}^{(k)}) - f(\boldsymbol{\psi}^{(k-1)})|}{|f(\boldsymbol{\psi}^{(k-1)})|} \leq r$$

Here, $\boldsymbol{\psi}$ denotes the vector of parameters that participate in the optimization and $f(\cdot)$ is the objective function. The same formula is used for the Nelder-Mead simplex technique, but $\boldsymbol{\psi}^{(k)}$ is defined as the vertex that has the lowest function value and $\boldsymbol{\psi}^{(k-1)}$ is defined as the vertex that has the highest function value in the simplex.

The default is $r = 10^{-\mathrm{FDIGITS}}$, where FDIGITS is $-\log_{10}(\epsilon)$ and ϵ is the machine precision.

FCONV2=*r*

specifies a second function convergence criterion. For all techniques except the Nelder-Mead simplex technique, termination requires a small predicted reduction of the objective function:

$$df^{(k)} \approx f(\boldsymbol{\beta}^{(k)}) - f(\boldsymbol{\beta}^{(k)} + \mathbf{s}^{(k)})$$

The predicted reduction

$$\begin{aligned} df^{(k)} &= -\mathbf{g}^{(k)\prime}\mathbf{s}^{(k)} - \frac{1}{2}\mathbf{s}^{(k)\prime}\mathbf{H}^{(k)}\mathbf{s}^{(k)} \\ &= -\frac{1}{2}\mathbf{s}^{(k)\prime}\mathbf{g}^{(k)} \leq r \end{aligned}$$

is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step,

$$\mathbf{s}^{(k)} = -[\mathbf{H}^{(k)}]^{-1}\mathbf{g}^{(k)}$$

For the Nelder-Mead simplex technique, termination requires a small standard deviation of the function values of the $p + 1$ simplex vertices $\boldsymbol{\beta}_l^{(k)}$, $l = 0, \ldots, p$,

$$\sqrt{\frac{1}{n+1}\sum_l \left[f(\boldsymbol{\beta}_l^{(k)}) - \overline{f}(\boldsymbol{\beta}^{(k)})\right]^2} \leq r$$

where $\overline{f}(\boldsymbol{\beta}^{(k)}) = \frac{1}{p+1}\sum_l f(\boldsymbol{\beta}_l^{(k)})$. If there are p_{act} boundary constraints active at $\boldsymbol{\beta}^{(k)}$, the mean and standard deviation are computed only for the $n + 1 - p_{act}$ unconstrained vertices.

The default value is *r* = 1E–6 for the Nelder-Mead simplex technique and *r*= 0 otherwise.

GCONV=*r*

specifies a relative gradient convergence criterion. For all techniques except the conjugate-gradient technique and the Nelder-Mead simplex technique, termination requires that the normalized predicted function reduction be small,

$$\frac{\mathbf{g}(\boldsymbol{\psi}^{(k)})'[\mathbf{H}^{(k)}]^{-1}\mathbf{g}(\boldsymbol{\psi}^{(k)})}{|f(\boldsymbol{\psi}^{(k)})|} \leq r$$

Here, $\boldsymbol{\psi}$ denotes the vector of parameters that participate in the optimization, $f(\cdot)$ is the objective function, and $\mathbf{g}(\cdot)$ is the gradient. For the conjugate-gradient technique (where a reliable Hessian estimate $\mathbf{H}$ is not available), the following criterion is used:

$$\frac{\| \mathrm{g}(\boldsymbol{\psi}^{(k)}) \|_2^2 \quad \| \mathrm{s}(\boldsymbol{\psi}^{(k)}) \|_2}{\| \mathrm{g}(\boldsymbol{\psi}^{(k)}) - \mathrm{g}(\boldsymbol{\psi}^{(k-1)}) \|_2 \, |f(\boldsymbol{\psi}^{(k)})|} \leq r$$

This criterion is not used by the Nelder-Mead simplex technique. The default value is *r*=1E–8.

GCONV2=*r*

specifies another relative gradient convergence criterion. For Newton-Raphson with ridging and Newton-Raphson techniques, the following criterion of Browne (1982) is used:

$$\max_j \frac{|\mathrm{g}_j(\boldsymbol{\beta}^{(k)})|}{\sqrt{f(\boldsymbol{\beta}^{(k)})\mathbf{H}^{(k)}_{j,j}}} \leq r$$

This criterion is not used by the other techniques. By default, GCONV2=0.

HESSTYPE=BFGS | FDFULL | FULL

specifies the type of Hessian to use in the optimization. You can specify the following values:

BFGS uses the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) approximation of the inverse Hessian matrix.

FDFULL uses the finite-difference Hessian.

FULL uses the exact Hessian or average information Hessian, assuming that it is available.

The default value is HESSTYPE=BFGS when there is no Hessian function available in the optimization.

This option is supported only when TECHNIQUE=ACTIVESET or IPDIRECT.

MAXFUNC=*n*

specifies the maximum number *n* of function calls in the optimization process. The optimization can terminate only after completing a full iteration. Therefore, the number of function calls that are performed can exceed *n*. The default values are as follows, depending on the optimization technique:

- When TECHNIQUE=TRUREG, NRRIDG, or NEWRAP, MAXFUNC=123 by default.
- When TECHNIQUE=QUANEW or DBLDOG, MAXFUNC=500 by default.
- When TECHNIQUE=CONGRA, MAXFUNC=1,000 by default.
- When TECHNIQUE=LBFGS, MAXFUNC=2,000 by default.
- When TECHNIQUE=NMSIMP, MAXFUNC=3,000 by default.

MAXITER=*n*

specifies the maximum number *n* of iterations in the optimization process. These default values also apply when *n* is specified as a missing value. The default values are as follows, depending on the optimization technique:

- When TECHNIQUE=TRUREG, NRRIDG, or NEWRAP, MAXITER=50 by default.
- When TECHNIQUE=QUANEW or DBLDOG, MAXITER=200 by default.
- When TECHNIQUE=CONGRA, MAXITER=400 by default.
- When TECHNIQUE=LBFGS or NMSIMP, MAXITER=1,000 by default.

MAXTIME=*r*

specifies an upper limit of *r* seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. The time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual run time can be longer than *r*.

MINITER=*n*

specifies the minimum number of iterations. The default value is 0. If you request more iterations than are needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

OPTTOL=*r*

specifies the criterion value by which the current iterate is determined to be an acceptable approximation of a local optimum, where *r* is a positive real number. Specifically, the optimizer determines that the current iterate is a local optimum when the norm of the scaled vector of the optimality conditions is less than *r*. By default, OPTTOL=1E–5.

This option is relevant only when you specify TECHNIQUE=ACTIVESET or IPDIRECT.

TECHNIQUE=*keyword*

TECH=*keyword*

specifies the optimization technique for obtaining restricted maximum likelihood estimation (REML) or maximum likelihood estimation (ML). There is no algorithm for optimizing general nonlinear functions that always finds the global optimum for a general nonlinear optimization problem in a reasonable amount of time. Because no single optimization technique is always superior to others, PROC LMIXED provides a variety of optimization techniques that work well in various circumstances.

For more information about traditional techniques such as Newton-Raphson optimization, see the section "Optimization Options" on page 57 in the chapter "Shared Concepts" of *SAS Visual Statistics: Procedures*.

For more information about modern techniques such as active-set and interior-point direct optimization, see the chapter "The Nonlinear Programming Solver" in *SAS/OR User's Guide: Mathematical Programming*.

You can specify the following *keywords*:

ACTIVESET | AS performs an active-set optimization.

CONGRA performs a conjugate-gradient optimization.

DBLDOG performs a version of double-dogleg optimization.

IPDIRECT | IP performs an interior-point direct optimization.

LBFGS performs a limited-memory BFGS optimization.

NEWRAP performs a Newton-Raphson optimization that combines a line-search algorithm with ridging.

NMSIMP performs a Nelder-Mead simplex optimization.

NONE performs no optimization.

NRRIDG performs a Newton-Raphson optimization with ridging.

QUANEW performs a dual quasi-Newton optimization.

TRUREG performs a trust-region optimization.

By default, TECHNIQUE=NRRIDG when DMMETHOD=DENSE. Otherwise, TECHNIQUE=QUANEW by default.

XCONV=*r*

specifies the relative parameter convergence criterion, which depends on the technique that is specified in the TECHNIQUE= option as follows:

- For all techniques except the Nelder-Mead simplex technique, termination requires a small relative parameter change in subsequent iterations:

$$\frac{\max_j |\psi_j^{(k)} - \psi_j^{(k-1)}|}{\max(|\psi_j^{(k)}|, |\psi_j^{(k-1)}|)} \leq r$$

- For the Nelder-Mead simplex technique, the same formula is used, but $\psi_j^{(k)}$ is defined as the vertex that has the lowest function value and $\psi_j^{(k-1)}$ is defined as the vertex that has the highest function value in the simplex.

The default value is r = 1E–8 for the NMSIMP technique and r = 0 otherwise.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < *=name* > >. . . < *keyword* < *=name* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics, which are computed after the model is fitted. The variables in the input data table are *not* included in the output data table in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option are included.

The output statistics are computed on the basis of the parameter estimates. By default, the predicted values are computed for observations that have missing response values. You can use the OUTPUT statement to obtain the predicted values for new observations.

You must specify the following option:

OUT=*libref.data-table*

names the output data table for PROC LMIXED to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 864.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

ALLSTATS
ALLSTAT
adds all available statistics to the output data table.

ALPHA=*number*
specifies the significance level for the construction of confidence intervals in the output data table. The confidence level is $1 - $ *number*, where *number* must be between 0 and 1. By default, *number* is equal to the value of the ALPHA= option in the MODEL statement, or 0.05 if that option is not specified.

COPYVAR=*variable*
COPYVARS=(*variables***)**
copies one or more *variables* from the input data table to the output data table.

keyword **<=***name***>**
specifies the statistics to include in the output data table and optionally names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign and a variable to contain the statistic.

If you specify *keyword=name*, the new variable that contains the requested statistic has the specified *name*. If you omit the optional *=name* after a *keyword*, then a default name is used.

You can specify the following values for *keyword* to request statistics:

Table 17.10 Keywords for Output Statistics

Keyword	Description	Expression
PRED	Linear predictor	$\widehat{\eta} = \mathbf{x}'\widehat{\boldsymbol{\beta}} + \mathbf{z}'\widehat{\boldsymbol{\gamma}}$
PREDPA	Marginal linear predictor	$\widehat{\eta}_m = \mathbf{x}'\widehat{\boldsymbol{\beta}}$
STDERR	Standard error of linear predictor	$\sqrt{\mathrm{Var}[\widehat{\eta} - \mathbf{z}'\boldsymbol{\gamma}]}$
STDERRPA	Standard error of marginal linear predictor	$\sqrt{\mathrm{Var}[\widehat{\eta}_m]}$
RESIDUAL	Residual	$r = y - \widehat{\eta}$
RESIDUALPA	Marginal residual	$r_m = y - \widehat{\eta}_m$
PEARSON	Pearson-type residual	$r/\sqrt{\widehat{\mathrm{Var}}[y\|\boldsymbol{\gamma}]}$
PEARSONPA	Marginal Pearson-type residual	$r_m/\sqrt{\widehat{\mathrm{Var}}[y]}$
STUDENT	Studentized residual	$r/\sqrt{\widehat{\mathrm{Var}}[r]}$
STUDENTPA	Studentized marginal residual	$r_m/\sqrt{\widehat{\mathrm{Var}}[r_m]}$
LCL	Lower prediction limit for linear predictor	
LCLPA	Lower confidence limit for marginal linear predictor	
UCL	Upper prediction limit for linear predictor	
UCLPA	Upper confidence limit for marginal linear predictor	
VARIANCE	Conditional variance of response variable	$\widehat{\mathrm{Var}}[y\|\boldsymbol{\gamma}]$
VARIANCEPA	Marginal variance of response variable	$\widehat{\mathrm{Var}}[y]$

PARMS Statement

PARMS < *(value-list)...* > < / *options* > **;**

The PARMS statement specifies initial values for the covariance parameters, or it requests a grid search over several values of these parameters. You must specify the values in the order in which they appear in the "Covariance Parameter Estimates" table.

When there is a BLUP statement, the PARMS statement is required and the specified values are not the initial values. They are the fixed covariance parameter values that are used in computing the best linear unbiased prediction (BLUP).

The *value-list* specification can take any of several forms:

m	a single value
$m_1, m_2, \ldots, m_n$	several values
m to n	a sequence in which m equals the starting value, n equals the ending value, and the increment equals 1
m to n by i	a sequence in which m equals the starting value, n equals the ending value, and the increment equals i
m_1, m_2 to m_3	mixed values and sequences

Suppose that a model has three covariance parameters that have known values of 2, 1, and 3. You can fix the variance components at these values by using the following statement:

```
parms (2) (1) (3) /hold;
```

The NOPROFILE option in the PROC LMIXED statement suppresses profiling of the residual variance parameter during its calculations, thereby enabling its value to be held at 3 as specified in the PARMS statement.

You can use the PARMS statement to input known parameters.

If you specify more than one set of initial values, the LMIXED procedure performs a grid search of the likelihood surface and uses the best point on the grid for subsequent analysis. Specifying a large number of grid points can result in long computing times.

The results from the PARMS statement are the values of the parameters on the specified grid (denoted by CovP1 through CovP*n*), the residual variance (possibly estimated) for models that have a residual variance parameter, and various functions of the likelihood.

If you specifies multiple PARMS statements, the LMIXED procedure uses the first one and ignores the rest.

You can specify the following *options* in the PARMS statement after a slash (/):

HOLD< =*order-list* **>**

EQCONS< =*order-list* **>**

HOLD< =ALL >

EQCONS< =ALL >

holds the values of the covariance parameters whose order is specified in the *order-list* to the initial values that are specified in the *value-list* in the RANDOM statement.

For example, the following statement constrains the first and third covariance parameters to equal 5 and 2, respectively:

```
parms (5) (3) (2) (3) / hold=1,3;
```

If you specify ALL or you do not specify *order-list*, then all covariance parameters are held to their initial values. When not all parameters are held to their initial values, this is referred to as partial holding.

Specifying the HOLD= option implies the specification of NOPROFILE option in the PROC LMIXED statement.

The partial holding cannot retain the values exactly for the TYPE=UN covariance structure. This is because the underlining structure is TYPE=CHOL in the optimization for covariance parameter estimation.

LOWERB=*value-list*

specifies the lower boundary constraints on the covariance parameters, where *value-list* is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that the LMIXED procedure uses for the covariance parameters, and each number corresponds to a lower boundary constraint. A missing value instructs the LMIXED procedure to use its default constraint. If you do not specify numbers for all the covariance parameters, the LMIXED procedure assumes that the remaining ones are missing.

This option is useful when you want to constrain the $\mathbf{G}$ matrix to be positive definite in order to avoid the more computationally intensive algorithms that would be required when $\mathbf{G}$ becomes singular. The corresponding statements for a random coefficients model are as follows:

```
proc lmixed;
   class person;
   model y = time;
   random int time / type=fa0(2) sub=person;
   parms / lowerb=1e-4,.,1e-4;
run;
```

The TYPE=FA0(2) structure specifies a Cholesky root parameterization for the 2×2 unstructured blocks in $\mathbf{G}$. This parameterization ensures that the $\mathbf{G}$ matrix is nonnegative definite, and the PARMS statement then ensures that it is positive definite by constraining the two diagonal terms to be greater than or equal to 1E–4.

NOITER

requests that no optimization iterations be performed and that the LMIXED procedure use the best value from the grid search to perform inferences.

PARMSDATA=*libref.data-table*

PDATA=*libref.data-table*

reads in covariance parameter values from a data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 864.

The data table should contain either the numerical variables Estimate and RowId or the numerical variables Covp1–Covp*q*, where *q* denotes the number of covariance parameters.

If the data table contains the numerical variables Covp1–Covp*q* and it contains multiple sets of values for covariance parameters, then the LMIXED procedure evaluates the initial objective function for each set of values and commences the optimization step by using the set that has the lowest functional value as the starting values. For example, the following statements request that the objective function be evaluated for three sets of initial values:

```
data mylib.data_covp;
   input covp1-covp4;
   datalines;
180 200 170 1000
170 190 160  900
160 180 150  800
;
proc lmixed;
   class A B C rep;
   model yield = A;
   random rep B C;
   parms / pdata=mylib.data_covp;
run;
```

Another way of specifying the initial values for the covariance parameters is to use the numerical variables Estimate and RowId in the data table. The values in RowId variable indicate the order of the covariance parameters in the "Covariance Parameter Estimates" table.

```
data mylib.covparm;
   input rowid estimate;
   datalines;
1  180
2  200
3  170
4  1000
;
```

A BY variable is not supported in the PARMSDATA= data table. The data table is processed in its entirety for every BY group and a message is written to the log. The same set of starting values is used by all BY groups.

```
data mylib.data_covp;
   input covp1-covp4;
   datalines;
180 200 170 1000
;
proc lmixed;
   class A B C rep;
   model yield = A;
   random rep B C;
   parms / pdata=mylib.data_covp;
```

```
   by year;
run;
```

UPPERB=*value-list*

specifies upper boundary constraints on the covariance parameters, where the *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that the LMIXED procedure uses for the covariance parameters, and each number corresponds to the upper boundary constraint. A missing value instructs the LMIXED procedure to use its default constraint. If you do not specify numbers for all of the covariance parameters, the LMIXED procedure assumes that the remaining ones are missing.

RANDOM Statement

RANDOM *random-effects* < / *options* > **;**

The RANDOM statement defines the random effects that constitute the $\boldsymbol{\gamma}$ vector in the mixed model. You can use this statement to specify traditional variance component models and to specify random coefficients. The random effects can be classification or continuous, and multiple RANDOM statements are allowed.

Using notation from the section "Linear Mixed Models Theory" on page 935, the purpose of the RANDOM statement is to define the $\mathbf{Z}$ matrix of the mixed model, the random effects in the $\boldsymbol{\gamma}$ vector, and the structure of $\mathbf{G}$. The $\mathbf{Z}$ matrix is constructed exactly as the $\mathbf{X}$ matrix for the fixed effects is constructed, and the $\mathbf{G}$ matrix is constructed to correspond with the effects that constitute $\mathbf{Z}$. The structure of $\mathbf{G}$ is defined by using the TYPE= option.

You can specify INTERCEPT (or INT) as a random effect to indicate the intercept. The LMIXED procedure does not include the intercept in the RANDOM statement by default as it does in the MODEL statement.

Table 17.11 summarizes the important options in the RANDOM statement. All options are subsequently discussed in alphabetical order.

Table 17.11 Summary of Important RANDOM Statement Options

Option	Description
Construction of Covariance Structure	
GROUP=	Defines an effect that specifies the covariance structure of groups
SUBJECT=	Identifies the subjects in the model
TYPE=	Specifies the covariance structure
Statistical Output	
ALPHA=α	Determines the confidence level $(1-\alpha)$
CL	Requests confidence limits for predictors of random effects
SOLUTION	Displays solutions $\widehat{\boldsymbol{\gamma}}$ of the random effects

You can specify the following *options* in the RANDOM statement after a slash (/):

ALPHA=*α*

sets the confidence level to be $1-\alpha$ for each confidence interval of the random-effects estimates, where α must be a number between 0 and 1. By default, ALPHA=0.05.

CL

constructs *t*-type confidence limits for each of the random-effect estimates. The confidence level is 0.95 by default; this can be changed with the ALPHA= option.

GROUP=*effect*

defines an effect that specifies heterogeneity in the covariance structure of $\mathbf{G}$. All observations that have the same level of the group effect have the same covariance parameters. Each new level of the group effect produces a new set of covariance parameters that has the same structure as the original group. You should exercise caution in defining the group effect, because strange covariance patterns can result from its misuse. Also, the group effect can greatly increase the number of estimated covariance parameters, which can impede the optimization process.

The group *effect* must consist of CLASS variables only.

SOLUTION

S

produces the solution for the random-effects parameters. Using notation from the section "Linear Mixed Models Theory" on page 935, these estimates are the empirical best linear unbiased predictors (EBLUPs), $\widehat{\boldsymbol{\gamma}} = \widehat{\mathbf{G}}\mathbf{Z}'\widehat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X}\widehat{\boldsymbol{\beta}})$. They can be useful for comparing the random effects from different experimental units and can also be treated as residuals in performing diagnostics for your mixed model.

The numbers displayed in the SE Pred column of the "Solution for Random Effects" table are not the standard errors of the $\widehat{\boldsymbol{\gamma}}$ that are displayed in the Estimate column; rather, they are the standard errors of predictions $\widehat{\boldsymbol{\gamma}}_i - \boldsymbol{\gamma}_i$, where $\widehat{\boldsymbol{\gamma}}_i$ is the *i*th EBLUP and $\boldsymbol{\gamma}_i$ is the *i*th random-effect parameter.

SUBJECT=*effect*

SUB=*effect*

identifies the subjects in your mixed model. Complete independence is assumed across subjects; thus, the SUBJECT= option produces a block-diagonal structure in $\mathbf{G}$ that has identical blocks. In fact, specifying an *effect* is equivalent to nesting all other effects in the RANDOM statement within the *effect*.

TYPE=*covariance-structure*

specifies the covariance structure of $\mathbf{G}$. Valid values for *covariance-structure* and their descriptions are listed in Table 17.12. Although a variety of structures are available, most applications call for either TYPE=VC or TYPE=UN.

By default, TYPE=VC (a structure that contains variance components), which models a different variance component for each random effect. The TYPE=UN (unstructured) option is useful for correlated random coefficient models. For example, the following statement specifies a random intercept-slope model that has different variances for the intercept and slope and a covariance between them:

```
random intercept age / type=un subject=student;
```

You can also use TYPE=FA0(2) to request a **G** estimate that is constrained to be nonnegative definite.

If you are constructing your own columns of **Z** by using continuous variables, you can use the TYPE=TOEP(1) structure to group them together to have a common variance component. If you want to have different covariance structures in different parts of **G**, you must use multiple RANDOM statements with different TYPE= options.

In Table 17.12, the Parameters column represents the number of covariance parameters in the structure, t is the overall dimension of the covariance matrix, and $1(A)$ equals 1 when A is true and 0 otherwise. For example, $1(i = j)$ equals 1 when $i = j$ and 0 otherwise, and $1(|i - j| < q)$ equals 1 when $|i - j| < q$ and 0 otherwise. For the TYPE=TOEPH structures, $\rho_0 = 1$; for the TYPE=UNR structures, $\rho_{ii} = 1$ for all i.

Table 17.12 Covariance Structures

Structure	Description	Parameters	(i, j) element
ANTE(1)	Antedependence	$2t - 1$	$\sigma_i \sigma_j \prod_{k=i}^{j-1} \rho_k$
AR(1)	Autoregressive(1)	2	$\sigma^2 \rho^{\lvert i-j \rvert}$
ARH(1)	Heterogeneous AR(1)	$t + 1$	$\sigma_i \sigma_j \rho^{\lvert i-j \rvert}$
ARMA(1,1)	Autoregressive moving average(1,1)	3	$\sigma^2[\gamma \rho^{\lvert i-j \rvert - 1} 1(i \neq j) + 1(i = j)]$
CHOL	Cholesky root	$t(t + 1)/2$	l_{ij}
CS	Compound symmetry	2	$\sigma_1 + \sigma^2 1(i = j)$
CSH	Heterogeneous compound symmetry	$t + 1$	$\sigma_i \sigma_j [\rho 1(i \neq j) + 1(i = j)]$
FA(q)	Factor analytic (FA)	$\frac{q}{2}(2t - q + 1) + t$	$\Sigma_{k=1}^{\min(i,j,q)} \lambda_{ik} \lambda_{jk} + \sigma_i^2 1(i = j)$
FA0(q)	No diagonal FA	$\frac{q}{2}(2t - q + 1)$	$\Sigma_{k=1}^{\min(i,j,q)} \lambda_{ik} \lambda_{jk}$
FA1(q)	Equal diagonal FA	$\frac{q}{2}(2t - q + 1) + 1$	$\Sigma_{k=1}^{\min(i,j,q)} \lambda_{ik} \lambda_{jk} + \sigma^2 1(i = j)$
HF	Huynh-Feldt	$t + 1$	$(\sigma_i^2 + \sigma_j^2)/2 + \lambda 1(i \neq j)$
SIMPLE	An alias for VC	q	$\sigma_k^2 1(i = j)$ for the kth effect
TOEP	Toeplitz	t	$\sigma_{\lvert i-j \rvert + 1}$
TOEP(q)	Banded Toeplitz (TOEP)	q	$\sigma_{\lvert i-j \rvert + 1} 1(\lvert i - j \rvert < q)$
TOEPH	Heterogeneous TOEP	$2t - 1$	$\sigma_i \sigma_j \rho_{\lvert i-j \rvert}$
TOEPH(q)	Banded heterogeneous TOEP	$t + q - 1$	$\sigma_i \sigma_j \rho_{\lvert i-j \rvert} 1(\lvert i - j \rvert < q)$
UC	Uniform correlation (UC)	2	$\sigma^2[\rho 1(i \neq j) + 1(i = j)]$
UCH	Heterogeneous UC	$t + 1$	$\sigma_i \sigma_j [\rho 1(i \neq j) + 1(i = j)]$
UN	Unstructured	$t(t + 1)/2$	σ_{ij}
UN(q)	Banded	$\frac{q}{2}(2t - q + 1)$	$\sigma_{ij} 1(\lvert i - j \rvert < q)$
UNR	Unstructured correlation	$t(t + 1)/2$	$\sigma_i \sigma_j \rho_{\max(i,j) \min(i,j)}$
VC	Variance components	q	$\sigma_k^2 1(i = j)$ for the kth effect

Table 17.13 lists the covariance types and applicable computing methods (sparse or dense) for each covariance type.

Table 17.13 Covariance Structures

Structure	Description	DMMETHOD=
ANTE(1)	Antedependence	DENSE
AR(1)	Autoregressive(1)	DENSE or SPARSE
ARH(1)	Heterogeneous AR(1)	DENSE
ARMA(1,1)	Autoregressive moving average(1,1)	DENSE
CHOL	Cholesky root	SPARSE
CS	Compound symmetry	DENSE or SPARSE
CSH	Heterogeneous compound symmetry	DENSE or SPARSE
FA(q)	Factor analytic (FA)	DENSE
FA0(q)	No diagonal FA	DENSE
FA1(q)	Equal diagonal FA	DENSE
HF	Huynh-Feldt	DENSE
SIMPLE	An alias for VC	DENSE or SPARSE
TOEP(1)	Toeplitz	DENSE or SPARSE
TOEP(q)	Banded Toeplitz (TOEP)	DENSE
TOEPH	Heterogeneous TOEP	DENSE
TOEPH(q)	Banded heterogeneous TOEP	DENSE
UC	Uniform correlation (UC)	SPARSE
UCH	Heterogeneous UC	SPARSE
UN	Unstructured	DENSE or SPARSE
UN(q)	Banded	DENSE
UNR	Unstructured correlation	DENSE
VC	Variance components	DENSE or SPARSE

Table 17.14 lists some examples of the structures in Table 17.12.

Table 17.14 Covariance Structure Examples

Description	Structure	Example
First-order antedependence	ANTE(1)	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_1 & \sigma_1\sigma_3\rho_1\rho_2 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_2\sigma_3\rho_2 \\ \sigma_3\sigma_1\rho_2\rho_1 & \sigma_3\sigma_2\rho_2 & \sigma_3^2 \end{bmatrix}$

Table 17.14 *continued*

Description	Structure	Example
First-order autoregressive	AR(1)	$\sigma^2 \begin{bmatrix} 1 & \rho & \rho^2 & \rho^3 \\ \rho & 1 & \rho & \rho^2 \\ \rho^2 & \rho & 1 & \rho \\ \rho^3 & \rho^2 & \rho & 1 \end{bmatrix}$
Heterogeneous autoregressive(1)	ARH(1)	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho & \sigma_1\sigma_3\rho^2 & \sigma_1\sigma_4\rho^3 \\ \sigma_2\sigma_1\rho & \sigma_2^2 & \sigma_2\sigma_3\rho & \sigma_2\sigma_4\rho^2 \\ \sigma_3\sigma_1\rho^2 & \sigma_3\sigma_2\rho & \sigma_3^2 & \sigma_3\sigma_4\rho \\ \sigma_4\sigma_1\rho^3 & \sigma_4\sigma_2\rho^2 & \sigma_4\sigma_3\rho & \sigma_4^2 \end{bmatrix}$
First-order autoregressive moving average	ARMA(1,1)	$\sigma^2 \begin{bmatrix} 1 & \gamma & \gamma\rho & \gamma\rho^2 \\ \gamma & 1 & \gamma & \gamma\rho \\ \gamma\rho & \gamma & 1 & \gamma \\ \gamma\rho^2 & \gamma\rho & \gamma & 1 \end{bmatrix}$
Cholesky root	CHOL	$\begin{bmatrix} l_{11} & 0 & 0 & 0 \\ l_{21} & l_{22} & 0 & 0 \\ l_{31} & l_{32} & l_{33} & 0 \\ l_{41} & l_{42} & l_{43} & l_{44} \end{bmatrix} \begin{bmatrix} l_{11} & l_{21} & l_{31} & l_{41} \\ 0 & l_{22} & l_{32} & l_{42} \\ 0 & 0 & l_{33} & l_{43} \\ 0 & 0 & 0 & l_{44} \end{bmatrix}$
Compound symmetry	CS	$\begin{bmatrix} \sigma^2+\sigma_1 & \sigma_1 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma^2+\sigma_1 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma^2+\sigma_1 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma_1 & \sigma^2+\sigma_1 \end{bmatrix}$
Heterogeneous compound symmetry	CSH	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho & \sigma_1\sigma_3\rho & \sigma_1\sigma_4\rho \\ \sigma_2\sigma_1\rho & \sigma_2^2 & \sigma_2\sigma_3\rho & \sigma_2\sigma_4\rho \\ \sigma_3\sigma_1\rho & \sigma_3\sigma_2\rho & \sigma_3^2 & \sigma_3\sigma_4\rho \\ \sigma_4\sigma_1\rho & \sigma_4\sigma_2\rho & \sigma_4\sigma_3\rho & \sigma_4^2 \end{bmatrix}$
First-order factor analytic	FA(1)	$\begin{bmatrix} \lambda_1^2+d_1 & \lambda_1\lambda_2 & \lambda_1\lambda_3 & \lambda_1\lambda_4 \\ \lambda_2\lambda_1 & \lambda_2^2+d_2 & \lambda_2\lambda_3 & \lambda_2\lambda_4 \\ \lambda_3\lambda_1 & \lambda_3\lambda_2 & \lambda_3^2+d_3 & \lambda_3\lambda_4 \\ \lambda_4\lambda_1 & \lambda_4\lambda_2 & \lambda_4\lambda_3 & \lambda_4^2+d_4 \end{bmatrix}$
Huynh-Feldt	HF	$\begin{bmatrix} \sigma_1^2 & \frac{\sigma_1^2+\sigma_2^2}{2}-\lambda & \frac{\sigma_1^2+\sigma_3^2}{2}-\lambda \\ \frac{\sigma_2^2+\sigma_1^2}{2}-\lambda & \sigma_2^2 & \frac{\sigma_2^2+\sigma_3^2}{2}-\lambda \\ \frac{\sigma_3^2+\sigma_1^2}{2}-\lambda & \frac{\sigma_3^2+\sigma_2^2}{2}-\lambda & \sigma_3^2 \end{bmatrix}$
Toeplitz	TOEP	$\begin{bmatrix} \sigma^2 & \sigma_1 & \sigma_2 & \sigma_3 \\ \sigma_1 & \sigma^2 & \sigma_1 & \sigma_2 \\ \sigma_2 & \sigma_1 & \sigma^2 & \sigma_1 \\ \sigma_3 & \sigma_2 & \sigma_1 & \sigma^2 \end{bmatrix}$
Toeplitz with two bands	TOEP(2)	$\begin{bmatrix} \sigma^2 & \sigma_1 & 0 & 0 \\ \sigma_1 & \sigma^2 & \sigma_1 & 0 \\ 0 & \sigma_1 & \sigma^2 & \sigma_1 \\ 0 & 0 & \sigma_1 & \sigma^2 \end{bmatrix}$

Table 17.14 *continued*

Description	Structure	Example
Heterogeneous Toeplitz	TOEPH	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_1 & \sigma_1\sigma_3\rho_2 & \sigma_1\sigma_4\rho_3 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_2\sigma_3\rho_1 & \sigma_2\sigma_4\rho_2 \\ \sigma_3\sigma_1\rho_2 & \sigma_3\sigma_2\rho_1 & \sigma_3^2 & \sigma_3\sigma_4\rho_1 \\ \sigma_4\sigma_1\rho_3 & \sigma_4\sigma_2\rho_2 & \sigma_4\sigma_3\rho_1 & \sigma_4^2 \end{bmatrix}$
Uniform correlation	UC	$\sigma^2 \begin{bmatrix} 1 & \rho & \rho & \rho \\ \rho & 1 & \rho & \rho \\ \rho & \rho & 1 & \rho \\ \rho & \rho & \rho & 1 \end{bmatrix}$
Heterogeneous UC	UCH	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho & \sigma_1\sigma_3\rho & \sigma_1\sigma_4\rho \\ \sigma_2\sigma_1\rho & \sigma_2^2 & \sigma_2\sigma_3\rho & \sigma_2\sigma_4\rho \\ \sigma_3\sigma_1\rho & \sigma_3\sigma_2\rho & \sigma_3^2 & \sigma_3\sigma_4\rho \\ \sigma_4\sigma_1\rho & \sigma_4\sigma_2\rho^2 & \sigma_4\sigma_3\rho & \sigma_4^2 \end{bmatrix}$
Unstructured	UN	$\begin{bmatrix} \sigma_1^2 & \sigma_{21} & \sigma_{31} & \sigma_{41} \\ \sigma_{21} & \sigma_2^2 & \sigma_{32} & \sigma_{42} \\ \sigma_{31} & \sigma_{32} & \sigma_3^2 & \sigma_{43} \\ \sigma_{41} & \sigma_{42} & \sigma_{43} & \sigma_4^2 \end{bmatrix}$
Banded main diagonal	UN(1)	$\begin{bmatrix} \sigma_1^2 & 0 & 0 & 0 \\ 0 & \sigma_2^2 & 0 & 0 \\ 0 & 0 & \sigma_3^2 & 0 \\ 0 & 0 & 0 & \sigma_4^2 \end{bmatrix}$
Unstructured correlations	UNR	$\begin{bmatrix} \sigma_1^2 & \sigma_1\sigma_2\rho_{21} & \sigma_1\sigma_3\rho_{31} & \sigma_1\sigma_4\rho_{41} \\ \sigma_2\sigma_1\rho_{21} & \sigma_2^2 & \sigma_2\sigma_3\rho_{32} & \sigma_2\sigma_4\rho_{42} \\ \sigma_3\sigma_1\rho_{31} & \sigma_3\sigma_2\rho_{32} & \sigma_3^2 & \sigma_3\sigma_4\rho_{43} \\ \sigma_4\sigma_1\rho_{41} & \sigma_4\sigma_2\rho_{42} & \sigma_4\sigma_3\rho_{43} & \sigma_4^2 \end{bmatrix}$
Variance components	VC (default)	$\begin{bmatrix} \sigma_B^2 & 0 & 0 & 0 \\ 0 & \sigma_B^2 & 0 & 0 \\ 0 & 0 & \sigma_{AB}^2 & 0 \\ 0 & 0 & 0 & \sigma_{AB}^2 \end{bmatrix}$

The following list provides some further information about these covariance structures:

TYPE=ANTE(1) specifies the first-order antedependence structure (Kenward 1987; Patel 1991; Macchiavelli and Arnold 1994). In Table 17.12, σ_i^2 is the i variance parameter, and ρ_k is the kth autocorrelation parameter that satisfies $|\rho_k| < 1$.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=AR(1) specifies a first-order autoregressive structure. The LMIXED procedure imposes the constraint $|\rho| < 1$ for stationarity.

TYPE=ARH(1) specifies a heterogeneous first-order autoregressive structure. As with TYPE=AR(1), the LMIXED procedure imposes the constraint $|\rho| < 1$ for stationarity.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=ARMA(1,1) specifies the first-order autoregressive moving average structure. In Table 17.12, ρ is the autoregressive parameter, γ models a moving average component, and σ^2 is the residual variance. In the notation of Fuller (1976, p. 68), $\rho = \theta_1$ and

$$\gamma = \frac{(1 + b_1\theta_1)(\theta_1 + b_1)}{1 + b_1^2 + 2b_1\theta_1}$$

The example in Table 17.14 and $|b_1| < 1$ imply that

$$b_1 = \frac{\beta - \sqrt{\beta^2 - 4\alpha^2}}{2\alpha}$$

where $\alpha = \gamma - \rho$ and $\beta = 1 + \rho^2 - 2\gamma\rho$. The LMIXED procedure imposes the constraints $|\rho| < 1$ and $|\gamma| < 1$ for stationarity, although the resulting covariance matrix is not positive definite for some values of ρ and γ in this region. When the estimated value of ρ becomes negative, the computed covariance is multiplied by $\cos(\pi d_{ij})$ to account for the negativity.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=CHOL specifies an unstructured variance-covariance matrix that is parameterized through its Cholesky root. All diagonal values are constrained to be positive. This parameterization guarantees a positive definite covariance matrix. For example, a 2×2 unstructured covariance matrix can be written as

$$\mathrm{Var}[\boldsymbol{\xi}] = \begin{bmatrix} \sigma_1^2 & \sigma_{21} \\ \sigma_{21} & \sigma_2^2 \end{bmatrix}$$

Without imposing constraints on the three parameters, there is no guarantee that the estimated variance matrix is positive definite. Even if σ_1^2 and σ_2^2 are nonzero, a large value for σ_{21} can lead to a negative eigenvalue of $\mathrm{Var}[\boldsymbol{\xi}]$. The Cholesky root of a positive definite matrix $\mathbf{A}$ is a lower triangular matrix $\mathbf{L}$ such that $\mathbf{L}\mathbf{L}' = \mathbf{A}$. The Cholesky root of the preceding 2×2 matrix can be written as

$$\mathbf{L} = \begin{bmatrix} l_{11} & 0 \\ l_{21} & l_{22} \end{bmatrix}$$

The elements of the unstructured variance matrix are then simply $\sigma_1^2 = l_{11}^2$, $\sigma_{21} = l_{21}l_{11}$, and $\sigma_2^2 = l_{21}^2 + l_{22}^2$. Similar operations yield the generalization to covariance matrices of higher orders.

For example, the following statements model the covariance matrix of each subject as an unstructured matrix:

```
proc lmixed;
   class sub;
   model y = x;
   random  time / sub=patient type=chol;
run;
```

The LMIXED procedure constrains the diagonal elements of the Cholesky root to be positive. This guarantees that the structure is positive definite.

This covariance type is available only when DMMETHOD=SPARSE.

TYPE=CS specifies the compound-symmetry structure, which has constant variance and constant covariance.

TYPE=CSH specifies the heterogeneous compound-symmetry structure. This structure has a different variance parameter for each diagonal element, and it uses the square roots of these parameters in the off-diagonal entries. In Table 17.12, σ_i^2 is the i variance parameter, and ρ is the correlation parameter that satisfies $|\rho| < 1$.

TYPE=FA(q) specifies the factor-analytic structure with q factors (Jennrich and Schluchter 1986). This structure is of the form $\mathbf{\Lambda}\mathbf{\Lambda}' + \mathbf{D}$, where $\mathbf{\Lambda}$ is a $t \times q$ rectangular matrix and $\mathbf{D}$ is a $t \times t$ diagonal matrix with t different parameters. When $q > 1$, the elements of $\mathbf{\Lambda}$ in its upper right corner (that is, the elements in the i row and j column for $j > i$) are set to 0 to fix the rotation of the structure.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=FA0(q) is similar to the FA(q) structure except that no diagonal matrix $\mathbf{D}$ is included. When $q < t$ (that is, when the number of factors is less than the dimension of the matrix), this structure is nonnegative definite but not of full rank. In this situation, you can use this structure for approximating an unstructured $\mathbf{G}$ matrix in the RANDOM statement. When $q = t$, you can use this structure to constrain $\mathbf{G}$ to be nonnegative definite in the RANDOM statement.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=FA1(q) is similar to the TYPE=FA(q) structure except that all the elements in $\mathbf{D}$ are constrained to be equal. This offers a useful and more parsimonious alternative to the full factor-analytic structure.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=HF specifies the Huynh-Feldt covariance structure (Huynh and Feldt 1970). This structure is similar to the TYPE=CSH structure in that it has the same number of parameters and heterogeneity along the main diagonal. However, it constructs the off-diagonal elements by taking arithmetic means rather than geometric means.

You can perform a likelihood ratio test of the Huynh-Feldt conditions by running the LMIXED procedure twice, once with TYPE=HF and once with TYPE=UN, and then subtracting their respective values of -2 times the maximized likelihood.

If the LMIXED procedure does not converge under your Huynh-Feldt model, you can specify your own starting values in the PARMS statement. The default MIVQUE0 starting values can sometimes be poor for this structure. A good choice for starting values is often the parameter estimates that correspond to an initial fit that uses TYPE=CS.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=SIMPLE is an alias for TYPE=VC.

TYPE=TOEP<(q)> specifies a banded Toeplitz structure. This structure can be viewed as a moving average structure with order equal to $q - 1$. The TYPE=TOEP option is a full Toeplitz matrix, which can be viewed as an autoregressive structure with order equal to the dimension of the matrix. The specification TYPE=TOEP(1) is the same as $\sigma^2 I$, where I is an identity matrix, and it can be useful for specifying the same variance component for several effects.

TYPE=TOEPH<(*q*)> specifies a heterogeneous banded Toeplitz structure. In Table 17.12, σ_i^2 is the i variance parameter and ρ_j is the j correlation parameter that satisfies $|\rho_j| < 1$. If you specify the order parameter q, then the LMIXED procedure estimates only the first q bands of the matrix, setting all higher bands equal to 0. TYPE=TOEPH(1) is equivalent to both TYPE=UN(1).

This covariance type is available only when DMMETHOD=DENSE.

TYPE=UC specifies the uniform correlation structure, which has constant variance and constant correlation,

$$\mathrm{Cov}\left[\xi_i, \xi_j\right] = \begin{cases} \sigma^2 & i = j \\ \sigma^2\rho & i \neq j \end{cases}$$

Under uniform correlation, the $\mathbf{G}$ matrix has the form $\sigma^2[(1-\rho)\mathbf{I} + \rho\mathbf{J}]$. The variance σ^2 is constrained to be positive, and the correlation ρ is constrained to be greater than $-1/(t-1)$, where t is the dimension of the structure. These constraints guarantee that the structure is positive definite. This structure is equivalent to the compound-symmetry structure with a better numerical property in terms of optimization.

The uniform correlation structure arises frequently in agriculture and animal sciences.

This covariance type is available only when DMMETHOD=SPARSE.

TYPE=UCH specifies the heterogeneous uniform correlation structure. This structure has a different variance parameter for each diagonal element, and it uses the square roots of these parameters in the off-diagonal entries. In Table 17.12, σ_i^2 is the ith variance parameter that satisfies $\sigma_i^2 > 0$, and ρ is the correlation parameter that satisfies $\rho > -1/(t-1)$, where t is the dimension of the structure. This guarantees that the structure is positive definite.

This covariance type is available only when DMMETHOD=SPARSE.

TYPE=UN specifies a completely general (unstructured) covariance matrix that is parameterized directly in terms of variances and covariances. The variances are constrained to be nonnegative, and the covariances are unconstrained. When DMMETHOD=DENSE, this structure is not constrained to be nonnegative definite in order to avoid nonlinear constraints; however, you can use the TYPE=FA0 structure if you want this constraint to be imposed by a Cholesky factorization. When DMMETHOD=SPARSE, this structure is constrained to be nonnegative definite by a Cholesky factorization.

TYPE=UN(*q*) specifies a banded unstructured covariance matrix that is parameterized directly in terms of variances and covariances. The LMIXED procedure estimates only the first q bands of the matrix, setting all higher bands equal to 0.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=UNR specifies a completely general (unstructured) covariance matrix that is parameterized in terms of variances and correlations. This structure fits the same model as the TYPE=UN option but with a different parameterization. The i variance parameter is σ_i^2. The parameter ρ_{jk} is the correlation between the j and k measurements; it satisfies $|\rho_{jk}| < 1$.

This covariance type is available only when DMMETHOD=DENSE.

TYPE=VC specifies standard variance components. This is the default structure for the RANDOM statements. In the RANDOM statement, a distinct variance component is assigned to each effect.

Jennrich and Schluchter (1986) provide general information about the use of covariance structures, and Wolfinger (1996) presents details about many of the heterogeneous structures.

REPEATED Statement

REPEATED *repeated-effect* < / *options* > **;**

The REPEATED statement defines the repeated effect and the residual covariance structure in the mixed model. The residual variance-covariance matrix is denoted as **R**. The *repeated-effect* is required and consists entirely of classification variables. The levels of the *repeated-effect* must be different for each observation within a subject in order to avoid the singular **R** matrix.

Table 17.15 summarizes the *options* available in the REPEATED statement.

Table 17.15 Summary of REPEATED Statement Options

Option	Description
Construction of Covariance Structure	
GROUP=	Defines an effect that specifies heterogeneity in the residual covariance structure
NOCONVERT	Prevents the covariance structure from being internally converted
SUBJECT=	Identifies the subjects in the residual covariance structure
TYPE=	Specifies the residual covariance structure (the default is VC)
Statistical Output	
R=	Displays blocks of the estimated **R** matrix
RC=	Display the Cholesky root (lower) of blocks of the estimated **R** matrix
RCI=	Displays the inverse Cholesky root (lower) of blocks of the estimated **R** matrix
RCORR=	Displays the correlation matrix that corresponds to blocks of the estimated **R** matrix
RI=	Displays the inverse of blocks of the estimated **R** matrix

In the current release, the REPEATED statement is supported only when DMMETHOD=SPARSE.

You must specify one or both of the following *options* after a slash (/):

GROUP=*effect*

GRP=*effect*

defines an effect that specifies heterogeneity in the residual covariance structure. All observations that have the same level of the *effect* have the same covariance parameters. Each new level of the *effect* produces a new set of covariance parameters that have the same structure as the original group. You

should exercise caution in defining the *effect*, because strange covariance patterns can result when it is misused. Also, the *effect* can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

NOCONVERT
prevents the covariance structure from being internally converted to an equivalent one that leads to efficient computation.

SUBJECT=*effect*
SUB=*effect*
identifies the subjects in your mixed model. Complete independence is assumed across subjects; therefore, this option produces a block-diagonal structure in **R** that has identical blocks. The data set is not required to be grouped by the *effect*. When the *effect* consists entirely of classification variables, the blocks of **R** correspond to observations that share the same level of that *effect*. These blocks are sorted according to this *effect* as well.

You can also specify the following *options* after a slash (/):

R<=*value-list***>**
displays blocks of the estimated **R** matrix. The first block that is determined by the SUBJECT= *effect* is the default displayed block.

The *value-list* indicates the subjects for which blocks of **R** are displayed. For example, the following statement displays block matrices for the first, third, and fifth persons:

```
repeated time / type=un subject=person r=1,3,5;
```

See the PARMS statement for the possible forms of *value-list*.

RC<=*value-list***>**
displays the Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as for the R= option.

RCI<=*value-list***>**
displays the inverse Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as for the R= option.

RCORR<=*value-list***>**
displays the correlation matrix that corresponds to blocks of the estimated **R** matrix. The *value-list* specification is the same as for the R= option.

RI<=*value-list***>**
produces the inverse of blocks of the estimated **R** matrix. The *value-list* specification is the same as for the R= option.

TYPE=*covariance-structure*
specifies the structure of the residual variance-covariance matrix **R**. The SUBJECT= option defines the blocks of **R**, and the TYPE= option specifies the structure of these blocks. In the current release, the valid values of *covariance-structure* are AR(1), CHOL, CS, CSH, UN, and VC.

For more information about these covariance structure types, see the description in the section "RANDOM Statement" on page 916.

SLICE Statement

SLICE *model-effect* < / *options* > **;**

The SLICE statement is similar to the LSMEANS statement. It provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects (Winer 1971). For the SLICE statement, these effects must be higher-order effects of at least two classification variables. Each effect is then sliced, or partitioned, into subsets that correspond to variables used in forming the effect.

By default, the interaction effect is partitioned by all main effects. For example, the following statements produce simple-effect differences among the A levels for each level of B and simple-effect differences among the B levels for each level of A:

```
class a b;
model y = a b a*b;
slice a*b / diff;
```

For example, if the *model-effect* is a three-way interaction effect, the default output includes comparisons of the two-way interaction means.

Suppose, for example, that the interaction effect A*B is significant in your analysis and that you want to test the effect of A for each level of B. The appropriate statement is

```
slice A*B / sliceBy = B;
```

This statement produces an F test for each level of B that compares the equality of the levels of A.

For example, assume that in a balanced design, factors A and B have $a = 4$ and $b = 3$ levels, respectively. Consider the following statements:

```
class a b;
model y = a b a*b;
slice a*b / sliceby=a diff;
```

The SLICE statement produces four F tests, one for each level of A. The first test is constructed by extracting the three rows that correspond to the first level of A from the coefficient matrix for the A*B interaction. Call this matrix $\mathbf{L}_{a1}$ and its rows $\mathrm{l}_{a1}^{(1)}$, $\mathrm{l}_{a1}^{(2)}$, and $\mathrm{l}_{a1}^{(3)}$. The SLICE statement tests the two-degrees-of-freedom hypothesis:

$$H: \begin{cases} \left(\mathrm{l}_{a1}^{(1)} - \mathrm{l}_{a1}^{(2)}\right)\boldsymbol{\beta} = 0 \\ \left(\mathrm{l}_{a1}^{(1)} - \mathrm{l}_{a1}^{(3)}\right)\boldsymbol{\beta} = 0 \end{cases}$$

In a balanced design, where μ_{ij} denotes the mean response if A is at level i and B is at level j, this hypothesis is equivalent to $H: \mu_{11} = \mu_{12} = \mu_{13}$. The DIFF option considers the three rows of $\mathbf{L}_{a1}$ in turn and performs tests of the difference between pairs of rows. By default, all pairwise differences within the subset of $\mathbf{L}$ are considered; in the example, this corresponds to tests of the form

$$H: \left(\mathrm{l}_{a1}^{(1)} - \mathrm{l}_{a1}^{(2)}\right)\boldsymbol{\beta} = 0$$
$$H: \left(\mathrm{l}_{a1}^{(1)} - \mathrm{l}_{a1}^{(3)}\right)\boldsymbol{\beta} = 0$$
$$H: \left(\mathrm{l}_{a1}^{(2)} - \mathrm{l}_{a1}^{(3)}\right)\boldsymbol{\beta} = 0$$

In the example, where $a = 4$ and $b = 3$, this produces four sets of least squares means differences. Within each set, factor A is held fixed at a particular level and each set consists of three comparisons.

Table 17.16 summarizes the *options* available in the SLICE statement.

Table 17.16 SLICE Statement Options

Option	Description
ADJUST=	Determines the method of multiple comparison adjustment of LS-means differences
ALPHA=	Specifies the confidence level
AT	Modifies covariate values in computing LS-means
CL	Constructs *t*-type confidence limits
CORR	Displays the estimated correlation matrix
COV	Displays the estimated covariance matrix
DF=	Specifies the degrees of freedom
DIFF	Displays the differences of the LS-means
E	Displays the matrix coefficients
MEANS	Displays the LS-means slice
NOF	Suppresses the *F* test
SINGULAR=	Tunes the estimability checking
SLICEBY	Partitions the interaction effects

You can specify the following *options* in the SLICE statement after a slash (/):

ADJUST=*method*
performs a multiple comparison adjustment of the *p*-values and confidence limits for the differences of LS-means. The adjusted quantities are produced along with the unadjusted quantities. This option works together with the DIFF option. If you omit the DIFF option, then the ADJUST= option implies the DIFF option except for ADJUST=T.

You can specify the following *methods*:

BON
performs Bonferroni *t* tests of differences between LS-means. This method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

DUNNETT
performs Dunnett's *t* test, which determines whether any treatments are significantly different from a single control for the effects in the SLICES statement. If the LS-means are correlated, PROC LMIXED uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment as "Dunnett-Hsu" in the results. The approximation derives approximate "effective sample sizes" for which exact critical values are computed.

NELSON
performs Nelson's *t* test of each LS-mean against an average of the LS-means (Ott 1967; Nelson 1982, 1991, 1993). When the LS-means

are correlated, PROC LMIXED uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment as "Nelson-Hsu" in the results. The approximation derives approximate "effective sample sizes" for which exact critical values are computed.

SCHEFFE performs Scheffé's multiple comparison procedure.

SIDAK performs pairwise *t* tests on differences between LS-means with levels adjusted according to Šidák's inequality. This method involves correction factors described in Chapter 53, "The GLM Procedure" (*SAS/STAT User's Guide*), and Chapter 86, "The MULTTEST Procedure" (*SAS/STAT User's Guide*); also see Westfall and Young (1993) and Westfall et al. (1999).

SIMULATE < (*simoptions***) >** performs the simulation-based multiple comparison procedure. This method computes adjusted *p*-values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate *t* random vector. All covariance parameters, except the residual scale parameter, are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates q, the true $(1-\alpha)$ quantile, where $1-\alpha$ is the confidence coefficient. For a description of the *simoptions* (except for the CVADJUST option, which you cannot use in the SLICE statement), see the ADJUST= option in the LSMEANS statement.

SMM | GT2 performs pairwise comparisons on the basis of the studentized maximum modulus and Šidák's uncorrelated-*t* inequality, yielding Hochberg's GT2 method when sample sizes are unequal.

T | NONE performs no adjustment for multiple comparisons.

TUKEY performs Tukey's studentized range test on LS-means. When your data are unbalanced, PROC LMIXED uses the approximation described in Kramer (1956) and identifies the adjustment as "Tukey-Kramer" in the results.

By default, ADJUST=T.

If you specify ADJUST=DUNNETT, the procedure analyzes differences between each level and the first control level unless you specify a different control level. If you specify ADJUST=NELSON, then DIFF=ANOM is assumed.

If you specify ADJUST=TUKEY, then DIFF=ALL is assumed. If you specify other *methods*, then the procedure performs all pairwise differences unless you specify the DIFF option.

Note that computing the exact adjusted *p*-values and critical values for unbalanced designs can be computationally intensive, especially when ADJUST=NELSON.

ALPHA=*number*

constructs a *t*-type confidence interval for each LS-means whose confidence level is $1-$ *number*. The value of *number* must be between 0 and 1, exclusive; by default, ALPHA=0.05.

AT *at-specification*

enables you to modify the values of the covariates that are used in computing LS-means. By default, all covariate effects are set equal to their mean values for computation of standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

You can specify the following *at-specifications*:

MEANS	sets covariates equal to their mean values (as with standard LS-means) and applies this adjustment to crossproducts of covariates.
variable=*value*	sets the covariate *variable* equal to *value*.
(*variable-list*)=(*value-list*)	sets covariates in the *variable-list* equal to values in the *value-list*.

As an example, consider the following invocation of PROC LMIXED:

```
proc lmixed;
   class A B;
   model Y = A*B x1 x2 x1*x2;
   SLICE A*B;
   SLICE A*B / at means;
   SLICE A*B / at x1=1.2;
   SLICE A*B / at (x1 x2)=(1.2 0.3);
run;
```

For the first two SLICE statements, the LS-means coefficient of x1 is $\overline{x}_1$ (the mean of x1) and of x2 is $\overline{x}_2$ (the mean of x2). For the first SLICE statement, the coefficient of x1*x2 is $\overline{x_1 x_2}$. However, for the second SLICE statement, the coefficient is $\overline{x}_1 \times \overline{x}_2$. The third SLICE statement sets the coefficient of x1 equal to 1.2 and leaves it at $\overline{x}_2$ for x2, and the final SLICE statement sets these values to 1.2 and 0.3, respectively.

Even if you specify a WEIGHT variable, the unweighted covariate means are used for the covariate coefficients if you omit the AT option. If you specify the AT option, then WEIGHT or FREQ variables are taken into account as follows. The weighted covariate means are used for the covariate coefficients for which no explicit AT option values are given, or if you specify the AT MEANS option. Observations that do not contribute to the analysis because of a missing dependent variable are used in computing the covariate means. You should use the E option in conjunction with the AT option to verify that the modified LS-means coefficients are the ones that you want.

CL

constructs *t*-type confidence limits for each of the LS-means. If DDFM=NONE, then PROC LMIXED uses infinite degrees of freedom for this test, essentially computing a z interval. By default, the confidence level is 0.95; you can change this by using the ALPHA= option.

CORR

displays the estimated correlation matrix of the LS-means as part of the "Least Squares Means" table.

COV
displays the estimated covariance matrix of the LS-means as part of the "Least Squares Means" table.

DF=*number*
specifies the degrees of freedom for the *t* test and confidence limits. The default is the residual degrees of freedom that you specify in the DDFM=RESIDUAL option.

DIFF<=*difftype***>**
PDIFF<=*difftype***>**
displays differences of the LS-means. You can specify the following values for the optional *difftype*:

ALL displays all pairwise differences; this is the default.

ANOM displays differences between each LS-mean and the average LS-mean, as in the analysis of means (Ott 1967). The average is computed as a weighted mean of the LS-means, where the weights are inversely proportional to the diagonal entries of the $\mathbf{L}\left(\mathbf{X}'\mathbf{X}\right)^{-}\mathbf{L}'$ matrix. When you specify a WEIGHT statement, this matrix is replaced by $\mathbf{L}\left(\mathbf{X}'\mathbf{W}\mathbf{X}\right)^{-}\mathbf{L}'$, where $\mathbf{W}$ is the diagonal matrix that contains the weights. If the LS-means are nonestimable, this design-based weighted mean is replaced by an equally weighted mean. Note that the ANOM procedure in SAS/QC software implements both tables and graphics for the analysis of means with a variety of response types. For one-way designs and normally distributed data, the DIFF=ANOM computations are equivalent to the results of PROC ANOM.

CONTROL displays differences with a control; by default, the control is the first level of each specified SLICE statement effect. To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the CONTROL keyword. For example, if the effects A, B, and C are classification variables, and each has two levels (1 and 2), then the following SLICE statement specifies the (1,2) level of A*B and the (2,1) level of B*C as controls:

```
lsmeans A*B B*C / diff=control('1' '2', '2' '1');
```

For multiple effects, the results depend on the order of the list, so you should check the output to make sure that the controls are correct.

The CONTROL keyword produces two-tailed tests and confidence limits.

CONTROLL displays one-tailed test results and performs tests to determine whether the noncontrol levels are significantly smaller than the control. The upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing.

CONTROLU displays one-tailed test results and performs tests to determine whether the noncontrol levels are significantly larger than the control. The upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

The differences of the LS-means are displayed in a table titled "Differences of Least Squares Means." The ODS table name is SliceDiffs.

E

displays the matrix coefficients for all specified SLICE statement effects. The name of this table is "Matrix Coefficients." The ODS table name is Coef.

MEANS

displays the LS-means.

NOF

suppresses the *F* test for testing the mutual equality of the estimable functions in the partition.

SINGULAR=*number*

tunes the estimability checking as documented for the SINGULAR= option in the CONTRAST statement.

SLICEBY *sliceby-spec-list*

SLICE *sliceby-spec-list*

determines how to construct the partition of the LS-means for the *model-effect*. The *sliceby-spec-list* is a list of *sliceby-specifications*. A *sliceby-specification* consists of an effect name followed by an optional list of formatted values. The *sliceby-spec-list* takes either of the following two forms:

< **=** > *sliceby-specification*

(*sliceby-specification* < *sliceby-specification* < . . . >>)

If you have only one *sliceby-specification*, use the first form. If you have one or more *sliceby-specifications*, you can use the second form.

The following SLICE statement contains one *sliceby-specification*. It creates partitions of the A*B interaction effect for all levels of variable A.

```
class a b;
model y = a b a*b;
slice a*b / sliceby=a;
```

The following SLICE statement contains one *sliceby-specification*. It creates one partition of the A*B interaction effect for one level, associated with the formatted value 'A1', of variable A.

```
class a b;
model y = a b a*b;
slice a*b / sliceby a='A1';
```

The following SLICE statement contains two *sliceby-specifications*. The first *sliceby-specification* creates two partitions of the A*B interaction effect for two levels, associated with the formatted values 'B2' and 'B3', of variable B. The second *sliceby-specification* creates one partition for the level, associated with the formatted values 'A1', of variable A.

```
class a b;
model y = a b a*b;
slice a*b / sliceby(b=('B2','B3') a='A1') diff;
```

The following SLICE statement contains one *sliceby-specification*. It creates two partitions of the A*B*C interaction effect for two levels of the B*C interaction effect. These two levels are associated with the two combinations of the formatted values: the combination of 'B1' and 'C1' and the combination of 'B1' and 'C2'.

```
class a b c;
model y = a b a*b*c;
slice a*b*c / sliceby b*c=('B1' 'C1', 'B1' 'C2');
```

The following SLICE statement contains two *sliceby-specifications*. The first *sliceby-specification* creates two partitions of the A*B*C interaction effect for two levels that are associated with the two combinations of the formatted values: the combination of 'B1' and 'C1' and the combination of 'B1' and 'C2'. The third *sliceby-specification* creates one partition for one level, associated with the formatted value 'A1', of variable A.

```
class a b c;
model y = a b a*b*c;
slice a*b*c / sliceby(b*c=('B1' 'C1', 'B1' 'C2') a='A1');
```

Notice that an interaction effect of B*C has the internal order of B and C or C and B. The order is determined by the order of these two variables in the CLASS statement. Thus, the order of formatted values in the *sliceby-specification* must follow the order of variables in the CLASS statement. For example, b*c=('B1' 'C1') is correct if B precedes C in the CLASS statement; otherwise, you have to use b*c=('C1' 'B1').

STORE Statement

STORE < **OUT=** >*libref.data-table* **;**

The STORE statement saves the model and results of the statistical analysis. The resulting analytic store has a binary file format that cannot be modified. At a later time you can use the saved results of that analysis to perform specific statistical analysis tasks, without having to fit the model again. The contents of the analytic store can be processed by the ASTORE procedure.

For more information about the ASTORE procedure, see the description in Chapter 4, "ASTORE Procedure" (*SAS Viya: Machine Learning Procedures*).

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 864.

TEST Statement

TEST *fixed-effects* < / *options* > **;**

The TEST statement performs hypothesis tests on the fixed effects. You can specify multiple effects in one TEST statement or in multiple TEST statements.

You can specify the following *options* in the TEST statement after a slash (/):

CHISQ
performs χ^2 tests in addition to any F tests. A χ^2 statistic equals its corresponding F statistic times the associated numerator degrees of freedom, and PROC LMIXED uses the same degrees of freedom to compute the p-value for the χ^2 test. This p-value is always less than that for the F test, because a χ^2 test effectively corresponds to an F test that has infinite denominator degrees of freedom.

DF=*number*
specifies the denominator degrees of freedom for the F test. The default is the residual degrees of freedom that you define by specifying the DDFM=RESIDUAL option.

E
displays matrix coefficients that are associated with test types for specified effects.

E3

EIII
displays Type III matrix coefficients if a Type III test is performed.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

The *variable* in the WEIGHT statement might also be used as a weight to compute the weighted predictive margins. For more information, see the description in the MARGINS statement.

Details: LMIXED Procedure

Linear Mixed Models Theory

This section provides an overview of a likelihood-based approach to linear mixed models. This approach simplifies and unifies many common statistical analyses, including those that involve repeated measures, random effects, and random coefficients. The basic assumption is that the data are linearly related to unobserved multivariate normal random variables. For extensions to nonlinear and nonnormal situations, see the documentation of the GLIMMIX and NLMIXED procedures in the *SAS/STAT User's Guide*. Additional theory and examples are provided in Littell et al. (2006); Verbeke and Molenberghs (1997, 2000); and Burdick and Graybill (1992).

Matrix Notation for General Linear Model

Suppose that you observe n data points $y_1, \ldots, y_n$ and you want to explain them by using n values for each of p explanatory variables $x_{11}, \ldots, x_{1p}, x_{21}, \ldots, x_{2p}, \ldots, x_{n1}, \ldots, x_{np}$. The x_{ij} values can be either regression-type continuous variables or dummy variables that indicate class membership. The general linear model for this setup is

$$y_i = \sum_{j=1}^{p} x_{ij}\beta_j + \epsilon_i \quad i = 1, \ldots, n$$

where $\beta_1, \ldots, \beta_p$ are unknown fixed-effects parameters to be estimated and $\epsilon_1, \ldots, \epsilon_n$ are unknown independent and identically distributed normal (Gaussian) random variables with mean 0 and variance σ^2.

The preceding equations can be written simultaneously by using vectors and a matrix, as follows:

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} x_{11} & x_{12} & \ldots & x_{1p} \\ x_{21} & x_{22} & \ldots & x_{2p} \\ \vdots & \vdots & & \vdots \\ x_{n1} & x_{n2} & \ldots & x_{np} \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_p \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

For convenience, simplicity, and extendability, this entire system is written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{y}$ denotes the vector of observed y_i's, $\mathbf{X}$ is the known matrix of x_{ij}'s, $\boldsymbol{\beta}$ is the unknown fixed-effects parameter vector, and $\boldsymbol{\epsilon}$ is the unobserved vector of independent and identically distributed Gaussian random errors.

In addition to denoting data, random variables, and explanatory variables in the preceding fashion, the subsequent sections make use of basic matrix operators such as transpose ($'$), inverse ($^{-1}$), generalized inverse ($^{-}$), determinant ($|\cdot|$), and matrix multiplication. See Searle (1982) for details about these and other matrix techniques.

Formulation of the Mixed Model

The previous general linear model is certainly a useful one (Searle 1971), and it is the one fitted by the GLM procedure. However, the distributional assumption about $\boldsymbol{\epsilon}$ is often too restrictive. The mixed model extends the general linear model by allowing a more flexible specification of the covariance matrix of $\boldsymbol{\epsilon}$. In other words, it allows for both correlation and heterogeneous variances, although normality is still assumed.

The mixed model is written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

where all components are the same as in the general linear model except for the addition of the known design matrix, $\mathbf{Z}$, and the vector of unknown random-effects parameters, $\boldsymbol{\gamma}$. The matrix $\mathbf{Z}$ can contain either continuous or dummy variables, just like $\mathbf{X}$. The name *mixed model* comes from the fact that the model contains both fixed-effects parameters, $\boldsymbol{\beta}$, and random-effects parameters, $\boldsymbol{\gamma}$. See Henderson (1990) and Searle, Casella, and McCulloch (1992) for history of the development of the mixed model.

A key assumption in the preceding analysis is that $\boldsymbol{\gamma}$ and $\boldsymbol{\epsilon}$ are normally distributed with

$$\mathrm{E}\begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}$$

$$\mathrm{Var}\begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} = \begin{bmatrix} \mathbf{G} & \mathbf{0} \\ \mathbf{0} & \mathbf{R} \end{bmatrix}$$

Therefore, the variance of $\mathbf{y}$ is $\mathbf{V} = \mathbf{Z}\mathbf{G}\mathbf{Z}' + \mathbf{R}$. You can model $\mathbf{V}$ by setting up the random-effects design matrix $\mathbf{Z}$ and specifying covariance structures for $\mathbf{G}$ and $\mathbf{R}$.

Note that this is a general specification of the mixed model, in contrast to many texts and articles that discuss only simple random effects. Simple random effects are a special case of the general specification in which $\mathbf{Z}$ contains dummy variables, $\mathbf{G}$ contains variance components in a diagonal structure, and $\mathbf{I}$ denotes the identity matrix. The general linear model is a further special case with $\mathbf{Z} = \mathbf{0}$.

The following example illustrates the most common formulation of the general linear mixed model.

Example: Split-Plot Design

The split-plot design involves two experimental treatment factors, A and B, and two different sizes of experimental units to which they are applied (Winer 1971; Snedecor and Cochran 1980; Milliken and Johnson 1992; Steel, Torrie, and Dickey 1997). The levels of A are randomly assigned to the larger-sized experimental units, called *whole plots*, whereas the levels of B are assigned to the smaller-sized experimental units, the *subplots*. The subplots are assumed to be nested within the whole plots, so that a whole plot consists of a cluster of subplots and a level of A is applied to the entire cluster.

Such an arrangement is often necessary by nature of the experiment; the classic example is the application of fertilizer to large plots of land and different crop varieties that are planted in subdivisions of the large plots. For this example, fertilizer is the whole-plot factor A and variety is the subplot factor B.

This example is a split-plot design for which the whole plots are arranged in a randomized block design. The appropriate PROC LMIXED statements are as follows:

```
proc lmixed;
   class a b block;
   model y = a b a*b;
   random block a*block;
run;
```

Here

$$\mathbf{R} = \sigma^2 \mathbf{I}_{24}$$

and $\mathbf{X}$, $\mathbf{Z}$, and $\mathbf{G}$ have the following forms:

$$\mathbf{X} = \begin{bmatrix}
1 & 1 & & & 1 & & 1 & & & & & \\
1 & 1 & & & & 1 & & 1 & & & & \\
1 & & 1 & & 1 & & & & 1 & & & \\
1 & & 1 & & & 1 & & & & 1 & & \\
1 & & & 1 & 1 & & & & & & 1 & \\
1 & & & 1 & & 1 & & & & & & 1 \\
\vdots & & \vdots & & \vdots & & & & \vdots & & & \\
1 & 1 & & & 1 & & 1 & & & & & \\
1 & 1 & & & & 1 & & 1 & & & & \\
1 & & 1 & & 1 & & & & 1 & & & \\
1 & & 1 & & & 1 & & & & 1 & & \\
1 & & & 1 & 1 & & & & & & 1 & \\
1 & & & 1 & & 1 & & & & & & 1
\end{bmatrix}$$

$$\mathbf{Z} = \begin{bmatrix}
1 & & 1 & & & & & & & \\
1 & & 1 & & & & & & & \\
1 & & & 1 & & & & & & \\
1 & & & 1 & & & & & & \\
1 & & & & 1 & & & & & \\
1 & & & & 1 & & & & & \\
 & 1 & & & & 1 & & & & \\
 & 1 & & & & 1 & & & & \\
 & 1 & & & & & 1 & & & \\
 & 1 & & & & & 1 & & & \\
 & 1 & & & & & & 1 & & \\
 & 1 & & & & & & 1 & & \\
 & & 1 & & & & & & 1 & \\
 & & 1 & & & & & & 1 & \\
 & & 1 & & & & & & & 1 \\
 & & 1 & & & & & & & 1
\end{bmatrix}$$

$$\mathbf{G} = \begin{bmatrix}
\sigma^2_B & & & & & & & \\
 & \sigma^2_B & & & & & & \\
 & & \sigma^2_B & & & & & \\
 & & & \sigma^2_B & & & & \\
 & & & & \sigma^2_{AB} & & & \\
 & & & & & \sigma^2_{AB} & & \\
 & & & & & & \ddots & \\
 & & & & & & & \sigma^2_{AB}
\end{bmatrix}$$

where σ^2_B is the variance component for Block and σ^2_{AB} is the variance component for A*Block. Changing the RANDOM statement as follows fits the same model, but with **Z** and **G** sorted differently:

```
random int a / subject=block;
```

$$\mathbf{Z} = \begin{bmatrix}
1 & 1 & & & & & & & & & & & & & & & & & & \\
1 & 1 & & & & & & & & & & & & & & & & & & \\
1 & & 1 & & & & & & & & & & & & & & & & & \\
1 & & 1 & & & & & & & & & & & & & & & & & \\
1 & & & 1 & & & & & & & & & & & & & & & & \\
1 & & & 1 & & & & & & & & & & & & & & & & \\
 & & & & 1 & 1 & & & & & & & & & & & & & & \\
 & & & & 1 & 1 & & & & & & & & & & & & & & \\
 & & & & 1 & & 1 & & & & & & & & & & & & & \\
 & & & & 1 & & 1 & & & & & & & & & & & & & \\
 & & & & 1 & & & 1 & & & & & & & & & & & & \\
 & & & & 1 & & & 1 & & & & & & & & & & & & \\
 & & & & & & & & 1 & 1 & & & & & & & & & & \\
 & & & & & & & & 1 & 1 & & & & & & & & & & \\
 & & & & & & & & 1 & & 1 & & & & & & & & & \\
 & & & & & & & & 1 & & 1 & & & & & & & & & \\
 & & & & & & & & 1 & & & 1 & & & & & & & & \\
 & & & & & & & & 1 & & & 1 & & & & & & & & \\
 & & & & & & & & & & & & 1 & 1 & & & & & & \\
 & & & & & & & & & & & & 1 & 1 & & & & & & \\
 & & & & & & & & & & & & 1 & & 1 & & & & & \\
 & & & & & & & & & & & & 1 & & 1 & & & & & \\
 & & & & & & & & & & & & 1 & & & 1 & & & & \\
 & & & & & & & & & & & & 1 & & & 1 & & & &
\end{bmatrix}$$

$$\mathbf{G} = \begin{bmatrix}
\sigma^2_B & & & & & & & & & & & & & & & & & & & \\
 & \sigma^2_{AB} & & & & & & & & & & & & & & & & & & \\
 & & \sigma^2_{AB} & & & & & & & & & & & & & & & & & \\
 & & & \sigma^2_{AB} & & & & & & & & & & & & & & & & \\
 & & & & \ddots & & & & & & & & & & & & & & & \\
 & & & & & \sigma^2_B & & & & & & & & & & & & & & \\
 & & & & & & \sigma^2_{AB} & & & & & & & & & & & & & \\
 & & & & & & & \sigma^2_{AB} & & & & & & & & & & & & \\
 & & & & & & & & \sigma^2_{AB} & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & & \\
 & & & & & & & & & & & & & & & & & & &
\end{bmatrix}$$

Estimating Covariance Parameters in the Mixed Model

Estimation is more difficult in the mixed model than in the general linear model. Not only do you have $\boldsymbol{\beta}$ as in the general linear model, but you also have unknown parameters in $\boldsymbol{\gamma}$, $\mathbf{G}$, and $\mathbf{R}$. Least squares is no longer the best method. Generalized least squares (GLS) is more appropriate; it minimizes

$$(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'\mathbf{V}^{-1}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})$$

However, GLS requires knowledge of $\mathbf{V}$ and therefore knowledge of $\mathbf{G}$ and $\mathbf{R}$. When such information is lacking, one approach is to use an *estimated* GLS, in which you insert some reasonable estimate for $\mathbf{V}$ into the minimization problem. The goal thus becomes to find a reasonable estimate of $\mathbf{G}$ and $\mathbf{R}$.

In many situations, the best approach is to use likelihood-based methods, which exploit the assumption that $\boldsymbol{\gamma}$ and $\boldsymbol{\epsilon}$ are normally distributed (Hartley and Rao 1967; Patterson and Thompson 1971; Harville 1977; Laird and Ware 1982; Jennrich and Schluchter 1986). The LMIXED procedure implements two likelihood-based methods: maximum likelihood (ML) and restricted (residual) maximum likelihood (REML). A favorable theoretical property of ML and REML is that they accommodate data that are missing at random (Rubin 1976; Little 1995).

The LMIXED procedure constructs an objective function that is associated with ML or REML and maximizes it over all unknown parameters. Using calculus, it is possible to reduce this maximization problem to one over only the parameters in $\mathbf{G}$ and $\mathbf{R}$. The corresponding log-likelihood functions are as follows:

$$\text{ML}: \quad l(\mathbf{G},\mathbf{R}) = -\frac{1}{2}\log|\mathbf{V}| - \frac{1}{2}\mathbf{r}'\mathbf{V}^{-1}\mathbf{r} - \frac{n}{2}\log(2\pi)$$

$$\text{REML}: \quad l_R(\mathbf{G},\mathbf{R}) = -\frac{1}{2}\log|\mathbf{V}| - \frac{1}{2}\log|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}| - \frac{1}{2}\mathbf{r}'\mathbf{V}^{-1}\mathbf{r} - \frac{n-p}{2}\log(2\pi)$$

where $\mathbf{r} = \mathbf{y} - \mathbf{X}(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$, p is the rank of $\mathbf{X}$, and n is the total number of observations. By default, the LMIXED procedure minimizes a normalized form of -2 times these functions by using a ridge-stabilized Newton-Raphson algorithm. Lindstrom and Bates (1988) provide reasons for preferring Newton-Raphson to the expectation-maximum (EM) algorithm that is described in Dempster, Laird, and Rubin (1977) and Laird, Lange, and Stram (1987); in addition, they provide analytical details for implementing a QR-decomposition approach to the problem. Wolfinger, Tobias, and Sall (1994) present the sweep-based algorithms that are implemented in the LMIXED procedure. You can change the optimization technique by specifying the TECHNIQUE= option in the OPTIMIZATION statement.

One advantage of using the Newton-Raphson algorithm is that the second derivative matrix of the objective function that is evaluated at the optima is available upon completion. Denote this matrix as $\mathbf{H}$; then the asymptotic theory of maximum likelihood (Serfling 1980) shows that $2\mathbf{H}^{-1}$ is an asymptotic variance-covariance matrix of the estimated parameters of $\mathbf{G}$ and $\mathbf{R}$.

The residual variance σ^2 is *profiled* out of the likelihood by default. This means solving analytically for the optimal σ^2 and plugging this expression back into the likelihood formula (Wolfinger, Tobias, and Sall 1994). This reduces the number of optimization parameters by 1 and can improve convergence properties.

Instead of ML or REML, you can use the noniterative MIVQUE0 method to estimate $\mathbf{G}$ and $\mathbf{R}$ (Rao 1972; LaMotte 1973; Wolfinger, Tobias, and Sall 1994). In fact, by default PROC LMIXED uses MIVQUE0 estimates as starting values for the ML and REML methods when DMMETHOD=DENSE. However, Swallow and Monahan (1984) present simulation evidence that favors REML and ML over MIVQUE0.

Computing Methodologies for REML in the Mixed Model

As a high-performance procedure, PROC LMIXED can use the distributed and multithreading capabilities of your system (for more information, see the section "Computational Method" on page 944) to speed up the fitting process in some linear mixed models that use the restricted maximum likelihood (REML) and the maximum likelihood (ML) approaches. This section illustrates how to use multithreaded computing or the sparse matrix technique to compute the objective function in REML.

The restricted log likelihood is defined as

$$\text{REML}: \quad l_R(\mathbf{G},\mathbf{R}) = -\frac{1}{2}\log|\mathbf{V}| - \frac{1}{2}\log|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}| - \frac{1}{2}\mathbf{r}'\mathbf{V}^{-1}\mathbf{r} - \frac{n-p}{2}\log(2\pi)$$

where $\mathbf{r} = \mathbf{y} - \mathbf{X}(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$, p is the rank of $\boldsymbol{X}$, and n is the total number of observations.

The computational complexity resides mostly in calculating these components: $\log|\mathbf{V}|$, $\log|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}|$, and $\mathbf{r}'\mathbf{V}^{-1}\mathbf{r}$. In directly handling a matrix $\mathbf{V}$ of dimension $n \times n$, a large value of n poses difficulties in both storage and computation.

In some situations, the computation of these $\mathbf{V}$-related quantities can be greatly simplified, thus enabling parallel computing. When you have a common subject effect, the data can be subsetted and worked with in a smaller size. This leads to simplification of the REML function components,

$$\log|\mathbf{V}| = \sum_{i=1}^{s} \log|V_i|$$

$$\log|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}| = \log|\sum_{i=1}^{s}(X_i'V_i^{-1}X_i)|$$

where s is the number of levels in the common subject effect and V_i is the covariance matrix of response variables that belong to subject level i. Because summations enable parallel accumulation of the individual pieces, they are ideal for multithreaded and distributed computing. The $\mathbf{r}'\mathbf{V}^{-1}\mathbf{r}$ term is calculated as a by-product of the determinant of $\sum_{i=1}^{s}(X_i'V_i^{-1}X_i)$. This method is called the dense method and can be specified in the DMMETHOD=DENSE option in the PROC LMIXED statement.

If the model does not have a common subject effect, the restricted log likelihood is computed using the mixed model equations (Henderson 1984). The three components can be rewritten as:

$$\log|\mathbf{V}| + \log|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}| = \log|\mathbf{M}| + \log|\mathbf{G}| + \log|\mathbf{R}|$$

$$\mathbf{r}'\mathbf{V}^{-1}\mathbf{r} = \mathbf{y}'\mathbf{R}^{-1}\mathbf{y} - \widehat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{R}^{-1}\mathbf{y} - \widehat{\boldsymbol{\gamma}}'\mathbf{Z}'\mathbf{R}^{-1}\mathbf{y}$$

where $\mathbf{M}$ is

$$\begin{bmatrix} \mathbf{X}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{X}'\mathbf{R}^{-1}\mathbf{Z} \\ \mathbf{Z}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{Z}'\mathbf{R}^{-1}\mathbf{Z} + \mathbf{G}^{-1} \end{bmatrix}$$

Generally speaking, matrix $\mathbf{M}$ is large and computing it requires substantial memory. Fortunately, $\mathbf{M}$ is often very sparse in many real-world problems if you work with categorical variables that have many levels (sparsity in $\mathbf{X}$ and $\mathbf{Z}$). The LMIXED procedure uses sparse matrix techniques to compute the objective function; these techniques can be substantially more efficient than the dense approach. This method is called the sparse method and can be specified in the DMMETHOD=SPARSE option in the PROC LMIXED statement.

Estimating Fixed and Random Effects in the Mixed Model

The maximum likelihood (ML) and the restricted maximum likelihood (REML) methods provide estimates of $\mathbf{G}$ and $\mathbf{R}$, which are denoted $\widehat{\mathbf{G}}$ and $\widehat{\mathbf{R}}$, respectively. To obtain estimates of $\boldsymbol{\beta}$ and predicted values of $\boldsymbol{\gamma}$, the standard method is to solve the mixed model equations (Henderson 1984):

$$\begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} + \widehat{\mathbf{G}}^{-1} \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\boldsymbol{\gamma}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \\ \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

Assume that the covariance matrix of response variables is $\widehat{\mathbf{V}}$. Then the solutions can be written as

$$\widehat{\boldsymbol{\beta}} = (\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-}\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{y}$$

$$\widehat{\boldsymbol{\gamma}} = \widehat{\mathbf{G}}\mathbf{Z}'\widehat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X}\widehat{\boldsymbol{\beta}})$$

and have connections with empirical Bayes estimators (Laird and Ware 1982; Carlin and Louis 1996). Note that the $\boldsymbol{\gamma}$ are random variables and not parameters (unknown constants) in the model. Technically, determining values for $\boldsymbol{\gamma}$ from the data is thus a prediction task, whereas determining values for $\boldsymbol{\beta}$ is an estimation task.

Statistical Properties

If $\mathbf{G}$ and $\mathbf{R}$ are known, $\widehat{\boldsymbol{\beta}}$ is the best linear unbiased estimator (BLUE) of $\boldsymbol{\beta}$, and $\widehat{\boldsymbol{\gamma}}$ is the best linear unbiased predictor (BLUP) of $\boldsymbol{\gamma}$ (Searle 1971; Harville 1988, 1990; Robinson 1991; McLean, Sanders, and Stroup 1991). Here, "best" means it has minimum mean square error. The covariance matrix of $(\widehat{\boldsymbol{\beta}} - \boldsymbol{\beta}, \widehat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})$ is

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{X}'\mathbf{R}^{-1}\mathbf{Z} \\ \mathbf{Z}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{Z}'\mathbf{R}^{-1}\mathbf{Z} + \mathbf{G}^{-1} \end{bmatrix}^{-}$$

where $^{-}$ denotes a generalized inverse (Searle 1971).

However, $\mathbf{G}$ and $\mathbf{R}$ are usually unknown and are estimated by using one of the aforementioned methods. These estimates, $\widehat{\mathbf{G}}$ and $\widehat{\mathbf{R}}$, are therefore simply substituted into the preceding expression to obtain

$$\widehat{\mathbf{C}} = \begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} + \widehat{\mathbf{G}}^{-1} \end{bmatrix}^{-}$$

as the approximate variance-covariance matrix of $(\widehat{\boldsymbol{\beta}} - \boldsymbol{\beta}, \widehat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})$. In this case, the BLUE and BLUP acronyms no longer apply, but the word *empirical* is often added to indicate such an approximation. The appropriate acronyms thus become EBLUE and EBLUP.

McLean and Sanders (1988) show that $\widehat{\mathbf{C}}$ can also be written as

$$\widehat{\mathbf{C}} = \begin{bmatrix} \widehat{\mathbf{C}}_{11} & \widehat{\mathbf{C}}_{21}' \\ \widehat{\mathbf{C}}_{21} & \widehat{\mathbf{C}}_{22} \end{bmatrix}$$

where

$$\widehat{\mathbf{C}}_{11} = (\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-}$$
$$\widehat{\mathbf{C}}_{21} = -\widehat{\mathbf{G}}\mathbf{Z}'\widehat{\mathbf{V}}^{-1}\mathbf{X}\widehat{\mathbf{C}}_{11}$$
$$\widehat{\mathbf{C}}_{22} = (\mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} + \widehat{\mathbf{G}}^{-1})^{-1} - \widehat{\mathbf{C}}_{21}\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{Z}\widehat{\mathbf{G}}$$

Note that $\widehat{\mathbf{C}}_{11}$ is the familiar estimated generalized least squares formula for the variance-covariance matrix of $\widehat{\boldsymbol{\beta}}$.

Common Subject Effect

PROC LMIXED is designed to fit a subclass of large (in number of observations and number of levels in a subject) linear mixed models. The procedure takes advantage of distributed and multithreading capabilities of your system by working on subsets of the data in parallel, and it aggregates results in the estimation process, which can lead to substantial speed improvements. This subclass of models requires that the $\mathbf{G}$ matrix have a block-diagonal structure, meaning that the data can be grouped according to a subject effect. This subject effect is referred to as a "common subject effect."

The common subject effect should be the only subject effect that is used in a program, and it must be specified as the same SUBJECT= effect in all RANDOM statements.

For example, a model that has a single RANDOM statement with a SUBJECT= specification has a common subject effect by definition:

```
random intercept age / subject=student;
```

You can have multiple RANDOM statements. The same SUBJECT= effect is the common subject:

```
random time          / subject=student*school;
random intercept age / subject=student*school;
```

In contrast, a single RANDOM statement without SUBJECT= specification, as shown in the following statements, implies that the model does not have a common subject effect:

```
random time;
```

More than one subject effect appearing in a program, as shown in the following statements, implies that the model does not have a common subject effect:

```
random time          / subject=student*school;
random intercept age / subject=student;
```

If you have a variance component model (TYPE=VC), in some situations, you can use a random effect as a subject effect, which leads to the same model specification but with a common subject effect. For example, the following two RANDOM statements are equivalent (the second specification has a common subject effect in time):

```
random time;

random int / subject=time;
```

Another equivalency is that

```
random time          / subject=student*school;
random intercept age / subject=student;
```

can be rewritten as

```
random time*school     / subject=student;
random intercept   age / subject=student;
```

where the student becomes the common subject effect.

Computational Method

Distributed Computing

Distributed computing refers to the use of multiple autonomous computers that communicate through a secure network. Distributed computing solves computational problems by dividing them into many tasks, each of which is solved by one or more computers. Each computer in this distributed environment is called a node.

Multithreading

The LMIXED procedure allocates data to different threads and calculates design matrices by accumulating the contributions from all threads. The LMIXED procedure also computes the log likelihood by accumulating the contributions from all threads. In addition, operations on matrices such as sweeps might be multithreaded if the matrices are of sufficient size to realize performance benefits from managing multiple threads for the particular matrix operation.

For more information about how the LMIXED procedure uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Displayed Output

The following sections describe the output that the LMIXED procedure produces. The output is organized into various tables, which are discussed in the order of their appearance.

Model Information

The "Model Information" table describes the model, some of the variables it involves, and the method used in fitting it. The "Model Information" table also has a row labeled Fixed Effects SE Method. This row describes the method that was used to compute the approximate standard errors for the fixed-effects parameter estimates and related functions of them.

Class Level Information

The "Class Level Information" table lists the levels of every variable that is specified in the CLASS statement.

Dimensions

The "Dimensions" table lists the sizes of relevant matrices. This table can be useful in determining the requirements for CPU time and memory.

Number of Observations

The "Number of Observations" table shows the number of observations that were read from the data table and the number of observations that were used in fitting the model.

Optimization Information

The "Optimization Information" table displays important details about the optimization process.

The number of parameters that are updated in the optimization equals the number of parameters in this table minus the number of equality constraints. The number of constraints is displayed if you fix covariance parameters by specifying the HOLD= option in the PARMS statement. The LMIXED procedure also lists the number of upper and lower boundary constraints. The LMIXED procedure might impose boundary constraints for certain parameters, such as variance components and correlation parameters. If you specify the HOLD= option in the PARMS statement, covariance parameters have an upper and lower boundary equal to the parameter value.

Descriptive Statistics

The "Descriptive Statistics" table lists simple statistics such as means and standard deviations for the dependent variable, for each covariate in the MODEL statement, and for the weight variable in the WEIGHT statement.

Iteration History

The "Iteration History" table describes the optimization of the restricted log likelihood or log likelihood. The function to be minimized (the *objective function*) is $-2l$ for ML and $-2l_R$ for REML; the column name of the objective function in the "Iteration History" table is "-2 Log Like" for ML and "-2 Res Log Like" for REML. The minimization is performed by using a ridge-stabilized Newton-Raphson algorithm, and the rows of this table describe the iterations that this algorithm takes in order to minimize the objective function.

The Evaluations column of the "Iteration History" table tells how many times the objective function is evaluated during each iteration.

The Criterion column of the "Iteration History" table is, by default, a relative Hessian convergence quantity,

$$\frac{\mathbf{g}_k' \mathbf{H}_k^{-1} \mathbf{g}_k}{|f_k|}$$

where f_k is the value of the objective function at iteration k, $\mathbf{g}_k$ is the gradient (first derivative) of f_k, and $\mathbf{H}_k$ is the Hessian (second derivative) of f_k. If $\mathbf{H}_k$ is singular, then the LMIXED procedure uses the following relative quantity:

$$\frac{\mathbf{g}_k' \mathbf{g}_k}{|f_k|}$$

To prevent division by $|f_k|$, specify the ABSGCONV= option in the OPTIMIZATION statement. To use a relative function or gradient criterion, specify the FCONV= or GCONV= option, respectively.

The Hessian criterion is considered superior to function and gradient criteria because it measures orthogonality rather than lack of progress (Bates et al. 1987). Provided that the initial estimate is feasible and the maximum number of iterations is not exceeded, the Newton-Raphson algorithm is considered to have converged when

the criterion is less than the tolerance specified in the FCONV= or GCONV= option in the OPTIMIZATION statement (or less than the default tolerance value of 1E–8). If convergence is not achieved, the LMIXED procedure displays the estimates of the parameters at the last iteration.

A convergence criterion that is missing indicates that a boundary constraint has been dropped; it is usually not a cause for concern.

Convergence Status

The "Convergence Status" table displays the status of the iterative estimation process at the end of the optimization. The status appears as a message in the listing, and this message is repeated in the log. The ODS object "ConvergenceStatus" also contains several nonprinting columns that can be helpful in checking the success of the iterative process, in particular during batch processing. The Status variable takes on the value 0 for a successful convergence (even if the Hessian matrix is not positive definite). The values 1 and 2 of the Status variable indicate lack of convergence and infeasible initial parameter values, respectively. The variable pdG can be used to check whether the $\mathbf{G}$ matrix is positive definite.

The "Convergence Status" table is not produced for models that are not fit iteratively, such as for models that have no random effects or when the NOITER option is in effect.

Covariance Parameter Estimates

The "Covariance Parameter Estimates" table contains the estimates of the parameters in $\mathbf{G}$ and $\mathbf{R}$. (See the section "Estimating Covariance Parameters in the Mixed Model" on page 939.) Their values are labeled in the table along with Subject information if applicable. The estimates are displayed in the Estimate column and are the results of one of the following estimation methods: REML, ML, and MIVQUE0.

Fit Statistics

The "Fit Statistics" table provides some statistics about the estimated mixed model. Expressions for -2 times the log likelihood are provided in the section "Estimating Covariance Parameters in the Mixed Model" on page 939. If the log likelihood is an extremely large number, then the LMIXED procedure has deemed the estimated $\mathbf{V}$ matrix to be singular. In this case, all subsequent results should be viewed with caution.

In addition, the "Fit Statistics" table lists three information criteria: AIC, AICC, and BIC. All these criteria are in smaller-is-better form and are described in Table 17.17.

Table 17.17 Information Criteria

Criterion	Formula	Reference
AIC	$-2\ell + 2d$	Akaike (1974)
AICC	$-2\ell + 2dn^*/(n^* - d - 1)$	Hurvich and Tsai (1989) Burnham and Anderson (1998)
BIC	$-2\ell + d \log n$ for $n > 0$	Schwarz (1978)

Here ℓ denotes the maximum value of the (possibly restricted) log likelihood; d is the dimension of the model; and n equals the number of effective subjects as displayed in the "Dimensions" table unless this value equals 1, in which case n equals the number of levels of the first random effect that is specified in the first RANDOM statement or the number of levels of the interaction of the first random effect with the noncommon

subject effect that is specified in the first RANDOM statement. If the number of effective subjects equals 1 and you have no RANDOM statements, then n equals the number of valid observations for maximum likelihood estimation or equals $n - p$ for restricted maximum likelihood estimation, where p equals the rank of $\mathbf{X}$. For AICC (a finite-sample corrected version of AIC), n^* equals the number of valid observations for maximum likelihood estimation and $n - p$ equals the number of valid observations for restricted maximum likelihood estimation, unless this number is less than $d + 2$, in which case it equals $d + 2$. When $n = 0$, the value of the BIC is -2ℓ. For restricted likelihood estimation, d equals q, the effective number of estimated covariance parameters. For maximum likelihood estimation, d equals $q + p$.

Timing Information

If you specify the TIMING option in the PROC LMIXED statement, the procedure also produces a "Timing" table in which the elapsed time for each main task of the procedure is displayed.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the LMIXED procedure creates has a name associated with it, and you must use this name to refer to the table when you use ODS statements. These names are listed in Table 17.18.

NOTE: The EFFECT statement also create tables which are not listed in this section. For information about these tables, see "ODS Table Names" on page 33 in Chapter 2, "Shared Concepts."

Table 17.18 ODS Tables Produced by PROC LMIXED

Table Name	Description	Required Statements	Required Option
Anova	Anova table for model without random effects	Default output for fixed models	
CholR	Cholesky root of blocks of the estimated **R** matrix	REPEATED	RC
ClassInfo	Level information from the CLASS	CLASS

Examples: LMIXED Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

Example 17.1: Mixed Model Analysis of Microarray Data

(View the complete code for this example (lmixedeg1.sas) in the example repository.)

Microarray experiments are an advanced genomic technique that is used in the discovery of new treatments for diseases. Microarray analysis enables tens of thousands of genes to be detected in a single DNA sample. A microarray is a glass slide or membrane that has been spotted or "arrayed" with DNA fragments (oligonucleotides) that represent specific genes. The response of the gene that is detected by a spot is proportional to the intensity of fluorescence associated with that spot. These gene responses can indicate associations with disease conditions, but they can also be affected by systematic biases and different treatments such as sex and genotypes. Statistical models for microarray data attempt to assess the significance and magnitude of gene effects across treatments while adjusting for these systematic biases and to evaluate the significance of differences between treatments.

There are two statistical approaches frequently used in mixed model analysis for microarray data. The first approach is to fit multiple gene-specific models to data that are normalized for systematic biases (Wolfinger et al. 2001; Gibson and Wolfinger 2004). This approach is based on assuming that the biases are independent from the gene effects. If this assumption is untenable, then a second approach fits a single model that combines both the systematic biases and the gene effects (Kerr, Martin, and Churchill 2000; Churchill 2002; Littell et al. 2006). When the number of genes is very large (several hundreds to tens of thousands), this is an analysis for which the sparse matrix approach that the LMIXED procedure implements is well suited.

The following SAS statements simulate a microarray experiment with a so-called loop design structure, which is commonly used in such studies. There are 500 genes, each gene occurs in six arrays, and each array has two dyes. You are interested in the best five and worst five genes based on the best linear unbiased predicted values (BLUP) of these 500 genes.

                         + sqrt(0.02)*rannor(12345);
                output;
             end;
          end;
       end;
    end;
run;
```

A linear mixed model for fitting the log intensity data Y_{ijkmnr} from such a design is described by Littell et al. (2006) as follows:

Y_{ijkmnr}	$=$		**Fixed Effects**
		μ	Overall mean
	$+$	λ_i	Gene
	$+$	τ_j	Treatment
	$+$	δ_k	Dye
	$+$	$(\tau\lambda)_{ij}$	Treatment-by-gene
	$+$	$(\delta\lambda)_{ik}$	Dye-by-gene
	$+$	p_r	Pin
			Random Effects
	$+$	a_m	Microarray
	$+$	$(a\lambda)_{im}$	Microarray-by-gene
	$+$	$d(a)_{mn}$	Dip-within-microarray
	$+$	$(ap)_{mr}$	Microarray-by-pin
	$+$	e_{ijkmnr}	Residual noise

You can use the LMIXED procedure with the following statements to fit this model:

```
ods select Dimensions covParms SolutionR;
proc lmixed data=mylib.microarray dmmethod=sparse;
   class marray dye trt gene pin dip;
   model log2i = dye trt gene dye*gene trt*gene pin;
   random int gene dip pin/subject=marray s;
   ods output solutionr=BLUPs;
run;
```

By default, because the program has a RANDOM statement with a SUBJECT= effect, PROC LMIXED uses the dense method (see the section "Common Subject Effect" on page 943) in the restricted maximum

likelihood (REML) estimation. However, because the design matrices are excessively large with **X** having 4,513 columns and **Z** having 3,054 columns (see table Output 17.1.1), the program can potentially exceed your computer's memory capacity. Here the sparse method (DMMETHOD=SPARSE) is used to improve the handling of these large and sparse design matrices.

Output 17.1.1 Mixed Model Dimensions

The LMIXED Procedure

Dimensions	
G-side Covariance Parameters	4
R-side Covariance Parameters	1
Columns in X	4513
Columns in Z per Subject	509
Subjects (Blocks in V)	6

Output 17.1.2 shows the "Covariance Parameter Estimation" table, which lists the estimations of covariances across each microarray.

Output 17.1.2 Covariance Parameter Estimation

Covariance Parameter Estimates		
Cov Parm	Subject	Estimate
Intercept	MArray	0.003096
Gene	MArray	0.001901
Dip	MArray	0.001924
Pin	MArray	0.03371
Residual		0.02008

The following program ranks genes on the basis of their BLUP estimates.

```
ods output off;
proc sort data=BLUPs(firstobs=2 obs=501);
    by descending Estimate;
run;

data BLUPs; set BLUPs;
   Rank = _N_;
run;
ods output on;

proc print data=BLUPs;
   where ((Rank <= 5) | (Rank >= 496));
   var Gene Estimate;
run;
```

The best five genes and worst five genes with their BLUP estimates are shown in Output 17.1.3.

Output 17.1.3 Highest and Lowest Gene BLUPs

Obs	Gene	Estimate
1	198	0.06753
2	268	0.06071
3	354	0.05124
4	489	0.04883
5	478	0.04558
496	383	-0.04642
497	333	-0.04684
498	351	-0.04846
499	54	-0.05353
500	144	-0.05541

Overview: LOGSELECT Procedure

The LOGSELECT procedure fits and performs model selection for logistic regression models in SAS Viya, including binary, binomial, and multinomial response models.

The models that PROC LOGSELECT supports can contain main effects that consist of both continuous and classification variables and interaction effects of these variables. The models can also include constructed effects such as splines. The procedure offers a number of effect-selection methods, including stepwise methods and modern LASSO methods. It also offers extensive capabilities for customizing the model selection by using a wide variety of selection and stopping criteria, from computationally efficient significance-level-based criteria to modern, computationally intensive validation-based criteria. PROC LOGSELECT also provides a variety of logistic regression diagnostics that are conditional on the selected model.

Logistic regression analysis is often used to investigate the relationship between discrete responses and a set of explanatory variables. The LOGSELECT procedure fits logistic regression models in the broader sense; the procedure permits several link functions and can handle ordinal and nominal response data that have more than two response categories (multinomial data).

The logistic model shares a common feature with a more general class of linear models: a function $g = g(\mu)$ of the mean of the response variable is assumed to be linearly related to the explanatory variables. Because the mean μ implicitly depends on the stochastic behavior of the response and the explanatory variables are assumed to be fixed, the function g provides the link between the random (stochastic) component and the

systematic (deterministic) component of the response variable Y. For this reason, Nelder and Wedderburn (1972) refer to $g(\mu)$ as a link function. The LOGSELECT procedure fits a broad class of binary response models of the form

$$g(\pi \mid \mathbf{x}) = \alpha + \boldsymbol{\beta}'\mathbf{x}$$

where the link functions that are available in PROC LOGSELECT and that are widely used in practice are the logit, probit, log-log, and complementary log-log functions, and the predicted probability of an event, π, is the mean μ of the response variable. One advantage of the logit function over other link functions is that differences on the logistic scale are interpretable regardless of whether the data are sampled prospectively or retrospectively (McCullagh and Nelder 1989, Chapter 4).

If your response Y has more than two values and they can be ordered (for example, $Y \in \{1, \ldots, J-1, J\}$), then the LOGSELECT procedure uses the preceding link functions and fits ordinal response models of the form

$$g(\pi_j \mid \mathbf{x}) = \alpha_j + \boldsymbol{\beta}'\mathbf{x}, \quad j = 1, \ldots, J-1$$

where $\pi_j = \Pr(Y \leq j)$ are cumulative probabilities of the ordered response categories.

If your response Y has more than two values and they have no natural ordering, then the LOGSELECT procedure fits a generalized or baseline-category logit model, which has the form

$$\log\left(\frac{\Pr(Y = j \mid \mathbf{x})}{\Pr(Y = J \mid \mathbf{x})}\right) = \alpha_j + \boldsymbol{\beta}_j'\mathbf{x}, \quad j = 1, \ldots, J-1$$

where the $\boldsymbol{\beta}_1, \ldots, \boldsymbol{\beta}_{J-1}$ are J–1 vectors of slope parameters. These models are a special case of the discrete choice or conditional logit models introduced by McFadden (1974).

The LOGSELECT procedure can also fit models to correlated responses by using the generalized estimating equations (GEE) method. PROC LOGSELECT supports many of the correlation structures from Liang and Zeger (1986).

Texts that discuss logistic regression include Agresti (2013); Allison (2012); Collett (2003); Cox and Snell (1989); Hosmer and Lemeshow (2013); Stokes, Davis, and Koch (2012).

PROC LOGSELECT Features

The LOGSELECT procedure estimates the parameters of a logistic regression model by using maximum likelihood techniques. It also does the following:

- provides model-building syntax with the CLASS, EFFECT, and effect-based MODEL statements, which are familiar from SAS/STAT analytic procedures (in particular, the GLM, LOGISTIC, GLIMMIX, and MIXED procedures)
- provides response-variable options as in the LOGISTIC procedure
- performs maximum likelihood estimation
- provides the logit, probit, log-log, and complementary log-log link functions
- provides cumulative link models for ordinal response data and generalized logit modeling for unordered multinomial data

- supports repeated measures analysis by using generalized estimating equations (GEEs) for binomial and binary response functions
- enables model building (variable selection) through the SELECTION statement
- provides a WEIGHT statement for weighted analysis
- provides a FREQ statement for grouped analysis
- provides a CODE statement to produce SAS code that can score a new data set
- provides an OUTPUT statement to produce a data table that contains predicted probabilities and other observationwise statistics
- uses ODS Graphics to create model selection plots as part of its output. For more information about ODS Graphics, see the section "ODS Graphics" on page 1046.

Because the LOGSELECT procedure runs on CAS, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode on CAS
- exploits all the available cores and concurrent threads. For information about how PROC LOGSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC LOGSELECT Compared with Other SAS Procedures

The LOGSELECT procedure provides logistic regression modeling functionality that is comparable to that of the HPLOGISTIC and LOGISTIC procedures in SAS/STAT software.

PROC LOGSELECT Compared with the HPLOGISTIC Procedure

The functionality of the LOGSELECT procedure closely resembles that of the HPLOGISTIC procedure, which is a high-performance procedure. The LOGSELECT procedure is the next generation of the HPLOGISTIC procedure, and it was developed specifically for SAS Viya. Both procedures are designed to run on a cluster of machines that distribute the data and the computations. Both procedures perform computations in multiple threads.

The LOGSELECT procedure provides all the model-fitting methods and postprocessing results that the HPLOGISTIC procedure provides. In addition, PROC LOGSELECT provides the full set of parameterizations available in PROC LOGISTIC and other modeling procedures; the ability to create complex constructed effects, including univariate spline and polynomial expansions; LASSO selection; elastic net selection; selection plots by using ODS Graphics; more regression diagnostics than PROC HPLOGISTIC produces; and odds ratios.

PROC LOGSELECT Compared with the LOGISTIC Procedure

The LOGSELECT procedure provides the full set of parameterizations that are available in PROC LOGISTIC. The LOGSELECT procedure uses the GLM parameterization for the CLASS variables by default. The LOGISTIC procedure uses the EFFECT parameterization for the CLASS variables by default. In either procedure, you can use the PARAM= option in the CLASS statement to change the parameterization.

The LOGISTIC procedure uses Fisher scoring by default. The LOGSELECT procedure uses a modification of the Newton-Raphson algorithm with a ridged Hessian by default. You can choose different optimization

techniques, including first-order methods that do not require a crossproducts matrix or Hessian, by using the TECHNIQUE= option in the PROC LOGSELECT statement.

The LOGSELECT procedure provides a richer set of model selection options than the LOGISTIC procedure, including LASSO selection, elastic net selection, information-criterion-based selection and stopping criteria, and validation-based criteria.

The LOGSELECT procedure uses ODS Graphics to display plots that help interpret the selection process; the LOGISTIC procedure displays many diagnostic and fit plots.

The LOGISTIC procedure offers a wide variety of postfitting analyses, such as contrasts, estimates, tests of model effects, and least squares means. The LOGSELECT procedure is limited in postfitting functionality, because for large data sets the focus is primarily on model fitting and scoring.

The LOGISTIC procedure provides an AGGREGATE option to compress your data before computing chi-square goodness-of-fit diagnostic statistics. To compute the same diagnostics with the LOGSELECT procedure, you have to aggregate your data appropriately before invoking the procedure, and you have to specify your model by using the events/trials or multinomial-trial syntax.

The LOGSELECT procedure is designed to operate in SAS Viya and performs computations in multiple threads. The LOGISTIC procedure executes in a single thread on a single machine.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: LOGSELECT Procedure

Binary Logistic Regression

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/loggs1.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The following DATA step creates the data table getStarted, which consists of 100 observations on a dichotomous response variable (y), a character variable (C), and 10 continuous variables (x1–x10):

```
data mylib.getStarted;
   input C$ y x1-x10;
   datalines;
   D  0  10.2  6  1.6  38  15  2.4  20  0.8  8.5  3.9
   F  1  12.2  6  2.6  42  61  1.5  10  0.6  8.5  0.7
   D  1   7.7  1  2.1  38  61    1  90  0.6  7.5  5.2
   J  1  10.9  7  3.5  46  42  0.3   0  0.2    6  3.6
   E  0  17.3  6  3.8  26  47  0.9  10  0.4  1.5  4.7

;
```

These statements assume that the CAS engine libref is named mylib, but you can substitute any appropriately named CAS engine libref.

The following statements fit a logistic model to these data by using a classification effect for variable C and 10 regressor effects for x1–x10. The ITHIST option displays a table that summarizes the steps of the optimization.

```
proc logselect data=mylib.getStarted ithist;
   class C;
   model y = C x1-x10;
run;
```

The output from this analysis is presented in Figure 18.1 through Figure 18.10.

Figure 18.1 displays the "Model Information" table. The LOGSELECT procedure uses a Newton-Raphson algorithm to model a binary distribution with a logit link function for the variable y. The CLASS variable C is parameterized using the GLM parameterization, which is the default.

Figure 18.1 Model Information

The LOGSELECT Procedure

Model Information	
Data Source	GETSTARTED
Response Variable	y
Distribution	Binary
Link Function	Logit
Optimization Technique	Newton-Raphson with Ridging

Figure 18.2 displays the "Number of Observations" table. All 100 observations in the data table are used in the analysis.

Figure 18.2 Number of Observations

Number of Observations Read	100
Number of Observations Used	100

The "Response Profile" table in Figure 18.3 is produced by default. It shows the breakdown of the response variable levels by frequency. By default for binary data, the LOGSELECT procedure models the probability of the event with the lower OrderedValue value in the "Response Profile" table, as indicated by the note that follows the table. In this example, the values that are represented by y = 0 are modeled as the "successes" in the Bernoulli experiments.

Figure 18.3 Response Profile

Response Profile

Ordered Value	y	Total Frequency
1	0	69
2	1	31

Probability modeled is y = 0.

You can use the response-variable options in the MODEL statement to choose which value of the response variable to model.

The CLASS variable C has 10 unique formatted levels that are displayed in the "Class Level Information" table in Figure 18.4.

Figure 18.4 Class Level Information

Class Level Information

Class	Levels	Values
C	10	A B C D E F G H I J

The "Iteration History" table is shown in Figure 18.5. The Newton-Raphson algorithm with ridging converged after four iterations, not counting the initial setup iteration.

Figure 18.5 Iteration History

Iteration History

Iteration	Evaluations	Objective Function	Change	Maximum Gradient
0	4	0.4493546916		0.410972
1	2	0.4436453992	0.00570929	0.081339
2	2	0.4435038109	0.00014159	0.003302
3	2	0.4435035933	0.00000022	5.623E-6
4	2	0.4435035933	0.00000000	1.59E-11

Figure 18.6 displays the final convergence status of the Newton-Raphson algorithm. The GCONV= relative convergence criterion is satisfied.

Figure 18.6 Convergence Status

Convergence criterion (GCONV=1E-8) satisfied.

Figure 18.7 displays the "Dimensions" table for this model. This table summarizes some important sizes of various model components. For example, it shows that the design matrix **X** has 21 columns, which correspond to 1 column for the intercept, 10 columns for the effect associated with the classification variable C, and 1 column each for the continuous variables x1–x10. However, the rank of the crossproducts matrix is only 20. Because the classification variable C uses GLM parameterization and because the model contains an intercept, there is one singularity in the crossproducts matrix of the model. Consequently, only 20 parameters enter the optimization.

Figure 18.7 Dimensions in Binary Logistic Regression

Dimensions	
Columns in Design	21
Number of Effects	12
Max Effect Columns	10
Rank of Design	20
Parameters in Optimization	20

Figure 18.8 shows the global test for the null hypothesis that all model effects jointly do not affect the probability of success of the binary response. The test is significant ($p = 0.0135$). One or more of the model effects thus significantly affect the probability of observing an event.

Figure 18.8 Null Test

Testing Global Null Hypothesis: BETA=0			
Test	**DF**	**Chi-Square**	**Pr > ChiSq**
Likelihood Ratio	19	35.1194	0.0135

The "Fit Statistics" table is shown in Figure 18.9. The –2 log likelihood at the converged estimates is 88.7007. You can use this value to compare the model to nested model alternatives by means of a likelihood ratio test. To compare models that are not nested, you can use information criteria such as AIC (Akaike's information criterion), AICC (Akaike's bias-corrected information criterion), and SBC (Schwarz Bayesian information criterion). These criteria penalize the –2 log likelihood for the number of parameters. Because of the large number of parameters relative to the number of observations, the discrepancy between the –2 log likelihood and, for example, AIC is substantial in this case.

Figure 18.9 Fit Statistics

Fit Statistics	
-2 Log Likelihood	88.70072
AIC (smaller is better)	128.70072
AICC (smaller is better)	139.33363
SBC (smaller is better)	180.80412

However, the "Parameter Estimates" table in Figure 18.10 shows that many parameters have fairly large p-values, indicating that one or more of the model effects might not be necessary.

Figure 18.10 Parameter Estimates

Parameter Estimates

Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
Intercept	1	1.210139	1.750750	0.4778	0.4894

Model Fitting	0.13	47.57%
Display	0.00	0.57%
Cleanup	0.00	0.00%
Total	0.27	100.00%

Syntax: LOGSELECT Procedure

The following statements are available in the LOGSELECT procedure:

PROC LOGSELECT < *options* > **;**
BY *variables* **;**
CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**
CODE < *options* > **;**
DISPLAY < *table-list* > < / *options* > **;**
DISPLAYOUT *table-spec-list* < / *options* > **;**
EFFECT *name***=***effect-type***(***variables* < / *options* >**)** **;**
FREQ *variable* **;**
MODEL *response*< **(***response-options***)** > **=** < *effects* > < / *model-options* > **;**
MODEL *events/trials* **=** < *effects* > < / *model-options* > **;**
MODEL *response-level1 response-level2*< . . . *response-levelJ* > **=** < *effects* > < / *model-options* > **;**
LSMEANS *model-effects* < / *options* > **;**
ODDSRATIO < *variable* < **(***options***)** > >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**
OUTPUT OUT=*libref.data-table* < *options* > < *keyword* < **=***name* > >. . . < *keyword* < **=***name* > > **;**
PARTITION *partition-options* **;**
REPEATED SUBJECT=*subject-effect* < / *repeated-options* > **;**
RISK < *variable-list* > < / *options* > **;**
SELECTION < **METHOD=***method*< **(***method-options***)** > >< *options* > **;**
STORE < **OUT=** >*libref.data-table* **;**
WEIGHT *variable* < / **NORMALIZE** > **;**

The CLASS statement can appear multiple times. If a CLASS statement is specified, it must precede the MODEL statement. If an LSMEANS statement is specified, it must follow the MODEL statement.

PROC LOGSELECT Statement

PROC LOGSELECT < *options* > **;**

The PROC LOGSELECT statement invokes the procedure. Table 18.1 summarizes the available *options* in the PROC LOGSELECT statement by function.

Table 18.1 PROC LOGSELECT Statement Options

Option	Description
ALPHA=	Specifies a global significance level
APPLYROWORDER	Uses group and order information from the input data table
BINEPS=	Specifies the precision for computing association and classification statistics
DATA=	Specifies the input data table
FITDATA	Declares the DATA= table to be the same input data table used to build the model
MAXRESPONSELEVELS=	Specifies the maximum number of response levels allowed when you have a polytomous response variable

Table 18.1 *continued*

Option	Description
MULTIPASS=	Specifies whether to levelize the data table every time it is read
PAGEOBS=	Specifies the maximum number of observations to be computed in each batch
RESTORE=	Specifies the input analytic store
SEED=	Specifies the random number seed for LS-means and partition fractions
Output Options	
ASSOCIATION	Produces association statistics
CLB	Constructs confidence limits for the parameter estimates
CORRB	Displays the "Parameter Estimates Correlation Matrix" table
COVB	Displays the "Parameter Estimates Covariance Matrix" table
CTABLE	Produces classification (ROC) statistics
ITHIST	Displays the "Iteration History" table
LACKFIT	Produces the Hosmer-Lemeshow goodness-of-fit test
NOCHECK	Disables checking for infinite parameters
NOCLPRINT	Limits or suppresses the display of class levels
NOSTDERR	Suppresses computation of the covariance matrix and standard errors
NOXPX	Suppresses computation of the Hessian matrices
PARTFIT	Displays the fit statistics that are produced when your data are partitioned
PLCONV=	Controls the convergence criterion for profile-likelihood confidence limits
PLMAXITER=	Specifies the maximum number of iterations for profile-likelihood confidence limits
PLSINGULAR=	Specifies the singularity tolerance for profile-likelihood confidence limits
STB	Displays standardized estimates
TYPE3	Produces the Type 3 or joint tests of effects
USELASTITER	Continues computations when the optimization fails
Optimization Options	
ABSCONV=	Tunes the absolute function convergence criterion
ABSFCONV=	Tunes the absolute function difference convergence criterion
ABSGCONV=	Tunes the absolute gradient convergence criterion
ABSXCONV=	Tunes the absolute parameter convergence criterion
FCONV=	Tunes the relative function difference convergence criterion
FCONV2=	Tunes the second relative function difference convergence criterion
GCONV=	Tunes the relative gradient convergence criterion
GCONV2=	Tunes the second relative gradient convergence criterion
INPARMEST=	Specifies starting values for the optimization
XCONV=	Tunes the relative gradient convergence criterion
MAXFUNC=	Specifies the maximum number of function evaluations in any optimization
MAXITER=	Specifies the maximum number of iterations in any optimization
MAXTIME=	Specifies the upper limit of CPU time (in seconds) for any optimization
MINITER=	Specifies the minimum number of iterations in any optimization
NORMALIZE=	Specifies whether the objective function is normalized during optimization
TECHNIQUE=	Selects the optimization technique

Table 18.1 *continued*

Option	Description
LASSO Options	
LASSORHO=	Specifies the base regularization parameter for the LASSO method
LASSOSTEPS=	Specifies the maximum number of steps for the LASSO method
LASSOTOL=	Specifies the convergence criterion for the LASSO method

The optimization options are fully described in the section "Optimization Options" on page 57 in Chapter 2, "Shared Concepts." The following list describes the other options available in the PROC LOGSELECT statement:

ALPHA=*number*

specifies a global significance level for the construction of confidence intervals. The confidence level is 1–*number*. The value of *number* must be between 0 and 1. You can override the global specification by specifying the ALPHA= option in the OUTPUT statement. By default, ALPHA=0.05.

APPLYROWORDER

uses group and order information from the input data table. You can add this information to the input table by using the **`partition`** action in the **`table`** action set. For more information, see the section "The APPLYROWORDER Option" on page 107 in Chapter 2, "Shared Concepts." By default, the APPLYROWORDER option is not enabled. If you specify this option but the table does not contain group and order information, the procedure terminates with an error.

NOTE: You can use group and order information for a repeated measures analysis if the group information meets certain criteria. For more information, see the section "Using a Preexisting Table Order" on page 1019.

ASSOCIATION

displays measures of association between predicted probabilities and observed responses for binary, binomial, and ordinal response models. These measures assess the predictive ability of the model. The displayed statistics are the concordance index *c* (the area under the ROC curve, AUC), Somers' *D* statistic (Gini's coefficient), the Goodman-Kruskal gamma statistic, and Kendall's tau-*a* statistic. These statistics are based on the number of pairs of observations that have different response values, the number of concordant pairs, and the number of discordant pairs. For more information, see the section "Association Statistics" on page 1024.

BINEPS=*number*

specifies the precision to use for the association, classification, and LACKFIT option computations. The predicted probabilities or scores are rounded to the nearest multiple of *number*, which effectively bins and sorts the observations. You can specify a *number* between 0 and 1; if *number* does not evenly divide the unit interval, then it is reduced to a valid value. By default, BINEPS=1E–5. For more information, see the section "Classification Table and ROC Curves" on page 1022.

CLB< =WALD | PL >
displays Wald confidence limits for each of the parameter estimates. If you specify CLB=PL, then profile-likelihood confidence limits are also displayed. The confidence level is 0.95 by default; you can change it by specifying the ALPHA= option. This option is not available when you use either LASSO selection or elastic net selection.

CORRB
creates the "Parameter Estimates Correlation Matrix" table. The correlation matrix is computed by normalizing the covariance matrix $\mathbf{\Sigma}$. That is, if σ_{ij} is an element of $\mathbf{\Sigma}$, then the corresponding element of the correlation matrix is $\sigma_{ij}/\sigma_i\sigma_j$, where $\sigma_i = \sqrt{\sigma_{ii}}$. The option is not available when you use either LASSO selection or elastic net selection.

COVB
creates the "Parameter Estimates Covariance Matrix" table. The covariance matrix is computed as the inverse of the negative of the matrix of second derivatives of the log-likelihood function with respect to the model parameters (the Hessian matrix). The option is not available when you use either LASSO selection or elastic net selection.

CTABLE< (*options*) >
displays a table for binary or binomial response models that, for a set of probabilities or cutpoints, contains the frequencies of observations that are correctly and incorrectly classified as events and nonevents, and optionally the sensitivity, the 1–specificity, the positive and negative predictive values, the correct classification rate, the error rate, and the lift.

Because the number of cutpoints that are generated from your data can be very large, you can write the classification table to an output data table, or you can specify your own list of cutpoints.

If you specify the PRIOR= option, then the reported predicted probabilities are unchanged, but the statistics that are specified by the keywords PPV, NPV, PC, ACCURACY, MISCLASS, and LIFT are modified.

If you specify a PARTITION statement, then a table is created for each role. If you do not specify the PRIOR= option, then the training proportions are used as the prevalences for computing the statistics that are specified by the keywords PPV, NPV, PC, ACCURACY, MISCLASS, and LIFT for the validation and test data.

You can specify the following *options*. For more information, see the section "Classification Table and ROC Curves" on page 1022.

ALL
requests all the statistics that are listed in Table 18.2.

CUTPT=*number-list*
specifies cutpoints to include in the classification table.

NOCOUNTS
suppresses the classification table columns that contain the number of true positives, the number of true negatives, the number of false positives, and the number of false negatives.

OUT=*libref.data-table*
suppresses the display of the classification table and names the output data table in which to store the classification table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 963.

keyword **<** **=***name* **>**
specifies statistics to include in the classification table and optionally names the statistics. If you do not provide a *name*, the LOGSELECT procedure uses the *keyword* as the *name*. Table 18.2 lists the available *keywords*.

Table 18.2 CTABLE Option Keywords

Keyword	Description
ACCURACY	Requests and names the accuracy
FNF	Requests and names the false negative fraction
FPF	Requests and names the false positive fraction. Also called 1–specificity.
LIFT	Requests and names the lift
MISCLASS	Requests and names the misclassification rate. Also called the error rate.
NPV	Requests and names the negative predictive value
PC	Requests and names the proportion classified correctly
PPV	Requests and names the positive predictive value. Also called the precision.
TNF	Requests and names the true negative fraction. Also called the specificity.
TPF	Requests and names the true positive fraction. Also called the sensitivity or recall.

DATA=*libref.data-table*
names the input data table for PROC LOGSELECT to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 963.

data-table specifies the name of the input data table.

FITDATA
declares the DATA= table to be the same input data table that is used for building the model, when you also specify the RESTORE= option. The FITDATA option enables you to specify the PARTFIT option to produce more fit statistics, to compute all the statistics from the OUTPUT statement that are available for your model, and to group computations according to the partition roles.

INPARMEST=*libref.data-table*
names an input data table that contains starting values. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 963.

The input data table must contain an Estimate column and a ParmName column, and it can optionally contain your BY variables. You can create a version of this table by using a DISPLAYOUT statement to produce the "Parameter Estimates" table from a PROC LOGSELECT program. For example:

```
displayout parameterestimates=pe;
```

You can then modify the parameter estimates in this table and copy them back in by using the following statement:

```
proc logselect inparmest=mylib.pe;
```

ITHIST
generates the "Iteration History" table.

LACKFIT<(*options***)>**
performs the Hosmer-Lemeshow goodness-of-fit test for binary and polytomous response models (Hosmer and Lemeshow 2000; Fagerland, Hosmer, and Bofin 2008; Fagerland and Hosmer 2013, 2016). The subjects are divided into at most G groups of approximately the same size. You can specify G as any integer greater than or equal to 5; by default, $G = 10$. The discrepancies between the observed and expected numbers of observations in these groups are summarized by the Pearson chi-square statistic, which is then compared to a chi-square distribution. The number of degrees of freedom that PROC LOGSELECT uses for this test depends on the specified model; you can override this number by specifying a nonnegative integer, df, and by modifying the reduction, r. A small p-value suggests that the fitted model is not an adequate model. For more information, see the section "The Hosmer-Lemeshow Goodness-of-Fit Test" on page 1032.

The following *options* are available:

CUTPT=*value-list*
specifies a list of cut points for grouping the subjects.

DF=*df*
specifies the number of degrees of freedom of the test, where $df \geq 1$. By default, $df = G - r$.

DFREDUCE=*r*
specifies the reduction in degrees of freedom. This option is ignored when you specify the DF= option. By default, DFREDUCE=2.

NGROUPS=*G*
specifies the number of groups in which to divide the subjects. You can specify $G \geq 5$. By default, NGROUPS=10.

NONCENTRALITY=*value*
requests that a noncentral chi-square test be performed, where *value* is the noncentrality parameter.

POWERADJ
for binary response data, chooses the number of groups G to maintain the same power as grouping 1,000 observations into 10 groups (Paul, Pennell, and Lemeshow 2013). If you have fewer than 1,000 observations, then $G = 10$ groups are used. If you have 1,000 to 25,000 observations, then the number of groups that are formed is

$$\max\left(10, \min\left(\frac{n_e}{2}, \frac{n_n}{2}, 2 + 8\left(\frac{n}{1000}\right)^2\right)\right)$$

where $n = n_e + n_n$ is the number of observations, n_e is the number of events, and n_n is the number of nonevents. If you have more than 25,000 observations, then this option is ignored.

LASSORHO=*r*
specifies the base regularization parameter for the LASSO model selection method. The regularization parameter for step i is r^i. By default, LASSORHO=0.8.

LASSOSTEPS=*n*
specifies the maximum number of steps for LASSO model selection. By default, LASSOSTEPS=20.

LASSOTOL=*r*
specifies the convergence tolerance for the optimization algorithm that solves for the LASSO parameter estimates at each step of LASSO model selection. By default, LASSOTOL=1E–6.

MAXRESPONSELEVELS=*value*
specifies the maximum number of response levels that are allowed when you have a polytomous response variable. By default, MAXRESPONSELEVELS=100.

MULTIPASS=TRUE | FALSE
specifies when to levelize the data—that is, when to generate the design rows for your model from the data. The default, MULTIPASS=FALSE, levelizes the data once and stores them in a temporary data table, then rereads the data from that table as needed; this method is fast but uses more memory. MULTIPASS=TRUE levelizes the data every time they are read; this method is slower but uses less memory. The MULTIPASS= option does not affect how the OUTPUT statement is processed. When MULTIPASS=TRUE, you can also use the PAGEOBS= option to improve performance.

NOCHECK
disables the checking process that determines whether maximum likelihood estimates of the regression parameters exist. For more information, see the section "Existence of Maximum Likelihood Estimates" on page 1013.

NOCLPRINT<=*number*>
suppresses the display of the "Class Level Information" table if you do not specify *number*. If you specify *number*, the values of the classification variables are displayed for only those variables whose number of levels is less than *number*. Specifying *number* helps to reduce the size of the "Class Level Information" table if some classification variables have a large number of levels.

NOSTDERR
suppresses computation of the covariance matrix and the standard errors of the regression coefficients. When the model contains many variables (thousands), the inversion of the Hessian matrix to derive the covariance matrix and the standard errors of the regression coefficients can be time-consuming. The CORRB, COVB, and TYPE3 options, and the OUTPUT statement options for confidence limits, are not available when the NOSTDERR option is specified. This option also disables the quasi-complete separation check; for more information, see the section "Existence of Maximum Likelihood Estimates" on page 1013.

NOXPX
suppresses Hessian and $\mathbf{X}'\mathbf{X}$ computations and invokes the NOSTDERR option. When the model contains many variables (thousands), computing the Hessian matrix during model fitting can be time-consuming. The CLB, CORRB, COVB, and TYPE3 options, the REPEATED statement, the OUTPUT statement options that rely on the covariance, and confidence limits for the parameters and for the ODDSRATIO, OUTPUT, RISK, and LSMEANS statements are not available when you specify the NOXPX option. The forward, backward, and stepwise selection methods are not available; however, you can specify the LASSO and elastic net methods. This option invokes the TECHNIQUE=LBFGS option by default, and the NEWRAP, NRRIDG, and TRUREG optimization techniques are not available. Because the method of identifying linearly dependent variables relies on the $\mathbf{X}'\mathbf{X}$ matrix, some parameters that should be assigned 0 degrees of freedom can be missed. This option also disables the quasi-complete separation check; for more information, see the section "Existence of Maximum Likelihood Estimates" on page 1013.

PAGEOBS=*number* | AUTO

MAXOPTBATCH=*number* | AUTO
specifies the maximum number of observations to be included in a batch. During the optimization, the LOGSELECT procedure reads at most *number* observations from the data table into memory, performs the appropriate log-likelihood, gradient, and Hessian computations on that batch of observations, then discards those observations and reads in the next batch of data for processing. Generally, a smaller *number* decreases memory usage but might lead to longer computation times, whereas a larger *number* might lead to shorter computation times but increases memory usage. The default PAGEOBS=AUTO option determines whether the entire data table can be conveniently held in memory; if it cannot, then *number* is set to 256. The PAGEOBS= option has the most benefit when you also specify the MULTIPASS=TRUE option; however, it can adversely affect performance when the default MULTIPASS=FALSE option is in effect. For more information, see the section "Memory Usage" on page 1036.

PARTFIT
displays fit statistics in the "Fit Statistics" table that are usually produced when your data are partitioned. This option is not required when you specify a PARTITION statement.

The additional statistics include the R-square, the adjusted R-square, McFadden's R-square, the average square error (Brier score), the misclassification rate, the null-model log likelihood, and the difference in means.

PLCONV=*value*
controls the convergence criterion for computing profile-likelihood confidence intervals. The *value* is a positive number. By default, PLCONV=1E–4. This option has no effect if you do not request profile-likelihood confidence intervals.

PLMAXITER=*number*
specifies the maximum number of iterations for profile-likelihood confidence interval searches. By default, PLMAXITER=25. If you do not reach convergence in *number* iterations, the confidence limit is set to missing. This option has no effect if you do not request profile-likelihood confidence intervals.

PLSINGULAR=*value*
specifies the tolerance for testing the singularity of the Hessian matrices that are computed during the profile-likelihood confidence interval searches. The test requires that a pivot for sweeping this matrix be at least the *value* times a norm of the matrix, where *value* is greater than 0. By default, *value* is the machine epsilon times 1E7, which is approximately 1E–9. This option has no effect if you do not request profile-likelihood confidence intervals.

RESTORE=*libref.data-table*
specifies the name of the analytic store that contains the context and results of a model that is selected and stored from a previous statistical analysis. The analytic store is created by a STORE statement from a previous PROC LOGSELECT call or by a **`store`** parameter that is specified in a previous **`logistic`** action call.

The displayed output can include the following content:

- information about the analytic store
- notes that are stored by the TEXT= option of the STORE statement
- a Replay section, consisting of tables that are produced when the stored model is fit
- a Restore section, consisting of tables that are produced by applying the stored model to a specified input data table

See Example 18.7 for further discussion of these outputs.

You can specify the STB and CLB options in the PROC LOGSELECT statement to modify the "Parameter Estimates" table; you can specify the CORRB, COVB, and TYPE3 options to display those tables; you can specify the CODE statement to produce SAS code for scoring; you can specify LSMEANS statements to compute least squares means; and you can specify ODDSRATIO statements to compute odds ratios. If you specify a DATA= data table, then you can also specify the ASSOCIATION, CTABLE, LACKFIT, and PARTFIT options, and you can score that data table by specifying the OUTPUT statement.

If the analytic store is created using BY-group processing, then the results are displayed according to each BY group. If you specify a DATA= input data table, then you must also specify the same BY statement that was used to create the store.

If a PARTITION statement is used to create the stored model, then the Replay section displays only information that is computed from the original training data. For the Restore section, if you create the partition for the stored model by using a ROLE variable and also specify the FITDATA option, then the ROLE variable must exist in the DATA= table and the Restore section displays results according to the roles. However, if the partitions for the stored model are created using a FRACTION option, then the roles are ignored because the roles cannot be reliably re-created; this means that output statistics that rely on the input data are not computed.

Because the selected model from a previous analysis is stored, statements and options specific to model specification, selection, and optimization are not available. In particular, the CLASS, EFFECT, FREQ, MODEL, PARTITION, REPEATED, SELECTION, STORE, and WEIGHT statements are not available to be used with the RESTORE= option, and the MULTIPASS= option is always set to TRUE.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 963.

SEED=*number*

specifies an integer to be used to start the pseudorandom number generator for the LSMEANS statement's ADJUST=SIMULATE option and for the PARTITION statement's FRACTION option. If you do not specify a seed, or if you specify a *number* less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

STB

displays the standardized estimates of the parameters in the "Parameter Estimates" table. The standardized estimate of β_i is given by $\widehat{\beta}_i/(s/s_i)$, where s_i is the total sample standard deviation for the ith explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{LOGIT and GLOGIT links} \\ 1 & \text{PROBIT link} \\ \pi/\sqrt{6} & \text{CLOGLOG and LOGLOG links} \end{cases}$$

The sample standard deviations for parameters that are associated with CLASS variables are computed using their codings. The standardized estimates are not computed for the intercept parameters.

TYPE3

computes Wald statistics for Type 3 contrasts for each effect that you specify in the MODEL statement. This option is not available when you specify a REPEATED statement. The option is also not available when you use either LASSO selection or elastic net selection. For more information, see the section "Joint Tests and Type 3 Tests" on page 1031.

USELASTITER

continues to perform computations by using the last iteration of the optimization when the optimization fails. By default, computations cease when a failure occurs.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC LOGSELECT to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CLASS Statement

CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. You can list the response variable for binary models in the CLASS statement, but this is not required. Table 18.3 summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section "CLASS Statement" on page 9 in Chapter 2, "Shared Concepts."

Table 18.3 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable
SPLIT	Splits levels of CLASS variables into independent effects

CODE Statement

CODE < *options* > **;**

The CODE statement writes SAS DATA step code for computing predicted values of the fitted model to a file or to a table. To score new data, you can then include the file in a DATA step, or you can specify the table in the **`runCodeTable`** action in the **`dataStep`** action set (for more information, see *SAS Viya: System Programming Guide*).

Table 18.4 summarizes the *options* available in the CODE statement.

Table 18.4 CODE Statement Options

Option	Description
COMMENT	Adds comments to the generated code
FILE=	Names the file in which to save the generated code
FORMATWIDTH=	Specifies the numeric format width for the regression coefficients
INDENTSIZE=	Specifies the number of spaces to indent the generated code
IPROB	Computes individual predicted probabilities for ordinal response models
LABELID=	Specifies a number used to construct names and labels
LINESIZE=	Specifies the line size for the generated code
NOTRIM	Compares formatted values, including blank padding
OUT=	Names an output table in which to save the generated code
PCATALL	Generates probabilities for all levels of categorical response variables

For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1044. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected.

Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value*	specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.
key	specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1044. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

EFFECT Statement

EFFECT *name*=*effect-type* **(***variables* < / *options* >**) ;**

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 67 in Chapter 2, "Shared Concepts."

You can specify the following *effect-types*:

COLLECTION specifies a collection effect that defines one or more variables as a single effect that has multiple degrees of freedom. The variables in a collection are considered as a unit for purposes of estimation and inference.

MULTIMEMBER | MM specifies a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.

POLYNOMIAL | POLY specifies a multivariate polynomial effect in the specified numeric variables.

SPLINE specifies a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 18.5 summarizes the *options* available in the EFFECT statement.

Table 18.5 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Multimember Effects Options	
DETAILS	Displays the levels of the multimember effect
NOEFFECT	Specifies that observations whose levels are all missing for the multimember variables should have 0 values in the corresponding design matrix columns
STDIZE	Standardizes the design matrix entries so that each observation has a sum of 1
WEIGHT=	Specifies the weight variable for the contributions of each classification effect

Table 18.5 *continued*

Option	Description
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect with multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots starting at the variables' maximum and ending at the KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots starting at the KNOTMIN= value and ending at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect
SEPARATE	Treats the spline basis for each variable as a separate effect when multiple variables are specified
SPLIT	Treats each design matrix column as a separate effect for selection methods

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 18 in Chapter 2, "Shared Concepts."

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC LOGSELECT treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1.

LSMEANS Statement

LSMEANS *model-effects* < / *options* > **;**

LSMEANS EFFECT=*model-effects* < / *options* > **;**

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

LS-means can be computed for any effect in the procedure's MODEL statement that involves only classification variables. You can specify multiple *model-effects* in one or more LSMEANS statements that appear after the MODEL statement. When you restore a model from an item store, you must specify the desired *model-effects* in the EFFECT= option before the slash (/).

Table 18.6 summarizes the *options* available in the LSMEANS statement.

Table 18.6 LSMEANS Statement Options

Option	Description
Construction and Computation of LS-Means	
AT	Modifies covariate values used to compute LS-means
ATVAR	Modifies covariate values for restored models
DIFF	Computes differences of LS-means
SINGULAR=	Tunes estimability checking
***p*-Values**	
ADJUST=	Specifies the multiple comparison adjustment method for LS-means differences
ALPHA=α	Specifies the confidence level ($1-\alpha$)
Statistical Output	
CL	Constructs confidence limits for means and mean differences
CORR	Displays the correlation matrix of LS-means
COV	Displays the covariance matrix of LS-means
E	Displays the **L** matrix

For more information about the syntax of the LSMEANS statement, see the section "LSMEANS Statement" on page 34 in Chapter 2, "Shared Concepts."

LS-means analysis is not available if you use LASSO or elastic net selection.

MODEL Statement

MODEL *response* < **(***response-options***)** > **=** < *effects* > < / *model-options* > **;**

MODEL *events* / *trials* **=** < *effects* > < / *model-options* > **;**

MODEL *response-level1 response-level2* < . . . *response-levelJ* > **=** < *effects* > < / *model-options* > **;**

The MODEL statement defines the statistical model in terms of a response or target, model *effects* that are constructed from variables in the input data table, and *model-options*. An intercept is included in the model by default. You can remove the intercept by specifying the NOINT option.

Three forms of the response can be specified. For the first form, *single-trial* syntax, you can specify a single *response* variable that contains your response values. Single-trial syntax is used when each observation in the DATA= data table contains information about only a single trial, such as a single subject in an experiment, and is applicable to binary, ordinal, and nominal response data.

The second form, *events/trials* syntax, is applicable to binomial response data, where one variable contains the number of positive responses (or events) and another variable contains the number of trials. Note that the values of both *events* and (*trials* – *events*) must be nonnegative and the value of *trials* must be positive.

The third form, *multinomial-trial* syntax, is used when each observation contains information about multiple trials, and you have one variable (*response-level1*) that contains the number of responses in the first level, another variable (*response-level2*) that contains the number of responses in the second level, and so on. The last level in the response-level list is the reference level. Multinomial-trial syntax is applicable to binomial, ordinal, and nominal response data. Note that the values of the *response-level1* through *response-levelJ* variables must be nonnegative.

For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

There are two sets of options in the MODEL statement. The *response-options* determine how the LOGSELECT procedure models probabilities for binary and multinomial data when you use single-trial syntax. The *model-options* control other aspects of model formation and inference. Table 18.7 summarizes these options.

Table 18.7 MODEL Statement Options

Option	Description
Response Variable Options	
DESCENDING	Reverses the response categories
EVENT=	Specifies the event category
ORDER=	Specifies the sort order
REF=	Specifies the reference category
Model Options	
CENTER	Centers and scales continuous main effects
CENTERLASSO	Centers and scales all effects for model selection by the LASSO method and the elastic net method
CLB	Requests Wald confidence limits
INCLUDE=	Includes effects in all models for model selection

Table 18.7 *continued*

Option	Description
INFORMATIVE	Models missing values by using extra indicator variables
LINK=	Specifies the link function
NOINT	Suppresses the intercept
OFFSET=	Specifies the offset variable
PRIOR=	Specifies prior probabilities
START=	Includes effects in the initial model for model selection
TYPE3	Displays the Type 3 or joint tests of effects

Response Variable Options

Response variable options determine how the LOGSELECT procedure models probabilities for binary and multinomial response data when you specify single-trial syntax. You can specify the following *response-options* by enclosing them in parentheses after the *response* or *trials* variable. These options are not available with multinomial-trial syntax.

DESCENDING
DESC
reverses the order of the response categories. If you specify both the DESCENDING and ORDER= options, PROC LOGSELECT orders the response categories according to the ORDER= option and then reverses that order.

EVENT='*category*' | **FIRST** | **LAST**
specifies the event category for the binary response model. PROC LOGSELECT models the probability of the event category. The EVENT= option has no effect when there are more than two response categories.

You can specify one of the following:

'*category*'
specifies the value (formatted, if a format is applied) of the event category in quotation marks.

FIRST
designates the first ordered category as the event.

LAST
designates the last ordered category as the event.

By default, EVENT=FIRST.

For example, the following statements specify that observations with the formatted value '1' represent events in the data. The probability that the LOGSELECT procedure models is thus the probability that the variable def takes on the (formatted) value '1'.

```
proc logselect data=mylib.MyData;
   class A B C;
   model def(event ='1') = A B C x1 x2 x3;
run;
```

ORDER=FORMATTED | FREQ | INTERNAL | '*level1*' '*level2*' . . .
specifies the sort order for the levels of the *response* variable. When ORDER=FORMATTED for numeric variables for which you have supplied no explicit format (that is, for which there is no corresponding FORMAT statement in the current PROC LOGSELECT run or in the DATA step that created the data table), the levels are ordered by their internal (numeric) value. The following table shows how to interpret the ORDER= keywords:

ORDER=	Levels Sorted By
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value; the sort order is machine-dependent.
FREQ	Descending frequency count (levels with the most observations come first in the order)
INTERNAL	Unformatted value; the sort order is machine-dependent.

By default, ORDER=FORMATTED.

You can also specify a particular order for the response variable by listing the levels in quotes in the desired order. For example:

```
model pet(order = 'dog' 'cat') = ...;
```

Any level of the pet variable that you do not specify is added to the end of the list in formatted order.

The ORDER= option does not apply to missing values, which are always ordered first.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Programmers Guide: Essentials*.

REF='*category*' **| FIRST | LAST**
specifies the reference category for the generalized logit model and the binary response model. For the generalized logit model, each logit contrasts a nonreference category with the reference category. For the binary response model, specifying one response category as the reference is the same as specifying the other response category as the event. You can specify one of the following:

'*category*'
specifies the value (formatted, if a format is applied) of the reference category in quotation marks.

FIRST
designates the first ordered category as the reference.

LAST
designates the last ordered category as the reference.

By default, REF=LAST.

Model Options

CENTER

requests that continuous main effects be centered and scaled internally. (Continuous main effects are centered and scaled to aid in computing maximum likelihood estimates.) Parameter estimates and related statistics are always reported on the original scale. This option has no effect if you specify the LASSO model selection method or the elastic net selection method; instead, you should specify the CENTERLASSO option.

CENTERLASSO< =TRUE | FALSE >

specifies whether all effects, including categorical effects, are centered and scaled internally for the LASSO model selection method or the elastic net selection method. (Effects are centered and scaled to aid in model selection by the LASSO method and the elastic net method.) Parameter estimates and related statistics are always reported on the original scale. By default, CENTERLASSO=TRUE.

CLB

displays Wald confidence limits for each of the parameter estimates. The confidence level is 0.95 by default; you can change it by specifying the ALPHA= option. The CLB option is not available when you use either LASSO selection or elastic net selection.

INCLUDE=*n*

INCLUDE=*single-effect*

INCLUDE=(*effect-list***)**

forces effects to be included in all models. If you specify INCLUDE=*n*, then the first *n* effects that are listed in the MODEL statement are included in all models. If you specify INCLUDE=*single-effect* or if you specify INCLUDE=(*effect-list*), then the specified effects are forced into all models. The effects that you specify in this option must be explanatory effects that are specified in the MODEL statement before the slash (/). This option is not available if you use elastic net selection.

INFORMATIVE

models missing values by using extra model effects. These effects consist of dummy variables that take the value 1 when the value of a continuous model variable involved in the effect is missing, and take the value 0 otherwise. The missing value in the original model effect is replaced by the average value of the effect for the nonmissing values. For continuous-by-class effects, such as A*x, where A is a classification variable and x is a continuous variable, informative missingness creates multiple dummy columns and substitutes the effect mean of x that corresponds to the respective level of A. Missing values for classification variables are treated as valid levels. For more information about informative missingness, see the section "Informative Missingness" on page 99 in Chapter 2, "Shared Concepts."

LINK=*keyword*

specifies the link function for the model. The default link is the logit. The *keywords* and the associated link functions are shown in Table 18.8.

Table 18.8 Built-In Link Functions of the LOGSELECT Procedure

Keyword	Link Function	$g(\pi) = \eta =$
CLOGLOG | CLL	Complementary log-log	$\log(-\log(1-\pi))$
GLOGIT	Generalized logit	$\log(\pi_j/\pi_J)$
LOGIT	Logit	$\log(\pi/(1-\pi))$
LOGLOG	Log-log	$-\log(-\log(\pi))$
PROBIT	Probit	$\Phi^{-1}(\pi)$

For the probit and cumulative probit links, $\Phi^{-1}(\cdot)$ denotes the quantile function of the standard normal distribution.

If the response variable has more than two categories, the LOGSELECT procedure fits a model that has a cumulative link function that is based on the specified link. However, if you specify LINK=GLOGIT, the procedure assumes a generalized logit model for nominal (unordered) data.

NOINT
requests that no intercept be included in the model. An intercept is included by default. The NOINT option is not available for multinomial models.

OFFSET=*variable*
specifies a *variable* to be used as an offset to the linear predictor. An offset plays the role of an effect whose coefficient is known to be 1. The offset variable cannot appear in the CLASS statement or elsewhere in the MODEL statement. Observations that have missing values for the offset variable are excluded from the analysis.

PRIOR=*number* | *number-list*
specifies prior probabilities (prevalences) that are used for computing posterior predicted probabilities. When you know what percentage of the population has a rare event and you oversample that rare event, specifying the prior probabilities as the prevalence of events in your population enables you to produce posterior probabilities that reflect the population, not the data. The priors do not affect the model-fitting process.

If you specify a *number-list* that has the same number of entries as there are response levels, then these values are scaled to sum to 1. If you specify a *number-list* that has one entry less than there are response levels, then the specified values should sum to less than 1, and the last response level is assigned the remaining value. For binary and binomial response models, you can thus specify the probability of an event as a single *number*. The scaled priors are displayed in the ResponseProfile table.

If your response Y takes values $i = 1, \ldots, k$ that have observed empirical training probabilities $\mathrm{OldPrior}_i = \frac{n_i}{n}$, you specify priors Prior_i, and your model predicted probabilities are $\hat{p}_i$, then the posterior predicted probabilities Post_i are computed as

$$\mathrm{Post}_i = \frac{\hat{p}_i \frac{\mathrm{Prior}_i}{\mathrm{OldPrior}_i}}{\sum_{j=1}^{k} \hat{p}_j \frac{\mathrm{Prior}_j}{\mathrm{OldPrior}_j}}$$

The POST= option in the OUTPUT statement writes the posterior to the output data table. If your priors are identical to the empirical probabilities, then the posteriors are identical to the model-predicted probabilities.

The priors adjust the "Classification" table statistics PPV, NPV, adequacy, percentage correct, misclassification rate, and lift as discussed in the section "Classification Table and ROC Curves" on page 1022. If you specify a PARTITION statement, then the posterior probabilities and the preceding statistics for the validation and test data also use the specified priors.

START=*n*

START=*single-effect*

START=(*effects***)**

begins the selection process from the designated initial model for the forward and stepwise selection methods. If you specify START=*n*, then the starting model includes the first *n* effects that are listed in the MODEL statement. If you specify START=*single-effect* or if you specify START=(*effects*), then the starting model includes those specified effects. The effects that you specify in the START= option must be explanatory effects that are specified in the MODEL statement before the slash (/). This option is not available when you specify METHOD=BACKWARD in the SELECTION statement or when you specify METHOD=ELASTICNET in the SELECTION statement.

TYPE3

computes Wald statistics for Type 3 contrasts for each effect that is specified in the MODEL statement. This option is not available when you specify a REPEATED statement. For more information, see the section "Joint Tests and Type 3 Tests" on page 1031.

ODDSRATIO Statement

ODDSRATIO < *variable* < **(***options***)** > > . . . < *variable* < **(***options***)** > > < / *global-options* > **;**

The ODDSRATIO statement produces odds ratios for each odds ratio *variable* that you use in your model even when the odds ratio variable is involved in interactions with other variables or is used by a constructed effect. You can specify at most one ODDSRATIO statement. If you do not specify any odds ratio *variables*, then odds ratios are computed for every variable in the model. Odds ratio estimation is not available if you use elastic net selection. For more information, see the section "Odds Ratio Estimation" on page 1033.

If your odds ratio *variable* is continuous, then by default the odds ratios compare the base subpopulation to one where that continuous variable is one unit larger. If your odds ratio *variable* is a classification variable, then by default the odds ratios compare each level of the odds ratio variable to its reference level.

If an odds ratio *variable* interacts with another variable, then the computed odds ratio depends on the value of the interacting variable. By default, interacting continuous variables are set to their means, and interacting classification variables are set to their reference level. The computed odds ratios are independent of the parameterization of any classification variable.

You can specify *options* for each individual odds ratio variable by enclosing the options in parentheses after the variable name. You can change the default options by specifying *global-options* after a slash (/). *Global-options* are applied to all the odds ratio variables; however, individual odds ratio variable *options* override the *global-options*.

You can specify the following *options* for the individual odds ratio requests in parentheses after the odds ratio *variable*:

AT(*var***=***var-options* **<...** *var***=***var-options***>)**
enables you to specify fixed values or levels for a variable in the model when it interacts with the odds ratio variable. The following *var-options* are enabled when the *var* variable interacts with the odds ratio variable:

value-list
specifies fixed values for the variable *var* when *var* interacts with the odds ratio variable.

When *var* is a continuous variable, you can specify one or more numbers in the *value-list*. By default, continuous variables are set to their means. When *var* is a classification variable, you can specify one or more formatted levels of the variable enclosed in single quotes (for example, **A='cat' 'dog'**). By default, CLASS variables are set to their reference level. For example, if your model includes a classification variable A={cat,dog} and a continuous variable B, then specifying either of the following statements (the second uses a *global-option*) sets A to 'cat' and sets B to 7 and then 9:

```
oddsratio X ( AT( A='cat' B=7 9 ) );
oddsratio X / AT( A='cat' B=7 9 );
```

When *var* is a continuous variable, the values in the *value-list* are also used to construct SPLINE and POLYNOMIAL effects of that variable.

REF
specifies the reference level of *var* when *var* is a classification variable. This is the default for classification variables.

ALL
specifies every level of *var* when *var* is a classification variable.

UNIT=*unit-list*
specifies one or more numbers that represent the units of change for a continuous odds ratio variable so that you can produce customized odds ratios. An estimate of the corresponding odds ratio is displayed for each specified unit of change. The UNIT= *option* is ignored for CLASS *variables*. For example, specifying either of the following statements (the second uses a *global-option*) requests an odds ratio that represents the change in the odds when the variable *X* is increased by two units:

```
oddsratio X ( UNIT=2 );
oddsratio X / UNIT(X=2);
```

By default, UNIT=1.

STDERR
indicates that the units of change specified in the *unit-list* of the UNIT= option represent multiples of the sample standard error of the odds ratio variable, based on the observations that are used to fit the model. If you specify the STDERR option without the UNIT= option, then the unit of change is 1 standard error.

You can also specify the following *global-options* after a slash (/):

ALPHA=*number*
sets the significance level for producing confidence intervals. The ALPHA= value that you specify in the PROC LOGSELECT statement is the default. If neither ALPHA= value is specified, then by default ALPHA=0.05.

AT(*var***=***var-options* **< . . .** *var***=***var-options* **>)**
enables you to specify fixed levels or values for variables in the model that might interact with the odds ratio variable. See the AT= individual option for more information.

CL< =WALD | PL >
displays Wald confidence limits. If you specify CL=PL, then profile-likelihood confidence limits are also displayed. The confidence level is 0.95 by default; you can change it by specifying the ALPHA= option.

DIFF=REF | ALL
specifies whether the odds ratios for a classification odds ratio variable are computed against the reference level, or whether all pairs of the odds ratio variable's levels are compared. By default, DIFF=REF. The DIFF= option has no effect when the odds ratio variable is continuous.

UNIT(*var***=***unit-list* **< . . .** *var***=***unit-list* **> < STDERR >)**
enables you to change the default units of change for continuous odds ratio variables. You specify *var* as the name of the continuous variable and *unit-list* as a list of the units. The STDERR option indicates that the *unit-list* represents multiples of the sample standard error of the variable. See the UNIT= and STDERR individual options for more information.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< *options* >
< *keyword* < **=***name* > > . . . < *keyword* < **=***name* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics that PROC LOGSELECT computes after fitting the model. In order to avoid data duplication for large data tables, the variables in the input data table are *not* included in the output data table unless you specify them in the COPYVAR= option.

If your response variable has more than two categories, you can request the "Basic Options" listed in Table 18.9; the other diagnostic statistics are not available unless you use multinomial-trial syntax. These statistics are computed for every response category, and the automatic variable _LEVEL_ identifies the response category on which the computed values are based. That is, every observation generates several rows in the output data set. If you also specify the OBSCAT option, then the observationwise statistics are computed only for the observed response category, which is indicated by the value of the _LEVEL_ variable. If you specify the PREDPROBS option, then only the PRED and IPRED statistics are output to the data table, and a variable is created to contain the values that correspond to each response category. PROC LOGSELECT names these variables by concatenating the PRED= or IPRED= *name* with the response category.

If you use multinomial-trial syntax, then the PREDPROBS option is invoked by default, and all the "Diagnostic Options" listed in Table 18.9 (except for the RESWORK statistic) are available as output to the data table. However, if you also specify the NOPREDPROBS option, then only the RESCHI, RESDEV, and RESRAW statistics are available.

The output statistics are computed based on the final parameter estimates. If the optimization does not converge, then the output data table is not created. If you perform elastic net or LASSO selection, or if you specify the NOXPX or NOSTDERR option, then your analysis does not generate a covariance matrix, and you cannot produce the basic and diagnostic statistics in Table 18.9 that require a covariance matrix.

For observations in which only the response variable is missing, values of the linear predictor and the predicted probabilities are computed even though these observations do not affect the model fit. This enables, for example, predicted probabilities to be computed for new observations.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC LOGSELECT to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 963.

data-table specifies the name of the output data table.

You can also specify the following options:

ALL
ALLSTAT
adds all available statistics to the output data table.

ALPHA=*number*
specifies the significance level for the construction of confidence intervals in the output data table. The confidence level is $1 - number$. The value of *number* must be between 0 and 1. By default, *number* is equal to the value of the ALPHA= option in the PROC LOGSELECT statement, or 0.05 if that option is not specified.

COPYVAR=*variable*
COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table.

FIXEDOFFSET=*number*
specifies a value to use as an offset to the linear predictor instead of obtaining the value from the offset variable. This option is ignored unless you also specify the OFFSET= variable in the MODEL statement.

OBSCAT
requests (for multinomial models) that observationwise statistics be produced only for the observed response level. If you do not specify this option and the response variable has J levels, then the following outputs are created: for cumulative link models, J–1 records are output for every observation in the input data that corresponds to the J–1 lower-ordered response categories; for generalized logit models, J records are output that correspond to all J response categories. This option is not available with multinomial-trial syntax.

PREDPROBS | NOPREDPROBS

creates variables (for multinomial models) for each response category that corresponds to the requested IPRED and PREDICTED keywords. If you use multinomial-trial syntax, then the PREDPROBS option is invoked by default and enables computation of most of the "Diagnostic Options" listed in Table 18.9. You can override this behavior by specifying the NOPREDPROBS option.

keyword **<=***name***>**

specifies a statistic to include in the output data table and optionally names the variable *name*. If you do not provide a *name*, the LOGSELECT procedure assigns a default name based on the type of statistic requested. If a statistic is not available for your model then that request is ignored.

Table 18.9 summarizes the *keywords* that are available in the OUTPUT statement.

Table 18.9 OUTPUT Statement Keywords

Keyword	Description	Default Name
Basic Options		
INDIVIDUAL	Specifies the individual predicted probabilities	_IPRED_
POST	Specifies the posterior predicted probabilities	_POST_
PREDICTED	Specifies the predicted probabilities	_PRED_
RESRAW	Specifies the raw residual	_RESRAW_
XBETA	Specifies the linear predictor	_XBETA_
Basic Options Requiring the Covariance		
LCL	Specifies the lower confidence limit for the linear predictor	_LCL_
LCLM	Specifies the lower confidence limit for the event probability	_LCLM_
STDXBETA	Specifies the standard error estimate of the linear predictor	_STDXBETA_
UCL	Specifies the upper confidence limit for the linear predictor	_UCL_
UCLM	Specifies the upper confidence limit for the event probability	_UCLM_
Diagnostic Options		
RESCHI	Specifies the Pearson chi-square residual	_RESCHI_
RESDEV	Specifies the deviance residual	_RESDEV_
RESWORK	Specifies the working residual	_RESWORK_
Diagnostic Options Requiring the Covariance		
CBAR	Specifies the confidence interval displacement	_CBAR_
DIFCHISQ	Specifies the deletion chi-square goodness-of-fit change	_DIFCHISQUARE_
DIFDEV	Specifies the deletion deviance change	_DIFDEVIANCE_
H	Specifies the leverage	_HATDIAG_
RESLIK	Specifies the likelihood residual	_RESLIK_
STDRESCHI	Specifies the standardized Pearson chi-square residual	_STDRESCHI_
STDRESDEV	Specifies the standardized deviance residual	_STDRESDEV_
Option for Generalized Estimating Equations		
CLEVERAGE	Names the cluster leverage	_CLEVERAGE_

Table 18.9 *continued*

Keyword	Description	Default Names
Miscellaneous Options		
INTO	Names the level into which the observation is classified	_INTO_
LEVEL	Names the response level for a row of the output	_LEVEL_
ROLE	Names the role played by the observation in fitting the model	_ROLE_

The following list describes these *keywords*. For more information, see the section "Predicted Probabilities and Regression Diagnostics" on page 1026.

CBAR
specifies the confidence interval displacement diagnostic that measures the overall change in the global regression estimates that results from deleting an individual observation. The default name is _CBAR_.

CLEVERAGE

CH

CLEV
specifies the cluster leverage for GEEs. For more information about diagnostic statistics, see the section "Diagnostics for Models Fit by Generalized Estimating Equations (GEEs)" on page 1030. The default name is _CLEVERAGE_.

DIFCHISQ
specifies the change in the chi-square goodness-of-fit statistic that results from deleting the individual observation. The default name is _DIFCHISQUARE_.

DIFDEV
specifies the change in the deviance that results from deleting the individual observation. The default name is _DIFDEVIANCE_. This statistic is not supported for GEEs.

H
specifies the diagonal element of the hat matrix $\mathbf{H}$ (leverage) for detecting extreme points in the design space. For GEEs, the leverage value is the corresponding diagonal element of the cluster leverage matrix. The default name is _HATDIAG_.

If you use multinomial-trial syntax and do not specify the NOPREDPROBS option, then the relevant portion of the hat matrix for observation i is a J–1-dimensional submatrix $\mathbf{H}_i$. Three statistics are computed from this submatrix: the determinant of $\mathbf{I}_{J-1} - \mathbf{H}_i$, the average diagonal element of $\mathbf{H}_i$, and the potential (average diagonal element of $(\mathbf{I}_{J-1} - \mathbf{H}_i)^{-1}\mathbf{H}_i$). These statistics are identified in the output table by appending the letters 'D', 'T', and 'P', respectively, to the provided *name*; by default, their names are _H_D, _H_T, and _H_P.

INDIVIDUAL

IPRED

IPROB

IP

specifies the individual predicted values for the multinomial response levels. For a response variable Y with three levels, 1, 2, and 3, the individual probabilities are $\Pr(Y = 1)$, $\Pr(Y = 2)$, and $\Pr(Y = 3)$. The default name is _IPRED_.

INTO< (*cutpoint*) >

names the variable that contains the level of the response into which an observation is classified. The default name is _INTO_. Multinomial models classify observations into the level that has the largest model-predicted probability. For binary or binomial response variables, if the predicted probability of an observation equals or exceeds the cutpoint, the observation is classified as an event; otherwise it is classified as a nonevent. You can specify the *cutpoint* value as a number between 0 and 1. The default value is 0.5.

LCL

LOWERXBETA

names the variable that contains the lower confidence limits for the linear predictor. You can set the confidence level by specifying the ALPHA= option. The default name is _LCL_.

LCLM

LOWERMEAN

LOWER

specifies the lower confidence limits for the probability of the event. You can set the confidence level by specifying the ALPHA= option. The default name is _LCLM_.

LEVEL

names the variable that contains the level of the response for a given row of the output. The default name is _LEVEL_.

POSTERIOR

POST

specifies the posterior predicted probability of each observation. If you do not specify the PRIOR= option in the MODEL statement, then the observed proportions from the training data are used as priors, in which case the posteriors from the training data are the same as the individual predicted probabilities. The default name is _POST_.

PREDICTED

PRED

PROB

P

specifies the predicted values (predicted probabilities of events) for binary and nominal response variables and the cumulative predicted probabilities for ordinal response variables. For a response variable Y with three levels, 1, 2, and 3, the cumulative probabilities are $\Pr(Y \leq 1)$ and $\Pr(Y \leq 2)$, but by default the last level, $\Pr(Y \leq 3) = 1$, is not output. The default name is _PRED_.

RESCHI

PEARSON

specifies the Pearson residual for identifying poorly fitted observations. The default name is _RESCHI_.

RESDEV

specifies the deviance residual for identifying poorly fitted observations. The default name is _RESDEV_. This statistic is not supported for GEEs.

RESLIK

specifies the likelihood residual for identifying poorly fitted observations. The default name is _RESLIK_. This statistic is not supported for GEEs.

RESRAW

RESIDUAL

R

specifies the raw residual for identifying poorly fitted observations. The default name is _RESRAW_.

RESWORK

specifies the working residual for identifying poorly fitted observations. This statistic is not available for multinomial response models. The default name is _RESWORK_.

ROLE

specifies the numeric variable that indicates the role played by each observation in fitting the model. The default name is _ROLE_. Table 18.10 shows how this variable is interpreted for each observation.

Table 18.10 Role Interpretation

Value	Observation Role
0	Not used
1	Training
2	Validation
3	Testing

If you do not partition the input data by specifying a PARTITION statement, then the role variable value is 1 for observations that are used in fitting the model and 0 for observations that have at least one missing or invalid value for the response, regressor, frequency, or weight variables.

STDRESCHI

specifies the standardized Pearson (chi-square) residual for identifying observations that are poorly accounted for by the model. The default name is _STDRESCHI_.

STDRESDEV
specifies the standardized deviance residual for identifying poorly fitted observations. The default name is _STDRESDEV_. This statistic is not supported for GEEs.

STDXBETA
specifies the standard error estimates of XBETA. The default name is _STDXBETA_.

UCL

UPPERXBETA
specifies the variable that contains the upper confidence limits for the linear predictor. The default name is _UCL_. You can set the confidence level by specifying the ALPHA= option.

UCLM

UPPERMEAN

UPPER
specifies the variable that contains the upper confidence limits for the probability of the event response. The default name is _UCLM_. You can set the confidence level by specifying the ALPHA= option.

XBETA

LINP
specifies the linear predictor. The default name is _XBETA_.

PARTITION Statement

PARTITION *partition-option* **;**

The PARTITION statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. For more information, see the section "Using Validation and Test Data" on page 101 in Chapter 2, "Shared Concepts." Either you can designate a variable in the input data table and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for randomly assigning observations to each role.

You must specify exactly one of the following *partition-options*:

FRACTION(< **TEST=***fraction* **> <** **VALIDATE=***fraction* **> <** **SEED=***number* **>)**
randomly assigns specified proportions of the observations in the input data table to the roles. You specify the proportions for testing and validation by using the TEST= and VALIDATE= suboptions. If you specify both the TEST= and VALIDATE= suboptions, then the sum of the specified fractions must be less than 1 and the remaining fraction is the proportion of the observations assigned to the training role. The SEED= option specifies an integer that is used to start the pseudorandom number generator for random partitioning of data for training, testing, and validation. If you do not specify SEED=*number* or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

ROLE=*variable* **(< TEST='***value***' > < TRAIN='***value***' > < VALIDATE='***value***' >)**

ROLEVAR=*variable* **(< TEST='***value***' > < TRAIN='***value***' > < VALIDATE='***value***' >)**

names the *variable* in the input data table whose values are used to assign roles to each observation. This *variable* cannot also appear as an analysis variable in other statements or options. The TEST=, TRAIN=, and VALIDATE= suboptions specify the formatted values of this variable that are used to assign observation roles. If you do not specify the TRAIN= suboption, then all observations whose role is not determined by the TEST= or VALIDATE= suboption are assigned to the training role.

For more information, see the section "Partition Fit Statistics" on page 1020. For an illustration, see Example 18.3.

REPEATED Statement

REPEATED SUBJECT=*<subject-effect>* **/** *< repeated-options >* **;**

The REPEATED statement performs a repeated measures analysis by using generalized estimating equations (GEEs). GEE analysis is available for binomial and binary response models. GEE analysis is not supported when you perform model selection or when you perform a partitioned analysis.

The *repeated-options* specify the working correlation structure, output options, and controls for the iterative fitting algorithm.

Table 18.11 summarizes the *repeated-options* in the REPEATED statement by function.

Table 18.11 REPEATED Statement Options

Option	Description
Basic Options	
SUBJECT=	Identifies subjects in the input data
TYPE=	Specifies the working correlation type
WITHIN=	Specifies a within-subject effect
Options Related to Output	
CORRB	Produces both the model-based and empirical estimated regression parameter correlation matrices
CORRW	Produces the working correlation matrix
COVB	Produces both the model-based and empirical estimated regression parameter covariance matrices
ECORRB	Produces the estimated regression parameter empirical correlation matrix
ECOVB	Produces the estimated regression parameter empirical covariance matrix
MCORRB	Produces the estimated regression parameter model-based correlation matrix
MCOVB	Produces the estimated regression parameter model-based covariance matrix
MODELSE	Produces a parameter estimates table that displays and uses the model-based standard errors
PRINTMLE	Produces a parameter estimates table that displays the maximum likelihood estimates

Basic Options

SUBJECT=*subject-effect*

identifies subjects in the input data set. A *subject-effect* is required; it can contain a single variable, an interaction effect, a nested effect, or a combination of these. Each variable that the *subject-effect* contains must be listed in the CLASS statement. Each distinct level of the effect identifies a different subject. Responses from different subjects are assumed to be independent, but responses within subjects are assumed to be correlated.

You can specify the following *options* after a slash (/):

TYPE=*<type>*

specifies the working correlation type that is used in the repeated measures analysis. The working correlation structure describes the way that a subject's repeated measures are assumed to correlate with each other.

You can specify one of the following working correlation types:

AR | AR(1)
specifies the autoregressive-1 working correlation.

CS | EXCH
specifies the exchangeable working correlation.

IND
specifies the independence working correlation.

MDEP*(m)* **| TOEP***(m)*
specifies the *m*-dependent working correlation. By default, *m* = 1.

UN | UNSTR | UNSTRUCTURED
specifies the unstructured working correlation.

By default, TYPE=IND.

WITHIN=*within-effect*

WITHINSUBJECT=*within-effect*
specifies a within-subject effect for the repeated measures model. This effect must be composed of CLASS variables. The purpose of the within-subject effect is to define an order for the repeated measures that correspond to each subject. This definition can be critical for reproducibility when you use an order-sensitive correlation structure.

If you do not specify a within-subject effect, the order of the repeated measures is determined by the order in which they are read. This order can vary, depending on your computing resources. Therefore, a within-subject effect is required when you specify the autoregressive, *m*-dependent, or unstructured working correlation type. When you use one of these working correlation types, the levels of the within-subject effect must be unique within each subject.

If you use multiple variables to define the within-subject effect, the specification of the variables within this effect will have an impact on the analysis if the working correlation type depends on the ordering of the repeated measures. The autoregressive, *m*-dependent, and unstructured working correlation types use the levelization of the within-subject effect to locate observations within the correlation matrix, and depend on the order that is produced by the levelization.

In particular, if you define the within-subject effect by using the interaction of two or more variables, then the hierarchy of levelization and the resulting ordering of the repeated measures will depend on the order in which you list the variables in the CLASS statement.

For example, assume that you are using the interaction of the variables w1 and w2 as the within-subject effect in a repeated measures analysis. Furthermore, assume that w1 takes the values 'A' and 'B' and w2 takes the values 'L' and 'H'. The following statements list these variables in the order w2, w1 in the CLASS statement:

```
proc logselect data=mylib.health;
   class subject w2 w1;
   model outcome(event='1') = x1 x2;
   repeated subject=subject / type=mdep(2) within=w1*w2;
run;
```

In this case, the order of the variables in the CLASS statement results in a levelization in which the value of w1 changes faster than the value of w2. Table 18.12 shows this levelization.

Table 18.12 Levelization Order When Variable Order Is w2, w1

Value of w1	Value of w2	Levelization Order
A	L	0
B	L	1
A	H	2
B	H	3

If you reverse the order of the variables in the CLASS statement, the levelization has a different hierarchy. In this hierarchy, the value of w2 changes faster than the value of w1. Table 18.13 shows that the levelization order that is assigned to each unique combination of the variables does not match the levelization order shown in Table 18.12.

Table 18.13 Levelization Order When Variable Order Is w1, w2

Value of w1	Value of w2	Levelization Order
A	L	0
B	L	2
A	H	1
B	H	3

Because the specified working correlation structure (*m*-dependent) relies on this ordering, the parameter estimates differ from those that are produced by the ordering shown in Table 18.12. The autoregressive and unstructured working correlation structures also result in different parameter estimates for the different orderings.

If you use two variables to define the within-subject effect, you can use a nested effect to enforce a specific levelization hierarchy. However, the best practice is to use a single variable in the within-subject effect.

Options Related to Output

CORRB
produces both the model-based and empirical estimated regression parameter correlation matrices.

CORRW
produces the estimated working correlation matrix. This matrix shows the estimated correlation between pairs of repeated measurements.

COVB
produces both the model-based and empirical estimated regression parameter covariance matrices.

ECORRB
produces the empirical estimated regression parameter correlation matrix.

ECOVB
produces the empirical estimated regression parameter covariance matrix.

MCORRB
produces the model-based estimated regression parameter correlation matrix.

MCOVB
produces the model-based estimated regression parameter covariance matrix.

MODELSE
produces a table that displays the parameter estimates from the repeated measures analysis, but using the model-based standard error estimates. By default, only a table that uses the empirical standard error estimates is shown.

PRINTMLE
produces a table that displays the parameter estimates and standard errors from maximum likelihood estimation, assuming no within-subject correlation. This table corresponds to the "Parameter Estimates" table that the procedure produces when you do not request a repeated measures analysis.

RISK Statement

RISK < *variable-list* > < / *options* > **;**

The RISK statement produces relative risks or risk differences for *variables* that are used in your model. Because risk statistics directly compare the event probabilities, they provide an easier method than odds ratios for comparing your model's implications for different subjects.

Given a population profile L, recall that the model-predicted event probability from a binary logistic regression model is computed as $p = \Pr(Y = \text{event}|L) = g^{(-1)}(L'\hat{\boldsymbol{\beta}})$, where $g(\cdot)$ is your link function. The risk difference is the difference between the *risk* or event probability p_1 of a subject having one population profile, L_1, and the event probability p_2 of having a different population profile, L_2. Specifying the TYPE= option enables you to compute the relative risk, or risk ratio, which is the quotient of these two probabilities. If you do not specify any risk variables, then risk statistics are computed for every variable in the model. In a similar fashion, if you specify a multinomial response variable as a risk variable, then a common population profile, L, is used to compare the probability between two different response levels; however, if you use multinomial-trial syntax, you cannot specify those response variables as risk variables. Standard errors and confidence limits are produced by using the delta method. You can specify at most one RISK statement.

By default, all continuous variables are set to their means and all classification variables are set to their reference levels. If your risk variable is continuous, then by default the risk statistics compare the base subpopulation where the risk variable is set to its mean value to a population where that variable is one unit larger. If your risk variable is a classification variable, then by default the risk statistics compare each level of the risk variable to its reference level. If your risk variable is a multinomial response variable, then the risk statistics compare each level of the response to its reference level. You can also specify variables that are used to construct SPLINE and POLYNOMIAL effects as risk variables.

If you specify the PRIOR= option, the risk computations use the posterior predicted probabilities instead of the individual predicted probabilities, and the gradients are computed by using a finite-difference method.

For more information about the risk computations, see the section "Risk Differences and Relative Risks" on page 1034.

You can specify the following *options* after a slash (/):

ALPHA=*number*
sets the significance level for producing confidence intervals. The ALPHA= value that you specify in the PROC LOGSELECT statement is the default. If neither ALPHA= option is specified, then by default ALPHA=0.05.

AT(*var***=***var-options* **<...** *var***=***var-options***>)**
enables you to specify fixed values or levels for a variable in the model. The following *var-options* are enabled when you specify the *var* variable:

value-list
specifies fixed values for the variable *var*. When *var* is a continuous variable, you can specify one or more numbers in the *value-list*. By default, continuous variables are set to their means. When *var* is a classification variable, you can specify one or more formatted levels of the variable enclosed in single quotes (for example, **A='cat' 'dog'**). By default, classification variables are set to their reference level. For example, if your model includes a classification variable A={cat,dog} and a continuous variable B, then specifying the following statements sets A to 'cat' and sets B to 7 and then 9:

```
risk X / AT(A='cat' B=7 9);
```

REF
specifies the reference level of *var* when *var* is a classification variable. This is the default for classification variables.

ALL
specifies every level of *var* when *var* is a classification variable.

DIFF=REF | ALL
specifies whether to compute the risk statistics for a classification risk variable against the reference level (DIFF=REF) or to compare all pairs of the risk variable's levels (DIFF=ALL). By default, DIFF=REF. The DIFF= option has no effect when the risk variable is continuous.

E
displays the L_1 and L_2 vectors; zero values are displayed as blanks. For cumulative response models, the intercept parameters are displayed as blanks and the slope parameters for a given risk are displayed only once. For the generalized logit model, the slope parameters that are used for a single response function are displayed, and the same parameters are used for all the other response functions. If you have a multinomial response model and also specify the dependent variable as a risk variable, then a single L vector is displayed.

REVERSE
swaps the L_1 and L_2 vectors in the computations. The risk difference is computed as $p_2 - p_1$ instead of $p_1 - p_2$, and the risk ratio is computed as p_2/p_1 instead of p_1/p_2.

SHOWPROBS
displays the two probabilities that are used in the risk statistic computations. These two values are always included in columns named P1 and P2 when you specify the DISPLAYOUT statement to output the "Risks" table.

TYPE=DIFFERENCE | RELATIVE
requests risk differences or relative risks. By default, TYPE=DIFFERENCE.

UNIT(*variable1***=***list1* **<...** *variable2***=***list2* **>)**
specifies one or more numbers that represent the units of change for a continuous risk variable so that you can produce customized risk statistics. An estimate of the corresponding risk statistic is displayed for each specified unit of change. The UNIT option is ignored for classification *variables*. For example, the following statement requests a risk difference that represents the change in the risk when the variable *X* is increased by two units:

```
risk X / UNIT(X=2);
```

By default, the unit of change is 1.

STDERR
indicates that the units of change that you specify in the UNIT option represent multiples of the sample standard error of the risk variable, based on the observations that are used to fit the model. If you specify the STDERR option without the UNIT option, then the unit of change is 1 standard error.

SELECTION Statement

SELECTION < **METHOD=***method*< *(method-options)* > >< *options* > **;**

The SELECTION statement performs model selection by examining whether effects should be added to or removed from the model according to rules that are defined by model selection methods. The statement is fully documented in the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

The LOGSELECT procedure supports the following effect-selection *methods* in the SELECTION statement:

BACKWARD performs backward elimination. This method starts with all effects in the model and deletes effects.

BACKWARD(FAST) performs fast backward elimination. This method starts with all effects in the model and deletes effects without refitting the model.

ELASTICNET performs elastic net selection. This method selects effects by fitting a sequence of candidate models with a grid of regularization parameters. For more information, see the section "Elastic Net Selection" on page 83 in Chapter 2, "Shared Concepts."

FORWARD performs forward selection. This method starts with no effects in the model and adds effects.

LASSO performs model selection by the group LASSO method. This method adds and removes effects by using a sequence of LASSO steps. For more information, see the section "Group LASSO Selection" on page 87 in Chapter 2, "Shared Concepts."

NONE results in no model selection. This method fits the full model.

STEPWISE performs stepwise selection. This method is similar to the FORWARD method except that effects already in the model do not necessarily stay there.

By default, METHOD=STEPWISE.

You can specify the following criteria in the SELECT=, CHOOSE=, and STOP= *method-options*:

AIC uses Akaike's information criterion (Akaike 1974) computed on the training data.

AICC uses a small-sample bias-corrected version of Akaike's information criterion, as promoted in Hurvich and Tsai (1989) and Burnham and Anderson (1998), computed on the training data.

SBC | BIC uses the Schwarz Bayesian criterion (Schwarz 1978) computed on the training data.

SL uses the significance level of the score test computed on the training data as the criterion (not available for the CHOOSE= option).

VALIDATE uses the average square error (ASE) computed on the validation data as the criterion (not available for the SELECT= option).

For more information, see the section "Information Criteria" on page 1020.

For effect-selection methods other than LASSO, the SELECT=, CHOOSE=, and STOP= *method-options* default to SBC. These defaults differ from their corresponding defaults in the HPLOGISTIC procedure in SAS/STAT software.

If you specify METHOD=LASSO, then the value of the CHOOSE= option is SBC by default, you can specify CHOOSE=NONE to select the model in the last LASSO step, and the STOPHORIZON= option has no effect.

If you specify METHOD=ELASTICNET, then the HIERARCHY= and STOPHORIZON= options have no effect.

NOTE: If you use the fast backward elimination method, then the –2 log likelihood, AIC, AICC, and SBC statistics are approximated at each step where the model is not refit, and hence they do not match the values that are computed when that model is fit outside the selection routine. Similarly, if you specify SELECT=AIC, AICC, or SBC, the selection criteria are estimated (Lawless and Singhal 1978), and hence they do not match the values that are computed when that model is fit outside the selection routine.

NOTE: The default model hierarchy method is HIERARCHY=NONE for the stepwise, forward, and fast backward selection methods. The backward elimination method always uses the HIERARCHY=SINGLE *method-option*.

The LASSO method produces a summary table that displays the effects that are added or removed at each step; the LASSO regularization parameter; and the AIC, AICC, and SBC fit statistics. The elastic net method produces a similar summary table that includes the selected effects, the regularization parameter, and the value of the CHOOSE= criterion. For the other methods, you can specify the following values for the DETAILS= option:

SUMMARY produces a summary table that shows the effect that is added or removed at each step along with the SELECT=, CHOOSE=, and STOP= criteria. The summary table is produced by default if the DETAILS= option is not specified.

STEPS produces the preceding summary table and displays the results from fitting each model at each step.

ALL produces the preceding tables and a detailed listing of all candidates at each step along with their ranking in terms of the selection criterion for addition to or removal from the model.

If you specify the PLOTS=CRITERIA or PLOTS=ALL option, then a plot of the fit criterion by the selection step is created for the AIC, AICC, and SBC statistics. If you also specify a PARTITION statement or the PARTFIT option, then the same type of plot is created for the ASE (for each role), max-rescaled R-square, McFadden's R-square, misclassification rate, and difference of means statistics.

If you specify the PLOTS=FITBYROLE or PLOTS=ALL option and a PARTITION statement, then a plot of the ASE by the selection step for each role is created.

The PLOTS= option is not available for the LASSO method or the elastic net method.

Model selection is not available for repeated measures (GEE) models.

STORE Statement

STORE < **OUT=***libref.data-table* > < / **NOTE** | **TEXT=***quoted-string* < *quoted-string . . .* > > **;**

The STORE statement saves the context and results of the statistical analysis. The resulting analytic store has a binary file format that cannot be modified. An example of analytic store technology is to perform a time-consuming analysis and to store its results by using the STORE statement. Later you can perform specific statistical analysis tasks based on the saved results of the previous analysis, without having to fit the model again. You can process the contents of the analytic store by specifying the RESTORE= option, as well as by specifying the ASTORE procedure and the **`logisticAssociation`**, **`logisticCode`**, **`logisticOddsRatio`**, **`logisticScore`**, and **`logisticType3`** actions in the **`regression`** action set (see Chapter 22, "Regression Action Set" (*SAS Visual Statistics: Programming Guide*)).

You specify the name of the analytic store by using the OUT= option. You can save notes to the analytic store by specifying them as quoted strings in the NOTE= or TEXT= option. Each quoted string begins a new line, preserves initial blanks, and can be at most 200 characters long. These text strings are displayed when you specify the item store in a RESTORE= option.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 963.

WEIGHT Statement

WEIGHT *variable* < / **NORMALIZE** > **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

You can specify the following option in the WEIGHT statement after a slash (/):

NORMALIZE

normalizes the weights that are specified by the WEIGHT *variable* so that they add up to the sample size. Weights are normalized by multiplying them by $\frac{\sum f_i t_i}{\sum w_i f_i t_i}$, where training observation i has a frequency equal to f_i and a weight equal to w_i, and t_i is the number of trials when you are using events/trials or multinomial-trial syntax; otherwise t_i is equal to 1. When you specify this option, the estimated covariance matrix of the parameter estimators is invariant to the scale of the WEIGHT *variable*.

CAUTION: PROC LOGSELECT does not compute the proper variance estimators if you are analyzing survey data and you use the WEIGHT statement to specify the sampling weights. Instead, use the SURVEYLOGISTIC procedure, which is designed to perform the necessary, and correct, computations.

Details: LOGSELECT Procedure

Missing Values

Any observation that has missing values for the response, frequency, weight, offset, or explanatory variables is excluded from the analysis; however, missing values are valid for response and explanatory variables that are specified along with the MISSING option in the CLASS statement. Observations that have a nonpositive weight or a frequency less than 1 are also excluded.

The estimated linear predictor and the fitted probabilities are not computed for any observation that has missing offset or explanatory variable values. However, if only the response value is missing, the linear predictor and the fitted probabilities can be computed and output to a data table by using the OUTPUT statement.

You can also model the missing values by specifying the INFORMATIVE option in the MODEL statement. For more information about informative missingness, see the section "Informative Missingness" on page 99 in Chapter 2, "Shared Concepts."

Response Distributions

The response distribution is the probability distribution of the response (target) variable. The LOGSELECT procedure can fit data for the following distributions:

- binary distribution
- binomial distribution
- multinomial distribution

The expressions for the log-likelihood functions of these distributions are given in the next section.

The binary (or Bernoulli) distribution is the elementary distribution of a discrete random variable that can take two values, which have the probabilities p and $1 - p$. Suppose the random variable is denoted as Y and

$$\Pr(Y = 0) = p$$
$$\Pr(Y = 1) = 1 - p$$

The value that is associated with probability p is often called the *event* or "success"; the complementary event is called the *nonevent* or "failure." A Bernoulli experiment is a random draw from a binary distribution and generates events with probability p. The following example fit a binary regression model to the response variable Y with regressors X1 and X2:

```
proc logselect;
   model Y = X1 X2;
run;
```

If $Y_1, \ldots, Y_n$ are n independent Bernoulli random variables, then their sum follows a binomial distribution. In other words, if $Y_i = 1$ denotes an event (success) in the ith Bernoulli trial, a binomial random variable is the number of events (successes) in n independent Bernoulli trials. If you use the events/trials syntax in the MODEL statement, the LOGSELECT procedure fits the model as if the data had arisen from a binomial distribution. For example, the following statements fit a binomial regression model with regressors X1 and X2. The variables E and T represent the events and trials for the binomial distribution.

```
proc logselect;
   model E/T = X1 X2;
run;
```

If the events/trials syntax is used, then both variables must be numeric and the value of the events variable cannot be less than 0 or exceed the value of the trials variable.

The multinomial distribution is a generalization of the binary distribution and allows for more than two outcome categories. Because there are more than two possible outcomes for the multinomial distribution, the terminology of "successes," "failures," "events," and "nonevents" no longer applies. With multinomial data, these outcomes are generically referred to as "categories" or levels.

If each observation represents a single trial, and the response is one of several categories, then when you specify your model with single-trial syntax, the LOGSELECT procedure determines that the response variable has more than two levels and fits the model as if the data had arisen from a multinomial distribution. For example, if the response variable Y takes values in {'a','b','c'}, then the following specification fits a multinomial logistic regression model:

```
proc logselect;
   model Y = X1 X2;
run;
```

Alternatively, if your subjects are grouped, and if the number of subjects in an observation with response Y='a', 'b', and 'c' are contained in the variables A, B, and C, respectively, then you can specify a multinomial logistic regression model by using multinomial-trial syntax as follows:

```
proc logselect;
   model A B C = X1 X2;
run;
```

By default, the procedure assumes that the response categories are ordered, and it fits a cumulative link model by applying the default or specified link function. For single-trial syntax, a cumulative link function compares the lower ordered categories to the higher ordered categories; for multinomial-trial syntax, a cumulative link function compares the first levels in the response-level list to the last levels.

If the response categories are unordered, then you should fit a generalized logit model by specifying the LINK=GLOGIT option in the MODEL statement. For single-trial syntax, the generalized logit link uses the last ordered category as the reference level by default; for multinomial-trial syntax, the last level in the response-level list is the reference level.

Log-Likelihood Functions

The LOGSELECT procedure forms the log-likelihood functions of the various models as

$$L(\boldsymbol{\mu};\mathbf{y}) = \sum_{i=1}^{n} f_i \, l(\mu_i; y_i, w_i)$$

where μ_i is the probability that the ith observation is an event, $l(\mu_i; y_i, w_i)$ is the log-likelihood contribution of the ith observation, w_i is the weight, and f_i is its frequency. For the determination of w_i and f_i, see the WEIGHT and FREQ statements. The individual log-likelihood contributions for the various distributions are described in the following sections.

Binary Distribution

The LOGSELECT procedure computes the log-likelihood function $l(\mu_i(\boldsymbol{\beta}); y_i)$ for the ith binary observation as

$$\begin{aligned} \eta_i &= \mathbf{x}_i'\boldsymbol{\beta} \\ \mu_i(\boldsymbol{\beta}) &= g^{-1}(\eta_i) \\ l(\mu_i(\boldsymbol{\beta}); y_i) &= y_i \log\{\mu_i\} + (1 - y_i)\log\{1 - \mu_i\} \end{aligned}$$

where the variable y_i takes the value 1 for an event and 0 for a nonevent. The inverse link function $g^{-1}(\cdot)$ maps from the scale of the linear predictor η_i to the scale of the mean. For example, for the logit link (the default),

$$\mu_i(\boldsymbol{\beta}) = \frac{\exp\{\eta_i\}}{1 + \exp\{\eta_i\}}$$

You can control which binary outcome in your data is modeled as the event by using the *response-options* in the MODEL statement, and you can choose the link function by using the LINK= option in the MODEL statement.

If a WEIGHT statement is specified and w_i denotes the weight for the current observation, the log-likelihood function is computed as

$$l(\mu_i(\boldsymbol{\beta}); y_i, w_i) = w_i l(\mu_i(\boldsymbol{\beta}); y_i)$$

Binomial Distribution

The LOGSELECT procedure computes the log-likelihood function $l(\mu_i(\boldsymbol{\beta}); y_i)$ for the ith binomial observation as

$$\begin{aligned} \eta_i &= \mathbf{x}_i'\boldsymbol{\beta} \\ \mu_i(\boldsymbol{\beta}) &= g^{-1}(\eta_i) \\ l(\mu_i(\boldsymbol{\beta}); y_i, w_i) &= w_i \left(y_i \log\{\mu_i\} + (n_i - y_i)\log\{1-\mu_i\}\right) \\ &\quad + w_i \log \binom{n_i}{y_i} \end{aligned}$$

where y_i and n_i are the values of the events and trials of the ith observation, respectively. The value μ_i measures the probability of events (successes) in the underlying Bernoulli distribution whose aggregate follows the binomial distribution.

Multinomial Distribution

The multinomial distribution that the LOGSELECT procedure models is a generalization of the binary distribution; it is the distribution of a single draw from a discrete distribution that has J possible values. Thus, the log-likelihood function for the ith observation is

$$l(\boldsymbol{\mu}_i; \mathbf{y}_i, w_i) = w_i \sum_{j=1}^{J} y_{ij} \log\{\mu_{ij}\}$$

In this expression, J denotes the number of response categories (the number of possible outcomes), y_{ij} takes the value 1 if the jth response is observed and 0 otherwise, and μ_{ij} is the probability that the ith observation takes on the response value associated with category j.

If you use the multinomial-trial form of the syntax, then the LOGSELECT procedure includes the constant term in the computation of the log-likelihood function

$$l(\boldsymbol{\mu}_i; \mathbf{y}_i, w_i) = w_i \sum_{j=1}^{J} y_{ij} \log\{\mu_{ij}\} + w_i \log \binom{y_i}{y_{i1} \cdots y_{iJ}}$$

where y_{ij} is the number of trials in the ith observation that have the jth ordered response and $y_i = \sum_{j=1}^{J} y_{ij}$ is the total number of trials in that observation.

The category probabilities must satisfy

$$\sum_{j=1}^{J} \mu_{ij} = 1$$

and the constraint is satisfied by modeling $J - 1$ categories. In models that have ordered response categories, the probabilities are expressed in cumulative form, so the last category is redundant. In generalized logit models (multinomial models that have unordered categories), one category is chosen as the reference category, and the linear predictor in the reference category is set to 0. For more information, see the REF=*response-option* in the MODEL statement.

Existence of Maximum Likelihood Estimates

The likelihood equation for a logistic regression model does not always have a finite solution. Sometimes there is a nonunique maximum on the boundary of the parameter space, at infinity. The existence, finiteness, and uniqueness of maximum likelihood estimates for the logistic regression model depend on the patterns of data points in the observation space (Albert and Anderson 1984; Santner and Duffy 1986).

Consider a binary response model. Let Y_j be the response of the jth subject, and let $\mathbf{x}_j$ be the vector of explanatory variables (including the constant 1 that is associated with the intercept). There are three mutually exclusive and exhaustive types of data configurations:

Complete separation There is a complete separation of data points if there exists a vector $\mathbf{b}$ that correctly allocates all observations to their response groups; that is,

$$\begin{cases} \mathbf{b}'\mathbf{x}_j > 0 & Y_j = 0 \\ \mathbf{b}'\mathbf{x}_j < 0 & Y_j = 1 \end{cases}$$

This configuration produces nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, then the log likelihood diminishes to 0 and the dispersion matrix becomes unbounded.

Quasi-complete separation The data are not completely separable, but there is a vector $\mathbf{b}$ such that

$$\begin{cases} \mathbf{b}'\mathbf{x}_j \geq 0 & Y_j = 0 \\ \mathbf{b}'\mathbf{x}_j \leq 0 & Y_j = 1 \end{cases}$$

and equality holds for at least one subject in each response group. This configuration also yields nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, then the dispersion matrix becomes unbounded and the log likelihood diminishes to a nonzero constant.

Overlap If neither complete nor quasi-complete separation exists in the sample points, there is an overlap of sample points. In this configuration, the maximum likelihood estimates exist and are unique.

The LOGSELECT procedure uses a simple empirical approach to recognize the data configurations that lead to infinite parameter estimates. The basis of this approach is that any convergence method of maximizing the log likelihood must yield a solution that indicates complete separation, if such a solution exists. Upon convergence, if the predicted response equals the observed response for every observation, there is a complete separation of data points.

If the data are not completely separated, if an observation is identified to have an extremely large probability (≥ 0.95) of predicting the observed response, and if there have been at least eight iterations, then there are two possible situations. First, there is overlap in the data set, the observation is an atypical observation of its own group, and the iterative process stopped when a maximum was reached. Second, there is quasi-complete separation in the data set, and the asymptotic dispersion matrix is unbounded. If any of the diagonal elements of the dispersion matrix for the standardized observation vector (all explanatory variables standardized to zero mean and unit variance) exceeds 5,000, then PROC LOGSELECT declares quasi-complete separation; if any of the diagonal elements exceeds 1,000, then the procedure displays a message indicating that quasi-complete separation might be detectable by increasing the number of iterations. If either complete separation or quasi-complete separation is detected, a note is displayed in the procedure output.

Checking for quasi-complete separation is less foolproof than checking for complete separation. If neither type of separation is discovered and your parameter estimates have large standard errors, then your data might be separable. The NOCHECK option in the MODEL statement turns off the process of checking for infinite parameter estimates; the MINITER= option in the PROC LOGSELECT statement increases the number of iterations.

The LASSO Method of Model Selection

The LOGSELECT procedure implements the group LASSO method, which is described in the section "Group LASSO Selection" on page 87 in Chapter 2, "Shared Concepts." The current section provides some background about the LASSO method that you need in order to understand the group LASSO method.

LASSO (least absolute shrinkage and selection operator) selection arises from a constrained form of ordinary least squares regression in which the sum of the absolute values of the regression coefficients is constrained to be smaller than a specified parameter. More precisely, let $\mathbf{X} = (\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_m)$ denote the matrix of covariates, and let $\mathbf{y}$ denote the response. Then for a given parameter t, the LASSO regression coefficients $\boldsymbol{\beta} = (\beta_1, \beta_2, \ldots, \beta_m)$ are the solution to the following constrained least squares problem:

$$\min ||\mathbf{y} - \mathbf{X}\boldsymbol{\beta}||^2 \qquad \text{subject to} \qquad \sum_{j=1}^{m} |\beta_j| \leq t$$

For generalized linear models, the LASSO regression coefficients $\boldsymbol{\beta} = (\beta_1, \beta_2, \ldots, \beta_m)$ are the solution to the following constrained optimization problem,

$$\min\{-L(\boldsymbol{\mu}; \mathbf{y})\} \qquad \text{subject to} \qquad \sum_{j=1}^{m} |\beta_j| \leq t$$

where L is the log-likelihood function defined in the section "Log-Likelihood Functions" on page 1011.

Provided that the LASSO parameter t is small enough, some of the regression coefficients will be exactly zero. Hence, you can think of the LASSO method as selecting a subset of the regression coefficients for each LASSO parameter. By increasing the LASSO parameter in discrete steps, you obtain a sequence of regression coefficients for which the nonzero coefficients at each step correspond to selected parameters. For more information about the LASSO method, see, for example, Hastie, Tibshirani, and Friedman (2009).

Generalized Estimating Equations

The analysis of correlated data that arise from repeated measurements when the measurements are assumed to be multivariate normal has been studied extensively. However, the normality assumption might not always be reasonable; for example, you must use a different methodology in the data analysis when the responses are discrete and correlated. Generalized estimating equations (GEEs) provide a practical method with reasonable statistical efficiency to analyze such data.

Liang and Zeger (1986) introduced GEEs as a method of dealing with correlated data when, except for the correlation among responses, the data can be modeled as a generalized linear model. For example, in many cases you can model correlated binary and count data in this way. For more information about GEEs, see Hardin and Hilbe (2003), Diggle, Liang, and Zeger (1994), and Lipsitz et al. (1994).

Let y_{ij}, $j = 1, \ldots, n_i$, $i = 1, \ldots, K$, represent the jth measurement on the ith subject. There are n_i measurements on subject i and $\sum_{i=1}^{K} f_i\, n_i$ total measurements, where f_i is the cluster frequency that you specify in the FREQ statement. If you omit the FREQ statement, then $f_i = 1$ for all observations. The frequencies must be the same for all observations within each cluster.

You model correlated data by using the same link function and linear predictor specification that you use to model independent data. You use the same variance functions as in the independent case, but you must also specify a structure for the correlation between the repeated measurements. In the following material, $v(\mu)$ denotes the variance function for the specified distribution.

Let the vector of measurements on the ith subject be $\mathbf{Y}_i = [y_{i1}, \ldots, y_{in_i}]'$, where the corresponding vector of means is $\boldsymbol{\mu}_i = [\mu_{i1}, \ldots, \mu_{in_i}]'$, and let $\mathbf{V}_i$ be the covariance matrix of $\mathbf{Y}_i$. Let the vector of independent, or explanatory, variables for the jth measurement on the ith subject be $\mathbf{x}_{ij} = [x_{ij1}, \ldots, x_{ijp}]'$. The generalized estimating equation of Liang and Zeger (1986) for estimating the $p \times 1$ vector of regression parameters $\boldsymbol{\beta}$ is an extension of the independence estimating equation to correlated data and is given by

$$\mathbf{S}(\boldsymbol{\beta}) = \sum_{i=1}^{K} f_i \mathbf{D}_i' \mathbf{V}_i^{-1} (\mathbf{Y}_i - \boldsymbol{\mu}_i(\boldsymbol{\beta})) = \mathbf{0}$$

where

$$\mathbf{D}_i = \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}$$

The relationship between the linear predictor and the mean is specified by

$$g(\mu_{ij}) = \mathbf{x}_{ij}{}'\boldsymbol{\beta}$$

where g is the link function, and so the $p \times n_i$ matrix of partial derivatives of the mean with respect to the regression parameters for the ith subject is given by

$$\mathbf{D}_i' = \frac{\partial \boldsymbol{\mu}_i'}{\partial \boldsymbol{\beta}} = \begin{bmatrix} \dfrac{x_{i11}}{g'(\mu_{i1})} & \cdots & \dfrac{x_{in_i1}}{g'(\mu_{in_i})} \\ \vdots & & \vdots \\ \dfrac{x_{i1p}}{g'(\mu_{i1})} & \cdots & \dfrac{x_{in_ip}}{g'(\mu_{in_i})} \end{bmatrix}$$

Working Correlation Matrix

Let $\mathbf{R}_i(\boldsymbol{\alpha})$ be an $n_i \times n_i$ "working" correlation matrix that is fully specified by the vector of parameters $\boldsymbol{\alpha}$. The covariance matrix of $\mathbf{Y}_i$ is modeled as

$$\mathbf{V}_i = \mathbf{A}_i^{\frac{1}{2}} \mathbf{W}_i^{-\frac{1}{2}} \mathbf{R}(\boldsymbol{\alpha}) \mathbf{W}_i^{-\frac{1}{2}} \mathbf{A}_i^{\frac{1}{2}}$$

where $\mathbf{A}_i$ is an $n_i \times n_i$ diagonal matrix whose jth diagonal element is $v(\mu_{ij})$, and $\mathbf{W}_i$ is an $n_i \times n_i$ diagonal matrix whose jth diagonal is w_{ij}, where w_{ij} is a weight specified in the WEIGHT statement. If there is no WEIGHT statement, then $w_{ij} = 1$ for all i and j. If $\mathbf{R}_i(\boldsymbol{\alpha})$ is the true correlation matrix of $\mathbf{Y}_i$, then $\mathbf{V}_i$ is the true covariance matrix of $\mathbf{Y}_i$.

The working correlation matrix is usually unknown and must be estimated. You estimate it in the iterative fitting process by using the current value of the parameter vector $\boldsymbol{\beta}$ to compute appropriate functions of the Pearson residual

$$e_{ij} = \frac{y_{ij} - \mu_{ij}}{\sqrt{v(\mu_{ij})/w_{ij}}}$$

If you specify the working correlation as $\mathbf{R}_0 = \mathbf{I}$, which is the identity matrix, the GEE reduces to the independence estimating equation.

Table 18.14 shows the working correlation types that the LOGSELECT procedure supports and the estimators that are used to estimate the working correlations.

Table 18.14 Working Correlation Structures and Correlation Parameter Estimators

Working Correlation Structure	Estimator
Autoregressive	
AR(1)	
$\mathrm{Corr}(Y_{ij}, Y_{i,j+t}) = \alpha^t$ for $t = 0, 1, 2, \ldots, n_i - j$	$\hat{\alpha} = \frac{1}{(K_1 - p)} \sum_{i=1}^{K} f_i \sum_{j \le n_i - 1} e_{ij} e_{i,j+1}$ $K_1 = \sum_{i=1}^{K} f_i (n_i - 1)$
Exchangeable	
$\mathrm{Corr}(Y_{ij}, Y_{ik}) = \begin{cases} 1 & j = k \\ \alpha & j \neq k \end{cases}$	$\hat{\alpha} = \frac{1}{(N^* - p)} \sum_{i=1}^{K} f_i \sum_{j<k} e_{ij} e_{ik}$ $N^* = 0.5 \sum_{i=1}^{K} f_i n_i (n_i - 1)$
Independence	
$\mathrm{Corr}(Y_{ij}, Y_{ik}) = \begin{cases} 1 & j = k \\ 0 & j \neq k \end{cases}$	The working correlation is not estimated in this case.
***m*-dependent**	
$\mathrm{Corr}(Y_{ij}, Y_{i,j+t}) = \begin{cases} 1 & t = 0 \\ \alpha_t & t = 1, 2, \ldots, m \\ 0 & t > m \end{cases}$	$\hat{\alpha}_t = \frac{1}{(K_t - p)} \sum_{i=1}^{K} f_i \sum_{j \le n_i - t} e_{ij} e_{i,j+t}$ $K_t = \sum_{i=1}^{K} f_i (n_i - t)$

Table 18.14 *continued*

Working Correlation Structure	Estimator
Unstructured	
$\mathrm{Corr}(Y_{ij}, Y_{ik}) = \begin{cases} 1 & j = k \\ \alpha_{jk} & j \neq k \end{cases}$	$\hat{\alpha}_{jk} = \frac{1}{(K-p)} \sum_{i=1}^{K} f_i e_{ij} e_{ik}$

Fitting Algorithm

The following algorithm fits the specified model by using GEEs. Note that this is not in general a likelihood-based method of estimation; inferences based on likelihoods are not possible for GEE methods.

1. Compute an initial estimate of $\boldsymbol{\beta}$ by using an ordinary generalized linear model, assuming independence.
2. Compute the working correlations $\mathbf{R}$ on the basis of the standardized residuals, the current $\boldsymbol{\beta}$, and the assumed structure of $\mathbf{R}$.
3. Compute an estimate of the covariance:

$$\mathbf{V}_i = \mathbf{A}_i^{\frac{1}{2}} \mathbf{W}_i^{-\frac{1}{2}} \hat{\mathbf{R}}(\boldsymbol{\alpha}) \mathbf{W}_i^{-\frac{1}{2}} \mathbf{A}_i^{\frac{1}{2}}$$

4. Update $\boldsymbol{\beta}$:

$$\boldsymbol{\beta}_{r+1} = \boldsymbol{\beta}_r + \left[\sum_{i=1}^{K} f_i \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}' \mathbf{V}_i^{-1} \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}} \right]^{-1} \left[\sum_{i=1}^{K} f_i \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}' \mathbf{V}_i^{-1} (\mathbf{Y}_i - \boldsymbol{\mu}_i) \right]$$

5. Repeat steps 2–4 until convergence.

Missing Data

See Diggle, Liang, and Zeger (1994, Chapter 11) for a discussion of missing values in longitudinal data. Suppose you intend to take measurements $Y_{i1}, \ldots, Y_{in}$ for the ith unit. Missing values for which Y_{ij} are missing whenever Y_{ik} is missing for all $j \geq k$ are called *dropouts*. Otherwise, missing values that are intermixed with nonmissing values are called *intermittent* missing values. PROC LOGSELECT can estimate the working correlation from data that contain both types of missing values by using the *all available pairs* method, in which all nonmissing pairs of data are used in the moment estimators of the working correlation parameters that are defined previously. The resulting covariances and standard errors are valid under the missing completely at random (MCAR) assumption.

For example, for the unstructured working correlation model,

$$\hat{\alpha}_{jk} = \frac{1}{(K' - p)} \sum f_i e_{ij} e_{ik}$$

where the sum is over the units that have nonmissing measurements at times j and k, and K' is the number of units that have nonmissing measurements at j and k. Estimates of the parameters for other working

correlation types are computed in a similar manner, using available nonmissing pairs in the appropriate moment estimators.

The contribution of the *i*th unit to the parameter update equation is computed by omitting the elements of $(\mathbf{Y}_i - \boldsymbol{\mu}_\mathbf{i})$, the columns of $\mathbf{D}_i' = \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}'$, and the rows and columns of $\mathbf{V}_i$ that correspond to missing measurements.

Parameter Estimate Covariances

The *model-based* estimator of $\mathrm{Cov}(\hat{\boldsymbol{\beta}})$ is given by

$$\boldsymbol{\Sigma}_m(\hat{\boldsymbol{\beta}}) = \mathbf{I}_0^{-1}$$

where

$$\mathbf{I}_0 = \sum_{i=1}^{K} f_i \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}' \mathbf{V}_i^{-1} \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}$$

This is a consistent estimator of the covariance matrix of $\hat{\boldsymbol{\beta}}$ if the mean model and the working correlation matrix are correctly specified.

The estimator

$$\boldsymbol{\Sigma}_e = \mathbf{I}_0^{-1}\mathbf{I}_1\mathbf{I}_0^{-1}$$

is called the *empirical*, or *robust*, estimator of the covariance matrix of $\hat{\boldsymbol{\beta}}$, where

$$\mathbf{I}_1 = \sum_{i=1}^{K} f_i \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}' \mathbf{V}_i^{-1} \mathrm{Cov}(\mathbf{Y}_i) \mathbf{V}_i^{-1} \frac{\partial \boldsymbol{\mu}_i}{\partial \boldsymbol{\beta}}$$

It has the property of being a consistent estimator of the covariance matrix of $\hat{\boldsymbol{\beta}}$, even if the working correlation matrix is misspecified—that is, if $\mathrm{Cov}(\mathbf{Y}_i) \neq \mathbf{V}_i$. For further information about the robust variance estimate, see Zeger, Liang, and Albert (1988), Royall (1986), and White (1982). In computing $\boldsymbol{\Sigma}_e$, the parameters $\boldsymbol{\beta}$ and ϕ are replaced by estimates, and $\mathrm{Cov}(\mathbf{Y}_i)$ is replaced by the estimate

$$(\mathbf{Y}_i - \boldsymbol{\mu}_i(\hat{\boldsymbol{\beta}}))(\mathbf{Y}_i - \boldsymbol{\mu}_i(\hat{\boldsymbol{\beta}}))'$$

Quasi-likelihood Information Criterion

The quasi-likelihood information criterion (QIC) was developed by Pan (2001) as a modification of the Akaike information criterion (AIC) to apply to models that are fit by GEEs.

Define the quasi-likelihood under the independence working correlation assumption, which is evaluated using the parameter estimates under the working correlation *R* as

$$Q(\hat{\boldsymbol{\beta}}(R)) = \sum_{i=1}^{K} f_i \sum_{j=1}^{n_i} Q(\hat{\boldsymbol{\beta}}(R); (Y_{ij}, \mathbf{X}_{ij}))$$

where the quasi-likelihood contribution of the *j*th observation in the *i*th cluster is defined in the section "Quasi-likelihood Functions" on page 1019 and $\hat{\boldsymbol{\beta}}(R)$ are the parameter estimates obtained from GEEs that use the working correlation *R*.

QIC is defined as

$$\mathrm{QIC}(R) = -2Q(\hat{\boldsymbol{\beta}}(R)) + 2\mathrm{trace}(\hat{\Omega}_I \hat{V}_R)$$

where $\hat{V}_R$ is the robust covariance estimate and $\hat{\Omega}_I$ is the inverse of the model-based covariance estimate under the independence working correlation assumption, evaluated at $\hat{\boldsymbol{\beta}}(R)$, which are the parameter estimates obtained from GEEs that use the working correlation R.

PROC LOGSELECT also computes an approximation to $\mathrm{QIC}(R)$, which Pan (2001) defines as

$$\mathrm{QIC}_u(R) = -2Q(\hat{\boldsymbol{\beta}}(R)) + 2p$$

where p is the number of regression parameters.

Pan (2001) notes that QIC is appropriate for selecting regression models and working correlations, whereas QIC_u is appropriate only for selecting regression models.

Quasi-likelihood Functions

For detailed discussions of quasi-likelihood functions, see McCullagh and Nelder (1989) and Hardin and Hilbe (2003). The contribution of observation j in cluster i to the quasi-likelihood function that is evaluated at the regression parameters $\boldsymbol{\beta}$ is given by $Q(\boldsymbol{\beta}; (Y_{ij}, \mathbf{X}_{ij})) = Q_{ij}$, where

$$Q_{ij} = w_{ij}[r_{ij}\log(p_{ij}) + (n_{ij} - r_{ij})\log(1 - p_{ij})]$$

These are used in the computation of the quasi-likelihood information criteria (QIC) for the goodness of fit of models that are fit using GEEs. The w_{ij} are prior weights, if any, that are specified in the WEIGHT or FREQ statement.

GEE analysis is not supported when you perform model selection or when you perform a partitioned analysis.

Using a Preexisting Table Order

You can add group and order information to a table by using the **partition** action in the **table** action set. If you want to use the group and order information in a table to achieve a reproducible processing order and you also want to do a repeated measures analysis, the group information must follow specific rules. In particular, the variables that you specify in the **groupBy** parameter of the **partition** action must match the variables that you specify in the SUBJECT option of the REPEATED statement.

There are some variations to this requirement, depending on which type of subject effect you specify and which other options you use. If you specify a single-variable subject effect or an interaction subject effect, you must use all these variables in the **groupBy** parameter of the **partition** action. If you specify a nested subject effect, you must include the nested variable in the **groupBy** parameter. You can also include the nesting variables in the **groupBy** parameter, but you cannot include any other variables in the **groupBy** parameter. However, if you specify the MULTIPASS option in the PROC LOGSELECT statement, you must include the nested variable and all nesting variables in the **groupBy** parameter. You cannot include any other variables in the **groupBy** parameter.

If you use an order-sensitive working correlation structure, you do not need to use the variables that form the within-subject effect in the **orderBy** parameter of the **partition** action. These sets of variables can overlap, but it is not required that the preexisting table order correspond to the ordering for the within-subject effect.

Partition Fit Statistics

Specifying a PARTITION statement modifies the display of many tables by adding separate rows or columns for the training, validation, and test data tables and adds statistics to the "Fit Statistics" table. These additional statistics are useful for assessing the model and should be very similar for the different roles when the training data are representative of the other data partitions: average square error, misclassification rate, and the difference of means. The R^2, maximum-rescaled R^2, and McFadden's R^2 are also computed. For more information, see the section "Model Fit and Assessment Statistics" on page 1020.

Model Fit and Assessment Statistics

The statistics that are defined in this section are useful for assessing the fit of the model to your data; they are displayed in the "Fit Statistics" table. The statistics are computed for each data role when you specify a PARTITION statement.

Information Criteria

The calculation of the information criteria uses the following formulas, where p denotes the number of effective parameters in the candidate model, F denotes the sum of frequencies used, and l is the log likelihood evaluated at the converged estimates:

$$\begin{aligned}
\text{AIC} &= -2l + 2p \\
\text{AICC} &= \begin{cases} -2l + 2pF/(F-p-1) & \text{when } F > p+2 \\ -2l + 2p(p+2) & \text{otherwise} \end{cases} \\
\text{SBC} &= -2l + p\log(F)
\end{aligned}$$

If you do not specify a FREQ statement, F equals n, the number of observations used.

Generalized Coefficient of Determination

The goal of a coefficient of determination, also known as an R-square measure, is to express the agreement between a stipulated model and the data in terms of variation in the data that is explained by the model. In linear models, the R-square measure is based on residual sums of squares; because these are additive, a measure bounded between 0 and 1 is easily derived.

In more general models where parameters are estimated by the maximum likelihood principle, Cox and Snell (1989, pp. 208–209) and Magee (1990) proposed the following generalization of the coefficient of determination:

$$R^2 = 1 - \left\{ \frac{L(\mathbf{0})}{L(\widehat{\boldsymbol{\beta}})} \right\}^{\frac{2}{n}}$$

Here, $L(\mathbf{0})$ is the likelihood of the intercept-only model, $L(\widehat{\boldsymbol{\beta}})$ is the likelihood of the specified model, and n denotes the number of observations used in the analysis. This number is adjusted for frequencies if a FREQ statement is present, and it is based on the trials variable for binomial models.

As discussed in Nagelkerke (1991), this generalized R-square measure has properties similar to those of the coefficient of determination in linear models. If the model effects do not contribute to the analysis, $L(\widehat{\boldsymbol{\beta}})$ approaches $L(\mathbf{0})$ and R^2 approaches zero.

However, R^2 does not have an upper limit of 1. Nagelkerke suggested a rescaled generalized coefficient of determination, R^2_N, which achieves an upper limit of 1 by dividing R^2 by its maximum value:

$$R^2_{\max} = 1 - \{L(\mathbf{0})\}^{\frac{2}{n}}$$
$$R^2_N = \frac{R^2}{R^2_{\max}}$$

Another measure, from McFadden (1974), is also bounded by 0 and 1:

$$R^2_M = 1 - \left(\frac{\log L(\widehat{\boldsymbol{\beta}})}{\log L(\mathbf{0})}\right)$$

These measures are most useful for comparing competing models that are not necessarily nested—that is, models that cannot be reduced to one another by simple constraints on the parameter space. Larger values of the measures indicate better models.

Average Square Error

The average square error (ASE) is the average of the squared differences between the responses and the predictions. When you have a discrete number of response levels, the ASE is modified as shown in Table 18.15 (Brier 1950; Murphy 1973); it is also called the Brier score or Brier reliability.

Table 18.15 Average Square Error Computations

Response Type	ASE (Brier Score)
Binary	$\frac{1}{F}\sum_i f_i(y_i(1-\widehat{\pi}_i)^2 + (1-y_i)\widehat{\pi}_i^2)$
Binomial	$\frac{1}{F}\sum_i f_i(r_i/t_i - \widehat{\pi}_i)^2$
Multinomial	$\frac{1}{F}\sum_i f_i \sum_j (y_{ij}/y_i - \widehat{\pi}_{ij})^2$

In Table 18.15, $F = \sum_i f_i$, r_i is the number of events, t_i is the number of trials in binomial response models, $y_i = 1$ for events and 0 for nonevents in binary response models, and $\widehat{\pi}_i$ is the predicted probability of an event. For polytomous response models specified with single-trial syntax, $y_{ij} = 1$ if the ith observation has response level j, $y_i = 1$, and π_{ij} is the model-predicted probability of response level j for observation i. However, if you specify multinomial-trial syntax, y_{ij} is the number of trials in the ith observation that have response j, and the total number of trials is $y_i = \sum_{j=1}^{J} y_{ij}$.

Difference of Means

For a binary response model, write the mean of the model-predicted probabilities of event (Y=0) observations as $\overline{X}_1 = \frac{\sum_{i=1}^{n}(\widehat{\pi}_i | y_i=0)}{n_0}$ and of nonevent (Y=1) observations as $\overline{X}_2 = \frac{\sum_{i=1}^{n}(\widehat{\pi}_i | y_i=1)}{n_0}$, where $\widehat{\pi}_i$ is the predicted probability of an event. The difference of means is $\overline{X}_1 - \overline{X}_2$, which Tjur (2009) relates to other R-square measures and calls the *coefficient of discrimination*, because it is a measure of the model's ability to distinguish between the event and nonevent distributions. The difference of means is also the d' or Δm statistic (with unit standard error) that is discussed in the signal detection literature (McNicol 2005), and it is also referred to as *Tjur's R-square*.

Classification Table and ROC Curves

For binary response data, the response Y is either an event or a nonevent; let the response Y take the value 1 for an event and 2 for a nonevent. From the fitted model, a predicted event probability $\hat{\pi}_i$ can be computed for each observation i. Define your decision rule as follows: if the predicted event probability equals or exceeds a cutpoint value $z \in [0, 1]$, the observation is classified as an event; otherwise, it is classified as a nonevent. Suppose n_1 of n individuals experience an event, such as a disease, and the remaining $n_2 = n - n_1$ individuals do not experience that event (are nonevents). The 2×2 classification (confusion, decision, error) matrix in Table 18.16 is obtained by cross-classifying the observed and predicted responses, where n_{ij} is the total number of observations that are observed to have $Y = i$ and are classified into j. In this table, let $Y = 1$ denote an observed event and $Y = 2$ denote a nonevent, and let $D = 1$ indicate that the observation is classified as an event and $D = 2$ denote that the observation is classified as a nonevent.

Table 18.16 Classification Matrix

	$D=1$ ($\hat{\pi} \geq z$)	$D=2$ ($\hat{\pi} < z$)	**Total**
$Y=1$ (event)	n_{11}	n_{12}	n_1
$Y=2$ (nonevent)	n_{21}	n_{22}	n_2

The cells of the classification matrix of Table 18.16 are as follows:

- n_{11} = the number of *true positives*, which is the number of event observations that are correctly classified as events
- n_{21} = the number of *false positives*, which is the number of nonevent observations that are incorrectly classified as events
- n_{12} = the number of *false negatives*, which is the number of event observations that are incorrectly classified as nonevents
- n_{22} = the number of *true negatives*, which is the number of nonevent observations that are correctly classified as nonevents
- n_1 = the total number of actual events
- n_2 = the total number of actual nonevents

The accuracy of the classification is measured by its ability to predict events and nonevents correctly. *Sensitivity* (true positive fraction, TPF, recall) is the proportion of event responses that are predicted to be events. *Specificity* (true negative fraction, 1–FPF) is the proportion of nonevent responses that are predicted to be nonevents.

You can also measure accuracy by how well the classification predicts the response. The *positive predictive value* (precision, PPV) is the proportion of observations classified as events that are correctly classified. The *negative predictive value* (NPV) is the proportion of observations classified as nonevents that are correctly classified. The *correct classification rate* (accuracy, PC) is the proportion of observations that are correctly classified, whereas the *misclassification rate* (error rate) is the proportion of observations that are incorrectly classified. The *lift* is the ratio of the proportion of correctly classified events to the proportion of observations classified as events.

The *prevalence*, $\Pr(Y = 1)$, is the prior probability of an event. If the prevalence is different from the observed empirical event probability in the training data, n_1/n, then applying Bayes' theorem shows that the PPV, NPV, accuracy, PC, misclassification rate, and lift equations depend on the prevalence (Fleiss, Levin, and Paik 2003). For a stratified sampling situation in which n_1 and n_2 are chosen a priori, n_1/n is not a desirable estimate of $\Pr(Y = 1)$. You can specify the prevalence by using the PRIOR= option in the MODEL statement. If you specify a PARTITION statement without specifying the PRIOR= option, then the observed empirical probabilities for the training data are used as prevalences for computations of the validation and test statistics.

PROC LOGSELECT constructs the data for a receiver operating characteristic (ROC) curve by initially rounding the predicted probabilities to the nearest multiple of the value of the BINEPS= option. This effectively sorts the observations in increasing order of their estimated event probability. A classification matrix is created for each of these bins by using the rounded probability as the cutpoint. As the cutpoint moves from 0 to 1, those cutpoints for which the classification matrix changes are selected.

Alternatively, if you do not want to generate the entire ROC curve, you can use the CUTPT= option to specify your own list of cutpoints. In this case, the specified cutpoints are used to generate the classification matrices without rounding the predicted probabilities.

You can specify the CTABLE option to produce a classification table that includes these cutpoints and, for each cutpoint, any of the statistics in Table 18.17 that you request.

Table 18.17 Statistics from the Classification Matrix with Cutpoint z

Statistic	Equation	Column Name
Cutpoint	z	ProbLevel
Number of true positives	n_{11}	TruePos
Number of true negatives	n_{22}	TrueNeg
Number of false positives	n_{21}	FalsePos
Number of false negatives	n_{12}	FalseNeg
True positive fraction (sensitivity)	n_{11}/n_1	TPF
False positive fraction (1–specificity)	n_{21}/n_2	FPF
True negative fraction	n_{22}/n_2	TNF
False negative fraction	n_{12}/n_1	FNF
Correct classification rate	$(n_{11} + n_{22})/n$	Accuracy
Percentage correct (PC)	100×Accuracy	PC
Misclassification rate	1 – Accuracy	Misclass
Positive predictive value	$n_{11}/(n_{11} + n_{21})$	PPV
Negative predictive value	$n_{22}/(n_{12} + n_{22})$	NPV
Lift	TPF $/((n_{11} + n_{21})/n)$	Lift

You can output this classification table by specifying the OUT= option, and you can display the ROC curve by using the SGPLOT procedure as shown in Example 18.2.

The area under the ROC curve (AUC), as determined by the trapezoidal rule, is given by the concordance index c, which is described in the section "Association Statistics" on page 1024.

For more information about the topics in this section, see Pepe (2003).

Association Statistics

If you specify the ASSOCIATION option in the PROC LOGSELECT statement, PROC LOGSELECT displays measures of association between predicted probabilities and observed responses for binary, binomial, and ordinal response models. These measures assess the predictive ability of a model.

For ordinal response data, let the predicted mean score of an observation be the sum of the OrderedValue values (shown in the "Response Profile" table) minus one, weighted by the corresponding predicted probabilities for that observation; that is, the predicted means score $= \sum_{i=1}^{k+1}(i-1)\widehat{\pi}_i$, where $k+1$ is the number of response levels and $\widehat{\pi}_i$ is the predicted probability of the ith (ordered) response.

For binary and binomial responses, let the predicted mean score be the predicted event probability.

The predicted mean score is rounded to the nearest multiple of the value that you specify in the BINEPS= option. This effectively sorts the observations in increasing order of their predicted mean score. Of the n pairs of observations in the data that have different responses, let n_c be the number of pairs where the observation that has the lower-ordered response value has a lower predicted mean score, let n_d be the number of pairs where the observation that has the lower-ordered response value has a higher predicted mean score, and let $n_t = n - n_c - n_d$ be the rest of the observations. Let N be the sum of observation frequencies in the data. Then the following statistics are reported:

concordance index c (AUC)	=	$(n_c + 0.5n_t)/n$
Somers' D (Gini coefficient)	=	$(n_c - n_d)/n$
Goodman-Kruskal gamma	=	$(n_c - n_d)/(n_c + n_d)$
Kendall's tau-a	=	$(n_c - n_d)/(0.5N(N-1))$

If there are no ties, then Somers' D (Gini's coefficient) = $2c - 1$. For binary responses, the concordance index, c, is an estimate of the AUC, which is the area under the ROC curve.

If you specify a PARTITION statement, then PROC LOGSELECT displays a column for each of the roles.

Confidence Intervals for Parameters

There are two methods of computing confidence intervals for the regression parameters. One method is based on the profile-likelihood function, and the other method is based on the asymptotic normality of the parameter estimators. The latter method is not as time-consuming as the former method, because it does not involve an iterative scheme; however, it is not thought to be as accurate as the former method, especially for a small sample size.

Likelihood-Ratio-Based Confidence Intervals

The likelihood-ratio-based confidence interval is also known as the profile-likelihood confidence interval. The construction of this interval is derived from the asymptotic χ^2 distribution of the generalized likelihood ratio test (Venzon and Moolgavkar 1988).

Suppose that the parameter vector is $\boldsymbol{\beta} = (\beta_0, \beta_1, \ldots, \beta_s)'$, and you want to compute a confidence interval for β_j. The profile-likelihood function for $\beta_j = \gamma$ is defined as

$$l_j^*(\gamma) = \max_{\boldsymbol{\beta} \in \mathcal{B}_j(\gamma)} l(\boldsymbol{\beta})$$

where $\mathcal{B}_j(\gamma)$ is the set of all $\boldsymbol{\beta}$ with the jth element fixed at γ, and $l(\boldsymbol{\beta})$ is the log-likelihood function for $\boldsymbol{\beta}$. If $l_{\max} = l(\widehat{\boldsymbol{\beta}})$ is the log likelihood evaluated at the maximum likelihood estimate $\widehat{\boldsymbol{\beta}}$, then $2(l_{\max} - l_j^*(\beta_j))$ has a limiting chi-square distribution with one degree of freedom if β_j is the true parameter value. Let $l_0 = l_{\max} - 0.5\chi_1^2(1-\alpha)$, where $\chi_1^2(1-\alpha)$ is the $100(1-\alpha)$th percentile of the chi-square distribution with one degree of freedom. A $100(1-\alpha)\%$ confidence interval for β_j is

$$\{\gamma : l_j^*(\gamma) \geq l_0\}$$

You find the endpoints of the confidence interval by solving numerically for values of β_j that satisfy equality in the preceding relation. To obtain an iterative algorithm for computing the confidence limits, you approximate the log-likelihood function in a neighborhood of $\boldsymbol{\beta}$ by using the quadratic function

$$\tilde{l}(\boldsymbol{\beta} + \boldsymbol{\delta}) = l(\boldsymbol{\beta}) + \boldsymbol{\delta}'\mathbf{g} + \frac{1}{2}\boldsymbol{\delta}'\mathbf{V}\boldsymbol{\delta}$$

where $\mathbf{g} = \mathbf{g}(\boldsymbol{\beta})$ is the gradient vector and $\mathbf{V} = \mathbf{V}(\boldsymbol{\beta})$ is the Hessian matrix. You obtain the increment $\boldsymbol{\delta}$ for the next iteration by solving the likelihood equations

$$\frac{d}{d\boldsymbol{\delta}}\{\tilde{l}(\boldsymbol{\beta} + \boldsymbol{\delta}) + \lambda(\mathbf{e}_j'\boldsymbol{\delta} - \gamma)\} = \mathbf{0}$$

where λ is the Lagrange multiplier, $\mathbf{e}_j$ is the jth unit vector, and γ is an unknown constant. The solution is

$$\boldsymbol{\delta} = -\mathbf{V}^{-1}(\mathbf{g} + \lambda\mathbf{e}_j)$$

By substituting this $\boldsymbol{\delta}$ into the equation $\tilde{l}(\boldsymbol{\beta} + \boldsymbol{\delta}) = l_0$, you can estimate λ as

$$\lambda = \pm\left(\frac{2(l_0 - l(\boldsymbol{\beta}) + \frac{1}{2}\mathbf{g}'\mathbf{V}^{-1}\mathbf{g})}{\mathbf{e}_j'\mathbf{V}^{-1}\mathbf{e}_j}\right)^{\frac{1}{2}}$$

You compute the upper confidence limit for β_j by starting at the maximum likelihood estimate of $\boldsymbol{\beta}$ and iterating with positive values of λ until you reach convergence. You repeat the process for the lower confidence limit by using negative values of λ.

You control convergence by the value ϵ that you specify in the PLCONV= option in the PROC LOGSELECT statement (the default value of ϵ is 1E–4). Convergence is declared if the following two conditions are satisfied:

$$|l(\boldsymbol{\beta}) - l_0| \leq \epsilon$$

and

$$(\mathbf{g} + \lambda\mathbf{e}_j)'\mathbf{V}^{-1}(\mathbf{g} + \lambda\mathbf{e}_j) \leq \epsilon$$

Wald Confidence Intervals

Wald confidence intervals are sometimes called the normal confidence intervals. They are based on the asymptotic normality of the parameter estimators. The $100(1-\alpha)\%$ Wald confidence interval for β_j is given by

$$\widehat{\beta}_j \pm z_{1-\alpha/2}\widehat{\sigma}_j$$

where z_p is the $100p$th percentile of the standard normal distribution, $\widehat{\beta}_j$ is the maximum likelihood estimate of β_j, and $\widehat{\sigma}_j$ is the standard error estimate of $\widehat{\beta}_j$.

Predicted Probabilities and Regression Diagnostics

For binary response data, you can produce observationwise predicted probabilities, confidence limits, and regression diagnostics developed by Pregibon (1981) by specifying the OUTPUT statement. For multinomial response data, you can likewise produce observationwise predicted probabilities, confidence limits, and raw residuals. If you use multinomial-trial syntax so that each observation represents an aggregate of trials, then extensions of Pregibon's diagnostics are also available (Lesaffre and Albert 1989; Williams 1987; Gupta, Nguyen, and Pardo 2008; Martín 2015).

For a binary response model, given a vector of covariates $\mathbf{x}_i$ for the ith observation in your data table and the model-predicted parameter estimates $\hat{\boldsymbol{\beta}}$, you can write the linear predictor $\hat{\eta}_i = \mathbf{x}_i'\hat{\boldsymbol{\beta}}$. The mean of the ith observation $\mu_i(\hat{\boldsymbol{\beta}})$, or the model-predicted event probability $\hat{\pi}_i$, is $\mu_i(\hat{\boldsymbol{\beta}}) = \hat{\pi}_i = g^{-1}(\eta_i)$, where you choose the link function g by specifying the LINK= option. The variance of the binary distribution is $V(\mu) = \mu(1-\mu) = \hat{\pi}_i(1-\hat{\pi}_i) = V(\pi)$, and $\boldsymbol{\Sigma}$ is the estimated covariance of $\hat{\boldsymbol{\beta}}$. Denote the frequency of the ith observation as f_i and the weight as w_i.

For ordinal response models, the predicted cumulative probabilities are computed in the same fashion by using the appropriate model-predicted intercept parameters $\hat{\alpha}_j$ and letting $\boldsymbol{\beta}$ consist of the slope parameters: $\hat{\eta}_{ij} = g(\Pr(Y \le j\,|\mathbf{x}_i) = \hat{\alpha}_j + \mathbf{x}_i'\hat{\boldsymbol{\beta}}$ and $\hat{\pi}_{ij} = \Pr(Y \le j\,|\mathbf{x}_i) = g^{-1}(\eta_{ij})$ for $1 \le j < J$.

For nominal response models, the predicted probabilities are computed by using the appropriate model-predicted intercept parameters $\hat{\alpha}_j$ and letting $\boldsymbol{\beta}_j$ consist of the slope parameters: $\hat{\eta}_{ij} = g(\Pr(Y = j\,|\mathbf{x}_i)) = \hat{\alpha}_j + \mathbf{x}_i'\hat{\boldsymbol{\beta}}_j$ and $\hat{\pi}_{ij} = \Pr(Y = j\,|\mathbf{x}_i) = g^{-1}(\eta_{ij})$ for $1 \le j < J$.

If you perform elastic net or LASSO selection, or if you specify the NOXPX or NOSTDERR option, then your analysis does not generate a covariance matrix, and you can produce only the predicted probabilities (individual, cumulative, and posterior when available) and the raw, Pearson, deviance, and working residuals.

Confidence Intervals

Approximate confidence intervals for predicted probabilities can be computed as follows. The variance of the linear predictor is estimated by

$$\hat{\sigma}^2(\eta_i) = \mathbf{x}_i'\boldsymbol{\Sigma}\mathbf{x}_i$$

For multinomial models, the variance also depends on the response function. Let $\boldsymbol{\delta}_j$ be a $(J–1)$ column vector whose jth entry is equal to 1 and all other entries are equal to 0. Redefine $\mathbf{x}_i = (\boldsymbol{\delta}_j', \mathbf{x}_i')'$, $\eta_i = \eta_{ij}$, and $\pi_i = \pi_{ij}$. Then

$$\hat{\sigma}^2(\eta_i) = \mathbf{x}_i'\boldsymbol{\Sigma}\mathbf{x}_i$$

The asymptotic $100(1-\alpha)\%$ confidence interval for η_i is

$$\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)$$

where $z_{\alpha/2}$ is the $100(1-\alpha/2)$th percentile point of a standard normal distribution.

The predicted probability and the $100(1-\alpha)\%$ confidence limits for π_i are obtained by back-transforming the corresponding measures for the linear predictor. So the confidence limits are

$$g^{-1}\left[\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)\right]$$

Hat-Matrix Diagonals

The diagonal elements of the hat matrix are useful in detecting extreme points in the design space, where they tend to have larger values. For the generalized linear model, the variance of the *i*th individual observation is

$$v_i = \frac{V(\pi_i)}{f_i w_i}$$

For the *i*th observation, let

$$w_{ei} = v_i^{-1}(g'(\pi_i))^{-2}$$

where $g'(\pi_i)$ is the derivative of the link function evaluated at π_i. The weight matrix $\mathbf{W}_e$ is a diagonal matrix, with w_{ei} denoting the *i*th diagonal element, which is used in computing the expected information matrix. Define the leverage, or hat-matrix diagonal, h_i, as the *i*th diagonal element of the matrix

$$\mathbf{W}_e^{\frac{1}{2}}\mathbf{X}(\mathbf{X}'\mathbf{W}_e\mathbf{X})^{-1}\mathbf{X}'\mathbf{W}_e^{\frac{1}{2}}$$

If the estimated probability is extreme (less than 0.1 and greater than 0.9, approximately), then the hat-matrix diagonal might be greatly reduced in value. Consequently, when an observation has a very large or very small estimated probability, its leverage is not a good indicator of the observation's distance from the design space (Hosmer and Lemeshow 2000, p. 171).

When you use multinomial-trial syntax to model aggregated multinomial response data and the PREDPROBS option is in effect, the relevant elements of the resulting hat matrix for observation i are a J–1×J–1 matrix $\mathbf{H}_i$. The following are three scalar representations of the leverage based on $\mathbf{H}_i$ and $\mathbf{M}_i = \mathbf{I}_{J-1} - \mathbf{H}_i$:

determinant:	$h_{Di} = \det(\mathbf{M_i})$
trace:	$h_{Ti} = \frac{1}{J-1}\mathrm{trace}(\mathbf{H}_i)$
potential:	$h_{Pi} = \frac{1}{J-1}\mathrm{trace}(\mathbf{M}_i^{-1}\mathbf{H}_i)$

Residuals

Residuals are useful in identifying observations that are not explained well by the model. For binary and binomial response data, the raw residuals are

$$r_i = y_i/t_i - \hat{\pi}_i$$

where y_i is the number of event responses out of t_i trials for the *i*th observation. For single-trial syntax, $t_i = 1$ and $y_i = 1$ if the ordered response is 1 and $y_i = 0$ otherwise.

For multinomial response data, the raw residuals are

$$r_{ij} = y_{ij}/y_i - \hat{\pi}_{ij}$$

where $\hat{\pi}_{ij}$ are the model-predicted probabilities of the ordered response j for observation i. With single-trial syntax, $y_{ij} = 1$ if the ith observation has ordered response j and $y_{ij} = 0$ otherwise, and $y_i = 1$. With multinomial-trial syntax, y_{ij} is the number of trials in the ith observation which have ordered response j, and $y_i = \sum_j y_{ij}$ is the total number of trials for the ith observation. If the PREDPROBS option is in effect and you use multinomial-trial syntax, the raw residuals are accumulated across the response levels as follows:

$$r_i = \sqrt{\sum_{j=1}^{J} y_{ij} r_{ij}^2}$$

Pearson residuals are the square root of the ith observation's contribution to Pearson's chi-square:

$$r_{Pi} = r_i \sqrt{\frac{w_i}{V(\pi_i)}}$$

where $V(\pi) = \hat{\pi}_i(1 - \hat{\pi}_i)/t_i$. If you use multinomial-trial syntax, the Pearson residuals for each response level j are

$$r_{Pij} = \frac{\sqrt{w_i}\, y_i\, r_{ij}}{\sqrt{y_i \hat{\pi}_{ij}}}$$

and if the PREDPROBS option is in effect, these values are accumulated across the response levels as

$$r_{Pi} = \sqrt{\sum_{j=1}^{J} r_{Pij}^2}$$

Deviance residuals are the square root of the contribution of the ith observation to the deviance, with the sign of the raw residual,

$$r_{Di} = \text{sign}(r_i)\sqrt{d_i}$$

where

$$d_i = 2w_i t_i \left[y_i/t_i \log\left(\frac{y_i/t_i}{\hat{\pi}_i}\right) + (1 - y_i/t_i) \log\left(\frac{1 - y_i/t_i}{1 - \hat{\pi}_i}\right)\right]$$

If you use multinomial-trial syntax, the deviance residuals for each response level j are

$$r_{Dij} = \text{sign}(r_{ij})\sqrt{2w_i y_{ij} \left|\log\left(\frac{y_{ij}}{y_i \hat{\pi}_{ij}}\right)\right|}$$

and if the PREDPROBS option is in effect, these values are accumulated across the response levels as

$$r_{Di} = \pm \sqrt{\left|\sum_{j=1}^{J} \text{sign}(r_{Dij}) r_{Dij}^2\right|}$$

where $\pm$ is the sign of the sum.

The working residuals are

$$r_{Wi} = r_i \left(\frac{\partial \pi_i}{\partial \eta_i} \right)^{-1}$$

Working residuals are not available for multinomial-response models when you specify multinomial-trial syntax or the PREDPROBS option.

The Pearson residuals, standardized to have unit asymptotic variance, are

$$r_{SPi} = \frac{r_{Pi}}{\sqrt{1 - h_i}}$$

If you use multinomial-trial syntax and the PREDPROBS option is in effect, the standardized Pearson residuals are

$$r_{SPi} = \sqrt{\mathbf{r}'_{Pi-J} \mathbf{M}_i^{-1} \mathbf{r}_{Pi-J}}$$

where $\mathbf{r}_{Pi-J} = (r_{Pi1}, \ldots, r_{Pi,J-1})'$.

The deviance residuals, standardized to have unit asymptotic variance, are

$$r_{SDi} = \frac{r_{Di}}{\sqrt{1 - h_i}}$$

If you use multinomial-trial syntax and the PREDPROBS option is in effect, the standardized deviance residuals are

$$r_{SDi} = \text{sign}(\mathbf{r}'_{Di-J} \mathbf{M}_i^{-1} \mathbf{r}_{Di-J}) \sqrt{|\mathbf{r}'_{Di-J} \mathbf{M}_i^{-1} \mathbf{r}_{Di-J}|}$$

where $\mathbf{r}_{Di-J} = (r_{Di1}, \ldots, r_{Di,J-1})'$.

The likelihood residuals, which estimate components of a likelihood ratio test of deleting an individual observation, are a weighted combination of the standardized Pearson and deviance residuals:

$$r_{Li} = \text{sign}(r_i) \sqrt{h_i r_{SPi}^2 + (1 - h_i) r_{SDi}^2}$$

If you use multinomial-trial syntax and the PREDPROBS option is in effect, the likelihood residuals are computed as

$$r_{Li} = \sqrt{\mathbf{r}'_{Pi-J} \mathbf{H}_i \mathbf{M}_i^{-1} \mathbf{r}_{Pi-J} + \mathbf{r}'_{Di-J} \mathbf{r}_{Di-J}} = \sqrt{\text{DIFDEV}_i}$$

Other Regression Diagnostics

The CBAR statistic is a confidence interval displacement diagnostic that provides a scalar measure of the influence of an individual observation on $\widehat{\boldsymbol{\beta}}$. This diagnostic is based on the same idea as the Cook distance in linear regression theory (Cook and Weisberg 1982), but it uses the one-step estimate:

$$\overline{C}_i = r_{Pi}^2 h_i / (1 - h_i)$$

If you use multinomial-trial syntax and the PREDPROBS option is in effect, this diagnostic is computed as follows:

$$\overline{C}_i = \mathbf{r}'_{Pi-J}\mathbf{M}_i^{-1}\mathbf{H}_i\mathbf{r}_{Pi-J}$$

The DIFDEV and DIFCHISQ statistics are diagnostics for detecting ill-fitted observations—observations that contribute heavily to the disagreement between the data and the predicted values of the fitted model. DIFDEV is the change in the deviance that results from deleting an individual observation, and DIFCHISQ is the change in the Pearson chi-square statistic that results from the same deletion. By using the one-step estimate, DIFDEV and DIFCHISQ for the ith observation are computed as follows:

$$\begin{aligned} \text{DIFDEV}_i &= r_{Di}^2 + \overline{C}_i \\ \text{DIFCHISQ}_i &= \overline{C}_i / h_i \end{aligned}$$

If you use multinomial-trial syntax and the PREDPROBS option is in effect, these statistics are computed as follows:

$$\begin{aligned} \text{DIFDEV}_i &= \mathbf{r}'_{Di-J}\mathbf{r}_{Di-J} + \overline{C}_i = r_{Li}^2 \\ \text{DIFCHISQ}_i &= \mathbf{r}'_{Pi-J}\mathbf{r}_{Pi-J} + \overline{C}_i \end{aligned}$$

Diagnostics for Models Fit by Generalized Estimating Equations (GEEs)

The diagnostic statistics in this section were developed by Preisser and Qaqish (1996). See the section "Generalized Estimating Equations" on page 1015 for further information and notation for generalized estimating equations (GEEs). The following additional notation is used in this section.

Partition the design matrix $\mathbf{X}$ and response vector $\mathbf{Y}$ by cluster; that is, let $\mathbf{X} = (X_1', \ldots, X_K')'$ and $\mathbf{Y} = (Y_1', \ldots, Y_K')'$, corresponding to the K clusters.

Let n_i be the number of responses for cluster i, and denote the total number of observations as $N = \sum_{i=1}^{K} n_i$. Denote the $n_i \times n_i$ diagonal matrix as A_i, where $V(\mu_{ij})$ is the jth diagonal element. If there is a WEIGHT statement, the diagonal element of A_i is $V(\mu_{ij})/w_{ij}$, where w_{ij} is the specified weight of the jth observation in the ith cluster. Let $\mathbf{B}$ be the $N \times N$ diagonal matrix with $g'(\mu_{ij})$ as diagonal elements, $i = 1, \ldots, K$, $j = 1, \ldots, n_i$. Let $\mathbf{B}_i$ be the $n_i \times n_i$ diagonal matrix that corresponds to cluster i, where $g'(\mu_{ij})$ is the jth diagonal element.

Let $\mathbf{W}$ be the $N \times N$ block diagonal weight matrix whose ith block, corresponding to the ith cluster, is the $n_i \times n_i$ matrix

$$\mathbf{W}_{ei} = \mathbf{B}_i^{-1}\mathbf{A}_i^{-\frac{1}{2}}\mathbf{R}_i^{-1}(\hat{\boldsymbol{\alpha}})\mathbf{A}_i^{-\frac{1}{2}}\mathbf{B}_i^{-1}$$

where $\mathbf{R}_i(\hat{\boldsymbol{\alpha}})$ is the working correlation matrix for cluster i that is computed using the estimated correlation parameters $\hat{\boldsymbol{\alpha}}$.

Let

$$\mathbf{Q}_i = \mathbf{X}_i(\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\mathbf{X}_i'$$

where $\mathbf{X}_i$ is the $n_i \times p$ design matrix that corresponds to cluster i.

The cluster leverage statistic represents the leverage of cluster i and is contained in the matrix $\mathbf{H}_i = \mathbf{Q}_i\mathbf{W}_{ei}$. The leverage of cluster i is summarized by the trace of $\mathbf{H}_i$:

$$ch_i = \mathrm{tr}(\mathbf{H}_i)$$

The leverage h_t of the tth observation in the ith cluster is the tth diagonal element of $\mathbf{H}_i$.

Joint Tests and Type 3 Tests

Linear hypotheses for $\boldsymbol{\beta}$ are expressed in matrix form as

$$H_0\colon \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

where $\mathbf{L}$ is a matrix of coefficients for the linear hypotheses and $\mathbf{c}$ is a vector of constants. The vector of regression coefficients $\boldsymbol{\beta}$ includes slope parameters and intercept parameters. The Wald chi-square statistic for testing H_0 is computed as

$$\chi^2_W = (\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})'[\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}']^{-1}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})$$

where $\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})$ is the estimated covariance matrix. Under H_0, χ^2_W has an asymptotic chi-square distribution with r degrees of freedom, where r is the rank of $\mathbf{L}$.

For models that use less-than-full-rank parameterization (as specified by the PARAM=GLM option in the CLASS statement), a Type 3 test of an effect of interest (main effect or interaction) is a test of the Type III estimable functions that are defined for that effect. When the model contains no missing cells, the Type 3 test of a main effect is equivalent to testing the hypothesis of equal marginal means. For more information about Type III estimable functions, see the chapter "The GLM Procedure" and the section "The Four Types of Estimable Functions" in *SAS/STAT User's Guide*. Also see Littell, Freund, and Spector (1991).

For models that use full-rank parameterization, all parameters are estimable when there are no missing cells, so it is unnecessary to define estimable functions. The standard test of an effect of interest in this case is the joint test that the values of the parameters associated with that effect are 0. For a model that uses effects parameterization (as specified by the PARAM=EFFECT option in the CLASS statement), the joint test for a main effect is equivalent to testing the equality of marginal means. For a model that uses reference parameterization (as specified by the PARAM=REF option in the CLASS statement), the joint test is equivalent to testing the equality of cell means at the reference level of the other model effects. For more information about the coding scheme and the associated interpretation of results, see Muller and Fetterman (2002, Chapter 14).

If there is no interaction term, the Type 3 test of an effect for a model that uses GLM parameterization is the same as the joint test of the effect for the model that uses full-rank parameterization. In this situation, the joint test is also called the Type 3 test. For a model that contains an interaction term and no missing cells, the Type 3 test of a component main effect under GLM parameterization is the same as the joint test of the component main effect under effect parameterization. Both test the equality of cell means. But this Type 3 test differs from the joint test under reference parameterization, which tests the equality of cell means at the reference level of the other component main effect. If some cells are missing, you can obtain meaningful tests only by testing a Type III estimation function, so in this case you should use GLM parameterization.

The results of a Type 3 test or a joint test do not depend on the order in which you specify the terms in the MODEL statement.

The Hosmer-Lemeshow Goodness-of-Fit Test

Sufficient replication within subpopulations is required to make the Pearson and deviance goodness-of-fit tests valid. When there are one or more continuous predictors in the model, the data are often too sparse to use these statistics. Hosmer and Lemeshow (2000) proposed a statistic that they show, through simulation, is distributed as chi-square when there is no replication in any of the subpopulations—in particular, when you have one or more continuous predictors in your model. Fagerland, Hosmer, and Bofin (2008) and Fagerland and Hosmer (2013, 2016) extend this test to polytomous response models.

The observations are sorted in increasing order of a scored value. For binary response variables, the scored value of an observation is its estimated event probability. The event is the response level that is specified in the response variable EVENT= option, the response level that is not specified in the REF= option, or, if neither of these options is specified, the response level identified in the "Response Profiles" table as "Ordered Value 1." For nominal response variables (LINK=GLOGIT), the scored value of an observation is 1 minus the estimated probability of the reference level (specified using the REF= option). For ordinal response variables, the scored value of an observation is $\sum_{i=1}^{K} i\,\widehat{\pi}_i$, where K is the number of response levels and $\widehat{\pi}_i$ is the predicted probability of the ith ordered response. This scored value is then rounded according to the value of the BINEPS= option.

The observations (and frequencies) are then combined into G groups. By default $G = 10$, but you can specify $G \geq 5$ in the NGROUPS= option of the LACKFIT option. For single-trial syntax, observations that have identical scored values are combined and are placed in the same group. Let F be the total frequency. The target frequency for each group is $T = \lfloor F/G + 0.5 \rfloor$, which is the integer part of $F/G + 0.5$. Load the first group ($g_j, j = 1$) with the observation that has the smallest scored value and with frequency f_1, and let the next-smallest observation have a frequency of f. PROC LOGSELECT performs the following steps for each observation to create the groups:

1. If $j = G$, then add this observation to group g_j.
2. Otherwise, if $f_j < T$ and $f_j + \lfloor f/2 \rfloor \leq T$, then add this observation to group g_j.
3. Otherwise, start loading the next group (g_{j+1}) with $f_{j+1} = f$, and set $j = j + 1$.

If the final group g_j has frequency $f_j < \frac{F}{2G}$, then add these observations to the preceding group. The total number of groups that are actually created, g, can be less than G. There must be at least three groups in order for the Hosmer-Lemeshow statistic to be computed.

For binary response variables, the Hosmer-Lemeshow goodness-of-fit statistic is obtained by calculating the Pearson chi-square statistic from the $2 \times g$ table of observed and expected frequencies, where g is the number of groups. The statistic is written

$$\chi^2_{\mathrm{HL}} = \sum_{j=1}^{g} \frac{(O_j - F_j \bar{\pi}_j)^2}{F_j \bar{\pi}_j (1 - \bar{\pi}_j)}$$

where F_j is the total frequency of subjects in the jth group, O_j is the total frequency of event outcomes in the jth group, and $\bar{\pi}_j$ is the average estimated predicted probability of an event outcome for the jth group. The Hosmer-Lemeshow statistic is then compared to a chi-square distribution with $(g - r)$ degrees of freedom, where the value of r can be specified in the DFREDUCE= suboption of the LACKFIT option. The default is $r = 2$.

For polytomous response variables, the Pearson chi-square statistic is computed from a $2K \times g$ table of observed and expected frequencies,

$$\chi^2_{\mathrm{HL}} = \sum_{j=1}^{g} \sum_{k=1}^{K} \frac{(O_{jk} - E_{jk})^2}{E_{jk}}$$

where O_{jk} is the sum of the observed frequencies and E_{jk} is the sum of the model-predicted probabilities of the observations in group j with response k. The Hosmer-Lemeshow statistic is then compared to a chi-square distribution. The number of degrees of freedom for this test of cumulative and adjacent-category logit models with the equal-slopes assumption is given by Fagerland and Hosmer (2013) and Fagerland and Hosmer (2016) as $(g–r)(K–1)+(K–2)$. The number of degrees of freedom for this test of the generalized logit model is given by Fagerland, Hosmer, and Bofin (2008) as $(g–r)(K–1)$, where K is the number of response levels. The degrees of freedom can also be specified using the DF= suboption of the LACKFIT option.

Large values of χ^2_{HL} (and small p-values) indicate a lack of fit of the model.

Odds Ratio Estimation

An odds ratio can be computed by exponentiating the difference of the logits between any two population profiles. Such computations are available regardless of parameterizations and interactions.

Specify one or more main-effects variables for which you want odds ratios to be computed in the ODDSRATIO statement. You can also specify variables on which constructed effects are based.

If your odds ratio variable is a classification variable, then the odds ratios that compare each pairwise difference between the levels of the odds ratio variable and its reference level are produced. You can compare all pairs of levels by setting the DIFF= option to ALL.

If your odds ratio variable is continuous, then the odds ratios compare the base subpopulation to one where that continuous variable is one unit larger. However, the change in odds for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight might be too small to be considered important, whereas a change of 10 pounds might be more meaningful. You can control the units by specifying the UNIT suboption. If you want your units to represent a multiple of the odds ratio variable's standard error, then specify the STDERR suboption.

The odds ratio for a given odds ratio variable depends on the values of any other covariate with which it interacts. By default, interacting classification covariates are set to their reference level, and interacting continuous covariates are set to their sample means. You can specify the AT option to modify these values. Note that covariates that you specify in the AT option are ignored unless they interact with the odds ratio variable.

Because the log-odds ratio is a linear function of the parameters, the Wald confidence interval for the log-odds ratio can be derived from the parameter estimates and the estimated covariance matrix. Wald confidence intervals for the odds ratios are obtained by exponentiating the corresponding confidence limits for the log-odds ratios. Profile-likelihood confidence intervals are computed as in "Confidence Intervals for Parameters" on page 1024 by replacing the jth unit vector (e_j) with the difference of the logits.

A p-value for an odds ratio is the significance level such that the two-sided Wald confidence interval for that odds ratio has "1" as one of its endpoints. The percentage change in the odds is computed as $100(\psi - 1)$, where ψ is the odds ratio. See Allison (2012) for more information about these statistics.

The odds ratios are uniquely labeled by concatenating the following terms to the odds ratio variable's name:

1. If your model has a generalized logit link, then an odds ratio is computed for each response function, and the odds ratio variable's name is prefixed by the response variable name and the level that describes the logit, followed by a colon; for example, "Y 0:".
2. If the odds ratio variable is continuous and the UNIT suboption provides a value, then append "units=value"; otherwise, if the odds ratio variable is a classification variable, then append the levels that are being contrasted; for example, "cat vs dog".
3. Append all interacting covariates, preceded by "at"; for example, "at X=1.2 A=cat".

Risk Differences and Relative Risks

For a base profile L_1 and a comparison profile L_2 with corresponding model-predicted probabilities $p_1 = g^{-1}(L_1'\boldsymbol{\beta})$ and $p_2 = g^{-1}(L_2'\boldsymbol{\beta})$, where $g^{-1}(\cdot)$ is the inverse link function, the following two risk statistics are available:

Relative risk	$f_r = \frac{p_1}{p_2}$
Risk difference	$f_d = p_1 - p_2$

The covariance of these functions is given by the delta method as $\mathbf{g}(\boldsymbol{\beta})'\mathbf{V}(\boldsymbol{\beta})\mathbf{g}(\boldsymbol{\beta})$, where $\mathbf{V}(\boldsymbol{\beta})$ is the covariance matrix of the model parameters and $\mathbf{g}(\boldsymbol{\beta})$ is the gradient of the function f_r or f_d:

$$\frac{df_r}{d\boldsymbol{\beta}} = \frac{p_2\frac{dp_1}{d\boldsymbol{\beta}} - p_1\frac{dp_2}{d\boldsymbol{\beta}}}{p_2^2}$$
$$\frac{df_d}{d\boldsymbol{\beta}} = \frac{dp_1}{d\boldsymbol{\beta}} - \frac{dp_2}{d\boldsymbol{\beta}}$$

If your risk *variable* is a multinomial response variable, then the risk statistics compare the probability of different response levels by using a common population profile, L. That is, either $f_r = \frac{\Pr(Y=i|L)}{\Pr(Y=J|L)}$ or $f_d = \Pr(Y=i|L) - \Pr(Y=J|L)$ is computed for $i = 1, \ldots, J-1$.

The risks are uniquely labeled in the same fashion as the odds ratios as described in the section "Odds Ratio Estimation" on page 1033, except that all variables that are not set to their default value are included in the label.

Multithreading

The LOGSELECT procedure allocates data to different threads and calculates the likelihood function, gradient, and Hessian by accumulating the values from all threads. For more information about how PROC LOGSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Optimization Algorithms

Several optimization techniques are available in PROC LOGSELECT. You can choose a particular optimizer by using the TECHNIQUE= option in the PROC LOGSELECT statement. Table 18.18 summarizes the optimization techniques available in PROC LOGSELECT.

Table 18.18 Optimization Techniques

TECHNIQUE=	Algorithm
TRUREG	Trust region method
NEWRAP	Newton-Raphson method with line search
NRRIDG	Newton-Raphson method with ridging
QUANEW	Quasi-Newton methods
DBLDOG	Double-dogleg method
CONGRA	Conjugate gradient methods
LBFGS	Limited-memory BFGS quasi-Newton method
NMSIMP	Nelder-Mead simplex method

There is no algorithm for optimizing general nonlinear functions that always finds the global optimum for a general nonlinear optimization problem in a reasonable amount of time. Because no single optimization technique is always superior to others, PROC LOGSELECT provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in PROC LOGSELECT can find the correct solution. Moreover, nonlinear optimization can be computationally expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem. The section "Choosing an Optimization Algorithm" on page 103 in Chapter 2, "Shared Concepts," is helpful in choosing a suitable optimization algorithm.

Memory Usage

In order to use memory efficiently in computing the components for optimization, PROC LOGSELECT reads your data table in multiple batches, or pages; each page contains at most a certain number of observations. During the optimization, the procedure reads the first page of observations from the data table into memory, creates the design rows, performs the appropriate log-likelihood, gradient, and Hessian computations on that page of observations, and then discards those observations and reads in the next page of data for processing.

Generally, smaller pages use less memory but can lead to longer computation times, whereas larger pages can run faster but use more memory. In particular, with sufficient memory, the optimization is typically fastest if you can fit all your data on a single page, because then you do not have to repeatedly reaccess the data table and recompute the design rows.

The default PAGEOBS=AUTO option determines that you have enough memory to use one page for the optimization if the number of observations in your data table for each thread on each machine node is less than $\min(b, 1\text{GB})/(8prt)$

where

- b = the approximate number of bytes available to a machine node, or 1GB
- t = the number of threads available to a machine node
- p = the number of parameters in your model
- r = $2n + 10$ for continuous response models
- r = $2n + y + 9$ for categorical response models
- n = the number of observations in the data table
- y = the number of response levels for categorical response models

If PROC LOGSELECT determines that you do not have enough memory, then PAGEOBS=256 is chosen to optimize the matrix computations, and a note is displayed in the SAS log that gives the value of the PAGEOBS= option that is required if you want to store all the data for a machine node on a single page.

Displayed Output

The following sections describe the output that PROC LOGSELECT produces. The output is organized into various tables, which are discussed in their order of appearance.

Store Information

The "Store Information" table displays basic information about the stored model: the item store name, the names of the library and data table used to create the model, the names of the action and procedure that created the item store, and the date when the model was stored. This table is not displayed when you fit a model.

Store Text

The "Store Text" table displays notes that are stored along with the stored model. This table is not displayed when you fit a model.

Model Information

The "Model Information" table displays basic information about the model, such as the response variable, the frequency variable, the link function, and the distribution of the data that is assumed by the LOGSELECT procedure. For information about how PROC LOGSELECT determines the response distribution, see the section "Response Distributions" on page 1010. If you specify the CODE statement, then the table displays the name of the variable in the scoring code that contains the classifications. If you do not also specify the PCATALL option, then the table also displays the name of the variable in the scoring code that contains the predicted probabilities.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis. If you specify a FREQ statement, the table displays the sum of the frequencies that are read and used. If you specify a WEIGHT statement, the table displays the sum of $f_i w_i$ that are read and used. If you specify a PARTITION statement, the table displays the values for each role.

Response Profile

The "Response Profile" table displays the ordered value from which the LOGSELECT procedure determines the probability that is being modeled as an event in a binary model and displays the ordering of categories in a multinomial model. For each response category level, the frequency that is used in the analysis is reported. If you also specify the PRIOR= option in the MODEL statement, then the scaled prior probabilities are also displayed. You can affect the ordering of the response values by specifying response-options in the MODEL statement. For a binary model, the note that follows the "Response Profile" table indicates which outcome is modeled as the event. For an ordinal multinomial model, the note that follows the "Response Profile" table indicates how the ordered response levels are accumulated; for a nominal multinomial model, the note indicates the reference response level. If you specify a PARTITION statement, the table displays the values for each role.

Class Level Information

The "Class Level Information" table lists the levels of every variable specified in the CLASS statement. You should check this information to make sure that the data are correct. You can adjust the order of the levels by using the ORDER= option in the CLASS statement. You can suppress the "Class Level Information" table completely or partially by using the NOCLPRINT= option in the PROC LOGSELECT statement.

If the classification variables use a nonsingular parameterization, the "Class Level Information" table also displays the reference value for each variable.

Selection Information

When you specify the SELECTION statement, the LOGSELECT procedure by default produces a series of tables that display information about the model selection. The "Selection Information" table informs you about the model selection method, selection and stop criteria, and other parameters that govern the selection. You can suppress this table by specifying the DETAILS=NONE option in the SELECTION statement.

Iteration History

When you specify the ITHIST option in the PROC LOGSELECT statement, the "Iteration History" table displays, for each iteration of the optimization, the number of function evaluations (including gradient and Hessian evaluations), the value of the objective function, the change in the objective function from the previous iteration, and the absolute value of the largest (projected) gradient element. The objective function that is used in the optimization in the LOGSELECT procedure is normalized by default to enable comparisons across data tables that have different sampling intensity. You can control normalization by specifying the NORMALIZE= option in the PROC LOGSELECT statement.

Convergence Status

The convergence status table is a small ODS table that appears as a message that indicates whether the optimization succeeded and which convergence criterion was met. If the optimization fails, the message indicates the reason for the failure. If you save the convergence status table to an output data set, a numeric Status variable is added that enables you to assess convergence programmatically. The values of the Status variable indicate the following:

0 Convergence was achieved, or an optimization was not performed (because the TECHNIQUE=NONE option is specified).

1 The objective function could not be improved.

2 Convergence was not achieved because of a user interruption or because a limit was exceeded, such as the maximum number of iterations or the maximum number of function evaluations. To modify these limits, see the MAXITER=, MAXFUNC=, and MAXTIME= options in the PROC LOGSELECT statement.

3 Optimization failed to converge because function or derivative evaluations failed at the starting values or during the iterations or because a feasible point that satisfies the parameter constraints could not be found in the parameter space.

A numeric Separation variable is also added to the output convergence status table unless the NOCHECK option in the MODEL statement is specified. The values of this variable indicate the following:

2 Complete separation is detected.

1 Quasi-complete separation is detected.

0 Separation is not detected.

-1 Quasi-complete separation is not detected, but at least one of the diagonal elements of the dispersion matrix for the standardized observation vector is larger than 1,000.

-2 Quasi-complete separation is not checked because the standard errors are not available.

-3 Quasi-complete separation is not checked because there are fewer than eight iterations.

Entry and Removal Candidates

When you specify the DETAILS=ALL or DETAILS=STEPS option in the SELECTION statement, the LOGSELECT procedure produces the "Entry Candidates" or "Removal Candidates" table, which displays the effect names and values of the criterion used to select entering or departing effects at each step of the selection process. For each step, the effects are displayed in sorted order from best to worst of the selection criterion.

Selection Summary

When you specify the SELECTION statement, the LOGSELECT procedure produces the "Selection Summary" table, which displays information about which effects were added to or removed from the model in the various steps of the model selection process. The statistic that led to the entry or removal decision is also displayed. You can request further details about the model selection steps by specifying the DETAILS=STEPS or DETAILS=ALL option in the SELECTION statement. You can suppress the display of the "Selection Summary" table by specifying the DETAILS=NONE option in the SELECTION statement.

If you specify the LASSO selection method, then this table displays information about which effect was added to the model, the number of effects in the model, the lambda value, and the information criteria.

Stop Reason

When you specify the SELECTION statement, the LOGSELECT procedure produces a simple table that tells you why model selection stopped.

Selection Reason

When you specify the SELECTION statement, the LOGSELECT procedure produces a simple table that tells you why the final model was selected.

Selected Effects

When you specify the SELECTION statement, the LOGSELECT procedure produces a simple table that tells you which effects are in the final model.

Dimensions

The "Dimensions" table displays size measures that are derived from the model. It displays the number of columns in the current design matrix, the number of effects in the current design, the largest number of design columns associated with an effect, the rank of the matrix, and the number of parameters in the current model, including any scale parameters.

Global Test

The "Global Test" table provides a likelihood ratio test for the hypothesis of whether the final model provides a better fit than a model without effects (an "intercept-only" model). This table is not produced when the NOSTDERR option is specified nor when LASSO selection is performed.

If you specify the NOINT option in the MODEL statement, the reference model is one where the linear predictor is 0 for all observations.

Fit Statistics

The "Fit Statistics" table displays a variety of likelihood-based measures of fit. The values that the "Fit Statistics" table displays are not based on a normalized log-likelihood function. If you specify the PARTITION statement or the PARTFIT option, the table displays the values for each role along with statistics for comparing the training, validation, and testing results.

For more information about the statistics displayed in this table, see the section "Model Fit and Assessment Statistics" on page 1020.

This table is not produced in a GEE analysis.

Parameter Estimates

The parameter estimates, their estimated (asymptotic) standard errors, and p-values for the hypothesis that the parameter is 0 are presented in the "Parameter Estimates" table. If you request confidence intervals by specifying the CLB option in the MODEL statement, confidence limits are produced for the estimates.

This table is not produced by default in a GEE analysis. You can produce this table by specifying the PRINTMLE option in the REPEATED statement. In this case, the table is labeled "Analysis of Initial Parameter Estimates."

Parameter Estimates Covariance Matrix

When you specify the COVB option in the PROC LOGSELECT statement, the LOGSELECT procedure displays the covariance matrix of the parameter estimates. The covariance matrix is computed as the inverse of the negative of the matrix of second derivatives of the log-likelihood function with respect to the model parameters (the Hessian matrix), evaluated at the parameter estimates.

This table is not produced in a GEE analysis.

Parameter Estimates Correlation Matrix

When you specify the CORRB option in the PROC LOGSELECT statement, the LOGSELECT procedure displays the correlation matrix of the parameter estimates.

This table is not produced in a GEE analysis.

GEE Model Information

When you specify the REPEATED statement, the "GEE Model Information" table displays basic information about the GEE model, including the subject effects, any within-subject effects, the working correlation type, and details about the size of the working correlation matrix.

GEE Parameter Estimates Covariance Matrix Using Model-Based Covariance

When you specify the MCOVB or COVB option in the REPEATED statement, the "GEE Parameter Estimates Covariance Matrix Using Model-Based Covariance" table displays the parameter estimates covariance matrix from the GEE analysis that uses the model-based covariance estimate. For more information about the covariance estimates that are used for GEE analysis, see the section "Parameter Estimate Covariances" on page 1018.

GEE Parameter Estimates Correlation Matrix Using Model-Based Covariance

When you specify the MCORRB or CORRB option in the REPEATED statement, the "GEE Parameter Estimates Correlation Matrix Using Model-Based Covariance" table displays the parameter estimates correlation matrix from the GEE analysis that uses the model-based covariance estimate. For more information about the covariance estimates that are used for GEE analysis, see the section "Parameter Estimate Covariances" on page 1018.

GEE Parameter Estimates Covariance Matrix Using Empirical Covariance

When you specify the ECOVB or COVB option in the REPEATED statement, the "GEE Parameter Estimates Covariance Matrix Using Empirical Covariance" table displays the parameter estimates covariance matrix from the GEE analysis that uses the empirical covariance estimate. For more information about the covariance estimates that are used for GEE analysis, see the section "Parameter Estimate Covariances" on page 1018.

GEE Parameter Estimates Correlation Matrix Using Empirical Covariance

When you specify the ECORRB or CORRB option in the REPEATED statement, the "GEE Parameter Estimates Correlation Matrix Using Empirical Covariance" table displays the parameter estimates correlation matrix from the GEE analysis that uses the empirical covariance estimate. For more information about the covariance estimates that are used for GEE analysis, see the section "Parameter Estimate Covariances" on page 1018.

GEE Working Correlation Matrix

When you specify the CORRW option in the REPEATED statement, the "GEE Working Correlation Matrix" table displays the correlation matrix of the repeated measures. Its dimension depends on the number of repeated measures and any within-subject effects.

GEE Exchangeable Correlation

When you specify the CORRW and TYPE=EXCH options in the REPEATED statement, the "GEE Exchangeable Correlation" table displays the exchangeable correlation parameter. For more information about the working correlation structures, see the section "Working Correlation Matrix" on page 1016.

GEE Fit Criteria

When you specify the REPEATED statement, the "GEE Fit Criteria" table displays the information criteria for the GEE model. For more information about the fit statistics that are used with GEE, see the section "Quasi-likelihood Information Criterion" on page 1018.

GEE Parameter Estimates Using Empirical Standard Errors

When you specify the REPEATED statement, the "GEE Parameter Estimates Using Empirical Standard Errors" table presents the parameter estimates from the GEE analysis. The table displays the standard errors that are derived from the empirical covariance matrix. The table includes the parameter estimates, their estimated standard errors, and p-values for the hypothesis that the parameter is 0. If you request confidence intervals by specifying the CLB option in the MODEL statement, confidence limits are produced for the estimates.

For more information about the covariance estimates that are used for GEE analysis, see the section "Parameter Estimate Covariances" on page 1018.

GEE Parameter Estimates Using Model-Based Standard Errors

When you specify the MODELSE option in the REPEATED statement, the "GEE Parameter Estimates Using Model-Based Standard Errors" table presents the parameter estimates from the GEE analysis. The table displays the standard errors that are derived from the model-based covariance matrix. The table includes the parameter estimates, their estimated standard errors, and p-values for the hypothesis that the parameter is 0. If you request confidence intervals by specifying the CLB option in the MODEL statement, confidence limits are produced for the estimates.

For more information about the covariance estimates that are used for GEE analysis, see the section "Parameter Estimate Covariances" on page 1018.

Model Analysis of Variance (Type III)

When you specify the TYPE3 option in the MODEL statement, the LOGSELECT procedure produces the "Model Analysis of Variance (Type III)" table. This table displays tests that all parameters for a particular effect are 0. For more information, see the section "Joint Tests and Type 3 Tests" on page 1031.

This table is not produced in a GEE analysis.

Postfit Information

The "Postfit Information" table displays the name of the data table that the stored model uses to create the results that are displayed in the Restore section of the output, the number of observations that are read from this data table, and the number of observations that are used in the analyses. If you specify a FREQ statement, the table displays the sum of the frequencies that are read and used. If you specify a WEIGHT statement, the table displays the sum of $f_i w_i$ that are read and used. If the stored model is created using a PARTITION statement, the table displays the values for each role. This table is not displayed when you fit a model. This table is followed by "Response Profile" and "Fit Statistics" tables that are computed by using the input data table.

Association Statistics

When you specify the ASSOCIATION option in the PROC LOGSELECT statement and have binary, binomial, or ordinal response data, the "Association Statistics" table displays the concordance index c (the area under the ROC curve, AUC), Somers' D statistic (Gini's coefficient), Goodman-Kruskal's gamma statistic, and Kendall's tau-a statistic, along with raw counts of pairs of observations. If you also specify a PARTITION statement, a row is displayed for each role. For more information, see the section "Association Statistics" on page 1024.

Classification Table

The "Classification" table is displayed if you specify the CTABLE option without specifying an output data set. If you also specify a PARTITION statement, a table is displayed for each role. For more information, see the section "Classification Table and ROC Curves" on page 1022.

Partition for the Hosmer and Lemeshow Test

If you specify the LACKFIT option in the PROC LOGSELECT statement, the "Partition for the Hosmer and Lemeshow Test" table displays the grouping that is used in the Hosmer-Lemeshow test. If you also specify a PARTITION statement, the grouping is displayed for each role. For more information, see the section "The Hosmer-Lemeshow Goodness-of-Fit Test" on page 1032. For examples of using this partition, see Hosmer and Lemeshow (2000).

Hosmer and Lemeshow Goodness-of-Fit Test

If you specify the LACKFIT option in the PROC LOGSELECT statement, the "Hosmer and Lemeshow Goodness-of-Fit Test" table is displayed. It provides a test of the fit of the model; small p-values reject the null hypothesis that the fitted model is adequate. If you also specify a PARTITION statement, a test is displayed for each role. For more information, see the section "The Hosmer-Lemeshow Goodness-of-Fit Test" on page 1032.

Odds Ratios

The "Odds Ratios" table is displayed when you specify the ODDSRATIO statement. It displays the odds ratio estimates, the optional Wald confidence limits, a p-value, and the percentage change in odds. For more information, see the section "Odds Ratio Estimation" on page 1033.

Coefficients for Risk Computations

The "Coefficients for Risk Computations" table is displayed when you specify the E option in the RISK statement. It displays the profile coefficients that are used by the risk computations. For more information, see the section "Risk Differences and Relative Risks" on page 1034.

Risks

The "Risks" table is displayed when you specify the RISK statement. It displays the risk estimates, confidence limits, and a p-value. For more information, see the section "Risk Differences and Relative Risks" on page 1034.

Score Code Variables for Predicted Probability

When you specify the PCATALL option in the CODE statement, PROC LOGSELECT produces the "Score Code Variables for Predicted Probability" table. For each level of the response variable, this table displays the corresponding variable in the scoring code that contains the predicted probability.

Timing

The "Timing" table displays the amount of time (in seconds) that PROC LOGSELECT required in order to perform different tasks in the analysis.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS procedure execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the LOGSELECT procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or ODS statements. These names are listed in Table 18.19.

The EFFECT and LSMEANS statements also create tables that are not listed in Table 18.19. For information about these tables, see the corresponding sections of Chapter 2, "Shared Concepts."

Table 18.19 ODS Tables Produced by PROC LOGSELECT

Table Name	Description	Statement	Options
Association	Association of predicted probabilities and observed responses	PROC LOGSELECT	ASSOCIATION
Classification	Classification table	PROC LOGSELECT	CTABLE
ClassInfo	Level information from the CLASS statement	CLASS	Default
ConvergenceStatus	Status of optimization at conclusion of optimization	Default	
CorrB	Correlation matrix of parameter estimates	PROC LOGSELECT	CORRB
CovB	Covariance matrix of parameter estimates	PROC LOGSELECT	COVB
Dimensions	Model dimensions	Default	
EntryCandidates	Details about candidates for entry into the model	SELECTION	METHOD=FORWARD or STEPWISE and DETAILS=STEP
FitStatistics	Fit statistics	Default	
GEEEmpPEst	GEE parameter estimates using empirical standard errors	REPEATED	Default
GEEExchCorr	Exchangeable correlation parameter	REPEATED	TYPE=EXCH
GEEFitCriteria	Measures of fit for GEE models	REPEATED	Default
GEEModInfo	Information about GEE model	REPEATED	Default
GEEModPEst	GEE parameter estimates using model-based standard errors	REPEATED	MODELSE

Table 18.19 *continued*

Table Name	Description	Statement	Options
GEENCorr	Correlation matrix of GEE parameter estimates using model-based covariance	REPEATED	CORRB or MCORRB
GEENCov	Covariance matrix of GEE parameter estimates using model-based covariance	REPEATED	COVB or MCOVB
GEERCorr	Correlation matrix of GEE parameter estimates using empirical covariance	REPEATED	CORRB or ECORRB
GEERCov	Covariance matrix of GEE parameter estimates using empirical covariance	REPEATED	COVB or ECOVB
GEEWCorr	Working correlation matrix of repeated measures	REPEATED	CORRW
GlobalTest	Test of the model versus the null model	Default	
IterHistory	Iteration history	PROC LOGSELECT	ITHIST
LackFitChiSq	Hosmer-Lemeshow chi-square test results	PROC LOGSELECT	LACKFIT
LackFitPartition	Partition for the Hosmer-Lemeshow test	PROC LOGSELECT	LACKFIT
LVectors	Coefficients for risk computations	RISK	E
ModelInfo	Information about the modeling environment	Default	
ModelAnova	Model analysis of variance (Type III)	MODEL	TYPE3
NObs	Number of observations read and used, and number of events and trials, if applicable	Default	
OddsRatios	Odds ratio estimates and Wald confidence intervals	ODDSRATIO	
OutputCasTables	See the section "OutputCasTables Table" on page 1044	OUTPUT DISPLAYOUT	OUT=
ParameterEstimates	Solutions for the parameter estimates associated with effects in MODEL statements	Default	
PostfitInfo	Input data table name and number of observations read and used for the restored model	PROC LOGSELECT	RESTORE= and DATA=

Table 18.19 *continued*

Table Name	Description	Statement	Options
PredProbName	Displays the predicted probability variable in the scoring code associated with each response level	CODE	PCATALL
RemovalCandidates	Details about candidates for removal from the model	SELECTION	METHOD=BACKWARD or STEPWISE and DETAILS=STEP
ResponseProfile	Response categories for binary and multinomial data	Default	
Risks	Risk estimates and Wald confidence intervals	RISK	
SelectedEffects	List of effects selected for the model	SELECTION	Default
SelectionInfo	Information about the settings for model selection	SELECTION	Default
SelectionReason	Reason why the particular model was selected	SELECTION	Default
SelectionSummary	Summary information about model selection steps	SELECTION	Default
StopReason	Reason for termination of model selection	SELECTION	Default
StoreInfo	Information about the restored model	PROC LOGSELECT	RESTORE=
StoreText	Notes stored along with the model	PROC LOGSELECT	RESTORE=
Timing	Absolute and relative times for tasks performed by the procedure	Default	

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

When ODS Graphics is enabled, the SELECTION statement can produce plots to help evaluate the selection process. For information about these plots, see the section "Model Selection Plots" on page 93 in Chapter 2, "Shared Concepts."

PROC LOGSELECT assigns a name to each graph that it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 18.20.

Table 18.20 Graphs Produced by PROC LOGSELECT

ODS Graph Name	Plot Description	PLOTS Option
CoefficientPanel	Coefficients and CHOOSE= criterion by step	COEFFICIENTS
ChooseCriterionPlot	CHOOSE= criterion by step	COEFFICIENTS(UNPACK)
CoefficientPlot	Coefficients by step	COEFFICIENTS(UNPACK)
CriterionPanel	Fit criteria by step	CRITERIA
AdjRSqPlot	Max-rescaled (adjusted) R-square by step	CRITERIA(UNPACK)
AICCPlot	Corrected Akaike's information criterion by step	CRITERIA(UNPACK)
AICPlot	Akaike's information criterion by step	CRITERIA(UNPACK)
DiffMeanPlot	Difference of means by step	CRITERIA(UNPACK)
McFaddenPlot	McFadden's R-square by step	CRITERIA(UNPACK)
MisclassPlot	Misclassification rate by step	CRITERIA(UNPACK)
SBCPlot	Schwarz Bayesian information criterion by step	CRITERIA(UNPACK)
TEST_ASEPlot	Average square error on testing data by step	CRITERIA(UNPACK)
TRAIN_ASEPlot	Average square error on training data by step	CRITERIA(UNPACK)
VAL_ASEPlot	Average square error on validation data by step	CRITERIA(UNPACK)
FitByRolePlot	Progression of average square error by role	FITBYROLE

Examples: LOGSELECT Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 18.1: Model Selection

(View the complete code for this example (logex1.sas) in the example repository.)

The following statements examine the same data as in the section "Getting Started: LOGSELECT Procedure" on page 964, but they request model selection via the forward selection technique. Effects that provide the best improvement to the selection criterion, SBC, are added until no more effects can improve the selection criterion. The DETAILS=ALL option in the SELECTION statement produces all tables that are related to model selection. The PLOTS=ALL option produces graphics to help you interpret the selection process. ODS Graphics must be enabled before you can request plots. For more information about ODS Graphics, see the section "ODS Graphics" on page 1046.

```
ods graphics on;

proc logselect data=mylib.getStarted;
   class C;
   model y = C x1-x10;
   selection method=forward details=all plots=all;
run;

ods graphics off;
```

The model selection tables are shown in Output 18.1.1 through Output 18.1.3. Results from the selected model are shown in Output 18.1.4 and Output 18.1.5. Selection graphics that the PLOTS= option produces are displayed in Output 18.1.6 and Output 18.1.7.

The "Selection Information" table in Output 18.1.1 summarizes the settings for the model selection. Effects are added to the model only if they produce a significant improvement, which is determined by comparing the values of their SBCs. The forward selection stops three steps after the smallest SBC is obtained or when all effects have been added to the model.

Output 18.1.1 Selection Information

Example 1: Model Selection

The LOGSELECT Procedure

Selection Information	
Selection Method	Forward
Select Criterion	SBC
Stop Criterion	SBC
Effect Hierarchy Enforced	None
Stop Horizon	3

For each step of the selection process, the DETAILS=ALL option displays the candidate effects for entering the model along with their SELECT= criterion. Output 18.1.2 displays this table for the first step; the other steps are not shown here.

Output 18.1.2 Step1 Entry Candidates

Best 10 Entry Candidates		
Rank	**Effect**	**SBC**
1	**x8**	128.7318
2	**x2**	129.0423
3	**x4**	129.3708
4	**x9**	131.0854
5	**x1**	131.8215
6	**x10**	132.4430
7	**x5**	132.9424
8	**x3**	132.9667
9	**x7**	133.0021
10	**x6**	133.0283

The DETAILS=ALL option also displays the dimensions, global test, fit statistics, and parameter estimates at each step of the selection process; these details are not shown here.

When the selection procedure is complete, the "Selection Summary" table in Output 18.1.3 shows the effects that were added to the model and the value of their selection criterion (and the choose and stop criteria, if they are specified). Step 0 refers to the null model that contains only an intercept. In the next step, effect x8 made the most significant contribution to the model among the candidate effects, according to the SBC statistic. In step 2, x2 made the most significant contribution when an effect was added to a model that contains the intercept and x8. In the three subsequent steps, no effect could be added to the model that would reduce the SBC, so variable selection stopped because the stop horizon (see Output 18.1.1) indicates that at most three steps beyond the minimum SBC value are taken.

In Output 18.1.3, the "Selection Summary" table is followed by three small tables that summarize why the process stopped and which model is selected.

Output 18.1.3 Selection Summary Information

Selection Summary			
Step	Effect Entered	Number Effects In	SBC
0	Intercept	1	128.4253
1	x8	2	128.7318
2	x2	3	128.2892*
3	x4	4	130.0901
4	x9	5	131.9534
5	x1	6	134.7945
* Optimal Value Of Criterion			

Selection stopped at a local minimum of the STOP criterion.

The model at step 2 is selected.

Selected Effects: Intercept x2 x8

Output 18.1.4 displays information about the selected model. Notice that the –2 log-likelihood value in the "Fit Statistics" table is larger than the value for the full model in Figure 18.9. This is expected because the selected model contains only a subset of the parameters. Because the selected model is more parsimonious than the full model, the discrepancy between the –2 log likelihood and the information criteria is less severe than previously noted.

Output 18.1.4 Fit Statistics and Null Test

Dimensions	
Columns in Design	3
Number of Effects	3
Max Effect Columns	1
Rank of Design	3
Parameters in Optimization	3

Testing Global Null Hypothesis: BETA=0			
Test	DF	Chi-Square	Pr > ChiSq
Likelihood Ratio	2	9.4237	0.0090

Fit Statistics	
-2 Log Likelihood	114.39646
AIC (smaller is better)	120.39646
AICC (smaller is better)	120.64646
SBC (smaller is better)	128.21197

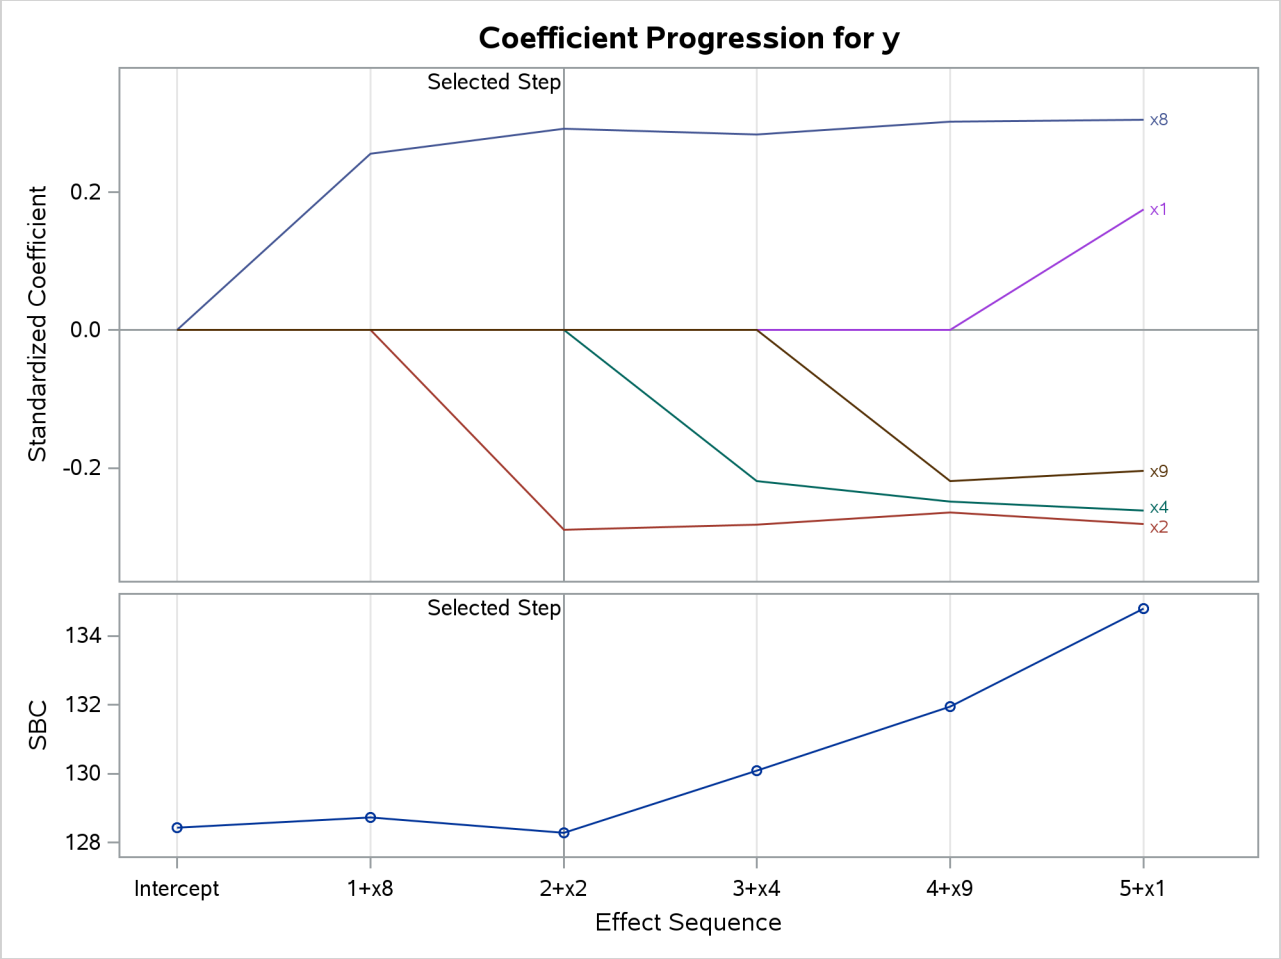
The parameter estimates of the selected model are shown in Output 18.1.5. Notice that the effects are listed in the "Parameter Estimates" table in the order in which they were specified in the MODEL statement and not in the order in which they were added to the model.

Output 18.1.5 Parameter Estimates

Parameter Estimates

Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
Intercept	1	0.858377	0.550302	2.4331	0.1188
x2	1	-0.250240	0.114578	4.7700	0.0290
x8	1	1.783956	0.790845	5.0885	0.0241

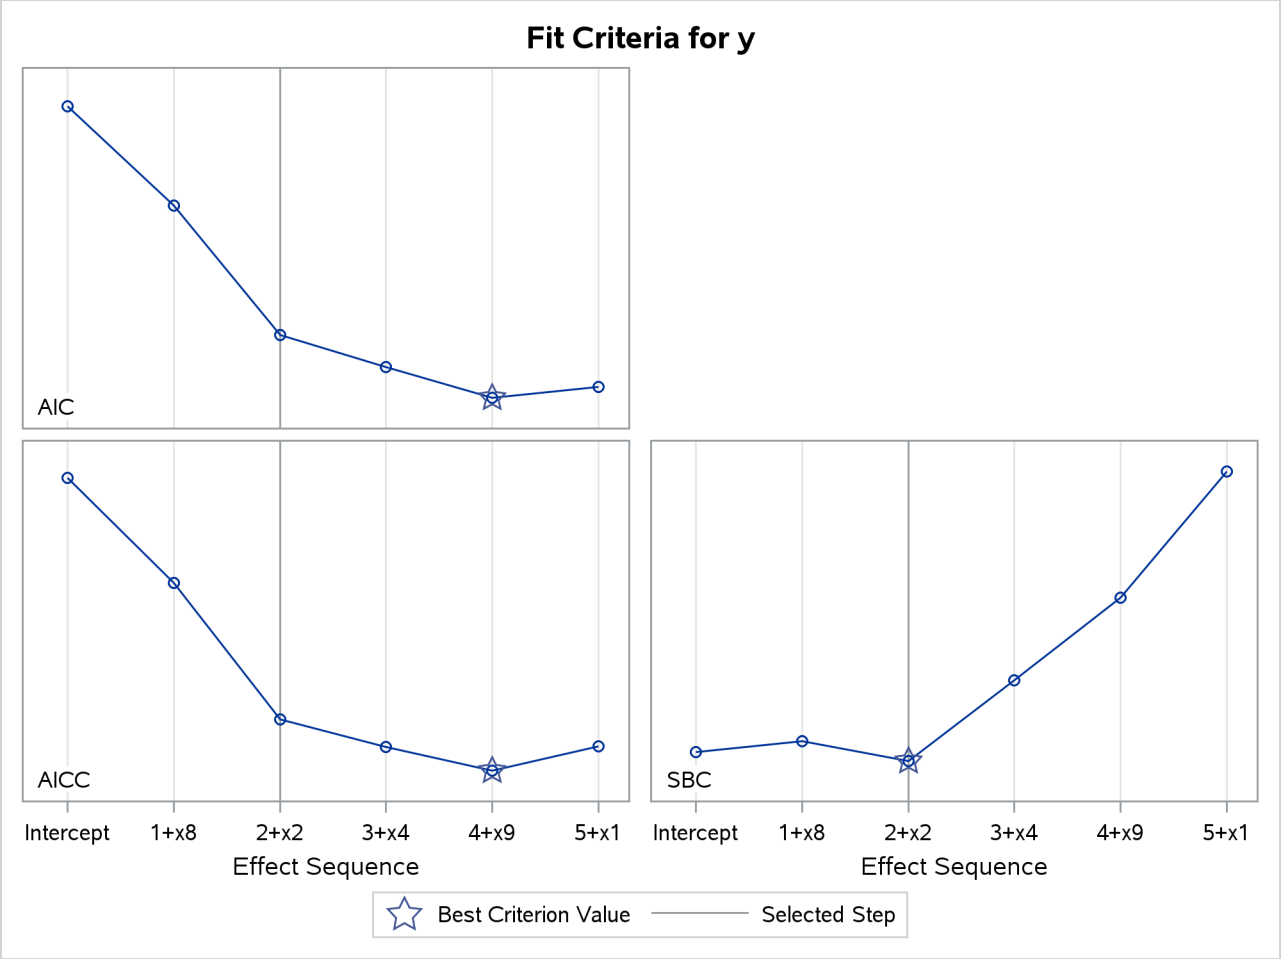
You can construct the prediction equation for this model from the parameter estimates as follows. The estimated linear predictor for an observation is



$$\widehat{\eta} = 0.8584 - 0.2502 \times x_2 + 1.7840 \times x_8$$

The predicted probability that variable y takes the value 0 is

$$\widehat{\Pr}(Y = 0) = \frac{1}{1 + \exp\{-\widehat{\eta}\}}$$



The coefficient panel in Figure 18.1.6 enables you to visualize the selection process. In this plot, standardized coefficients of all the effects that are selected at some step of the stepwise method are plotted as a function of the step number. This enables you to assess the relative importance of the effects that are selected at any step of the selection process and to know when effects entered the model. The lower plot in the panel shows how the criterion that is used to choose the selected model changes as effects enter or leave the model.

Output 18.1.6 Coefficient Progression

The criterion panel in Figure 18.1.7 provides a graphical view of the progression of the fit criteria as the selection process evolves. Notice at Step 0 that the SBC criterion seems to be at its minimum. Because the stop horizon value is 3 (see Output 18.1.1), three more steps are taken in case Step 0 is a local optimum. In this example, the global optimum is found two steps later.

Output 18.1.7 Criterion Panel

Example 18.2: Modeling Binomial Data

(View the complete code for this example (logex2.sas) in the example repository.)

If $Y_1, \ldots, Y_n$ are independent binary (Bernoulli) random variables with common success probability π, then their sum is a binomial random variable. In other words, a binomial random variable with parameters n and π can be generated as the sum of n Bernoulli(π) random experiments. The LOGSELECT procedure uses a special syntax, the events/trials syntax, to express data in binomial form.

Consider the following data, taken from Cox and Snell (1989, pp. 10–11), of the number of ingots not ready for rolling (r) out of n tested for a number of combinations of heating time and soaking time. If each test is carried out independently and if for a particular combination of heating and soaking time there is a constant probability that the tested ingot is not ready for rolling, then the random variable r follows a binomial(n, π) distribution, where the success probability π is a function of heating and soaking time.

```
data Ingots;
   input Heat Soak r n @@;
   Obsnum= _n_;
   datalines;
7 1.0 0 10  14 1.0 0 31  27 1.0 1 56  51 1.0 3 13
7 1.7 0 17  14 1.7 0 43  27 1.7 4 44  51 1.7 0  1
7 2.2 0  7  14 2.2 2 33  27 2.2 0 21  51 2.2 0  1
7 2.8 0 12  14 2.8 0 31  27 2.8 1 22  51 4.0 0  1
7 4.0 0  9  14 4.0 0 19  27 4.0 1 16
;
data mylib.Ingots;
   set Ingots;
run;
```

The following statements show the use of the events/trials syntax to model the binomial response. The events variable in this situation is *r* (the number of ingots not ready for rolling), and the trials variable is *n* (the number of ingots that are tested). The dependency of the probability of not being ready for rolling is modeled as a function of heating time, soaking time, and their interaction. The ASSOCIATION option displays ordinal measures of association between the observed responses and the predicted probabilities. The CTABLE option saves statistics to the mylib.Roc data table that are used to evaluate the predictive power of the model. The OUTPUT statement stores the linear predictors and the predicted probabilities in the mylib.Out data table along with the other variables from the input data table.

```
proc logselect data=mylib.Ingots association ctable(out=mylib.Roc nocounts tpf fpf);
   model r/n = Heat Soak Heat*Soak;
   output out=mylib.Out xbeta predicted=Pred copyvars=(Heat Soak);
run;
```

The "Model Information" table shows that the data are modeled as binomially distributed with a logit link function (Output 18.2.1). This is the default link function in the LOGSELECT procedure for binary and binomial data. The procedure estimates the parameters of the model by a Newton-Raphson algorithm.

Output 18.2.1 Model Information and Number of Observations

The LOGSELECT Procedure

Model Information	
Data Source	INGOTS
Response Variable (Events)	r
Response Variable (Trials)	n
Distribution	Binomial
Link Function	Logit
Optimization Technique	Newton-Raphson with Ridging

Number of Observations Read	19
Number of Observations Used	19

Response Profile		
Ordered Value	**Binary Outcome**	**Total Frequency**
1	**Event**	12
2	**Nonevent**	375

The second table in Output 18.2.1 shows that all 19 observations in the input data table were used in the analysis and the "Response Profile" table shows that the total number of events and nonevents equals 12 and 387, respectively.

Output 18.2.2 displays the convergence status table for this run. The LOGSELECT procedure satisfies the GCONV= convergence criterion.

Output 18.2.2 Convergence Status

Convergence criterion (GCONV=1E-8) satisfied.

Output 18.2.3 displays the "Dimensions" table for the model. The design matrix of the model (the **X** matrix) has four columns, which correspond to the intercept, the Heat effect, the Soak effect, and the interaction of the Heat and Soak effects. The model is nonsingular because the rank of the crossproducts matrix equals the number of columns in **X**. All parameters are estimable, and all participate in the optimization.

Output 18.2.3 Dimensions in Binomial Logistic Regression

Dimensions	
Columns in Design	4
Number of Effects	4
Max Effect Columns	1
Rank of Design	4
Parameters in Optimization	4

Output 18.2.4 displays the "Fit Statistics" table for this run. Evaluated at the converged estimates, –2 times the value of the log-likelihood function equals 27.9569. Further fit statistics are also displayed, all of them in "smaller is better" form. The AIC, AICC, and SBC criteria are used to compare non-nested models and to penalize the model fit for the number of observations and parameters. You can use the –2 log-likelihood value to compare nested models by way of a likelihood ratio test.

Output 18.2.4 Fit Statistics

Fit Statistics	
-2 Log Likelihood	27.95689
AIC (smaller is better)	35.95689
AICC (smaller is better)	38.81403
SBC (smaller is better)	39.73464

Output 18.2.5 shows the test of the global hypothesis that the effects jointly do not affect the probability of ingot readiness. You can obtain the chi-square test statistic by comparing the –2 log-likelihood value of the model with covariates to the value in the intercept-only model. The test is significant, with a p-value of 0.0082. One or more of the effects in the model have a significant impact on the probability of ingot readiness.

Output 18.2.5 Null Test

Testing Global Null Hypothesis: BETA=0			
Test	**DF**	**Chi-Square**	**Pr > ChiSq**
Likelihood Ratio	3	11.7663	0.0082

The "Parameter Estimates" table in Output 18.2.6 displays the estimates and standard errors of the model effects.

Output 18.2.6 Parameter Estimates

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
Intercept	1	-5.990191	1.666622	12.9183	0.0003
Heat	1	0.096339	0.047067	4.1896	0.0407
Soak	1	0.299574	0.755068	0.1574	0.6916
Heat * Soak	1	-0.008840	0.025319	0.1219	0.7270

Output 18.2.7 displays the "Association Statistics" table, which is produced when you specify the ASSOCIATION option in the PROC LOGSELECT statement. The table contains four measures of association for assessing the predictive ability of a model. For more information, see the section "Association Statistics" on page 1024.

Output 18.2.7 Association of Observed Responses and Predicted Probabilities

Association of Predicted Probabilities and Observed Responses	
Concordance Index (AUC)	0.7706
Somers' D	0.5411
Gamma	0.5858
Tau-a	0.0326
Pairs	4500
Percent Concordant	73.2444
Percent Discordant	19.1333
Percent Tied	7.6222

You can construct the prediction equation of the model from the "Parameter Estimates" table. For example, an observation with Heat equal to 14 and Soak equal to 1.7 has the linear predictor

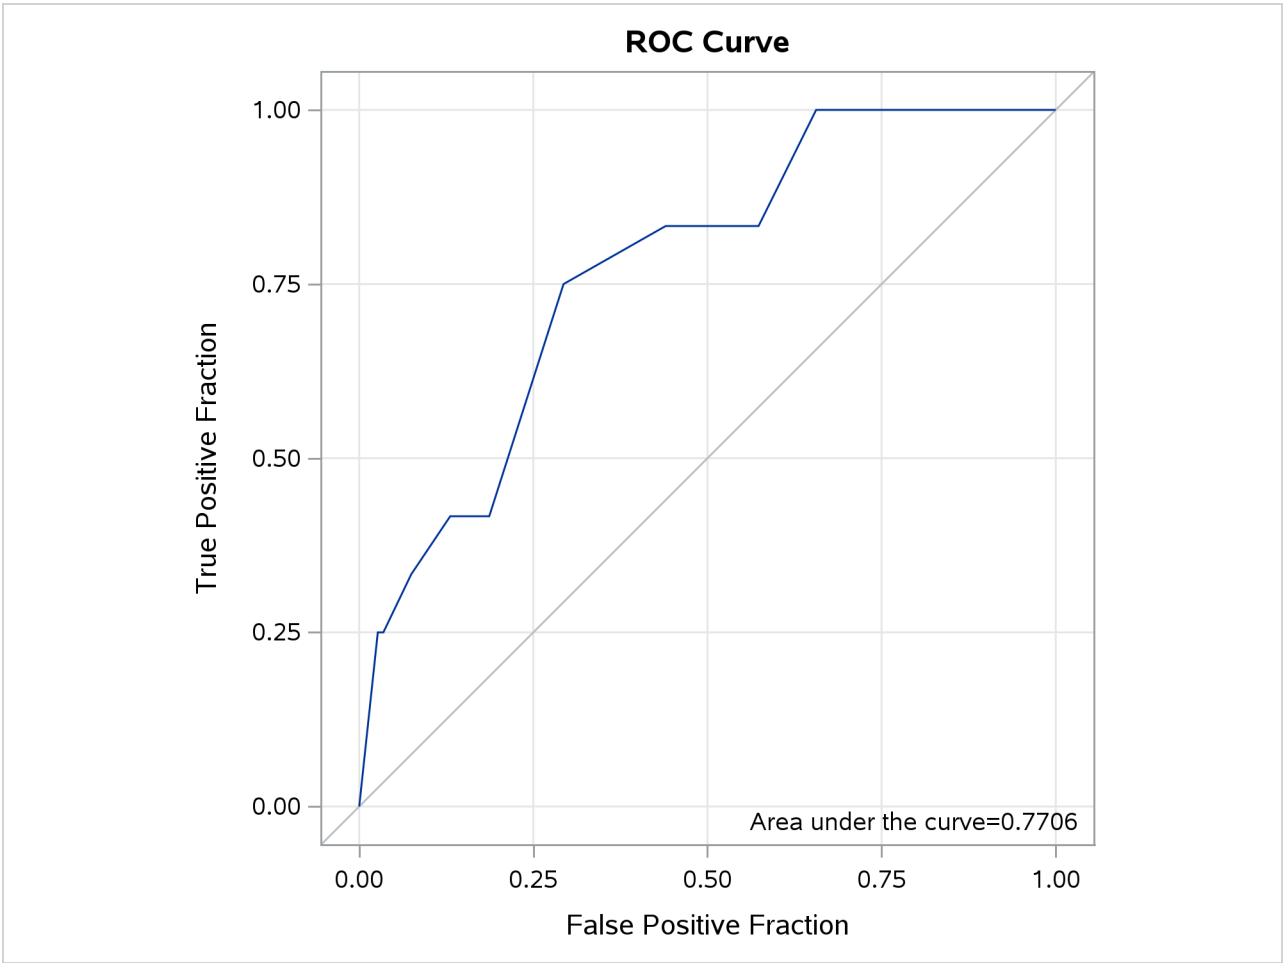
$$\widehat{\eta} = -5.9902 + 0.09634 \times 14 + 0.2996 \times 1.7 - 0.00884 \times 14 \times 1.7 = -4.3425$$

The probability that an ingot with these characteristics is not ready for rolling is

$$\widehat{\pi} = \frac{1}{1 + \exp\{-(-4.3425)\}} = 0.01284$$

PROC LOGSELECT computes these linear predictors and probabilities and stores them in the mylib.Out data table. The following PROC PRINT statement produces Output 18.2.8, which shows the probability that an ingot with Heat equal to 14 and Soak equal to 1.7 is not ready for rolling:

```
proc print data=mylib.Out;
   where Heat=14 & Soak=1.7;
run;
```



Output 18.2.8 Predicted Probability for Heat=14 and Soak=1.7

Obs	Pred	_XBETA_	Heat	Soak
1	0.012836	-4.34256	14	1.7

The CTABLE option computes statistics for binary response models (on the basis of classifying observations according to whether their predicted probabilities exceed certain values) and stores the results in the mylib.Roc data table. For more information, see the section "Classification Table and ROC Curves" on page 1022. You can use this data table to display the ROC curve by using the SGPLOT procedure as follows:

```
ods graphics on;
proc sgplot data=mylib.Roc aspect=1 noautolegend;
   title 'ROC Curve';
   xaxis values=(0 to 1 by 0.25) grid offsetmin=.05 offsetmax=.05;
   yaxis values=(0 to 1 by 0.25) grid offsetmin=.05 offsetmax=.05;
   lineparm x=0 y=0 slope=1 / lineattrs=(color=ligr);
   series x=FPF y=TPF;
   inset 'Area under the curve=0.7706' / position=bottomright;
run;
```

Output 18.2.9 Receiver Operating Characteristics Curve

Multinomial-Trial Syntax for Grouped Binary Data

You can perform the same analysis by using the multinomial-trial syntax. First you need to compute the number of ingots that are ready for rolling, *a*:

```
data mylib.Ingots2;
   set Ingots;
   a = n - r;
run;
```

Then you specify the event variable, followed by the nonevent variable, in the MODEL statement:

```
proc logselect data=mylib.Ingots2 association ctable(out=mylib.Roc nocounts tpf fpf);
   model r a = Heat Soak Heat*Soak;
   output out=mylib.Out xbeta predicted=Pred copyvars=(Heat Soak);
run;
```

The only difference from the preceding results is that in this case the "Model Information" table shown in Output 18.2.10 displays the event and nonevent variables.

Output 18.2.10 Model Information

The LOGSELECT Procedure

Model Information	
Data Source	INGOTS2
Response Variable (Events)	r
Response Variable (Nonevents)	a
Distribution	Binomial
Link Function	Logit
Optimization Technique	Newton-Raphson with Ridging

Single-Trial Syntax for Binary Data

Binomial data are a form of grouped binary data in which "successes" in the underlying Bernoulli trials are totaled. You can thus unwind data for which you use the events/trials syntax and fit these data by using techniques for binary data.

The following DATA step expands the Ingots data table, which contains 12 events in 387 trials, into a data table that has 387 observations:

```
data mylib.Ingots_binary;
   set Ingots;
   do i=1 to n;
     if i <= r then y=1; else y = 0;
     output;
   end;
run;
```

The following statements fit the model that contains the Heat effect, the Soak effect, and their interaction to the data table. The `event='1'` response-variable option in the MODEL statement ensures that the LOGSELECT procedure models the probability that the variable y takes the value 1.

```
proc logselect data=mylib.Ingots_binary;
   model y(event='1') = Heat Soak Heat*Soak;
run;
```

Output 18.2.11 displays the "Model Information," "Number of Observations," and "Response Profile" tables. The data are now modeled as binary (Bernoulli distributed) with a logit link function. The "Response Profile" table shows that the binary response breaks down into 375 observations where y=0 and 12 observations where y=1.

Output 18.2.11 Model Information in Binary Model

The LOGSELECT Procedure

Model Information	
Data Source	INGOTS_BINARY
Response Variable	y
Distribution	Binary
Link Function	Logit
Optimization Technique	Newton-Raphson with Ridging

Number of Observations Read	387
Number of Observations Used	387

Response Profile

Ordered Value	y	Total Frequency
1	**0**	375
2	**1**	12

Probability modeled is y = 1.

Output 18.2.12 displays the result of the test of the global null hypothesis and the parameter estimates. These results match those in Output 18.2.5 and Output 18.2.6.

Output 18.2.12 Null Test and Parameter Estimates

Testing Global Null Hypothesis: BETA=0

Test	DF	Chi-Square	Pr > ChiSq
Likelihood Ratio	3	11.7663	0.0082

Parameter Estimates

Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
Intercept	1	-5.990191	1.666622	12.9183	0.0003
Heat	1	0.096339	0.047067	4.1896	0.0407
Soak	1	0.299574	0.755068	0.1574	0.6916
Heat * Soak	1	-0.008840	0.025319	0.1219	0.7270

Example 18.3: Partitioning Data

(View the complete code for this example (logex3.sas) in the example repository.)

The Sashelp.JunkMail data set comes from a study that classifies whether an email is junk email (coded as 1) or not (coded as 0). The data were collected by Hewlett-Packard Labs and donated by George Forman. The data set, which is specified in the following DATA step, contains 4,601 observations, with 2 binary variables and 57 continuous explanatory variables. The response variable, Class, is a binary indicator of whether an email is considered spam or not. The partitioning variable, Test, is a binary indicator that is used to divide the data into training and testing sets. The 57 explanatory variables are continuous variables that represent frequencies of some common words and characters and lengths of uninterrupted sequences of capital letters in emails.

```
data mylib.JunkMail;
   set Sashelp.JunkMail;
run;
```

In the following program, the PARTITION statement divides the data into two parts. The training data have a Test value of 0 and contain about two-thirds of the data; the rest of the data are used to evaluate the fit. A forward selection method selects the best model based on the training observations.

```
proc logselect data=mylib.JunkMail;
   model Class(event='1')=Make Address All _3d Our Over Remove Internet Order
         Mail Receive Will People Report Addresses Free Business Email You
         Credit Your Font _000 Money HP HPL George _650 Lab Labs Telnet _857
         Data _415 _85 Technology _1999 Parts PM Direct CS Meeting Original
         Project RE Edu Table Conference Semicolon Paren Bracket Exclamation
         Dollar Pound CapAvg CapLong CapTotal;
   partition rolevar=Test(train='0' test='1');
   selection method=forward;
run;
```

Selected results from the analysis are shown in Output 18.3.1 and Output 18.3.2.

The "Number of Observations" and "Response Profile" tables in Output 18.3.1 are divided into training and testing columns.

Output 18.3.1 Partitioned Counts

The LOGSELECT Procedure

Number of Observations

Description	Total	Training	Testing
Number of Observations Read	4601	3065	1536
Number of Observations Used	4601	3065	1536

Response Profile

Ordered Value	Class	Total Frequency	Training	Testing
1	0	2788	1847	941
2	1	1813	1218	595

Probability modeled is Class = 1.

The likelihood-based fit statistics for the selected model are displayed in the "Fit Statistics" table in Output 18.3.2, which has columns for the training and testing subsets.

Output 18.3.2 Partitioned Fit Statistics

Fit Statistics		
Description	**Training**	**Testing**
-2 Log Likelihood	1242.59491	823.68742
AIC (smaller is better)	1292.59491	873.68742
AICC (smaller is better)	1293.02268	874.54835
SBC (smaller is better)	1443.28998	1007.11085
Average Square Error	0.05659	0.06353
-2 Log L (Intercept-only)	4118.98701	2050.73514
R-Square	0.60877	0.55016
Max-rescaled R-Square	0.82359	0.74661
McFadden's R-Square	0.69833	0.59835
Misclassification Rate	0.07471	0.07813
Difference of Means	0.75122	0.73431

These statistics are computed for both the training and testing data. The statistics include the likelihood-based R-square statistics as well as several prediction-based statistics that are described in the section "Model Fit and Assessment Statistics" on page 1020. The ASE, the misclassification rate, and the difference of means should be very similar between the two groups when the training data are representative of the testing data; for this model, the values of these statistics seem similar between the two disjoint subsets.

If you want to display all the fit statistics without partitioning your data table, you can specify the PARTFIT option as follows:

```
proc logselect data=mylib.JunkMail(where Test=0) partfit;
   model Class(event='1')= Our Over Remove Internet Order Will
         Free Business You Your Font _000 Money HP George Parts
         Meeting RE Edu Semicolon Exclamation Dollar CapAvg
         CapLong;
run;
```

The resulting "Fit Statistics" table is identical to the Training column in Output 18.3.2.

Example 18.4: Ordinal Logistic Regression

(View the complete code for this example (logex4.sas) in the example repository.)

Consider a study of the effects of various cheese additives on taste. Researchers tested four cheese additives and obtained 52 response ratings for each additive. Each response was measured on a scale of nine categories ranging from strong dislike (1) to excellent taste (9). The data, given in McCullagh and Nelder (1989, p. 175) in the form of a two-way frequency table of additive by rating, are saved in the data table mylib.Cheese by using the following program. The variable y contains the response rating. The variable Additive specifies the cheese additive (1, 2, 3, or 4). The variable freq gives the frequency with which each additive received each rating.

```
data mylib.Cheese;
   do Additive = 1 to 4;
      do y = 1 to 9;
         input freq @@;
         output;
      end;
   end;
   label y='Taste Rating';
   datalines;
0  0  1  7  8  8 19  8  1
6  9 12 11  7  6  1  0  0
1  1  6  8 23  7  5  1  0
0  0  0  1  3  7 14 16 11
;
```

The response variable y is ordinally scaled. A cumulative logit model is used to investigate the effects of the cheese additives on taste. The following statements invoke PROC LOGSELECT to fit this model with y as the response variable and three indicator variables as explanatory variables, with the fourth additive as the reference level. With this parameterization, each Additive parameter compares an additive to the fourth additive.

```
proc logselect data=mylib.Cheese;
   freq freq;
   class Additive(ref='4') / param=ref;
   model y=Additive;
run;
```

Results from the logistic analysis are shown in Output 18.4.1 through Output 18.4.3.

The "Response Profile" table in Output 18.4.1 shows that the strong dislike (y=1) end of the rating scale is associated with lower OrderedValue values in the "Response Profile" table; hence the probability of disliking the additives is modeled.

Output 18.4.1 Proportional Odds Model Regression Analysis

The LOGSELECT Procedure

Model Information	
Data Source	CHEESE
Response Variable	y
Number of Response Levels	9
Frequency Variable	freq
Distribution	Multinomial
Link Type	Cumulative

Class Level Information		
Class	Levels	Values
Additive	4	1 2 3 4

Output 18.4.2 Proportional Odds Model Regression Analysis

Convergence criterion (GCONV=1E-8) satisfied.

Dimensions	
Columns in Design	11
Number of Effects	2
Max Effect Columns	8
Rank of Design	11
Parameters in Optimization	11

Testing Global Null Hypothesis: BETA=0			
Test	DF	Chi-Square	Pr > ChiSq
Likelihood Ratio	3	148.4539	<.0001

Fit Statistics	
-2 Log Likelihood	711.34790
AIC (smaller is better)	733.34790
AICC (smaller is better)	734.69484
SBC (smaller is better)	770.06082

The positive value (1.6128) for the parameter estimate for Additive=1 in Output 18.4.3 indicates a tendency toward the lower-numbered categories of the first cheese additive relative to the fourth. In other words, the fourth additive tastes better than the first additive. Similarly, the second and third additives are both less favorable than the fourth additive. The relative magnitudes of these slope estimates imply the preference ordering: fourth, first, third, second.

Output 18.4.3 Proportional Odds Model Regression Analysis

Parameter Estimates

Parameter	y	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
Intercept	1	1	-7.080166	0.564010	157.5844	<.0001

Additive 3		1	3.322683	0.421830	62.0444	<.0001

Multinomial-Trial Syntax for Grouped Data

These data can be grouped according to the value of the Additive variable in the following DATA step:

```
data mylib.Cheese;
   do Additive = 1 to 4;
      input y1-y9;
      output;
   end;
   datalines;
0  0  1  7  8  8 19  8  1
6  9 12 11  7  6  1  0  0
1  1  6  8 23  7  5  1  0
0  0  0  1  3  7 14 16 11
;
```

The analysis proceeds as before with multinomial-trial syntax:

```
proc logselect data=mylib.Cheese;
   class Additive(ref='4') / param=ref;
   model y1-y9=Additive;
run;
```

Parameter estimates and tests are the same as for the preceding analysis and are not displayed here. The tables displayed in Output 18.4.4 and Output 18.4.5 are different from those produced by the preceding analysis: the "Model Information" and "Response Profile" tables include the nine response variables, there are only four observations in the data, and the fit statistics are modified by the inclusion of the constant term in the log likelihood.

This example uses data that are examined in the section "Getting Started: LOGSELECT Procedure" on page 964 and in Example 18.4 to demonstrate how you can use the ODDSRATIO statement to produce and customize odds ratios.

In the following code, the ODDSRATIO statement is specified with no options to produce odds ratios for all the main effects as shown in Output 18.5.1:

```
proc logselect data=mylib.getStarted;
   model y(event='1') = x2 x5;
   oddsratio;
run;
```

Output 18.5.1 Odds Ratios or Main-Effects Model

Example 5: Odds Ratios

The LOGSELECT Procedure

Odds Ratios					
Description	Estimate	95% Wald Confidence Limits		p-Value	Percent Change
x2	1.233	0.999	1.521	0.0507	23.31
x5	1.002	0.987	1.016	0.8381	0.15

From Output 18.5.1, a subject whose X2 value is one unit larger (than its current value) has 1.233 times the odds of having a Y = 1 response, and a subject whose X5 value is one unit larger has 1.002 times the odds.

If your model has interactions, then the odds ratio computations depend on the values of the interacting variables. The following code produces odds ratios for the main effects, but because of interactions, these odds ratios depend on the values of the interacting variables as displayed in Output 18.5.2:

```
proc logselect data=mylib.getStarted;
   model y(event='1') = x2|x5;
   oddsratio;
run;
```

Output 18.5.2 Odds Ratios with Interactions

Example 5: Odds Ratios

The LOGSELECT Procedure

Odds Ratios					
Description	Estimate	95% Wald Confidence Limits		p-Value	Percent Change
x2 at x5=49.6	1.302	1.033	1.641	0.0252	30.24
x5 at x2=3.41	1.004	0.989	1.020	0.5843	0.44

The odds ratios shown in Output 18.5.2 are computed at the mean values of the interacting variables as computed from the data used to fit the model. You can change these values by specifying an AT option for each individual odds ratio, as follows. The output is shown in Output 18.5.3.

```
proc logselect data=mylib.getStarted;
   model y(event='1') = x2|x5;
   oddsratio x2(at(x5=1)) x5(at(x2=3));
run;
```

Output 18.5.3 Odds Ratios with the AT Option

Example 5: Odds Ratios

The LOGSELECT Procedure

Odds Ratios					
Description	Estimate	95% Wald Confidence Limits		p-Value	Percent Change
x2 at x5=1	1.925	1.160	3.193	0.0112	92.48
x5 at x2=3	1.008	0.991	1.025	0.3648	0.77

Alternatively, you can obtain the same results shown in Output 18.5.3 by specifying the following AT global option:

```
proc logselect data=mylib.getStarted;
   model y(event='1') = x2|x5;
   oddsratio x2 x5 / at(x5=1 x2=3);
run;
```

When odds ratios are computed for continuous variables, by default the odds ratio compares the odds computed at the mean of the continuous variable to the odds computed one unit higher than the mean. However, it might be more interesting to compare larger differences; for example, if you are comparing ages, a 10-year difference might be more interesting than a 1-year difference. You can customize the odds ratios accordingly by specifying the desired unit difference as an individual option or as a global option. In the following code, the global options set the units for X2 to 2 and 3 and for X5 to 4. However, the individual odds ratio unit option for X2 overrides the global option value and sets the units for X2 to 5.

```
proc logselect data=mylib.getStarted;
   model y(event='1') = x2|x5;
   oddsratio x2(unit=5) x5 / unit(x2=2 3 x5=4);
run;
```

Output 18.5.4 Odds Ratios with the UNIT Option

Example 5: Odds Ratios

The LOGSELECT Procedure

Odds Ratios					
Description	Estimate	95% Wald Confidence Limits		p-Value	Percent Change
x2 units=5 at x5=49.6	3.747	1.179	11.911	0.0252	274.72
x5 units=4 at x2=3.41	1.018	0.956	1.084	0.5843	1.77

When odds ratios are computed for classification variables, by default the odds ratio compares the odds computed at each level of the classification variable to the odds computed at the reference level. For example, consider the ordinal response data from Example 18.4. The following program displays the default odds ratios in Output 18.5.5:

```
proc logselect data=mylib.Cheese;
   class Additive(ref='4') / param=ref;
   model y1-y9=Additive;
   oddsratio;
run;
```

Output 18.5.5 Odds Ratios for Ordinal Response Model

Example 5: Odds Ratios

The LOGSELECT Procedure

Odds Ratios					
Description	Estimate	95% Wald Confidence Limits		p-Value	Percent Change
Additive 1 vs 4	5.017	2.380	10.577	<.0001	401.68
Additive 2 vs 4	143.257	56.277	364.671	<.0001	14225.70
Additive 3 vs 4	27.735	12.133	63.399	<.0001	2673.47

From the first line in Output 18.5.5, subjects who eat cheese with Additive = 1 have 5.017 times the odds to dislike it (Y1 end of the scale) than to like it (Y9 end of the scale) than subjects who eat cheese with Additive = 4.

By default, the odds ratios shown in Output 18.5.5 compare each level of Additive to its reference level, Additive = 4. Output 18.5.6 compares all pairs of Additive levels by specifying the DIFF=ALL global option in the following program:

```
proc logselect data=mylib.Cheese;
   class Additive(ref='4') / param=ref;
   model y1-y9=Additive;
   oddsratio / diff=all;
run;
```

Output 18.5.6 Odds Ratios with the DIFF=ALL Option

Example 5: Odds Ratios

The LOGSELECT Procedure

Odds Ratios					
Description	Estimate	95% Wald Confidence Limits		p-Value	Percent Change
Additive 1 vs 2	0.035	0.015	0.081	<.0001	-96.50
Additive 1 vs 3	0.181	0.087	0.375	<.0001	-81.91
Additive 2 vs 3	5.165	2.475	10.778	<.0001	416.53
Additive 1 vs 4	5.017	2.380	10.577	<.0001	401.68
Additive 2 vs 4	143.257	56.277	364.671	<.0001	14225.70
Additive 3 vs 4	27.735	12.133	63.399	<.0001	2673.47

Example 18.6: Binary Model with Repeated Measures

(View the complete code for this example (logex6.sas) in the example repository.)

This example uses data from the "Six Cities" study of the effects of air pollution on health (Ware et al. 1984). The analysis concerns the 16 selected cases in Lipsitz et al. (1994). The response is binary and indicates the wheezing status of 16 children. The children were assessed at ages 9, 10, 11, and 12 years. A value of 1 for wheezing status indicates the occurrence of wheezing at that age. The following statements create the data set:

```
data mylib.six;
     input case city$ @@;
   do i=1 to 4;
      input age smoke wheeze @@;
      output;
   end;
   datalines;
 1 portage   9 0 1  10 0 1  11 0 1  12 0 0
 2 kingston  9 1 1  10 2 1  11 2 0  12 2 0
 3 kingston  9 0 1  10 0 0  11 1 0  12 1 0
 4 portage   9 0 0  10 0 1  11 0 1  12 1 0
 5 kingston  9 0 0  10 1 0  11 1 0  12 1 0
 6 portage   9 0 0  10 1 0  11 1 0  12 1 0
 7 kingston  9 1 0  10 1 0  11 0 0  12 0 0
 8 portage   9 1 0  10 1 0  11 1 0  12 2 0
 9 portage   9 2 1  10 2 0  11 1 0  12 1 0
10 kingston  9 0 0  10 0 0  11 0 0  12 1 0
11 kingston  9 1 1  10 0 0  11 0 1  12 0 1
12 portage   9 1 0  10 0 0  11 0 0  12 0 0
13 kingston  9 1 0  10 0 1  11 1 1  12 1 1
14 portage   9 1 0  10 2 0  11 1 0  12 2 1
15 kingston  9 1 0  10 1 0  11 1 0  12 2 1
16 portage   9 1 1  10 1 1  11 2 0  12 1 0
;
```

The mean response is modeled by using a logistic regression model. The explanatory variables are city of residence (city), age in years (age), and maternal smoking status at each age (smoke). The responses for each child are assumed to be equally correlated, indicating that an exchangeable correlation structure is appropriate. The following statements fit the model by using generalized estimating equations (GEEs) and the chosen correlation structure:

```
proc logselect data=mylib.six;
   class case city;
   model wheeze(event='1') = city age smoke;
   repeated subject=case / type=exch covb corrw printmle;
run;
```

The MODEL statement specifies the mean model for the wheeze response variable as a logistic regression that uses city, age, and smoke as explanatory variables. This is the same specification that you use for an ordinary logistic regression.

The REPEATED statement uses GEE for parameter estimation, specifies the working correlation structure, and controls the output that is displayed. The SUBJECT=CASE option specifies that the case variable identifies the individual subjects in the data set. The case variable must be listed in the CLASS statement. The TYPE=EXCH option specifies that the procedure use the exchangeable working correlation structure. The exchangeable correlation structure does not rely on an order in the repeated measurements, so you do not need to specify a within-subject effect in the WITHIN= option. The COVB option displays the parameter estimates covariance matrix, and the CORRW option displays the final working correlation matrix. The PRINTMLE option displays a table of the initial parameter estimates that are produced by maximum likelihood estimation.

The initial parameter estimates for the GEE fit are computed by an ordinary logistic regression, which assumes no dependence between the repeated measurements.

Figure 18.6.1 displays general information about the GEE model fit.

Output 18.6.1 GEE Model Information

The LOGSELECT Procedure

GEE Model Information	
Correlation Structure	Exchangeable
Subject Effect	case (16 levels)
Number of Clusters	16
Correlation Matrix Dimension	4
Maximum Cluster Size	4
Minimum Cluster Size	4

Figure 18.6.2 displays the estimated parameter covariance matrices. The COVB option produces both the model-based and empirical covariance matrices.

Output 18.6.2 GEE Parameter Estimate Covariance Matrices

GEE Parameter Estimates
Model-Based Covariance Matrix

	Intercept	city kingston	age	smoke
Intercept	5.7495	-0.2226	-0.5347	0.01655
city kingston	-0.2226	0.4548	-0.00241	0.01876
age	-0.5347	-0.00241	0.05300	-0.01658
smoke	0.01655	0.01876	-0.01658	0.1910

GEE Parameter Estimates
Empirical Covariance Matrix

	Intercept	city kingston	age	smoke
Intercept	9.3399	-0.8510	-0.8325	-0.1653

Row3	0.1648	0.1648	1.0000	0.1648
Row4	0.1648	0.1648	0.1648	1.0000

The exchangeable working correlation structure is characterized by a single parameter. Figure 18.6.4 shows the table that contains this information.

Output 18.6.4 GEE Exchangeable Correlation

GEE Exchangeable Correlation

Correlation	0.164816

Figure 18.6.5 displays the "GEE Parameter Estimates" table. This table shows the parameter estimates, standard errors, chi-square values, and *p*-values for the parameter estimates. The table uses the empirical standard error estimates. You can also produce a table that uses the model-based standard error estimates by specifying the MODELSE option in the REPEATED statement.

Output 18.6.5 GEE Parameter Estimates Table

Analysis of GEE Parameter Estimates
Using Empirical Standard Error Estimates

Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
Intercept	1	1.2751	3.0561	0.1741	0.6765
city kingston	1	0.1223	0.6882	0.0316	0.8589
city portage	0	0	.	.	.
age	1	-0.2036	0.2789	0.5327	0.4655
smoke	1	-0.0935	0.3613	0.0670	0.7957

You can compare the GEE parameter estimates to the parameter estimates from the initial model. The parameter estimates from the initial model are displayed in Figure 18.6.6.

Output 18.6.6 Initial Parameter Estimates Table

Analysis of Initial Parameter Estimates

Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
Intercept	1	1.259707	2.610423	0.2329	0.6294
city kingston	1	0.139098	0.552686	0.0633	0.8013
city portage	0	0	.	.	.
age	1	-0.200315	0.250815	0.6379	0.4245
smoke	1	-0.128364	0.410239	0.0979	0.7544

The GEE parameter estimates are not substantially different from the parameter estimates in the initial model.

The GEE parameter estimates in Figure 18.6.5 and the empirical covariance matrix in Figure 18.6.2 are used for subsequent processing by the ASSOCIATION, CTABLE, and LACKFIT options and the ODDSRATIO and OUTPUT statements.

Example 18.7: Restoring a Stored Model

(View the complete code for this example (logex7.sas) in the example repository.)

The Sashelp.JunkMail data set from Example 18.3 is used here to show how to store a model and later how to restore that same model for further processing. The following program fits a model by using a SELECTION statement, then stores the model by using a STORE statement. The NOTE= option in the STORE statement stores a few notes along with the model; you might also want to store the submitted program. The DISPLAY statement suppresses all output.

```
data mylib.JunkMail;
   set Sashelp.JunkMail;
run;

proc logselect data=mylib.JunkMail;
   model Class(event='1')=Make Address All _3d Our Over Remove Internet Order
         Mail Receive Will People Report Addresses Free Business Email You
         Credit Your Font _000 Money HP HPL George _650 Lab Labs Telnet _857
```

```
         Data _415 _85 Technology _1999 Parts PM Direct CS Meeting Original
         Project RE Edu Table Conference Semicolon Paren Bracket Exclamation
         Dollar Pound CapAvg CapLong CapTotal;
   display / excludeall;
   selection method=forward(maxstep=5);
   store mylib.mymodel /
         note="Generated with stepwise selection.";
run;
```

The following program replays the standard tables from the fitted model. You can also specify the STB, CLB, CORRB, COVB, and TYPE3 options and the CODE and ODDSRATIO statements, because they do not require access to data.

```
proc logselect restore=mylib.mymodel stb clb corrb covb type3;
   code;
   oddsratio;
run;
```

Information about the item store is displayed in Output 18.7.1. The Replay section is displayed in Output 18.7.2 through Output 18.7.5.

The fit statistics shown in Output 18.7.4 are those that are computed when the original model is fit. If you specify the PARTFIT option or a PARTITION statement when the original model is fit, then this table always includes the additional statistics. However, specifying a PARTFIT option when you restore the model does not include the additional statistics in this table in the Replay section. Instead, the same table that appears in the Restore section is expanded; see Output 18.7.8.

If you specify the CTABLE, LACKFIT, ASSOCIATION, or PARTFIT option or the OUTPUT statement, then you must also specify an input data table. The following program requests these tables; the Replay section tables are produced but not displayed here.

```
proc logselect restore=mylib.mymodel data=mylib.JunkMail
   association ctable(cutpt=0.1 to 0.9 by 0.1) lackfit partfit;
   output out=mylib.out p cbar;
proc print data=mylib.out(obs=1);
run;
```

The first table that is displayed in the Restore section (Output 18.7.8) is the "Postfit Information" table, which contains the name of the input data table and information usually displayed in an "NObs" table. The next two tables are the "Response Profile" and "Fit Statistics" tables, which are computed from the JunkMail data.

Output 18.7.8 Restore Section

Example 18.8: Modeling Microarray Data with Elastic Net

(View the complete code for this example (logex8.sas) in the example repository.)

This example uses data from a cancer study that attempts to determine whether a patient has type 1 leukemia (acute lymphoblastic leukemia) or type 2 leukemia (acute myeloid leukemia) on the basis of the patient's gene expression measurements (Golub et al. 1999; Zou and Hastie 2005). The data sets, which are specified in the following DATA steps, contain 38 observations for training and 34 observations for testing prediction accuracy. Each observation contains 7,129 continuous variables that are gene expression measurements. The response variable is a binary indicator that is coded as 1 for type 1 leukemia and –1 for type 2 leukemia. An additional role variable is added to the training data set so that a subset of training observations are used for computing the validation error.

```
data LeuTrain;
   set Sashelp.LeuTrain;
   call streamInit(123);
   if rand('UNIFORM')<0.6 then role='train'; else role='valid';
run;
data mylib.LeuTrain;
   set LeuTrain;
run;
data mylib.LeuTest;
   set Sashelp.LeuTest;
run;
```

This study tries to find genes that can help identify the leukemia type most effectively. Because the number of variables is much greater than the number of observations, and because many measurements are highly correlated, model selection methods that are based on maximum likelihood estimation are not suitable choices. In this case, penalized selection methods provide solutions that can achieve a better trade-off between bias and variance. In particular, elastic net selection inherits advantages from both LASSO selection, which can return sparse models, and ridge regression, which can handle wide data sets that contain highly correlated variables. The following program builds a predictive model by using the SELECTION statement with the elastic net method, then stores the model by using the STORE statement. The SELECTION statement uses the average square error that is computed from the validation data as the criterion to determine the best candidate. The PARTITION statement uses the role variable to divide the training data so that approximately 40% of the observations are used for validation.

```
proc logselect data=mylib.LeuTrain partfit;
   model y=x1-x7129;
   selection method=elasticnet(choose=validate);
   partition role=role(train='train' validate='valid');
   store mylib.ElasticNetModel / note="Microarray data with Elastic Net.";
run;
```

The "Selection Information" table in Output 18.8.1 displays information about the selection process. The maximum lambda value is the upper bound of the regularization parameter for the LASSO penalty such that there can be at least one nonzero regression parameter estimate before lambda reaches that value and all estimates reduce to zero when lambda increases further. There are a total of 20 regularization parameters that elastic net selection uses to fit candidate models. By default, elastic net uses a balanced LASSO and ridge penalty.

Output 18.8.1 Selection Information

Selection Information	
Selection Method	Elastic Net
Choose Criterion	Validation ASE
Maximum Lambda	0.763464
Lambda Steps	20
Regularization Balance	0.5

The "Selected Effects" table in Output 18.8.2 shows the genes that are selected from the total of 7,129 genes by the elastic net selection method.

Output 18.8.2 Selected Genes

Selected Effects:	Intercept x50 x136 x494 x1092 x1095 x1247 x1394 x1745 x1779 x1834 x1882 x2020 x2043 x2186 x2242 x2288 x2402 x3012 x3123 x3258 x3320 x3847 x4052 x4196 x4197 x4229 x4279 x4289 x4377 x4407 x4461 x4847 x5039 x5122 x5231 x5794 x5954 x6185 x6201 x6215 x6362 x6405 x6539 x6677 x6797 x6803 x6806 x6919 x6989

Because the data for assessing test error are in a separate data set, you can compute the assessment statistics by using the stored model in several ways. One way is to use the RESTORE option in the PROC LOGSELECT statement to load the selected model and compute values from the new data. The following statements restore the selected model mylib.ElasticNetModel and compute the test error from the test data set mylib.LeuTest. Output 18.8.3 displays the fit statistics, including the misclassification rate. Compared to other selection methods—including LASSO, which returns models that have the number of selected variables only up to the training sample size—elastic net selection can select more variables and thus provide better prediction accuracy.

```
proc logselect restore=mylib.ElasticNetModel data=mylib.LeuTest partfit;
run;
```

Output 18.8.3 Fit Statistics

Results for LEUTEST

Fit Statistics	
-2 Log Likelihood	12.83258
AIC (smaller is better)	112.83258
AICC (smaller is better)	5212.83258
SBC (smaller is better)	189.15060
Average Square Error	0.04512
-2 Log L (Intercept-only)	46.06962
R-Square	0.62377

McFadden's R-Square	0.72145
Misclassification Rate	0.02941
Difference of Means	0.77283

Example 18.9: Risks

(View the complete code for this example (logex9.sas) in the example repository.)

The following data set comes from an environmental study of workers in a cotton factory. A similar data set is analyzed in Ibrahim, Chen, and Lipsitz (2001). A contingency table is created from the study, where 912 workers are checked for dyspnea (difficult or labored respiration) and their exposure to cotton dust is recorded. The variable y indicates whether the worker has developed dyspnea, expd indicates whether the worker was exposed to cotton dust, and count is the number of workers with that profile.

```
data mylib.d3;
   input y expd count;
   datalines;
0 0 349
0 1 284
1 0 118
1 1 161
;
```

The syntax for computing risk statistics is very similar to that for the ODDSRATIO statement, except that you can specify only global options; there are no options for modifying individual risks. In the following program, both the ODDSRATIO and RISK statements are specified with no risk variables, so by default the expd variable is analyzed. The E option displays the profiles that are used in the computations of the model-predicted probabilities, and the SHOWPROBS option displays those probabilities.

```
proc logselect data=mylib.d3;
   freq count;
   class expd(ref='0');
   model y(event='1')=expd;
   oddsratio;
   risk / e showprobs;
run;
```

The population profiles that you are comparing are displayed in Output 18.9.1. The rows of this table are in the same order as the rows in the "Parameter Estimates" table. Using the notation from the section "Risk Differences and Relative Risks" on page 1034, the profile $L_1 = (1, 1, 0)$ is multiplied by the parameter estimates $\boldsymbol{\beta} = (-1.084387, 0.516817, 0)$, and applying the inverse-logit function gives $p_1 = 0.361798$, as displayed in the P1 column of the "Risks" table in Output 18.9.2.

Output 18.9.1 Risk Coefficients

Coefficients for Risk Computations		
Parameter	**L1_1**	**L1_2**
Parm1	1	1
Parm2	1	
Parm3		1

In Output 18.9.2, both the odds ratio results and the risk results show that exposure to cotton dust is a significant factor in a worker's having dyspnea.

Output 18.9.2 Odds Ratio and Risk Difference

Odds Ratios

Overview: MBC Procedure

The MBC procedure fits mixtures of multivariate Gaussian and uniform distributions to achieve unsupervised and semisupervised clustering of data. It treats the cluster memberships as missing data and uses the expectation-maximization (EM) algorithm to maximize the likelihood. The procedure can produce output data tables that contain cluster membership weights and component log likelihoods. PROC MBC can also store the fitted model for scoring subsequent input data.

PROC MBC assumes that the data can be described by a mixture of multivariate Gaussian components and an optional noise component. The procedure also assumes that the data are continuous, and it does not support CLASS variables.

PROC MBC fits Gaussian mixtures by using two types of covariance structures:

- Nine covariance structures that have specific constraints in the covariance matrices across components. These are referred to as Gaussian mixture models.
- Eight covariance structures that are derived from factor models, with specific constraints in the factor loading matrices and unique error variance matrices across components. These are referred to as parsimonious Gaussian mixture models, or PGMMs (McNicholas and Murphy 2008). The term "parsimonious" indicates that using factor models can reduce the dimension of the data during modeling.

Motivation for Model-Based Clustering

The traditional goal of clustering has been to identify groups of observations that are similar by some measurement. Standard clustering methods achieve this primarily through heuristic methods, by using a measurement such as the distance to a center or a boundary. These methods appeal to intuition, but they cannot answer fundamental questions about the number of clusters, the suitability of certain cluster structures, or the handling of outliers. In addition, standard methods do not have well-defined statistical properties and so do not support formal inference.

In contrast, model-based clustering (MBC) models the observations by using a mixture of specific distributions. In this framework, the qualities of these clusters and cluster membership are parameters to be estimated by formal statistical methods.

The MBC procedure implements model-based clustering by using mixtures of multivariate Gaussian distributions. PROC MBC allows for a noise component and automatic model selection through the use of information criteria. In addition, it provides posterior scoring of new input data.

PROC MBC Compared with Other Procedures

SAS/STAT and SAS Viya offer several other clustering and mixture-modeling procedures.

PROC MBC is based on the model likelihood, whereas the clustering methods in the FASTCLUS, CLUSTER, KCLUS, MODECLUS, and FASTKNN procedures use a distance-based clustering criterion. The likelihood-based approach allows direct comparison of models through the use of information criteria.

This likelihood-based approach means that the MBC procedure can produce "soft" clusterings, which are based on posterior probabilities. These clusterings indicate relative strengths of affinity that each observation has for each cluster in the model. In contrast, the other clustering procedures produce "hard" clusterings, which associate each observation with a single cluster.

Like PROC MBC, the FMM and HPFMM procedures use a likelihood-based approach. PROC FMM and PROC HPFMM can fit several different univariate finite mixture models, but they cannot fit multivariate models. PROC MBC uses the expectation-maximization (EM) technique (Dempster, Laird, and Rubin 1977) to find parameter estimates, whereas the FMM and HPFMM procedures use traditional maximum likelihood and Bayesian techniques.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: MBC Procedure

Old Faithful Data

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/mbcgs1.sas.)

This example uses the Old Faithful data on geyser eruptions (Cook and Weisberg 1982) to illustrate a mixture of multivariate Gaussian components. This data set contains time before eruption and duration of eruption for Old Faithful geyser in Yellowstone National Park in the United States. The following DATA step creates the data table mylib.getStarted, which consists of 272 observations on the duration of each eruption and the wait time until the next eruption. Both duration and wait time are measured in minutes.

```
data mylib.getStarted;
  input Duration Wait @@;
  datalines;
3.600 79  1.800 54  3.333 74  2.283 62  4.533 85  2.883 55  4.700 88  3.600 85

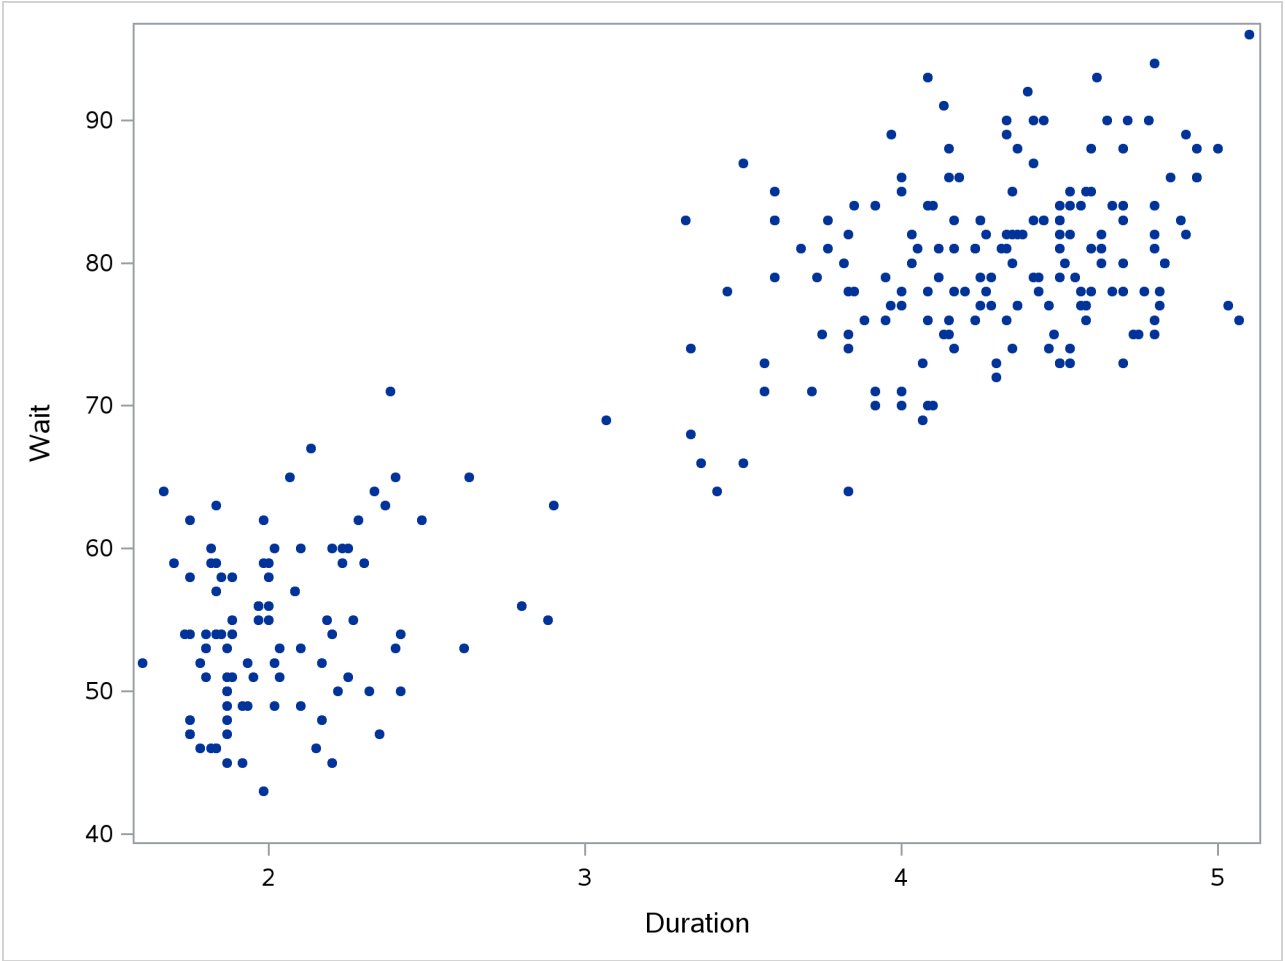
;
```



These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

The following statements produce a scatter plot of the duration and wait times:

```
proc sgplot data=mylib.getStarted;
  scatter x=duration y=wait / markerattrs=(symbol=circlefilled size=4);
run; quit;
```

It is clear from the scatter plot in Figure 19.1 that there are two clusters of eruptions. The first consists of short, frequent eruptions, and the second consists of long, infrequent eruptions. However, the shape of these clusters is not spherical. The MBC procedure can help you explore the shapes.

Figure 19.1 Scatter Plot of Old Faithful Data

The following statements fit several different mixture models to these data:

```
proc mbc data=mylib.getStarted nclusters=(1 to 5)
                               noise=(YES NO)
                               covstruct=(EEV EII VVV)
                               seed=1418410433;
  var duration wait;
  output out=mylib.scores copyvars=(duration wait);
run;
```

The NCLUSTERS= option list fits separate models by using one to five Gaussian clusters. The NOISE= option list fits these models with and without noise. The COVSTRUCT= option list fits each of these models by using three different covariance structures. Finally, the SEED= option specifies a starting random seed to generate initial cluster weights. In total, PROC MBC fits 30 different models, corresponding to the unique combinations of each element in the NCLUSTERS=, NOISE=, and COVSTRUCT= option lists.

The VAR statement identifies the two variables, Duration and Wait, that define the points to be clustered.

The OUTPUT statement specifies a data table to contain the posterior cluster weights for each observation. The COPYVARS= option includes the two analysis variables, Duration and Wait, in the output data table.

After fitting all 30 models, PROC MBC chooses the model that has the best Bayesian information criterion (BIC) value. BIC is a quantity composed of the log likelihood and a penalty term. Smaller BIC values indicate models with better fit. The "Fit Summary" table in Figure 19.2 shows model information for the 10 models that have the best (smallest) BIC values, sorted so that the best model appears first. The selected model has two nonspherical clusters, as suggested by the plot in Figure 19.1.

Figure 19.2 Summary of Fit Statistics

The MBC Procedure

Model Selection Summary

Covariance Structure	Number of Clusters	Noise Component	Number of Parameters	-2 Log L	AIC	AICC	BIC
VVV	2	N	11	2260.52818	2282.52818	2283.54356	2322.19200
VVV	2	Y	13	2260.61415	2286.61415	2288.02500	2333.48957
VVV	3	N	17	2238.48109	2272.48109	2274.89054	2333.77973
EEV	2	Y	11	2278.66416	2300.66416	2301.67955	2340.32798
VVV	3	Y	19	2238.48207	2276.48207	2279.49794	2344.99231
VVV	4	N	23	2216.08379	2262.08379	2266.53541	2345.01724
EEV	4	Y	19	2241.44464	2279.44464	2282.46051	2347.95488
EEV	3	Y	15	2266.00364	2296.00364	2297.87864	2350.09067
EEV	5	N	21	2239.56249	2281.56249	2285.25849	2357.28433
VVV	5	N	29	2208.49803	2266.49803	2273.68811	2371.06629

Figure 19.3 shows the "Model Information" table. This table summarizes the characteristics of the selected model and of the modeling technique that was used.

Figure 19.3 Model Information for Selected Model

The MBC Procedure

Model Information	
Number of Gaussian Clusters	2
Covariance Structure	VVV
Noise Cluster Present	No
Expectation Technique	EM
Model Selection Criterion	BIC
Initialization Method	Random
Convergence Test	Log Likelihood
EM Convergence Criterion	1e-05
Singularity Criterion	1e-08
Parameter Criterion	1e-08
Random Seed	1418410433

The "Parameter Estimates" table in Figure 19.4 contains the estimates of the centers of the two clusters and the estimates of the covariance for the multivariate Gaussian that is represented by each cluster.

Figure 19.4 Mean and Covariance Estimates for Selected Model

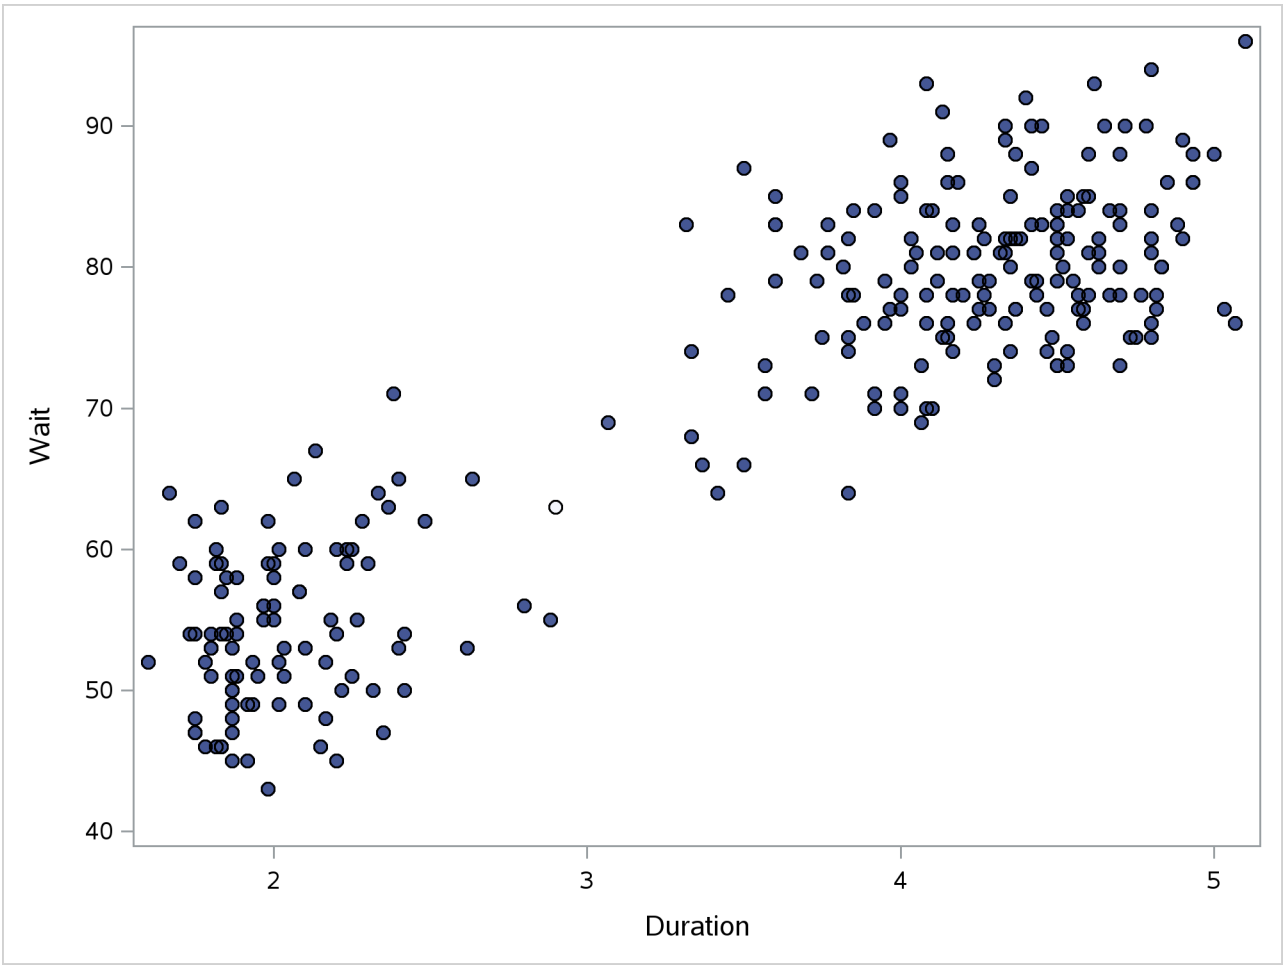
Parameter Estimates for Selected Model				
			Covariance	
Cluster	**Variable**	**Mean**	**Duration**	**Wait**
1	**Duration**	4.28979	0.16980	0.93852
	Wait	79.96968		36.02280
2	**Duration**	2.03654	0.06928	0.43639
	Wait	54.48000		33.70574

If you compare the mean estimates to the plot in Figure 19.1, you can see that the estimates correspond well to the data.

Figure 19.1 suggests that one cluster is slightly heavier than the other. The "Mixing Estimates" table in Figure 19.5 supports this impression.

Figure 19.5 Mixing Weight Estimates for Selected Model

Mixing Probability Estimates for Selected Model	
Mixing Component	**Mixing Probability**
1	0.64407
2	0.35593



The following statements use the output table mylib.scores to produce a plot of the maximum posterior weights for each observation:

```
data scores;
  set mylib.scores;
  maxwt = max(of next:);
run;

proc sgplot data=scores noautolegend;
  * ---- shaded corresponding to maximum posterior weight --------- ;
  scatter x=duration y=wait   / markerattrs=(symbol=circlefilled)
                                colorresponse=maxwt
                                colormodel=TwoColorRamp;
  scatter x=duration y=wait   / markerattrs=(symbol=circle color=black);
run;
quit;
```

Figure 19.6 plots the observations with shading to indicate the strength of the affinity that each point has for the cluster that it is more strongly associated with. Only one point has light shading, indicating that it is in a region where the larger posterior cluster weight is not as large as it is in other regions. This indicates a region where the posterior weights for the two clusters are closer in value.

Figure 19.6 Old Faithful Data and Selected Model

Syntax: MBC Procedure

The following statements are available in the MBC procedure:

PROC MBC < *options* > **;**
BY *variables* **;**
VAR *variables* **;**
INIT *variables* **;**
OUTPUT OUT=*libref.data-table* < *keyword* < **=***name* > >. . . < *keyword* < **=***name* > > < *options* > **;**
DISPLAY < *table-list* > < / *options* > **;**
DISPLAYOUT *table-spec-list* < / *options* > **;**
STORE < **OUT=** >*libref.data-table* **;**

The PROC MBC statement is required.

PROC MBC Statement

PROC MBC < *options* > **;**

The PROC MBC statement invokes the procedure. Table 19.1 summarizes the available *options* in the PROC MBC statement by function. They are then described fully in alphabetical order.

Table 19.1 PROC MBC Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data table
Options Related to Model Fitting	
CONVTEST=	Specifies the convergence test to use for model fitting
COVSTRUCT=	Specifies the covariance structure
CRITERION=	Specifies the fit statistic to use for model selection
EMCRITERION=	Tunes the expectation-maximization (EM) convergence criterion
FACTORDETAILS	Includes factor loadings and unique error variances in the ParameterEstimates table
INIT=	Specifies the initialization method
ITHIST=	Displays the iteration history
MAXITER=	Specifies the maximum number of EM iterations
NCLUSTERS=	Specifies the number of Gaussian components
NFACTORS=	Specifies the number of latent factors
NOISE=	Specifies the presence of noise
SEED=	Specifies the pseudorandom number seed
SINGPARM=	Tunes the parameter singularity criterion
SINGULAR=	Tunes the singularity criterion
TECHNIQUE=	Specifies the EM technique
TOPMODELS=	Specifies the number of models to display in summary

The following options are available in the PROC MBC statement:

CONVTEST=AITKEN | LOGL
specifies the convergence test to use. You can specify the following values:

AITKEN uses Aitken's acceleration (McLachlan and Krishnan 1997) with the stopping criterion described in Böhning et al. (1994) for computing the test value in the following steps:

1. $a^{(k)} = \frac{\ell^{(k+1)} - \ell^{(k)}}{\ell^{(k)} - \ell^{(k-1)}}$, where $\ell^{(k)}$ is the log-likelihood value at the kth iteration.
2. $\ell_{\infty}^{(k+1)} = \ell^{(k)} + \frac{1}{1-a^{(k)}} \left(\ell^{(k+1)} - \ell^{(k)} \right)$
3. Compute $\left| \ell_{\infty}^{(k+1)} - \ell_{\infty}^{(k)} \right|$ and compare this value to the convergence criterion value.

LOGL uses the relative log-likelihood change test: $|\ell^{(k+1)} - \ell^{(k)}| / |\ell^{(k)}|$, where $\ell^{(k)}$ is the model log likelihood after the kth iteration.

By default, CONVTEST=LOGL. If the convergence test value is less than or equal to the value specified in the EMCRITERION= option, the process is considered to have converged.

COVSTRUCT=*name* | (*name* < *name* ... *name* >) | ALLGMIX | ALLPGMIX | ALL
specifies the covariance structure for the Gaussian components. The value of *name* can be one of the covariance structures for Gaussian mixture modeling or parsimonious Gaussian mixture modeling.

Nine covariance structures are available for fitting Gaussian mixture models (GMMs):
COVSTRUCT=EEE | EEI | EEV | EII | EVI | EVV | VII | VVI | VVV.

Eight covariance structures are available for fitting parsimonious Gaussian mixture models (PGMMs):
COVSTRUCT=CCC | CCU | CUC | CUU | UCC | UCU | UUC | UUU.

By default, COVSTRUCT=VVV.

The GMM structures impose one or more constraints on the covariance matrices in the separate Gaussian components, whereas the PGMM structures constrain the factor loading matrices and the unique error variance matrices. For a complete discussion of the different covariance structures, see the section "Covariance Structures" on page 1110.

If you specify a list of covariance structures, PROC MBC fits a separate model for each value in the list and for each value of the NCLUSTERS= and NOISE= options. For any covariance structure that belongs to the set of PGMM covariance structures, the procedure also fits a separate model for each value of the NFACTORS= option.

If you specify the ALLGMIX value, the procedure fits models by using each Gaussian mixture covariance structure. If you specify the ALLPGMIX value, the procedure fits models by using each parsimonious Gaussian mixture covariance structure. Specifying the ALL value is equivalent to specifying both ALLGMIX and ALLPGMIX.

If you specify one of the parsimonious Gaussian mixture covariance structures, the ALLPGMIX value, or the ALL value, you can also specify the number of latent factors by using the NFACTORS= option. The procedure identifies the model that has the best fit, where the fit is computed according to the value of the CRITERION= option.

CRITERION=AIC | AICC | BIC | LOGL
specifies the model fit criterion to use in model selection. You can specify the following values:

AIC	specifies Akaike's information criterion.
AICC	specifies Akaike's information criterion (corrected).
BIC	specifies the Bayesian information criterion.
LOGL	specifies the log likelihood.

By default, CRITERION=BIC. Each criterion is defined so that a model with a smaller value for the criterion is judged to have a better fit than a model with a larger value for the same criterion.

DATA=*libref.data-table*
names the input data table for PROC MBC to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref	refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1093.
data-table	specifies the name of the input data table.

EMCRITERION=*number*
specifies the convergence criterion for the expectation-maximization (EM) technique. The EM process terminates when the value of the test that you specify in the CONVTEST= option is less than or equal to *number*. The value of *number* must be greater than or equal to 0. The default value depends on the value of the CONVTEST= option. If you specify CONVTEST=LOGL or do not specify a value for CONVTEST, then by default EMCRITERION=1E–5. If you specify CONVTEST=AITKEN, then by default EMCRITERION=1E–3.

FACTORDETAILS
includes the factor loadings and the unique error variances in the "Parameter Estimates" table. These estimates provide a fuller picture of the model. In general, the estimated factor loadings are subject to rotational indeterminacy, and thus they are not indicative of the associations between the factors and the observed variables. This option has no effect on models that do not use one of the parsimonious Gaussian mixture model covariance structures. For a complete description of the different types of covariance structures, see the COVSTRUCT= option.

INIT=KMEANS | RANDOM
specifies which method to use to initialize cluster membership. This option is ignored if you specify initial weights in the INIT statement. You can specify one of the following values:

KMEANS	uses *k*-means clustering to generate starting values. BY-group processing is not available when you specify this method.
RANDOM	specifies the random weight method.

By default, INIT=RANDOM.

If you use the INIT statement to specify initialization variables, the procedure uses those variables for initialization and ignores any INIT= option.

ITHIST < =DETAILS | NONE | SUMMARY >
produces the "Iteration History" table. You can specify one of the following levels:

DETAILS	produces a table that contains expanded information about each iteration.
NONE	suppresses the production of the table.
SUMMARY	produces a table that contains basic information about each iteration.

If you specify the ITHIST option but do not specify one of the levels, the procedure uses the SUMMARY level.

MAXITER=*number*
specifies the maximum number of expectation-maximization (EM) iterations before termination. The EM process terminates after the specified *number* of iterations, even if the process has not converged. By default, MAXITER=500.

NCLUSTERS=*number* | (*number* < *number* **...** *number* >) | (*number* **to** *number* < **by** *number* >)
specifies the number of Gaussian components in the model. If you specify a list of numbers or a range of numbers, PROC MBC fits a separate model for each value in the list or range and for all values of the NOISE= and COVSTRUCT= options. For any covariance structure that belongs to the set of PGMM covariance structures, the procedure also fits a separate model for each value of the NFACTORS= option. The procedure identifies the model that has the best fit, where the fit is computed according to the value of the CRITERION= option. By default, NCLUSTERS=2.

If you use the (*smallest* to *largest* by *increment*) syntax, the list contains the values (*smallest*, *smallest*+*increment*, *smallest*+2**increment*, . . ., *smallest*+*p***increment*), where each value in the list is less than or equal to *largest*. If the resulting list contains any noninteger values or values less than 1, the procedure terminates with a syntax error.

NFACTORS=*number* | (*number* < *number* **...** *number* >) | (*number* **to** *number* < **by** *number* >)
specifies the number of latent factors to use with PGMM covariance structures. All specified values must be less than or equal to the number of variables that you specify in the VAR statement. If you specify a list of numbers or a range of numbers, PROC MBC fits a separate model for each value in the list or range, for all values of the NOISE= option, for all values of the NCLUSTERS= option, and for values of the COVSTRUCT= option that belong to the set of PGMM covariance structures. The procedure identifies the model that has the best fit, where the fit is computed according to the value of the CRITERION= option. By default, NFACTORS=1.

If you use the (*smallest* to *largest* by *increment*) syntax, the list contains the values (*smallest*, *smallest*+*increment*, *smallest*+2**increment*, . . ., *smallest*+*p***increment*), where each value in the list is less than or equal to *largest*. If the resulting list contains any noninteger values or values less than 1, the procedure terminates with a syntax error.

NOISE=YES | NO | (*value* < *value* . . . *value* >)
specifies whether to include a noise component. If you specify a list of values, PROC MBC fits a separate model for each distinct value in the list and for all values of the COVSTRUCT= and NCLUSTERS= options. For any covariance structure that belongs to the set of PGMM covariance structures, the procedure also fits a separate model for each value of the NFACTORS= option. The procedure identifies the model that has the best fit, where the fit is computed according to the value of the CRITERION= option. By default, NOISE=NO.

SEED=*integer*
specifies the pseudorandom number seed for generating random starting weights. Random starting weights are used only when you do not specify starting weight variables in the INIT statement and when you do not specify INIT=RANDOM. If you do not specify a seed, then the seed is derived from the default random number generator on the controller.

SINGPARM=*number*
specifies the parameter singularity criterion. If the mixing estimate for a model component is less than or equal to *number*, it is considered to be zero. In models that have noise components, if the computed noise volume is less than or equal to *number*, the procedure will not fit the model. The value of *number* must be greater than zero. By default, SINGPARM=1E–8.

SINGULAR=*number*
specifies the general singularity criterion to use in matrix operations. The value of *number* must be greater than or equal to zero. By default, SINGULAR=1E–8.

TECHNIQUE=EM | CEM
specifies the expectation-maximization (EM) technique to use. You can specify the following values:

EM specifies the traditional EM technique.

CEM specifies the classification EM technique.

By default, TECHNIQUE=EM.

TOPMODELS=*number*
specifies the maximum number of models to include in the FitSummary table. The value of *number* must be an integer greater than or equal to 1. This option is applicable only when at least one of the NCLUSTERS=, NOISE=, or COVSTRUCT= options has multiple values. The FitSummary table displays summary information for *number* of models or for as many models as were fit, whichever is smaller. By default, TOPMODELS=10.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC MBC to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1116. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value*	specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.
key	specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1116. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

INIT Statement

INIT *variables* **;**

The INIT statement specifies the variables that contain initial weights for the mixture components. By convention, if the model includes a noise component, the first *variable* in the INIT statement list defines the observation's initial weight for the noise component. If you are fitting many different models by using the NCLUSTERS=, NOISE=, or COVSTRUCT= option, you must supply enough INIT *variables* for the model combination that has the most components. The INIT statement is not required. You can specify at most one INIT statement.

If any of the variables have negative values or if the sum of the variables is less than the value specified in the SINGULAR= option, the procedure will use equal initial weights on each cluster for that observation.

Without an INIT statement, PROC MBC uses the default initialization method.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *keyword* < **=***name* > >. . . < *keyword* < **=***name* > > < *options* > **;**

The OUTPUT statement creates a data table that contains observationwise statistics that PROC MBC computes after fitting the model. The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVAR= option are included. The output statistics are computed on the basis of the final parameter estimates. If no model converges, then the output data table is not created.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC MBC to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1093.

data-table specifies the name of the output data table.

You can also specify the following options:

ALL

ALLSTAT
adds all available statistics to the output data table.

COPYVAR=*variable*

COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table.

keyword **<=***name***>**
specifies a statistic to include in the output data table and optionally names the variable *name*. If you provide the *keyword* but do not provide a *name*, PROC MBC assigns a default name that is based on the type of statistic requested. PROC MBC produces the NEXTCLUS statistics even if you do not provide the corresponding keyword.

Table 19.2 summarizes the *keywords* available in the OUTPUT statement.

Table 19.2 OUTPUT Statement Keywords

Keyword	Description	Default Name
Statistic Options		
CURRCLUS	Specifies the cluster weights that produce the final parameter estimates	CURR
LOGLIK	Specifies the log likelihood produced by the final parameter estimates	LOGLIK
MAXPOST	Specifies the index of the component with the maximum posterior probability	MAXPOST
NEXTCLUS	Specifies the cluster weights produced by the final parameter estimates	NEXT

The following list describes these *keywords*. For more information, see the section "Posterior Probabilities and Clustering" on page 1109.

CURRCLUS <=*name***>**
specifies the cluster weights that produce the final parameter estimates. The default name is CURR*n*, where *n* indicates the cluster index. You can modify the name by specifying the *name* option.

LOGLIK <=*name***>**
specifies the component and total log likelihood by using the final parameter estimates. The default name for the component log likelihoods is LOGLIK*n*, where *n* indicates the cluster index. The default name for the total log likelihood is LOGLIK. You can modify this name by specifying the *name* option.

MAXPOST <=*name***>**
specifies the identification of the cluster that has the maximum posterior weight by using the final parameter estimates. The default name for this variable in the output data set is MAXPOST. You can modify this name by specifying the *name* option. During scoring, if an observation has the same posterior weight for multiple clusters, the value of the output variable *name* for that observation is set to the lowest cluster number among those clusters.

NEXTCLUS <=*name***>**
specifies the cluster weights that the final parameter estimates produce. The default name is NEXT*n*, where *n* indicates the cluster index. You can modify the name by specifying the *name* option.

STORE Statement

STORE <OUT=>*libref.data-table* **;**

The STORE statement enables you to save the fitted model to an analytic store. The contents of the analytic store can be processed by the ASTORE procedure and by the **`mbcScore`** action in the **`mbc`** action set.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1093. You can specify at most one STORE statement.

VAR Statement

VAR *variables* **;**

The VAR statement specifies the variables that you want to cluster. This statement is required, and you can specify at most one VAR statement.

Details: MBC Procedure

Log-Likelihood Definitions

The MBC procedure uses two definitions of the log likelihood to assess convergence. Which definition the procedure uses depends on the value of the TECHNIQUE= option.

If you do not specify the TECHNIQUE= option or if you specify TECHNIQUE=EM, PROC MBC uses the mixture log likelihood ℓ_{mix}, defined as

$$\ell_{\text{mix}} = \sum_{i=1}^{N} \log \left[\sum_{k=0}^{G} \tau_k f\left(\mathbf{y}_i | \boldsymbol{\theta}_k\right) \right]$$

where τ_k are the mixture weights and $\boldsymbol{\theta}_k$ are the mixture component parameters.

If you specify TECHNIQUE=CEM, the procedure uses the classification complete data log likelihood ℓ_{CDL}, defined as

$$\ell_{\text{CDL}} = \sum_{i=1}^{N} \sum_{k=0}^{G} \tilde{z}_{ik} \log \left[\tau_k f\left(\mathbf{y}_i | \boldsymbol{\theta}_k\right)\right]$$

In this definition, $\tilde{z}_{ik}$ is an indicator variable.

Posterior Probabilities and Clustering

In the OUTPUT statement, the CURRCLUS and NEXTCLUS options produce posterior probabilities (weights) for each observation. The weights that are computed for the CURRCLUS option are the observation weights that produce the final parameter estimates. In contrast, the weights that are produced for the NEXTCLUS option are the weights that the final parameter estimates produce for each observation.

The MAXPOST option outputs the index of the cluster that has the maximum posterior probability for each observation. This maximum is taken over the posterior probabilities that are produced by the final parameter estimates.

Expectation-Maximization (EM) Algorithm

Traditional EM

The expectation-maximization (EM) algorithm (Dempster, Laird, and Rubin 1977) is a tool that addresses problems of missing data. The EM algorithm proceeds by finding the conditional expectation of the missing data, given the observed data, treating that conditional expectation as observed data, and iterating until the model converges. In the Gaussian mixture models that PROC MBC fits, the missing data are the identity of the cluster to which each observation belongs. The steps of the EM algorithm follow:

1. Initialize the cluster membership for each observation through the specified technique (INIT= or INIT statement).
2. Update the cluster-specific parameters by using the current cluster memberships. Retain these new parameters as $\hat{\boldsymbol{\theta}}^{(t+1)}$.
3. Given the current parameters $\hat{\boldsymbol{\theta}}^{(t+1)}$, compute the conditional expected values of cluster membership for each observation. These are estimates $\hat{z}_{ik}$ such that

$$\hat{z}_{ik} = \text{estimated probability that observation } i \text{ belongs to cluster } k; 0 \leq z_{ik} \leq 1 \; \forall i,k; \; \sum_{k=1}^{G} \hat{z}_{ik} = 1$$

4. Evaluate the current value of the convergence criterion. You specify the convergence criterion by using the CONVTEST= option. If the convergence criterion is less than or equal to the specified value of the EMCRITERION= option, terminate the algorithm. Otherwise, go to step 2.

Classification EM

Classification EM (Celeux and Govaert 1995) proceeds in the same manner as traditional EM, but it uses the classification log likelihood to assess convergence in step 4 and replaces the "fuzzy" $\hat{z}_{ik}$ in step 3 with hard classifications: $\tilde{z}_{ik} = 1$ if $\hat{z}_{ik} = \max_j\{\hat{z}_{ij}\}$, $\tilde{z}_{ik} = 0$ otherwise.

Alternating Expectation-Conditional Maximization

PROC MBC uses the alternating expectation-conditional maximization (AECM) algorithm (Meng and Van Dyk 1997) in the estimation process for the parsimonious Gaussian mixture models (PGMMs). The PGMMs rely on latent factors, which are not observed. The AECM algorithm provides a framework for estimation in the presence of this additional source of missing data. AECM adds a step to the EM algorithm process in order to update the covariance parameters.

Singular Covariance Matrices

In some circumstances, the covariance matrix for a Gaussian component can become singular during the progress of the EM algorithm. This terminates the model fitting process. This can happen if the cluster represents a single observation or a set of effectively identical observations. When this happens, PROC MBC issues a note that indicates the existence of the singularity. You might be able to use a different initialization method or random seed to alter the progress of the algorithm and so avoid the singularity, but this is not possible in all cases.

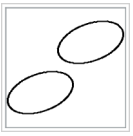
Covariance Structures

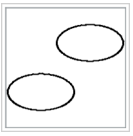
PROC MBC supports two types of Gaussian mixtures. The two types are distinguished by their use of latent factors in the model. The models that do not use latent factors are referred to as Gaussian mixture models (GMMs), and the models that use latent factors are referred to as parsimonious Gaussian mixture models (PGMMs). These models use different sets of covariance structures. The covariance structures of the Gaussian mixture models are directly specified and constrained. In contrast, the covariance structures of the PGMMs are derived from the underlying factor models. The constraints for PGMMs are set through the factor loading and unique error variance matrices.

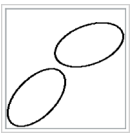
Gaussian Mixtures

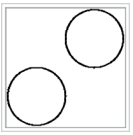
The covariance structures available in PROC MBC follow the notation of Banfield and Raftery (1993). In this treatment, the three aspects of each component's covariance (shape, volume, and orientation) can be left arbitrary or can be forced to be equal across clusters. In addition, the shape can be forced to be spherical, and the orientation can be forced to align with the coordinate axes.

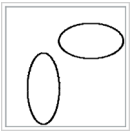
The eigenvalue decomposition of the covariance matrix for the kth Gaussian mixture component is written as

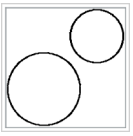


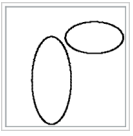












$$\mathbf{\Sigma}_k = \lambda_k \mathbf{D}_k \mathbf{A}_k \mathbf{D}_k'$$

where λ_k is the volume factor for $\mathbf{\Sigma}_k$, $\mathbf{A}_k$ is a diagonal matrix with the normalized eigenvalues of $\mathbf{\Sigma}_k$ on the diagonal, and $\mathbf{D}_k$ is the matrix of eigenvectors of $\mathbf{\Sigma}_k$. In a geometric description of the covariance matrix $\mathbf{\Sigma}_k$, λ_k characterizes the volume, $\mathbf{A}_k$ characterizes the shape, and $\mathbf{D}_k$ characterizes the orientation.

There are several ways to restrict the covariance structures across the Gaussian clusters. You can hold the volume constant by setting each λ_k equal to λ. To leave the shape arbitrary but common across the clusters, you can require each $\mathbf{A}_k$ to equal $\mathbf{A}$. To require spherical covariance matrices, you can restrict each $\mathbf{A}_k$ to equal $\mathbf{I}$, the identity matrix. If you hold each $\mathbf{D}_k$ equal to $\mathbf{D}$, then all covariance matrices will have the same orientation. You can also require all covariance matrices to be oriented to the coordinate axes by specifying $\mathbf{D}_k$ equal to $\mathbf{I}$.

PROC MBC accommodates a subset of the possible covariance structure restrictions. Table 19.3 describes the structures that the procedure supports. The Name column indicates how you specify each structure when invoking the MBC procedure. The Profile column shows a two-dimensional visualization of the covariance structure in a model that contains two clusters.

Table 19.3 Covariance Structures for Gaussian Mixtures

Name	Structure	Volume	Shape	Orientation	Profile
EEE	$\lambda\mathbf{DAD}'$	Equal	Equal	Equal	
EEI	$\lambda\mathbf{A}$	Equal	Equal	Coordinate axes	
EEV	$\lambda\mathbf{D}_k\mathbf{AD}_k'$	Equal	Equal	Variable	
EII	$\lambda\mathbf{I}$	Equal	Spherical	Coordinate axes	
EVI	$\lambda\mathbf{A}_k$	Equal	Variable	Coordinate axes	
EVV	$\lambda\mathbf{D}_k\mathbf{A}_k\mathbf{D}_k'$	Equal	Variable	Variable	
VII	$\lambda_k\mathbf{I}$	Variable	Spherical	Coordinate axes	
VVI	$\lambda_k\mathbf{A}_k$	Variable	Variable	Coordinate axes	
VVV	$\lambda_k\mathbf{D}_k\mathbf{A}_k\mathbf{D}_k'$	Variable	Variable	Variable	

Parsimonious Gaussian Mixtures

The PGMM covariance structures assume that the observed values $\boldsymbol{y}_i$ are related to latent (unobserved) quantities $\boldsymbol{u}_i$ by a set of factor loadings and that the conditional variance of the $\boldsymbol{y}_i$ is described by a diagonal matrix, called the *unique error variance* matrix. In the mixture context, the PGMMs use a set of constraints that are defined by the invariance of factor loadings and unique error variances across mixture components. In the PGMMs, the distribution of $\boldsymbol{y}_i$ in the kth Gaussian component is based on the sampling model

$$\boldsymbol{y}_i|\boldsymbol{u}_{ik} \sim N(\boldsymbol{\mu}_k + \boldsymbol{\Lambda}_k \boldsymbol{u}_{ik}, \boldsymbol{\Psi}_k)$$

where the latent factor $\boldsymbol{u}_{ik} \sim N(\mathbf{0}, \mathbf{I}_q)$ and q is the number of latent factors. $\boldsymbol{\Lambda}_k$ is a matrix of factor loadings for the kth component, and $\boldsymbol{\Psi}_k$ is a diagonal matrix of unique error variances for the kth component. The marginal distribution of the $\boldsymbol{y}_i$ in the kth component after integrating out the $\boldsymbol{u}_i$ is then

$$\boldsymbol{y}_i \sim N(\boldsymbol{\mu}_k, \boldsymbol{\Lambda}_k \boldsymbol{\Lambda}_k' + \boldsymbol{\Psi}_k)$$

The general form of the covariance matrix in the kth component is $\boldsymbol{\Lambda}_k \boldsymbol{\Lambda}_k' + \boldsymbol{\Psi}_k$. The eight covariance structures for the PGMMs are derived according to whether the factor loading matrices $\boldsymbol{\Lambda}_k$ are constrained to be equal across components ($\boldsymbol{\Lambda}_k = \boldsymbol{\Lambda}$), whether the error covariance matrices $\boldsymbol{\Psi}_k$ are constrained to be equal across components ($\boldsymbol{\Psi}_k = \boldsymbol{\Psi}$), and whether the error covariance matrices are isotropic ($\boldsymbol{\Psi}_k = \psi_k \mathbf{I}_p$). The eight covariance structures are summarized in Table 19.4. The UUU structure corresponds to the general mixture of factor analyzers model (Ghahramani and Hinton 1997; Yung 1997).

Table 19.4 Covariance Structures for Parsimonious Gaussian Mixtures

Name	$\boldsymbol{\Sigma}_k$ Structure	Factor Loadings	Error Variance	Isotropic Errors
CCC	$\boldsymbol{\Lambda}\boldsymbol{\Lambda}' + \psi \mathbf{I}_d$	Constrained	Constrained	Constrained
CCU	$\boldsymbol{\Lambda}\boldsymbol{\Lambda}' + \boldsymbol{\Psi}$	Constrained	Constrained	Unconstrained
CUC	$\boldsymbol{\Lambda}\boldsymbol{\Lambda}' + \psi_k \mathbf{I}_d$	Constrained	Unconstrained	Constrained
CUU	$\boldsymbol{\Lambda}\boldsymbol{\Lambda}' + \boldsymbol{\Psi}_k$	Constrained	Unconstrained	Unconstrained
UCC	$\boldsymbol{\Lambda}_k \boldsymbol{\Lambda}_k' + \psi \mathbf{I}_d$	Unconstrained	Constrained	Constrained
UCU	$\boldsymbol{\Lambda}_k \boldsymbol{\Lambda}_k' + \boldsymbol{\Psi}$	Unconstrained	Constrained	Unconstrained
UUC	$\boldsymbol{\Lambda}_k \boldsymbol{\Lambda}_k' + \psi_k \mathbf{I}_d$	Unconstrained	Unconstrained	Constrained
UUU	$\boldsymbol{\Lambda}_k \boldsymbol{\Lambda}_k' + \boldsymbol{\Psi}_k$	Unconstrained	Unconstrained	Unconstrained

For example, in the CUC structure, the first letter in the structure name indicates that the $\boldsymbol{\Lambda}_k$ are constrained to be equal, so that $\boldsymbol{\Lambda}$ is the common factor loading matrix for all components in the mixture. The second letter in the name indicates that the unique error variance matrices, $\boldsymbol{\Psi}_k$, are not constrained to be equal across components, so there is a different $\boldsymbol{\Psi}_k$ for each component. The final letter in the name indicates that within each Gaussian component, the unique error variance matrix $\boldsymbol{\Psi}_k$ is constrained to be isotropic, so that $\boldsymbol{\Psi}_k = \psi_k \mathbf{I}_d$.

If you choose a number of latent factors q that is smaller than the number of variables d, you can reduce the dimension of the data. This reduction in dimension is the motivation for the use of the term "parsimonious" in the name of these models. When the variability in the data is adequately explained in a lower-dimensional space, the model can achieve good performance without the complexity of a model in the original space. The choice of $q < d$ can also substantially reduce the number of parameters in the model. For more information

about the effect that the choice of q and specific constraints has on the number of parameters, see the section "Number of Parameters" on page 1114.

Noise Component

A noise component is uniform noise. This can be useful for modeling outliers. PROC MBC estimates the density of this cluster as the inverse of the volume of the space that contains the observations. The procedure computes the volume as the product of the range of the data in each dimension.

Missing Data

PROC MBC excludes from the analysis observations that have missing values for any variables in the VAR list.

If you use the INIT statement to specify initial weights and any of the variables in the INIT list have missing values, PROC MBC uses a small positive weight for each variable that has a missing value.

Model Selection

You can evaluate several different models by specifying lists of numbers of components, covariance structures, or noise components in the PROC MBC statement. The CRITERION= option in the PROC MBC statement specifies the model fit criterion that the procedure uses to compare different models. Each criterion uses the log likelihood of the model, given the training data, with a criterion-specific penalty term that favors smaller models.

Table 19.5 summarizes the computation of the available criteria.

Table 19.5 Model Selection Criteria

Name	Definition
AIC	$-2LL + 2p$
AICC	$-2LL + \frac{2pn}{n-p-1}$
BIC	$-2LL + p\log(n)$
LOGL	$-2\sum_{i=1}^{n}\log\left[\sum_{k=1}^{K}\tau_k f_k(y_i\|\theta_k)\right]$

Number of Parameters

The section "Model Selection" on page 1113 section defines each information criterion as a function of the number of observations n and the number of parameters p. The number of parameters depends on the number and type of components in the model, as well as the covariance structure that is chosen for the Gaussian components. Table 19.6 summarizes the methods that PROC MBC uses to determine the number of parameters in a particular model. In this table, G refers to the number of Gaussian components in the mixture model, d refers to the number of variables in the model, and q refers to the number of factors in the model. In the entries for each Gaussian mixture covariance structure, the total number of parameters is presented as the sum of contributions from volume, shape, and orientation. In the entries for each parsimonious Gaussian mixture covariance structure, the total number of parameters is presented as the sum of contributions from the factor loading matrices $\mathbf{\Lambda}_k$ and the unique error variance matrices $\mathbf{\Psi}_k$. The contribution from the $\mathbf{\Lambda}_k$ reflects that $q(q-1)/2$ constraints are necessary in order for $\mathbf{\Lambda}_k$ to be uniquely identified in the component factor models.

Table 19.6 Number of Parameters Computation

Source	Number of Parameters		
Mixing probabilities τ_k	$G-1$ without noise; G with noise		
Cluster means $\boldsymbol{\mu}_k$	Gd

UUU	$G\,[dq-q(q-1)/2]$	+	Gd

Displayed Output

The following sections describe the output that PROC MBC produces. The output is organized into various tables, which are discussed in their order of appearance.

Model Information

The "Model Information" table displays basic information about the model, including the number of Gaussian clusters, the covariance structure of those clusters, and whether a noise component is included in the model. The table also includes information about the method that is used to estimate the parameters in the model and the tolerances for covariance matrices and parameters. If you specify multiple models, the table displays information about the selected model and also includes the model selection criterion that is used.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis.

Iteration History

The "Iteration History" table displays the progress of the estimation algorithm for each model that is fitted. By default, this table includes information about the model, the iteration number, the log likelihood at that iteration, the change in the log likelihood, and the computed convergence criterion value. If you specify the ITHIST=DETAILS option, the table also includes the values of the model parameters at each iteration.

Convergence Status

The "Convergence Status" table displays the convergence status of each model. The table includes information about the model and a message that indicates whether the model converged or encountered an error.

Fit Statistics

The "Fit Statistics" table displays several likelihood-based measures of fit for the specified model. If you specify more than one model, these values correspond to the selected model. The table also includes the number of parameters that are used in the computation of the fit statistics. For more information about the computation of the fit statistics, see Table 19.5.

Parameter Estimates

The "Parameter Estimates" table displays the mean and covariance estimates for the specified model. If you specify more than one model, these values correspond to the selected model.

Mixing Estimates

The "Mixing Estimates" table displays the mixing probability estimates for the specified model. These values correspond to the τ_k that is presented in the section "Log-Likelihood Definitions" on page 1108. If you specify more than one model, these values correspond to the selected model.

Fit Summary

The "Fit Summary" table displays the fit statistics for a number of the fitted models. By default, this table shows the 10 models that have the best (smallest) value of the model selection criterion that is specified in the CRITERION= option. You can modify the number of models that the table includes by using the TOPMODELS= option. This table is displayed only if you specify more than one model.

Timing

The "Timing" table displays the amount of time (in seconds) that PROC MBC required to perform different tasks in the analysis.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the MBC procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or ODS statements. These names are listed in Table 19.7.

Table 19.7 ODS Tables Produced by PROC MBC

Table Name	Description	Statement	Option
ConvergenceStatus	Convergence status of each model	PROC MBC	Default
FitStatistics	Fit statistics for specified or selected model	PROC MBC	Default
FitSummary	Comparison of fit statistics for all models	PROC MBC	Multiple values in COVSTRUCT=, NOISE=, or NCLUSTERS=
IterHistory	Iteration history from the EM algorithm	PROC MBC	ITHIST
MixingEstimates	Estimates for mixing proportions	PROC MBC	Default
ModelInfo	Information about the fitted model	PROC MBC	Default

Table 19.7 *continued*

Table Name	Description	Statement	Option
NObs	Information about observations	PROC MBC	Default
OutputCasTables	See the section "OutputCasTables Table" on page 1116	OUTPUT DISPLAYOUT	OUT=
ParameterEstimates	Mean and covariance estimates	PROC MBC	Default
Timing	Time used for different tasks	PROC MBC	Default

Examples: MBC Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

The examples in this section provide further applications of the MBC procedure and illustrate other aspects of its syntax.

Example 19.1: Storing and Scoring

(View the complete code for this example (mbcex1.sas) in the example repository.)

When you use PROC MBC to fit a model, you can use the STORE statement to save the model for later application to a new data table. For example, you can score new observations to find their posterior probabilities of cluster membership for each cluster in the model. This example uses PROC CAS to run the **mbcScore** action to do this subsequent scoring.

The following statements generate a data table that represents a scenario in product marketing. The different market segments are distinguished by different levels of certain financial characteristics.

Segment 1 is a generally younger group with a higher debt-to-income ratio, and it might be attracted by newer, more luxurious goods. When marketing to this group, you would like to highlight newer lines with higher price points. In contrast, segment 2, with a low debt-to-income ratio and an average age between that of segments 1 and 3, might represent a group of bargain hunters who would prefer a product that offers the best value. The customers in segment 3 have a higher average age and a moderate debt-to-income ratio, and they represent a group that is not interested in luxury items and not strongly motivated by price. Finally, segment 4 represents customers who do not fit into these groups and so might respond to a variety of offers.

These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.marketdata;
  label moninc  = 'Monthly Income'
        mondebt = 'Monthly Debt'
        tenancy = 'Months at Current Residence'
        ageyrs  = 'Age';
```

```
  call streaminit(869884);

  * -- Segment 1 : Young Spenders ------------ ;
  do j = 1 to 1000;
    moninc  = 12 + sqrt(2)    * rand('normal');
    mondebt =  6 + sqrt(1)    * rand('normal');
    tenancy = 18 + sqrt(2)    * rand('normal');
    ageyrs =  30 + sqrt(8)    * rand('normal');
    output;
  end;
  * -- Segment 2 : Middle-Aged Savers -------- ;
  do j = 1 to 3000;
    moninc  = 10 + sqrt(2.5)  * rand('normal');
    mondebt =  2 + sqrt(0.25) * rand('normal');
    tenancy = 24 + sqrt(3)    * rand('normal');
    ageyrs =  40 + sqrt(8)    * rand('normal');
    output;
  end;
  * -- Segment 3 : Comfortably Established --- ;
  do j = 1 to 6000;
    moninc  = 15 + sqrt(2)    * rand('normal');
    mondebt =  3 + sqrt(0.5)  * rand('normal');
    tenancy = 32 + sqrt(4)    * rand('normal');
    ageyrs =  50 + sqrt(5)    * rand('normal');
    output;
  end;
  * -- Segment 4: Defying Classification ----- ;
  do j = 1 to 300;
    moninc  = rand('uniform') * 15 +  5;
    mondebt = rand('uniform') *  9 +  0;
    tenancy = rand('uniform') * 30 + 10;
    ageyrs  = rand('uniform') * 40 + 20;
    output;
  end;
  drop j;
;
```

The existence of outliers is a good motivation to include a noise component in the model, because the outliers can otherwise distort the cluster structure in the model. You can use the NOISE=YES option to specify this directly. The following statements fit a range of models to these data. Each model includes a noise component.

```
proc mbc data=mylib.marketdata nclusters=(2 3 4 5) noise=YES seed=1389035719;
  var moninc mondebt tenancy ageyrs;
run;
```

Output 19.1.1 shows the "Fit Summary" table, indicating that the model with the best fit has three Gaussian clusters and a noise component.

Output 19.1.1 Mean and Covariance Estimates for Selected Model

The MBC Procedure

Model Selection Summary

Covariance Structure	Number of Clusters	Noise Component	Number of Parameters	-2 Log L	AIC	AICC	BIC
VVV	3	Y	46	170967	171059	171059	171392
VVV	4	Y	61	170965	171087	171088	171529
VVV	5	Y	76	170942	171094	171095	171644
VVV	2	Y	31	182253	182315	182315	182539

The goal of this analysis is to identify segments within the group of customers, and you can use the OUTPUT statement to label each customer with its most strongly associated segment. The MAXPOST option in the following OUTPUT statement includes the index of the component that has the highest posterior clustering probability for each observation. The indices start at zero for a model that includes a noise component:

```
proc mbc data=mylib.marketdata nclusters=(2 3 4 5) noise=YES;
  var moninc mondebt tenancy ageyrs;
  output out=mylib.mktscore copyvars=(moninc mondebt tenancy ageyrs) maxpost;
run;
```

In Output 19.1.2, the "Mixing Estimates" table indicates a mixture component with index 0; this is the noise component.

Output 19.1.2 Mixing Estimates for Selected Model

Mixing Probability Estimates for Selected Model

Mixing Component	Mixing Probability
0	0.02865
1	0.58248
2	0.09776
3	0.29110

Output 19.1.3 shows the parameter estimates for the selected model.

Output 19.1.3 Parameter Estimates for Selected Model

Parameter Estimates for Selected Model

Cluster	Variable	Mean	Covariance			
			moninc	mondebt	tenancy	ageyrs
1	moninc	15.00354	2.05211	0.01309	-0.00126	0.02988
	mondebt	3.00321		0.50819	0.05722	0.00485
	tenancy	31.99125			4.01148	-0.03269
	ageyrs	50.04533				5.03305
2	moninc	11.96829	2.12425	0.02417	0.07263	-0.09442
	mondebt	6.01248		1.06665	-0.00584	0.05854
	tenancy	17.99029			2.01793	0.03317
	ageyrs	29.99537				7.41317
3	moninc	9.99463	2.52433	-0.01639	0.05279	0.10067
	mondebt	1.99783		0.24534	0.00233	0.00226
	tenancy	24.01474			2.93710	0.05776
	ageyrs	39.91170				8.17630

The clusters that the procedure has identified align well with the segments that are generated in the example.

To market effectively to these different groups, you want to be able to assign a cluster membership score to each potential customer. You can use the STORE statement as follows to save the fitted model for later scoring:

```
proc mbc data=mylib.marketdata nclusters=(2 3 4 5) noise=YES seed=1389035719;
  var moninc mondebt tenancy ageyrs;
  store mylib.mktgroups;
run;
```

The mylib.mktgroups store contains a representation of the model that you can apply to a new set of customer data. You can use the **mbcScore** action to score new observations according to this saved model.

The following statements show a possible set of new data:

```
data mylib.newcusts;
input moninc    mondebt    tenancy     ageyrs;
datalines;
 7       5       20       35
12       6       20       30
18       4       31       52
10       4       25       37
;
```

The following statements show how to score the new set by using PROC CAS to invoke the **mbcScore** action. The **mbcScore** action call takes several parameters. You specify the new observations to score by using the **table** parameter. The saved model mylib.mktgroups is specified in the **restore** parameter. You use the **casOut** parameter to designate that the data table mylib.newScores will contain the scores for the new data. The **copyvars** parameter includes the listed input variables in the output data table. The **maxpost** parameter requests that the variable Group in the output set identify the cluster that has the highest posterior weight for each observation. Finally, you use the **nextclus** parameter to specify the root of the variable name for each cluster weight.

```
proc cas;
  action mbc.mbcScore /
    table={name='newcusts'}
    restore={name='mktgroups'}
    casOut={name='newScores', replace=true}
    copyvars={'moninc' , 'mondebt' , 'tenancy' , 'ageyrs'}
    maxpost='group'
    nextclus='cluswt';
  run;
quit;
```

When the scoring is finished, you can examine the clusterings in the data table mylib.newScores.

Output 19.1.4 shows the input data and the resulting weights and clustering.

Output 19.1.4 Weights and Scores for New Data

cluswt0	cluswt1	cluswt2	cluswt3	group	moninc	mondebt	tenancy	ageyrs
0.73350	0.00000	0.26650	0.00000	0	7	5	20	35
0.00096	0.00000	0.99904	0.00000	2	12	6	20	30
0.00176	0.99824	0.00000	0.00000	1	18	4	31	52
0.35676	0.00000	0.00001	0.64323	3	10	4	25	37

You can use the values in the Group variable to decide what action to take for each customer. You can also consider the strength of the association shown in the variables cluswt0 through cluswt3.

In this case, each observation has a strong association with its assigned cluster, but one observation has a noticeable affinity for the noise cluster as well.

Example 19.2: Adjusting Starting Values

(View the complete code for this example (mbcex2.sas) in the example repository.)

This example shows how you can use alternative starting values to influence the model fitting process.

The data in this example consist of physical measurements of 159 freshwater fish. The data set is available from Puranen (1917).

Each measurement includes species, weight, height, width, and three length variables. The values that are recorded for height and width are percentages of the third length variable.

The following DATA step creates the data table mylib.fish. These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.fish (drop=HtPct WidthPct);
   input Species Weight Length1 Length2 Length3 HtPct WidthPct @@;

   *** transform variables;
   if Weight <= 0 or Weight =. then delete;
   Weight3=Weight**(1/3);
   Height=HtPct*Length3/(Weight3*100);
   Width=WidthPct*Length3/(Weight3*100);
```

```
   Length1=Length1/Weight3;
   Length2=Length2/Weight3;
   Length3=Length3/Weight3;
   logLengthRatio=log(Length3/Length1);

   datalines;

This example uses the variables height, width, and weight3 for analysis. Your goal is to find the model that best represents the clustering in these three variables.

The "Getting Started" example and "Example 19.1: Storing and Scoring" on page 1117 both show how to use PROC MBC to compare several models, but both examples rely on random starting values to begin the model fitting. PROC MBC provides two other ways to generate starting values: the *k*-means technique and predefined starting values.

When you specify INIT=KMEANS, the procedure uses the *k*-means technique to get starting values for the cluster weights, means, and covariances. This is equivalent to starting with the M-step in the EM algorithm. The *k*-means method might be a better method for starting values in some situations, particularly where the clusters are roughly spherical.

You use the INIT statement to specify variables that contain initial cluster assignment weights for each observation. The procedure uses these weights for the initial E-step in the EM algorithm. You might want to use the INIT statement in cases where you have prior knowledge of clustering and want to use that knowledge to influence the model fitting process.

The following statements use the default, or random start, method to generate initial values and to choose from several models that are distinguished by covariance structure:

```
proc mbc data=mylib.fish seed=9982346 covstruct=(eee eei eev eii evi evv vii vvi vvv)
  nclusters=3;
  var height width weight3;
run;
```

Output 19.2.1 summarizes the parameter estimates, mixing estimates, and fit statistics for the selected model, which has three clusters and uses the VVV covariance structure.

Output 19.2.1 Selected Model Using INIT=RANDOM Option

The MBC Procedure

VVV	3	N	29	6.22721	64.22721	77.92800	152.85834
EEV	3	N	23	131.15440	177.15440	185.45515	247.44805
VII	3	N	14	1026.60551	1054.60551	1057.56325	1097.39295
EII	3	N	12	1075.29202	1099.29202	1101.45868	1135.96697

To see the effect of a different method of determining starting values, you can use the INIT=KMEANS option. The following statements use the *k*-means method of initialization:

```
proc mbc data=mylib.fish seed=9982346 init=kmeans
         covstruct=(eee eei eev eii evi evv vii vvi vvv)
  nclusters=3;
  var height width weight3;
run;
```

Output 19.2.2 summarizes the model selection process for the *k*-means method. The selected model uses the EVV covariance structure, and the fit statistics for other models are different from the result that uses the default random start method. In particular, the log-likelihood statistic for each of the top three models is a good deal worse with the *k*-means method than with the default method. This might be associated with

the fact that the three clusters are not really spherical, so the starting values that are determined using the *k*-means method might not be suitable in this situation.

Output 19.2.2 Model Selection Summary Using INIT=KMEANS Option

The MBC Procedure

Model Selection Summary

Covariance Structure	Number of Clusters	Noise Component	Number of Parameters	-2 Log L	AIC	AICC	BIC
EVV	3	N	27	-9.23633	44.76367	56.48460	127.28231
VVI	3	N	20	162.69679	202.69679	208.87326	263.82170
VVV	3	N	29	157.72594	215.72594	229.42673	304.35707
EEV	3	N	23	256.65424	302.65424	310.95500	372.94790
EEE	3	N	17	289.96205	323.96205	328.36493	375.91823
EVI	3	N	18	303.23126	339.23126	344.18779	394.24369
EEI	3	N	14	324.15413	352.15413	355.11188	394.94157
VII	3	N	14	1026.60549	1054.60549	1057.56324	1097.39293
EII	3	N	12	1075.29276	1099.29276	1101.45942	1135.96771

Output 19.2.3 shows the parameter estimates and mixing estimates for the selected model. The parameter estimates and mixing estimates are broadly similar to those for the default initialization method, but dissimilar enough to drive the difference in the selected model.

Output 19.2.3 Parameter Estimates and Mixing Estimates Using INIT=KMEANS Option

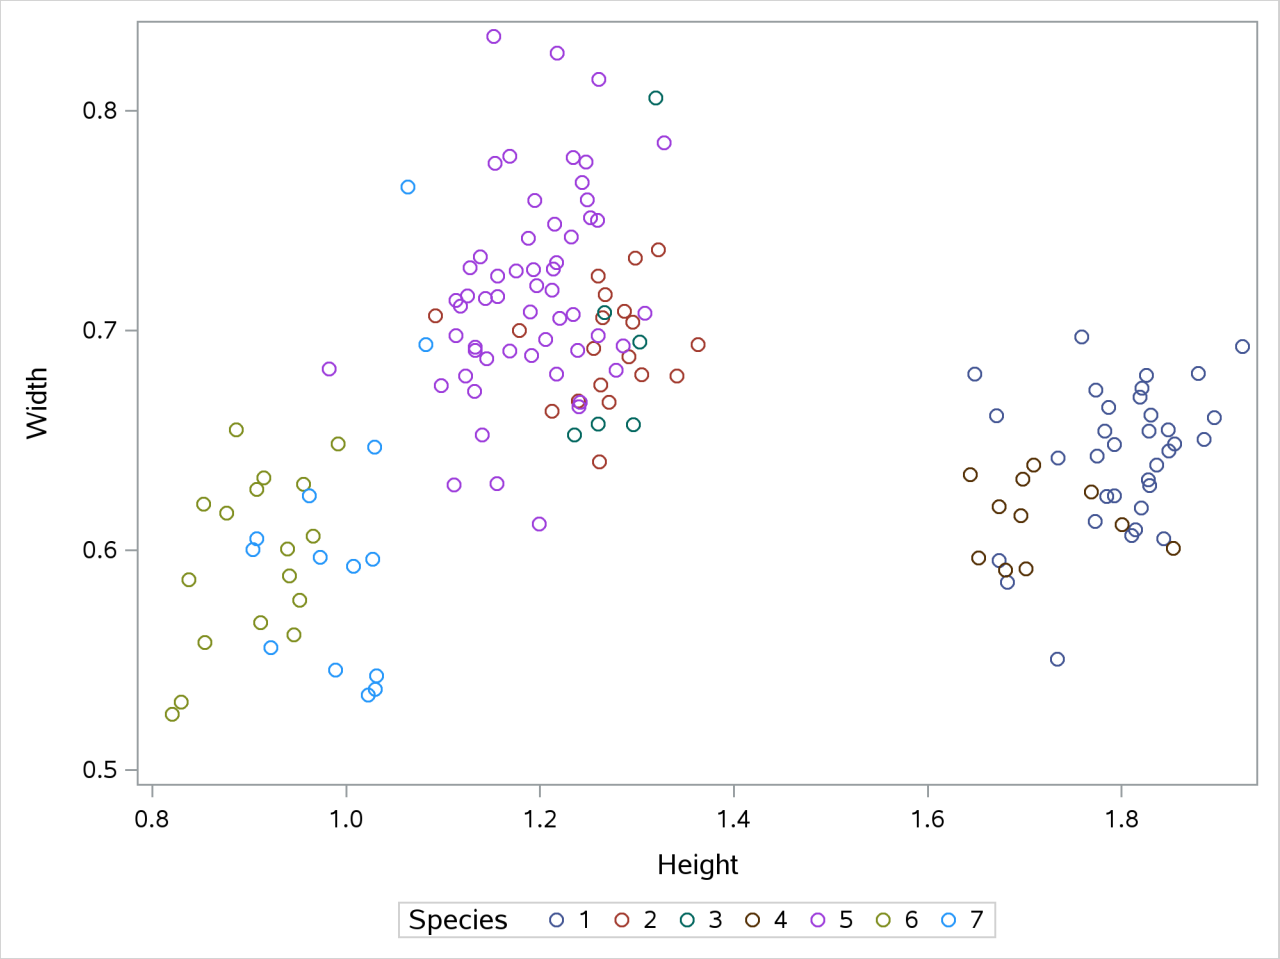
Parameter Estimates for Selected Model

Cluster	Variable	Mean	Covariance Height	Width	Weight3
1	Height	1.21348	0.00430	0.00014041	0.03749
	Width	0.71109		0.00176	0.02778
	Weight3	6.27437			4.08255
2	Height	0.93892	0.00327	0.00015841	-0.11160
	Width	0.59277		0.00135	0.01159
	Weight3	5.88795			9.76185
3	Height	1.77964	0.00757	0.00124	0.08550
	Width	0.63619		0.00142	0.03318
	Weight3	7.65945			4.02246

Mixing Probability Estimates for Selected Model

Mixing Component	Mixing Probability
1	0.52337
2	0.19001
3	0.28662

The remaining option for adjusting starting values is the INIT statement. Using the INIT statement requires you to specify variables that give initial weights for each observation.



The following statements produce a scatter plot of the Height and Width variables, labeling each point with a

species number:

```
proc sgplot data=mylib.fish;
  scatter x=height y=width / group=species;
run; quit;
```

Output 19.2.4 suggests that the species encodes useful information about the clustering.

Output 19.2.4 Fish Measurement Data with Species Labels

You can use these visible clusterings to generate initialization variables. The following DATA step shows one way to generate initialization variables that reflect your observations:

```
data mylib.fishlbl;
   set mylib.fish;
  if      (species in (6,7)) then do; z1=1; z2=0; z3=0; end;
  else if (species in (1,4)) then do; z1=0; z2=1; z3=0; end;
  else                            do; z1=0; z2=0; z3=1; end;
;
```

PROC MBC uses the initialization values for each observation as a set of weights that drive the parameter estimates and mixing estimates for the first EM iteration. The following statements use these initialization values by including them in the desired order in the INIT statement:

```
proc mbc data=mylib.fishlbl
         covstruct=(eee eei eev eii evi evv vii vvi vvv)
  nclusters=3;
  var height width weight3;
  init z1 z2 z3;
run;
```

Output 19.2.5 summarizes the model selection process. The ordering of models does not match that from either of the previous results, but the selected model uses the same covariance structure (VVV) as the random start approach.

Output 19.2.5 Model Selection Summary Using INIT Statement

The MBC Procedure

Model Selection Summary

Covariance Structure	Number of Clusters	Noise Component	Number of Parameters	-2 Log L	AIC	AICC	BIC
VVV	3	N	29	-19.57464	38.42536	52.12615	127.05649
EVV	3	N	27	-9.23633	44.76367	56.48460	127.28230
EEV	3	N	23	12.65665	58.65665	66.95741	128.95031
EEE	3	N	17	48.50809	82.50809	86.91097	134.46427
EEI	3	N	14	64.01230	92.01230	94.97005	134.79974
EVI	3	N	18	45.24591	81.24591	86.20243	136.25834
VVI	3	N	20	36.63419	76.63419	82.81066	137.75911
VII	3	N	14	1026.60540	1054.60540	1057.56314	1097.39284
EII	3	N	12	1075.29045	1099.29045	1101.45712	1135.96540

Output 19.2.6 shows the parameter estimates and mixing estimates. The selected model matches the selected model from the random start approach, but with a different order for the clusters.

Output 19.2.6 Parameter Estimates and Mixing Estimates Using INIT Statement

Parameter Estimates for Selected Model

Cluster	Variable	Mean	Covariance Height	Width	Weight3
1	Height	0.93901	0.00394	0.00019642	-0.13391
	Width	0.59276		0.00162	0.01388
	Weight3	5.88904			11.69267
2	Height	1.77964	0.00529	0.00086794	0.05971
	Width	0.63619		0.00098863	0.02317
	Weight3	7.65945			2.80942
3	Height	1.21341	0.00472	0.00015780	0.04118
	Width	0.71108		0.00192	0.03042
	Weight3	6.27394			4.46530

Output 19.2.6 *continued*

Mixing Probability Estimates for Selected Model	
Mixing Component	Mixing Probability
1	0.18995
2	0.28662
3	0.52343

This approach results in different fit statistics for some of the other models that are considered. In this case, the use of initialization variables through the INIT statement does not select a model different from that selected using the default method. However, the difference in the fit statistics for the other models that are considered in the selection process shows the effect of the different initialization method.

Overview: MODELMATRIX Procedure

The MODELMATRIX procedure creates a design matrix (matrix of covariates) that is associated with a user-specified MODEL statement and a user-specified data table in SAS Viya.

The design matrix is the fundamental component of any regression model; it is often expressed as the **X** matrix.

Each observation in the user-specified data table corresponds to a row in the design matrix. The columns of the design matrix are the parameters that are included in a regression model.

The models that PROC MODELMATRIX supports can contain main effects for continuous and classification variables and interaction effects of these variables. The models can also include constructed effects such as splines.

PROC MODELMATRIX Features

The MODELMATRIX procedure has the following main features:

- **Model specification**
  - supports multiple parameterizations for classification effects
  - supports any degree of interaction (crossed effects) and nested effects
  - supports a hierarchy among effects
  - provides a FREQ statement for grouped analysis
  - provides a WEIGHT statement for weighted analysis
- **Display and output**
  - produces an output data table that contains the design matrix
  - produces an output data table (OutDesignInfo) that names the parameters (columns) of the design matrix
  - produces output data tables that provide information about the number of observations read (NObs), model information (ModelInfo), dimensions information (Dimensions), class levelization details (ClassInfo), and effect details
  - supports custom prefixing for the names of the columns of the design matrix along with a default value (Col) if the prefix is not specified

Because the MODELMATRIX procedure runs in the CAS environment, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode
- exploits all the available cores and concurrent threads

For information about how PROC MODELMATRIX uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC MODELMATRIX Compared with Other SAS Procedures

The MODELMATRIX procedure is the counterpart of the GLMMOD procedure (in SAS/STAT). It creates a design matrix from explanatory variables in a regression model. A number of other procedures, including the LOGISTIC and GLMSELECT procedures in SAS/STAT, enable you to create the design matrix as a by-product of other statistical analysis.

PROC MODELMATRIX produces a global design matrix across all BY groups. In other words, the columns of the design matrix represent the union of the parameters across all BY groups. The elements of any design row that do not belong to a BY group are replaced with missing values.

PROC MODELMATRIX Compared with the LOGISTIC Procedure

The functionality of the MODELMATRIX procedure closely resembles that of the LOGISTIC procedure when you specify the OUTDESIGNONLY option in the PROC LOGISTIC statement. The only difference between the results of the MODELMATRIX and LOGISTIC procedures is in the way invalid and missing variables in the FREQ and WEIGHT statements are treated. In PROC MODELMATRIX, rows that have invalid values (< 1 for the FREQ statement or ≤ 0 for the WEIGHT statement) are filled in with missing values. Observations that have missing covariates are treated in the same way. In short, all the columns of invalid observations are filled in with missing values. In contrast, PROC LOGISTIC does not treat invalid observations differently. If data are missing for a variable (including FREQ and WEIGHT variables), only the corresponding column (in the case of interval variables) or columns (in the case of categorical variables) are filled in with missing values. In addition, PROC LOGISTIC uses the EFFECT encoding for parameterization of the categorical variables by default, whereas PROC MODELMATRIX uses the GLM encoding.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the

CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: MODELMATRIX Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/modelmatrixgs.sas.)

The Sashelp.Baseball data set contains salary and performance information for Major League Baseball players, excluding pitchers, who played at least one game in both the 1986 and 1987 seasons. The salaries (*Sports Illustrated,* April 20, 1987) are from the 1987 season, and the performance measures are from 1986 (Collier Books, *The 1987 Baseball Encyclopedia Update*). The following step displays (in Figure 20.1) the variables in the data set that are used in this example:

```
proc contents varnum data=sashelp.baseball
(KEEP = League Division nHits yrMajor);
   ods select position;
run;
```

Figure 20.1 Sashelp.Baseball Data Set

The CONTENTS Procedure

Variables in Creation Order

#	Variable	Type	Len	Label
4	nHits	Num	8	Hits in 1986
9	YrMajor	Num	8	Years in the Major Leagues
16	League	Char	8	League at the End of 1986
17	Division	Char	8	Division at the End of 1986

Assume that you want to predict the logSalary by using the categorical variables League and Division and the interaction of the nHits and YrMajor variables. The goal is to create a design matrix that represents this regression model. This example shows how you can use PROC MODELMATRIX for this purpose. Because the variation in salaries is much greater for the higher salaries, a log transformation is first applied to the salaries.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

You can load the Sashelp.Baseball data set by using the following DATA step:

```
data mylib.baseball;
   set sashelp.baseball;
   index = _N_;
run;
```

These statements assume that your libref is named mylib, as in the section "Using CAS Sessions and CAS Engine Librefs" on page 1131, but you can substitute any appropriately defined libref.

The following statements define the described model, create the design matrix, and store the design matrix in the output table mylib.designMat:

```
proc modelmatrix data=mylib.baseball;
  class League Division;
  model logSalary = League Division nHits*yrMajor;
  output out = mylib.designMat copyvar=index;
run;
```

The output from this analysis is presented in Figure 20.2 through Figure 20.4.

Figure 20.2 Number of Observations, Dimensions, and Column Names of the Design Matrix

The MODELMATRIX Procedure

Number of Observations Read	322
Number of Observations Used	263

Dimensions	
Number of Effects	4
Number of Parameters	6

Column Names of the Design Matrix	
Name	**Parameter**
Col1	Intercept
Col2	League American
Col3	League National
Col4	Division East
Col5	Division West
Col6	nHits * YrMajor

Figure 20.2 displays the "Number of Observations," "Dimensions," and the "Column Names of the Design Matrix" tables. The "Number of Observations" table shows that only 263 of the 322 observations in the input data are used, because some of the observations contain missing data. When you specify effects that contain classification variables, the number of parameters is usually larger than the number of effects. The "Dimensions" table shows the number of effects and the number of parameters that are considered.

The "Column Names of the Design Matrix" table lists all the parameters that are included in the design matrix and indicates the column name that is associated with each parameter. As presented in Figure 20.2, the model includes a total of six parameters (two categorical variables with two levels each, one interaction variable, and the intercept), and therefore the design matrix has six columns. Because the OUTPUT statement does not specify a PREFIX= option, the default prefix (col) is used for the column names. For more information about how to change the column names, see the PREFIX= option and Examples.

The "Model Information" table in Figure 20.3 shows the main components of the model.

Figure 20.3 Model Information Table

The MODELMATRIX Procedure

Model Information	
Data Source	BASEBALL
Response Variable	logSalary

To be able to inspect the created design matrix, you first need to transfer the output data table (mylib.designMat) from the computing cluster to a local data table (designMat) and then use the PRINT procedure. Note that PROC MODELMATRIX does not preserve the order of the rows in the original data table. Therefore the design matrix that is produced is sorted before printing. The following statements show how you can use a DATA step along with a PROC PRINT step to display the first 15 rows of the transferred design matrix:

```
data designMat;
 set mylib.designMat;
run;

proc sort data=designMat;
 by index;
run;

proc print data = designMat(obs=15 drop=index) label;
label COL1='Intercept'
      COL2='League American'
      COL3='League National'
      COL4='Division East'
      COL5='Division West'
      COL6='nHits * YrMajor';
run;
```

Figure 20.4 First 15 Rows of the Design Matrix Stored in the designMat Data Table

Obs	Intercept	League American	League National	Division East	Division West	nHits * YrMajor
1	.	.	.	.	.	.
2	1	0	1	0	1	1134
3	1	1	0	0	1	390
4	1	0	1	1	0	1551
5	1	0	1	1	0	174
6	1	1	0	0	1	1859
7	1	0	1	1	0	74
8	1	1	0	0	1	219
9	1	0	1	0	1	162
10	1	1	0	1	0	1196
11	1	1	0	1	0	1590
12	1	0	1	0	1	477
13	1	0	1	1	0	452
14	1	1	0	1	0	360
15	1	0	1	1	0	559

Syntax: MODELMATRIX Procedure

The following statements are available in the MODELMATRIX procedure:

PROC MODELMATRIX < *options* > **;**
BY *variables* **;**
CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**
DISPLAY < *table-list* > < / *options* > **;**
DISPLAYOUT *table-spec-list* < / *options* > **;**
EFFECT *name* **=** *effect-type* **(***variables* < / *options* >**) ;**
FREQ *variable* **;**
MODEL *dependent* **=** < *effects* > < / *model-options* > **;**
OUTPUT OUT=*libref.data-table* < *options* > **;**
WEIGHT *variable* **;**

The PROC MODELMATRIX statement, a single MODEL statement, and a single OUTPUT statement are required. All other statements are optional.

The CLASS statement can appear multiple times. If a CLASS statement is specified, it must precede the MODEL statement.

The rest of this section provides detailed syntax information about each of the preceding statements, beginning with the PROC MODELMATRIX statement. The remaining statements are described in alphabetical order.

PROC MODELMATRIX Statement

PROC MODELMATRIX < *options* > **;**

The PROC MODELMATRIX statement invokes the procedure. Table 20.1 summarizes the options in the PROC MODELMATRIX statement by function.

Table 20.1 PROC MODELMATRIX Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data table

You can specify the following *options*:

DATA=*libref.data-table*
names the input data table for PROC MODELMATRIX to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME

statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1131.

data-table specifies the name of the input data table.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC MODELMATRIX to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CLASS Statement

CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. Table 20.2 summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section "CLASS Statement" on page 9 in Chapter 2, "Shared Concepts."

Table 20.2 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable
SPLIT	Splits levels of CLASS variables into independent effects

DISPLAY < *table-list* > < / *options* > **;**

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1144. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value* specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1144. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

EFFECT Statement

EFFECT *name*=*effect-type* **(***variables* < / *options* >**) ;**

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 67 in Chapter 2, "Shared Concepts."

You can specify the following *effect-types*:

COLLECTION specifies a collection effect that defines one or more variables as a single effect that has multiple degrees of freedom. The variables in a collection are considered as a unit for purposes of estimation and inference.

MULTIMEMBER | MM specifies a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.

POLYNOMIAL | POLY specifies a multivariate polynomial effect in the specified numeric variables.

SPLINE specifies a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 20.3 summarizes the *options* available in the EFFECT statement.

Table 20.3 EFFECT Statement Options

Option	Description
Collection Effects Option	
DETAILS	Displays the constituents of the collection effect
Multimember Effects Options	
DETAILS	Displays the levels of the multimember effect
NOEFFECT	Specifies that observations whose levels are all missing for the multimember variables should have values of 0 in the corresponding design matrix columns
STDIZE	Standardizes the design matrix entries so that each observation has a sum of 1
WEIGHT=	Specifies the weight variable for the contributions of each classification effect
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect that has multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial

Table 20.3 *continued*

Option	Description
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots that start at the variables' maximum and end at the specified KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots that start at the specified KNOTMIN= value and end at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect
SEPARATE	Treats the spline basis for each variable as a separate effect when multiple variables are specified
SPLIT	Treats each design matrix column as a separate effect

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 18 in Chapter 2, "Shared Concepts."

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the data set that contains the frequency of occurrence of each observation. PROC MODELMATRIX treats each observation as if it appears f times, where f is the value of the *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, all the columns of the design matrix for that observation are filled in with missing values. When the FREQ statement is omitted, each observation is assigned a frequency of 1.

MODEL Statement

MODEL *dependent* **=** < *effects* > / < *model-options* > **;**

The MODEL statement names the dependent variable and the explanatory effects, including covariates, main effects, interactions, and nested effects. If you omit the explanatory effects, the procedure produces a single column of ones.

After the keyword MODEL, the dependent (response) variable is specified, followed by an equal sign. The explanatory effects follow the equal sign.

For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

The *model-options* control other aspects of model formation and inference. Table 20.4 summarizes these options.

Table 20.4 MODEL Statement Options

Option	Description
Model Options	
INFORMATIVE	Models missing values by using extra indicator variables
NOINT	Suppresses the intercept

Model Options

You can specify the following *model-options* in the MODEL statement after a slash (/):

INFORMATIVE
models missing values by using extra model effects. These effects consist of dummy variables that take the value 1 when the value of a continuous model variable involved in the effect is missing, and take the value 0 otherwise. The missing value in the original model effect is replaced by the average value of the effect for the nonmissing values. For continuous-by-class effects, such as A*x, where A is a classification variable and x is a continuous variable, informative missingness creates multiple dummy columns and substitutes the effect mean of x that corresponds to the respective level of A. Missing values for classification variables are treated as valid levels. For more information about informative missingness, see the section "Informative Missingness" on page 99 in Chapter 2, "Shared Concepts."

NOINT
suppresses the intercept term that is otherwise included in the model.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *options* > **;**

The OUTPUT statement creates an output table that contains the design matrix, which is computed after the model parameters are created (and levelized when CLASS variables are included). The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option are included.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC MODELMATRIX to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1131.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

PREFIX=*name*
enforces the column names of the design matrix to be a user-defined prefix appended to a sequence of one-based indices in the OUTDESIGN= data set. The default prefix is Col and the column name is formed by appending the column number to the prefix, so that by default the columns are named Col1, Col2, and so on.

COPYVAR=*variable*

COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table and appends them to the right end of the design matrix in the specified order.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight. Observations that have nonpositive or missing weights are considered missing in the produced design matrix. If a WEIGHT statement is not included, all observations that are used are assigned a weight of 1.

Details: MODELMATRIX Procedure

Computational Method

Multithreading

The MODELMATRIX procedure uses the parallel and multithreaded capabilities of the host environment. When the input data table is distributed across multiple nodes, the resulting design matrix is written in a distributed fashion. The user can specify the number of threads. For more information about how PROC MODELMATRIX uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Displayed Output

The following sections describe the output that PROC MODELMATRIX produces. The output is organized into various tables, which are discussed in their order of appearance.

Column Names of the Design Matrix

The "OutDesignInfo" table displays the column names (valid SAS names) that are assigned to the model parameters (which can include complex parameters from interaction effects and levelization of the classification variables). Unless the user specifies a different value for the PREFIX= option, the default prefix (Col) is used for naming the columns; hence the column names are Col1, Col2, and so on. The "OutDesignInfo" table lists the names of the columns in the design matrix that correspond to each model parameter.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in constructing the design matrix. If you specify a FREQ statement, this table displays the sum of frequencies that are read and used. If you specify a WEIGHT statement, the table displays the sum of $f_i w_i$ that are read and used.

Class Level Information

The "Class Level Information" table lists the levels of every variable that you specify in the CLASS statement. You can adjust the order of the CLASS variable levels by specifying the ORDER= option in the CLASS statement.

If the classification variables use a nonsingular parameterization, the "Class Level Information" table also displays the reference value for each variable. This table is produced for each BY group separately.

Dimensions

The "Dimensions" table displays the number of effects and the number of parameters for each BY group.

Model Information

The "Model Information" table lists a summary of the model variables. It includes the data source name and the name of the response variables. If you specify the FREQ and WEIGHT statements, the names of the FREQ and WEIGHT variables are displayed in the "Model Information" table.

Effect Details

If you specify the DETAILS option in the EFFECT statement, a table is displayed that lists all constructed effects in the model.

ODS Table Names

Each table that the MODELMATRIX procedure creates has a name associated with it. You must use this name to refer to the table when you use ODS statements. These names are listed in Table 20.5.

NOTE: The EFFECT statement also create tables which are not listed in this section. For information about these tables, see "ODS Table Names" on page 33 in Chapter 2, "Shared Concepts."

Table 20.5 ODS Tables Produced by PROC MODELMATRIX

Table Name	Description	Statement	Option
ClassInfo	Level information from the CLASS statement	CLASS	Default
Dimensions	Model dimensions	Default	
ModelInfo	Information about the modeling environment	Default	
NObs	Number of observations read and used	Default	
OutDesignInfo	Column names of the design matrix	Default	
OutputCASTables	A special ODS table that has information about the tables that are created	OUTPUT DISPLAYOUT	Default
Timing	Absolute and relative times for tasks performed by the procedure	Default	

Examples: MODELMATRIX Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 20.1: Spline Effects and BY-Group Processing

(View the complete code for this example (modelmatrixex1.sas) in the example repository.)

This example showcases several features of the MODELMATRIX procedure. It demonstrates the use of classification variables in a MODEL statement along with the use of interaction and SPLINE effects in a MODEL statement. In addition, it demonstrates how the procedure handles BY-group processing for a particular model.

The following DATA step produces analysis data that contain a variable that has 20 observations. These statements assume that your libref is named mylib, as in the section "Using CAS Sessions and CAS Engine Librefs" on page 1131, but you can substitute any appropriately defined libref.

```
data mylib.sample;
call streaminit(1);
    do byVar=1 to 2;
      do i=1 to 10;
               if byVar=1 then c=rand("Integer",0,3);
          else  if byVar=2 then c=rand("Integer",0,1);
          x=rand("Normal");
          y=1;
          wgt = 1;
          if i=5 and byVar=2 then frq  = -1; else frq=1;
          index + 1;
          output;
      end;
    end;
run;
```

The preceding DATA step generates a data table (mylib.sample) that contains 20 observations. It has two continuous variables (x and y) and a single classification variable (c), which can have a maximum of four unique values for 10 observations and a maximum of two unique values for the rest of the observations. Also, a BY variable named byVar is defined that divides the data table into two equally sized BY groups, each of which has 10 observations. Also included are the frq and wgt variables that are going to be used as the FREQ and WEIGHT variables, respectively. For simplicity, all the WEIGHT variables are assigned a value of 1. The same applies to FREQ variables, with the exception of the observation where INDEX=15, which

has an invalid FREQ value (that is, –1). This invalid FREQ value demonstrates how the MODELMATRIX procedure treats observations that have invalid FREQ values.

The following DATA step and PROC PRINT statement show the contents of the mylib.sample data table. The output of these statements is displayed in Output 20.1.1.

```
data sample;
  set mylib.sample;
run;

proc print data=sample;
run;
```

Output 20.1.1 Contents of the mylib.sample Data Table

Obs	byVar	i	c	x	y	wgt	frq	index
1	1	1	3	0.46319	1	1	1	1
2	1	2	3	0.00741	1	1	1	2
3	1	3	2	-0.06703	1	1	1	3
4	1	4	3	1.52070	1	1	1	4
5	1	5	2	0.51495	1	1	1	5
6	1	6	3	1.00574	1	1	1	6
7	1	7	3	0.36049	1	1	1	7
8	1	8	3	-1.75802	1	1	1	8
9	1	9	2	1.02322	1	1	1	9
10	1	10	1	0.33004	1	1	1	10
11	2	1	1	1.48699	1	1	1	11
12	2	2	0	-0.31012	1	1	1	12
13	2	3	1	0.60637	1	1	1	13
14	2	4	0	1.96293	1	1	1	14
15	2	5	0	-1.21157	1	1	-1	15
16	2	6	1	-1.22244	1	1	1	16
17	2	7	1	0.53368	1	1	1	17
18	2	8	1	1.27392	1	1	1	18
19	2	9	0	-0.99679	1	1	1	19
20	2	10	0	-1.55454	1	1	1	20

To demonstrate the capabilities of the MODELMATRIX procedure, the following code includes BY-group processing, CLASS variables, the interaction effect, and the SPLINE effect. It also demonstrates how you can change the name of the output data table by using the PREFIX= option. Moreover, the OUTPUT statement enables you to include the input data table variables as additional columns in the output data table by using the COPYVARS= option.

```
proc modelmatrix data=mylib.sample nthreads=1;
  by byVar;
  class c;
  freq frq;
  weight wgt;
  effect spl= spline(x);
  model y = x c spl x*c;
  output out=mylib.designMat prefix=param copyVars=(c frq index);
run;
```

The output tables are displayed in Output 20.1.2, Output 20.1.3, and Output 20.1.4.

Output 20.1.2 Model Information and Column Names of the Design Matrix

The MODELMATRIX Procedure

Model Information	
Data Source	SAMPLE
Response Variable	y
Frequency Variable	frq
Weight Variable	wgt

Column Names of the Design Matrix	
Name	**Parameter**
param1	Intercept
param2	x
param3	c 1
param4	c 2
param5	c 3
param6	c 0
param7	spl 1
param8	spl 2
param9	spl 3
param10	spl 4
param11	spl 5
param12	spl 6
param13	spl 7
param14	x * c 1
param15	x * c 2
param16	x * c 3
param17	x * c 0

The "Column Names of the Design Matrix" table in Output 20.1.2 shows that the defined model creates a total of 17 parameters across the two BY groups. Therefore, the design matrix has 17+3 columns (the additional columns are reserved for the variables c, frq, and index that you append to the design matrix by using the COPYVARS= option).

Apart from the intercept, the continuous variable x is included as a main effect. However, because c is defined as a classification variable, all of its unique values (0–3) are considered to be separate parameters (a total of four). Output 20.1.2 shows that the SPLINE effect adds seven more parameters to the model. Finally, the interaction of x and c ($x * c$) adds four more parameters.

Also shown in Output 20.1.2 is the "Model Information" table, which displays a brief summary of the response variable, the FREQ variable, and the WEIGHT variable.

The rest of the output tables depend on the BY groups. Therefore, they are produced separately and are shown in Output 20.1.3 and Output 20.1.4.

Output 20.1.3 Number of Observations, Class Level Information, and Dimensions Tables for BY Group 2

The MODELMATRIX Procedure

byVar=1

Number of Observations Read	10
Number of Observations Used	10
Sum of Frequencies Read	10
Sum of Frequencies Used	10
Sum of Weights Read	10
Sum of Weights Used	10

byVar=1

Class Level Information

Class	Levels	Values
c	3	1 2 3

byVar=1

Dimensions	
Number of Effects	5
Number of Parameters	15

Output 20.1.4 Number of Observations, Class Level Information, and Dimensions Tables for BY Group 2

The MODELMATRIX Procedure

byVar=2

Number of Observations Read	10
Number of Observations Used	9
Sum of Frequencies Read	9
Sum of Frequencies Used	9
Sum of Weights Read	9
Sum of Weights Used	9

byVar=2

Class Level Information

Class	Levels	Values
c	2	0 1

byVar=2

Dimensions	
Number of Effects	5
Number of Parameters	13

For each BY group, PROC MODELMATRIX displays the number of observations that are read and used. Because the FREQ and WEIGHT variables are defined, the procedure displays the number of FREQ and WEIGHT variables that are read and used. You can see that BY group 2 (Output 20.1.4) has one invalid

observation (the observation where INDEX=15). Therefore, the number of FREQ variables that are used is 9, which is different from BY group 1, where all FREQ variables have a value of 1.

The "Dimensions" table shows the number of effects and parameters that are considered within each BY group. Notice that the number of considered effects for both BY groups is equal to five. However, neither BY group includes all the parameters listed in the OutDesignInfo table, so for all BY groups, the number of parameters is less than 17.

This fact can be seen in the "Class Level Information" tables shown in Output 20.1.3 and Output 20.1.4. These tables show the levelization of the classification variables within each BY group. You can see that none of the BY groups include all levels of c (that is, 0, 1, 2, and 3), which is why the number of parameters is less than 17 for all BY groups.

PROC MODELMATRIX constructs a global design matrix. Therefore, it constructs a table that includes the union of all parameters in each BY group. To inspect the design matrix, follow the same steps that are given in the previous example. The constructed table with 20 rows can be displayed by using the following statements. The output is displayed in Output 20.1.5.

```
data work.designMat;
  set mylib.designMat;
run;

proc print data=designMat;
  format BEST 5. param1-param17;
  var index c frq param1-param7 param17;
  where
    (index < 11) or
    (index = 15);
run;
```

Output 20.1.5 Rows with index Values of 1–10 and Row with index Value of 15 from Design Matrix

Obs	index	c	frq	param1	param2	param3	param4	param5	param6	param7	param17
1	1	3	1	1	0.46319	0	0	1	.	0.00000	.
2	2	3	1	1	0.00741	0	0	1	.	0.00000	.
3	3	2	1	1	-0.06703	0	1	0	.	0.00000	.
4	4	3	1	1	1.52070	0	0	1	.	0.00000	.
5	5	2	1	1	0.51495	0	1	0	.	0.00000	.
6	6	3	1	1	1.00574	0	0	1	.	0.00000	.
7	7	3	1	1	0.36049	0	0	1	.	0.00000	.
8	8	3	1	1	-1.75802	0	0	1	.	0.16667	.
9	9	2	1	1	1.02322	0	1	0	.	0.00000	.
10	10	1	1	1	0.33004	1	0	0	.	0.00000	.
15	15	0	-1	.	.	.	.	.	.	.	.

Output 20.1.5 displays rows of the design matrix whose index value is 1–10 and the row whose index value is 15. Only the index, c, frq, param1–param7, and param17 variables are shown. As expected, the generated data table contains 20 rows associated with each observation and 20 columns (17 parameters plus three columns for the input variables c, frq, and index). You can see that the column names are param1 through param17, based on the PREFIX= option specified in the OUTPUT statement.

The "Column Names of the Design Matrix" table lists the model parameters with their corresponding column

names in the design matrix. Columns param3 through param6 contain all levels of the c variable. The rows in the design matrix whose index value is less than 11 belong to the first BY group (byVar=1), and according to the "Class Information" table, level $c3$ does not exist in either BY group. This observation can be confirmed by the fact that the param6 and param17 columns of the design matrix (which are associated with the $c3$ and $x * c3$ parameters, respectively) are empty.

You can also see that the row of the design matrix whose index value is 15 is all blanks. This is because the value of the defined FREQ variable for this observation is invalid and equal to –1 (see the frq column in the design matrix), and therefore this observation is not considered when the design matrix is created.

Overview: MVOUTLIER Procedure

The MVOUTLIER procedure performs robust principal component analysis (PCA) to identify outliers and leverage points in any numeric multivariate data set. It is especially useful for correlated high-dimensional data, because the PCA subspace serves as a robust lower-dimensional representation of the data—robust in the sense of minimizing the impact of extreme observations while estimating the covariance structure.

The MVOUTLIER procedure divides observations into four main categories in terms of their relationship to the subspace:

- a homogeneous group that is close to the center of the PCA subspace
- high-leverage observations that are close to the subspace but far from its center
- outlying observations that are far from the subspace but close to its center after being projected onto it
- observations that are both far from the subspace and far from its center after being projected onto it

Often the lower-dimensional representation of the data that you obtain from robust PCA is used for some other multivariate analysis, such as cluster analysis or discriminant analysis. An initial identification of outliers and leverage points from robust PCA can better inform the subsequent analysis.

The method combines and extends two popular PCA approaches: one based on robust covariance estimation, and the other based on projection pursuit. In addition to its purpose of identifying outliers and leverage points, it also serves the traditional purpose of PCA—dimension reduction—by projecting the data onto an optimal subspace that contains most of the information, even if there are outliers.

PROC MVOUTLIER applies naturally to any situation that involves numeric multivariate data in which either anomaly detection or PCA (or both) is desired.

PROC MVOUTLIER Features

The MVOUTLIER procedure provides the following features:

- performs robust dimension reduction that assumes a particular contamination level
- determines the number of principal components needed to explain a target proportion of variance
- displays a scree plot to help choose the final number of principal components
- calculates cutoff values for the two metrics—orthogonal and robust score distances—that identify outliers and leverage points
- optionally incorporates criteria for "marginal" outliers and leverage points, either to identify observations that are below but close to cutoff values or to hide the more moderate outliers and leverage points from being displayed
- displays a diagnostic plot that separates the data into four quadrants on the basis of high and low outlyingness and leverage, or up to nine sectors if marginal outlier and leverage criteria are used
- displays a summary table that contains counts of outliers and leverage points
- displays a table of observations that have the most extreme outlyingness or leverage
- produces an output data table that contains observationwise statistics
- enables reproducibility of observation order
- exploits all the available cores and concurrent threads. For information about how PROC MVOUTLIER uses threads, see the section "Multithreading" on page 102.

Because PROC MVOUTLIER runs on CAS, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode on CAS

PROC MVOUTLIER Compared with Other SAS Software

A number of other SAS products have features in procedures, CAS actions, and solutions that address outlier detection, leverage, PCA, and robust estimation:

- SAS Visual Statistics
  - The **pca** action set and its associated PCA procedure perform PCA for dimension reduction by using methods such as eigenvalue decomposition, nonlinear iterative partial least squares, Gram-Schmidt orthogonalization, and random projection. They mostly supersede the capabilities of the PRINCOMP and HPPRINCOMP procedures in SAS/STAT.
- SAS Visual Analytics
  - The **outlier** action in the **dataPreprocess** action set performs univariate outlier detection and treatment. Outlier cutoff thresholds can be defined as percentiles, standard or robust Z-scores, or user-supplied values. Outliers can be either removed or replaced with location estimates, lower or upper cutoff thresholds, or user-supplied values.
  - The **rustats** action in the **dataPreprocess** action set computes many different robust univariate statistics, such as quantiles, centralized and standardized moments, and skewness estimates.
- Machine Learning
  - The **robustpca** action in the **robustPca** action set and its associated RPCA procedure perform robust PCA by using principal component pursuit to decompose the input data matrix into the sum of a low-rank matrix $\mathbf{L}$ and a sparse matrix $\mathbf{S}$. PCA is performed on $\mathbf{L}$, and anomaly detection is performed on $\mathbf{S}$. Outliers are defined as observations whose count of variables that exceed a user-supplied standardized sparse value threshold exceeds a user-supplied count threshold.
  - The **mwpca** action in the **robustPca** action set and its associated MWPCA procedure perform moving windows PCA to capture changes in principal components over time. The same type of robust PCA that is performed in the **robustpca** action can be used in each window to exclude outliers from the analysis.
  - The **kPca** action set and its associated KPCA procedure perform nonlinear kernel-based PCA. Rather than finding a linear projection onto a subspace, it embeds the data in a high-dimensional Hilbert space and uses kernel-based linear dimensionality reduction to find a nonlinear manifold that contains the input data.
- Model Studio (Data Mining and Machine Learning Projects)
  - The Anomaly Detection Data Mining Preprocessing node uses the support vector data description (SVDD) formulation to identify and exclude outliers.

  - The Feature Extraction Data Mining Preprocessing node performs dimension reduction based on a choice of several types of PCA, such as traditional, singular value decomposition, and robust PCA that is based on the **robustpca** action in the **robustPca** action set.

- SAS/STAT
  - The CALIS procedure identifies outliers and leverage points in structural equation models. It provides options to downweight outliers by using robust estimation methods based on iteratively weighted least squares in computing parameter estimates, model fit statistics, case-level residuals, residual M-distances, and leverage M-distances. The ALPHAOUT= and ALPHALEV= options in the PROC CALIS statement, like the ALPHAOUTLIER= and ALPHALEVERAGE= options in the PROC MVOUTLIER statement, enable adjustment of the outlier and leverage cutoffs.
  - The ROBUSTREG procedure identifies outliers and leverage points and downweights outliers in linear regression analysis. Its robust estimation methods include Huber M estimation and methods with high breakdown value, such as least trimmed squares, S estimation, and MM estimation. In analysis of leverage points for covariates, it provides several options for adjusting cutoff values. Many computations involve a generalized version of FAST-MCD, a minimum covariance determinant (MCD) estimation method similar to the deterministic MCD methods used in PROC MVOUTLIER.
  - The FACTOR procedure performs PCA by default and also implements several varieties of factor analysis and factor rotation. The NFACTORS= and PROPORTION= options in the PROC FACTOR statement are analogous to the NPRINCOMP= and PROPVARIANCE= options, respectively, in the PROC MVOUTLIER statement. The FACTOR procedure also provides a third way to determine the number of factors: the MINEIGEN= option in the PROC FACTOR statement, which specifies the smallest eigenvalue for which to retain a factor in reducing dimension.

- SAS/QC
  - The MVPMODEL, MVPMONITOR, and MVPDIAGNOSE procedures provide traditional PCA as an alternative to classical T^2 charts, intended for situations in which there is high correlation among process variables.

- SAS IML
  - The MCD and MVE subroutines perform robust estimation of multivariate location and scatter. The MCD subroutine uses a FAST-MCD estimator, and the MVE subroutine uses a minimum volume ellipsoid estimator.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: MVOUTLIER Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/mvogs1.sas.)

This example demonstrates how to identify outliers and leverage points in a robust principal component analysis. It illustrates two different strategies for choosing the number of principal components to retain for the final subspace:

- Perform only the initial steps of the analysis in order to obtain information about the amount of variance explained by each component, use that information to choose the number of components, and then specify your chosen number in a full analysis.
- Specify a desired proportion of variance to be explained by the principal components, and let the procedure choose the number of components automatically in a full analysis.

The following DATA step creates the data table mylib.cars, which consists of 11 measurements on 111 cars.

NOTE: Input data must be a stored in a table on your CAS server, and a CAS session must be set up. For more information, see "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7.

```
data mylib.cars;
   format MakeModel $char20.;
   input MakeModel Length Wheelbase Width Height FrontHd RearHd /
         FrtLegRoom RearSeating FrtShld RearShld Luggage;
   datalines;
AcuraIntegra          -0.2222222     0  -0.5  -2.5   0  -0.5
 0  -0.6666667     -1     -1     1
DodgeColt             -2.2222222  -1.6    -1     0  -1     0
-2          -2   -0.5  -0.75    -1
DodgeOmni             -1.7777778  -0.6  -0.5     1  -1  -1.5
-1          -1  -1.75   -1.5   0.5

   ... more lines ...

NissanAxxess          -0.7777778   0.2  -0.5     8   1   2.5
-2   0.6666667   0.25   1.25  -8.5
NissanVan             -0.1111111  -1.8  -0.5  15.5   0     3
-1         -19      1   2.25    -8
VolkswagenVanagon      0.1111111    -1   2.5  20.5   3     7
-5   6.3333333   3.25  -7.25    -8
 ;
```

These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

Many of the measurements are highly correlated with each other. Consequently, PCA is a potentially useful method to reduce the dimension and find the most important sources of variation.

In order to determine the number of principal components to use, you can use the following statements to produce a table and scree plot of the eigenvalues of the initial robust subspace:

```
ods graphics on;
proc mvoutlier data=mylib.cars initonly plots=scree;
   var :;
   id MakeModel;
run;
```

When you specify the INITONLY option in the PROC MVOUTLIER statement, the procedure saves computational time and resources by stopping as soon as these eigenvalues are computed and displayed. The variable name wildcard, which is the colon (:) in the VAR statement, specifies all variables, and the procedure automatically excludes the MakeModel variable because it is nonnumeric. The MakeModel variable that is specified in the ID statement displays MakeModel values instead of automatically assigned observation numbers wherever there is observationwise output. The default CONTAMINATION= option value, 0.25, assumes that 25% of the observations lie outside a more homogeneous group to be used in robust computations.

Model information and observation counts are shown in Figure 21.1 and Figure 21.2.

Figure 21.1 Model Information

8	0.269918	0.074896	0.0150	0.9799
9	0.195022	0.080927	0.0109	0.9907
10	0.114096	0.062195	0.0064	0.9971
11	0.051901		0.0029	1.0000

Figure 21.5 Scree Plot of Proportion of Variance Explained

The cumulative proportion of variance explained can inform your choice of how many principal components to retain for the final subspace—a choice that must be made at this point in order to proceed. You can set this number yourself by using the NPRINCOMP= option in the PROC MVOUTLIER statement, or you can use the PROPVARIANCE= option in the PROC MVOUTLIER statement to set it automatically to the number required to explain a target proportion of variance.

The following statements set that target to 0.9 (90%), which should automatically choose five principal components for the final subspace, and perform an analysis of outliers:

```
proc mvoutlier data=mylib.cars propvariance=0.9 plots=diagnostic;
   var :;
   id MakeModel;
   display NVars EigenvaluesFinal Cutoffs DiagSummary Diagnostics;
run;
```

Figure 21.6 confirms that five principal components have been chosen, and Figure 21.7 shows the eigenvalues of this final five-dimensional subspace.

Figure 21.6 Number of Variables and All Subspace Dimensions

The MVOUTLIER Procedure

Number of Variables	11
Inherent Data Dimensionality	11
Dimension of Initial Robust Subspace	11
Number of Principal Components	5

Figure 21.7 Eigenvalues of Final Subspace

Eigenvalues for Final Subspace

	Eigenvalue	Difference	Proportion	Cumulative
1	10.040616	6.199163	0.5522	0.5522
2	3.841453	1.391151	0.2113	0.7634
3	2.450302	1.417185	0.1347	0.8982
4	1.033117	0.214541	0.0568	0.9550
5	0.818576		0.0450	1.0000

The defaults of 0.025 for the ALPHAOUTLIER= and ALPHALEVERAGE= options define outliers as observations in the most extreme 2.5% of the estimated distribution of orthogonal distances, and they define leverage points as observations in the most extreme 2.5% of the estimated distribution of robust score distances. The corresponding cutoff values are shown in Figure 21.8.

Figure 21.8 Outlier and Leverage Cutoffs

Outlier and Leverage Cutoffs

Criterion	Distance Type	Cutoff Alpha	Cutoff Value
Outlier	**Orthogonal**	**0.025**	2.13882
Leverage	**Robust Score**	**0.025**	3.58225

Figure 21.9 shows the counts of observations that are identified as outliers and/or leverage points, and Figure 21.10 shows their orthogonal and robust score distances along with asterisks (*) to indicate outlyingness and leverage.

"Leverage" observations lie close to the final subspace but, when projected onto it, appear extreme. "Outliers" lie far away from the final subspace but, when projected onto it, no longer appear extreme. "Outlier and Leverage" observations appear extreme both relative to and within the subspace. The remaining observations exceed neither of the distance cutoff values.

The ALPHAMARGINALOUTLIER= and ALPHAMARGINALLEVERAGE= options in the PROC MVOUTLIER statement control which observations to include in the Diagnostics table. By

default, they are set to the values of the ALPHAOUTLIER= and ALPHALEVERAGE= options in the PROC MVOUTLIER statement, respectively, such that only the observations identified as outliers and/or leverage points are included. You can include *more* observations by *increasing* one or both alpha values, and you can include *fewer* observations by *decreasing* these values. You can also place an upper limit on the total number of observations to include in the Diagnostics table by using the DIAGNOSTICOPTIONS(MAXOBS=) option.

A graphical representation of the outlier and leverage classifications is shown in Figure 21.11.

Figure 21.11 Outlier and Leverage Diagnostic Plot

The ALPHAMARGINALOUTLIER= and ALPHAMARGINALLEVERAGE= suboptions of the PLOTS=DIAGNOSTIC option control which observations are labeled in the diagnostic plot. By default, they are set to the values of the ALPHAMARGINALOUTLIER= and ALPHAMARGINALLEVERAGE= options in the PROC MVOUTLIER statement, respectively. You can also place an upper limit on the total number of observations to include in the diagnostic plot by using the PLOTS=DIAGNOSTIC(MAXOBS=) option.

Syntax: MVOUTLIER Procedure

The following statements are available in the MVOUTLIER procedure:

PROC MVOUTLIER < *options* > **;**
BY *variables* **;**
VAR *variables* **;**
ID *variables* **;**
DISPLAY < *table-list* > < / *options* > **;**
DISPLAYOUT *table-spec-list* < / *options* > **;**
OUTPUT OUT=*libref.data-table* < *keyword* < **=***name* > >. . . < *keyword* < **=***name* > > < *options* > **;**

The PROC MVOUTLIER statement is required.

The rest of this section provides detailed syntax information about each of the preceding statements, beginning with the PROC MVOUTLIER statement. The remaining statements are described in alphabetical order.

PROC MVOUTLIER Statement

PROC MVOUTLIER < *options* > **;**

The PROC MVOUTLIER statement invokes the MVOUTLIER procedure. Optionally, it also identifies the input data set, specifies the analyses to be performed, and controls displayed output. Table 21.1 summarizes the *options* available in the PROC MVOUTLIER statement by function. They are then described fully in alphabetical order.

Table 21.1 PROC MVOUTLIER Statement Options

Option	Description
Option Related to Input Data	
DATA=	Specifies the input data table
Options Related to Number of Principal Components	
INITONLY	Stops the analysis just before the final number of principal components is determined
NPRINCOMP=	Specifies the number of principal components for the final subspace
NPRINCOMPMAX=	Specifies the largest feasible number of principal components, used in conjunction with the PROPVARIANCE= option
PROPVARIANCE=	Specifies the target proportion of variance to be explained by the principal components
Option Related to Robustness	
CONTAMINATION=	Specifies the fraction of observations that are corrupted
Options Related to Outlier and Leverage Assessment	
ALPHALEVERAGE=	Determines the robust score distance cutoff value that is used to identify leverage points
ALPHAOUTLIER=	Determines the orthogonal distance cutoff value that is used to identify outliers
Options Related to Output Tables and Graphs	
ALPHAMARGINALLEV=	Determines the robust score distance cutoff value to use for inclusion in tables or labeling in plots
ALPHAMARGINALOUT=	Determines the orthogonal distance cutoff value to use for inclusion in tables or labeling in plots
DIAGNOSTICOPTIONS	Specifies options for the Diagnostics table
EIGENVEC	Produces the Eigenvectors table
LOADINGS	Produces the Loadings table
PLOTS	Specifies options that control the details of the plots
PREFIX=	Specifies a prefix for naming the principal components
Options Related to Computation	
APPLYROWORDER	Specifies that the procedure use a prespecified data distribution
SEED=	Specifies the seed to use for random number generation

The following list provides details about these *options*.

ALPHALEVERAGE=*p*

ALPHALEV=*p*

specifies the tail probability that determines the robust score distance cutoff value that is used to identify leverage points, where $0 \leq p \leq 1$. By default, ALPHALEVERAGE=0.025.

ALPHAMARGINALLEVERAGE=*p*

ALPHAMARGINALLEV=*p*

ALPHAMARGLEV=*p*

specifies the tail probability that determines the robust score distance cutoff value to use for inclusion in the Diagnostics table or labeling in the diagnostic plot, where $0 \leq p \leq 1$. An observation whose robust score distance exceeds the cutoff determined by the ALPHAMARGINALLEVERAGE= option value is, by default, included in the Diagnostics table and labeled in the diagnostic plot. However, it is still possible for the value of the DIAGNOSTICOPTIONS(MAXOBS=) option to exclude the observation from the Diagnostics table, or for either the PLOTS=DIAGNOSTIC(MAXOBS=) option value or the PLOTS=DIAGNOSTIC(LABEL=NONE) option to remove the observation's label in the diagnostic plot.

The higher the value, the more observations are included or labeled. By default, the option is set to the value of the ALPHALEVERAGE= option, which causes observations to be included or labeled according to the ALPHALEVERAGE= option value.

A value greater than the ALPHALEVERAGE= option value might include or label some observations whose robust score distances do *not* exceed the cutoff determined by the ALPHALEVERAGE= option value. A value less than the ALPHALEVERAGE= option value might exclude or disable labels for some observations whose robust score distances *do* exceed the cutoff determined by the ALPHALEVERAGE= option value.

ALPHAMARGINALOUTLIER=*p*

ALPHAMARGINALOUT=*p*

ALPHAMARGOUT=*p*

specifies the tail probability that determines the orthogonal distance cutoff value to use for inclusion in the Diagnostics table or labeling in the diagnostic plot, where $0 \leq p \leq 1$. An observation whose orthogonal distance exceeds the cutoff determined by the ALPHAMARGINALOUTLIER= option value is, by default, included in the Diagnostics table and labeled in the diagnostic plot. However, it is still possible for the value of the DIAGNOSTICOPTIONS(MAXOBS=) option to exclude the observation from the Diagnostics table, or for either the PLOTS=DIAGNOSTIC(MAXOBS=) option value or the PLOTS=DIAGNOSTIC(LABEL=NONE) option to remove the observation's label in the diagnostic plot.

The higher the value, the more observations are included or labeled. By default, the option is set to the value of the ALPHAOUTLIER= option, which causes observations to be included or labeled according to the ALPHAOUTLIER= option value.

A value greater than the ALPHAOUTLIER= option value might include or label some observations whose orthogonal distances do *not* exceed the cutoff determined by the ALPHAOUTLIER= option value. A value less than the ALPHAOUTLIER= option value might exclude or disable labels for some observations whose orthogonal distances *do* exceed the cutoff determined by the ALPHAOUTLIER= option value.

ALPHAOUTLIER=*p*

ALPHAOUT=*p*

specifies the tail probability that determines the orthogonal distance cutoff value that is used to identify outliers, where $0 \leq p \leq 1$. By default, ALPHAOUTLIER=0.025.

APPLYROWORDER
uses a data distribution and row order as determined by a previous **partition** action call. For more information, see the section "The APPLYROWORDER Option" on page 107 in Chapter 2, "Shared Concepts."

CONTAMINATION=*p*

CONTAM=*p*

CORRUPTED=*p*
specifies the fraction of observations that are corrupted, where $0 \leq p \leq 0.5$. By default, CONTAMINATION=0.25.

DATA=*libref.data-table*
names the input data table for PROC MVOUTLIER to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1155.

data-table specifies the name of the input data table.

DIAGNOSTICOPTIONS <(*options***)>**

DIAGOPTIONS <(*options***)>**

DIAGOPTS <(*options***)>**
specifies options for the Diagnostics table.

You can specify the following *options*:

MAXOBS=*number*
specifies the maximum number of observations to include in the Diagnostics table. If *number* is less than the number of observations, then observations are prioritized from highest to lowest as follows:

1. Outlier and Leverage, sorted by $(d_o/c_o)^2 + (d_s/c_s)^2$, where d_o and c_o are orthogonal distance and its cutoff, and c_s and o_s are robust score distance and its cutoff
2. Outlier, sorted by orthogonal distance
3. Leverage, sorted by robust score distance
4. Neither, sorted by the same formula as Outlier and Leverage

SHOWOBSID

OBSID
includes the automatically assigned observation ID in the Diagnostics table. This option is automatically enabled if you omit the ID statement.

EIGENVEC
creates the Eigenvectors table, which is produced only if you specify this option.

INITONLY
INITIALONLY
stops the analysis just before the point where the final number of principal components is determined. This saves computation time if you want to obtain only the information relevant to determining how many principal components to retain for the final subspace.

LOADINGS
creates the Loadings table, which is produced only if you specify this option.

NPRINCOMP=*number*
NCOMP=*number*
NPC=*number*
N=*number*
specifies the number of principal components to retain for the final subspace. You must specify either this option or the PROPVARIANCE= option. You cannot specify both.

NPRINCOMPMAX=*number*
NCOMPMAX=*number*
NPCMAX=*number*
NMAX=*number*
specifies the largest feasible number of principal components that you would expect to retain for the final subspace, given the target proportion of variance to explain. This number does not limit the number of components that are actually used; rather, it is used to calculate an observation subset size that must be calculated before the final number of components is determined. It is used in conjunction with the PROPVARIANCE= option; by default, NPRINCOMPMAX=10.

PLOTS <(*global-plot-options***) > <= ***plot-request* **<(***options***) > >**
PLOTS <(*global-plot-options***) > <= (***plot-request* **<(***options***) > < . . . ***plot-request* **<(***options***) > >) >**
controls the plots that are produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around it.

You can specify the following *global-plot-option*:

UNPACKPANEL
UNPACK
suppresses paneling in the scree plot. By default, multiple plots can appear in an output panel. Specify UNPACKPANEL if you want each plot to appear in a separate panel. You can specify PLOTS(UNPACKPANEL) to unpack the default plots. You can also specify UNPACKPANEL as a suboption of the SCREE option: PLOTS=SCREE(UNPACKPANEL).

You can specify the following *plot-requests*:

ALL
produces all appropriate plots. You can specify other options along with ALL; for example, to request all plots and set the maximum number of observations for the diagnostic plot to 500, specify PLOTS=(ALL DIAGNOSTIC(MAXOBS=500)).

NONE
suppresses the display of all plots.

DIAGNOSTIC < (*diagnostic-options*) >
produces a plot of orthogonal distances versus robust score distances that identifies outliers and leverage points.

You can specify the following *diagnostic-options*:

ALPHAMARGINALLEVERAGE=*p*

ALPHAMARGINALLEV=*p*

ALPHAMARGLEV=*p*
specifies the tail probability that determines the robust score distance cutoff value for labeling an observation in the diagnostic plot, where $0 \leq p \leq 1$. An observation whose robust score distance exceeds the cutoff determined by the ALPHAMARGINALLEVERAGE= option value is labeled in the diagnostic plot unless the PLOTS=DIAGNOSTIC(LABEL=NONE) option is specified or the PLOTS=DIAGNOSTIC(MAXOBS=) option value excludes the observation. The higher the value, the more labels are used.

The default value depends on whether you specify the ALPHAMARGINALLEVERAGE= option in the PROC MVOUTLIER statement. If it is specified, then the default is set to its value. If it is omitted, then the default is set to the value of the ALPHALEVERAGE= option in the PROC MVOUTLIER statement.

ALPHAMARGINALOUTLIER=*p*

ALPHAMARGINALOUT=*p*

ALPHAMARGOUT=*p*
specifies the tail probability that determines the orthogonal distance cutoff value for labeling an observation in the diagnostic plot, where $0 \leq p \leq 1$. An observation whose orthogonal distance exceeds the cutoff determined by the ALPHAMARGINALOUTLIER= option value is labeled in the diagnostic plot unless the PLOTS=DIAGNOSTIC(LABEL=NONE) option is specified or the PLOTS=DIAGNOSTIC(MAXOBS=) option value excludes the observation. The higher the value, the more labels are used.

The default value depends on whether you specify the ALPHAMARGINALOUTLIER= option in the PROC MVOUTLIER statement. If it is specified, then the default is set to its value. If it is omitted, then the default is set to the value of the ALPHAOUTLIER= option in the PROC MVOUTLIER statement.

LABEL=NONE | ID | NUMBER
specifies the type of label to use for outliers and leverage points in the diagnostic plot. You can specify the following values:

NONE shows no labels.

ID uses values of the first ID variable.

NUMBER uses an automatically assigned observation ID.

MAXOBS=*number*
specifies the maximum number of observations to display in the diagnostic plot. If *number* is less than the number of observations, then observations are prioritized from highest to lowest as follows:

1. Outlier and Leverage, sorted by $(d_o/c_o)^2 + (d_s/c_s)^2$, where d_o and c_o are orthogonal distance and its cutoff, and c_s and o_s are robust score distance and its cutoff
2. Outlier, sorted by orthogonal distance
3. Leverage, sorted by robust score distance
4. Neither, sorted by the same formula as Outlier and Leverage

SCREE <(*scree-options***)>**

EIGEN <(*scree-options***)>**

EIGENVALUE <(*scree-options***)>**
produces a scree plot of eigenvalues and proportion of variance explained for the initial robust subspace, at the stage where the final number of principal components must be chosen. By default, both plots appear in the same panel.

You can specify the following *scree-options*:

NPRINCOMPDISPLAY=*number*

NCOMPDISPLAY=*number*

NDISPLAY=*number*
specifies the number of principal components to display in the scree plot. If you omit both NPRINCOMPDISPLAY= and PROPVARDISPLAYMAX=, then all components are displayed. If you specify both, then NPRINCOMPDISPLAY= takes precedence.

PROPVARDISPLAYMAX=*p*

PROPVARIANCEDISPLAYMAX=*p*

PROPVARDISPMAX=*p*
sets the number of principal components to display in the scree plot to the lowest number that explains at least the specified proportion of variance, where $0 \leq p \leq 1$. If you omit both PROPVARDISPLAYMAX= and NPRINCOMPDISPLAY=, then all components are displayed. If you specify both, then NPRINCOMPDISPLAY= takes precedence.

UNPACKPANEL

UNPACK
suppresses paneling for the scree plot so that the eigenvalue plot and proportion of variance plot appear in separate panels.

PREFIX=*name*

specifies a prefix for naming the principal components in the Eigenvectors and Loadings tables. The default *name* is Prin, which produces the component names Prin1, Prin2, Prin3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables must not exceed the current name length that is defined by the VALIDVARNAME= system option.

PROPVARIANCE=*p*

PROPORTIONVARIANCE=*p*

PROPVAR=*p*

specifies the target proportion of variance to be explained by the principal components, where $0 \leq p \leq 1$. You must specify either this option or the NPRINCOMP= option. You cannot specify both. If you specify the PROPVARIANCE= option, then the NPRINCOMPMAX= option also applies.

SEED=*number*

RANDOMSEED=*number*

specifies the seed to use for random number generation.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC MVOUTLIER to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1176. A path is a table name that is prefixed with dot-separated grouping information. For example, a

SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

key=value specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1176. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

ID Statement

ID *variables* **;**

In output that includes information about individual observations, the variables that you list in the ID statement are displayed instead of the automatically assigned observation ID. You can use these variables to identify each observation. If you omit the ID statement, the automatically assigned observation ID is used to identify the observations.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < **=***name* > > . . . < *keyword* < **=***name* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics, which are computed after PROC MVOUTLIER fits the model. If you do not specify a *keyword*, then the orthogonal distance and robust score distance are included.

The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option *are* included. ID variables are automatically included, and if no ID variables are specified then the automatically assigned observation ID is included.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC MVOUTLIER to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1155.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

COPYVARS=(*variables***)**

COPYVAR=*variable*

transfers one or more *variables* from the input data table to the output data table.

keyword **<=***name***>**

specifies a statistic to include in the output data table and optionally a *name* that is used either as a prefix, for statistics that have more than one variable, or as a name otherwise. If you do not provide a *name*, the MVOUTLIER procedure assigns a default *name* according to the type of statistic that you specify.

You can specify the following *keywords* to add statistics to the OUTPUT data table:

LEVERAGE

specifies a leverage indicator that is set to 1 if the robust score distance exceeds its cutoff and 0 otherwise. The default variable name is Leverage.

NODEID

specifies the node ID of the computer that processes the observation. The default variable name is NodeId.

OBSID

specifies the automatically assigned observation ID. The default variable name is ObsId.

ORTHDIST

specifies the orthogonal distance between the observation and the final subspace. Orthogonal distances are scale-dependent in PROC MVOUTLIER; this means that they are interpreted with respect to the scale of the data. You should consider standardizing or rescaling the data prior to the analysis carefully, on a case-by-base basis. The default variable name is OrthDist.

OUTLIER

specifies an outlier indicator that is set to 1 if the orthogonal distance exceeds its cutoff and 0 otherwise. The default variable name is Outlier.

SCORE

specifies principal component scores for each principal component. The default variable prefix is Score.

SCOREDIST

specifies the robust score distance, which is the distance between the observation after being projected onto the final subspace and the robust location estimate of the subspace mean. The default variable name is ScoreDist.

The output variables that contain the specified statistic are named as follows, according to the *keyword* that you specify:

- The *keyword* SCORE defines an output variable for each principal component, so the variables that correspond to each successive component are named by appending the component number to the prefix. For example, if the model has three principal components, then SCORE=T produces the variables T1, T2, and T3.
- The *keywords* LEVERAGE, NODEID, OBSID, ORTHDIST, OUTLIER, and SCOREDIST each define a single output variable, so the variable name matches the prefix.

VAR Statement

VAR *variables* **;**

The VAR statement lists the numeric variables to be analyzed. If you omit this statement, all numeric variables that are not specified in other statements are analyzed.

Details: MVOUTLIER Procedure

Displayed Output

The following sections describe the output that PROC MVOUTLIER produces. The output is organized into various tables, which are discussed in their order of appearance.

Model Information

The "Model Information" table displays the following basic information about the model and input options:

- Input data table
- Number of analysis variables
- orderBy and groupBy variables, if the input data table has been processed by the **`partition`** action in the **`table`** action set
- Assumed contamination proportion
- Requested number of principal components, if you specify the NPRINCOMP= option in the PROC MVOUTLIER statement
- Target proportion of variance explained and maximum number of principal components, if you specify the PROPVARIANCE= option in the PROC MVOUTLIER statement
- Alpha for outlier cutoff
- Alpha for marginal outlier cutoff, if you specify the ALPHAMARGINALOUTLIER= option in the PROC MVOUTLIER statement
- Alpha for leverage cutoff
- Alpha for marginal leverage cutoff, if you specify the ALPHAMARGINALLEVERAGE= option in the PROC MVOUTLIER statement
- Seed for random numbers

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis.

Number of Variables

The "Number of Variables" table displays the following information about the data dimension at different stages in the analysis:

- Number of analysis variables
- Inherent data dimension, which is the rank of the input data matrix
- Dimension of the initial robust subspace, which is the rank of the initial least-outlying subset of observations and also an upper bound for the final number of principal components
- Number of principal components to be extracted for the final subspace

Eigenvalues for Initial Robust Subspace

The "Eigenvalues for Initial Robust Subspace" table displays eigenvalues of the initial robust subspace, along with the difference between successive eigenvalues, the proportion of variance explained by each eigenvalue, and the cumulative proportion of variance explained.

If the number of principal components to retain for the final subspace is not specified explicitly using the NPRINCOMP= option in the PROC MVOUTLIER statement, these eigenvalues are used to determine the final number of principal components.

Eigenvalues for Final Subspace

The "Eigenvalues for Final Subspace" table displays eigenvalues of the final subspace, along with the difference between successive eigenvalues, the proportion of variance explained by each eigenvalue, and the cumulative proportion of variance explained.

Eigenvectors

The "Eigenvectors" table displays the eigenvectors of the final subspace. The EIGENVEC option in the PROC MVOUTLIER statement is required for this table to be displayed.

Eigenvectors describe the orientation of the principal components relative to the original variables. You can project the original variables onto the final subspace by multiplying them by the eigenvector matrix.

Loadings

The "Loadings" table displays the loadings of the final subspace; loadings are the weights of each original variable in each of the principal components.

The loadings describe how much each variable contributes to each principal component. They are the scaled eigenvectors, which result from multiplying each eigenvector by the square root of its corresponding eigenvalue.

Outlier and Leverage Cutoffs

The "Outlier and Leverage Cutoffs" table displays the orthogonal and robust score distance cutoff values that are based in the ALPHAOUTLIER= and ALPHALEVERAGE= options in the PROC MVOUTLIER statement. An observation is identified as an outlier if its orthogonal distance exceeds the outlier cutoff and as a leverage point if its robust score distance exceeds the leverage cutoff.

If you specify the ALPHAMARGINALOUTLIER= option in the PROC MVOUTLIER statement, the orthogonal distance cutoff value that controls inclusion in the Diagnostics table and labeling in the diagnostic plot is displayed. Similarly, if you specify the ALPHAMARGINALLEVERAGE= option in the PROC MVOUTLIER statement, the robust score distance cutoff value that controls inclusion in the Diagnostics table and labeling in the diagnostic plot is displayed.

Diagnostic Summary

The "Diagnostic Summary" table displays counts of observations that are identified as both outlier and leverage, outlier only, or leverage only. If you specify the DIAGNOSTICOPTIONS(MAXOBS=) option in the PROC MVOUTLIER statement and one or more observations are excluded from the Diagnostics table because of their value, then the same three counts for excluded observations are also displayed.

Outlier and Leverage Diagnostics

The "Outlier and Leverage Diagnostics" table displays information about the observations that have the most extreme orthogonal and robust score distances. Observations are included if they exceed either the outlier cutoff determined by the ALPHAMARGINALOUTLIER= option in the PROC MVOUTLIER statement or the leverage cutoff determined by the ALPHAMARGINALLEVERAGE= option in the PROC MVOUTLIER statement, or both.

The table includes an outlier indicator, which shows an asterisk (*) for observations whose orthogonal distances exceed the cutoff determined by the ALPHAOUTLIER= option in the PROC MVOUTLIER statement, and a leverage indicator, which shows an asterisk (*) for observations whose robust score distances exceed the cutoff determined by the ALPHALEVERAGE= option in the PROC MVOUTLIER statement.

The orthogonal and robust score distances are also included, along with either the values of the ID variables (if you specify the ID statement) or automatically assigned observation IDs (if you omit the ID statement, or if you specify the DIAGNOSTICOPTIONS(SHOWOBSID) option in the PROC MVOUTLIER statement).

Timing Information

The "Timing" table displays the elapsed time of each main task of the procedure.

ODS Table Names

Each table that the MVOUTLIER procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or the Output Delivery System (ODS) statements. These names are listed in Table 21.2.

Table 21.2 ODS Tables Produced by PROC MVOUTLIER

Table Name	Description	Required Statement / Option
Cutoffs	Orthogonal and robust score distance cutoffs for outlyingness and leverage, respectively	Default output
Diagnostics	Most extreme outliers and leverage points	Default output
DiagSummary	Counts of observations identified as outliers and/or leverage points	Default output
EigenvaluesFinal	Eigenvalues for the final subspace	Default output
EigenvaluesInit	Eigenvalues for the initial robust subspace	Default output
Eigenvectors	Eigenvectors	EIGENVEC option in the PROC MVOUTLIER statement
Loadings	Loadings	LOADINGS option in the PROC MVOUTLIER statement
ModelInfo	Basic information about the model and input options	Default output
NObs	Number of observations read and used	Default output
NVars	Number of variables, subspace dimensions, and principal components	Default output
OutputCasTables	A special ODS table that has information about all the CAS tables that are created during a CAS action execution	DISPLAYOUT statement or OUTPUT statement
Timing	Absolute and relative times of tasks performed by the procedure	Default output

ODS Graphics

You can refer to every graph produced through ODS Graphics by name. The names of the graphs that PROC MVOUTLIER generates are listed in Table 21.3, along with a description of each graph and the required statements and options.

Table 21.3 Graphics Produced by PROC MVOUTLIER

ODS Graph Name	Plot Description	Required Statement / Option
DiagnosticPlot	Plot of orthogonal distances versus robust score distances that identifies outliers and leverage points	Default output | PLOTS=DIAGNOSTIC
ScreePlot	Series plot of eigenvalues of the principal components that define the initial robust subspace and, if the UNPACKPANEL option is omitted, a series plot of the variance explained by the principal components	Default output | PLOTS=SCREE
VariancePlot	Series plot of the variance explained by the principal components that define the initial robust subspace	PLOTS=SCREE(UNPACKPANEL)

Examples: MVOUTLIER Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 21.1: Breast Cancer Diagnosis

(View the complete code for this example (mvoex1.sas) in the example repository.)

The Wisconsin breast cancer diagnosis data set at `https://archive.ics.uci.edu/ml/datasets/Breast+Cancer+Wisconsin+%28Diagnostic%29` is frequently used to assess classification methods in statistical data analysis and machine learning (Dua and Graff 2019). It consists of 30 different features that are computed from digitized images of 569 specimens from fine-needle aspiration of breast mass biopsies, along with each specimen's diagnosis as either benign or malignant.

The data set that this example uses is modified from the original in the same way as on the Outlier Detection Datasets (ODDS) website `http://odds.cs.stonybrook.edu/wbc/`, keeping the 357 specimens that have a benign diagnosis and sampling 21 specimens at random from the 212 specimens that have a malignant diagnosis. The diagnosis information is removed, and the collection of 378 specimens is assumed to be corrupted data, with a contamination percentage of $21/357 \approx 6\%$.

The goal is to use PROC MVOUTLIER to identify the malignant cases as outliers in a robust principal component analysis.

The following DATA step creates the data table mylib.wbc, which consists of a unique specimen number and 30 features for each breast mass. These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.wbc;
   input Specimen mean_radius mean_texture mean_perimeter mean_area mean_smoothness
     mean_compactness mean_concavity mean_concave_points mean_symmetry
     mean_fractal_dimension /
     stderr_radius stderr_texture stderr_perimeter stderr_area stderr_smoothness
     stderr_compactness stderr_concavity stderr_concave_points stderr_symmetry
     stderr_fractal_dimension /
     max_radius max_texture max_perimeter max_area max_smoothness max_compactness
     max_concavity max_concave_points max_symmetry max_fractal_dimension;

;
```

For easier interpretation of results, the Specimen numbers in the mylib.wbc data table have been assigned intentionally so that specimens 1 through 21 correspond to the breast masses that have a malignant diagnosis. The order of observations has been shuffled randomly and uniformly, and the analysis itself is blind to the actual cancer diagnoses.

The following statements request outlier and leverage diagnostics for a robust principal component analysis that automatically chooses the number of principal components that are needed to explain at least 95% of the variance, assuming that 6% of the data are corrupted:

```
ods graphics on;
proc mvoutlier data=mylib.wbc contamination=0.06 propvariance=0.95
               plots=diagnostic;
   var mean_: stderr_: max_:;
   id Specimen;
run;
```

Model information and observation counts are shown in Output 21.1.1 and Output 21.1.2.

Output 21.1.1 Model Information

The MVOUTLIER Procedure

Model Information	
Data Source	WBC
Assumed Contamination Proportion	0.06
Target Proportion of Variance Explained	0.95
Maximum Number of Principal Components	10
Alpha for Outlier Cutoff	0.025
Alpha for Leverage Cutoff	0.025
Random Number Seed	1

Output 21.1.2 Number of Observations

Number of Observations Read	378
Number of Observations Used	378

The default maximum of 10 principal components merely provides an approximation at the beginning of the algorithm for the largest feasible number of principal components that will be selected later in the algorithm. It is unlikely to affect the final results. The defaults of 0.025 for the ALPHAOUTLIER= and ALPHALEVERAGE= options define outliers as observations in the most extreme 2.5% of the estimated distribution of orthogonal distances, and they define leverage points as observations in the most extreme 2.5% of the estimated distribution of robust score distances.

Output 21.1.3 reveals that the data are highly correlated, having a low rank (6) compared to the number of parameters (30). The initial robust subspace further reduces the dimension by one; this subspace is the basis for selecting the final number of principal components to retain, and its dimension (5) serves as an upper bound.

Output 21.1.3 Number of Variables and Subspace Dimensions

Number of Variables	30
Inherent Data Dimensionality	6
Dimension of Initial Robust Subspace	5
Number of Principal Components	1

Output 21.1.4 shows that the very first eigenvalue of the initial robust subspace explains more than 98% of the variance, surpassing the target of 95% that is specified by the PROPVARIANCE=0.95 option. The choice of one component is stated explicitly in the last row of Output 21.1.3.

Output 21.1.4 Eigenvalues of Initial Robust Subspace

Eigenvalues for Initial Robust Subspace				
	Eigenvalue	**Difference**	**Proportion**	**Cumulative**
1	42247	41793	0.9867	0.9867
2	454.116191	391.459322	0.0106	0.9973
3	62.656869	19.597906	0.0015	0.9988
4	43.058963	34.062911	0.0010	0.9998
5	8.996052		0.0002	1.0000

Output 21.1.5 shows the cutoff values for orthogonal and robust score distances that define outliers and leverage points, respectively, and Output 21.1.6 reveals how many observations have been identified as outliers, leverage points, or both.

Output 21.1.5 Outlier and Leverage Cutoffs

Outlier and Leverage Cutoffs			
Criterion	Distance Type	Cutoff Alpha	Cutoff Value
Outlier	Orthogonal	0.025	37.08827
Leverage	Robust Score	0.025	2.24140

Output 21.1.6 Diagnostic Summary

Diagnostics Summary	
Number of Outlier and Leverage Observations	20
Number of Outlier Only Observations	33
Number of Leverage Only Observations	6

Output 21.1.7 shows the observations that are identified as outliers and/or leverage points, along with their orthogonal and robust score distances.

Output 21.1.7 Outlier and Leverage Diagnostics

Outlier and Leverage Diagnostics

	Distances			
Specimen	Orthogonal	Robust Score	Outlier	Leverage

Entries in the Diagnostics table are ordered as follows:

- First, the 20 observations identified as both outliers and leverage points, ordered by a combination of orthogonal and robust score distances—in particular, highest to lowest sum of squares of each of the two distances divided by its corresponding cutoff value.
- Next, the 33 observations identified as outliers but not leverage points, ordered from highest to lowest orthogonal distance.
- Last, the 6 observations identified as leverage points but not outliers, ordered from highest to lowest robust score distance.

The Diagnostics table would finally show any of the remaining 319 observations that meet its inclusion criterion, ordered by the same combination of distances as for the first set of observations. By default, as in this example, only the observations that are identified as outliers or leverage points (or both) are included.

Output 21.1.8 shows the diagnostic plot of orthogonal and robust score distances. It divides the observations into quadrants that are defined by the outlier and leverage point cutoffs.

Output 21.1.8 Outlier and Leverage Diagnostic Plot

The inclusion criteria for both the Diagnostics table and the diagnostic plot are further explored in Example 21.2.

Note that 18 of the 21 specimens that were diagnosed as malignant are among the 20 observations identified as both outliers and leverage points. These observations are orthogonal outliers in the sense that they are far from the one-dimensional subspace that was found by robust PCA to explain more than 98% of the variance of the collection of all 30 features. They are also leverage points in the sense that they would be likely to have a large influence in data analyses performed on the one-dimensional representation of the 30-dimensional data set.

Two of the remaining specimens that were diagnosed as malignant (specimens 20 and 12) are among the most extreme outliers that are not also identified as leverage points.

Specimen 2 is the only specimen diagnosed as malignant whose observation is not identified as either an outlier or a leverage point.

Example 21.2: Ensuring Reproducible Observation Order

(View the complete code for this example (mvoex2.sas) in the example repository.)

This example demonstrates how to use the APPLYROWORDER option in the PROC MVOUTLIER statement and the **partition** action in the **table** action set to ensure that observations in an input data table are processed in the same order in repeated MVOUTLIER procedure calls.

Why might you want to have reproducible row order? In the random PCA step of PROC MVOUTLIER's algorithm, a set of observation pairs is randomly sampled from the input data table. Even if you use the same SEED= option value in the PROC MVOUTLIER statement, a change in the order of the data on the CAS server could cause different sets of pairs to be selected and produce different results.

In this example, you learn how to specify an ordering of your data table and instruct PROC MVOUTLIER to use it.

The data that this example uses are from Example 21.1; they consist of 30 different features that are computed from digitized images of 378 specimens from fine-needle aspiration of breast mass biopsies that are associated with a mix of benign and malignant diagnoses. The following DATA step generates the data. These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.wbc;
   input Specimen mean_radius mean_texture mean_perimeter mean_area mean_smoothness
     mean_compactness mean_concavity mean_concave_points mean_symmetry
     mean_fractal_dimension /

In preparation for a demonstration of the **partition** action in the **table** action set and the APPLYROWORDER option in the PROC MVOUTLIER statement, several options are added to the last run of the MVOUTLIER procedure in Example 21.1 to show more information about observations:

- The SHOWOBSID suboption of the DIAGNOSTICOPTIONS option in the PROC MVOUTLIER statement shows automatically assigned observation numbers in the Diagnostics table.

- The OUTPUT statement creates an output table displaying observationwise statistics that include the automatically assigned observation number.
- The MAXOBS= suboption of the DIAGNOSTIC plot option limits the number of observations shown in the diagnostic plot. This enables you to better identify observations in the crowded homogeneous cluster in the lower left corner of the plot.

The following SAS statements add these options and display the first 25 observations in the output data table:

```
ods graphics on;
proc mvoutlier data=mylib.wbc contamination=0.06 propvariance=0.95
               plots=diagnostic(maxobs=100) diagnosticoptions(showobsid);
   var mean_: stderr_: max_:;
   id Specimen;
   output out=mylib.wbcOut obsid orthdist scoredist outlier leverage;
run;
proc cas;
   fetch / table={name="wbcOut"} to=25;
run;
quit;
```

Output 21.2.1 through Output 21.2.5 show all relevant output tables, which will serve as a basis for comparison later in this example.

The MVOUTLIER procedure assigns observation numbers as follows:

1. Nodes in your distributed system and threads within nodes are numbered.
2. Observations are numbered across nodes and threads according to the order in which the observations are processed, counting from lowest- to highest-numbered threads on lowest- to highest-numbered nodes.

What the **`partition`** action and APPLYROWORDER option provide for you is a way to ensure that observations are processed in such a way that their automatically assigned numbers have the same order as the sort order of any variable (or set of variables) of your choosing in your input data table.

The following statements use the **`partition`** action to create a copy of the mylib.wbc data table called mylib.wbcSorted that—if you use the APPLYROWORDER option—is automatically recognized by PROC MVOUTLIER as a data table to be processed in the same sort order as the Specimen variable:

```
data mylib.wbc;
   set mylib.wbc;
   Part = 1;
run;

proc cas;
   action table.partition / table={name="wbc", groupby={name="Part"},
                                   orderby={name="Specimen"}},
                            casout={name="wbcSorted", replace=1};
run;
quit;
```

NOTE: Although this example does not use the groupBy information, use of the APPLYROWORDER option does require at least one groupBy variable to be specified. Instead of setting the groupBy variable Part to a single value, you could use the variable to specify partitions of your data such that all observations that have the same partition key would reside on the same node and same thread in your distributed system.

The following statements add the APPLYROWORDER option to run the previous analysis again but with reproducible row order:

```
proc mvoutlier data=mylib.wbcSorted contamination=0.06 propvariance=0.95
               plots=diagnostic(maxObs=100) diagnosticoptions(showobsid)
               applyroworder;
   var mean_: stderr_: max_:;
   id Specimen;
   output out=mylib.wbcOut obsid orthdist scoredist outlier leverage;
run;
proc cas;
   fetch / table={name="wbcOut"} to=25;
run;
quit;
```

The orderBy and groupBy variables are shown in the "Model Information" table in Output 21.2.6, and Output 21.2.7 through Output 21.2.11 show the other relevant output tables.

The results in Output 21.2.7 through Output 21.2.11 do in fact differ from those in Output 21.2.1 through Output 21.2.5. Most notable is that two extra observations (Specimens 111 and 345) have been identified as outliers in the second analysis. Their orthogonal distances have changed only slightly, but so has the orthogonal distance cutoff, and that is enough to cross the threshold of the default ALPHAOUTLIER=0.025 option.

You can also see small differences in the orthogonal and robust score differences for specimens 8, 11, 21, and 25 because of their inclusion in both Output 21.2.5 and Output 21.2.11. Different observations have also been selected in the lower left corner of the diagnostic plot (Output 21.2.4 and Output 21.2.10).

Example 21.3: Using Marginal Outlyingness and Leverage

(View the complete code for this example (mvoex3.sas) in the example repository.)

This example demonstrates two ways that you can use the ALPHAMARGINALOUTLIER= and ALPHAMARGINALLEVERAGE= options in the PROC MVOUTLIER statement to control which observations to include in the Diagnostics table or label in the diagnostic plot:

- Specify a marginal alpha value that is *higher* than the corresponding main alpha value to add more observations to the Diagnostics table and label them in the diagnostic plot. The observations that are added or newly labeled are the ones between the main cutoff and the marginal cutoff.
- Specify a marginal alpha value that is *lower* than the corresponding main alpha value to remove some observations from the Diagnostics table and remove their labels in the diagnostic plot. The observations and labels that are removed are the ones beyond the marginal cutoff, which in this case is more restrictive than the main cutoff.

The data that this example uses are from Example 21.1; they consist of 30 different features that are computed from digitized images of 378 specimens from fine-needle aspiration of breast mass biopsies that are associated with a mix of benign and malignant diagnoses. The following DATA step generates the data. These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

```

The following statements set the ALPHAMARGINALOUTLIER= option to a value higher than the default ALPHAOUTLIER=0.025 option value and the ALPHAMARGINALLEVERAGE= option to a value lower than the default ALPHALEVERAGE=0.025 option value:

```
ods graphics on;
proc mvoutlier data=mylib.wbc contamination=0.06 propvariance=0.95
               plots=diagnostic(maxobs=100) diagnosticoptions(showobsid)
               alphamarginaloutlier=0.05 alphamarginalleverage=0.0125;
   var mean_: stderr_: max_:;
   id Specimen;
run;
```

The main and marginal alpha values are displayed in the "Model Information" table (Output 21.3.1, compared to Output 21.1.1), and their corresponding outlier and leverage cutoff values are displayed in the "Outlier and Leverage Cutoffs" table (Output 21.3.2, compared to Output 21.1.5).

Output 21.3.1 Model Information

The MVOUTLIER Procedure

Model Information	
Data Source	WBC
Assumed Contamination Proportion	0.06
Target Proportion of Variance Explained	0.95
Maximum Number of Principal Components	10
Alpha for Outlier Cutoff	0.025
Alpha for Leverage Cutoff	0.025
Alpha for Marginal Outlier Cutoff	0.05
Alpha for Marginal Leverage Cutoff	0.0125
Random Number Seed	1

Output 21.3.2 Outlier and Leverage Cutoffs

Outlier and Leverage Cutoffs			
Criterion	Distance Type	Cutoff Alpha	Cutoff Value
Outlier	Orthogonal	0.0250	37.08827
Marginal Outlier	Orthogonal	0.0500	33.71677
Leverage	Robust Score	0.0250	2.24140
Marginal Leverage	Robust Score	0.0125	2.49771

An extra row in the "Diagnostic Summary" table (Output 21.3.3, compared to Output 21.1.6) indicates that two leverage observations have been excluded from the "Outlier and Leverage Diagnostics" table (Output 21.3.4, compared to Output 21.1.7). Labels are removed from these same observations, specimens 57 and 77, in the diagnostic plot (Output 21.3.5, compared to Output 21.1.8).

Output 21.3.5 Outlier and Leverage Diagnostic Plot

Several outlier observations have been added at the bottom of the "Outlier and Leverage Diagnostics" table (Output 21.3.4), and these same observations have acquired labels in the diagnostic plot (Output 21.3.5).

The more forgiving marginal outlier cutoff and the more restrictive marginal leverage cutoff in this example are somewhat analogous to the concepts of noninferiority and superiority tests, because they have margins in opposite directions to each other.

Overview: NLMOD Procedure

The NLMOD procedure fits nonlinear regression models with standard or general distributions in SAS Viya.

PROC NLMOD enables you to specify the model by using SAS programming statements, which give you greater flexibility in modeling the relationship between the response variable and independent (regressor) variables than SAS procedures that use a more structured MODEL statement. The NLMOD procedure uses either nonlinear least squares or maximum likelihood to fit nonlinear regression models.

PROC NLMOD Features

The NLMOD procedure does the following:

- is highly multithreaded during all phases of analytic execution
- computes analytical derivatives of user-provided expressions for more robust parameter estimations
- evaluates user-provided expressions and their confidence limits by using the ESTIMATE and PREDICT statements
- estimates parameters without specifying a particular distribution function by using the least squares method
- estimates parameters by using the maximum likelihood method when either a built-in distribution function is specified or a likelihood function is provided
- exploits all the available cores and concurrent threads, regardless of execution mode. For information about how PROC NLMOD uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Because the NLMOD procedure runs on CAS, it also does the following:

- enables you to run in distributed mode on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode on CAS

PROC NLMOD Compared with Other SAS Procedures

The NLMOD procedure provides nonlinear regression modeling functionality that is comparable to that of the HPNLMOD, NLIN, and NLMIXED procedures in SAS/STAT software.

PROC NLMOD Compared with the HPNLMOD Procedure

The functionality of the NLMOD procedure is identical to the HPNLMOD procedure, which is a high-performance procedure. The NLMOD procedure is the next generation of the HPNLMOD procedure, and it was developed specifically for SAS Viya. Both procedures are designed to run on a cluster of machines that distribute the data and the computations. Both procedures perform computations in multiple threads.

Both the NLMOD and HPNLMOD procedures fit nonlinear regression models.

PROC NLMOD Compared with the NLIN Procedure

Like the NLIN procedure in SAS/STAT software, the NLMOD procedure estimates parameters by using least squares minimization for models that are specified by SAS programming statements. However, PROC NLMOD can also perform maximum likelihood estimation when information about the response variable's distribution is provided. PROC NLMOD also has a RESTRICT statement for specifying restrictions on parameter estimates that are more general than those available in PROC NLIN. Because the NLMOD and NLIN procedures use different optimization techniques, the available options that control the estimation process and resulting parameter estimates can differ between these procedures when equivalent models and data are analyzed.

PROC NLMOD Compared with the NLMIXED Procedure

Although it does not support the specification of random effects, PROC NLMOD is similar to the NLMIXED procedure in SAS/STAT. Both procedures perform maximum likelihood estimation by using the same programming syntax and set of distributions to specify the model's mean term. In addition, both PROC NLMOD and PROC NLMIXED use the same optimization techniques and options. However, PROC NLMIXED does not support least squares parameter estimation.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: NLMOD Procedure

The most common use of the NLMOD procedure is to estimate the parameters in a model in which the response variable is a nonlinear function of one or more of the parameters.

Least Squares Model

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/nlmodgs1.sas.)

The Michaelis-Menten model of enzyme kinetics (Ratkowsky 1990, p. 59) relates a substrate's concentration to its catalyzed reaction rate. You can analyze the Michaelis-Menten model by using a least squares estimation because it does not specify how the reaction rate is distributed around its predicted value. The relationship between reaction rate and substrate concentration is

$$f(\mathbf{x}, \boldsymbol{\theta}) = \frac{\theta_1 x_i}{\theta_2 + x_i}, \quad \text{for } i = 1, 2, \ldots, n$$

where x_i represents the concentration for n trials and $f(\mathbf{x}, \boldsymbol{\theta})$ is the reaction rate. The vector $\boldsymbol{\theta}$ contains the rate parameters.

The input data must be a table on your CAS server, and a CAS session must be set up. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts." The following DATA step creates the Enzyme data table, which consists of experimental measurements of reaction rate and concentration, in your CAS session:

```
data mylib.Enzyme;
   input conc rate @@;
   datalines;
0.26 124.7   0.30 126.9
0.48 135.9   0.50 137.6
0.54 139.6   0.68 141.1
0.82 142.8   1.14 147.6
1.28 149.8   1.38 149.4
1.80 153.9   2.30 152.5
2.44 154.5   2.48 154.7
;
```

These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

The following SAS statements estimate the parameters θ_1 and θ_2:

```
proc nlmod data=mylib.Enzyme;
   parms theta1=0 theta2=0;
   model rate ~ residual(theta1*conc / (theta2 + conc));
run;
```

The least squares estimation that PROC NLMOD performs for this enzyme kinetics problem produces the analysis of variance table in Figure 22.1. The table displays the degrees of freedom, sums of squares, and mean squares along with the model F test.

The NLMOD Procedure

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Approx Pr > F
Model	2	290116	145058	88537.2	<.0001
Error	12	19.6606	1.6384		
Uncorrected Total	14	290135			

An intercept was not specified for this model.

Finally, Figure 22.2 displays the parameter estimates, standard errors, t statistics, and 95% confidence intervals for θ_1 and θ_2.

Figure 22.2 Parameter Estimates and Approximate 95% Confidence Intervals

Parameter Estimates

Parameter	Estimate	Standard Error	DF	t Value	Approx Pr > |t|	Approximate 95% Confidence Limits Lower	Upper
theta1	158.1	0.6737	12	234.67	<.0001	156.6	159.6
theta2	0.0741	0.00313	12	23.69	<.0001	0.0673	0.0809

In the enzyme kinetics model, no information was supplied about the distribution of the reaction rate around the model's mean value. Therefore, the residual model distribution was specified to perform a least squares parameter fit.

Binomial Model

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/nlmodgs2.sas.)

In the example "Probit Model with Likelihood Function" in the chapter "The NLIN Procedure" in *SAS/STAT User's Guide*, cancer remission is modeled by expressing the maximum likelihood function for a binary distribution as a nonlinear least squares optimization. The following statements show an equivalent formulation of this model that uses PROC NLMOD and specifies the binary distribution explicitly:

```
data mylib.Remiss;
   input remiss cell smear infil li blast temp;
   label remiss = 'complete remission';
   like = 0;
   label like = 'dummy variable for nlin';
   datalines;
 1 0.8  .83 .66 1.9 1.10   .996
 1 0.9  .36 .32 1.4 0.74   .992
 0 0.8  .88 .70 0.8 0.176  .982
 0 1    .87 .87 0.7 1.053  .986
 1 0.9  .75 .68 1.3 0.519  .980
 0 1    .65 .65 0.6 0.519  .982
 1 0.95 .97 .92 1   1.23   .992
 0 0.95 .87 .83 1.9 1.354 1.020
 0 1    .45 .45 0.8 0.322  .999
 0 0.95 .36 .34 0.5 0     1.038
 0 0.85 .39 .33 0.7 0.279  .988
 0 0.7  .76 .53 1.2 0.146  .982
 0 0.8  .46 .37 0.4 0.38  1.006
 0 0.2  .39 .08 0.8 0.114  .990
 0 1    .90 .90 1.1 1.037  .990
 1 1    .84 .84 1.9 2.064 1.020
 0 0.65 .42 .27 0.5 0.114 1.014
 0 1    .75 .75 1   1.322 1.004
 0 0.5  .44 .22 0.6 0.114  .990
 1 1    .63 .63 1.1 1.072  .986
 0 1    .33 .33 0.4 0.176 1.010
 0 0.9  .93 .84 0.6 1.591 1.020
 1 1    .58 .58 1   0.531 1.002
 0 0.95 .32 .30 1.6 0.886  .988
 1 1    .60 .60 1.7 0.964  .990
 1 1    .69 .69 0.9 0.398  .986
 0 1    .73 .73 0.7 0.398  .986
 ;

proc nlmod data=mylib.Remiss corr;
   parms int=-10 a=-2 b=-1 c=6;
   linp = int + a*cell + b*li + c*temp;
   p = probnorm(linp);
   model remiss ~ binary(1-p);
```

```
run;
```

This binary distribution model displays information about the quality of the estimation that is different from the information displayed in the section "Least Squares Model" on page 1204. No analysis of variance table is produced for this model; fit statistics based on the value of the likelihood function are displayed in Figure 22.3.

Figure 22.3 Nonlinear Likelihood Function Statistics

The NLMOD Procedure

Fit Statistics	
-2 Log Likelihood	21.9002
AIC (smaller is better)	29.9002
AICC (smaller is better)	31.7183
BIC (smaller is better)	35.0835

Parameter estimates for the binary distribution model that uses the same quantities as in the section "Least Squares Model" on page 1204 are displayed in Figure 22.4.

Figure 22.4 Parameter Estimates and Approximate 95% Confidence Intervals

Parameter Estimates

Parameter	Estimate	Standard Error	DF	t Value	Approx Pr > |t|	Approximate 95% Confidence Limits Lower	Upper
int	-36.7548	32.3607	27	-1.14	0.2660	-103.2	29.6439
a	-5.6298	4.6376	27	-1.21	0.2353	-15.1454	3.8858
b	-2.2513	0.9790	27	-2.30	0.0294	-4.2599	-0.2426
c	45.1815	34.9095	27	1.29	0.2065	-26.4469	116.8

Syntax: NLMOD Procedure

The following statements are available in the NLMOD procedure:

PROC NLMOD < *options* > ;
BOUNDS *constraint* < , *constraint . . .* > ;
BY *variables* ;
DISPLAY < *table-list* >< / *options* > ;
DISPLAYOUT *table-spec-list*< / *options* > ;
ESTIMATE '*label*' *expression* < *options* > ;
ID *variables* ;
MODEL *dependent-variable* ∼ *distribution* ;
PARAMETERS < *parameter-specification* > < ,*. . .* , *parameter-specification* > < / *options* > ;
PREDICT '*label*' *expression* < *options* > ;
RESTRICT *restriction1* < , *restriction2 . . .* > ;
Programming Statements ;

The PROC NLMOD statement and exactly one MODEL statement are required.

PROC NLMOD Statement

PROC NLMOD < *options* > ;

The PROC NLMOD statement invokes the procedure. Table 22.1 summarizes important options in the PROC NLMOD statement by function. These and other options in the PROC NLMOD statement are then described fully in alphabetical order.

Table 22.1 PROC NLMOD Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data table
OUT=	Specifies the output data table
Output Options	
CORR	Specifies the correlation matrix
COV	Specifies the covariance matrix
ECORR	Specifies the correlation matrix of additional estimates
ECOV	Specifies the covariance matrix of additional estimates
DF	Specifies the default degrees of freedom
NOPRINT	Suppresses ODS output
NOITPRINT	Suppresses output about iterations within the optimization process
Optimization Options	
ABSCONV=	Tunes an absolute function convergence criterion
ABSFCONV=	Tunes an absolute difference function convergence criterion
ABSGCONV=	Tunes the absolute gradient convergence criterion

Table 22.1 *continued*

Option	Description
FCONV=	Tunes the relative function convergence criterion
GCONV=	Tunes the relative gradient convergence criterion
MAXITER=	Chooses the maximum number of iterations in any optimization
MAXFUNC=	Specifies the maximum number of function evaluations in any optimization
MAXTIME=	Specifies the upper limit (in seconds) of CPU time for any optimization
MINITER=	Specifies the minimum number of iterations in any optimization
TECHNIQUE=	Selects the optimization technique
Tolerance Options	
SINGULAR=	Tunes the general singularity criterion

The optimization options are fully described in the section "Optimization Options" on page 57 in Chapter 2, "Shared Concepts." Other options available in the PROC NLMOD statement are described in the following sections.

You can specify the following *options* in the PROC NLMOD statement:

ALPHA=α
specifies the level of significance α that is used in constructing $100(1-\alpha)\%$ confidence intervals. The value must be strictly between 0 and 1; the default value of $\alpha = 0.05$ results in 95% intervals. This value is used as the default confidence level for limits that are computed in the "Parameter Estimates" table and is used in the LOWER and UPPER options in the PREDICT statement.

CORR
requests the approximate correlation matrix for the parameter estimates.

COV
requests the approximate covariance matrix for the parameter estimates.

DATA=*libref.data-table*
names the input data table for PROC NLMOD to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1203.

data-table specifies the name of the input data table.

DF=*n*
specifies the default number of degrees of freedom to use in the calculation of *p*-values and confidence limits for additional parameter estimates.

ECORR
requests the approximate correlation matrix for all expressions that are specified in ESTIMATE statements.

ECOV
requests the approximate covariance matrix for all expressions that are specified in ESTIMATE statements.

NOITPRINT
suppresses the display of the "Iteration History" table.

NOPRINT
suppresses the generation of ODS output.

OUT=*libref.data-table*
names the output data table for PROC NLMOD to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1203.

data-table specifies the name of the output data table.

A single OUT= data table is created to contain all predicted values when more than one PREDICT statement is specified. An error message is generated if a PREDICT statement is specified and an OUT= data table is not specified. The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the ID statement are included.

SINGULAR=*number*
tunes the general singularity criterion that is applied in sweeps and inversions. The default is 1E4 times the machine epsilon; this product is approximately 1E-12 on most computers.

BOUNDS Statement

BOUNDS *constraint* < , *constraint . . .* > **;**

where *constraint* represents

< *number operator* > *parameter-list* < *operator number* >

Boundary constraints are specified in a BOUNDS statement. One- or two-sided boundary constraints are allowed. Elements in a list of boundary constraints are separated by commas. For example:

```
bounds 0 <= a1-a9 X <= 1, -1 <= c2-c5;
bounds b1-b10 y >= 0;
```

You can specify more than one BOUNDS statement. If you specify more than one lower (or upper) bound for the same parameter, the maximum (or minimum) of these is taken.

If the maximum l_j of all lower bounds is larger than the minimum of all upper bounds u_j for the same parameter θ_j, the boundary constraint is replaced by $\theta_j := l_j := \min(u_j)$, which is defined by the minimum of all upper bounds specified for θ_j.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC NLMOD to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1227. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

key=value specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1227. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

ESTIMATE Statement

ESTIMATE '*label*' *expression* < *options* > **;**

The ESTIMATE statement enables you to compute an additional estimate that is a function of the parameter values. You must provide a quoted string to identify the estimate and then provide a valid SAS expression. Multiple ESTIMATE statements are permitted, and results from all ESTIMATE statements are listed in a common table. PROC NLMOD computes approximate standard errors for the estimates by using the delta method (Billingsley 1986). It uses these standard errors to compute corresponding t statistics, p-values, and confidence limits.

The ECOV option in the PROC NLMOD statement produces a table that contains the approximate covariance matrix of all the additional estimates that you specify. The ECORR option produces the corresponding correlation matrix.

You can specify the following *options*:

ALPHA=α
specifies the alpha level to be used to compute confidence limits. The default value corresponds to the ALPHA= option in the PROC NLMOD statement.

DF=d
specifies the degrees of freedom to be used to compute p-values and confidence limits. The default value corresponds to the DF= option in the PROC NLMOD statement.

ID Statement

ID *variables* **;**

The ID statement lists one or more variables from the input data table that are transferred to output data tables that PROC NLMOD creates, provided that the output data table contains one or more records per input observation. For example, when you use an OUT= option in the PROC NLMOD statement to produce prediction statistics, ID variables are added to the output data table.

By default, PROC NLMOD does not include all variables from the input data table in output data tables.

MODEL Statement

MODEL *dependent-variable* ∼ *distribution* **;**

The MODEL statement is the mechanism for either using a distribution specification to specify the distribution of the data or using the RESIDUAL distribution to specify a predicted value. You must specify a single dependent variable from the input data table, a tilde (∼), and then a distribution and its parameters. You can specify the following values for *distribution*:

RESIDUAL(*m*) or **LS**(*m*) specifies no particular distribution. Instead the sum of squares of the differences between *m* and the dependent variable is minimized.

NORMAL(*m*, *v*) specifies a normal (Gaussian) distribution that has mean *m* and variance *v*.

BINARY(*p*) specifies a binary (Bernoulli) distribution that has probability *p*.

BINOMIAL(*n*, *p*) specifies a binomial distribution that has count *n* and probability *p*.

GAMMA(*a*, *b*) specifies a gamma distribution that has shape *a* and scale *b*.

NEGBIN(*n*, *p*) specifies a negative binomial distribution that has count *n* and probability *p*.

POISSON(*m*) specifies a Poisson distribution that has mean *m*.

GENERAL(*ll*) specifies a general log-likelihood function that you construct by using SAS programming statements.

The MODEL statement must follow any SAS programming statements that you specify for computing parameters of the preceding distributions. For information about the built-in log-likelihood functions, see the section "Built-In Log-Likelihood Functions" on page 1222.

PARAMETERS Statement

PARAMETERS < *parameter-specification* > < *,. . . , parameter-specification* > < */ options* > **;**

PARMS < *parameter-specification* > < *,. . . , parameter-specification* > < */ options* > **;**

The purpose of the PARAMETERS statement is to provide starting values for the NLMOD procedure. You can provide values that define a single point in the parameter space or that define a set of points. For more information about the *parameter-specification*, see the section "Assigning Starting Values by Using a Parameter Specification" on page 1215.

You can specify the following *options* after a slash (/):

BEST=*i* > 0

specifies the maximum number of parameter grid points and the corresponding objective function values to display in the "Parameters" table. If you specify this option, the parameter grid points are listed in ascending order of objective function value. By default, all parameter grid points are displayed.

PDATA=*libref.data-table*

DATA=*libref.data-table*

specifies the data table that provides parameter starting values. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1203.

START=*value*
DEFSTART=*value*
specifies a default starting value for all parameters.

Four methods are available for providing starting values to the optimization process. In order of precedence, the methods are as follows:

1. Specify values directly in the PARAMETERS statement.
2. Specify values in the PDATA= data table option.
3. Specify a single value for all parameters by using the START= option.
4. Use the default value 1.0.

The names that you assign to parameters must be valid SAS names and must not be the same as names of variables in the input data table (see the DATA= option in the PROC NLMOD statement). Parameters that are assigned starting values through the PARAMETERS statement can be omitted from the estimation if the expression in the MODEL statement does not depend on them.

Assigning Starting Values by Using a Parameter Specification

A *parameter-specification* has the following general form, where *name* identifies the parameter and *value-list* provides the set of starting values for the parameter:

name **=** *value-list*

Often the *value-list* contains only a single value, but you can use more general and flexible list specifications such as these:

m	a single value
m1, *m2*, . . . , *mn*	several values
m TO *n*	a sequence in which *m* equals the starting value, *n* equals the ending value, and the increment is 1
m TO *n* BY *i*	a sequence in which *m* equals the starting value, *n* equals the ending value, and the increment is *i*
m1, *m2* TO *m3*	mixed values and sequences

When you specify more than one value for a parameter, PROC NLMOD sorts the values in ascending order and removes duplicate values from the parameter list before forming the grid for the parameter search. If you specify several values for each parameter, PROC NLMOD evaluates the model at each point on the grid. The iterations then commence from the point on the grid that yields the smallest objective function value.

For example, the following PARMS statement specifies five parameters and sets their possible starting values as shown in the table:

```
parms  b0 = 0
       b1 = 4 to 8
       b2 = 0 to .6 by .2
       b3 = 1, 10, 100
       b4 = 0, .5, 1 to 4;
```

Possible Starting Values				
B0	B1	B2	B3	B4
0	4	0.0	1	0.0
	5	0.2	10	0.5
	6	0.4	100	1.0
	7	0.6		2.0
	8			3.0
				4.0

The objective function values are calculated for each of the $1 \times 5 \times 4 \times 3 \times 6 = 360$ combinations of possible starting values.

If you specify a starting value by using a *parameter-specification*, any starting values that are provided for this parameter through the PDATA= data table are ignored. The *parameter-specification* overrides the information in the PDATA= data table.

Assigning Starting Values from a Data Table That Resides in a Library

The PDATA= option in the PARAMETERS statement enables you to assign starting values for parameters by using a data table. You must specify the library where your data table resides and the data table name. The data table must contain at least two variables: a character variable named Parameter (or Parm) that identifies the parameter, and a numeric variable named Estimate (or Est) that contains the starting values. For example, the PDATA= option enables you to use the contents of the "ParameterEstimates" table from one PROC NLMOD run to supply starting values for a subsequent run, as follows:

```
proc nlmod data=mylib.D(obs=30);
   parameters alpha=100 beta=3 gamma=4;
   Switch = 1/(1+gamma*exp(beta*log(dose)));
   model y ~ residual(alpha*Switch);
   displayout ParameterEstimates=pest;
run;

proc nlmod data=mylib.D;
   parameters / pdata=mylib.pest;
   Switch = 1/(1+gamma*exp(beta*log(dose)));
   model y ~ residual(alpha*Switch);
run;
```

You can specify multiple values for a parameter in the PDATA= data table, and the parameters can appear in any order. The starting values are collected by parameter and arranged in ascending order, and duplicate values are removed. The parameter names in the PDATA= data table are not case-sensitive. For example, the following DATA step defines starting values for three parameters and a starting grid that has $1 \times 3 \times 1 = 3$ points:

```
data mylib.Test;
   input Parameter $ Estimate;
   datalines;
 alpha  100
 BETA     4
 beta     4.1
```

```
 beta      4.2
 beta      4.1
 gamma    30
;
```

PREDICT Statement

PREDICT '*label*' *expression* < *options* > **;**

PREDICT '*label*' **MEAN** < *options* > **;**

The PREDICT statement enables you to construct predictions of an expression across all the observations in the input data table. Multiple PREDICT statements are permitted. Results for all PREDICT statements are displayed in the output data table that you specify in the OUT= option in the PROC NLMOD statement. The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the ID statement are included.

You must specify the following arguments:

'*label*'
identifies the predicted expression.

expression | **MEAN**
provides the predicted value.You can specify the predicted value either by using a SAS programming expression that contains the input data table variables and parameters or by using the keyword MEAN. If you specify the keyword MEAN, the predicted mean value for the distribution specified in the MODEL statement is used. Predicted values are computed using the final parameter estimates. Standard errors of prediction are computed using the delta method (Billingsley 1986; Cox 1998).

You can also specify the following *options*:

ALPHA=α
specifies the alpha level to be used to compute confidence limits. The default value corresponds to the ALPHA= option in the PROC NLMOD statement.

DF=*d*
specifies the degrees of freedom to be used to compute confidence limits. The default value corresponds to the DF= option in the PROC NLMOD statement.

LOWER=*name*
specifies a variable that contains the lower confidence limit of the predicted value.

PRED=*name*
specifies a variable that contains the predicted value.

PROBT=*name*
specifies a variable that contains the *p*-value of the predicted value.

STDERR=*name*
specifies a variable that contains the standard error of the predicted value.

TVALUE=*name*
specifies a variable that contains the *t* statistic for the predicted value.

UPPER=*name*
specifies a variable that contains the upper confidence limit of the predicted value.

RESTRICT Statement

RESTRICT *restriction1* < , *restriction2 . . .* > **;**

The RESTRICT statement imposes linear restrictions on the model's parameters estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an expression, optionally followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression **<** *operator expression* **>**

The *operator* can be =, <, >, <= , or >=. The operator and second expression are optional. When they are omitted, the *operator* defaults to = and the second *expression* defaults to the value 0.

Restriction expressions can be composed of parameter names, arithmetic operators, functions, and constants. You cannot use comparison operators (such as = or <) or logical operators (such as &) in RESTRICT statement expressions. Parameters that are named in restriction expressions must be among the parameters that are estimated by the model. Restriction expressions cannot refer to other variables that are defined in the program or in the DATA= data table. The restriction expressions must be linear functions of the parameters.

The following example illustrates how to use the RESTRICT statement to impose a linear constraint on parameters:

```
proc nlmod;
   parms alpha beta;
   f = (x/alpha + beta)**2
   model y ~ residual(f);
   restrict beta < 2*(alpha + constant('pi'));
run;
```

The preceding RESTRICT statement represents the following model constraint:

$$\beta < 2(\alpha + \pi)$$

Programming Statements

Programming statements define the arguments of the MODEL, ESTIMATE, and PREDICT statements in PROC NLMOD. Most of the programming statements that you can use in the SAS DATA step can also be used in the NLMOD procedure. For a description of SAS programming statements, see *SAS Language Reference: Concepts*. You can use the following programming statements:

ABORT;
CALL *name* **[(** *expression* **[,** *expression* **. . .])];**
DELETE;
DO[*variable* **=** *expression*
[TO *expression***] [BY** *expression***]**
[, *expression* **[TO** *expression***] [BY** *expression* **] . . .]**
]
[WHILE *expression* **] [UNTIL** *expression* **] ;**
END;
GOTO *statement_label*;
IF *expression*;
IF *expression* **THEN** *program_statement*;
ELSE *program_statement*;
variable **=** *expression*;
variable **+** *expression*;
LINK *statement_label*;
PUT [*variable***] [=] [. . .];**
RETURN;
SELECT[(*expression***)];**
STOP;
SUBSTR(*variable***,** *index***,** *length* **)=** *expression*;
WHEN (*expression***)** *program_statement*;
OTHERWISE *program_statement*;

For the most part, these SAS programming statements work the same as they do in the SAS DATA step, as documented in *SAS Language Reference: Concepts*. However, they differ as follows:

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus, PROC NLMOD supports the first of the following statements, but not the second:

```
do i = 1,2,3;

do i = 'A','B','C';
```

- In contrast to other procedures that share PROC NLMOD's programming syntax, PROC NLMOD does not support the LAG function. Because observations are not processed sequentially when high-performance analytical procedures perform the parameter optimization, information for computing lagged values is not available.

- The PUT statement, used mostly for program debugging in PROC NLMOD, supports only some of the features of the DATA step PUT statement, and it has some new features that the DATA step PUT statement does not have:
  - The PROC NLMOD PUT statement does not support line pointers, factored lists, iteration factors, overprinting, _INFILE_, the colon (:) format modifier, or "$".
  - The PROC NLMOD PUT statement supports expressions, but the expression must be enclosed in parentheses. For example, the following statement displays the square root of x:

```
put  (sqrt(x));
```

  - The PROC NLMOD PUT statement supports the item _PDV_, which displays a formatted listing of all variables in the program. For example, the following statement displays a much more readable listing of the variables than the _ALL_ print item:

```
put _pdv_;
```

- The WHEN and OTHERWISE statements enable you to specify more than one programming statement. That is, DO/END groups are not necessary for multiple WHEN statements. For example, the following syntax is valid:

```
select;
   when (exp1) stmt1;
               stmt2;
   when (exp2) stmt3;
               stmt4;
end;
```

When you write your programming statements, avoid defining variables that begin with an underscore (_), because they might conflict with internal variables that PROC NLMOD creates. The MODEL statement must follow any SAS programming statements that define or modify terms that are used to specify the model.

Special Variable _WEIGHT_

Defining the special variable _WEIGHT_ in your PROC NLMOD programming statements enables you either to request weighted nonlinear least squares estimation of parameters or to request that each observation in the input data set be weighted by a value.

You can define the _WEIGHT_ variable as in the following statement:

```
_weight_ = expression;
```

When you specify this statement, the expression on the right-hand side of the assignment statement is evaluated for each observation in the data set. You can simply provide a variable name instead of an expression. PROC NLMOD uses the value of the _WEIGHT_ variable in two ways, depending on which type of model you request:

- When you do not specify a particular distribution, PROC NLMOD performs the weighted nonlinear least squares method by using the value of the _WEIGHT_ expression for each observation. These

values multiplied by $1/\sigma^2$ are taken as inverse elements of the diagonal variance-covariance matrix of the dependent variable. The larger the _WEIGHT_ value, the more importance the observation is given.

- When you specify either a built-in distribution function or a general likelihood function, PROC NLMOD performs the maximum likelihood method by weighting each observation in the input data set by the value of the _WEIGHT_ expression.

Note that the _WEIGHT_ expression can be a function of the estimated parameters. For estimation purposes, the derivative of the _WEIGHT_ expression with respect to the parameters is not included in the gradient and Hessian of the loss function. This is usually the desired approach for iteratively reweighted least squares estimation. When the _WEIGHT_ expression is a function of the parameters, the gradient and Hessian that are used can lead to poor convergence or nonconvergence of the requested estimation. To have the derivative of the _WEIGHT_ expression with respect to the parameters included in the gradient and Hessian of the loss function, do not use the _WEIGHT_ programming statement. Instead, redefine the model as

$$(y - f(x,\beta)) \times \sqrt{\mathrm{wgt}(\beta)}$$

where y is the original dependent variable, $f(x,\beta)$ is the nonlinear model, and $\mathrm{wgt}(\beta)$ is the weight that is a function of the parameters.

Details: NLMOD Procedure

Least Squares Estimation

Models that are estimated by PROC NLMOD can be represented by using the equations

$$\begin{aligned} \mathbf{Y} &= \mathbf{f}(\boldsymbol{\beta}; \mathbf{z}_1, \ldots, \mathbf{z}_k) + \boldsymbol{\epsilon} \\ \mathrm{E}[\boldsymbol{\epsilon}] &= \mathbf{0} \\ \mathrm{Var}[\boldsymbol{\epsilon}] &= \sigma^2 \mathbf{I} \end{aligned}$$

where

$\mathbf{Y}$	is the $(n \times 1)$ vector of observed responses.
$\mathbf{f}$	is the nonlinear prediction function of parameters and regressor variables.
$\boldsymbol{\beta}$	is the vector of model parameters to be estimated.
$\mathbf{z}_1, \ldots, \mathbf{z}_k$	are the $(n \times 1)$ vectors of each of the k regressor variables.
$\boldsymbol{\epsilon}$	is the $(n \times 1)$ vector of residuals.
σ^2	is the variance of the residuals.

In these models, the distribution of the residuals is not specified and the model parameters are estimated using the least squares method. For the standard errors and confidence limits in the "ParameterEstimates" table to apply, the errors are assumed to be homoscedastic and uncorrelated and to have zero mean.

Built-In Log-Likelihood Functions

For models in which the distribution of model errors is specified, the NLMOD procedure estimates parameters by maximizing the value of a log-likelihood function for the specified distribution. The log-likelihood functions that PROC NLMOD uses for the supported error distributions are as follows:

$Y \sim \text{normal}(m, v)$

$$
\begin{aligned}
l(m, v; y) &= -\frac{1}{2}\left(\log\{2\pi\} + \frac{(y-m)^2}{v} + \log\{v\}\right) \\
\mathrm{E}[Y] &= m \\
\mathrm{Var}[Y] &= v \\
v &> 0
\end{aligned}
$$

$Y \sim \text{binary}(p)$

$$
\begin{aligned}
l_1(p; y) &= \begin{cases} y \ \log\{p\} & y > 0 \\ 0 & \text{otherwise} \end{cases} \\
l_2(p; y) &= \begin{cases} (1-y) \ \log\{1-p\} & y < 1 \\ 0 & \text{otherwise} \end{cases} \\
l(p; y) &= l_1(p; y) + l_2(p; y) \\
\mathrm{E}[Y] &= p \\
\mathrm{Var}[Y] &= p\,(1-p) \\
0 &< p < 1
\end{aligned}
$$

$Y \sim \text{binomial}(n, p)$

$$
\begin{aligned}
l_c &= \log\{\Gamma(n+1)\} - \log\{\Gamma(y+1)\} - \log\{\Gamma(n-y+1)\} \\
l_1(n, p; y) &= \begin{cases} y \ \log\{p\} & y > 0 \\ 0 & \text{otherwise} \end{cases} \\
l_2(n, p; y) &= \begin{cases} (n-y) \ \log\{1-p\} & n-y > 0 \\ 0 & \text{otherwise} \end{cases} \\
l(n, p; y) &= l_c + l_1(n, p; y) + l_2(n, p; y) \\
\mathrm{E}[Y] &= n\,p \\
\mathrm{Var}[Y] &= n\,p\,(1-p) \\
0 &< p < 1
\end{aligned}
$$

$Y \sim \text{gamma}(a, b)$

$$
\begin{aligned}
l(a, b; y) &= -a\log\{b\} - \log\{\Gamma(a)\} + (a-1)\log\{y\} - y/b \\
\mathrm{E}[Y] &= ab \\
\mathrm{Var}[Y] &= ab^2 \\
a &> 0 \\
b &> 0
\end{aligned}
$$

This parameterization of the gamma distribution differs from the parameterization that the GENSELECT procedure use. The scale parameter in PROC NLMOD is expressed as the inverse of the scale parameter that PROC GENSELECT uses. The PROC NLMOD parameter represents the scale of the magnitude of the residuals. You can estimate the scale parameter in PROC GENSELECT by using the following statements:

```
proc genselect;
   model y = x / dist=gamma s;
run;
```

PROC NLMOD uses the following statements to estimate the equivalent scale parameter:

```
proc nlmod;
   parms b0=1 b1=0 scale=14;
   linp = b0 + b1*x;
   mu   = exp(linp);
   b    = mu*scale;
   model y ~ gamma(1/scale,b);
run;
```

$Y \sim \text{negbin}(n, p)$

$$
\begin{aligned}
l(n, p; y) &= \log\{\Gamma(n + y)\} - \log\{\Gamma(n)\} - \log\{\Gamma(y + 1)\} \\
&\quad + n \log\{p\} + y \log\{1 - p\} \\
\text{E}[Y] &= n \left(\frac{1 - p}{p} \right) \\
\text{Var}[Y] &= n \left(\frac{1 - p}{p^2} \right) \\
n &\geq 0 \\
0 &< p < 1
\end{aligned}
$$

The value of parameter n can be a real number; it does not have to be an integer.

$Y \sim \text{Poisson}(m)$

$$
\begin{aligned}
l(m; y) &= y \log\{m\} - m - \log\{\Gamma(y + 1)\} \\
\text{E}[Y] &= m \\
\text{Var}[Y] &= m \\
m &> 0
\end{aligned}
$$

Multithreading

The NLMOD procedure allocates data to different threads and calculates the likelihood function, gradient, and Hessian by accumulating the values from all threads. For more information about how PROC NLMOD uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Optimization Algorithms

Several optimization techniques are available in PROC NLMOD. You can choose a particular optimizer by using the TECHNIQUE= option in the PROC NLMOD statement. Table 22.3 summarizes the optimization techniques available in PROC NLMOD.

Table 22.3 Optimization Techniques

TECHNIQUE=	Algorithm
TRUREG	Trust region method
NEWRAP	Newton-Raphson method with line search
NRRIDG	Newton-Raphson method with ridging
QUANEW	Quasi-Newton methods
DBLDOG	Double-dogleg method
CONGRA	Conjugate gradient methods
LEVMAR	Levenberg-Marquardt method
NMSIMP	Nelder-Mead simplex method

There is no algorithm for optimizing general nonlinear functions that always finds the global optimum for a general nonlinear optimization problem in a reasonable amount of time. Because no single optimization technique is always superior to others, PROC NLMOD provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in PROC NLMOD can find the correct solution. Moreover, nonlinear optimization can be computationally expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem. The section "Choosing an Optimization Algorithm" on page 103 in Chapter 2, "Shared Concepts," is helpful in choosing a suitable optimization algorithm.

Displayed Output

The following sections describe the output that PROC NLMOD produces by default. The output is organized into various tables, which are discussed in their order of appearance.

Specifications

The "Specifications" table displays basic information about the model, such as the data source, the dependent variable, the distribution being modeled, and the optimization technique.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis.

Dimensions

The "Dimensions" table displays the number of parameters that are estimated in the model and the number of upper and lower bounds that are imposed on the parameters.

Parameters

The "Parameters" table displays the initial values of parameters that are used to start the estimation process. You can limit this information by specifying the BEST= option in the PARAMETERS statement when you specify a large number of initial parameter value combinations. The parameter combinations and their corresponding objective function values are listed in increasing order of objective function value.

Iteration History

For each iteration of the optimization, the "Iteration History" table displays the number of function evaluations (including gradient and Hessian evaluations), the value of the objective function, the change in the objective function from the previous iteration, and the absolute value of the largest (projected) gradient element.

Convergence Status

The convergence status table is a small ODS table that appears as a message that indicates whether the optimization succeeded and which convergence criterion was met. If the optimization fails, the message indicates the reason for the failure. If you save the convergence status table to an output data set, a numeric Status variable is added that enables you to programmatically assess convergence. The values of the Status variable indicate the following:

0	Convergence was achieved or an optimization was not performed because TECHNIQUE=NONE.
1	The objective function could not be improved.
2	Convergence was not achieved because of a user interruption or because a limit (such as the maximum number of iterations or the maximum number of function evaluations) was reached. To modify these limits, see the MAXITER=, MAXFUNC=, and MAXTIME= options in the PROC NLMOD statement.

3 Optimization failed to converge because function or derivative evaluations failed at the starting values or during the iterations or because a feasible point that satisfies the parameter constraints could not be found in the parameter space.

Linear Constraints

The "Linear Constraints" table summarizes the linear constraints that are applied to the model by using the RESTRICT statements. The table lists all the constraints that are specified in the model, along with information about whether each constraint represents an inequality or equality condition and whether that constraint is active for the final parameter estimates.

Fit Statistics

The "Fit Statistics" table displays a variety of measures of fit, depending on whether the model was estimated using least squares or maximum likelihood. In both cases, smaller values of the fit statistics indicate better fit.

For least squares estimations, the table displays the sum of squares of errors and the variance of errors.

For maximum likelihood estimations, the table uses the following formulas to display information criteria, where p denotes the number of effective parameters, n denotes the number of observations used, and l is the log likelihood that is evaluated at the converged estimates:

$$\begin{aligned}
\mathrm{AIC} &= -2l + 2p \\
\mathrm{AICC} &= \begin{cases} -2l + 2pn/(n-p-1) & n > p+2 \\ -2l + 2p(p+2) & \text{otherwise} \end{cases} \\
\mathrm{BIC} &= -2l + p\log(n)
\end{aligned}$$

The information criteria values that are displayed in the "Fit Statistics" table are not based on a normalized log-likelihood function.

ANOVA

The "Analysis of Variance" (ANOVA) table is displayed only for least squares estimations. It displays the number of degrees of freedom and the sum of squares that are attributed to the model, the error, and the total. The ANOVA table also reports the variance of the model and the errors, the F statistic, and its probability for the model.

Parameter Estimates

The "Parameter Estimates" table displays the parameter estimates, their estimated (asymptotic) standard errors t statistics, and associated p-values for the hypothesis that the parameter is 0. Confidence limits, which are displayed for each parameter, are based on the value of the ALPHA= option that you specify in the PROC NLMOD statement.

Additional Estimates

The "Additional Estimates" table displays the same information as the "Parameter Estimates" table for the expressions that appear in the optional ESTIMATE statements. The table is generated when you specify one or more ESTIMATE statements. Because you can specify a separate ALPHA= option for each ESTIMATE statement, the "Additional Estimates" table also includes a column that indicates each confidence interval's corresponding significance level.

Covariance

The "Covariance" table appears when you specify the COV option in the PROC NLMOD statement. It displays a matrix of covariances between each pair of estimated parameters.

Correlation

The "Correlation" table appears when you specify the CORR option in the PROC NLMOD statement. It displays the correlation matrix for the estimated parameters.

Additional Estimates Covariance

The "Covariance of Additional Estimates" table appears when you specify the ECOV option in the PROC NLMOD statement. It displays a matrix of covariances between each pair of expressions that are specified in ESTIMATE statements.

Additional Estimates Correlation

The "Correlation of Additional Estimates" table appears when you specify the ECORR option in the PROC NLMOD statement. It displays the correlation matrix for the expressions that are specified in ESTIMATE statements.

Procedure Task Timing

The "Timing" table displays the amount of time (in seconds) that PROC NLMOD required to perform different tasks in the analysis.

ODS Table Names

Each table that the NLMOD procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or ODS statements. These names are listed in Table 22.4.

Table 22.4 ODS Tables Produced by PROC NLMOD

Table Name	Description	Statement	Option
AdditionalEstimates	Functions of estimated parameters and their associated statistics	ESTIMATE	Default
ANOVA	Least squares analysis of variance information	MODEL	RESIDUAL
Constraints	Information about the model's linear constraints	RESTRICT	Default
ConvergenceStatus	Optimization success and convergence information	PROC NLMOD	Default
CorrB	Parameter correlation matrix	PROC NLMOD	CORR
CovB	Parameter covariance matrix	PROC NLMOD	COV
Dimensions	Number of parameters and their bounds	PROC NLMOD	Default
ECorrB	Additional estimates' correlation matrix	PROC NLMOD	ECORR
ECovB	Additional estimates' covariance matrix	PROC NLMOD	ECOV
FitStatistics	Statistics about the quality of the fit	PROC NLMOD	Default
IterHistory	Optimizer iteration information	PROC NLMOD	Default
NObs	Number of observations read and used	PROC NLMOD	Default
OutputCasTables	A special ODS table that has information about all the CAS tables that are created during a CAS action execution	PROC NLMOD DISPLAYOUT	OUT=
ParameterEstimates	Parameter estimates and associated statistics	PROC NLMOD	Default
Parameters	Initial parameter values	PROC NLMOD	Default
Specifications	Basic model characteristics	PROC NLMOD	Default
Timing	Absolute and relative times for tasks performed by the procedure	PROC NLMOD	Default

Examples: NLMOD Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

Example 22.1: Segmented Model

(View the complete code for this example (nlmodex1.sas) in the example repository.)

Suppose you are interested in fitting a model that consists of two segments that connect in a smooth fashion. For example, the following model states that the mean of Y is a quadratic function in x for values of x less than x_0 and that the mean of Y is constant for values of x greater than x_0:

$$\mathrm{E}[Y|x] = \begin{cases} \alpha + \beta x + \gamma x^2 & \text{if } x < x_0 \\ c & \text{if } x \geq x_0 \end{cases}$$

In this model equation, α, β, and γ are the coefficients of the quadratic segment, and c is the plateau of the mean function. The NLMOD procedure can fit such a segmented model even when the join point, x_0, is unknown.

Suppose you also want to impose conditions on the two segments of the model. First, the curve should be continuous—that is, the quadratic and the plateau section need to meet at x_0. Second, the curve should be smooth—that is, the first derivative of the two segments with respect to x needs to coincide at x_0.

The continuity condition requires that

$$c = \mathrm{E}[Y|x_0] = \alpha + \beta x_0 + \gamma x_0^2$$

The smoothness condition requires that

$$\frac{\partial \mathrm{E}[Y|x_0]}{\partial x} = \beta + 2\gamma x_0 \equiv 0$$

If you solve for x_0 and substitute your result in the expression for c, the two conditions jointly imply that

$$x_0 = -\beta/2\gamma$$
$$c = \alpha - \beta^2/4\gamma$$

Although there are five unknowns, the model contains only three independent parameters. Together the continuity and smoothness restrictions completely determine two parameters, given the other three.

The following DATA step creates the data table for this example in your CAS session:

```
data mylib.A;
   input y x @@;
   datalines;
.46 1  .47  2 .57  3 .61  4 .62  5 .68  6 .69  7
.78 8  .70  9 .74 10 .77 11 .78 12 .74 13 .80 13
.80 15 .78 16
 ;
```

The following PROC NLMOD statements fit this segmented model:

```
proc nlmod data=mylib.A out=mylib.B;
   parms alpha=.45 beta=.05 gamma=-.0025;

   x0 = -.5*beta / gamma;

   if (x < x0) then
        yp = alpha + beta*x  + gamma*x*x;
   else
        yp = alpha + beta*x0 + gamma*x0*x0;

   model y ~ residual(yp);

   estimate 'join point' -beta/2/gamma;
   estimate 'plateau value c' alpha - beta**2/(4*gamma);
   predict 'predicted' yp pred=yp;
   predict 'response' y pred=y;
   predict 'x' x pred=x;
run;
```

The parameters of the model are α, β, and γ, which are represented in the PROC NLMOD statements by the variables alpha, beta, and gamma, respectively. To model the two segments, a conditional statement assigns the appropriate expression to the mean function, depending on the value of x_0. The ESTIMATE statements compute the values of x_0 and c. The PREDICT statement computes predicted values for plotting and saves them to data table b.

The results from fitting this model are shown in Output 22.1.1 through Output 22.1.3. The iterative optimization converges after six iterations (Output 22.1.1). Output 22.1.2 shows the estimated parameters. Output 22.1.3 indicates that the join point is 12.7477 and the plateau value is 0.7775.

Overview: NMF Procedure

The NMF procedure performs nonnegative matrix factorization in SAS Viya.

Nonnegative matrix factorization seeks to approximately decompose a nonnegative data matrix into two low-rank nonnegative factor matrices; that is, $\mathbf{X} \approx \mathbf{WH}$, where $\mathbf{X}$ is the nonnegative data matrix and $\mathbf{W}$ and $\mathbf{H}$ are the two low-rank nonnegative factor matrices. $\mathbf{W}$ is usually called the features (or basis) matrix, and $\mathbf{H}$ is usually called the weights (or coefficients) matrix, or vice versa, depending on the interpretation of the data matrix. You can use nonnegative matrix factorization for dimension reduction, feature identification, and feature extraction in applications in many different fields, such as image processing, text mining, bioinformatics, and spectral data analysis.

PROC NMF Features

The NMF procedure has the following main features:

- provides a VAR statement to specify the numeric variables for the analysis
- supports scaling and missing data imputation
- supports L_1-norm and L_2-norm regularized nonnegative matrix factorization
- produces output data tables that contain the low-dimensional factor matrices
- supports low-rank matrix completion to recover missing entries of the input data table that is incompletely sampled

PROC NMF implements the following methods:

- alternating proximal gradient
- compressed alternating proximal gradient method using random projections

Because PROC NMF runs on SAS Cloud Analytic Services (CAS), it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode
- exploits all the available cores and concurrent threads. For information about how PROC NMF uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: NMF Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/nmfgs.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The example in this section illustrates how to use the NMF procedure to factorize a document-by-term data matrix, where each row represents a document and each element in the document represents the weight of a certain term. The data that this example uses are generated from the Sashelp data set Sashelp.JunkMail, which contains 4,601 observations with 59 variables. The following step displays (in Figure 23.1) the variables in the Sashelp.JunkMail data set:

```
proc contents data=sashelp.JunkMail varnum;

The Sashelp.JunkMail data set comes from a study that classifies whether an email is junk email or not. For the purpose of this example, two variables of the binary indicator, Test and Class, and three variables that record the lengths of uninterrupted sequences of capital letters, CapAvg, CapLong, and CapTotal, are deleted from Sashelp.JunkMail. The data set that this example uses then contains 4,601 observations (documents) with 54 variables (terms) that record the frequencies of some common words and characters in emails. The following DATA step generates the data:

```
data mylib.emails;
   set sashelp.JunkMail;
   drop test class capavg caplong captotal;
run;
```

These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

The following statements invoke the NMF procedure, which requests nonnegative matrix factorization of the data, outputs the factor matrices **W** and **H** to output data tables, and produces the tables in Figure 23.2:

```
proc nmf data=mylib.emails seed=789 rank=5 outh=mylib.H;
   output out=mylib.W;
run;
```

Figure 23.2

displays the PROC NMF output. The "Model Information" table identifies the data source and shows that the nonnegative matrix factorization method is alternating proximal gradient, which is the default. Projected gradient is used as the stopping criterion, the input data are scaled to between 0 and 1, and the missing values are excluded from the analysis; these are the defaults. The table indicates that there are 54 variables used in the analysis and the target rank of factor matrices is five. The table also displays parameters that are used in the factorization method, including maximum number of iterations, the number of matrix updates at each iteration, the convergence tolerance, and the extrapolation weight coefficient. The random number seed is set to 789. Random number generation is used to initialize the factor matrices **W** and **H**. Changing the random number seed value changes the initial factor matrices, yielding different estimated factor matrices.

The "Number of Observations" table shows that all 4,601 observations in the input data are used in the analysis; all the observations are used because they all contain complete data.

The "Iteration Results" table displays the matrix factorization accuracy information, which includes the number of iterations, the relative error at which the iteration stops, and the initial and final projected gradient norms, because projected gradient is used as the stopping criterion. It also displays the sparsity of the factor matrices **W** and **H**.

Figure 23.2 Model Information, Number of Observations, and Iteration Results

The NMF Procedure

Model Information	
Data Source	EMAILS
Factorization Method	Alternating Proximal Gradient
Stopping Criterion	Projected Gradient
Scale Input Data	Yes
Missing Values	Excluded
Number of Variables	54
Target Rank of Factor Matrices	5
Maximum Number of Iterations	500
Matrix Updates at each Iteration	10
Convergence Tolerance	1E-7
Random Number Seed	789
Extrapolation Weight Coefficient	0.9999

Number of Observations Read	4601
Number of Observations Used	4601
Number of Observations with Missing Values	0

Iteration Results	
Number of Iterations	41
Relative Error	9.122635E-8
Initial Projected Gradient Norm	51894
Final Projected Gradient Norm	0.00473
Sparsity of Factor Matrix W	0.29155
Sparsity of Factor Matrix H	0.41481

The output data tables mylib.W and mylib.H contain the factor matrices **W** and **H**, respectively. Because the data that this example uses are treated as a document-by-term matrix, **H** can be seen as a features matrix that has five rows and 54 columns, and **W** can be seen as a weights matrix that has 4,061 rows and five columns. Each row in **H** is a feature, which can be considered as a document archetype that contains a set of terms. Each term's cell value defines the term's significance in the feature; the higher a term's cell value, the more the term contributes to the feature. A row in the weights matrix **W** represents an original document whose cell value defines the document's significance in a feature.

In applications of topic modeling, a feature is usually referred to as a topic. Nonnegative matrix factorization is capable of discovering topics from a document-by-term matrix or a term-by-document matrix, which would group together into a topic the terms that are somewhat coherent or probably related. Using the output data table mylib.H, you can obtain the most important terms (that is, the terms that have the largest cell values) in each topic. The following statements use the output data table mylib.H to produce the data table topics, which

contains the five discovered topics with the top 10 terms (sorted by descending cell values) to characterize each topic:

```
proc transpose data=mylib.H out=H2 name=Term prefix=Topic;
   id _Index_;
run;

%macro Top(din, rank, k, dout);
   %do i = 1 %to &rank;
      data b; set &din;
         keep Term Topic&i;
      proc sort data=b;
         by descending Topic&i;
      run;
      %if (&i = 1) %then %do;
         data &dout; merge b(obs=&k keep=Term);
            rename Term=Topic&i;
         run;
         %end;
      %else %do;
         data &dout; merge &dout b(obs=&k keep=Term);
            rename Term=Topic&i;
         run;
      %end;
   %end;
%mend;

%Top(H2, 5, 10, topics);

proc print data=topics;
run;
```

Figure 23.3

shows the contents of the topics data table.

Syntax: NMF Procedure

The following statements are available in the NMF procedure:

```
PROC NMF < options > ;
    BY variables ;
    DISPLAY < table-list > < / options > ;
    DISPLAYOUT table-spec-list < / options > ;
    IMPUTE impute-options ;
    OUTPUT OUT=libref.data-table
            < COPYVARS=(variables) >
            < keyword < =prefix > > . . . < keyword < =prefix > > ;
    VAR variables ;
```

The PROC NMF statement is required. All other statements are optional. The following sections describe the PROC NMF statement and then describe the other statements in alphabetical order.

PROC NMF Statement

```
PROC NMF < options > ;
```

The PROC NMF statement invokes the NMF procedure. Table 23.1 summarizes the options available in the PROC NMF statement.

Table 23.1 PROC NMF Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data table
OUTH=	Specifies the output data table that contains the factor matrix **H**
Analysis Options	
ITDETAILS	Displays the matrix factorization accuracy for each iteration
METHOD=	Specifies the matrix factorization method to use
MISSING=	Specifies how to handle observations that have missing values
NOSCALE	Suppresses scaling of the numeric variables to analyze to between 0 and 1
PREFIX=	Specifies a prefix for naming the columns in the factor matrix **W**
RANK=	Specifies the target rank of the low-dimensional factor matrices to compute
REG=	Specifies the regularization method to use
SEED=	Specifies the seed value for pseudorandom number generation
STOP=	Specifies the stopping criterion

The following list provides details about these *options*.

DATA=*libref.data-table*
names the input data table for PROC NMF to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1235.

data-table specifies the name of the input data table.

ITDETAILS
ITERDETAIL
lists the matrix factorization accuracy information for each iteration.

METHOD=APG< (*apg-options***) > | RANDOM< (***random-options***) >**
specifies the matrix factorization method to use. You can specify the following values:

APG< (*apg-options***) >**
requests the alternating proximal gradient method. You can specify the following *apg-options*:

DELTA=*n*
specifies the coefficient to use to control the extrapolation weight, where $0 < n < 1$. By default, DELTA=0.9999.

MAXITER=*n*
specifies the maximum number of iterations to perform. By default, MAXITER=500.

TOL=*n*
TOLERANCE=*n*
specifies the convergence criterion. By default, TOL=1E–7.

UPDATES=*n*
specifies the number of updates on the factor matrices $\mathbf{W}$ and $\mathbf{H}$ at each iteration. By default, UPDATES=10. If you specify the IMPUTE statement, then by default UPDATES=1.

RANDOM< (*random-options***) >**
request the compressed alternating proximal gradient method using random projections. You can specify the following *random-options*:

DELTA=*n*
specifies the coefficient to use to control the extrapolation weight, where $0 < n < 1$. By default, DELTA=0.9999.

MAXITER=*n*
specifies the maximum number of iterations to perform. By default, MAXITER=500.

OVERSAMP=*n*

OVERSAMPLING=*n*
specifies the size of oversampling. By default, OVERSAMP=10.

SUBITER=*n*
specifies the number of subspace iterations to perform. By default, SUBITER=4.

TOL=*n*

TOLERANCE=*n*
specifies the convergence criterion. By default, TOL=1E–7.

UPDATES=*n*
specifies the number of updates on the factor matrices **W** and **H** at each iteration. By default, UPDATES=10.

By default, METHOD=APG. If you specify the IMPUTE statement, only the METHOD=APG option is supported.

MISSING=MEAN | NONE
specifies how to handle observations that have missing values. You can specify the following values:

MEAN
imputes missing values to the mean of the corresponding variable.

NONE
excludes all observations that have missing values from the analysis.

By default, MISSING=NONE. If you specify the IMPUTE statement, the MISSING= option is ignored.

NOSCALE
suppresses scaling of the numeric variables to analyze to between 0 and 1.

OUTH=*libref.data-table*

OUTPUTH=*libref.data-table*
creates an output data table to contain the factor matrix **H**. The data table contains the following variables:

- the BY variables, if any
- _Index_, a variable that contains observation numbers starting from 1
- the variables that are analyzed (that is, those in the VAR statement); or, if there is no VAR statement, all numeric variables not listed in any other statement

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1235.

PREFIX=*name*

specifies a prefix for naming the columns in the factor matrix $\mathbf{W}$. By default, the *names* are Comp1, Comp2, ..., Comp$n$. If you specify PREFIX=Abc, the components are named Abc1, Abc2, Abc3, and so on. The number of characters in the prefix plus the number of digits that are required in order to designate the variables should not exceed the current name length that is defined by the VALIDVARNAME= system option.

RANK=*number*

specifies the target rank of the low-dimensional factor matrices to compute. You must specify the *number*, which must be an integer greater than 0.

REG=L1<(*l1-options***)> | L2<(***l2-options***)>**

REGULARIZATION=L1<(*l1-options***)> | L2<(***l2-options***)>**

PENALTY=L1<(*l1-options***)> | L2<(***l2-options***)>**

specifies the regularization method to use. You can specify the following values:

L1<(*l1-options***)>**

requests the L_1-norm regularization method. You can specify the following *l1-options*:

ALPHA=*n*

specifies the regularization weight of the factor matrix $\mathbf{W}$, where $n \geq 0$. By default, ALPHA=1.

BETA=*n*

specifies the regularization weight of the factor matrix $\mathbf{H}$, where $n \geq 0$. By default, BETA=1.

L2<(*l2-options***)>**

requests the L_2-norm regularization method. You can specify the following *l2-options*:

ALPHA=*n*

specifies the regularization weight of the factor matrix $\mathbf{W}$, where $n \geq 0$. By default, ALPHA=1. This option is ignored if you specify the LCURVE *l2-option*.

BETA=*n*

specifies the regularization weight of the factor matrix $\mathbf{H}$, where $n \geq 0$. By default, BETA=1. This option is ignored if you specify the LCURVE *l2-option*.

LCURVE

uses the L-curve approach to perform L_2-norm regularization. This option is ignored if you specify the METHOD=RANDOM option, the STOP=OBJFUNC option, or the IMPUTE statement.

SEED=*number*

specifies an integer as the seed value for pseudorandom number generation. PROC NMF uses random values to initialize the factor matrices and the random projection matrices. If you do not specify this option or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock. By default, SEED=0.

STOP=PROJGRAD | OBJFUNC
STOPMEASURE=PROJGRAD | OBJFUNC
specifies the stopping criterion. You can specify the following values:

OBJFUNC
uses the objective function.

PROJGRAD
uses the projected gradient.

By default, STOP=PROJGRAD. If you specify METHOD=RANDOM, only STOP=PROJGRAD is supported.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC NMF to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1255. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value*	specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.
key	specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1255. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

IMPUTE Statement

IMPUTE *impute-options* **;**

The IMPUTE statement invokes low-rank matrix completion by using nonnegative matrix factorization to recover missing entries of the input data table.

You must specify exactly one of the following *impute-options*:

OUT=NONE
suppresses creation of an output data table that contains imputation results.

OUT=*libref.data-table* **<** *out-options* **>**
creates an output data table that contains imputation results. The data table contains all variables in the VAR statement (if there is no VAR statement, it contains all numeric variables not listed in any other statement), with missing values being replaced by the imputed values. You must specify OUT=*libref.data-table* before the *out-options* in the IMPUTE statement.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1235.

You can specify the following *out-options*:

COPYVAR=*variable*
COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table.

IMPUTEDROWSONLY
keeps only the rows that contain the imputed values in the output data table.

PREDONLY
sets the observed values to missing values in the output data table.

If you specify both the IMPUTEDROWSONLY and PREDONLY options, only the rows that contain the imputed values are kept in the output data table, and the observed values in those rows are set to missing.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < **=***prefix* > > . . . < *keyword* < **=***prefix* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics, which are computed after PROC NMF fits the model. If you do not specify a *keyword*, then only values of the factor matrix **W** are included.

The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option are included.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC NMF to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1235.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

COPYVAR=*variable*
COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table.

keyword **< =***prefix* **>**
specifies a statistic to include in the output data table and optionally a *prefix* for naming the output variables. If you do not provide a *prefix*, PROC NMF assigns a default prefix that is based on the type of statistic requested.

You can specify the following *keywords* to add statistics to the output data table:

COMP
COMPONENT
requests the source values for each column in the factor matrix **W**. The default prefix is the one that you specify in the PREFIX= option in the PROC NMF statement.

The output variables that contain the requested statistic are named as follows, according to the *keyword* that you specify:

- The *keyword* COMP defines an output variable for each column in the factor matrix **W**, so the variables that correspond to each successive component are named by appending a number to the prefix. For example, if you specify RANK=3 in the PROC NMF statement, then COMP=C produces the variables C1, C2, and C3.

VAR Statement

VAR *variables* **;**

The VAR statement lists the numeric variables to analyze. If you omit this statement, all numeric variables that are not specified in other statements are analyzed.

Details: NMF Procedure

Computing Matrix Factorization

Given a nonnegative data matrix $\mathbf{X}$, nonnegative matrix factorization (NMF) attempts to find two low-rank nonnegative matrices $\mathbf{W}$ and $\mathbf{H}$ such that $\mathbf{X}$ is approximated by the product of $\mathbf{W}$ and $\mathbf{H}$. Formally, NMF can be modeled by the following minimization problem,

$$\underset{\mathbf{W},\mathbf{H}}{\text{minimize}}\ f(\mathbf{W},\mathbf{H}) = \frac{1}{2}\|\mathbf{X}-\mathbf{W}\mathbf{H}\|_F^2, \quad \text{subject to } \mathbf{W}\in\mathbb{R}_+^{n\times r},\ \mathbf{H}\in\mathbb{R}_+^{r\times v}$$

where $\mathbf{X}\in\mathbb{R}_+^{n\times v}$ is the given $n\times v$ nonnegative data matrix; $\|\cdot\|_F$ is the matrix Frobenius norm; and $r<\min\{n,v\}$, which is predetermined.

The NMF procedure implements two methods for performing nonnegative matrix factorization: the alternating proximal gradient (APG) method (Guan et al. 2012; Xu and Yin 2013) and the compressed alternating proximal gradient method using random projections (RANDOM) (Tepper and Sapiro 2016; Yahaya et al. 2018).

APG Method

The alternating proximal gradient (APG) method alternatively applies the proximal gradient with Nesterov-type acceleration technique to minimize the objective function f with respect to $\mathbf{W}$ and $\mathbf{H}$, updating one matrix at a time, while keeping the other matrix fixed. At each iteration, $\mathbf{W}$ and $\mathbf{H}$ are updated by

$$\begin{aligned}
\alpha_t &= \frac{1}{2}\left(1+\sqrt{1+4\alpha_{t-1}^2}\right)\\
\mathbf{W}^t &\leftarrow \mathbf{W}^t + \min\left\{\frac{\alpha_{t-1}-1}{\alpha_t}, \delta\sqrt{\frac{L_{\mathbf{W}}^{t-1}}{L_{\mathbf{W}}^t}}\right\}(\mathbf{W}^t-\mathbf{W}^{t-1})\\
\mathbf{H}^t &\leftarrow \mathbf{H}^t + \min\left\{\frac{\alpha_{t-1}-1}{\alpha_t}, \delta\sqrt{\frac{L_{\mathbf{H}}^{t-1}}{L_{\mathbf{H}}^t}}\right\}(\mathbf{H}^t-\mathbf{H}^{t-1})\\
\mathbf{W}^{t+1} &= \max\left\{0, \mathbf{W}^t - \nabla_{\mathbf{W}} f(\mathbf{W}^t,\mathbf{H}^t)/L_{\mathbf{W}}^t\right\}\\
\mathbf{H}^{t+1} &= \max\left\{0, \mathbf{H}^t - \nabla_{\mathbf{H}} f(\mathbf{W}^{t+1},\mathbf{H}^t)/L_{\mathbf{H}}^t\right\}
\end{aligned}$$

where t is the iteration counter; $\alpha_{-1}=1$; $0<\delta<1$ is a coefficient that controls the extrapolation weight; $L_{\mathbf{W}}^t = \|\mathbf{H}^t{\mathbf{H}^t}^T\|_2$; and $L_{\mathbf{H}}^t = \|{\mathbf{W}^{t+1}}^T\mathbf{W}^{t+1}\|_2$. $L_{\mathbf{W}}$ and $L_{\mathbf{H}}$ are Lipschitz constants of the gradient functions $\nabla_{\mathbf{W}} f$ and $\nabla_{\mathbf{H}} f$, respectively.

The APG method implements two types of stopping criterion to check the convergence of the iterative algorithm: projected gradient and objective function. For the criterion that uses the projected gradient, the APG method stops the iteration after the norm of the projected gradient satisfies the condition

$$\left\| \left[\nabla^P_{\mathbf{W}} f(\mathbf{W}^t, \mathbf{H}^t), \nabla^P_{\mathbf{H}} f(\mathbf{W}^t, \mathbf{H}^t)^T \right] \right\|_F < \epsilon \left\| \left[\nabla^P_{\mathbf{W}} f(\mathbf{W}^0, \mathbf{H}^0), \nabla^P_{\mathbf{H}} f(\mathbf{W}^0, \mathbf{H}^0)^T \right] \right\|_F$$

where ϵ is a tolerance, $\mathbf{W}^0$ and $\mathbf{H}^0$ are initial values, and $\nabla^P_{\mathbf{W}} f(\mathbf{W}, \mathbf{H})$ and $\nabla^P_{\mathbf{H}} f(\mathbf{W}, \mathbf{H})$ are the projected gradient that is defined respectively by

$$\nabla^P_{\mathbf{W}} f(\mathbf{W}, \mathbf{H})_{ij} = \begin{cases} \nabla_{\mathbf{W}} f(\mathbf{W}, \mathbf{H})_{ij} & \text{if } \mathbf{W}_{ij} > 0 \\ \min\left\{0, \nabla_{\mathbf{W}} f(\mathbf{W}, \mathbf{H})_{ij}\right\} & \text{if } \mathbf{W}_{ij} = 0 \end{cases}$$

$$\nabla^P_{\mathbf{H}} f(\mathbf{W}, \mathbf{H})_{ij} = \begin{cases} \nabla_{\mathbf{H}} f(\mathbf{W}, \mathbf{H})_{ij} & \text{if } \mathbf{H}_{ij} > 0 \\ \min\left\{0, \nabla_{\mathbf{H}} f(\mathbf{W}, \mathbf{H})_{ij}\right\} & \text{if } \mathbf{H}_{ij} = 0 \end{cases}$$

The projected gradient criterion measures how close the computed solution $(\mathbf{W}^t, \mathbf{H}^t)$ is to a stationary point.

For the stopping criterion that uses the objective function, the APG method stops the iteration after the following condition is satisfied:

$$\left| \frac{f(\mathbf{W}^{t-1}, \mathbf{H}^{t-1}) - f(\mathbf{W}^t, \mathbf{H}^t)}{f(\mathbf{W}^0, \mathbf{H}^0) - f(\mathbf{W}^t, \mathbf{H}^t)} \right| < \epsilon$$

RANDOM Method

The compressed alternating proximal gradient method using random projections (RANDOM) performs NMF by using a two-step process. The first step constructs two approximate basis matrices with orthonormal columns for the range of the input data matrix $\mathbf{X}$: $\mathbf{L} \in \mathbb{R}^{n \times (r+r_o)}$ and $\mathbf{R} \in \mathbb{R}^{v \times (r+r_o)}$, where r_o is the oversampling parameter and $r + r_o \leq \min\{n, v\}$. The construction is done by using the randomized subspace iterations. The initial basis matrix is a random projection of the data matrix $\mathbf{X}$: $\mathbf{L}^0 = \mathbf{X}\boldsymbol{\Omega}_l$ and $\mathbf{R}^0 = \mathbf{X}^T\boldsymbol{\Omega}_r$, where $\boldsymbol{\Omega}_l$ and $\boldsymbol{\Omega}_r$ are random Gaussian projection matrices. Each iteration ($t = 0, 1, 2, \ldots, k$) then consists of calculating the subspace defined by the QR factorization of the random projection and orthonormalization steps,

$$\begin{aligned} \mathbf{L}^t &\leftarrow \mathrm{QR}(\mathbf{L}^t) & \mathbf{R}^t &\leftarrow \mathrm{QR}(\mathbf{R}^t) \\ \mathbf{Q}_l &\leftarrow \mathrm{QR}(\mathbf{X}^T\mathbf{L}^t) & \mathbf{Q}_r &\leftarrow \mathrm{QR}(\mathbf{X}\mathbf{R}^{\mathrm{t}}) \\ \mathbf{L}^{t+1} &= \mathbf{X}\mathbf{Q}_l & \mathbf{R}^{t+1} &= \mathbf{X}^T\mathbf{Q}_r \end{aligned}$$

where QR() is the reduced QR factorization operation that returns a matrix with orthonormal columns. When $t = k$, $\mathbf{L}^t$ and $\mathbf{R}^t$ are the desired orthonormal basis matrices.

The second step computes two compressed data matrices, $\mathbf{X}_l$ and $\mathbf{X}_r$, by using $\mathbf{L}$ and $\mathbf{R}$: $\mathbf{X}_l = \mathbf{L}^T\mathbf{X}$,

$\mathbf{X}_r = \mathbf{XR}$. $\mathbf{W}$ and $\mathbf{H}$ are then computed by the APG method with slight modifications at each iteration:

$$
\begin{aligned}
\alpha_t &= \frac{1}{2}\left(1+\sqrt{1+4\alpha_{t-1}^2}\right) \\
\mathbf{W}^t &\leftarrow \mathbf{W}^t + \min\left\{\frac{\alpha_{t-1}-1}{\alpha_t}, \delta\sqrt{\frac{L_{\mathbf{W}}^{t-1}}{L_{\mathbf{W}}^t}}\right\}(\mathbf{W}^t - \mathbf{W}^{t-1}) \\
\mathbf{H}^t &\leftarrow \mathbf{H}^t + \min\left\{\frac{\alpha_{t-1}-1}{\alpha_t}, \delta\sqrt{\frac{L_{\mathbf{H}}^{t-1}}{L_{\mathbf{H}}^t}}\right\}(\mathbf{H}^t - \mathbf{H}^{t-1}) \\
\mathbf{H}_r^t &= \mathbf{H}^t\mathbf{R} \\
\mathbf{W}^{t+1} &= \max\left\{0, \mathbf{W}^t - \nabla_{\mathbf{W}} f_1(\mathbf{W}^t, \mathbf{H}_r^t)/L_{\mathbf{W}}^t\right\} \\
\mathbf{W}_l^{t+1} &= \mathbf{L}^T\mathbf{W}^{t+1} \\
\mathbf{H}^{t+1} &= \max\left\{0, \mathbf{H}^t - \nabla_{\mathbf{H}} f_2(\mathbf{W}_l^{t+1}, \mathbf{H}^t)/L_{\mathbf{H}}^t\right\}
\end{aligned}
$$

where $f_1 = \frac{1}{2}\|\mathbf{X}_r - \mathbf{WH}_r\|_F^2$, $f_2 = \frac{1}{2}\|\mathbf{X}_l - \mathbf{W}_l\mathbf{H}\|_F^2$, $L_{\mathbf{W}}^t = \|\mathbf{H}_r^t{\mathbf{H}_r^t}^T\|_2$, and $L_{\mathbf{H}}^t = \|{\mathbf{W}_l^{t+1}}^T\mathbf{W}_l^{t+1}\|_2$.

The RANDOM method uses the projected gradient as the only stopping criterion, which stops the iteration after the norm of the projected gradient satisfies the following condition:

$$
\left\|\left[\nabla_{\mathbf{W}}^P f_1(\mathbf{W}^t, \mathbf{H}_r^t), \nabla_{\mathbf{H}}^P f_2(\mathbf{W}_l^t, \mathbf{H}^t)^T\right]\right\|_F < \epsilon\left\|\left[\nabla_{\mathbf{W}}^P f_1(\mathbf{W}^0, \mathbf{H}_r^0), \nabla_{\mathbf{H}}^P f_2(\mathbf{W}_l^0, \mathbf{H}^0)^T\right]\right\|_F
$$

Regularization

The NMF procedure implements two methods of performing regularized nonnegative matrix factorization: L_1-norm regularization and L_2-norm regularization.

L_1-norm regularization is usually applied in NMF to control the solution sparsity. L_1-norm-regularized NMF is modeled by the following minimization problem:

$$
\underset{\mathbf{W},\mathbf{H}}{\text{minimize}}\ f(\mathbf{W},\mathbf{H}) = \frac{1}{2}\|\mathbf{X}-\mathbf{WH}\|_F^2 + \alpha\|\mathbf{W}\|_1 + \beta\|\mathbf{H}\|_1, \quad \text{subject to } \mathbf{W}\in\mathbb{R}_+^{n\times r},\ \mathbf{H}\in\mathbb{R}_+^{r\times v}
$$

where $\|\cdot\|_1$ is the L_1-norm, and α and β are the regularization weights of the factor matrices $\mathbf{W}$ and $\mathbf{H}$, respectively. Because both $\mathbf{W}$ and $\mathbf{H}$ are nonnegative matrices, $\|\mathbf{W}\|_1 = \Sigma_{ij}\mathbf{W}_{ij}$ and $\|\mathbf{H}\|_1 = \Sigma_{ij}\mathbf{H}_{ij}$.

L_2-norm regularization, which is also called Tikhonov regularization, is usually applied in NMF to control the solution smoothness. L_2-norm-regularized NMF is modeled by the following minimization problem:

$$
\underset{\mathbf{W},\mathbf{H}}{\text{minimize}}\ f(\mathbf{W},\mathbf{H}) = \frac{1}{2}\|\mathbf{X}-\mathbf{WH}\|_F^2 + \frac{\alpha}{2}\|\mathbf{W}\|_F^2 + \frac{\beta}{2}\|\mathbf{H}\|_F^2, \quad \text{subject to } \mathbf{W}\in\mathbb{R}_+^{n\times r},\ \mathbf{H}\in\mathbb{R}_+^{r\times v}
$$

where α and β are the regularization weights of the factor matrices $\mathbf{W}$ and $\mathbf{H}$, respectively.

If you request L_2-norm regularization and specify REG=L2(LCURVE), PROC NMF calculates and updates the regularization weights at each iteration by using the L-curve approach to the L_2-norm-regularized NMF

with the following formulas (Mirzal 2014):

$$\alpha^{t+1} \leftarrow \frac{\|\mathbf{X} - \mathbf{W}^t\mathbf{H}^t\|_F^2}{nv\|\mathbf{W}^t\|_F^2}$$
$$\beta^{t+1} \leftarrow \frac{\|\mathbf{X} - \mathbf{W}^t\mathbf{H}^t\|_F^2}{nv\|\mathbf{H}^t\|_F^2}$$

Matrix Completion

If you specify the IMPUTE statement, the NMF procedure performs low-rank matrix completion with nonnegative matrix factorization, in order to recover missing entries of a low-rank matrix that is incompletely sampled (Nguyen, Kim, and Shim 2019; Xu and Yin 2013).

Low-rank matrix completion with NMF is modeled by the following minimization problem:

$$\underset{\mathbf{X},\mathbf{W},\mathbf{H}\geq\mathbf{0}}{\text{minimize}}\ f(\mathbf{X},\mathbf{W},\mathbf{H}) = \frac{1}{2}\|\mathbf{X} - \mathbf{W}\mathbf{H}\|_F^2, \quad \text{subject to } \mathcal{P}_\Omega(\mathbf{X}) = \mathcal{P}_\Omega(\mathbf{A})$$

where $\mathbf{A}$ is the observed low-rank nonnegative data matrix with missing entries; $\mathbf{X}$ is the low-rank nonnegative matrix that estimates $\mathbf{A}$; Ω is the index set of the observed entries of $\mathbf{A}$; and $\mathcal{P}_\Omega(\cdot)$ is the sampling operator, where $\mathcal{P}_\Omega(\mathbf{A})$ is defined as

$$[\mathcal{P}_\Omega(\mathbf{A})]_{ij} = \begin{cases} \mathbf{A}_{ij} & (i,j) \in \Omega \\ 0 & \text{otherwise} \end{cases}$$

The NMF procedure implements low-rank matrix completion by using the alternating proximal gradient (APG) method with modifications (Guan et al. 2012; Xu and Yin 2013). The modified APG method initializes the estimated matrix $\mathbf{X}$ by replacing missing values with zero in the observed data matrix $\mathbf{A}$: $\mathbf{X}^0 = \mathcal{P}_\Omega(\mathbf{A})$. At each iteration, $\mathbf{X}$ is then computed by using $\mathbf{A}$ and the latest update of $\mathbf{W}$ and $\mathbf{H}$:

$$\mathbf{X}^{t+1} = \mathcal{P}_\Omega(\mathbf{A}) + \mathcal{P}_{\Omega^c}(\mathbf{W}^{t+1}\mathbf{H}^{t+1})$$

where Ω^c is the complement of Ω and $\mathcal{P}_{\Omega^c}(\cdot)$ is the sampling operator, with $\mathcal{P}_{\Omega^c}(\mathbf{X})$ defined as

$$[\mathcal{P}_{\Omega^c}(\mathbf{X})]_{ij} = \begin{cases} 0 & (i,j) \in \Omega \\ \mathbf{X}_{ij} & \text{otherwise} \end{cases}$$

To invoke the modified APG method, you specify the METHOD=APG option in the PROC NMF statement. The METHOD=RANDOM option is not supported for low-rank matrix completion.

The NMF procedure also performs low-rank matrix completion with regularized nonnegative matrix factorization. You can specify the REG= option in the PROC NMF statement to use either the L_1-norm or L_2-norm regularization method. If the observed data matrix contains a large proportion of missing entries, you can use the regularization method to mitigate the impact of the initial factor matrices $\mathbf{W}$ and $\mathbf{H}$ on the imputation results.

Initial Values

The NMF procedure initializes the factor matrices $\mathbf{W}$ and $\mathbf{H}$ by using random values that are drawn from the uniform distribution in the interval of [0, 1]. If you specify METHOD=RANDOM, PROC NMF generates the random projection matrices by using random values that are drawn from the standard Gaussian distribution, where negative values are set to positive. You can use the SEED= option to set the seed value for the random number generator. Changing the seed value changes the initial factor matrices and the random projection matrices, resulting in different estimated factor matrices.

The initial factor matrix $\mathbf{W}$ and the random projection matrix $\mathbf{\Omega}_r$ are generated according to how the data are distributed. Changing the number of compute nodes and the number of threads that are used changes the initial distribution of data. Thus, you might get a different initial factor matrix $\mathbf{W}$ and a different random projection matrix $\mathbf{\Omega}_r$, resulting in different estimated factor matrices.

Missing Values

If you specify MISSING=NONE in the PROC NMF statement, which is the default, observations that have missing values for any variable in the VAR statement are omitted from the analysis, and they are given missing values for values of the factor matrix $\mathbf{W}$ in the OUT= data table that is specified in the OUTPUT statement. If you specify MISSING=MEAN, observations that have missing values for any variable in the VAR statement are not omitted from the analysis, and the missing values are imputed to the mean of the corresponding variable.

If you specify the IMPUTE statement, the NMF procedure performs low-rank matrix completion and the MISSING= option is ignored. Observations that have missing values for all variables in the VAR statement are omitted from the analysis, and they are set to missing in the recovered matrix $\mathbf{X}$ in the OUT= data table that you specify in the IMPUTE statement.

Displayed Output

The following sections describe the output that PROC NMF produces. The output is organized into various tables, which are discussed in their order of appearance.

Model Information

The "Model Information" table displays basic information about the model, including the input data table, the number of VAR statement variables, the target rank of factor matrices, the factorization method, and the stopping criterion used in the computation. It also displays information about the factorization method, including the maximum number of iterations, the number of matrix updates at each iteration, the convergence tolerance, the random number seed, whether to scale input data or not, the way to handle the missing values, and the coefficient for extrapolation weight. If you specify METHOD=RANDOM in the PROC NMF statement, the table also displays information about the oversampling size and the number of subspace iterations.

Regularization Information

If you specify the REG= option in the PROC NMF statement, the NMF procedure produces a "Regularization Information" table to display the regularization method and the regularization weight values.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table, the number of observations that are used in the analysis, and the number of observations that have missing values. If you specify the IMPUTE statement, the table also displays the number of observations that have missing values for all variables in the VAR statement.

Imputation Summary

If you specify the IMPUTE statement, the NMF procedure produces an "Imputation Summary" table to display the degree of freedom of the recovered data matrix, the number of observed values of the data matrix, the number of imputed values, and the proportion of imputed values. The degree of freedom of an $n \times v$ matrix with rank r is $(n + v)r - r^2$, which is a lower bound of the number of observed values to ensure the exact recovery of the rank r matrix.

Iteration Results

The "Iteration Results" table displays the matrix factorization accuracy information, which includes the number of iterations, the relative error at which the iteration stops, and the stopping criterion. If you specify STOP=PROJGRAD in the PROC NMF statement, the table displays the initial and final projected gradient norms. If you specify STOP=OBJFUNC, the table displays the initial and final objective function values. The table also displays the sparsity of the factor matrices $\mathbf{W}$ and $\mathbf{H}$. The sparsity of a matrix is the proportion of the number of zero-valued elements to the total number of elements in the matrix.

Iteration Details

If you specify the ITDETAILS option in the PROC NMF statement, the NMF procedure produces an "Iteration Details" table to display the matrix factorization accuracy information for each iteration, including the iteration step, relative error, and projected gradient norm (if you specify STOP=PROJGRAD in the PROC NMF statement) or objective function value (if you specify STOP=OBJFUNC). If you specify REG=L2(LCURVE) in the PROC NMF statement, the table also displays the regularization weight values for each iteration.

Timing Information

The "Timing" table displays the elapsed time of each main task of the procedure.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the NMF procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or the Output Delivery System (ODS) statement. These names are listed in Table 23.2.

Table 23.2 ODS Tables Produced by PROC NMF

Table Name	Description	Required Statement / Option
ImputationSummary	Summary of imputation results	IMPUTE statement
IterDetail	Accuracy information for each iteration	PROC NMF statement / ITDETAILS option
IterResult	Iteration results	Default output
ModelInfo	Model information	Default output
NObs	Number of observations read and used	Default output
OutputCasTables	See the section "OutputCasTables Table" on page 1254	DISPLAYOUT statement, OUTPUT statement, PROC NMF statement / OUTH= option, or IMPUTE statement / OUT= option
RegInfo	Regularization information	PROC NMF statement / REG= option
Timing	Absolute and relative times of tasks that are performed by the procedure	Default output

Examples: NMF Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 23.1: Discovering Topics from Documents

(View the complete code for this example (nmfex1.sas) in the example repository.)

This example illustrates how you can use the NMF procedure to discover topics (main themes) from contents of the documents. The following DATA step creates the data table mylib.ex1Data, which contains 16 observations that have two variables, in your CAS session. The variable text contains the input documents, and the variable did contains the IDs of the documents. Each row in the data table represents a document for analysis.

```
data mylib.ex1Data;
   infile datalines delimiter='|' missover;
   length text $150;
   input text$ did;
   datalines;
      Reduces the cost of maintenance. Improves revenue forecast.        | 1

run;
```

These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

In order to use PROC NMF to perform topic discovery, you first need to obtain a term-by-document matrix from the mylib.ex1Data data table. You can use PROC TEXTMINE to generate a data table that contains the term-by-document matrix. For more information about the TEXTMINE procedure, see Chapter 41, "TEXTMINE Procedure" (*SAS Viya: Machine Learning Procedures*).

Many text mining applications benefit from the use of a stop list, which contains a set of commonly used terms in a language. Those terms are commonly eliminated because they can be distracting and noninformative and can incur additional memory overhead. The following DATA step creates the stop list for use in PROC TEXTMINE to eliminate noisy, noninformative terms:

```
data mylib.en_stoplist;
   length Term $16;
   input Term;
   datalines;
about
and
are
```

```
as
between
for
from
in
is
of
or
than
the
this
to
with
;
```

The following statements invoke PROC TEXTMINE to run on the mylib.ex1Data data table and specify that all terms in the input document collection, except for those on the stop list, are to be kept for generating the term-by-document matrix. The summary information about the terms in the document collection is stored in a data table named mylib.terms. The term-by-document matrix is stored in a data table named mylib.termdoc.

```
proc textmine data=mylib.ex1Data;
   doc_id     did;
   variables  text;
   parse      stop      = mylib.en_stoplist
              outterms  = mylib.terms
              outparent = mylib.termdoc
              reducef   = 1;
run;
```

The mylib.termdoc data table that PROC TEXTMINE generates contains a compressed representation of the sparse term-by-document matrix, which is stored in the coordinate list (COO) format. In this format, the matrix is represented as a set of triples $(i,\ j,\ x)$, where x is an entry in the matrix and i and j denote its row and column indices, respectively. The NMF procedure does not support input data in COO format. The following statements convert the mylib.termdoc data table that is stored in COO format to a data table named mylib.termdoc2 that is stored in dense format. The mylib.termdoc2 data table contains 18 columns: ID (ID of the terms), Term, and DOC1, DOC2, . . ., DOC16 (which correspond to the 16 documents). Each row in the data table contains the term counts of a certain term in every document.

```
data terms; set mylib.terms; keep Term Key;
   rename Key=_termnum_;
run;
proc sort data=terms; by _termnum_; run;

data termdoc; set mylib.termdoc; run;
proc sort data=termdoc; by _termnum_ _document_; run;

data termdoc1; merge terms termdoc; by _termnum_;
   if missing(_count_) then delete;
run;

proc sql noprint;
   select max(_document_) into :max_docid from termdoc1;
run;
%let maxid = &max_docid;
```

```
data mylib.termdoc2;
   length id 8;
   array docs{&maxid} doc1 - doc&maxid;
   retain doc1 - doc&maxid;
   set termdoc1;
   by _termnum_;
   id = _termnum_;
   if First._termnum_ then do;
      do i= 1 to &maxid;
         docs{i} = 0;
      end;
   end;
   docs{_document_} = _count_;
   if Last._termnum_;
   drop i _termnum_ _document_ _count_;
run;
```

You can specify RANK=5 in PROC NMF to derive five topics from the mylib.termdoc2 data table. The following statements invoke the NMF procedure to run on this data table and output the factor matrices **W** and **H** to the output data tables mylib.W and mylib.H, respectively:

```
proc nmf data=mylib.termdoc2 seed=789 rank=5 outh=mylib.H;
   var doc1-doc&maxid;
   output out=mylib.W comp=Topic copyvar=Term;
run;
```

Because the mylib.termdoc2 data table is treated as a term-by-document matrix, **W** is considered a features matrix, where each column in **W** is a feature (topic) vector, and **H** is considered a weights matrix, where each column in **H** represents the topic membership values in a document. As the example in the Getting Started section shows, nonnegative matrix factorization would group together into a topic the terms that are somewhat coherent or probably related. Using the output data table mylib.W, you can obtain the most important terms (that is, the terms that have the largest cell values) in each topic. The following PROC CAS statements use the output data table mylib.W and the **table.fetch** action to obtain the top 10 terms for one of the five discovered topics, Topic3:

```
proc cas;
   action table.fetch /
      table='W'
      fetchVars={'Term', 'Topic3'}
      sortby={{name='Topic3' order='descending'}}
      to=10;
run;
quit;
```

Output 23.1.1 displays the top 10 terms for the topic Topic3 and the cell value for each term, which defines the significance of a term in the topic.

Output 23.1.1 Top 10 Terms for Topic3

Results from table.fetch

Selected Rows from Table W		
Index	Term	Topic3
1	application developer	0.1868321986
2	application	0.1868321986
3	casual	0.1868321986
4	data scientist	0.1868321986
5	scientist	0.1868321986
6	developer	0.1868321986
7	user	0.1868321986
8	business user	0.1868321986
9	business	0.1306168732
10	data	0.0698839337

You can also use the output data table mylib.W and the **table.fetch** action to generate the results table "Topics," which contains the five discovered topics with the top 10 terms (sorted by descending cell values) to characterize each topic. The following PROC CAS statements generate and display the "Topics" table:

```
proc cas;
   topic=${Topic1-Topic5};
   cols='_Index_' + topic;
   coltypes=${integer, varchar, varchar, varchar, varchar, varchar};
   Topics=newtable('Topics', cols, coltypes);

   t={};
   do i=1 to 5;
      table.fetch result=r /
         table='W'
         fetchVars={'Term'}
         sortby={{name=topic[i] order='descending'}}
         to=10;
      t[i]=r.Fetch[, 'Term'];
   end;

   row={};
   do j=1 to 10;
      row[1]=j;
      do i=1 to 5; row[i+1]=t[i][j]; end;
      addrow(Topics, row);
   end;

   print Topics;
run;
quit;
```

Output 23.1.2 shows the contents of the "Topics" results table.

Output 23.1.2 Topics with Top 10 Terms

Topics: Results

Index	Topic1	Topic2	Topic3	Topic4	Topic5
1	reduce	technique	application developer	easy deployment	viya
2	fast	apply	application	deployment	data analysis

10	cost	hold	data	on-site	associate

Example 23.2: Making Recommendations Using Matrix Completion

(View the complete code for this example (nmfex2.sas) in the example repository.)

This example illustrates how you can use the NMF procedure to build a simple recommender system that aims at predicting the preference (or rating) of a user for an item and making recommendations based on the prediction. The data in this example are derived from the MovieLens data set, which was developed by the GroupLens project at the University of Minnesota and is available at `http://grouplens.org/datasets/movielens`. This example uses the MovieLens 100K version. You can download the compressed archive file from the website at `http://files.grouplens.org/datasets/movielens/ml-100k.zip` and use any third-party unzip tool to extract all the files in the archive to the destination directory of your choice.[1]

The file that contains the movie ratings is *u.data*, which lists four columns: user ID, item ID (each item is a movie), rating, and timestamp. The data set is very sparse because most combinations of users and movies are not rated. Assuming that the file is located in the directory */path/to/your/directory*, the following statements invoke the PYTHON procedure to load the data from the directory, store it in dense matrix format, and transfer it to a SAS data table named mylib.ratings in your CAS session. Here, the **`SAS.df2sd`** callback method is used in PROC PYTHON to transfer data from a Python Pandas DataFrame to a SAS data set; the CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref. The mylib.ratings data table contains the following columns: UserID and M1, M2, M3, etc. (which correspond to all the movies). Each row in the data table contains the ratings that a certain user gave to the movies. If the user did not rate a movie, the corresponding rating is missing.

```
proc python;
   submit;

import pandas as pd
import numpy as np

# load data from the file
colname = ['userID', 'movieID', 'rating']
colpick = [0, 1, 2]
df = pd.read_csv('u.data', delimiter='\t', usecols=colpick, names=colname)

# store data in dense matrix format
nrow = max(df.loc[:, 'userID'])
ncol = max(df.loc[:, 'movieID']) + 1
mat = np.full((nrow, ncol), np.nan)

for i in range(0, nrow):
   mat[i, 0] = i+1

for idx, rowSeries in df.iterrows():
   val = rowSeries.values
   mat[val[0]-1, val[1]] = val[2]

# transfer data to a SAS data table
cols = ['UserID'] + ['M%d' %i for i in range(1, ncol)]
matdf = pd.DataFrame(mat, columns=cols)

SAS.df2sd(matdf, 'mylib.ratings')

   endsubmit;
run;
```

You specify the IMPUTE statement in the NMF procedure to enable low-rank matrix completion to recover the missing entries in the mylib.ratings data table. The following statements invoke the NMF procedure for this data table and output the imputation results to the output data table mylib.outX. Because the file that contains the movie genres, *u.genre*, lists 19 genres, the PROC NMF statement specifies RANK=19 to compute 19 feature vectors during the factorization. The mylib.ratings data table is very sparse, so to ensure convergence for low-rank matrix completion and mitigate the impact of the initial factor matrices on the imputation results, the PROC NMF statement specifies 600 as the maximum number of iterations for the APG method by using the MAXITER= suboption and requests the L_2-norm regularization method by using the REG= option. The IMPUTEDROWSONLY and PREDONLY options in the IMPUTE statement keep only the rows that contain the imputed values in the output data table mylib.outX and set the observed values in those rows as missing values.

```
proc nmf data=mylib.ratings rank=19 seed=6789
         method=apg(maxiter=600) reg=L2(alpha=5 beta=5);
   var m:;
   impute out=mylib.outX imputedRowsOnly predOnly copyvar=UserID;
run;
```

The following statements invoke PROC PYTHON to fetch from the mylib.outX data table the first 10 observations that contain the predicted ratings of the first 10 users (the **SAS.sd2df** callback method is used

in PROC PYTHON to transfer data from a SAS data set to a Python Pandas DataFrame); load information about the movies from the file *u.item* that is located in the directory */path/to/your/directory*; produce the top 10 recommended movies for the 9th user; and generate a table that contains the top 5 recommended movies for each of the first 10 users:

```
proc python;
   submit;

import pandas as pd
import numpy as np
import csv

# fetch the first 10 observations
df = SAS.sd2df('mylib.outX(obs=10)')

# load information about the movies
movieDict = {}
csvFile = csv.reader(open('u.item', encoding='latin-1'), delimiter='|')
for row in csvFile:
   key = 'M' + row[0]
   movieDict[key] = row[1]

# top 10 recommended movies for a single user
row = 8
uid = df.iloc[row, 0]
rating = df.iloc[row, 1:].sort_values(ascending=False, inplace=False)
colUid = [uid]*10
colRank = np.arange(1, 11).tolist()
colMid = rating.index.tolist()[0:10]
colRate = rating.values.tolist()[0:10]
colTitle = []
for i in range(0, 10):
   colTitle.append(movieDict[rating.index[i]])

cols = ['UserID', 'Rank', 'MovieID', 'Title', 'PredictedRating']
topRating = pd.DataFrame(list(zip(colUid, colRank, colMid, colTitle, colRate)),
                         columns=cols)
SAS.df2sd(topRating, 'topRating')

# top 5 recommended movies for each of the 10 users
movies = []
for idx, rowSeries in df.iterrows():
   uid = rowSeries.pop('UserID')
   rowSeries.sort_values(ascending=False, inplace=True)
   row = [uid]
   for i in range(0, 5):
      row.append(movieDict[rowSeries.index[i]])
   movies.append(row)

cols = ['UserID', '_1_', '_2_', '_3_', '_4_', '_5_']
topRecom = pd.DataFrame(movies, columns=cols)
SAS.df2sd(topRecom, 'topRecom')
```

```
   endsubmit;
run;
```

The following statements print the top 10 recommended movies along with the predicted ratings for the 9th user, as shown in Output 23.2.1:

```
proc print data=topRating;
run;
```

Output 23.2.1 Top 10 Recommended Movies with Predicted Ratings for Single User

Obs	UserID	Rank	MovieID	Title	PredictedRating
1	9	1	M313	Titanic (1997)	4.08736
2	9	2	M272	Good Will Hunting (1997)	4.07087
3	9	3	M302	L.A. Confidential (1997)	4.03031
4	9	4	M127	Godfather, The (1972)	3.99586
5	9	5	M318	Schindler's List (1993)	3.97899
6	9	6	M64	Shawshank Redemption, The (1994)	3.92072
7	9	7	M100	Fargo (1996)	3.89836
8	9	8	M515	Boot, Das (1981)	3.87869
9	9	9	M269	Full Monty, The (1997)	3.84054
10	9	10	M315	Apt Pupil (1998)	3.80159

The following statements print the top 5 recommended movies (sorted by descending predicted ratings) for each of the 10 users, as shown in Output 23.2.2:

```
proc print data=topRecom;
run;
```

Output 23.2.2 Top 5 Recommended Movies for 10 Users

Obs	UserID	_1_	_2_	_3_	_4_	_5_
1	1	Close Shave, A (1995)	Casablanca (1942)	Secrets & Lies (1996)	L.A. Confidential (1997)	Dr. Strangelove or: How I Learned to Stop Worrying and Love the Bomb (1963)

Overview: PARTITION Procedure

The PARTITION procedure performs sampling in SAS Viya. It performs simple random sampling, stratified sampling, oversampling, or *k*-fold partitioning to produce a table that contains a subset of the observations or that contains partitioned observations.

The PARTITION procedure creates the following:

- one output data table, which contains the subset or partitioned data table
- one summary table, which contains the numbers of observations and variables in the output data table
- one frequency table, which contains the frequency information for the population and sample or for each fold for *k*-fold partitioning
- one partition indicator map table, which contains the mapping of each partition indicator to each target. This table is created when the TARGET statement is specified.
- one sample frequency map table, which contains the mapping of each sample frequency to each target. This table is created when both the TARGET statement and the FREQ statement are specified.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: PARTITION Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/partition_gs.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

This example performs stratified partitioning of 5,960 fictitious mortgages, with the BY variable BAD used as the stratum. The input data table mylib.hmeq includes information about the fictitious mortgages. Each observation represents an applicant for a home equity loan, and all applicants have an existing mortgage.

You can load the sampsio.hmeq data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements perform the partitioning:

```
proc partition data=mylib.hmeq samppct=10 samppct2=20 seed=1234 partind;
   by BAD;
   output out=mylib.out1 copyvars=(BAD loan derog mortdue value yoj
          delinq clage ninq clno debtinc);
run;
```

The SAMPPCT=10 option requests that 10% of the input data be included in the training partition, and the SAMPPCT2=20 option requests that 20% of the input data be included in the testing partition. The SEED= option specifies 1234 as the random seed to be used in the partitioning process. The PARTIND option requests that the output data table, mylib.out1, include an indicator that shows whether each observation is selected to a partition (1 for training or 2 for testing) or not (0). The binary BY variable BAD indicates whether an applicant eventually defaulted or was ever seriously delinquent. The BY statement triggers stratified sampling, which enables you to sample each subpopulation in the BY variable (stratum) independently. The OUTPUT statement creates a new data table to contain the variables from the input data table that are listed in the COPYVARS= option and the partition indicator. The displayed output includes a frequency table (Figure 24.1) that shows the frequency of observations in each level of BAD.

Figure 24.1 Frequency Information Table

The PARTITION Procedure

Stratified Sampling Frequency				
Index	BAD	Number of Obs	Sample Size 1	Sample Size 2
0	0	4771	477	954
1	1	1189	119	238

Syntax: PARTITION Procedure

The following statements are available in the PARTITION procedure:

PROC PARTITION < *options* > **;**
BY *variable* < *variable . . . variable* > **;**
DISPLAY < *table-list* > < */options* > **;**
DISPLAYOUT *table-spec-list* < */options* > **;**
FREQ *variable* **;**
OUTPUT OUT=*libref.data-table* < *options* > **;**
TARGET *variable* < / **LEVEL=NOMINAL** | **INTERVAL** > **;**

The BY statement is required for stratified sampling and oversampling. The OUTPUT statement is required for all sampling methods. The FREQ statement is supported in simple random sampling, stratified sampling, and oversampling.

PROC PARTITION Statement

PROC PARTITION < *options* > **;**

The PROC PARTITION statement invokes the procedure.

You can specify the following *options* for all types of sampling:

APPLYROWORDER
uses a data distribution and row order as determined by a previous **`partition`** action call. For more information, see the section "The APPLYROWORDER Option" on page 107 in Chapter 2, "Shared Concepts."

DATA=*libref.data-table*
names the input data table for PROC PARTITION to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1266.

data-table specifies the name of the input data table.

NTHREADS=*number-of-threads*
specifies the number of threads to be used. The default is the CPU count on each node.

PARTIND
adds to the output data table a partition indicator, _PartInd_, which indicates whether an observation is selected to a partition (1 or 2) or not (0).

SEED=*random-seed*
specifies an integer that is used to start the pseudorandom number generator. If you do not specify a seed or you specify a value less than or equal to 0, the seed is generated from reading the time of day from the computer's clock. The SEED= option enables you to reproduce the same sample output.

You can specify the following *options* only for simple random sampling and stratified sampling:

FIXEDOBS=*fixed-observations*
specifies the number of samples. In simple random sampling, this is the total number of samples. In stratified sampling, this is the number of samples from each stratum. When you specify this option, the SAMPPCT= option and SAMPPCT2= option are ignored. When you specify this option along with the PARTIND option, the sampled observations have a _PartInd_ of 1.

SAMPPCT=*sample-percentage*
specifies what percentage of the data is to be sampled, where *sample-percentage* is a positive number less than or equal to 100. For example, SAMPPCT=50.5 samples 50.5% of data. When you specify this option along with the PARTIND option, the percentage of the sample whose _PartInd_ is 1 is specified in *sample-percentage*, and the percentage of the sample whose _PartInd_ is 0 is 100 minus *sample-percentage*.

SAMPPCT2=*sample-percentage-2*
partitions the input data into three parts when specified along with the SAMPPCT= and PARTIND options. The percentage of the sample whose _PartInd_ is 1 is specified in the SAMPPCT= option, the percentage of the sample whose _PartInd_ is 2 is specified in the SAMPPCT2= option, and the percentage of the sample whose _PartInd_ is 0 is 100 minus the sum of the values of the SAMPPCT= and SAMPPCT2= options. The sum of the *sample-percentages* that you specify in the SAMPPCT= and SAMPPCT2= options must be a positive number less than or equal to 100.

The following formulas are used to calculate sample sizes for partitions:

$$n = \mathrm{round}((\textit{sample-percentage} + \textit{sample-percentage-2}) \times N)$$

$$n_1 = \mathrm{round}((\textit{sample-percentage}/(\textit{sample-percentage} + \textit{sample-percentage-2})) \times n$$

$$n_2 = n - n_1$$

where N is the number of observations in the input data, n is the total number of observations in the partitions, n_1 is the number of observations in the first sample, and n_2 is the number of observations in the second sample.

You can specify the following *options* only for oversampling:

EVENT=*"rare-event-level"*
specifies the level (category) that corresponds to a rare event of the variable that is specified in the BY statement. If you have a format applied to the variable, you should specify the formatted event level in this option. If you specify this option, PROC PARTITION uses an oversampling technique to adjust the class distribution of the data, and the following two options are required.

EVENTPROP=*event-proportion*
specifies the proportion of rare events that you want in the sample, where *event-proportion* is a positive number less than or equal to 1. For example, EVENTPROP=0.3 specifies that 30% of the sample are rare events and 70% are not rare.

SAMPPCTEVT=*sample-event-percentage*
specifies the sample percentage from the rare event level, where *sample-event-percentage* is a positive number less than or equal to 100. For example, SAMPPCTEVT=50.5 specifies that you want to sample 50.5% of the rare events.

You can specify the following *option* only for *k*-fold partitioning:

KFOLD=*k*
specifies the number of folds you want to partition the data into, where *k* is a positive integer greater than or equal to 2.

BY Statement

BY *variable* < *variable . . . variable* > **;**

The BY statement specifies classification variables to use for stratification. There is no limit on the BY variables for stratified sampling or *k*-fold partitioning, but only one BY variable is allowed for oversampling. If the TARGET statement is specified, each target variable is combined with the BY variables for stratification in order to perform stratified partitioning.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1275. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value*	specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.
key	specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1275. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

FREQ Statement

FREQ *variable* **;**

The FREQ statement specifies a numeric variable in the data set that contains the frequency of occurrence of each observation. In simple random sampling, stratified sampling, and oversampling, the PARTITION procedure treats each observation as if it appears f times, where f is the value of the FREQ statement variable for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used for sampling or partitioning. When you omit this statement, each observation is assigned a frequency of 1.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *options* > **;**

The OUTPUT statement creates a data table to contain the sampled observations and stratification information for the sample.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC PARTITION to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1266.

data-table specifies the name of the output data table.

This table includes variables that are specified in the COPYVARS= option. In the K-fold partition case, the output includes one more column, _Fold_. In other cases, if you also specify the PARTIND option in the PROC PARTITION statement, the output includes one more column, _PartInd_. In the oversampling case, an additional column, _Freq_, is provided. It is calculated as the ratio of target level's proportion in the population to its proportion in the sample. _Fold_, _PartInd_ and _Freq_ are reserved names. If they exist in the input data table and you specify them in the COPYVARS= option, you need to use the FOLDNAME=, PARTINDNAME= and FREQNAME= options to change the generated columns' names.

You can also specify the following *options*:

COPYVAR=*variable*

COPYVARS=(*variables***)**

lists one or more variables from the input data table to be transferred to the output data table.

If the COPYVARS= option is not specified, all the variables in the input data table are transferred to the output data table.

FOLDNAME=*fold-name*

renames the output data table's _Fold_ column (which is generated when *k*-fold partitioning is requested) to the specified *fold-name*.

FREQNAME=*freq-name*

renames the output data table's _Freq_ column (which is generated when oversampling is requested) to the specified *freq-name*.

PARTINDNAME=*partition-indicator-name*

renames the generated partition indicator, _PartInd_, in the output data table to the specified *partition-indicator-name.*

SAMPLEFREQNAME=*sample-frequency-name*

renames the generated sample frequency variable, _SampleFreq_, in the output data table by using the specified *sample-frequency-name.*

TARGET Statement

TARGET *variable* < / **LEVEL=NOMINAL** | **INTERVAL** > **;**

If BY (segment) variables are present, the TARGET statement performs segment-stratified partitioning for each target variable as follows: each nominal target variable is combined with the BY variables for stratification; for each interval target variable, only the BY variables are used for stratification. If BY (segment) variables are not present, the TARGET statement performs stratified partitioning for each nominal target variable and simple random sampling for each interval target variable. If target variables or BY variables have lots of levels, the memory consumption can be huge and an insufficient memory issue might occur. In this case, decreasing the number of threads by using NTHREADS= option in the PROC PARTITION statement might help because memory consumption depends on the number of threads.

You can specify the following option:

LEVEL=NOMINAL | INTERVAL

specifies the level of measurement. You can specify the following values:

NOMINAL specifies that the level of measurement of the variables is nominal.

INTERVAL specifies that the level of measurement of the variables is interval.

By default, LEVEL=INTERVAL for numeric variables and LEVEL=NOMINAL for categorical variables.

Details: PARTITION Procedure

Folds

You can use the PARTITION procedure to partition the input data table into equal-size disjoint subsets for *k*-fold cross validation. When you specify the number of folds *k* in the KFOLD= option, the _Fold_ column in the output data table shows which fold each observation is selected to. _Fold_ takes values between 1 and *k*.

Training, Validation, and Test Data

You can use the PARTITION procedure to partition the input data table into disjoint subsets for model training, validation, and testing. When you specify the percentages for training and testing partitions in the SAMPPCT= and SAMPPCT2= options, the _PartInd_ indicator shows whether each observation is selected to the training partition (1) or the testing partition (2), respectively. The remaining observations are assigned 0 for _PartInd_ and belong to the validation partition.

Classification Level

For classification variables, a classification level is an observed value that is distinct after beginning and ending white space have been removed. For example, the values "**`MyLevel`**" and "**`MYLEVEL`**" are treated as different levels in the data table. But," a" and "a " are treated as the same level.

Displayed Output

The following sections describe the output that PROC PARTITION produces. The output is organized into various tables, which are discussed in the order of their appearance.

Frequency Information Table

For simple random sampling, the "Simple Random Sampling Frequency" table lists the number of observations in the input data table and in the sample output data table.

For stratified sampling, the "Stratified Sampling Frequency" table lists the respective frequency in each stratum for the input data and the sample. If one BY variable is specified, each level of the BY variable represents a stratum; if two BY variables are specified, a combination of the levels of two BY variables represents a stratum.

For oversampling, the "Oversampling Frequency" table lists the number of observations in each stratum for the input data and the sample.

For *k*-fold partitioning, the "*k*-Fold Partition Frequency" table lists the input data size and fold sizes. Depending on whether you specify "options VALIDVARNAME=V7;" or "options VALIDVARNAME=ANY;", the names of the NFold variables in the frequency table KFOLDFreq are different. If you specify "options VALIDVARNAME=V7;", the names of the NFold variables in the frequency table KFOLDFreq are "NFold_i", where i is the fold number. If you specify "options VALIDVARNAME=ANY;", the names are "NFold i", where i is the fold number.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the PARTITION procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement or ODS statements. These names are listed in Table 24.1.

Table 24.1 ODS Tables Produced by PROC PARTITION

Table Name	Description	Statements	Option
KFOLDFreq	Frequency table of input data size and fold sizes	PROC PARTITION	KFOLD=
OutputCasTables	See the section "OutputCasTables Table" on page 1275	OUTPUT	OUT=

Table 24.1 *continued*

Table Name	Description	Statements	Option
OVERFreq	Frequency table of input data size and sample size in different levels of the BY variable for the oversampling level of the BY variable (this table is produced for oversampling)	PROC PARTITION	EVENT =
PartIndMap	Table that maps each partition indicator to each target (this table is produced for segment-stratified sampling for each target variable)	TARGET	Default
SampleFreqMap	Table that maps each sample frequency to each target	TARGET, FREQ	Default
SRSFreq	Frequency table of input data size and sample size (this table is produced for simple random sampling)	PROC PARTITION	Default
STRAFreq	Frequency table of input data size and sample size in different stratification levels that are defined by BY variables (this table is produced for stratified sampling)	BY	Default

Examples: PARTITION Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 24.1: Simple Random Sampling

(View the complete code for this example (partition_ex1.sas) in the example repository.)

This example demonstrates how to use PROC PARTITION to perform simple random sampling on the mylib.hmeq data table.

You can load the sampsio.hmeq data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements perform the sampling:

```
proc partition data=mylib.hmeq samppct=10 seed=10 nthreads=1;
   output out=mylib.out2 copyvars=(job reason loan value delinq derog);
   display 'SRSFreq';
run;

proc print data=mylib.out2(obs=20);
run;
```

The SAMPPCT=10 option requests that 10% of the input data be sampled. The OUTPUT statement requests that the sampled data be stored in a table named mylib.out2, and the COPYVARS= option lists the variables to be copied from mylib.hmeq to mylib.out2. The DISPLAY statement requests that the SRSFreq ODS table be displayed.

Output 24.1.1 shows the number of observations in the mylib.hmeq data table and the number of samples in the mylib.out2 data table .

Output 24.1.1 Frequency Information Table

The PARTITION Procedure

Simple Random Sampling Frequency	
Number of Obs	Number of Samples
5960	596

Output 24.1.2 shows the sample data, which are stored in the mylib.out2 data table.

Output 24.1.2 Sample Data

Example 24.2: Stratified Sampling

(View the complete code for this example (partition_ex2.sas) in the example repository.)

This example demonstrates how to use PROC PARTITION to perform stratified sampling to partition the data; it uses the same data table as is used in Example 24.1.

You can load the sampsio.hmeq data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements perform the partitioning:

```
proc partition data=mylib.hmeq samppct=10 samppct2=20 seed=10 partind nthreads=3;
   by BAD;
   output out=mylib.out3 copyvars=(job reason loan value delinq derog);
run;

proc print data=mylib.out3(obs=20);
run;
```

The SAMPPCT=10 option requests that 10% of the input data be included in the training partition, and the SAMPPCT2=20 option requests that 20% of the input data be included in the testing partition. The SEED=

option specifies 10 as the random seed to be used in the partitioning process. The PARTIND option requests that the output data table, mylib.out3, include an indicator that shows whether each observation is selected to a partition (1 for training or 2 for testing) or not (0). The OUTPUT statement requests that the sampled data be stored in a table named mylib.out3, and the COPYVARS= option lists the variables to be copied from mylib.hmeq to mylib.out3.

Output 24.2.1 shows the frequency information for each level of the BY variable BAD in the mylib.out3 data table.

Output 24.2.1 Frequency Information Table

The PARTITION Procedure

Stratified Sampling Frequency

Index	BAD	Number of Obs	Sample Size 1	Sample Size 2
0	0	4771	477	954
1	1	1189	119	238

Output 24.2.2 shows the first 20 output sample observations in mylib.out3; the _PartInd_ column shows which partition the observation is selected for (1 for training or 2 for testing) or none (0).

Output 24.2.2 Sample Output with Partition Indicator

Example 24.3: Oversampling

(View the complete code for this example (partition_ex3.sas) in the example repository.)

This example demonstrates how to use PROC PARTITION to perform oversampling; it uses the same data table as in Example 24.1.

You can load the sampsio.hmeq data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements perform oversampling:

```
proc partition data=mylib.hmeq samppctevt=90 eventprop=0.5
               event="1" seed=10 nthreads=1;
   by BAD;
   ods output OVERFREQ=outFreq;
   output out=mylib.out4 copyvars=(job loan value delinq derog)
          freqname=_Freq2_;
run;

proc print data=mylib.out4(obs=20);
run;
```

The EVENTPROP=0.5 option specifies that 50% of the sample are rare events. The SAMPPCTEVT=90 option requests that 90% of the rare events be sampled. The EVENT="1" option specifies that the second level of the variable BAD corresponds to a rare event. The OUTPUT statement requests that the sampled data be stored in a table named mylib.out4, specifies the variables to be transferred from the input data table, requests that the _Freq_ column be renamed to _Freq2_.

Output 24.3.1 shows the number of observations in the sample and in each level of the BY variable BAD in the mylib.out4 data table.

Output 24.3.1 Frequency Information Table

The PARTITION Procedure

Oversampling Frequency

Index	BAD	Number of Obs	Number of Samples
0	0	4771	1070
1	1	1189	1070

Output 24.3.2 shows the first 20 output sample observations in the mylib.out4 data table; the _Freq2_ column shows the ratio of target level's proportion in the population to its proportion in the sample.

Output 24.3.2 Output Data Table

Example 24.4: *k*-Fold Partitioning

(View the complete code for this example (partition_ex4.sas) in the example repository.)

This example demonstrates how to use PROC PARTITION to perform stratified *k*-fold partitioning to partition the data; it uses the same data table as is used in Example 24.1.

You can load the sampsio.hmeq data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements perform the partitioning:

```
proc partition data=mylib.hmeq kfold=10 seed=10 nthreads=3;
   by BAD;
   output out=mylib.out5 copyvars=(job reason loan value delinq derog);
run;

proc print data=mylib.out5(obs=20);
run;
```

The KFOLD=10 option requests that the input data be partitioned to 10 equal-size folds within each level of the BY variable BAD. The SEED= option specifies 10 as the random seed to be used in the partitioning

process. The OUTPUT statement requests that the sampled data be stored in a table named mylib.out5, and the COPYVARS= option lists the variables to be copied from mylib.hmeq to mylib.out5. The output data table, mylib.out5, includes an indicator that shows which fold each observation is selected to.

Output 24.4.1 shows the frequency information for each level of the BY variable BAD in the mylib.out5 data table.

Output 24.4.1 Frequency Information Table

The PARTITION Procedure

k-Fold Partition Frequency

Example 24.5: Segment-Stratified Sampling for Each Target

(View the complete code for this example (partition_ex5.sas) in the example repository.)

This example demonstrates how to use PROC PARTITION to perform segment-stratified partitioning for each target; it uses the same data table as is used in Example 24.1.

You can load the sampsio.hmeq data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements perform the partitioning:

```
proc partition data=mylib.hmeq samppct=10 samppct2=20 seed=10 nthreads=3;
   by bad;
   target job reason;
   output out=mylib.out3 copyvars=(job reason loan value delinq derog);
run;

proc print data=mylib.out3(obs=20);
run;
```

The SAMPPCT=10 option requests that 10% of the input data be included in the training partition, and the SAMPPCT2=20 option requests that 20% of the input data be included in the testing partition. The SEED= option specifies 10 as the random seed to be used in the partitioning process. The BY statement requests that the BY variable bad be used as the segmentation variable. The TARGET statement requests that stratified sampling be performed for each target variable job and reason in each segment level. The OUTPUT statement requests that the sampled data be stored in a table named mylib.out3, and the COPYVARS= option lists the variables to be copied from mylib.hmeq to mylib.out3. The output data table, mylib.out3, includes two indicators that show whether each observation is selected to a partition (1 for training, 2 for testing, or 0 for not selected) for each target variable in each segment level in the BY variable bad.

Output 24.5.1 shows the frequency information for each level combination of the BY variable bad and each target variable in the mylib.out3 data table.

Output 24.5.1 Frequency Information Table

The PARTITION Procedure

Example 24.6: Segment-Stratified Sampling for Each Target Using the FREQ Statement

(View the complete code for this example (partition_ex6.sas) in the example repository.)

This example demonstrates how to use PROC PARTITION to perform segment-stratified partitioning for each target with the FREQ statement. It uses the same data table as in Example 24.1.

You can load the sampsio.hmeq data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
   id = _N_;
   freqVar = 10;
run;
```

Note that the frequency variable freqVar is set to 10 for all the observations in the hmeq data set in the CAS engine libref mylib.

The following statements perform the partitioning:

```
proc partition data=mylib.hmeq samppct=10 samppct2=20 seed=10;
   by bad;
   target job reason;
   freq freqVar;
   output out=mylib.out6 copyvars=(job reason loan value delinq derog);
run;

proc print data=mylib.out6(obs=20);
run;
```

The SAMPPCT=10 option requests that 10% of the input data be included in the training partition, and the SAMPPCT2=20 option requests that 20% of the input data be included in the testing partition. The SEED= option specifies 10 as the random seed to be used in the partitioning process. The BY statement requests that the BY variable bad be used as the segmentation variable. The TARGET statement requests that stratified sampling be performed for each target variable job and reason in each segment level. The FREQ statement requests that the variable freqVar be used as the frequency variable. In this example, the procedure treats each observation as if it appears 10 times. The OUTPUT statement requests that the sampled data be stored in a table named mylib.out6, and the COPYVARS= option lists the variables to be copied from mylib.hmeq to mylib.out6. The output data table, mylib.out6, also includes one partition indicator variable that shows whether each observation is selected for a partition (1 for training, 2 for testing, or 0 for not selected), as well as two sample frequency variables (one for each target variable in each segment level in the BY variable bad).

Output 24.6.1 shows the frequency information for each level combination of the BY variable bad and each target variable in the mylib.out6 data table.

Output 24.6.1 Frequency Information Table

The PARTITION Procedure

Stratified Sampling Frequency

Target Name	Target Level	BAD	Number of Obs	Sample Size 1	Sample Size 2
JOB		0	2560	256	512
JOB	Mgr	0	5880	588	1176
JOB	Office	0	8230	823	1646
JOB	Other	0	18340	1834	3668
JOB	ProfExe	0	10640	1064	2128
JOB	Sales	0	710	71	142

REASON	DebtCon	1	7450	745	1490
REASON	HomeImp	1	3960	396	792

Output 24.6.2 shows the map of each sample frequency to each target variable.

Output 24.6.2 Sample Frequency Map

Sample Frequency Map

Sample Frequency Name	Target Name
SampleFreq1	JOB
SampleFreq2	REASON

Output 24.6.3 shows the first 20 output sample observations in mylib.out6. Each observation is duplicated by three rows in the output, with the _PartInd_ column showing which partition each observation is selected for (1 for training, 2 for testing, or 0 for not selected). The _SampleFreq1_ column shows the sample frequency for each partition for the target variable job. The _SampleFreq2_ column shows the sample frequency for each partition for the target variable reason. Note that the rows for which all the _SampleFreq_ columns have a value of 0 are not included in the output.

Output 24.6.3 Sample Output with Partition Indicator

Obs	JOB	REASON	LOAN	VALUE	DELINQ	DEROG	_PartInd_	_SampleFreq1_	_SampleFreq2_

Overview: PCA Procedure

The PCA procedure performs principal component analysis in SAS Viya.

Principal component analysis is a multivariate technique for examining relationships among several quantitative variables. It provides an optimal way to reduce dimensionality by projecting the data onto a lower-dimensional orthogonal subspace that explains as much variation as possible in those variables. The choice between using factor analysis and using principal component analysis depends in part on your research objectives. You should use the PCA procedure if you are interested in summarizing data and detecting linear relationships. You can use principal component analysis to reduce the number of variables in regression, clustering, and so on.

PROC PCA Features

The PCA procedure does the following:

- provides a PARTIAL statement for analyzing a partial correlation or covariance matrix
- provides a FREQ statement for grouped analysis
- provides a WEIGHT statement for weighted analysis
- provides a CODE statement for scoring new data
- produces an output data table that contains principal component scores and other observationwise statistics
- produces an output data table that contains means, standard deviations, number of observations, correlations or covariances, eigenvalues, and eigenvectors

- produces a scree plot of eigenvalues and proportion variance explained and a pattern profile plot

The PCA procedure implements the following methods:

- eigenvalue decomposition, which uses the correlation or covariance of the data matrix and calculates all the principal components simultaneously
- the nonlinear iterative partial least squares (NIPALS) method, which uses the data matrix and extracts the principal components successively
- the iterative method based on the Gram-Schmidt orthogonalization (ITERGS) of Andrecut (2009), which uses the data matrix and extracts the principal components successively. The algorithm applies reorthogonalization correction to both the scores and the loadings at each iteration step.
- the iterative method based on random projection (RANDOM) of Halko, Martinsson, and Tropp (2011), which uses the data matrix and extracts all requested principal components simultaneously. Because of the nature of the algorithm, the principal components are an approximation of the actual principal components.

Because the PCA procedure runs on CAS, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode on CAS
- exploits all the available cores and concurrent threads. For information about how PROC PCA uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC PCA Compared with Other SAS Procedures

The PCA procedure provides functionality to perform principal component analysis that is comparable to that of the HPPRINCOMP and PRINCOMP procedures in SAS/STAT software.

PROC PCA Compared with the HPPRINCOMP Procedure

The functionality of the PCA procedure closely resembles that of the HPPRINCOMP procedure, which is a high-performance procedure. The PCA procedure is the next generation of the HPPRINCOMP procedure, and it was developed specifically for SAS Viya. Both procedures are designed to run on a cluster of machines that distribute the data and the computations.

The PCA procedure and the HPPRINCOMP procedure have the similarities and differences shown in Table 25.1.

Table 25.1 Comparison of PROC PCA and PROC HPPRINCOMP

Feature	PROC PCA	PROC HPPRINCOMP
Supports various methods to extract principal components by using the METHOD= option in the PROC statement	Yes	Yes
Supports BY statement	Yes	Yes
Supports DISPLAY and DISPLAYOUT statements	Yes	No
Supports CODE and OUTPUT statements	Yes	Yes
Supports ID statement	No	Yes
Supports PLOTS= option	Yes, with limited number of options	No
Includes input variables in output data table	Not by default, in order to avoid data duplication for large data tables. To include input variables, specify them in the COPYVARS= option in the OUTPUT statement.	Not by default, in order to avoid data duplication for large data sets. To include input variables, specify them in the ID statement.
Threading	Specifically designed for CAS; executes on multiple threads	Primarily designed for a distributed environment; executes on multiple threads

PROC PCA Compared with the PRINCOMP Procedure

The PCA procedure and the PRINCOMP procedure have the similarities and differences shown in Table 25.2.

Table 25.2 Comparison of PROC PCA and PROC PRINCOMP

Feature	PROC PCA	PROC PRINCOMP
Supports various methods to extract principal components by using the METHOD= option in the PROC statement	Yes	No, supports only eigenvalue decomposition
Supports BY statement	Yes	Yes
Supports DISPLAY and DISPLAYOUT statements	Yes	No
Supports CODE and OUTPUT statements	Yes	No
Supports ID statement	No	Yes
Supports PLOTS= option	Limited number of options	Full set of options

Table 25.2 *continued*

Feature	PROC PCA	PROC PRINCOMP
Accepts input data	Only CAS input data tables	Ordinary SAS data sets and certain types of special SAS data sets
Includes input variables in output data table	Not by default, in order to avoid data duplication for large data tables. To include input variables, specify them in the COPYVARS= option in the OUTPUT statement.	Yes
Threading	Specifically designed for CAS; executes on multiple threads	Executes on a single thread

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: PCA Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/pcags.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The following DATA step creates the Crime data table, which provides crime rates per 100,000 people in seven categories for each of the 50 US states in 1977, in your CAS session:

```
data mylib.Crime;
   title 'Crime Rates per 100,000 Population by State';
   input State $1-15 Murder Rape Robbery Assault
         Burglary Larceny Auto_Theft;
   datalines;
Alabama        14.2 25.2  96.8 278.3 1135.5 1881.9 280.7

;
```

These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

The following statements invoke the PCA procedure, which requests a principal component analysis of the data and produces Figure 25.1 through Figure 25.4:

```
proc pca data=mylib.Crime;
run;
```

Figure 25.1 displays the "Model Information," "Number of Variables," "Number of Observations," and "Simple Statistics" tables.

The "Model Information" table identifies the data source and shows that the principal component extraction method is eigenvalue decomposition, which is the default.

The "Number of Variables" table indicates that there are seven variables to be analyzed and seven principal components to be computed. By default, if you omit the VAR statement, all numeric variables that are not listed in other statements are used in the analysis.

The "Number of Observations" table shows that of the 50 observations in the input data, only 48 observations are used in the analysis, because some observations have incomplete data.

The "Simple Statistics" table displays the mean and standard deviation of the analysis variables.

Figure 25.1 Model Information and Simple Statistics

Crime Rates per 100,000 Population by State

The PCA Procedure

Model Information	
Data Source	CRIME
Component Extraction Method	Eigenvalue Decomposition

Number of Variables	7
Number of Principal Components	7

Number of Observations Read	50
Number of Observations Used	48

Simple Statistics

Variable	Mean	Standard Deviation
Murder	7.51667	3.93059
Rape	26.07500	10.81304
Robbery	127.55625	88.49374
Assault	214.58750	100.64360
Burglary	1316.37917	423.31261
Larceny	2696.88542	714.75023
Auto_Theft	383.97917	194.37033

Figure 25.2 displays the "Correlation Matrix" table. By default, the PROC PCA statement requests that principal components be computed from the correlation matrix, so the total variance is equal to the number of variables, 7.

Figure 25.2 Correlation Matrix Table

Correlation Matrix

Variable	Murder	Rape	Robbery	Assault	Burglary	Larceny	Auto_Theft
Murder	1.0000	0.6000	0.4768	0.6485	0.3778	0.0925	0.0555
Rape	0.6000	1.0000	0.5817	0.7316	0.7038	0.6009	0.3282
Robbery	0.4768	0.5817	1.0000	0.5452	0.6200	0.4371	0.5787
Assault	0.6485	0.7316	0.5452	1.0000	0.6082	0.3791	0.2520
Burglary	0.3778	0.7038	0.6200	0.6082	1.0000	0.7932	0.5390
Larceny	0.0925	0.6009	0.4371	0.3791	0.7932	1.0000	0.4246
Auto_Theft	0.0555	0.3282	0.5787	0.2520	0.5390	0.4246	1.0000

Figure 25.3 displays the "Eigenvalues" table. The first principal component accounts for about 57.8% of the total variance, the second principal component accounts for about 18.1%, and the third principal component accounts for about 10.7%. Note that the eigenvalues sum to the total variance.

The eigenvalues indicate that two or three components provide a good summary of the data: two components account for 76% of the total variance, and three components account for 87%. Subsequent components account for less than 5% each.

Figure 25.3 Eigenvalues Table

Eigenvalues of the Correlation Matrix				
	Eigenvalue	Difference	Proportion	Cumulative
1	4.045824	2.781795	0.5780	0.5780
2	1.264030	0.516529	0.1806	0.7586
3	0.747500	0.421175	0.1068	0.8653
4	0.326325	0.061119	0.0466	0.9120
5	0.265207	0.036843	0.0379	0.9498
6	0.228364	0.105613	0.0326	0.9825
7	0.122750		0.0175	1.0000

Figure 25.4 displays the "Eigenvectors" table. From the eigenvectors matrix, you can represent the first principal component, Prin1, as a linear combination of the original variables:

$$\begin{aligned}\text{Prin1} = &-0.30289 \times (\text{Murder}) \\ &- 0.43410 \times (\text{Rape}) \\ &- 0.39705 \times (\text{Robbery}) \\ &\vdots \\ &- 0.28834 \times (\text{Auto\_Theft})\end{aligned}$$

Similarly, the second principal component, Prin2, is

$$\begin{aligned}\text{Prin2} = &\ 0.61893 \times (\text{Murder}) \\ &+ 0.17053 \times (\text{Rape}) \\ &- 0.04713 \times (\text{Robbery}) \\ &\vdots \\ &- 0.50400 \times (\text{Auto\_Theft})\end{aligned}$$

where the variables are standardized.

Figure 25.4 Eigenvectors Table

Eigenvectors							
Variable	**Prin1**	**Prin2**	**Prin3**	**Prin4**	**Prin5**	**Prin6**	**Prin7**
Murder	-0.30289	0.61893	0.17353	-0.23308	-0.54896	0.26371	-0.26428
Rape	-0.43410	0.17053	-0.23539	0.06540	-0.18075	-0.78232	0.27946
Robbery	-0.39705	-0.04713	0.49208	-0.57470	0.50808	-0.09452	0.02497
Assault	-0.39622	0.35142	-0.05343	0.61743	0.51525	0.17395	-0.19921
Burglary	-0.44164	-0.20861	-0.22454	-0.02750	-0.11273	0.52340	0.65085
Larceny	-0.35634	-0.40570	-0.53681	-0.23231	-0.02172	0.04085	-0.60346
Auto_Theft	-0.28834	-0.50400	0.57524	0.41853	-0.35939	-0.06024	-0.15487

The first component is a measure of the overall crime rate, because the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high negative loadings on the variables Auto_Theft and Larceny and high positive loadings on the variables Murder and Assault. There is also a small negative loading on the variable Burglary and a small positive loading on the variable Rape. This component seems to measure the preponderance of property crime compared to violent crime. The interpretation of the third component is not obvious.

Syntax: PCA Procedure

The following statements are available in the PCA procedure:

```
PROC PCA < options > ;
    BY variables ;
    CODE < options > ;
    DISPLAY < table-list > < / options > ;
    DISPLAYOUT table-spec-list < / options > ;
    FREQ variable ;
    OUTPUT OUT=libref.data-table
           < COPYVARS=(variables) >
           < keyword < =prefix > >. . . < keyword < =prefix > > ;
    PARTIAL variables ;
    STORE < OUT= >libref.data-table ;
    VAR variables ;
    WEIGHT variable ;
```

The rest of this section provides detailed syntax information about each of the preceding statements, beginning with the PROC PCA statement. The remaining statements are described in alphabetical order.

PROC PCA Statement

```
PROC PCA < options > ;
```

The PROC PCA statement invokes the PCA procedure. Optionally, it also identifies the input and output data sets, specifies the analyses to be performed, and controls displayed output. Table 25.3 summarizes the options available in the PROC PCA statement.

Table 25.3 PROC PCA Statement Options

Option	Description
Specify Data Sets	
DATA=	Specifies the input data table
OUTSTAT=	Specifies the output data table that contains various statistics
Specify Details of Analysis	
COV	Computes the principal components from the covariance matrix

Table 25.3 *continued*

Option	Description
GPU	Uses graphics processing units (GPUs) to perform model computation
METHOD=	Specifies the principal component extraction method to be used
N=	Specifies the number of principal components to be computed
NOINT	Omits the intercept from the model
PARPREFIX=	Specifies a prefix for naming the residual variables
PREFIX=	Specifies a prefix for naming the principal components
SINGULAR=	Specifies the singularity criterion
STD	Standardizes the principal component scores
VARDEF=	Specifies the divisor to use for calculating variances and standard deviations
Specify ODS Graphics Details	
PLOTS=	Specifies options that control the details of the plots

The following list provides details about these *options*.

COVARIANCE

COV

computes the principal components from the covariance matrix. If you omit this option, the correlation matrix is analyzed. The COV option causes variables that have large variances to be more strongly associated with components that have large eigenvalues, and it causes variables that have small variances to be more strongly associated with components that have small eigenvalues. You should not specify this option unless the units in which the variables are measured are comparable or the variables are standardized in some way.

DATA=*libref.data-table*

names the input data table for PROC PCA to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1293.

data-table specifies the name of the input data table.

GPU

enables PROC PCA to use graphics processing units (GPUs) to perform model computation on GPU-equipped machines (one GPU is used on each machine). Currently the eigenvalue decomposition (EIG) method, the nonlinear iterative partial least squares (NIPALS) method, and the iterative method based on random projection (RANDOM) support this option. If you specify any other principal component extraction method or specify the BY statement or PARTIAL statement, the GPU option is ignored. If no GPU is available, the CPU is used to perform model computation.

PROC PCA uses CUDA 11.8, and the NVIDIA V100 and P100 GPUs are supported.[1]

METHOD=EIG | ITERGS< (*iter-options*) > | NIPALS< (*nipals-options*) > | RANDOM< (*rand-options*) >
specifies the principal component extraction method to be used. You can specify the following values:

EIG
requests eigenvalue decomposition.

ITERGS< (*iter-options*) >
requests the iterative method based on Gram-Schmidt orthogonalization (ITERGS) of Andrecut (2009). You can specify the following *iter-options*.

EPSILON=*n*
specifies the convergence criterion for the iterative method. By default, EPSILON=1E–12.

MAXITER=*n*
specifies the maximum number of iterations for the iterative method. By default, MAXITER=500.

NOCENTER
suppresses centering of the numeric variables to be analyzed. This option is useful if the analysis variables are already centered and scaled.

NOSCALE
suppresses scaling of the numeric variables to be analyzed. This option is useful if the analysis variables are already centered and scaled.

NIPALS< (*nipals-options*) >
requests the nonlinear iterative partial least squares (NIPALS) method. You can specify the following *nipals-options*.

EPSILON=*n*
specifies the convergence criterion for the iterative method. By default, EPSILON=1E–12.

MAXITER=*n*
specifies the maximum number of iterations for the iterative method. By default, MAXITER=500.

NOCENTER
suppresses centering of the numeric variables to be analyzed. This option is useful if the analysis variables are already centered and scaled.

NOSCALE
suppresses scaling of the numeric variables to be analyzed. This option is useful if the analysis variables are already centered and scaled.

[1] The version information and corresponding GPU architectures depend on your SAS Viya version. Make sure that you are consulting the correct version of the documentation for your specific SAS Viya version.

RANDOM< (*rand-options*) >
requests the iterative method based on random projection (RANDOM) of Halko, Martinsson, and Tropp (2011). You can specify the following *rand-options*.

NITER=*n*
specifies the number of iterations. By default, NITER=1.

NOCENTER
suppresses centering of the numeric variables to be analyzed. This option is useful if the analysis variables are already centered and scaled.

NOSCALE
suppresses scaling of the numeric variables to be analyzed. This option is useful if the analysis variables are already centered and scaled.

SEED=*number*
specifies an integer as the seed value for pseudorandom number generation. PROC PCA uses random values to initialize the Gaussian random projection matrix. If you do not specify this option or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock. By default, SEED=0.

By default, METHOD=EIG. If you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM, the following options in the PROC PCA statement are not supported: COV, NOINT, OUTSTAT=, PARPREFIX=, SINGULAR=, and STD.

N=*number*
specifies the number of principal components to be computed. If you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=EIG, the default is the number of variables. If you specify METHOD=RANDOM, the default is 1. The *number* must be an integer greater than or equal to 0. If N=0, the default is used.

NOINT
omits the intercept from the model. In other words, this option requests that the covariance or correlation matrix not be corrected for the mean. When you specify this option, the covariance matrix and, hence, the standard deviations are not corrected for the mean. If you want to obtain the standard deviations corrected for the mean, you can obtain them by using a procedure such as PROC MEANS in Base SAS.

OUTSTAT=*libref.data-table*
creates an output data table to contain means, standard deviations, number of observations, correlations or covariances, eigenvalues, and eigenvectors. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1293.

If you specify the COV option, the output data table contains a covariance matrix, and the corresponding _TYPE_ variable value is `'COV'` or `'UCOV'`, depending on the value of the NOINT option; otherwise, the output data table contains a correlation matrix, and the corresponding _TYPE_ variable value is `'CORR'` or `'UCORR'`, depending on the value of the NOINT option. If you specify the PARTIAL statement, the OUTSTAT= data table also contains R-squares.

For more information about the OUTSTAT= data table, see the section "OUTSTAT= Data Table" on page 1313.

PLOTS <(*global-plot-options*)> <= *plot-request* <(*options*)> >

PLOTS <(*global-plot-options*)> <= (*plot-request* <(*options*)> <... *plot-request* <(*options*)> >) >

controls the plots that are produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around it. Some examples follow:

```
plots
plots=none
plots=(eigen profile)
plots(unpack)=scree
plots=pattern(ncomp=3 circles=25 50 75 1)
```

ODS Graphics must be enabled before you can request plots. For example:

```
ods graphics on;
proc pca plots=all;
   var x1--x10;
run;
ods graphics off;
```

You must specify the PLOTS option in order for the PCA procedure to produce plots. If you do not specify a *plot-request*, PROC PCA produces the scree plot by default.

You can specify the following *global-plot-options*:

UNPACKPANEL

UNPACK

suppresses paneling in the scree plot. By default, multiple plots can appear in an output panel. Specify UNPACKPANEL if you want each plot to appear in a separate panel. You can specify PLOTS(UNPACKPANEL) to unpack the default plots. You can also specify UNPACKPANEL as a suboption of the SCREE option (such as PLOTS=SCREE(UNPACKPANEL)).

You can specify the following *plot-requests*:

ALL

produces all appropriate plots. You can specify other options along with ALL; for example, to request all plots and unpack only the scree plot, specify PLOTS=(ALL SCREE(UNPACKPANEL)).

EIGEN <(UNPACKPANEL)>

EIGENVALUE <(UNPACKPANEL)>

SCREE <(UNPACKPANEL)>

produces the scree plot of eigenvalues and proportion variance explained. By default, both plots appear in the same panel. Specify PLOTS= SCREE(UNPACKPANEL) if you want each plot to appear in a separate panel.

NONE
suppresses the display of all plots.

PATTERN < (*pattern-options*) >
produces the pairwise component pattern plots. Each variable is plotted as an observation whose coordinates are correlations between the variable and the two corresponding components in the plot. Use the NCOMP= option (for example, PLOTS=PATTERN(NCOMP=3)) as described in the following list to control the number of plots to display.

You can specify the following *pattern-options*:

CIRCLES < =*number-list* >
plots the variance percentage circles. For each number c ($0 < c \leq 1$) that you specify, a ($c \times 100\%$) variance circle is displayed. For each number c ($c > 1$) that you specify, a $c\%$ variance circle is displayed. You can specify either CIRCLES=0.05 1 or CIRCLES=5 100 to display 5% and 100% variance circles. PLOTS=PATTERN(CIRCLES) and PLOTS=PATTERN(VECTOR) both display a unit circle (100% variance). By default, no circle is displayed when you specify PLOTS=PATTERN.

FLIP
interchanges (flips) the X-axis and Y-axis dimensions of the component pattern plots.

NCOMP=*n*
specifies the number of components n (≥ 2) to be plotted. The default is 5 or the total number of components m (≥ 2), whichever is smaller. If $n > m$, NCOMP=m is used. Be aware that the number of plots ($n \times (n-1)/2$) that are produced grows quadratically when *n* increases.

VECTOR
plots the pattern in a vector form.

PATTERNPROFILE

PROFILE
produces the pattern profile plot. Each component has its own profile. The Y-axis value represents the correlation between the variable (corresponding to the X-axis value) and the profiled principal component.

PREFIX=*name*
specifies a prefix for naming the principal components. By default, the *names* are Prin1, Prin2, ..., Prin*n*. If you specify PREFIX=Abc, the components are named Abc1, Abc2, Abc3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables should not exceed the current name length that is defined by the VALIDVARNAME= system option.

PARPREFIX=*name*

PPREFIX=*name*

RPREFIX=*name*
specifies a prefix for naming the residual variables in the OUTSTAT= data table. By default, the prefix is R_. The number of characters in the prefix plus the maximum length of the variable names should not exceed the current name length that is defined by the VALIDVARNAME= system option.

SINGULAR=*p*

SING=*p*

specifies the singularity criterion, where $0 < p < 1$. If a variable in a PARTIAL statement has an R-square as large as $1 - p$ when predicted from the variables listed before it in the statement, the variable is assigned a standardized coefficient of 0. By default, SINGULAR=1E–8.

STANDARD

STD

standardizes the principal component scores in the OUT= data table in the OUTPUT statement to unit variance. If you omit this option, the scores have a variance equal to the corresponding eigenvalue. Note that this option has no effect on the eigenvalues themselves.

VARDEF=DF | N | WDF | WEIGHT | WGT

specifies the divisor to be used to calculate variances and standard deviations. By default, VARDEF=DF. The following table displays the values and associated divisors:

Value	Divisor	Formula	
DF	Error degrees of freedom	$n - i$	(before partialing)
		$n - p - i$	(after partialing)
N	Number of observations	n	
WEIGHT | WGT	Sum of weights	$\sum_{j=1}^{n} w_j$	
WDF	Sum of weights minus one	$\left(\sum_{j=1}^{n} w_j\right) - i$	(before partialing)
		$\left(\sum_{j=1}^{n} w_j\right) - p - i$	(after partialing)

In the formulas for VARDEF=DF and VARDEF=WDF, p is the number of degrees of freedom of the variables in the PARTIAL statement, and i is 0 if you specify the NOINT option and 1 otherwise.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC PCA to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CODE Statement

CODE < *options* > **;**

The CODE statement writes SAS DATA step code for computing the principal component scores either to a file, to a catalog entry, or to a data table. To score new data, you can then include the file in a DATA step, or you can specify the table in the **runCodeTable** action in the **dataStep** action set (for more information, see *SAS Viya: System Programming Guide*).

The CODE statement is not supported when you specify the PARTIAL statement. If you specify more than one CODE statement, only the first one specified is used.

Table 25.4 summarizes the *options* available in the CODE statement.

Table 25.4 CODE Statement Options

Option	Description
COMMENT	Adds comments to the generated code
FILE=	Names the file in which to save the generated code
FORMATWIDTH=	Specifies the numeric format width for the regression coefficients
INDENTSIZE=	Specifies the number of spaces to indent the generated code
LABELID=	Specifies a number used to construct names and labels
LINESIZE=	Specifies the line size for the generated code
NOTRIM	Compares formatted values, including blank padding
OUT=	Names an output table in which to save the generated code

For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1317. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value* specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1317. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC PCA treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1.

The FREQ statement is not supported if you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM in the PROC PCA statement.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < **=***prefix* > >. . . < *keyword* < **=***prefix* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics, which are computed after PROC PCA fits the model. If you do not specify a *keyword*, then only the principal component scores are included.

The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option are included.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC PCA to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1293.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

COPYVAR=*variable*

COPYVARS=(*variables***)**

transfers one or more *variables* from the input data table to the output data table.

keyword **< =***prefix* **>**

specifies a statistic to include in the output data table and optionally a *prefix* for naming the output variables. If you do not provide a *prefix*, the PCA procedure assigns a default prefix based on the type of statistic requested. For example, for the VAR statement variables x1 and x2, RESIDUAL produces two residual value variables, R_x1 and R_x2.

You can specify the following *keywords* to add statistics to the OUTPUT data table:

H

requests the approximate leverage. The default prefix is H.

STD

requests standardized (centered and scaled) VAR statement variable values for each VAR statement variable. The default prefix is Std.

STDSSE

requests the sum of squares of residuals for standardized VAR statement variables. The default prefix is StdSSE.

TSQUARE

T2

requests scaled sum of squares of score values. The default prefix is TSquare.

RESIDUAL

RESID

R

requests residuals for each VAR statement variable. The default prefix is R.

SCORE

requests principal component scores for each principal component. The default prefix is Score.

If you specify METHOD=EIG, the only valid *keywords* are RESIDUAL (if you also specify the PARTIAL statement; PROC PCA computes the residuals by predicting the VAR statement variables from the PARTIAL statement variables) and SCORE. Other *keywords* are ignored. The output variables that contain the principal component scores have mean 0 and a variance equal to the corresponding eigenvalue, unless you specify the STANDARD option to standardize the scores to unit variance. Also, if you specify the COV option, PROC PCA computes the principal component scores from the corrected variables or (if the NOINT option is specified) uncorrected variables rather than from the standardized variables.

The output variables that contain the requested statistic are named as follows, according to the *keyword* that you specify:

- The *keywords* RESIDUAL and STD define an output variable for each VAR statement variable, so the variables that correspond to each VAR statement variable are named by appending the name of the VAR statement variable to the prefix. For example, if the model has the VAR statement variables x1 and x2, then RESIDUAL=R produces the variables R_x1 and R_x2.
- The *keyword* SCORE defines an output variable for each principal component, so the variables that correspond to each successive component are named by appending the component number to the prefix. For example, if the model has three principal components, then SCORE=T produces the variables T1, T2, and T3.
- The *keywords* H, STDSSE, and TSQUARE each define a single output variable, so the variable name matches the prefix.

PARTIAL Statement

PARTIAL *variables* **;**

If you want to analyze a partial correlation or covariance matrix, use the PARTIAL statement to specify the names of the numeric variables to be partialed out. The PCA procedure computes the principal components of the residuals by predicting the VAR statement variables from the PARTIAL statement variables. If you request an OUTSTAT= data table, the residual variables are named by prefixing either the characters R_ (by default) or the string specified in the PARPREFIX= option to the VAR statement variable names.

The PARTIAL statement is not supported if you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM in the PROC PCA statement.

STORE Statement

STORE < **OUT=** >*libref.data-table* **;**

The STORE statement saves the context and results of the statistical analysis. The resulting analytic store has a binary file format that you cannot modify. An example of analytic store technology is to perform a time-consuming analysis and to store its results by using the STORE statement. Later you can perform specific statistical analysis tasks that are based on the saved results of the previous analysis, without having to fit the model again. You can process the contents of the analytic store by using the ASTORE procedure or the **score** action in the **aStore** action set. For more information, see Chapter 4, "ASTORE Procedure" (*SAS Viya: Machine Learning Procedures*).

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1293.

The STORE statement is ignored if you specify the BY statement or the PARTIAL statement.

VAR Statement

VAR *variables* **;**

The VAR statement lists the numeric variables to be analyzed. If you omit the VAR statement, all numeric variables that are not specified in other statements are analyzed.

WEIGHT Statement

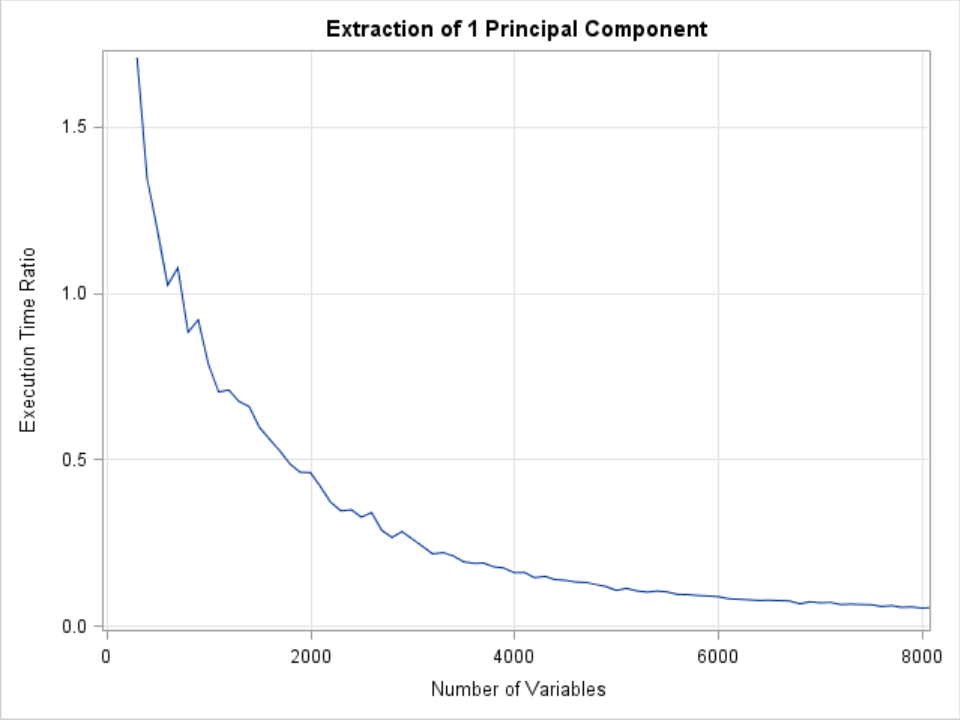
WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

The WEIGHT statement is not supported if you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM in the PROC PCA statement.

Details: PCA Procedure

Computing Principal Components



The PCA procedure implements several methods of calculating principal components: eigenvalue decomposition (EIG), the nonlinear iterative partial least squares (NIPALS) method, the iterative method based on the Gram-Schmidt orthogonalization (ITERGS) of Andrecut (2009), and the iterative method based on random projection (RANDOM) of Halko, Martinsson, and Tropp (2011). The EIG, NIPALS, and ITERGS methods provide exact principal component solutions, whereas the RANDOM method gives approximate principal components.

Each method has computational strengths; Table 25.5 provides guidelines for selecting an efficient (fast) method. The guidelines include the concept of a "small to moderate" and "moderate to large" number of variables. This concept depends on the number of data set observations, the number of principal components required, the PCA method parameter settings, and the grid computing environment. As a simple illustration of the efficiency relationship between the EIG and RANDOM methods, consider a scenario in which one principal component is extracted from a data set that consists of 1,000,000 observations that are distributed across a grid of 16 servers. Figure 25.5 depicts execution time for RANDOM divided by the execution time of EIG (labeled "Execution Time Ratio") as a function of the number of data set variables. Where execution time ratio is greater than 1, EIG is more efficient than RANDOM. For this scenario, "small to moderate" means approximately 700 variables or less and "moderate to large" means anything more than 700 variables.

Table 25.5 Guidelines for PCA Method Selection

Method	Efficient in These Scenarios
EIG	Small to moderate number of variables, and/or computing all principal components
NIPALS	Computing only the first few principal components
ITERGS	Computing only the first few principal components
RANDOM	Moderate to large number of variables

Figure 25.5 Illustration of Efficiency Crossover Point for EIG and RANDOM Methods

Eigenvalue Decomposition

Let $\mathbf{X}$ be a centered and scaled data matrix that has k numeric variables. The eigenvalue decomposition method bases the component extraction on the eigenvalue decomposition of the covariance matrix $\mathbf{X}'\mathbf{X}$, which extracts all the k principal components simultaneously. Each principal component is a linear combination of the original variables, and each component is orthogonal, with coefficients equal to the eigenvectors of the covariance matrix $\mathbf{X}'\mathbf{X}$. The eigenvectors are usually normalized to have unit length. The principal components are sorted by descending order of the eigenvalues, which are equal to the variances of the components.

NIPALS

The nonlinear iterative partial least squares (NIPALS) method extracts the principal components successively based on the data matrix $\mathbf{X}$. The NIPALS method starts by calculating the loadings, $\mathbf{p}$, as $\mathbf{p}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'\mathbf{X}$, where $\mathbf{t}$ is the score vector. It then calculates an improved score vector, $\mathbf{t} = \mathbf{X}\mathbf{p}$. The method iteratively computes the improved $\mathbf{p}$ and $\mathbf{t}$ until convergence is reached.

This process accounts for how the first principal component is extracted. The second component is extracted in the same way, by replacing $\mathbf{X}$ with the residual from the first component: $\mathbf{E} = \mathbf{X} - \mathbf{t}\mathbf{p}'$.

For large data matrices or matrices that have a high degree of column collinearity, the NIPALS method suffers from loss of orthogonality because of the machine-precision errors that accumulate at each iteration step. In practice, the NIPALS method is used to extract only the first few principal components.

ITERGS

The iterative method based on Gram-Schmidt orthogonalization (ITERGS) of Andrecut (2009) overcomes the issue of loss of orthogonality in the NIPALS method by applying Gram-Schmidt reorthogonalization correction to both the loadings and the scores at each iteration step:

$$\begin{aligned} \mathbf{p}_c &= \mathbf{p} - \mathbf{P}_k\mathbf{P}_k'\mathbf{p} \\ \mathbf{t}_c &= \mathbf{t} - \mathbf{T}_k\mathbf{T}_k'\mathbf{t} \end{aligned}$$

Here, $\mathbf{p}_c$ and $\mathbf{t}_c$ are the corrected loading vector and score vector, respectively. $\mathbf{P}_k$ is the matrix that is formed by using the first k loadings. $\mathbf{T}_k$ is the matrix that is formed by using the first k scores.

The ITERGS method stabilizes the iterative process at the cost of increased computational effort.

RANDOM

The iterative method based on random projection (RANDOM) of Halko, Martinsson, and Tropp (2011) computes approximate scores and loadings by using a two-step process. The first step calculates an approximate basis for the range of $\mathbf{X}$ (that is, $\mathbf{X} \approx \mathbf{Q}\mathbf{Q}^T\mathbf{X}$), where $\mathbf{Q}$ has orthonormal columns. The second step computes a sketch of $\mathbf{X}$ from $\mathbf{B} = \mathbf{Q}^T\mathbf{X}$. The singular value decomposition of $\mathbf{B}$ gives an equivalent representation $\tilde{\mathbf{U}}\mathbf{S}\mathbf{V}^T$, and simple manipulations of these matrices provide the approximate loadings $\mathbf{P} = \mathbf{V}$ and the scores $\mathbf{T} = \mathbf{Q}\tilde{\mathbf{U}}\mathbf{S}$.

The iterative part of this method is the construction of the orthonormal basis matrix $\mathbf{Q}$. Conceptually, you can obtain $\mathbf{Q}$ by QR factorization of $\mathbf{Y} = (\mathbf{X}\mathbf{X}^T)^i\mathbf{X}\boldsymbol{\Omega}$, where $\boldsymbol{\Omega}$ is a random Gaussian projection matrix and i is the number of iterations. Here the notion of iteration refers to multiplication of a sample matrix by $\mathbf{X}^T$ and then $\mathbf{X}$. This conceptual approach is susceptible to rounding error, so in practice you orthonormalize the columns of the sample matrix for numerical stability. Here, the initial sample matrix is the subspace defined by the QR factorization of a random projection of the data matrix $\mathbf{X}\boldsymbol{\Omega} = \mathbf{Q}_0\mathbf{R}_0$. Each iteration ($j = 1, 2, \ldots, i$) then consists of alternating projection and orthonormalization steps of

$$\begin{aligned} \tilde{\mathbf{Y}}_j &= \mathbf{X}^T\mathbf{Q}_{j-1} \\ \tilde{\mathbf{Q}}_j\tilde{\mathbf{R}}_j &= \tilde{\mathbf{Y}}_j \end{aligned}$$

and

$$\begin{aligned} \mathbf{Y}_j &= \mathbf{X}\tilde{\mathbf{Q}}_j \\ \mathbf{Q}_j\mathbf{R}_j &= \mathbf{Y}_j \end{aligned}$$

When $j = i$, $\mathbf{Q}_j$ is the desired orthonormal basis matrix.

Missing Values

Observations that have missing values for any variable in the VAR, PARTIAL, FREQ, or WEIGHT statement are omitted from the analysis and are given missing values for principal component scores in the OUT= data table that is specified in the OUTPUT statement.

OUTSTAT= Data Table

The OUTSTAT= data table contains the following variables:

- the BY variables, if any
- two new variables, _TYPE_ and _NAME_, both character variables
- the variables that are analyzed (that is, those in the VAR statement); or, if there is no VAR statement, all numeric variables not listed in any other statement; or, if there is a PARTIAL statement, the residual variables that contain the residuals computed by predicting the VAR statement variables from the PARTIAL statement variables.

Each observation in the new data table contains some type of statistic, as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:

TYPE	Contents
MEAN	mean of each variable. If you specify the PARTIAL statement, this observation is omitted.
STD	standard deviations. If you specify the COV option, this observation is omitted. If you specify the PARTIAL statement, the standard deviation of a variable is computed as its root mean squared error as predicted from the PARTIAL statement variables.
USTD	uncorrected standard deviations. When you specify the NOINT option in the PROC PCA statement, the OUTSTAT= data table contains standard deviations not corrected for the mean. However, if you also specify the COV option in the PROC PCA statement, this observation is omitted.
N	number of observations on which the analysis is based. This value is the same for each variable. If you specify the PARTIAL statement and the value of the VARDEF= option is DF or unspecified, then the number of observations is decremented by the degrees of freedom for the PARTIAL statement variables.

SUMWGT	the sum of the weights of the observations. This value is the same for each variable. If you specify the PARTIAL statement and VARDEF=WDF, then the sum of the weights is decremented by the degrees of freedom for the PARTIAL statement variables. This observation is output only if the value is different from that in the observation for which _TYPE_='N'.
CORR	correlations between each variable and the variable specified by the _NAME_ variable. The number of observations for which _TYPE_='CORR' is equal to the number of variables being analyzed. If you specify the COV option, no _TYPE_='CORR' observations are produced. If you use the PARTIAL statement, then the partial correlations, not the raw correlations, are output.
UCORR	uncorrected correlation matrix. When you specify the NOINT option without the COV option in the PROC PCA statement, the OUTSTAT= data table contains a matrix of correlations not corrected for the means. However, if you also specify the COV option in the PROC PCA statement, this observation is omitted.
COV	covariances between each variable and the variable specified by the _NAME_ variable. _TYPE_='COV' observations are produced only if you specify the COV option. If you specify the PARTIAL statement, the partial covariances, not the raw covariances, are output.
UCOV	uncorrected covariance matrix. When you specify the NOINT and COV options in the PROC PCA statement, the OUTSTAT= data table contains a matrix of covariances not corrected for the means.
EIGENVAL	eigenvalues. If the N= option requests less than the maximum number of principal components, only the specified number of eigenvalues are produced, and missing values fill out the observation.
SCORE	eigenvectors. The _NAME_ variable contains the name of the corresponding principal component as constructed from the PREFIX= option. The number of observations for which _TYPE_='SCORE' equals the number of principal components computed. The eigenvectors have unit length unless you specify the STD option, in which case the unit-length eigenvectors are divided by the square roots of the eigenvalues to produce scores that have unit standard deviations. To obtain the principal component scores, if the COV option is not specified, these coefficients should be multiplied by the standardized data. For the COV option, these coefficients should be multiplied by the centered data. To center and standardize the data, you should use means that are obtained from the observation for which _TYPE_='MEAN' and standard deviations that are obtained from the observation for which _TYPE_='STD'.
USCORE	scoring coefficients to be applied without subtracting the mean from the raw variables. Observations for which _TYPE_='USCORE' are produced when you specify the NOINT option in the PROC PCA statement. To obtain the principal component scores, these coefficients should be multiplied by the data that are standardized by the uncorrected standard deviations obtained from the observation for which _TYPE_='USTD'.
RSQUARED	R-squares for each VAR statement variable as predicted by the PARTIAL statement variables.
B	regression coefficients for each VAR statement variable as predicted by the PARTIAL statement variables. This observation is produced only if you specify the COV option.

STB standardized regression coefficients for each VAR statement variable as predicted by the PARTIAL statement variables. If you specify the COV option, this observation is omitted.

Displayed Output

The following sections describe the output that PROC PCA produces. The output is organized into various tables, which are discussed in their order of appearance.

Model Information

The "Model Information" table displays basic information about the model, including the input data table and the principal component extraction method that is used in the analysis.

Number of Variables

The "Number of Variables" table displays the number of VAR statement variables, the number of PARTIAL statement variables, and the number of principal components to be extracted.

Number of Observations

The "Number of Observations" table displays the number of observations read from the input data table and the number of observations used in the analysis. If you specify a FREQ statement, the table also displays the sum of frequencies read and used.

Simple Statistics

If you specify METHOD=EIG, the PCA procedure produces a "Simple Statistics" table that displays the mean and standard deviation (std) for each variable. If you specify the NOINT option, the uncorrected standard deviation (ustd) is displayed.

Centering and Scaling Information

If you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM, the PCA procedure produces a "Centering and Scaling Information" table that displays the centering and scaling information for each variable.

Explained Variation of Variables

If you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM, the PCA procedure produces an "Explained Variation of Variables" table that displays the fraction of variation that is accounted for in each variable by each successive principal component.

Correlation Matrix

If you specify METHOD=EIG, the PCA procedure produces a "Correlation Matrix" table that displays the correlation matrix or, if you specify the COV option, the covariance matrix.

Regression Statistics

When you specify the PARTIAL statement, the PCA procedure produces a "Regression Statistics" table that displays the R-square and root mean squared error (RMSE) for each VAR statement variable as predicted by the PARTIAL statement variables.

Regression Coefficients

When you specify the PARTIAL statement, the PCA procedure produces a "Regression Coefficients" table that displays standardized regression coefficients or, if you specify the COV option, regression coefficients for predicting the VAR statement variables from the PARTIAL statement variables.

Partial Correlation Matrix

When you specify the PARTIAL statement, the PCA procedure produces a "Partial Correlation Matrix" table that displays the partial correlation matrix or, if you specify the COV option, the partial covariance matrix.

Total Variance

If you specify METHOD=EIG and the COV option, the PCA procedure produces a simple table that displays the total variance.

Eigenvalues

The "Eigenvalues" table displays eigenvalues of the correlation or covariance matrix (if you specify METHOD=EIG) or eigenvalues of the data matrix (if you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM), along with the difference between successive eigenvalues, the proportion of variance explained by each eigenvalue, and the cumulative proportion of variance explained.

Eigenvectors

If you specify METHOD=EIG, the PCA procedure produces an "Eigenvectors" table that displays the eigenvectors.

Loadings

If you specify METHOD=ITERGS, METHOD=NIPALS, or METHOD=RANDOM, the PCA procedure produces a "Loadings" table that displays the loadings.

Timing Information

The "Timing" table displays the elapsed time of each main task of the procedure.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the PCA procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or the Output Delivery System (ODS) statements. These names are listed in Table 25.6.

Table 25.6 ODS Tables Produced by PROC PCA

Table Name	Description	Required Statement / Option
CenScaleInfo	Centering and scaling information	METHOD=ITERGS | NIPALS | RANDOM
Corr	Correlation matrix	METHOD=EIG
Cov	Covariance matrix	METHOD=EIG and COV
Eigenvalues	Eigenvalues	Default output
Eigenvectors	Eigenvectors	METHOD=EIG
Loadings	Loadings	METHOD=ITERGS | NIPALS | RANDOM
ModelInfo	Model information	Default output
NObs	Number of observations read and used	Default output
NVars	Number of variables, partial variables, and principal components	Default output
OutputCasTables	See the section "OutputCasTables Table" on page 1317	DISPLAYOUT statement | OUTPUT statement / OUTSTAT=
ParCorr	Partial correlation matrix	PARTIAL statement
ParCov	Uncorrected partial covariance matrix	PARTIAL statement and COV
RegCoef	Regression coefficients	PARTIAL statement and COV
RSquareRMSE	Regression statistics: R-squares and RMSEs	PARTIAL statement
SimpleStatistics	Simple statistics	METHOD=EIG
StdRegCoef	Standardized regression coefficients	PARTIAL statement
Timing	Absolute and relative times of tasks that are performed by the procedure	Default output
TotalVariance	Total variance	METHOD=EIG and COV
Variation	Explained variation of variables	METHOD=ITERGS | NIPALS | RANDOM

ODS Graphics

You can refer to every graph produced through ODS Graphics by name. The names of the graphs that PROC PCA generates are listed in Table 25.7, along with a description of each graph and the required statements and options.

Table 25.7 Graphics Produced by PROC PCA

ODS Graph Name	Plot Description	Required Statement / Option
PatternPlot	Component pattern plot	PLOTS=PATTERN
PatternProfilePlot	Component pattern profile plot	PLOTS=PATTERNPROFILE
ScreePlot	Scree and variance plots	Default output | PLOTS=SCREE
VariancePlot	Variance proportion-explained plot	PLOTS=SCREE(UNPACKPANEL)

Examples: PCA Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 25.1: Analyzing Mean Temperatures of US Cities

(View the complete code for this example (pcaex1.sas) in the example repository.)

This example analyzes mean daily temperatures of selected US cities in January and July. The following DATA step creates the data:

```
data mylib.Temperature;
   length Cityid $ 2;
   title 'Mean Temperature of Selected Cities in January and July';
   input City $1-15 January July;
   Cityid = substr(City,1,2);
   datalines;
Mobile          51.2 81.6
Phoenix         51.2 91.2
Little Rock     39.5 81.4
Sacramento      45.1 75.2
Denver          29.9 73.0

   ... more lines ...
```

```
Cheyenne        26.6 69.1
;
```

The following statements invoke the PCA procedure, which requests a principal component analysis of these data and outputs the scores to an output data table. The Cityid variable is also included in the output data table (COPYVARS= Cityid).

```
title 'Mean Temperature of Selected Cities in January and July';
proc pca data=mylib.Temperature cov;
   var July January;
   output out=mylib.Scores copyVars=Cityid;
run;
```

Output 25.1.1 displays the PROC PCA output. The standard deviation of January (11.712) is higher than the standard deviation of July (5.128). The COV option in the PROC PCA statement requests that the principal components be computed from the covariance matrix. The total variance is 163.474. The first principal component accounts for about 94% of the total variance, and the second principal component accounts for only about 6%. The eigenvalues sum to the total variance.

Note that January receives a higher loading on Prin1 because it has a higher standard deviation than July. Also note that the PCA procedure calculates the scores by using the centered variables rather than the standardized variables.

Example 25.2: Extracting Principal Components with NIPALS

(View the complete code for this example (pcaex2.sas) in the example repository.)

This example demonstrates the NIPALS method in PROC PCA, which extracts principal components successively. The data that this example uses are from the Getting Started section; they provide crime rates per 100,000 people in seven categories for each of the 50 US states in 1977. The following DATA step generates the data:

```
data mylib.Crime;
   title 'Crime Rates per 100,000 Population by State';
   input State $1-15 Murder Rape Robbery Assault
         Burglary Larceny Auto_Theft;
   datalines;
Alabama        14.2 25.2  96.8 278.3 1135.5 1881.9 280.7
Alaska         10.8 51.6  96.8 284.0 1331.7 3369.8 753.3
Arizona         9.5 34.2 138.2 312.3 2346.1 4467.4 439.5
Arkansas        8.8 27.6  83.2 203.4  972.6 1862.1 183.4
California     11.5 49.4 287.0 358.0 2139.4 3499.8 663.5

   ... more lines ...

Wisconsin       2.8 12.9  52.2  63.7  846.9 2614.2 220.7
Wyoming           .  21.9  39.7 173.9  811.6 2772.2 282.0
;
```

The following statements use PROC PCA to extract principal components by using the NIPALS method, and produce default plots:

```
ods graphics on;

proc pca data=mylib.Crime method=nipals plots;
run;
```

Output 25.2.1 displays the PROC PCA output. The "Model Information" table shows that the NIPALS method is used to extract principal components. The "Explained Variation of Variables" table lists the fraction of variation that is accounted for in each variable by each of the seven principal components. All the variation in each variable is accounted for by seven principal components because there are only seven variables. The eigenvalues indicate that two or three components provide a good summary of the data: two components

account for 76% of the total variance, and three components account for 87%. Subsequent components account for less than 5% each.

Note that in the Getting Started section, the principal components are extracted from the same data by using the eigenvalue decomposition method; the "Eigenvalues" table that is generated there matches the one generated by the NIPALS method. Also, the eigenvectors in the "Eigenvectors" table match the loading factors in the "Loadings" table.

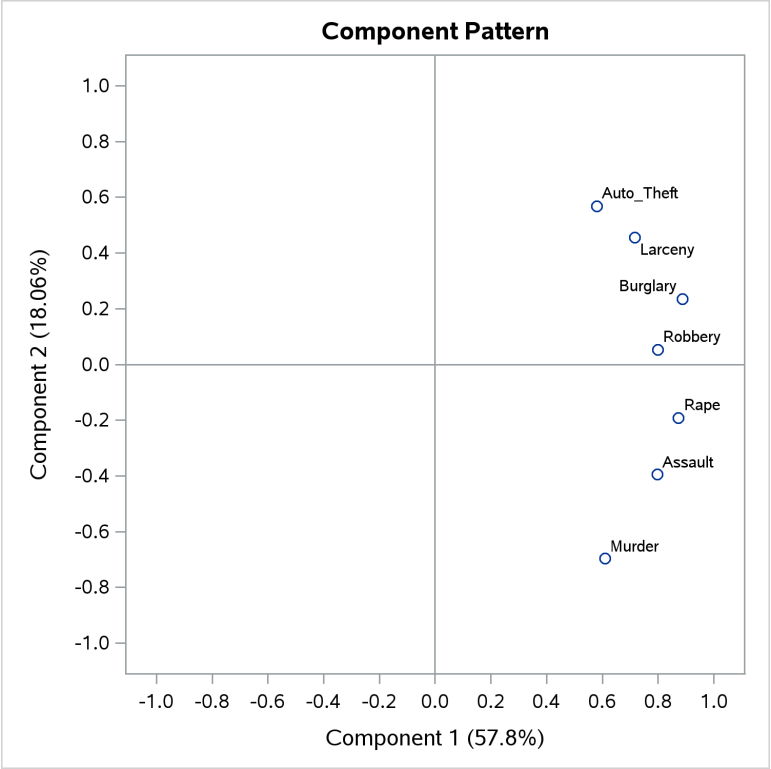
PROC PCA produces the scree plot as shown in Output 25.2.2 by default when ODS Graphics is enabled and no plot request is specified in the PLOTS option. You can obtain more plots by specifying the plot requests in the PLOTS option in the PROC PCA statement.

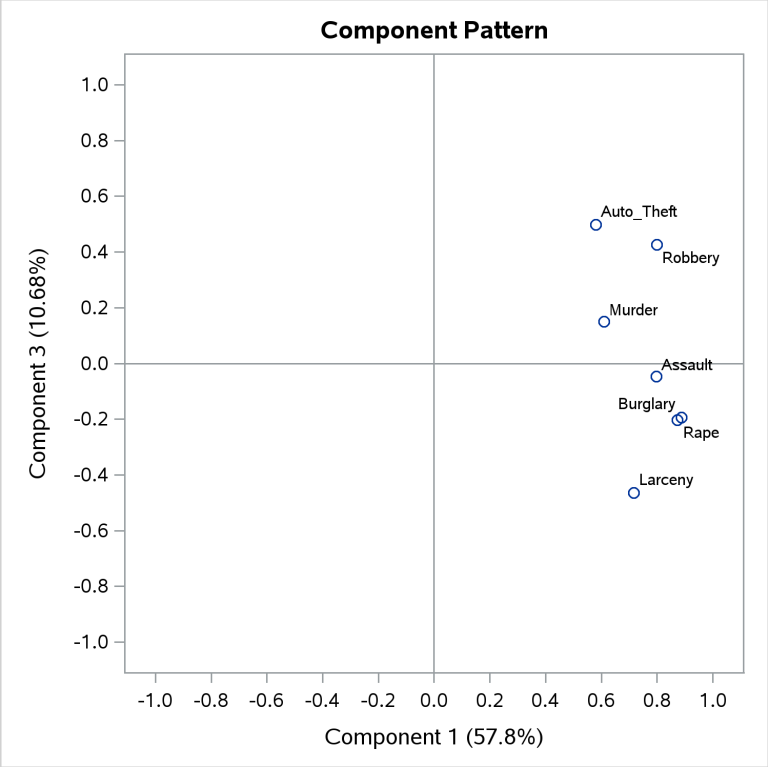
The scree plot on the left shows that the eigenvalue of the first component is approximately 4 and the eigenvalue of the second component is largely decreased to under 1.5. The variance-explained plot on the right shows that the first two principal components account for nearly 80% of the total variance.

Output 25.2.2 Scree Plot from the PCA Procedure



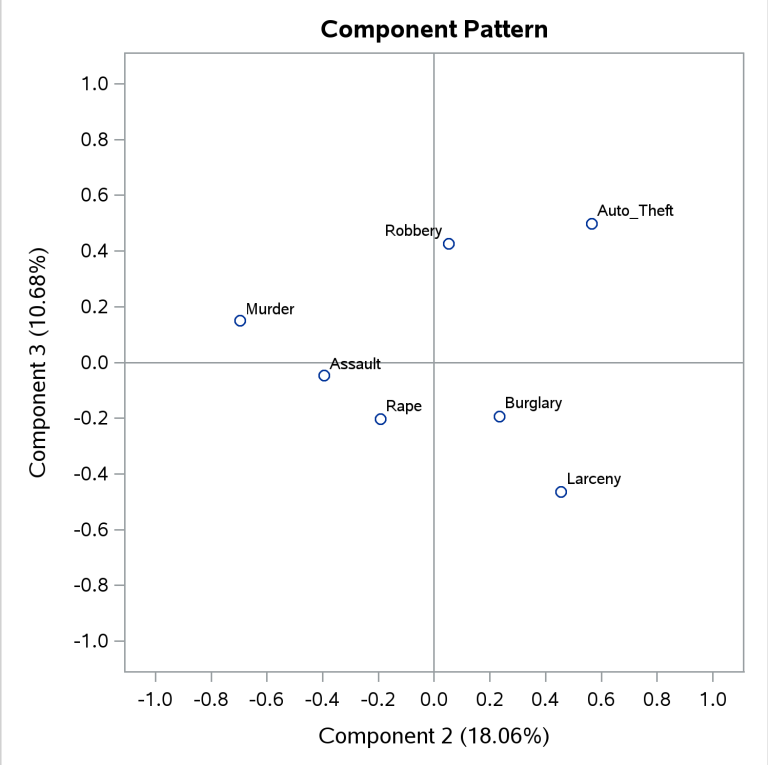
In addition to the scree plot, PROC PCA also produces the component pattern plot and the component pattern profile plot. The following statements request these plots:

```
proc pca data=mylib.Crime method=nipals
         plots=(pattern(ncomp=3) patternprofile);
run;
```



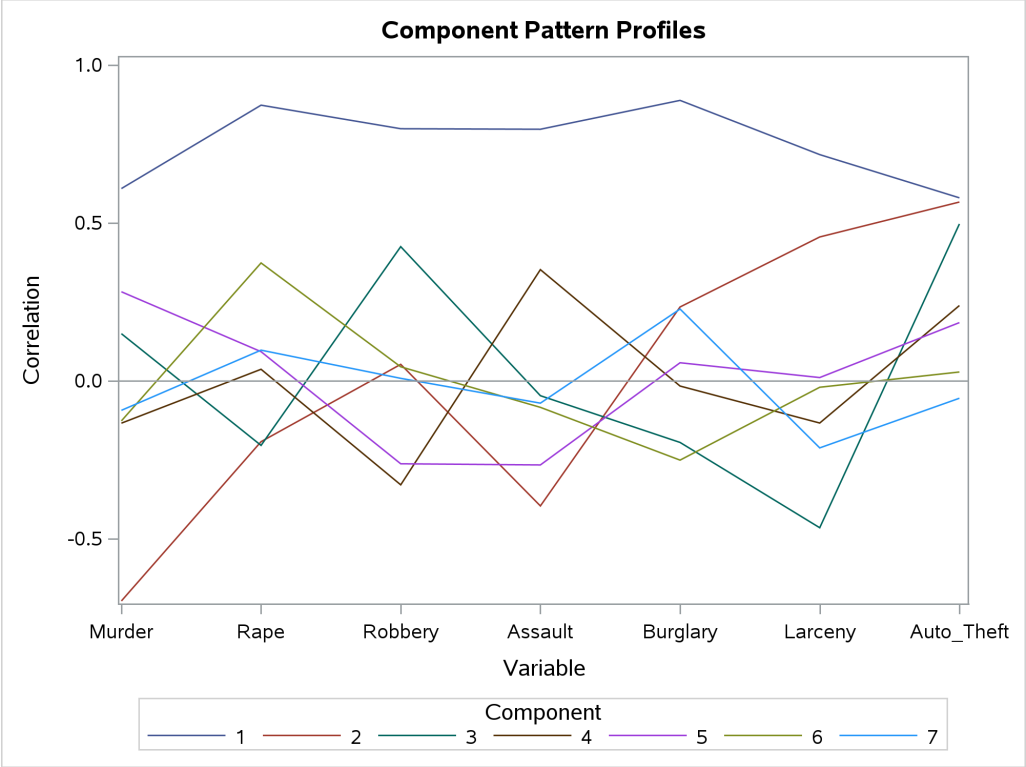
The pairwise component pattern plots are shown in Output 25.2.3 through Output 25.2.5. The pattern plots show the following:

- All variables positively and evenly correlate with the first principal component (Output 25.2.3 and Output 25.2.4).
- The variable Auto_Theft correlates highly with the second component, and the variable Murder correlates highly but negatively with the second component (Output 25.2.3).
- All the variables have low correlations (either positively or negatively) with the third component (Output 25.2.4).
- The variable Auto_Theft correlates highly with the second component, but it has low correlation with the third component; the variable Murder correlates highly but negatively with the second component, but it has very low correlation with the third component (Output 25.2.5).



Output 25.2.3 Pattern Plot of Component 2 by Component 1

Output 25.2.4 Pattern Plot of Component 3 by Component 1



Output 25.2.5 Pattern Plot of Component 3 by Component 2

Output 25.2.6 shows a component pattern profile. As shown in the pattern plots, the nearly horizontal profile of the first component indicates that the first component is mostly correlated evenly across all variables.

Output 25.2.6 Component Pattern Profile Plot from the PCA Procedure

Example 25.3: Approximating Principal Components with the RANDOM Method

(View the complete code for this example (pcaex3.sas) in the example repository.)

This example illustrates that the iterative method based on random projection (RANDOM) of Halko, Martinsson, and Tropp (2011) provides a good approximation to the true principal components by using simulated data. The data for this example are the result of multiplying the low-rank matrices **A** and **B** and adding random noise. Matrix **A** is 10,000 rows by 50 columns, and matrix **B** is 50 rows by 2,000 columns, so the final data table consists of 10,000 observations and 2,000 variables.

The following DATA step generates the data:

```
data mylib.testdata;
   title;
   keep x:;
   drop rank number_of_obs number_of_var sigma ii idum;
   drop rv1 rv2 rsq fac row col;
   drop nobs_per_thread nextras start_obs obs j k;
   array B[50,2000];          /* dimensions: rank, number_of_var */
   array A[50];               /* dimension: rank */
   array x[2000] x1-x2000;    /* dimension: number_of_var */

   target_nthreads = min(_nthreads_,96);
   if (_threadid_ = 1) then
```

```
   put "Number of threads = " target_nthreads;
rank=50;
number_of_obs=10000;
number_of_var=2000;
sigma=0.1;

call streaminit(1);

if (_threadid_ <= target_nthreads) then do;
   ii = 0;
   idum = 0;
   do while (ii < rank * number_of_var);
      idum = mod(mod(1664525*idum,4294967296)+1013904223,4294967296);
      rv1 = 2.0*(idum/4294967296)-1.0;
      idum = mod(mod(1664525*idum,4294967296)+1013904223,4294967296);
      rv2 = 2.0*(idum/4294967296)-1.0;
      rsq = rv1*rv1+rv2*rv2;
      if ((rsq < 1.0) and (rsq ^= 0.0)) then do;
         fac = sqrt(-2.0*log(rsq)/rsq);
         row = int(ii/number_of_var)+1;
         col = mod(ii,number_of_var)+1;
         B[row,col] = rv1*fac;
         ii = ii + 1;
         if (ii < rank * number_of_var) then do;
            row = int(ii/number_of_var)+1;
            col = mod(ii,number_of_var)+1;
            B[row,col] = rv2*fac;
            ii = ii + 1;
         end;
      end;
   end;

   nobs_per_thread = int(number_of_obs /target_nthreads);
   nextras = number_of_obs - nobs_per_thread*target_nthreads;
   if (_threadid_ <= nextras) then do;
      nobs_per_thread = nobs_per_thread+1;
      start_obs = (_threadid_-1)*nobs_per_thread+1;
   end;
   else
      start_obs = nextras+(_threadid_-1)*nobs_per_thread+1;

   do obs = start_obs to (start_obs+nobs_per_thread-1);
      do j = 1 to rank;
         A[j] = rand('Normal');
      end;
      do k = 1 to number_of_var;
         x[k] = sigma*rand('Normal');
         do j = 1 to rank;
            x[k] = x[k] + A[j]*B[j,k];
         end;
      end;
      output;
   end;
end;
```

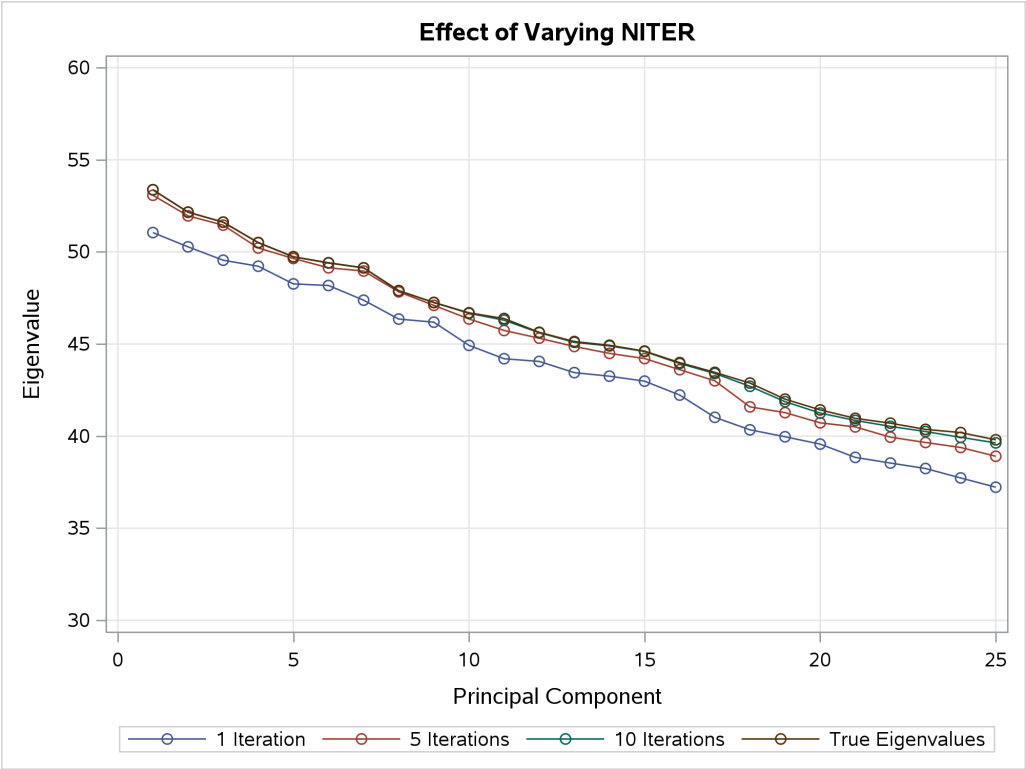
```
run;
```

The following statements use PROC PCA to extract principal components by using the RANDOM and EIG methods. The suboptions for the RANDOM method specify 1, 5, or 10 iterations. Both the EIG and RANDOM methods extract 25 principal components. The DISPLAY statement suppresses the default output except for eigenvalues, and the DISPLAYOUT statement saves the computed eigenvalues to specific output data tables.

```
proc pca data=mylib.testdata n=25 method=random(niter=1 seed=6789);
   var x:;
   display Eigenvalues;
   displayout Eigenvalues=oneiter;
run;

proc pca data=mylib.testdata n=25 method=random(niter=5 seed=6789);
   var x:;
   display Eigenvalues;
   displayout Eigenvalues=fiveiter;
run;

proc pca data=mylib.testdata n=25 method=random(niter=10 seed=6789);
   var x:;
   display Eigenvalues;
   displayout Eigenvalues=teniter;
run;



proc pca data=mylib.testdata n=25 method=eig;
   var x:;
   display Eigenvalues;
   displayout Eigenvalues=trueeig;
run;
```

To assess the accuracy of the RANDOM method, compare the estimated eigenvalues to those computed by the EIG method. Using the DATA step and PROC SGPLOT (code not shown), you can combine the estimated eigenvalue data sets with the true eigenvalue data set and plot the results. Output 25.3.1 shows this composite plot and demonstrates the following heuristic rules for the RANDOM method:

- One iteration usually provides a reasonable approximation of the true eigenvalues.
- Three to five iterations usually provide the best trade-off between approximation accuracy and computational cost.
- Beyond five iterations, the improvement in approximation accuracy is usually small compared to the computational cost.

For additional examples that show the impact of the number of iterations for both simulated and real data, see Halko, Martinsson, and Tropp (2011).

Output 25.3.1 RANDOM Method Performance with Varying Number of Iterations

NOTE: The heuristic rules provide guidance for selecting the number of iterations for data tables that are (approximately) low-rank. You might need to increase the number of iterations beyond what is recommended for data tables that are not low-rank.

Overview: PHSELECT Procedure

The PHSELECT procedure fits the Cox proportional hazards regression models for survival data and performs variable selection in SAS Viya.

The models that PROC PHSELECT supports can contain main effects that consist of both continuous and classification variables and interaction effects of these variables. The models can also include constructed effects such as splines. The procedure offers a number of effect-selection methods, including stepwise methods and modern LASSO methods. It also offers extensive capabilities for customizing the model selection by using a wide variety of selection and stopping criteria, from computationally efficient significance-level-based criteria to modern, computationally intensive validation-based criteria. PROC PHSELECT also provides a variety of Cox regression diagnostics that are conditional on the selected model.

PROC PHSELECT Features

The PHSELECT procedure estimates the parameters of a Cox regression model by maximizing the partial likelihood. It also does the following:

- provides model-building syntax through the CLASS, EFFECT, and effect-based MODEL statements, which are familiar from SAS/STAT analytic procedures (in particular, the GLM, LOGISTIC, GLIMMIX, and PHREG procedures)
- enables model building (variable selection) through the SELECTION statement
- enables you to split classification effects into individual components by using the SPLIT option in the CLASS statement
- permits any degree of interaction effects that involve classification and continuous variables
- provides a WEIGHT statement for weighted analysis
- provides a FREQ statement for grouped analysis
- provides a STRATA statement for stratified analysis
- provides a CODE statement to produce SAS code that can score a new data set
- provides an OUTPUT statement to produce a data table that contains predicted values and other observationwise statistics
- uses ODS Graphics to create model selection plots as part of its output. For more information about ODS Graphics, see the section "ODS Graphics" on page 1368.

Because the PHSELECT procedure runs on CAS, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode
- exploits all the available cores and concurrent threads. For information about how PROC PHSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC PHSELECT Compared with the PHREG Procedure

The PHSELECT procedure provides the full set of parameterizations that are available in the PHREG procedure. The PHSELECT procedure uses the GLM parameterization for the CLASS variables by default. The PHREG procedure uses the REF parameterization for the CLASS variables by default. In either procedure, you can use the PARAM= option in the CLASS statement to change the parameterization.

The PHSELECT procedure uses a quasi-Newton algorithm by default. You can choose different optimization techniques, including second-order methods that require a crossproducts matrix, by using the TECHNIQUE= option in the PROC PHSELECT statement. The PHREG procedure uses the Newton-Raphson optimization algorithm exclusively.

The PHREG procedure can fit a variety of models, but it has very limited model selection capability. The PHSELECT procedure provides a richer set of model selection options, including LASSO selection, information-criterion-based selection and stopping criteria, and validation-based criteria.

The PHSELECT procedure uses ODS Graphics to display plots that help interpret the selection process; the PHREG procedure use ODS graphics to display predicted survival curves.

The PHSELECT procedure is specifically designed to operate in SAS Viya and performs computations in multiple threads. The PHREG procedure executes in a single thread on a single machine.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: PHSELECT Procedure

Cox Regression

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/coxgs1.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The following DATA step creates the data table mylib.getStarted in your CAS session. This data table consists of 100 observations on a failure time variable (Time), an indicator variable (Status) that has two values (0 for censored observations and 1 for event observations), three classification variables (C1–C3), and four continuous variables (X1–X4). This DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.getStarted;
   input Time Status C1$ C2 C3$ X1-X4;
   datalines;

   89      1      High        1    M     1.32    1.623    3.6532    14.0
;
```

The following statements fit a Cox proportional hazards model to these data by using three classification effects for the variables C1–C3 and four regressor effects for the variables X1–X4. The ITHIST option displays a table that summarizes the steps of the optimization.

```
proc phselect data=mylib.getStarted ithist;
   class C1-C3;
   model Time*Status(0) = C1-C3 X1-X4;
run;
```

The output from this analysis is presented in Figure 26.1 through Figure 26.8.

Figure 26.1 displays the "Model Information" table. The variable Time is the failure time variable. The variable Status is the censoring variable; the value 0 indicates censored observations. The PHSELECT procedure uses a quasi-Newton algorithm to maximize the partial likelihood to estimate the regression coefficients.

Figure 26.1 Model Information

The PHSELECT Procedure

Model Information	
Data Source	GETSTARTED
Response Variable	Time
Censoring Variable	Status
Censoring Values	0
Optimization technique	Dual Quasi-Newton

Figure 26.2 displays the "Number of Observations" table. All 100 observations in the data table are used in

the analysis; of them, 26 are censored and 74 are uncensored.

Figure 26.2 Number of Observations

Number of Observations			
Description	**Total**	**Event**	**Censored**
Number of Observations Read	100	74	26
Number of Observations Used	100	74	26

The classification variables C1–C3 are parameterized using the GLM parameterization, which is the default. The variable C1 has four unique formatted levels; each of the two variables C2 and C3 has two levels. The classification levels are displayed in the "Class Level Information" table in Figure 26.3.

Figure 26.3 Class Level Information

Class Level Information		
Class	**Levels**	**Values**
C1	4	Critical High Low Medium
C2	2	0 1
C3	2	F M

The "Iteration History" table is shown in Figure 26.4. The quasi-Newton algorithm converged after 12 iterations, not counting the initial setup iteration.

Figure 26.4 Iteration History

Iteration History				
Iteration	**Evaluations**	**Objective Function**	**Change**	**Max Gradient**
0	4	272.56284984	.	65.17039
1	3	267.70594206	4.85690778	7.86724
2	2	261.80868056	5.89726150	4.723085
3	2	256.62059571	5.18808485	4.650619
4	2	255.59346125	1.02713446	1.0462
5	2	255.44142594	0.15203531	1.018105
6	3	255.40692196	0.03450398	0.353611
7	3	255.39461736	0.01230460	0.415741
8	3	255.39362671	0.00099065	0.074411
9	3	255.39339211	0.00023460	0.062435
10	3	255.39336653	0.00002558	0.004922
11	3	255.39336262	0.00000391	0.002273
12	3	255.39336237	0.00000026	0.000452

Figure 26.5 displays the final convergence status of the quasi-Newton algorithm. The GCONV=1E-8 convergence criterion is satisfied.

Figure 26.5 Convergence Status

Convergence criterion (GCONV=1E-8) satisfied.

Figure 26.6 displays the "Dimensions" table for this model. This table summarizes some important sizes of various model components. For example, it shows that the design matrix **X** has 12 columns: 4 columns for the effects that are associated with the classification variable C1, 2 columns for each of the classification variables C2 and C3, and 1 column for each of the continuous variables X1–X4. However, the rank of the crossproducts matrix is only 9. Because the classification variables C1–C3 use GLM parameterization, there is one singularity in the crossproducts matrix of the model for each classification variable. Consequently, only nine parameters enter the optimization.

Figure 26.6 Dimensions in Cox Regression

Dimensions	
Number of Effects	7
Max Effect Columns	4
Columns in Design	12
Rank of Design	9

The "Fit Statistics" table is shown in Figure 26.7. The –2 log likelihood at the converged estimates is 510.78672. You can use this value to compare the model to nested model alternatives by means of a likelihood ratio test. To compare models that are not nested, you can use information criteria such as Akaike's information criterion (AIC), Akaike's bias-corrected information criterion (AICC), and the Schwarz Bayesian information criterion (BIC). These criteria penalize the –2 log partial likelihood for the number of parameters.

Figure 26.7 Fit Statistics

Fit Statistics	
-2 Log Likelihood	510.78672
AIC (smaller is better)	528.78672
AICC (smaller is better)	531.59922
SBC (smaller is better)	549.52331

The "Parameter Estimates" table in Figure 26.8 shows that many parameters have fairly large *p*-values, indicating that one or more of the model effects might not be necessary.

Figure 26.8 Parameter Estimates

Parameter Estimates					
Parameter	**DF**	**Estimate**	**Standard Error**	**Chi-Square**	**Pr > ChiSq**
C1 Critical	1	0.400493	0.489562	0.6692	0.4133
C1 High	1	-0.990602	0.325145	9.2821	0.0023
C1 Low	1	-0.665495	0.339148	3.8504	0.0497
C1 Medium	0	0	.	.	.
C2 0	1	0.410704	0.398833	1.0604	0.3031
C2 1	0	0	.	.	.
C3 F	1	-0.172550	0.337940	0.2607	0.6096
C3 M	0	0	.	.	.
X1	1	1.970488	0.524142	14.1335	0.0002
X2	1	0.726605	0.415141	3.0634	0.0801
X3	1	0.725390	0.585658	1.5341	0.2155
X4	1	-0.131226	0.057103	5.2810	0.0216

Finally, the procedure displays the table in Figure 26.9, which shows the amount of time (in seconds) that PROC PHSELECT required to perform different tasks in the analysis.

Figure 26.9 Procedure Timing

Task Timing		
Task	**Seconds**	**Percent**
Setup and Parsing	0.02	9.03%
Levelization	0.02	8.67%
Model Initialization	0.01	2.18%
SSCP Computation	0.00	0.79%
Model Fitting	0.19	77.72%
Cleanup	0.00	0.46%
Total	0.24	100.00%

Syntax: PHSELECT Procedure

The following statements are available in the PHSELECT procedure:

PROC PHSELECT < *options* > **;**
BY *variables* **;**
CLASS *variable* < **(***options***)** > . . . < *variable* < **(***options***)** > > < / *global-options* > **;**
CODE < *options* > **;**
DISPLAY < *table-list* > < / *options* > **;**
DISPLAYOUT *table-spec-list* < / *options* > **;**
EFFECT *name***=***effect-type***(***variables* < / *options* >**)** **;**
FREQ *variable* **;**
MODEL *response* < ∗ *censor***(***list***)** > **=** < *effects* > < / *model-options* > **;**
OUTPUT OUT=*libref.data-table* < *options* > < *keyword* < **=***name* > > . . . < *keyword* < **=***name* > > **;**
PARTITION *partition-options* **;**
SELECTION < **METHOD=***method* < **(***method-options***)** > >< *options* > **;**
STRATA *variable* < **MISSING** > **;**
WEIGHT *variable* **;**

The PROC PHSELECT statement and the MODEL statement are required. The CLASS statement can appear multiple times. If you use a CLASS statement, it must precede the MODEL statements.

PROC PHSELECT Statement

PROC PHSELECT < *options* > **;**

The PROC PHSELECT statement invokes the procedure. Table 26.1 summarizes the available *options* in the PROC PHSELECT statement by function. They are then described fully in alphabetical order.

Table 26.1 PROC PHSELECT Statement Options

Option	Description
ALPHA=	Specifies a global significance level
DATA=	Specifies the CAS input data table
MULTIPASS=	Specifies whether to levelize the data table every time it is read
Output Options	
CORRB	Displays the "Parameter Estimates Correlation Matrix" table
COVB	Displays the "Parameter Estimates Covariance Matrix" table
ITHIST	Displays the "Iteration History" table
LOGLIKENULL	Displays the "–2 Log Likelihood for Null Model" table
NOCLPRINT	Limits or suppresses the display of class levels
NOSTDERR	Suppresses computation of the covariance matrix and standard errors
Optimization Options	
ABSCONV=	Tunes the absolute function convergence criterion
ABSFCONV=	Tunes the absolute function difference convergence criterion
ABSGCONV=	Tunes the absolute gradient convergence criterion
ABSXCONV=	Tunes the absolute parameter convergence criterion
FCONV=	Tunes the relative function difference convergence criterion
FCONV2=	Tunes the second relative function difference convergence criterion
GCONV=	Tunes the relative gradient convergence criterion
GCONV2=	Tunes the second relative gradient convergence criterion
XCONV=	Tunes the relative gradient convergence criterion
HESSIAN	Uses analytic Hessian instead of finite-difference Hessian
MAXFUNC=	Specifies the maximum number of function evaluations in any optimization
MAXITER=	Specifies the maximum number of iterations in any optimization
MAXTIME=	Specifies the upper limit of CPU time (in seconds) for any optimization
MINITER=	Specifies the minimum number of iterations in any optimization
TECHNIQUE=	Selects the optimization technique
LASSO Options	
LASSORHO=	Specifies the base regularization parameter for the LASSO method
LASSOSTEPS=	Specifies the maximum number of steps for the LASSO method
LASSOTOL=	Specifies the convergence criterion for the LASSO method

The optimization options, with the exception of the HESSIAN option, are fully described in the section "Optimization Options" on page 57 in Chapter 2, "Shared Concepts." The following list describes the other options available in the PROC PHSELECT statement:

ALPHA=*number*

specifies a global significance level for the construction of confidence intervals. The confidence level is 1–*number*. The value of *number* must be between 0 and 1. By default, ALPHA=0.05.

CORRB

creates the "Parameter Estimates Correlation Matrix" table. The correlation matrix is computed by normalizing the covariance matrix $\mathbf{\Sigma}$. That is, if σ_{ij} is an element of $\mathbf{\Sigma}$, then the corresponding element of the correlation matrix is $\sigma_{ij}/\sigma_i\sigma_j$, where $\sigma_i = \sqrt{\sigma_{ii}}$.

COVB

creates the "Parameter Estimates Covariance Matrix" table. The covariance matrix is computed as the inverse of the negative Hessian matrix, which is the matrix of second derivatives of the log-likelihood function with respect to the model parameters.

DATA=*libref.data-table*

names the input data table for PROC PHSELECT to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1333.

data-table specifies the name of the input data table.

HESSIAN

computes the Hessian matrix by using the analytic expression for the second-order derivatives of the log partial likelihood function instead of using the finite-difference method. When you specify this option, the optimization technique defaults to the Newton-Raphson method with ridging (TECH=NRRIDG), but you can use the TECH= option to specify the technique of your choice. The HESSIAN option requires a large amount of memory for each machine in the cluster.

ITHIST

generates the "Iteration History" table.

LASSORHO=*r*

specifies the base regularization parameter for the LASSO model selection method. The regularization parameter for step i is r^i. By default, LASSORHO=0.8.

LASSOSTEPS=*n*

specifies the maximum number of steps for LASSO model selection. By default, LASSOSTEPS=20.

LASSOTOL=*r*

specifies the convergence tolerance for the optimization algorithm that solves for the LASSO parameter estimates at each step of LASSO model selection. By default, LASSOTOL=1E–6.

LOGLIKENULL
creates the "–2 Log Likelihood for the Null Model" table. If you also specify the PARTITION statement, the table displays the –2 log likelihood for the null model for each data partition.

MULTIPASS=TRUE | FALSE
specifies when to levelize the data table—that is, when to generate the design rows for your model from the data. This option does not affect how the OUTPUT statement is processed. You can specify the following values:

TRUE levelizes the data every time they are read. This method is slower but uses less memory.

FALSE levelizes the data once and stores them in a temporary data table, then rereads the data from that table as needed. This method is faster but uses more memory.

By default, MULTIPASS=FALSE.

NOCLPRINT< =*number* **>**
suppresses the display of the "Class Level Information" table if you do not specify *number*. If you specify *number*, the values of the classification variables are displayed for only those variables whose number of levels is less than *number*. Specifying *number* helps reduce the size of the "Class Level Information" table if some classification variables have a large number of levels.

NOSTDERR
suppresses computation of the covariance matrix and the standard errors of the regression coefficients. When the model contains many variables (such as thousands), inverting the Hessian matrix to derive the covariance matrix and the standard errors of the regression coefficients can be time-consuming. The CORRB, COVB, and TYPE3 options are not available when you specify this option.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC PHSELECT to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CLASS Statement

CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. You can list the response variable for binary models in the CLASS statement, but this is not required. Table 26.2 summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section "CLASS Statement" on page 9 in Chapter 2, "Shared Concepts."

Table 26.2 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable
SPLIT	Splits levels of CLASS variables into independent effects

CODE Statement

CODE < *options* > **;**

The CODE statement writes SAS DATA step code for computing predicted values of the fitted model to a file or to a table. The predicted values include survival probabilities and cumulative hazards at specific time points. To score new data, you can then include the file in a DATA step, or you can specify the table in the **`runCodeTable`** action in the **`dataStep`** action set (for more information, see *SAS Viya: System Programming Guide*).

Table 26.3 summarizes the *options* available in the CODE statement.

Table 26.3 CODE Statement Options

Option	Description
COMMENT	Adds comments to the generated code
CUMHAZ	Generates cumulative hazard values at specified time points
FILE=	Names the file in which to save the generated code
FORMATWIDTH=	Specifies the numeric format width for the regression coefficients
INDENTSIZE=	Specifies the number of spaces to indent the generated code
LABELID=	Specifies a number used to construct names and labels
LINESIZE=	Specifies the line size for the generated code
NOSURVIVAL	Suppresses the generation of survival probabilities
NOTRIM	Compares formatted values, including blank padding
OUT=	Names an output table in which to save the generated code
SHOWTIME	Creates variables that contain the time points at which predictions are made
TIMEPOINT=	Specifies the time points at which survival probabilities or cumulative hazards are predicted

The following CODE statement *options* are particularly important:

CUMHAZ
generates SAS code to predict the cumulative hazard function at the time points that you specify in the TIMEPOINT= option.

FILE=*filename*
names the external file that saves the generated code. When enclosed in a quoted string (for example, FILE="c:\mydir\scorecode.sas"), this option specifies the path and filename for writing the code to an external file. If you do not specify a path but your SAS client has a default path, then the code is written to an external file named *filename* at that location. You can also specify an unquoted *filename* of no more than eight characters. If the *filename* is assigned as a fileref in a Base SAS FILENAME statement, the file that is specified in the FILENAME statement is opened; otherwise, if your SAS client has a default path, an external file named *filename* is created. This option cannot be specified together with the OUT= option.

NOSURVIVAL
suppresses SAS code for survival probabilities prediction. If you do not specify this option, PROC PHSELECT generates SAS code to predict survival probabilities at the time points that you specify in the TIMEPOINT= option.

SHOWTIME
creates variables that contain the time points at which predictions are made. If T is the name of the failure time variable, these time point variables are named T_1, T_2, and so on.

TIMEPOINT=*list* | **QUANTILE(***probability-list***)**

TIME=*list* | **QUANTILE(***probability-list***)**
specifies the time points at which survival probabilities or cumulative hazards are predicted. You can specify a list of numbers that represent exact time points. For example:

```
code cumhaz timepoint = 40 to 60 by 10;
```

If T is the name of the failure time variable, the preceding specification requests the predicted cumulative hazard and survival probability at the time points T=40, T=50, and T=60. If you also specify the SHOWTIME option, these time points are saved in the variables T_1, T_2, and T_3, respectively. The predicted variables are named and labeled as shown in Table 26.4.

Table 26.4 Predicted Variables

T	Name	Label
40	C_T_1	Cumulative Hazard at T_1
50	C_T_2	Cumulative Hazard at T_2
60	C_T_3	Cumulative Hazard at T_3
40	S_T_1	Survival Probability at T_1
50	S_T_2	Survival Probability at T_2
60	S_T_3	Survival Probability at T_3

Alternatively, you can use the keyword QUANTILE to specify a list of quantile probabilities. For example:

```
code timepoint = quantile(.2, .5, .8);
```

The PHSELECT procedure computes the 20th, 50th, and 80th percentiles from the Kaplan-Meier curve (or the Breslow curve if you also specify the ENTRY= option in the MODEL statement) and use them as the time points for the prediction.

By default, TIMEPOINT=QUANTILE(0.25, 0.50, 0.75).

For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE

statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1366. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value* specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1366. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

EFFECT Statement

EFFECT *name*=*effect-type* **(***variables* < / *options* >**) ;**

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 67 in Chapter 2, "Shared Concepts."

You can specify the following *effect-types*:

COLLECTION specifies a collection effect that defines one or more variables as a single effect that has multiple degrees of freedom. The variables in a collection are considered as a unit for purposes of estimation and inference.

MULTIMEMBER | MM specifies a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.

POLYNOMIAL | POLY specifies a multivariate polynomial effect in the specified numeric variables.

SPLINE specifies a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 26.5 summarizes the *options* available in the EFFECT statement.

Table 26.5 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect

Table 26.5 *continued*

Option	Description
Multimember Effects Options	
DETAILS	Displays the levels of the multimember effect
NOEFFECT	Specifies that observations whose levels are all missing for the multimember variables should have 0 values in the corresponding design matrix columns
STDIZE	Standardizes the design matrix entries so that each observation has a sum of 1
WEIGHT=	Specifies the weight variable for the contributions of each classification effect
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect with multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots starting at the variables' maximum and ending at the KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots starting at the KNOTMIN= value and ending at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect
SEPARATE	Treats the spline basis for each variable as a separate effect when multiple variables are specified
SPLIT	Treats each design matrix column as a separate effect for selection methods

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 18 in Chapter 2, "Shared Concepts."

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC PHSELECT treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1.

MODEL Statement

MODEL *response* < ∗ *censor* **(***list***)** > **=** *effects* < / *options* > **;**

The MODEL statement identifies the variables to be used as the failure time variable, the optional censoring variable, and the explanatory effects, including covariates, main effects, interactions, and nested effects.

The name of the failure time variable precedes the equal sign. This name can optionally be followed by an asterisk, the name of the censoring variable, and a list of censoring values (separated by blanks or commas) enclosed in parentheses.

The censoring variable must be numeric, and the failure time variables must contain nonnegative values. Any observation that has a negative failure time is excluded from the analysis, as is any observation that has a missing value for any of the variables listed in the MODEL statement. Failure time variables in SAS date format are not recommended, because the dates might be translated into negative numbers and consequently the corresponding observations would be discarded.

If the censoring variable takes one of these values, the corresponding failure time is considered to be censored. Following the equal sign are the explanatory effects (sometimes called independent variables or covariates) for the model.

For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

Table 26.6 summarizes the *options* available in the MODEL statement. You can specify these *options* after a slash (/).

Table 26.6 MODEL Statement Options

Option	Description
Model Options	
CLB	Requests confidence limits
ENTRY=	Specifies the left-truncation time variable
INCLUDE=	Includes effects in all models for model selection
INFORMATIVE	Models missing values by using extra indicator variables
OFFSET=	Specifies the offset variable
START=	Includes effects in the initial model for model selection
TYPE3	Displays the Type 3 or joint tests of effects

The following list describes these options:

CLB
constructs confidence limits for each of the parameter estimates. The confidence level is 0.95 by default; you can change it by specifying the ALPHA= option in the PROC PHSELECT statement.

ENTRY=*variable*
specifies the left-truncation time variable. The left-truncation time is the time at which an individual starts to be observed.

INCLUDE=*n* | *single-effect* | **(***effects***)**
forces effects to be included in all models. If you specify INCLUDE=*n*, then the first *n* effects that you list in the MODEL statement are included in all models. If you specify INCLUDE=*single-effect* or INCLUDE=(*effects*), then the specified *effects* are forced into all models. The *effects* that you specify in this option must be explanatory effects that you specify in the MODEL statement before the slash (/).

INFORMATIVE
models missing values by using extra model effects. These effects consist of dummy variables that take the value 1 when the value of a continuous model variable involved in the effect is missing, and take the value 0 otherwise. The missing value in the original model effect is replaced by the average value of the effect for the nonmissing values. For continuous-by-class effects, such as A*x, where A is a classification variable and x is a continuous variable, informative missingness creates multiple dummy columns and substitutes the effect mean of x that corresponds to the respective level of A. Missing values for classification variables are treated as valid levels. For more information about informative missingness, see the section "Informative Missingness" on page 99 in Chapter 2, "Shared Concepts."

OFFSET=*variable*
specifies a *variable* to be used as an offset to the linear predictor. An offset plays the role of an effect whose coefficient is known to be 1. The offset variable cannot appear in the CLASS statement or elsewhere in the MODEL statement. Observations that have missing values for the offset variable are excluded from the analysis.

START=*n* | *single-effect* | **(***effects***)**
begins the selection process from the designated initial model for the forward and stepwise selection methods. If you specify START=*n*, then the starting model includes the first *n* effects that you list in the MODEL statement. If you specify START=*single-effect* or START=(*effects*), then the starting model includes those specified *effects*. The *effects* that you specify in the START= option must be explanatory effects that you specify in the MODEL statement before the slash (/). This option is not available when you specify METHOD=BACKWARD in the SELECTION statement.

TYPE3
requests that Wald statistics for Type 3 contrasts be computed for each effect that you specify in the MODEL statement. For more information, see the section "Joint Tests and Type 3 Tests" on page 1361.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=(***variables***)** >
< *keyword* < *=name* > >. . . < *keyword* < *=name* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics that PROC PHSELECT computes after fitting the model. In order to avoid data duplication for large data tables, the variables in the input data table are *not* included in the output data table unless you specify them in the COPYVAR= option.

The output statistics are computed based on the final parameter estimates. If the optimization does not converge, then the output data table is not created.

For observations in which only the censoring variable is missing, values of the linear predictor and the predicted survival probabilities are computed even though these observations do not affect the model fit. This enables, for example, predicted survival probabilities to be computed for new observations.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC PHSELECT to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1333.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

COPYVAR=*variable*
COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table.

keyword **< =***name* **>**
specifies a statistic to include in the output data table. Four statistics (DFBETA, RESSCH, RESSCO, and WTRESSCH) are multidimensional; each has a dimension equal to the number of parameters in the model. For the one-dimensional statistic, you can name the variable *name*. For the multidimensional statistic, *name* is used as the prefix; for example, if X1–X10 are the explanatory variables in the model, specifying RESSCH=sch creates the variables schX1–schX10 as the 10-dimensional Schoenfeld residual variables. If you do not provide a *name*, the PHSELECT procedure assigns a default name based on the type of statistic that is requested.

Table 26.7 summarizes the *keywords* available in the OUTPUT statement.

Table 26.7 OUTPUT Statement Keywords

Keyword	Description	Default Names
Statistic Options		
CUMHAZ	Specifies the predicted cumulative hazard	_CUMHAZ_
STDXBETA	Specifies the standard error estimate of the linear predictor	_STDXBETA_
SURVIVAL	Specifies the predicted survival probability	_SURVIVAL_
XBETA	Specifies the linear predictor	_XBETA_
Diagnostic Options		
DFBETA	Specifies the standardize deletion parameter differences	_DFBETA_
LD	Specifies the likelihood displacement	_LD_
RESDEV	Specifies the deviance residual	_RESDEV_
RESMART	Specifies the martingale residual	_RESMART_
RESSCH	Specifies the Schoenfeld residuals	_RESSCH_
RESSCO	Specifies the score residuals	_RESSCO_
WTRESSCH	Specifies the weighted Schoenfeld residuals	_WTRESSCH_
Other Option		
ROLE	Specifies the observation role	_ROLE_

The following list describes these *keywords*. For more information, see the section "Predicted Values and Regression Diagnostics" on page 1359.

CUMHAZ
specifies the predicted cumulative hazard function at the observed time. The default *name* is _CUMHAZ_.

DFBETA
requests the approximate changes in the parameter estimates $(\hat{\boldsymbol{\beta}} - \hat{\boldsymbol{\beta}}_{(j)})$ when the jth observation is omitted. These variables are a weighted transform of the score residual variables and are useful in assessing local influence. The default *name* that is used as a prefix is _DFBETA_.

LD
specifies the approximate likelihood displacement when the observation is omitted. This diagnostic can be used to assess the impact of each observation on the overall fit of the model. The default *name* is _LD_.

RESDEV
specifies the deviance residual. This variable is a transform of RESMART to achieve a more symmetric distribution. The default *name* is _RESDEV_.

RESMART
specifies the martingale residual, which, at the observed time t, can be interpreted as the difference over $[0, t]$ in the observed number of events minus the expected number of events. The default *name* is _RESMART_.

RESSCH
requests the Schoenfeld residuals, which are useful in assessing the proportional hazards assumption. Schoenfeld residuals are computed only at uncensored times and are missing for censored times. If an effect in the MODEL statement is not included in the final model, the corresponding Schoenfeld residuals are set to missing. The default *name* that is used as a prefix is _RESSCH_.

RESSCO
requests the score residuals, which are a decomposition of the first partial derivative of the log likelihood. They can be used to assess the leverage that each subject exerts in the parameter estimation. The default *name* that is used as a prefix is _RESSCO_.

ROLE
specifies the numeric variable that indicates the role that each observation plays in fitting the model. The default *name* is _ROLE_. Table 26.8 shows how this variable is interpreted for each observation.

Table 26.8 Role Interpretation

Value	Observation Role
0	Not used
1	Training
2	Validation
3	Testing

If you do not partition the input data by specifying a PARTITION statement, then the role variable value is 1 for observations that are used in fitting the model and 0 for observations that have at least one missing or invalid value for the response, regressor, frequency, or weight variables.

STDXBETA
specifies the standard error estimates of XBETA. The default *name* is _STDXBETA_.

SURVIVAL
requests the predicted survival probabilities at the observed times. The default *name* is _SURVIVAL_.

WTRESSCH
requests the weighted Schoenfeld residuals, which are useful in investigating the nature of nonproportionality if the proportional hazard assumption does not hold. If an effect in the MODEL statement is not included in the final model, the corresponding weighted Schoenfeld residuals are set to missing. The default *name* that is used as a prefix is _WTRESSCH_.

XBETA
specifies the linear predictor. The default *name* is _XBETA_.

PARTITION Statement

PARTITION *partition-option* **;**

The PARTITION statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. For more information, see the section "Using Validation and Test Data" on page 101 in Chapter 2, "Shared Concepts." Either you can designate a variable in the input data table and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for randomly assigning observations to each role.

You must specify exactly one of the following *partition-options*:

FRACTION(<TEST=*fraction***> <VALIDATE=***fraction***> <SEED=***number***>)**
randomly assigns specified proportions of the observations in the input data table to the roles. You specify the proportions for testing and validation by using the TEST= and VALIDATE= suboptions. If you specify both the TEST= and VALIDATE= suboptions, then the sum of the specified fractions must be less than 1 and the remaining fraction is the proportion of the observations assigned to the training role. The SEED= option specifies an integer that is used to start the pseudorandom number generator for random partitioning of data for training, testing, and validation. If you do not specify SEED=*number* or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

ROLE=*variable* **(<TEST='***value***'> <TRAIN='***value***'> <VALIDATE='***value***'>)**
ROLEVAR=*variable* **(<TEST='***value***'> <TRAIN='***value***'> <VALIDATE='***value***'>)**
names the *variable* in the input data table whose values are used to assign roles to each observation. This *variable* cannot also appear as an analysis variable in other statements or options. The TEST=, TRAIN=, and VALIDATE= suboptions specify the formatted values of this variable that are used to assign observation roles. If you do not specify the TRAIN= suboption, then all observations whose role is not determined by the TEST= or VALIDATE= suboption are assigned to the training role.

SELECTION Statement

SELECTION <**METHOD=***method*< *(method-options)*>>< *options*> **;**

The SELECTION statement performs model selection by examining whether effects should be added to or removed from the model according to rules that are defined by model selection methods. You can use the PLOT= option to produce graphical summaries of the selection process or the HIERARCHY= option to specify whether and how a requirement of model hierarchy is applied. The statement is fully documented in the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

The PHSELECT procedure supports the following effect-selection *methods* in the SELECTION statement:

BACKWARD performs backward elimination. This method starts with all effects in the model and deletes effects.

BACKWARD(FAST) performs fast backward elimination. This method starts with all effects in the model and deletes effects without refitting the model.

FORWARD performs forward selection. This method starts with no effects in the model and adds effects.

LASSO performs model selection by the group LASSO method. This method adds and removes effects by using a sequence of LASSO steps. For more information, see the section "Group LASSO Selection" on page 87 in Chapter 2, "Shared Concepts."

NONE results in no model selection. This method fits the full model.

STEPWISE performs stepwise selection. This method is similar to the FORWARD method, except that effects already in the model do not necessarily stay there.

By default, METHOD=STEPWISE.

The SELECT=, CHOOSE=, and STOP= *method-options* default to the Schwartz Bayesian criterion (SBC).

You can specify the following criteria in the SELECT=, CHOOSE=, and STOP= *method-options*:

AIC uses Akaike's information criterion (Akaike 1974) on the training data.

AICC uses a small-sample bias-corrected version of Akaike's information criterion, as promoted by Hurvich and Tsai (1989) and Burnham and Anderson (1998), on the training data.

SBC | BIC uses the Schwarz Bayesian criterion (Schwarz 1978) on the training data.

SL uses the significance level of the score test as the criterion on the training data (not available for the CHOOSE= option).

VALIDATE uses the –2 log-likelihood (M2LL) value computed on the validation data as the criterion (not available for the SELECT= option).

If you specify METHOD=LASSO and do not specify either the CHOOSE= or STOP= option, then the model in the last LASSO step is chosen as the selected model.

NOTE: If you use the fast backward elimination method, then the –2 log-likelihood, AIC, AICC, and SBC statistics are approximated at each step where the model is not refit, and hence they do not match the values that are computed when that model is fit outside the selection routine. Similarly, if you specify SELECT=AIC, AICC, or SBC, the selection criteria are estimated (Lawless and Singhal 1978), and hence they do not match the values that are computed when that model is fit outside the selection routine.

NOTE: The default model hierarchy method is HIERARCHY=NONE for the stepwise, forward, and fast backward selection methods. The backward elimination method always uses the HIERARCHY=SINGLE *method-option*.

If you specify DETAILS=ALL, the LASSO method produces a table that displays the effects that are added or removed at each step and the corresponding fit statistics. For the other methods, you can specify the following values for the DETAILS= option:

SUMMARY produces a summary table that shows the effect that is added or removed at each step along with the criteria specified in the SELECT=, CHOOSE=, and STOP= *method-options*. The summary table is produced by default if you do not specify the DETAILS= option.

STEPS produces the preceding summary table and displays the results from fitting each model at each step.

ALL produces the preceding tables and a detailed listing of all candidates at each step along with their ranking in terms of the selection criterion for addition to or removal from the model.

If you specify the PLOTS=CRITERIA or PLOTS=ALL option, then a plot of the fit criterion by the selection step is created for the AIC, AICC, and SBC statistics. If you also specify a PARTITION statement, then the same type of plot is created for the M2LL statistics.

If you specify the PLOTS=FITBYROLE or PLOTS=ALL option and a PARTITION statement, then a plot of the M2LL by the selection step for each role is created.

The PLOTS= option is not available for the LASSO method.

STRATA Statement

STRATA *variable* < / **MISSING** > **;**

The STRATA statement specifies a *variable* whose values determine the stratification of the data. Strata are formed according to the nonmissing values of the STRATA *variable* unless you specify the MISSING option.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

Details: PHSELECT Procedure

Missing Values

Any observation that has missing values for the response, frequency, weight, offset, or explanatory variables is excluded from the analysis; however, missing values are valid for response and explanatory variables that are specified along with the MISSING option in the CLASS statement. Observations that have a nonpositive weight or a frequency less than 1 are also excluded.

The estimated linear predictor and the fitted probabilities are not computed for any observation that has missing offset or explanatory variable values. However, if only the response value is missing, the linear predictor and the fitted probabilities can be computed and output to a data table by using the OUTPUT statement.

You can also model the missing values by specifying the INFORMATIVE option in the MODEL statement. For more information about informative missingness, see the section "Informative Missingness" on page 99 in Chapter 2, "Shared Concepts."

Cox Proportional Hazards Regression Model

The Cox proportional hazards regression model is a semiparametric model that assumes a parametric form for the effects of the explanatory variables, but it allows an unspecified form for the underlying survivor function. The survival time of each member of a population is assumed to follow its own hazard function, $\lambda_j(t)$, expressed as

$$\lambda_j(t) = \lambda(t; \mathbf{Z}_j) = \lambda_0(t) \exp(\mathbf{Z}_j' \boldsymbol{\beta})$$

where $\lambda_0(t)$ is an arbitrary and unspecified baseline hazard function, $\mathbf{Z}_j$ is the vector of explanatory variables for the jth individual, and $\boldsymbol{\beta}$ is the vector of unknown regression parameters that is associated with the explanatory variables.

The population under study can consist of a number of subpopulations, each of which has its own baseline hazard function. A stratified analysis is needed to adjust for such subpopulation differences. Under the stratified model, the hazard function for the jth individual in the ith stratum is expressed as

$$\lambda_{ij}(t) = \lambda_{i0}(t) \exp(\mathbf{Z}_{ij}' \boldsymbol{\beta})$$

where $\lambda_{i0}(t)$ is the baseline hazard function for the ith stratum and $\mathbf{Z}_{ij}$ is the vector of explanatory variables for the individual. The regression coefficients are assumed to be the same for all individuals across all strata.

To estimate $\boldsymbol{\beta}$, Cox (1972, 1975) introduced the partial likelihood function, which eliminates the unknown baseline hazard functions and accounts for censored survival times.

Partial Likelihood for the Cox Model

Let $\mathbf{Z}_l$ denote the vector explanatory variables for the lth individual, and let w_l be the associated weight. Let $t_1 < t_2 < \cdots < t_k$ denote the k distinct, ordered event times. Let d_i denote the multiplicity of failures at t_i; that is, d_i is the size of the set $\mathcal{D}_i$ of individuals that fail at t_i. Let $\mathcal{R}_i$ be the risk set at t_i. Using this notation, the following equations describe the partial likelihood functions that PROC PHSELECT uses to estimate $\boldsymbol{\beta}$.

Breslow Likelihood

$$L(\boldsymbol{\beta}) = \prod_{i=1}^{k} \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} \mathbf{Z}_j}}{\left[\sum_{l \in \mathcal{R}_i} e^{\boldsymbol{\beta}' \mathbf{Z}_l} \right]^{d_i}}$$

If you incorporate weights, the Breslow likelihood becomes

$$L(\boldsymbol{\beta}) = \prod_{i=1}^{k} \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} w_j \mathbf{Z}_j}}{\left[\sum_{l \in \mathcal{R}_i} w_l e^{\boldsymbol{\beta}' \mathbf{Z}_l} \right]^{\sum_{j \in \mathcal{D}_i} w_j}}$$

In a stratified analysis, the partial likelihood is the product of the partial likelihood functions for the individual strata.

The regression coefficients are estimated by maximizing the log of the partial likelihood function with respect to $\boldsymbol{\beta}$.

The LASSO Method of Model Selection

LASSO Selection

The PHSELECT procedure implements the group LASSO method, which is described in the section "Group LASSO Selection" on page 87 in Chapter 2, "Shared Concepts." The current section provides some background about the LASSO method that you need in order to understand the group LASSO method.

LASSO (least absolute shrinkage and selection operator) selection arises from a constrained form of ordinary least squares regression in which the sum of the absolute values of the regression coefficients is constrained to be smaller than a specified parameter. More precisely, let $\mathbf{Z} = (\mathbf{z}_1, \mathbf{z}_2, \ldots, \mathbf{z}_m)$ denote the matrix of covariates, and let $\mathbf{y}$ denote the response. Then for a given parameter t, the LASSO regression coefficients $\boldsymbol{\beta} = (\beta_1, \beta_2, \ldots, \beta_m)$ are the solution to the following constrained least squares problem:

$$\min ||\mathbf{y} - \mathbf{Z}\boldsymbol{\beta}||^2 \qquad \text{subject to} \quad \sum_{j=1}^{m} |\beta_j| \leq t$$

For the Cox proportional hazards regression model, the LASSO regression coefficients $\boldsymbol{\beta} = (\beta_1, \beta_2, \ldots, \beta_m)$ are the solution to the following constrained optimization problem,

$$\min\{-l(\boldsymbol{\beta})\} \qquad \text{subject to} \quad \sum_{j=1}^{m} |\beta_j| \leq t$$

where $l(\boldsymbol{\beta})$ is the log of the partial likelihood function $L(\boldsymbol{\beta})$ defined in the section "Partial Likelihood for the Cox Model" on page 1357.

Provided that the LASSO parameter t is small enough, some of the regression coefficients will be exactly 0. Hence, you can think of the LASSO method as selecting a subset of the regression coefficients for each LASSO parameter. By increasing the LASSO parameter in discrete steps, you obtain a sequence of regression coefficients for which the nonzero coefficients at each step correspond to selected parameters. For more information about the LASSO method, see, for example, Hastie, Tibshirani, and Friedman (2009).

Model Fit and Assessment Statistics

The statistics that are defined in this section are useful for assessing the fit of the model to your data; they are displayed in the "Fit Statistics" table. The statistics are computed for each data role when you specify a PARTITION statement.

Information Criteria

The calculation of the information criteria uses the following formulas, where p denotes the number of effective parameters in the candidate model, F denotes the sum of the frequencies of the uncensored observations that are used, and l is the log partial likelihood that is evaluated at the converged estimates:

$$\begin{aligned}
\text{AIC} &= -2l + 2p \\
\text{AICC} &= \begin{cases} -2l + 2pF/(F-p-1) & \text{when } F > p+2 \\ -2l + 2p(p+2) & \text{otherwise} \end{cases} \\
\text{SBC} &= -2l + p\log(F)
\end{aligned}$$

If you do not specify a FREQ statement, F equals n, the number of uncensored observations that are used.

Predicted Values and Regression Diagnostics

For the ith observation, let $\{(X_i, \Delta_i, \mathbf{Z}_i)\}$ represent the failure time, the event indicator, and the vector of covariate values, respectively. Let $\boldsymbol{\beta}$ be the vector of regression coefficients. For $t \geq 0$, let

$$\begin{aligned}
Y_i(t) &= I(X_i \geq t) \\
N_i(t) &= I(X_i \leq t) \\
S^{(0)}(\boldsymbol{\beta}, t) &= \sum_i Y_i(t)\mathrm{e}^{\boldsymbol{\beta}'\mathbf{Z}_i} \\
S^{(1)}(\boldsymbol{\beta}, t) &= \sum_i Y_i(t)\mathrm{e}^{\boldsymbol{\beta}'\mathbf{Z}_i}\mathbf{Z}_i \\
\bar{\mathbf{Z}}(\boldsymbol{\beta}, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)} \\
d\Lambda_0(\boldsymbol{\beta}, t) &= \sum_i \frac{dN_i(t)}{S^{(0)}(\boldsymbol{\beta}, t)} \\
dM_i(\boldsymbol{\beta}, t) &= dN_i(t) - Y_i(t)\mathrm{e}^{\boldsymbol{\beta}'\mathbf{Z}_i(t)}d\Lambda_0(\boldsymbol{\beta}, t)
\end{aligned}$$

Let $\hat{\boldsymbol{\beta}}$ be the estimator of $\boldsymbol{\beta}$, and let $\mathcal{I}(\hat{\boldsymbol{\beta}})$ be the observed information matrix.

Predicted Values

Let $\mathbf{z}$ be a vector of covariates. The linear predictor and its standard error estimate are, respectively,

$$\mathbf{z}'\hat{\boldsymbol{\beta}} \quad \text{and} \quad \sqrt{\mathbf{z}'\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})\mathbf{z}}$$

The predicted cumulative hazard at a time point t is

$$\hat{\Lambda}(t, \mathbf{z}) = \mathrm{e}^{\hat{\boldsymbol{\beta}}'\mathbf{z}} \int_0^t d\Lambda_0(\hat{\boldsymbol{\beta}}, s)$$

and the predicted survival probability is

$$\hat{\mathbf{S}}(t, \mathbf{z}) = \mathrm{e}^{-\hat{\Lambda}(t,\mathbf{z})}$$

Residuals

The martingale residual for the *i*th observation is

$$\hat{M}_i = \Delta_i - \hat{\Lambda}(X_i, \mathbf{Z}_i)$$

The deviance residual is a transform of the martingale residual,

$$\hat{D}_i = \text{sign}(\hat{M}_i)\sqrt{2[-\hat{M}_i - \Delta_i \log(\Delta_i - \hat{M}_i)]}$$

The square root shrinks large negative martingale residuals, and the logarithmic transformation expands martingale residuals that are close to unity.

The Schoenfeld (1982) residual vector is calculated per event time. If the *i*th observation is uncensored, the Schoenfeld residual vector is

$$\hat{\mathbf{U}}_i = \mathbf{Z}_i - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, X_i)$$

Otherwise, the elements of the Schoenfeld residual vector are set to missing values. Under the proportional hazards assumption, the Schoenfeld residuals have the sample path of a random walk; therefore, they are useful in assessing time trend or lack of proportionality. Harrell (1986) proposed a z-transform of the Pearson correlation between these residuals and the rank order of the failure time as a test statistic for nonproportional hazards.

The score residual vector for the *i*th observation is

$$\hat{\mathbf{L}}_i = \int_0^\infty [\mathbf{Z}_i(s) - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, s)] dM_i(\hat{\boldsymbol{\beta}}, s)$$

The score residuals are a decomposition of the first partial derivative of the log likelihood. They are useful in assessing the influence of each observation on individual parameter estimates. Therneau, Grambsch, and Fleming (1990) have considered a Kolmogorov-type test based on the cumulative sum of the residuals for detecting nonproportional hazards.

Other Regression Diagnostics

The vector of weighted Schoenfeld residuals, $\mathbf{W}_i$, is computed as

$$\mathbf{W}_i = n_e \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})\hat{\mathbf{U}}_i$$

where n_e is the total number of events and $\hat{\mathbf{U}}_i$ is the vector of Schoenfeld residuals for the i observation. The weighted Schoenfeld residuals are useful in assessing the proportional hazards assumption. The idea is that most of the common alternatives to the proportional hazards can be cast in terms of a time-varying coefficient model,

$$\lambda(t, \mathbf{Z}) = \lambda_0(t)\exp(\beta_1(t)Z_1 + \beta_2(t)Z_2 + \cdots)$$

where $\lambda(t, \mathbf{Z})$ and $\lambda_0(t)$ are hazard rates. Let $\hat{\beta}_j$ and r_{ij} be the jth component of $\hat{\boldsymbol{\beta}}$ and $\mathbf{r}_i$, respectively. Grambsch and Therneau (1994) suggest using a smoothed plot of $(\hat{\beta}_j + r_{ij})$ versus t_i to discover the functional form of the time-varying coefficient $\beta_j(t)$. A zero slope indicates that the coefficient does not vary with time.

The DFBETA diagnostics approximate the changes in the parameter estimates, $\delta_i \hat{\boldsymbol{\beta}}_i = \hat{\boldsymbol{\beta}} - \hat{\boldsymbol{\beta}}_{(-i)}$, when the *i*th observation is left out. The *j*th component of $\delta_i \hat{\boldsymbol{\beta}}$ can be used to assess any unusual effect of the *i*th observation on $\hat{\beta}_j$. The exact computation of $\delta_i \hat{\boldsymbol{\beta}}$ involves refitting the model each time a subject is omitted. Cain and Lange (1984) derived the following approximation of $\delta_i \hat{\boldsymbol{\beta}}$ as weighted score residuals,

$$\text{DFBETA}_i = \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})\hat{\mathbf{L}}_i$$

where $\hat{\mathbf{L}}_i$ is the score residual vector of the *i*th observation.

The LD statistic approximates the likelihood displacement, which is the amount by which minus twice the log likelihood ($-2 \log L(\hat{\boldsymbol{\beta}})$), under a fitted model, changes when each observation in turn is left out. When the *i*th subject is omitted, the likelihood displacement is

$$2 \log L(\hat{\boldsymbol{\beta}}) - 2 \log L(\hat{\boldsymbol{\beta}}_{(-i)})$$

where $\hat{\boldsymbol{\beta}}_{(-i)}$ is the vector of parameter estimates that you obtain by fitting the model without the *i*th observation. Instead of refitting the model without the *i*th observation, Pettitt and Bin Daud (1989) propose that the likelihood displacement for the *i*th observation be approximated by

$$\text{LD}_i = \hat{\mathbf{L}}_i' \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})\hat{\mathbf{L}}_i$$

where $\hat{\mathbf{L}}_i$ is the score residual vector of the *i*th observation.

Joint Tests and Type 3 Tests

Linear hypotheses for $\boldsymbol{\beta}$ are expressed in matrix form as

$$H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

where $\mathbf{L}$ is a matrix of coefficients for the linear hypotheses and $\mathbf{c}$ is a vector of constants. The vector of regression coefficients $\boldsymbol{\beta}$ includes slope parameters and intercept parameters. The Wald chi-square statistic for testing H_0 is computed as

$$\chi^2_W = (\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})'[\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}']^{-1}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})$$

where $\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})$ is the estimated covariance matrix. Under H_0, χ^2_W has an asymptotic chi-square distribution with r degrees of freedom, where r is the rank of $\mathbf{L}$.

For models that use less-than-full-rank parameterization (as specified by the PARAM=GLM option in the CLASS statement), a Type 3 test of an effect of interest (main effect or interaction) is a test of the Type III estimable functions that are defined for that effect. When the model contains no missing cells, the Type 3 test of a main effect is equivalent to testing the hypothesis of equal marginal means. For more information about Type III estimable functions, see the chapter "The GLM Procedure" and the section "The Four Types of Estimable Functions" in *SAS/STAT User's Guide*. Also see Littell, Freund, and Spector (1991).

For models that use full-rank parameterization, all parameters are estimable when there are no missing cells, so it is unnecessary to define estimable functions. The standard test of an effect of interest in this case is the joint test that the values of the parameters associated with that effect are 0. For a model that uses effects parameterization (as specified by the PARAM=EFFECT option in the CLASS statement), the joint test for a main effect is equivalent to testing the equality of marginal means. For a model that uses

reference parameterization (as specified by the PARAM=REF option in the CLASS statement), the joint test is equivalent to testing the equality of cell means at the reference level of the other model effects. For more information about the coding scheme and the associated interpretation of results, see Muller and Fetterman (2002, Chapter 14).

If there is no interaction term, the Type 3 test of an effect for a model that uses GLM parameterization is the same as the joint test of the effect for the model that uses full-rank parameterization. In this situation, the joint test is also called the Type 3 test. For a model that contains an interaction term and no missing cells, the Type 3 test of a component main effect under GLM parameterization is the same as the joint test of the component main effect under effect parameterization. Both test the equality of cell means. But this Type 3 test differs from the joint test under reference parameterization, which tests the equality of cell means at the reference level of the other component main effect. If some cells are missing, you can obtain meaningful tests only by testing a Type III estimation function, so in this case you should use GLM parameterization.

The results of a Type 3 test or a joint test do not depend on the order in which you specify the terms in the MODEL statement.

Multithreading

The PHSELECT procedure allocates data to different threads and calculates the likelihood function, gradient, and Hessian by accumulating the values from all threads. For more information about how PROC PHSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Optimization Algorithms

Several optimization techniques are available in PROC PHSELECT. You can choose a particular optimizer by using the TECHNIQUE= option in the PROC PHSELECT statement. Table 26.9 summarizes the optimization techniques available in PROC PHSELECT.

Table 26.9 Optimization Techniques

TECHNIQUE=	Algorithm
TRUREG	Trust region method
NEWRAP	Newton-Raphson method with line search
NRRIDG	Newton-Raphson method with ridging
QUANEW	Quasi-Newton methods
DBLDOG	Double-dogleg method
CONGRA	Conjugate gradient methods
NMSIMP	Nelder-Mead simplex method

There is no algorithm for optimizing general nonlinear functions that always finds the global optimum for a general nonlinear optimization problem in a reasonable amount of time. Because no single optimization technique is always superior to others, PROC PHSELECT provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in PROC PHSELECT can find the correct solution. Moreover, nonlinear optimization can be computationally

expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem. The section "Choosing an Optimization Algorithm" on page 103 in Chapter 2, "Shared Concepts," is helpful in choosing a suitable optimization algorithm.

In addition, PROC PHSELECT uses the finite-difference method to compute second-order derivatives, unless you specify the HESSIAN option. The HESSIAN option requires extra memory, the size of which also depends on the number of distinct uncensored failure times in the data.

Displayed Output

The following sections describe the output that PROC PHSELECT produces. The output is organized into various tables, which are discussed in their order of appearance.

Model Information

The "Model Information" table displays basic information about the model, such as the response variable, the frequency variable, the link function, and the distribution of the data that is assumed by the PHSELECT procedure.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis. If you specify a FREQ statement, the table displays the sum of the frequencies that are read and used. If you specify a WEIGHT statement, the table displays the sum of $f_i w_i$ that are read and used. If you specify a PARTITION statement, the table displays the values for each role.

–2 Log Likelihood for Null Model

When you specify the LOGLIKENULL option in the PROC PHSELECT statement, the PHSELECT procedure displays the –2 log-likelihood value of the null model for the training data. If you also specify a PARTITION statement, PROC PHSELECT displays the corresponding statistic for the validation data and the test data.

Class Level Information

The "Class Level Information" table lists the levels of every variable that you specify in the CLASS statement. You should check this information to make sure that the data are correct. You can adjust the order of the CLASS variable levels by using the ORDER= option in the CLASS statement. You can suppress the "Class Level Information" table completely or partially by using the NOCLPRINT= option in the PROC PHSELECT statement.

If the classification variables use a nonsingular parameterization, the "Class Level Information" table also displays the reference value for each variable.

Selection Information

When you specify the SELECTION statement, the PHSELECT procedure by default produces a series of tables that display information about the model selection. The "Selection Information" table informs you about the model selection method, selection and stop criteria, and other parameters that govern the selection. You can suppress this table by specifying DETAILS=NONE in the SELECTION statement.

Iteration History

When you specify the ITHIST option in the PROC PHSELECT statement, the "Iteration History" table displays, for each iteration of the optimization, the number of function evaluations (including gradient and Hessian evaluations), the value of the objective function, the change in the objective function from the previous iteration, and the absolute value of the largest (projected) gradient element.

Convergence Status

The convergence status table is a small ODS table that appears as a message that indicates whether the optimization succeeded and which convergence criterion was met. If the optimization fails, the message indicates the reason for the failure. If you save the convergence status table to an output data set, a numeric Status variable is added that enables you to assess convergence programmatically. The values of the Status variable indicate the following:

0 Convergence was achieved, or an optimization was not performed (because TECHNIQUE=NONE is specified).

1 The objective function could not be improved.

2 Convergence was not achieved because of a user interruption or because a limit was exceeded, such as the maximum number of iterations or the maximum number of function evaluations. To modify these limits, see the MAXITER=, MAXFUNC=, and MAXTIME= options in the PROC PHSELECT statement.

3 Optimization failed to converge because function or derivative evaluations failed at the starting values or during the iterations or because a feasible point that satisfies the parameter constraints could not be found in the parameter space.

Entry and Removal Candidates

When you specify DETAILS=ALL or DETAILS=STEPS in the SELECTION statement, the PHSELECT procedure produces the "Entry Candidates" or "Removal Candidates" table, which displays the effect names and values of the criterion used to select entering or departing effects at each step of the selection process. For each step, the effects are displayed in sorted order from best to worst of the selection criterion.

Selection Summary

When you specify the SELECTION statement, the PHSELECT procedure produces the "Selection Summary" table, which displays information about which effects were added to or removed from the model in the various steps of the model selection process. The statistic that led to the entry or removal decision is also displayed. You can request further details about the model selection steps by specifying DETAILS=STEPS or DETAILS=ALL in the SELECTION statement. You can suppress the display of this table by specifying DETAILS=NONE in the SELECTION statement.

If you specify the LASSO selection method, then this table displays information about which effect was added to the model, the number of effects in the model, the lambda value, and the information criteria.

Stop Reason

When you specify the SELECTION statement, the PHSELECT procedure produces a simple table that tells you why model selection stopped.

Selection Reason

When you specify the SELECTION statement, the PHSELECT procedure produces a simple table that tells you why the final model was selected.

Selected Effects

When you specify the SELECTION statement, the PHSELECT procedure produces a simple table that tells you which effects are in the final model.

Dimensions

The "Dimensions" table displays size measures that are derived from the model. It displays the number of columns in the current design matrix, the number of effects in the current design, the largest number of design columns associated with an effect, the rank of the matrix, and the number of parameters in the current model, including any scale parameters.

Fit Statistics

The "Fit Statistics" table displays a variety of likelihood-based measures of fit. The values that the "Fit Statistics" table displays are not based on a normalized log-likelihood function. If you specify a PARTITION statement, the table displays the values for each role along with statistics for comparing the training, validation, and testing results. For more information about the statistics that this table displays, see the section "Model Fit and Assessment Statistics" on page 1358.

Parameter Estimates

The parameter estimates, their estimated (asymptotic) standard errors, and p-values for the hypothesis that the parameter is 0 are displayed in the "Parameter Estimates" table. If you request confidence intervals by specifying the CLB option in the MODEL statement, confidence limits are displayed for the parameters.

Parameter Estimates Covariance Matrix

When you specify the COVB option in the PROC PHSELECT statement, the PHSELECT procedure displays the covariance matrix of the parameter estimates. The covariance matrix is computed as the inverse of the negative of the matrix of second derivatives of the log-likelihood function with respect to the model parameters (the Hessian matrix), evaluated at the parameter estimates.

Parameter Estimates Correlation Matrix

When you specify the CORRB option in the PROC PHSELECT statement, the PHSELECT procedure displays the correlation matrix of the parameter estimates.

Model Analysis of Variance (Type III)

When you specify the TYPE3 option in the MODEL statement, the PHSELECT procedure produces the "Model Analysis of Variance (Type III)" table. This table displays tests that all parameters for a particular effect are equal to zero. For more information, see the section "Joint Tests and Type 3 Tests" on page 1361.

Timing

The "Timing" table displays the amount of time (in seconds) that PROC PHSELECT required to perform different tasks in the analysis.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the PHSELECT procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or ODS statements. These names are listed in Table 26.10.

NOTE: The EFFECT statement also create tables which are not listed in this section. For information about these tables, see "ODS Table Names" on page 33 in Chapter 2, "Shared Concepts."

Table 26.10 ODS Tables Produced by PROC PHSELECT

Table Name	Description	Statement	Option
ClassInfo	Level information from the CLASS statement	CLASS	Default
ConvergenceStatus	Status of optimization at conclusion of optimization	Default	
CorrB	Correlation matrix of parameter estimates	PROC PHSELECT	CORRB
CovB	Covariance matrix of parameter estimates	PROC PHSELECT	COVB
Dimensions	Model dimensions	Default	

Table 26.10 *continued*

Table Name	Description	Statement	Option
EntryCandidates	Details about candidates for entry into the model	SELECTION	METHOD=FORWARD or STEPWISE and DETAILS=STEP
FitStatistics	Fit statistics	Default	
IterHistory	Iteration history	PROC PHSELECT	ITHIST
LogLikeNull	–2 log likelihood for null model	PROC PHSELECT	LOGLIKENULL
ModelAnova	Model analysis of variance (Type III)	MODEL	TYPE3
ModelInfo	Information about the modeling environment	Default	
NObs	Number of observations read and used, and breakdown of censored and uncensored values	Default	
OutputCasTables	See the section "OutputCasTables Table" on page 1366	OUTPUT DISPLAYOUT	OUT=
ParameterEstimates	Solutions for the parameter estimates associated with effects in MODEL statements	Default	
RemovalCandidates	Details about candidates for removal from the model	SELECTION	METHOD=BACKWARD or STEPWISE and DETAILS=STEP
SelectedEffects	List of effects selected for the model	SELECTION	Default
SelectionInfo	Information about the settings for model selection	SELECTION	Default
SelectionReason	Reason why the particular model was selected	SELECTION	Default
SelectionSummary	Summary information about model selection steps	SELECTION	Default
StopReason	Reason for termination of model selection	SELECTION	Default
Timing	Absolute and relative times for tasks performed by the procedure	Default	

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in the "Statistical Graphics Using ODS" chapter in *SAS/STAT User's Guide*.

Before you create graphs, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

When ODS Graphics is enabled, the SELECTION statement can produce plots to help evaluate the selection process. For information about these plots, see the section "Model Selection Plots" on page 93 in Chapter 2, "Shared Concepts."

PROC PHSELECT assigns a name to each graph that it creates using ODS. You can use these names to refer to the graphs when using ODS. The names are listed in Table 26.11.

Table 26.11 Graphs Produced by PROC PHSELECT

ODS Graph Name	Plot Description	PLOTS= Option
CoefficientPanel	Coefficients and CHOOSE= criterion by step	COEFFICIENTS
ChooseCriterionPlot	CHOOSE= criterion by step	COEFFICIENTS(UNPACK)
CoefficientPlot	Coefficients by step	COEFFICIENTS(UNPACK)
CriterionPanel	Fit criteria by step	CRITERIA
TEST_M2LLPlot	–2 log likelihood on testing data by step	CRITERIA(UNPACK)
TRAIN_M2LLPlot	–2 log likelihood on training data by step	CRITERIA(UNPACK)
VAL_M2LLPlot	–2 log likelihood on validation data by step	CRITERIA(UNPACK)
FitByRolePlot	Progression of average square error by role	FITBYROLE

Examples: PHSELECT Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The following examples assume that your libref is named mylib, but you can substitute any appropriately defined libref.

Example 26.1: Model Selection

(View the complete code for this example (phex1.sas) in the example repository.)

The following statements examine the same data as in the section "Getting Started: PHSELECT Procedure" on page 1334, but they request model selection via the forward selection technique. Effects that provide the best improvement to the selection criterion, the Schwartz Bayesian criterion (SBC), are added until no more effects can improve the selection criterion. The DETAILS=ALL option in the SELECTION statement produces all tables that are related to model selection. The PLOTS=ALL option produces graphics to help you interpret the selection process. ODS Graphics must be enabled before you can request plots. (For more information about ODS Graphics, see the section "ODS Graphics" on page 1368.)

```
ods graphics on;

proc phselect data=mylib.getStarted;
   class C1-C3;
   model Time*Status(0) = C1-C3 X1-X4;
   selection method=forward(stop=sbc select=sbc) details=all plots=all;
run;
```

The model selection tables are shown in Output 26.1.1 through Output 26.1.3. Results from the selected model are shown in Output 26.1.4 and Output 26.1.5. Selection graphics that the PLOTS= option produces are displayed in Output 26.1.6 and Output 26.1.7.

The "Selection Information" table in Output 26.1.1 summarizes the settings for the model selection. Effects are added to the model only if they produce a significant improvement, which is determined by comparing their SBC values. The forward selection stops three steps after the smallest SBC is obtained or when all effects have been added to the model.

Output 26.1.1 Selection Information

The PHSELECT Procedure

Selection Information	
Description	**Value**
Selection Method	Forward
Select Criterion	SBC
Stop Criterion	SBC
Effect Hierarchy Enforced	None
Stop Horizon	3

For each step of the selection process, the DETAILS=ALL option displays the candidate effects for entering the model along with their SELECT= criterion. Output 26.1.2 displays this table for the first step; the other steps are not shown here.

Output 26.1.2 Step1 Entry Candidates

The PHSELECT Procedure

Forward Selection: Step 1
Effect Entered: X1

Entry Candidates		
Rank	**Effect**	**SBC**
1	**X1**	536.7462
2	**X4**	539.8497
3	**C2**	544.9948
4	**X3**	548.2815
5	**X2**	548.9490
6	**C3**	549.1132
7	**C1**	551.8649

The DETAILS=ALL option also displays the dimensions, fit statistics, and parameter estimates at each step of the selection process; these details are not shown here.

When the selection procedure is complete, the "Selection Summary" table in Output 26.1.3 shows the effects that were added to the model and the value of their selection criterion (and the choose and stop criteria, if they are specified). In step 1, effect X1 made the most significant contribution to the model among the candidate effects, according to the SBC statistic. In step 2, X4 made the most significant contribution when an effect was added to a model that contains X1. In the three subsequent steps, no effect could be added to the model that would reduce the SBC value, so variable selection stopped because the stop horizon (see Output 26.1.1) indicates that at most three steps beyond the minimum SBC value are taken.

In Output 26.1.3, the "Selection Summary" table is followed by three small tables that summarize why the process stopped and which model is selected.

Output 26.1.3 Selection Summary Information

The PHSELECT Procedure

Selection Details

Selection Summary

Step	Effect Entered	Number Effects In	SBC
1	X1	1	536.7462
2	X4	2	535.1652*
3	C1	3	538.2917
4	X2	4	539.2661
5	X3	5	542.4842

* Optimal Value Of Criterion

Selection stopped at a local minimum of the SBC criterion.

The model at step 2 is selected.

Selected Effects: X1 X4

Output 26.1.4 displays information about the selected model. Notice that the –2 log-likelihood value in the "Fit Statistics" table is larger than the value for the full model in Figure 26.7. This is expected because the selected model contains only a subset of the parameters. Because the selected model is more parsimonious than the full model, the discrepancy between the –2 log likelihood and the information criteria is less severe than that shown in Figure 26.7 in the "Getting Started" example.

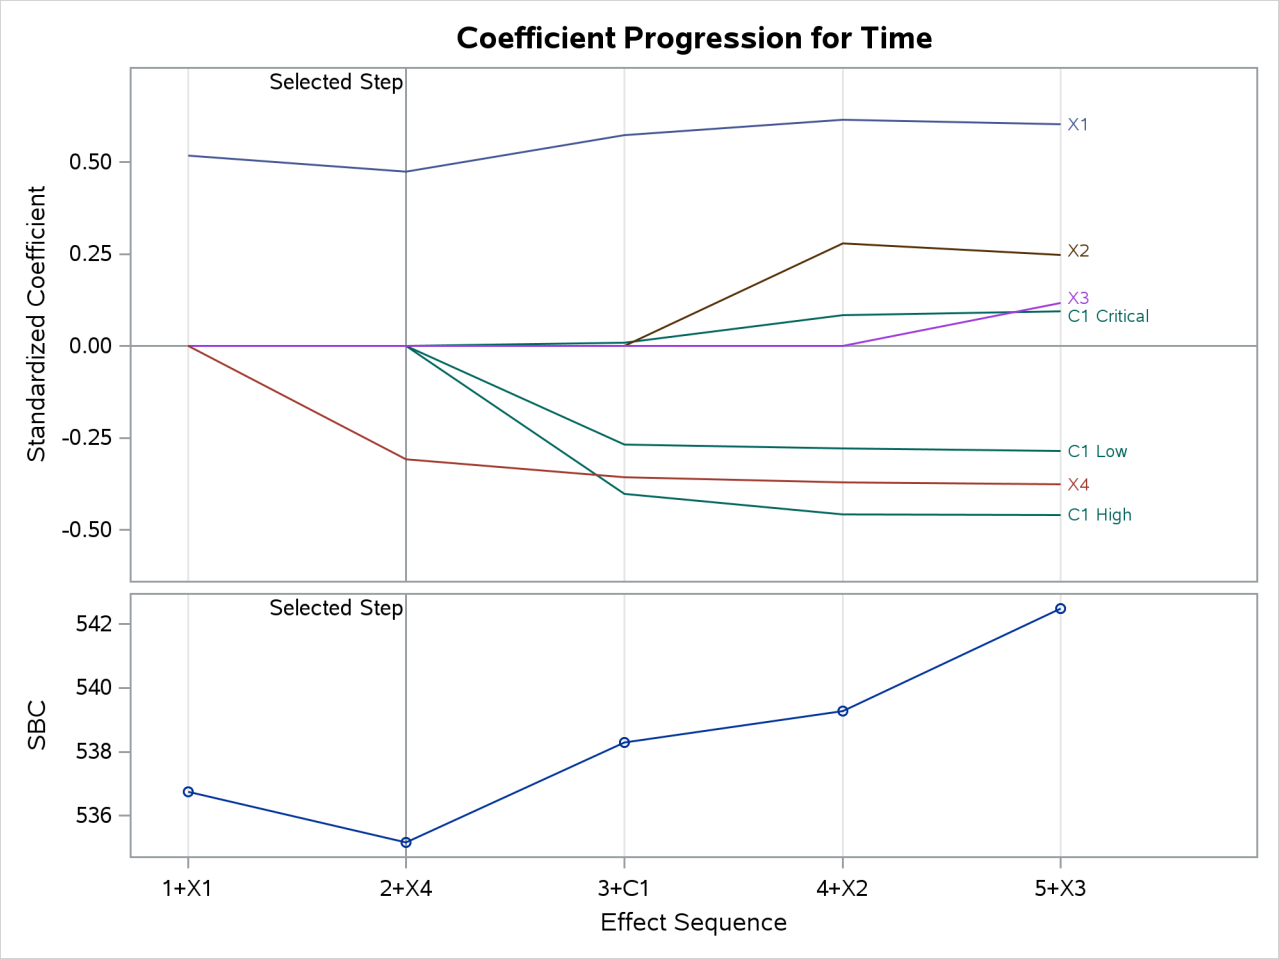
Output 26.1.4 Dimensions and Fit Statistics

The PHSELECT Procedure

Selected Model

Dimensions	
Number of Effects	2
Max Effect Columns	1
Columns in Design	2
Rank of Design	2

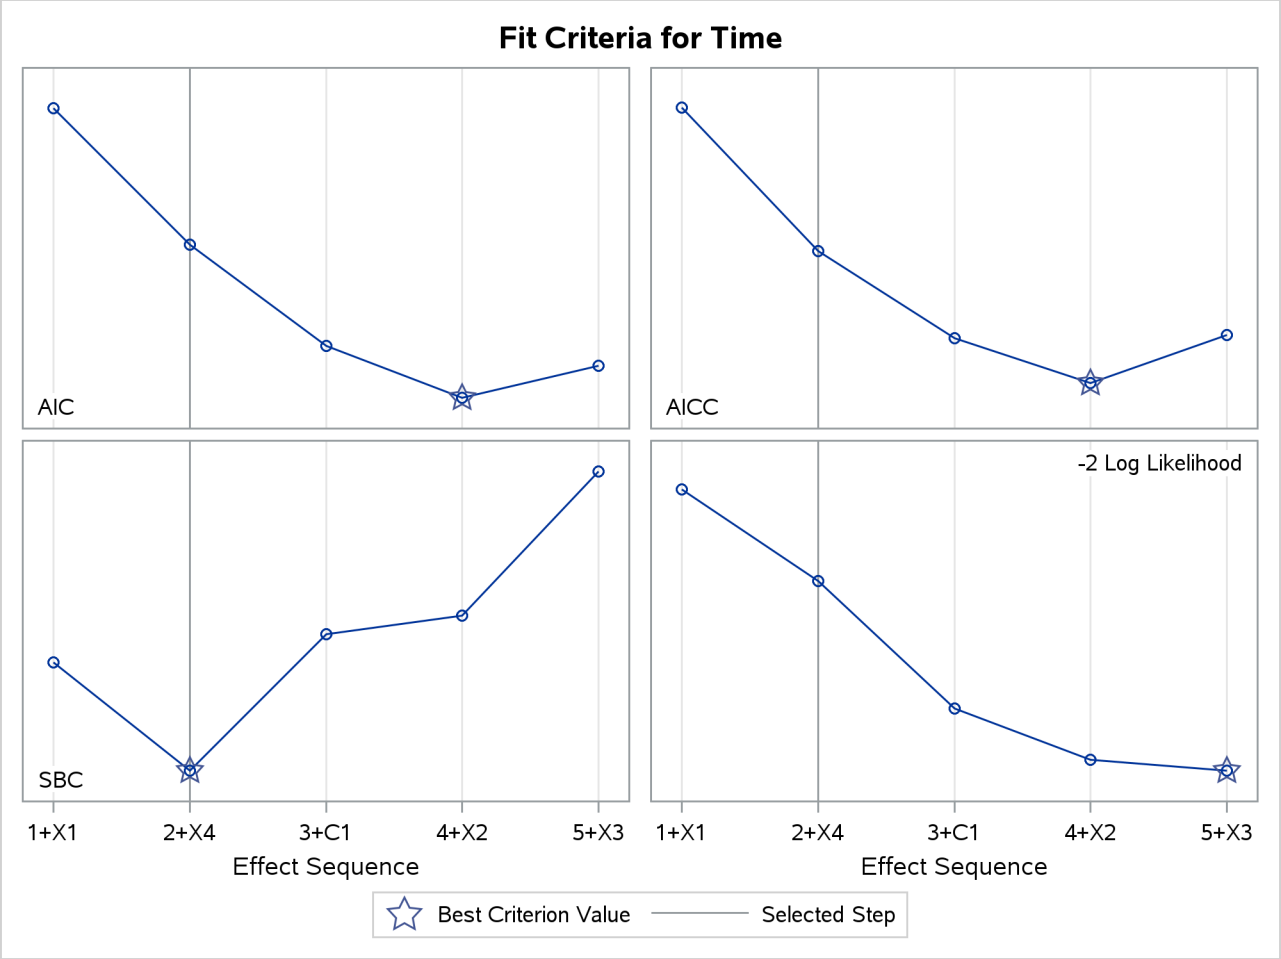
Fit Statistics	
-2 Log Likelihood	526.74445
AIC (smaller is better)	530.74445
AICC (smaller is better)	530.91346
SBC (smaller is better)	535.35258



The parameter estimates of the selected model are shown in Output 26.1.5. Notice that the effects are listed in the "Parameter Estimates" table in the order in which they are specified in the MODEL statement and not necessarily in the order in which they are added to the model.

Output 26.1.5 Parameter Estimates

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
X1	1	1.605306	0.513811	9.7613	0.0018
X4	1	-0.123304	0.046697	6.9723	0.0083



The coefficient panel in Figure 26.1.6 enables you to visualize the selection process. In this plot, standardized coefficients of all the effects that are selected at some step of the stepwise method are plotted as a function of the step number. This enables you to assess the relative importance of the effects that are selected at any step of the selection process and to know when effects entered the model. The lower plot in the panel shows how the criterion that is used to choose the selected model changes as effects enter or leave the model.

Output 26.1.6 Coefficient Progression

The criterion panel in Figure 26.1.7 provides a graphical view of the progression of the fit criteria as the selection process evolves. Notice at Step 2 that the SBC value seems to be at its minimum. Because the stop horizon value is 3 (see Output 26.1.1), three more steps are taken to determine if Step 2 is a global optimum. None of these three subsequent steps have a smaller SBC value than in Step 2, so the global optimum is at step 2.

Output 26.1.7 Criterion Panel

Example 26.2: Stratified Analysis

(View the complete code for this example (phex2.sas) in the example repository.)

In the getStarted data set that is presented in the section "Getting Started: PHSELECT Procedure" on page 1334, suppose the variable C3 represents the gender of the subjects. It is conceivable that males and females belong to different subpopulations and might have different baseline hazard functions. A stratified analysis is conducted by specifying C3 as the stratifying variable in the STRATA statement. The CODE statement requests that a text file named *ScoreCode.txt* be created. This file contains SAS DATA step code to predict survival probabilities at time points that are specified by the TIMEPOINT= option. By default, PROC PHSELECT uses the estimated quartiles of the KM curve (no covariates) of the training data. The SHOWTIME option produces variables that contain these estimated time points.

```
proc phselect data=mylib.getStarted;
   class C1 C2;
   model Time*Status(0) = C1 C2 X1-X4;
   strata C3;
   code file='ScoreCode.txt' showtime;
```

```
run;
```

The "Parameter Estimates" table in Output 26.2.1 shows the resulting regression parameter estimates of the stratified analysis.

Output 26.2.1 Parameter Estimates

The PHSELECT Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	Chi-Square	Pr > ChiSq
C1 Critical	1	0.301314	0.512375	0.3458	0.5565
C1 High	1	-1.030679	0.334457	9.4966	0.0021
C1 Low	1	-0.649179	0.342083	3.6014	0.0577
C1 Medium	0	0	.	.	.
C2 0	1	0.519843	0.405972	1.6396	0.2004
C2 1	0	0	.	.	.
X1	1	1.970290	0.534947	13.5656	0.0002
X2	1	0.752247	0.419589	3.2142	0.0730
X3	1	0.959931	0.600959	2.5515	0.1102
X4	1	-0.117182	0.059406	3.8910	0.0485

You can use the DATA step code from the CODE statement to compute direct adjusted survival probabilities by taking the average of individual predicted survival probabilities. The method of direct adjustment controls for possible confounders that result from an imbalance of subject characteristics between groups. This adjustment is especially useful in nonrandomized studies. In the following statements, the DATA step code is applied to the getStarted data set to obtain the predicted survival probabilities for individuals in that data set and the predicted probabilities at each time point are averaged by gender:

```
data Scores;
   set mylib.getStarted;
   %inc 'ScoreCode.txt';
run;

proc print data=Scores (obs=1);
   var Time_:;
run;

proc means data=Scores mean;
   class C3;
   var S_Time_:;
run;
```

Output 26.2.2 displays the time points at which the survival probabilities were predicted. These time points, Time_1=7, Time_2=19, and Time_3=54, are the quartiles of the failure times based on the Kaplan-Meier curve. Output 26.2.3 displays the direct adjusted survival probabilities at these quartiles. The predicted survival probability at Time_1 for females is slightly lower than that for males, but at Time_3 the direction is reversed. Also revealed is that the getStarted data set has 76 males but only 24 females.

Output 26.2.2 Quartiles of the Observed Failure Times

Obs	Time_1	Time_2	Time_3
1	7	19	54

Output 26.2.3 Direct Adjusted Survival Probabilities

The MEANS Procedure

C3	N Obs	Variable	Label	Mean
F	24	S_Time_1	Survival Probability at Time_1	0.7016195
		S_Time_2	Survival Probability at Time_2	0.3693234
		S_Time_3	Survival Probability at Time_3	0.2765601
M	76	S_Time_1	Survival Probability at Time_1	0.7485799
		S_Time_2	Survival Probability at Time_2	0.4568778
		S_Time_3	Survival Probability at Time_3	0.2354066

Overview: PLSMOD Procedure

The PLSMOD procedure fits reduced-rank linear models in SAS Viya

by using any one of a number of linear predictive methods, including *partial least squares* (PLS).

Ordinary least squares regression, as implemented in SAS/STAT procedures such as the GLM and REG procedures, has the single goal of minimizing sample response prediction error, and it seeks linear functions of the predictors that explain as much variation in each response as possible. The PLSMOD procedure implements techniques that have the additional goal of accounting for variation in the predictors, under the assumption that directions in the predictor space that are well sampled should provide better prediction for *new* observations when the predictors are highly correlated. All the techniques that the PLSMOD procedure implements work by extracting successive linear combinations of the predictors, called *factors* (also called *components*, *latent vectors*, or *latent variables*), that optimally address one or both of these two goals: explaining response variation and explaining predictor variation. In particular, the method of partial least squares balances the two objectives by seeking factors that explain both response and predictor variation.

The name "partial least squares" also applies to a more general statistical method that is *not* implemented in this procedure. The partial least squares method was originally developed in the 1960s by the econometrician Herman Wold (1966) for modeling "paths" of causal relation between any number of "blocks" of variables. However, the PLSMOD procedure fits only *predictive* partial least squares models that have one "block" of predictors and one "block" of responses. If you are interested in fitting more general path models, consider using the CALIS procedure in SAS/STAT.

PROC PLSMOD Features

The main features of the PLSMOD procedure are as follows:

- provides model-building syntax with classification variables, continuous variables, interactions, and nestings
- provides effect-construction syntax for polynomial and spline effects
- supports partitioning of data into training and testing roles
- provides test set validation to choose the number of extracted factors, where the model is fit to only part of the available data (the training set) and the fit is evaluated over the other part of the data (the test set)
- produces an output data table that contains predicted values and other observationwise statistics

The PLSMOD procedure implements the following methods:

- principal component regression, which extracts factors to explain as much predictor sample variation as possible
- reduced rank regression, which extracts factors to explain as much response variation as possible. This technique, also known as (maximum) redundancy analysis, differs from multivariate linear regression only when there are multiple responses.
- partial least squares regression, which balances the two objectives of explaining response variation and explaining predictor variation. Two different formulations for partial least squares are available: the original predictive method of Wold (1966) and the straightforward implementation of a statistically inspired modification of the partial least squares (SIMPLS) method of De Jong (1993).

Because the PLSMOD procedure runs on SAS Cloud Analytic Services (CAS), it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode
- exploits all the available cores and concurrent threads. For information about how PROC PLSMOD uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC PLSMOD Compared with Other SAS Procedures

The PLSMOD procedure provides functionality to fit reduced-rank linear models that is comparable to that of the HPPLS and PLS procedures in SAS/STAT software.

PROC PLSMOD Compared with the HPPLS Procedure

The functionality of the PLSMOD procedure closely resembles that of the HPPLS procedure, which is a high-performance procedure. The PLSMOD procedure is the next generation of the HPPLS procedure, and it was developed specifically for SAS Viya. Both procedures are designed to run on a cluster of machines that distribute the data and the computations.

The PLSMOD procedure and the HPPLS procedure have the similarities and differences shown in Table 27.1.

Table 27.1 Comparison of PROC PLSMOD and PROC HPPLS

Feature	PROC PLSMOD	PROC HPPLS
Supports general factor extraction methods	Yes	Yes
Supports EFFECT statement	Yes	No
Supports DISPLAY and DISPLAYOUT statements	Yes	No
Supports BY statement	Yes	Yes
Supports ID statement	No	Yes
Supports MISSING=, VARSCALE, and PLOTS options	No	No
Supports cross validation methods	Only test set validation by using the PARTITION statement	Only test set validation by using the PARTITION statement
Includes input variables in output data table	Not by default, in order to avoid data duplication for large data tables. To include input variables, specify them in the COPYVARS= option in the OUTPUT statement.	Not by default, in order to avoid data duplication for large data sets. To include input variables, specify them in the ID statement.
Supports parameterization of classification variables	Full set of parameterizations (supports all values of the PARAM= option in the CLASS statement)	Supports only PARAM=GLM or PARAM=REFERENCE
Threading	Specifically designed for CAS; executes on multiple threads	Primarily designed for a distributed environment; executes on multiple threads

PROC PLSMOD Compared with the PLS Procedure

The PLSMOD procedure and the PLS procedure have the similarities and differences shown in Table 27.2.

Table 27.2 Comparison of PROC PLSMOD and PROC PLS

Feature	PROC PLSMOD	PROC PLS
Supports general factor extraction methods	Yes	Yes
Supports EFFECT statement	Yes	Yes
Supports DISPLAY and DISPLAYOUT statements	Yes	No
Supports BY statement	Yes	Yes
Supports ID statement	No	Yes
Supports MISSING=, VARSCALE, and PLOTS options	No	Yes
Supports cross validation methods	Only test set validation by using the PARTITION statement	Various methods
Syntax of OUTPUT statement	No prefix needed; default prefix used if none is provided. If you do not specify any keywords, the output data table includes predicted values for response variables.	You must provide keyword and prefix
Includes input variables in output data table	Not by default, in order to avoid data duplication for large data tables. To include input variables, specify them in the COPYVARS= option in the OUTPUT statement.	Yes
Supports parameterization of classification variables	Full set of parameterizations (supports all values of the PARAM= option in the CLASS statement)	Only GLM parameterization
Threading	Specifically designed for CAS; executes on multiple threads	Executes on a single thread

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “Introduction to Shared Concepts” on page 6 in Chapter 2, “Shared Concepts.”

Getting Started: PLSMOD Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/plsmodgs1.sas.)

The example in this section illustrates basic features of the PLSMOD procedure. The data are reported in Umetrics (1995); the original source is Lindberg, Persson, and Wold (1983). Suppose you are researching pollution in the Baltic Sea and you want to use the fluorescence spectra of seawater samples to determine the amounts of three compounds present: lignin sulfonate (ls: pulp industry pollution), humic acids (ha: natural forest products), and optical whitener from detergent (dt). Spectrometric calibration is a type of problem in which partial least squares can be very effective. The predictors are the spectra emission intensities at different frequencies in a sample spectrum, and the responses are the amounts of various chemicals in the sample.

For the purpose of calibrating the model, samples that have known compositions are used. The calibration data consist of 16 samples of known concentrations of ls, ha, and dt, with spectra based on 27 frequencies (or, equivalently, wavelengths). In order to demonstrate the use of test set validation, the data contain a variable Role, which is used to assign observations to the training and testing roles. In this case, the training role has nine samples and the testing role has seven samples.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The following DATA step creates the mylib.Sample data table, which provides the calibration data, in your CAS session. These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.Sample;
   input obsnam $ v1-v27 ls ha dt Role $5. @@;

Fitting a PLS Model

To isolate a few underlying spectral factors that provide a good predictive model, you can fit a PLS model to the 16 samples by using the following SAS statements:

```
proc plsmod data=mylib.sample;
   model ls ha dt = v1-v27;
run;
```

By default, the PLSMOD procedure extracts at most 15 factors. The default output from this analysis is presented in Figure 27.1 and Figure 27.2.

Figure 27.1 displays the "Model Information," "Dimensions," and "Number of Observations" tables.

The "Model Information" table identifies the data source and shows that the factor extraction method is partial least squares regression (which is the default) and that the nonlinear iterative partial least squares (NIPALS) algorithm (which is also the default) is used to compute extracted PLS factors.

The "Dimensions" table shows the number of response variables, the number of effects, the number of predictor parameters, and the number of factors to extract.

The "Number of Observations" table shows that all 16 of the sample observations in the input data are used in the analysis; all the samples are used because they all contain complete data.

Figure 27.1 Model Information, Dimensions, and Number of Observations

The PLSMOD Procedure

Model Information	
Data Source	SAMPLE
Factor Extraction Method	Partial Least Squares
PLS Algorithm	NIPALS
Validation Method	None

Dimensions	
Number of Response Variables	3
Number of Effects	27
Number of Predictor Parameters	27
Number of Factors	15

Number of Observations Read	16
Number of Observations Used	16

Figure 27.2 lists the amount of variation, both individual and cumulative, that is accounted for by each of the 15 factors. All the variation in both the predictors and the responses is accounted for by only 15 factors because there are only 16 sample observations. More important, almost all the variation is accounted for by even fewer factors—one or two for the predictors and three to eight for the responses.

Figure 27.2 PLS Variation Summary

Percentage Variation Accounted for by Partial Least Squares Factors

Selecting the Number of Factors by Test Set Validation

A PLS model is not complete until you choose the number of factors. You can choose the number of factors by using test set validation, in which the data table is divided into two groups called the training data and test data. You fit the model to the training data, and then you check the capability of the model to predict responses for the test data. The predicted residual sum of squares (PRESS) statistic is based on the residuals that are generated by this process.

To select the number of extracted factors by test set validation, you use the PARTITION statement to specify how to logically divide observations in the input data table into two subsets for model training and testing. For example, you can designate a variable in the input data table and a set of formatted values of that variable to determine the role of each observation, as in the following SAS statements:

```
proc plsmod data=mylib.sample;
   model ls ha dt = v1-v27;
   partition roleVar = Role(train='TRAIN' test='TEST');
run;
```

The resulting output is shown in Figure 27.3 through Figure 27.5.

Figure 27.3 Model Information, Dimensions, and Number of Observations with Test Set Validation

Percentage Variation Accounted for by Partial Least Squares Factors				
	Model Effects		Response Variables	
Number of Extracted Factors	Current	Total	Current	Total
1	95.92495	95.92495	37.27071	37.27071
2	3.86407	99.78903	32.38167	69.65238
3	0.10170	99.89073	20.76882	90.42120
4	0.08979	99.98052	4.66666	95.08787
5	0.01142	99.99194	3.88184	98.96971

In Figure 27.3, the "Model Information" table indicates that test set validation is used. The "Dimensions" table shows that the maximum number of factors to extract is nine. The "Number of Observations" table shows that nine sample observations are assigned for training roles and seven are assigned for testing roles.

Figure 27.4 provides details about the results from test set validation. These results show that the absolute minimum PRESS is achieved with five extracted factors. Notice, however, that this is not much smaller than the PRESS for three factors. By using the CVTEST option, you can perform a statistical model comparison that is suggested by Van der Voet (1994) to test whether this difference is significant, as shown in the following SAS statements:

```
proc plsmod data=mylib.sample cvtest(pval=0.15 seed=12345);
   model ls ha dt = v1-v27;
   partition roleVar = Role(train='TRAIN' test='TEST');
run;
```

The model comparison test is based on a rerandomization of the data. By default, the seed for this randomization is based on the system clock, but it is specified here. The resulting output is presented in Figure 27.6 through Figure 27.8.

Figure 27.8 PLS Variation Summary for Tested Test-Set-Validated Model

Percentage Variation Accounted for by Partial Least Squares Factors				
	Model Effects		Response Variables	
Number of Extracted Factors	Current	Total	Current	Total
1	95.92495	95.92495	37.27071	37.27071
2	3.86407	99.78903	32.38167	69.65238
3	0.10170	99.89073	20.76882	90.42120

The "Model Information" table in Figure 27.6 displays information about the options that are used in the model comparison test. In Figure 27.7, the *p*-value in comparing the test-set-validated residuals from models that have five and three factors indicates that the difference between the two models is insignificant; therefore, the model with fewer factors is preferred. The variation summary in Figure 27.8 shows that more than 99% of the predictor variation and more than 90% of the response variation are accounted for by the three factors.

Predicting New Observations

Now that you have chosen a three-factor PLS model for predicting pollutant concentrations that are based on sample spectra, suppose that you have two new samples. The following SAS statements create a data table that contains the spectra for the new samples:

```
data newobs;
   input obsnam $ v1-v27 @@;
   datalines;

;
```

You can apply the PLS model to these samples to estimate pollutant concentration by appending the new samples to the original 16 and specifying that the predicted values for all 18 samples be output to a data table, as shown in the following statements:

```
data mylib.all;
   set mylib.sample newobs;
run;

proc plsmod data=mylib.all nfac=2;
   model ls ha dt = v1-v27;
   partition roleVar = Role(train='TRAIN' test='TEST');
   output out=mylib.result pred=p copyvars=(obsnam);
run;
```

```
proc print data=mylib.result;
   where (obsnam in ('EM17','EM25'));
   var obsnam p_ls p_ha p_dt;
run;
```

The COPYVARS= option in the OUTPUT statement requests that the variable obsnam from the input data table be copied to the output data table. The new observations are not used in calculating the PLS model because they have no response values. Their predicted concentrations are shown in Figure 27.9.

Figure 27.9 Predicted Concentrations for New Observations

Obs	obsnam	p_ls	p_ha	p_dt
1	EM17	2.63326	0.22343	80.2027
2	EM25	0.69865	0.14308	98.9937

Syntax: PLSMOD Procedure

The following statements are available in the PLSMOD procedure:

PROC PLSMOD < *options* > **;**
BY *variables* **;**
CLASS *variable* < **(***options***)** >*...* < *variable* < **(***options***)** > > < */ global-options* > **;**
DISPLAY < *table-list* > < */ options* > **;**
DISPLAYOUT *table-spec-list* < */ options* > **;**
EFFECT *name* **=** *effect-type* **(***variables* < */ options* >**)** **;**
MODEL *response-variables* **=** *predictor-effects* < */ options* > **;**
OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < **=***prefix* > >*...* < *keyword* < **=***prefix* > > **;**
PARTITION *partition-options* **;**

The PROC PLSMOD statement and a single MODEL statement are required. All other statements are optional. The CLASS statement can appear multiple times. If a CLASS statement is specified, it must precede the MODEL statement. The following sections describe the PROC PLSMOD statement and then describe the other statements in alphabetical order.

PROC PLSMOD Statement

PROC PLSMOD < *options* > **;**

The PROC PLSMOD statement invokes the PLSMOD procedure. Table 27.3 summarizes the options available in the PROC PLSMOD statement.

Table 27.3 PROC PLSMOD Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data table
Model Fitting Options	
CVTEST	Requests that van der Voet's (1994) randomization-based model comparison test be performed
METHOD=	Specifies the general factor extraction method to be used
NFAC=	Specifies the number of factors to extract
NOCENTER	Suppresses centering of the responses and predictors before fitting
NOCVSTDIZE	Suppresses re-centering and rescaling of the responses and predictors when cross validating
NOSCALE	Suppresses scaling of the responses and predictors before fitting
Output Options	
CENSCALE	Displays the centering and scaling information
DETAILS	Displays the details of the fitted model
NOCLPRINT	Limits or suppresses the display of class levels
VARSS	Displays the amount of variation accounted for in each response and predictor

The following list provides details about these *options*.

CENSCALE
lists the centering and scaling information for each response and predictor.

CVTEST < **(***cvtest-options***)** >
requests that van der Voet's (1994) randomization-based model comparison test be performed to test models that have different numbers of extracted factors against the model that minimizes the predicted residual sum of squares. For more information, see the section "Test Set Validation" on page 1407. You can also specify the following *cvtest-options* in parentheses:

NSAMP=*number*
specifies the number of randomizations to perform. By default, NSAMP=1000.

PVAL=*number*
specifies the cutoff probability for declaring an insignificant difference. By default, PVAL=0.10.

SEED=*number*
specifies the seed value for the random number stream. If you do not specify this option or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

Analyses that use the same (nonzero) seed are not completely reproducible if they are executed on a different number of compute nodes, because the random number streams in separate compute nodes are independent.

STAT=PRESS | T2
specifies the test statistic for the model comparison. You can specify the following values:

PRESS	uses the predicted residual sum of squares.
T2	uses Hotelling's T^2 statistic.

By default, STAT=T2.

DATA=*libref.data-table*
names the input data table for PROC PLSMOD to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref	refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1382.
data-table	specifies the name of the input data table.

DETAILS
lists the details of the fitted model for each successive factor. The listed details are different for different extraction methods. For more information, see the section "Displayed Output" on page 1409.

METHOD=PLS< (*PLS-options***) > | SIMPLS | PCR | RRR**
specifies the general factor extraction method to be used. You can specify the following values:

PCR
uses principal component regression.

PLS< (*PLS-options***) >**
uses partial least squares. You can also specify the following optional *PLS-options* in parentheses:

ALGORITHM=NIPALS | SVD | EIG
names the specific algorithm to use to compute extracted PLS factors. You can specify the following values:

NIPALS requests the usual iterative NIPALS algorithm.

SVD bases the extraction on the singular value decomposition of $\mathbf{X}'\mathbf{Y}$. This algorithm is the most accurate but least efficient approach.

EIG bases the extraction on the eigenvalue decomposition of $\mathbf{Y}'\mathbf{X}\mathbf{X}'\mathbf{Y}$.

By default, ALGORITHM=NIPALS.

EPSILON=*number*
specifies the convergence criterion for the NIPALS algorithm. By default, EPSILON=10^{-12}.

MAXITER=*number*
specifies the maximum number of iterations for the NIPALS algorithm. By default, MAXITER=200.

RRR
uses reduced rank regression.

SIMPLS
uses the straightforward implementation of a statistically inspired modification of the partial least squares (SIMPLS) method of De Jong (1993).

By default, METHOD=PLS(NIPALS).

NFAC=*number*
specifies the number of factors to extract. The default is $\min\{15, p, N\}$, where p is the number of predictors (or the number of response variables when METHOD=RRR) and N is the number of runs (observations). You probably do not need to extract this many factors for most applications. Extracting too many factors can lead to an overfitted model (one that matches the training data too well), sacrificing predictive ability. Thus, if you use the default, you should also either specify the PARTITION statement to select the appropriate number of factors for the final model or consider the analysis to be preliminary and examine the results to determine the appropriate number of factors for a subsequent analysis.

NOCENTER
suppresses centering of the responses and predictors before fitting. This option is useful if the analysis variables are already centered and scaled. For more information, see the section "Centering and Scaling" on page 1408.

NOCLPRINT<=*number***>**
suppresses the display of the "Class Level Information" table if you do not specify *number*. If you specify *number*, the values of the classification variables are displayed only for variables whose number of levels is less than *number*. Specifying a *number* helps to reduce the size of the "Class Level Information" table if some classification variables have a large number of levels.

NOCVSTDIZE
suppresses re-centering and rescaling of the responses and predictors before each model is fit in the cross validation. For more information, see the section "Centering and Scaling" on page 1408.

NOSCALE
suppresses scaling of the responses and predictors before fitting. This option is useful if the analysis variables are already centered and scaled. For more information, see the section "Centering and Scaling" on page 1408.

VARSS
lists, in addition to the average response and predictor sum of squares accounted for by each successive factor, the amount of variation accounted for in each response and predictor.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC PLSMOD to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CLASS Statement

CLASS *variable* <**(***options***)**>. . . <*variable* <**(***options***)**>> </ *global-options*> **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. You can list the response variable for binary models in the CLASS statement, but this is not required. Table 27.4 summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section "CLASS Statement" on page 9 in Chapter 2, "Shared Concepts."

Table 27.4 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable
SPLIT	Splits levels of CLASS variables into independent effects

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1411. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value* specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1411. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

EFFECT Statement

EFFECT *name*=*effect-type* **(***variables* < / *options* >**) ;**

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 67 in Chapter 2, "Shared Concepts."

You can specify the following *effect-types*:

COLLECTION specifies a collection effect that defines one or more variables as a single effect that has multiple degrees of freedom. The variables in a collection are considered as a unit for purposes of estimation and inference.

MULTIMEMBER | MM specifies a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.

POLYNOMIAL | POLY specifies a multivariate polynomial effect in the specified numeric variables.

SPLINE specifies a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 27.5 summarizes the *options* available in the EFFECT statement.

Table 27.5 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Multimember Effects Options	
DETAILS	Displays the levels of the multimember effect
NOEFFECT	Specifies that observations whose levels are all missing for the multimember variables should have 0 values in the corresponding design matrix columns
STDIZE	Standardizes the design matrix entries so that each observation has a sum of 1
WEIGHT=	Specifies the weight variable for the contributions of each classification effect
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect with multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial

Table 27.5 *continued*

Option	Description
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots starting at the variables' maximum and ending at the KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots starting at the KNOTMIN= value and ending at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect
SEPARATE	Treats the spline basis for each variable as a separate effect when multiple variables are specified
SPLIT	Treats each design matrix column as a separate effect for selection methods

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 18 in Chapter 2, "Shared Concepts."

MODEL Statement

MODEL *response-variables* **=** *predictor-effects* < / *options* > **;**

The MODEL statement names the responses and the predictors, which determine, respectively, the **Y** and **X** matrices of the model. You can simply list the names of the predictor variables as the model effects, but you can also specify other types of effects, including polynomial effects and interactions. For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

The MODEL statement is required. You can specify only one MODEL statement.

You can specify the following *options* after a slash (/).

INTERCEPT
overrides the default, in which the responses and predictors are centered. When responses and predictors are centered, no intercept is required in the model.

SOLUTION
lists the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses that are based on the centered and scaled predictors are displayed, in addition to the coefficients for predicting the raw responses that are based on the raw predictors.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < **=***prefix* > > . . . < *keyword* < **=***prefix* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics, which are computed after fitting the model. If you do not specify any *keywords*, then only the predicted values for responses are included.

The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option are included.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC PLSMOD to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1382.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

COPYVAR=*variable*
COPYVARS=(*variables***)**
copies one or more *variables* from the input data table to the output data table.

keyword **< =***prefix* **>**
specifies a statistic to include in the output data table and optionally a *prefix* for naming the output variables. If you do not provide a *prefix*, the PLSMOD procedure assigns a default prefix based on the type of statistic requested. For example, for response variables y1 and y2, a specification of PREDICTED produces two predicted value variables, Pred_y1 and Pred_y2.

You can specify the following *keywords* to add statistics to the OUTPUT data table:

H
requests the approximate leverage. The default prefix is H.

PREDICTED
PRED
P
requests predicted values for each response. The default prefix is Pred.

PRESS
requests approximate predicted residuals for each response. The default prefix is PRESS.

ROLE
requests numeric values that indicate the role played by each observation in fitting the model. The default prefix is _ROLE_. Table 27.6 shows the interpretation of this variable for each observation.

Table 27.6 Role Interpretation

Value	Observation Role
0	Not used
1	Training
2	Testing

If you do not partition the input data by using a PARTITION statement, then the role variable value is 1 for observations that are used in fitting the model, and 0 for observations that have at least one missing or invalid value for the responses or predictors.

STDX
requests standardized (centered and scaled) predictor values for each predictor. The default prefix is StdX.

STDXSSE
requests the sum of squares of residuals for standardized predictors. The default prefix is StdXSSE.

STDY
requests standardized (centered and scaled) response values for each response. The default prefix is StdY.

STDYSSE
requests the sum of squares of residuals for standardized responses. The default prefix is StdYSSE.

TSQUARE
T2
requests a scaled sum of squares of score values. The default prefix is TSquare.

XRESIDUAL
XRESID
XR
requests residuals for each predictor. The default prefix is XResid.

XSCORE
requests extracted factors (X-scores, latent vectors, latent variables, and T) for each selected model factor. The default prefix is XScore.

YRESIDUAL
YRESID
YR
requests residuals for each response. The default prefix is YResid.

YSCORE
requests extracted responses (Y-scores and U) for each selected model factor. The default prefix is YScore.

The output variables that contain the requested statistic are named as follows, according to the *keyword* that you specify:

- The *keywords* XRESIDUAL and STDX define an output variable for each predictor, so the variables that correspond to each predictor are named by appending a number (which starts from 1) to the prefix. For each defined variable, a label is also generated automatically; the label contains the prefix of the variable and the name of the predictor. For example, if the model has three predictors, then a specification of XRESIDUAL=XR produces the variables XR1, XR2, and XR3.
- The *keywords* PREDICTED, YRESIDUAL, STDY, and PRESS define an output variable for each response, so the variables that correspond to each response are named by appending an underscore followed by the name of the response variable to the prefix. For example, if the model has response variables y1 and y2, then a specification of PREDICTED=P produces the variables P_y1 and P_y2.
- The *keywords* XSCORE and YSCORE define an output variable for each selected model factor, so the variables that correspond to each successive factor are named by appending the factor number to the prefix. For example, if the model has three selected factors, then a specification of XSCORE=T produces the variables T1, T2, and T3.
- The *keywords* H, TSQUARE, STDXSSE, STDYSSE, and ROLE each define a single output variable, so the variable name matches the prefix.

PARTITION Statement

PARTITION *partition-options* **;**

The PARTITION statement specifies how to logically partition observations in the input data table into disjoint subsets for model training and testing. Either you can designate a variable in the input data table and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for random assignment of observations to each role.

You must specify exactly one of the following *partition-options*:

FRACTION(<TEST=*fraction***> <SEED=***number***>)**
requests that specified proportions of the observations in the input data table be randomly assigned training and testing roles. You specify the proportions for testing by using the TEST= suboption; the specified fraction must be less than 1 and the remaining fraction of the observations are assigned to the training role. If you do not specify the TEST= suboption, all observations are assigned to the training role. The SEED= suboption specifies an integer that is used to start the pseudorandom number generator for random partitioning of data for training and testing. If you do not specify SEED=*number* or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

Because *fraction* is a per-observation probability (which means that any particular observation has a probability of *fraction* of being assigned the testing role), using the FRACTION option can cause different numbers of observations to be assigned training and testing roles. You can specify the SEED= suboption to create the same partition data tables for a particular number of compute nodes. However, changing the number of compute nodes changes the initial distribution of data, resulting in different partition data tables.

ROLEVAR | ROLE=*variable* **(<TEST='***value***'> <TRAIN='***value***'>)**
names the *variable* in the input data table whose values are used to assign roles to each observation. This *variable* cannot also appear as an analysis variable in other statements or options. The TEST= and TRAIN= suboptions specify the formatted values of this variable that are used to assign observation roles. If you specify only the TEST= suboption, then all observations whose role is not determined by the TEST= suboption are assigned to training.

For more information, see the section "Test Set Validation" on page 1407. For an illustration, see Example 27.1.

Details: PLSMOD Procedure

Regression Methods

All the predictive methods that PROC PLSMOD implements work essentially by finding linear combinations of the predictors (factors) to use to predict the responses linearly. The methods differ only in how the factors are derived, as explained in the following sections.

Partial Least Squares

Partial least squares (PLS) works by extracting one factor at a time. Let $\mathbf{X} = \mathbf{X}_0$ be the centered and scaled matrix of predictors, and let $\mathbf{Y} = \mathbf{Y}_0$ be the centered and scaled matrix of response values. The PLS method starts with a linear combination $\mathbf{t} = \mathbf{X}_0\mathbf{w}$ of the predictors, where $\mathbf{t}$ is called a *score vector* and $\mathbf{w}$ is its associated *weight vector*. The PLS method predicts both $\mathbf{X}_0$ and $\mathbf{Y}_0$ by regression on $\mathbf{t}$:

$$\begin{aligned} \hat{\mathbf{X}}_0 &= \mathbf{t}\mathbf{p}', \quad \text{where} \quad \mathbf{p}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'\mathbf{X}_0 \\ \hat{\mathbf{Y}}_0 &= \mathbf{t}\mathbf{c}', \quad \text{where} \quad \mathbf{c}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'\mathbf{Y}_0 \end{aligned}$$

The vectors $\mathbf{p}$ and $\mathbf{c}$ are called the X- and Y-*loadings*, respectively.

The specific linear combination $\mathbf{t} = \mathbf{X}_0\mathbf{w}$ is the combination that has maximum covariance $\mathbf{t}'\mathbf{u}$ with some response linear combination $\mathbf{u} = \mathbf{Y}_0\mathbf{q}$. Another characterization is that the X-weight, $\mathbf{w}$, and the Y-weight, $\mathbf{q}$, are proportional to the first left- and right-singular vectors, respectively, of the covariance matrix $\mathbf{X}_0'\mathbf{Y}_0$ or, equivalently, the first eigenvectors of $\mathbf{X}_0'\mathbf{Y}_0\mathbf{Y}_0'\mathbf{X}_0$ and $\mathbf{Y}_0'\mathbf{X}_0\mathbf{X}_0'\mathbf{Y}_0$, respectively.

This accounts for how the first PLS factor is extracted. The second factor is extracted in the same way by replacing $\mathbf{X}_0$ and $\mathbf{Y}_0$ with the X- and Y-residuals from the first factor:

$$\begin{aligned}\mathbf{X}_1 &= \mathbf{X}_0 - \hat{\mathbf{X}}_0 \\ \mathbf{Y}_1 &= \mathbf{Y}_0 - \hat{\mathbf{Y}}_0\end{aligned}$$

These residuals are also called the *deflated* $\mathbf{X}$ and $\mathbf{Y}$ blocks. The process of extracting a score vector and deflating the data matrices is repeated for as many extracted factors as you want.

SIMPLS

The fact that each extracted PLS factor is defined in terms of different X-variables $\mathbf{X}_i$ leads to difficulties in comparing different scores, weights, and so on. The SIMPLS method of De Jong (1993) overcomes these difficulties by computing each score $\mathbf{t}_i = \mathbf{X}\mathbf{r}_i$ in terms of the original (centered and scaled) predictors $\mathbf{X}$. The SIMPLS X-weight vectors r_i are similar to the eigenvectors of $\mathbf{S}\mathbf{S}' = \mathbf{X}'\mathbf{Y}\mathbf{Y}'\mathbf{X}$, but they satisfy a different orthogonality condition. The $\mathbf{r}_1$ vector is just the first eigenvector $\mathbf{e}_1$ (so that the first SIMPLS score is the same as the first PLS score). However, the second eigenvector maximizes

$$\mathbf{e}_1'\mathbf{S}\mathbf{S}'\mathbf{e}_2 \quad \text{subject to} \quad \mathbf{e}_1'\mathbf{e}_2 = 0$$

whereas the second SIMPLS weight $\mathbf{r}_2$ maximizes

$$\mathbf{r}_1'SS'\mathbf{r}_2 \quad \text{subject to} \quad \mathbf{r}_1'\mathbf{X}'\mathbf{X}\mathbf{r}_2 = \mathbf{t}_1'\mathbf{t}_2 = 0$$

The SIMPLS scores are identical to the PLS scores for one response but slightly different for more than one response; see De Jong (1993) for details. The X- and Y-loadings are defined as in PLS, but it is easy to compute the overall model coefficients $\mathbf{B}$ because the scores are all defined in terms of $\mathbf{X}$:

$$\begin{aligned}\hat{\mathbf{Y}} &= \sum_i \mathbf{t}_i\mathbf{c}_i' \\ &= \sum_i \mathbf{X}\mathbf{r}_i\mathbf{c}_i' \\ &= \mathbf{X}\mathbf{B}, \text{ where } \mathbf{B} = \mathbf{R}\mathbf{C}'\end{aligned}$$

Principal Component Regression

Like the SIMPLS method, principal component regression (PCR) defines all the scores in terms of the original (centered and scaled) predictors $\mathbf{X}$. However, unlike both the PLS and SIMPLS methods, the PCR method chooses the X-weights and X-scores without regard to the response data. The X-scores are chosen to explain as much variation in $\mathbf{X}$ as possible; equivalently, the X-weights for the PCR method are the eigenvectors of the predictor covariance matrix $\mathbf{X}'\mathbf{X}$. Again, the X- and Y-loadings are defined as in PLS; but, as in SIMPLS, it is easy to compute overall model coefficients for the original (centered and scaled) responses $\mathbf{Y}$ in terms of the original predictors $\mathbf{X}$.

Reduced Rank Regression

As discussed in the preceding sections, partial least squares depends on selecting the factors $\mathbf{t} = \mathbf{X}\mathbf{w}$ of the predictors and $\mathbf{u} = \mathbf{Y}\mathbf{q}$ of the responses that have maximum covariance, whereas principal component regression effectively ignores $\mathbf{u}$ and selects $\mathbf{t}$ to have maximum variance, subject to orthogonality constraints. In contrast, reduced rank regression selects $\mathbf{u}$ to account for as much variation in the *predicted* responses as possible, effectively ignoring the predictors for the purpose of factor extraction. In reduced rank regression, the Y-weights, $\mathbf{q}_i$, are the eigenvectors of the covariance matrix $\hat{\mathbf{Y}}'_{\mathrm{LS}}\hat{\mathbf{Y}}_{\mathrm{LS}}$ of the responses that are predicted by ordinary least squares regression, and the X-scores are the projections of the Y-scores, $\mathbf{Y}\mathbf{q}_i$, onto the X space.

Relationships between Methods

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/plsmodgs2.sas.)

When you develop a predictive model, it is important to consider not only the explanatory power of the model for current responses, but also how well the predictive functions are sampled, because the sampling affects how well the model can extrapolate to future observations. All the techniques that the PLSMOD procedure implements work by extracting successive factors (linear combinations of the predictors) that optimally address one or both of these two goals: explaining response variation and explaining predictor variation. In particular, principal component regression selects factors that explain as much predictor variation as possible, reduced rank regression selects factors that explain as much response variation as possible, and partial least squares balances the two objectives, seeking factors that explain both response and predictor variation.

To see the relationships between these methods, consider how each one extracts a single factor from the following artificial data table, artData, which consists of two predictors and one response:

```
data artData;
   input x1 x2 y;
   datalines;
    3.37651  2.30716        0.75615
    0.74193 -0.88845        1.15285
    4.18747  2.17373        1.42392
    0.96097  0.57301        0.27433
   -1.11161 -0.75225       -0.25410
   -1.38029 -1.31343       -0.04728
    1.28153 -0.13751        1.00341
   -1.39242 -2.03615        0.45518
    0.63741  0.06183        0.40699
   -2.52533 -1.23726       -0.91080
    2.44277  3.61077       -0.82590
```

```
;

data mylib.artData;
   set artData;
run;

proc plsmod data=mylib.artData nfac=1 method=rrr;
   model y = x1 x2;
run;

proc plsmod data=mylib.artData nfac=1 method=pcr;
   model y = x1 x2;
run;

proc plsmod data=mylib.artData nfac=1 method=pls;
   model y = x1 x2;
run;
```

The amount of model and response variation that are explained by the first factor for each method is shown in Figure 27.10 through Figure 27.12.

Figure 27.10 Variation Explained by the First Reduced Rank Regression Factor

The PLSMOD Procedure

Percentage Variation Accounted for by Reduced Rank Regression Factors

	Model Effects		Response Variables	
Number of Extracted Factors	Current	Total	Current	Total
1	15.06605	15.06605	100.00000	100.00000

Figure 27.11 Variation Explained by the First Principal Component Regression Factor

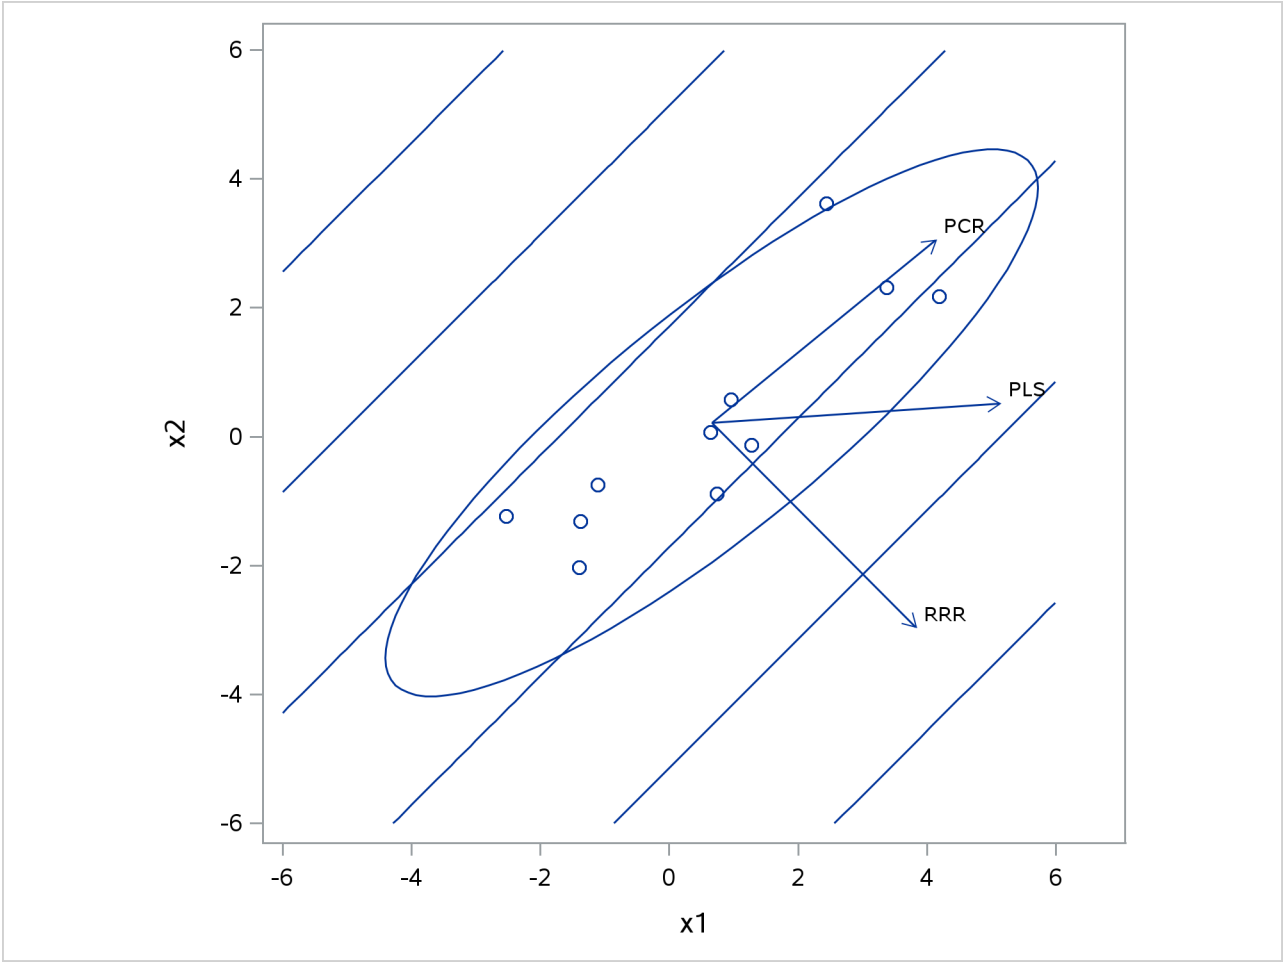
The PLSMOD Procedure

Percentage Variation Accounted for by Principal Components

	Model Effects		Response Variables	
Number of Extracted Factors	Current	Total	Current	Total
1	92.99959	92.99959	9.37874	9.37874

Figure 27.12 Variation Explained by the First Partial Least Squares Regression Factor

The PLSMOD Procedure



Percentage Variation Accounted for by Partial Least Squares Factors

	Model Effects		Response Variables	
Number of Extracted Factors	Current	Total	Current	Total
1	88.53567	88.53567	26.53038	26.53038

Notice that although the first reduced rank regression factor explains *all* of the response variation, it accounts for only about 15% of the predictor variation. In contrast, the first principal component regression factor accounts for most of the predictor variation (93%) but only 9% of the response variation. The first partial least squares factor accounts for only slightly less predictor variation than principal components but about three times as much response variation.

Figure 27.13 illustrates how partial least squares balances the goals of explaining response and predictor variation in this case.

Figure 27.13 Depiction of the First Factors for Three Different Regression Methods

The ellipse shows the general shape of the 11 observations in the predictor space, with the contours of increasing y overlaid. Also shown are the directions of the first factor for each of the three methods. Notice that although the predictors vary most in the x1 = x2 direction, the response changes most in the orthogonal x1 = –x2 direction. This explains why the first principal component accounts for little variation in the response and why the first reduced rank regression factor accounts for little variation in the predictors. The direction of the first partial least squares factor represents a compromise between the other two directions.

Test Set Validation

None of the regression methods that the PLSMOD procedure implements fit the observed data any better than ordinary least squares (OLS) regression; in fact, all the methods approach OLS as more factors are extracted. Basing the model on more extracted factors improves the model fit to the observed data, but extracting too many factors can cause *overfitting*—that is, tailoring the model too much to the current data to the detriment of future predictions. So the crucial point is that when there are many predictors, OLS can *overfit* the observed data; biased regression methods that use fewer extracted factors can provide better predictability of *future* observations. However, as the preceding observations imply, the quality of the observed data fit cannot be used to choose the number of factors to extract; the number of extracted factors must be chosen on the basis of how well the model fits observations that are not involved in the modeling procedure itself.

PROC PLSMOD implements the *test set validation* method of choosing the number of extracted factors. When you have sufficient data, you can subdivide your data into two parts: training data and test data. During the validation process, the model is fit on the training data, and the predicted residual sum of squares (PRESS) for models that have different numbers of extracted factors is found by using the test data. The number of factors chosen is usually the one that minimizes PRESS.

You use the PARTITION statement to logically subdivide the DATA= data table into separate roles. You can name the fractions of the data that you want to reserve as training data and test data. For example, the following statements randomly subdivide the inData data table, reserving 50% each for training and testing:

```
proc plsmod data=mylib.inData;
   partition fraction(test=0.5);
   ...
run;
```

In some cases you might need to exercise more control over the partitioning of the input data table. You can do this by naming both a variable in the input data table and a formatted value of that variable for each role. For example, the following statements assign roles to the observations in the inData data table based on the value of the variable Group in that data table. Observations whose value of Group is `'group 1'` are assigned for training, and those whose value is `'group 2'` are assigned to testing. All other observations are ignored.

```
proc plsmod data=mylib.inData;
   partition roleVar=Group(train='group 1' test='group 2')
   ...
run;
```

By default, the number of extracted factors is chosen to be the one that minimizes PRESS. However, models that have fewer factors often have PRESS statistics that are only marginally larger than the absolute minimum. To address this, Van der Voet (1994) proposed a statistical test for comparing the predicted residuals from

different models; when you apply van der Voet's test, the number of factors chosen is the fewest while still producing residuals that are insignificantly larger than the residuals of the model that has a minimum PRESS.

To see how van der Voet's test works, let $R_{i,jk}$ be the jth predicted residual for response k for the model that has i extracted factors. Then, the PRESS statistic is $\sum_{jk} R^2_{i,jk}$. Also, let $i_{\min}$ be the number of factors for which PRESS is minimized. The critical value for van der Voet's test is based on the differences between squared predicted residuals:

$$D_{i,jk} = R^2_{i,jk} - R^2_{i_{\min},jk}$$

One alternative for the critical value is $C_i = \sum_{jk} D_{i,jk}$, which is simply the difference between the PRESS statistics for i and $i_{\min}$ factors; alternatively, van der Voet suggests Hotelling's T^2 statistic $C_i = \mathbf{d}'_{i,.}\mathbf{S}_i^{-1}\mathbf{d}_{i,.}$, where $\mathbf{d}_{i,.}$ is the sum of the vectors $\mathbf{d}_{i,j} = \{D_{i,j1}, \ldots, D_{i,jN_y}\}'$ and $\mathbf{S}_i$ is the sum of squares and crossproducts matrix,

$$\mathbf{S}_i = \sum_j \mathbf{d}_{i,j}\mathbf{d}'_{i,j}$$

Theoretically, the significance level for van der Voet's test is obtained by comparing C_i with the distribution of values that result from randomly exchanging $R^2_{i,jk}$ and $R^2_{i_{\min},jk}$. In practice, a Monte Carlo sample of such values is simulated and the significance level is approximated as the proportion of simulated critical values that are greater than C_i. If you apply van der Voet's test by specifying the CVTEST option, then, by default, the number of extracted factors that are chosen is the smallest number of factors that have an approximate significance level that is greater than 0.1.

Centering and Scaling

By default, the predictors and the responses are centered and scaled to have mean 0 and standard deviation 1. Centering the predictors and the responses ensures that the criterion for choosing successive factors is based on how much *variation* they explain in either the predictors or the responses or in both. (For more information about how different methods explain variation, see the section "Regression Methods" on page 1402.) Without centering, both the value of the mean variable and the variation around that mean are involved in selecting factors. Scaling serves to place all predictors and responses on an equal footing relative to their variation in the data. For example, if Time and Temp are two of the predictors, then scaling says that a change of std(Time) in Time is approximately equivalent to a change of std(Temp) in Temp.

Usually, both the predictors and responses should be centered and scaled. However, if their values already represent variation around a nominal or target value, then you can use the NOCENTER option in the PROC PLSMOD statement to suppress centering. Likewise, if the predictors or responses are already all on comparable scales, then you can use the NOSCALE option to suppress scaling.

If the predictors involve crossproduct terms, PROC PLSMOD does not standardize the variables before it standardizes the crossproduct. That is, if the *i*th values of two predictors are denoted x_i^1 and x_i^2, then the default standardized *i*th value of the crossproduct is

$$\frac{x_i^1 x_i^2 - \text{mean}_j(x_j^1 x_j^2)}{\text{std}_j(x_j^1 x_j^2)}$$

When test set validation is performed for the number of effects, some practitioners disagree as to whether the training data should be retransformed. By default, PROC PLSMOD does retransform the training data, but you can suppress this behavior by specifying the NOCVSTDIZE option in the PROC PLSMOD statement.

Missing Values

Observations that have any missing independent variables (including all classification variables) are excluded from the analysis, and no predictions are computed for such observations. However, if you specify the MISSING option in the CLASS statement, missing values are treated as valid values for the classification variable. Observations that have no missing independent variables but do have missing response variables are also excluded from the analysis, but predictions are computed. If you use the PARTITION statement and specify the ROLEVAR= option, observations that contain missing values for the ROLEVAR= variable are excluded from the analysis, but predictions are computed for them.

Displayed Output

The following sections describe the output that PROC PLSMOD produces. The output is organized into various tables, which are discussed in the order of their appearance.

Model Information

The "Model Information" table displays basic information about the model, such as the input data table, the factor extraction method, the validation method, and the type of parameterization used for classification variables that are named in the CLASS statement. If you use the PARTITION statement, the table also displays the random number seed for partitioning, the validation testing criterion, the number of random permutations, and the random number seed for permutation, depending on whether you specify the FRACTION option in the PARTITION statement and the CVTEST option in the PROC PLSMOD statement.

Dimensions

The "Dimensions" table displays information about the number of response variables, the number of effects, and the number of predictor parameters. It also displays the number of factors to extract.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis. If you use a PARTITION statement, the table also displays the number of observations that are used for each data role.

Class Level Information

The "Class Level Information" table lists the levels of every variable that is specified in the CLASS statement. You should check this information to make sure that the data are correct. You can adjust the order of the CLASS variable levels by specifying the ORDER= option in the CLASS statement. You can suppress the "Class Level Information" table completely or partially by specifying the NOCLPRINT= option in the PROC PLSMOD statement.

If the classification variables use a nonsingular parameterization, the "Class Level Information" table also displays the reference value for each variable.

Centering and Scaling Information

If you specify the CENSCALE option in the PROC PLSMOD statement, the PLSMOD procedure produces "Model Effect Centering and Scaling" and "Response Variable Centering and Scaling" tables, which display the centering and scaling information for each predictor and response.

Test Set Validation

If you use the PARTITION statement to perform a test set validation for choosing the number of extracted factors, the PLSMOD procedure produces a "Test Set Validation Residual Summary" table to display a residual summary of the validation for each number of factors. It also produces a "Test Set Validation Results" table to display information about the optimal number of factors.

Percentage Variation Accounted for by Extracted Factors

By default, the PLSMOD procedure produces the "Percentage Variation Accounted for by Extracted Factors" table to display the amount of predictor variation and response variation that are accounted for by each factor. If you specify the VARSS option in the PROC PLSMOD statement, the PLSMOD procedure also produces the "Model Effect Percentage Variation Accounted for by Extracted Factors" table and the "Response Variable Percentage Variation Accounted for by Extracted Factors" table to display the amount of variation that is accounted for in each predictor and response, in addition to the average predictor and response sum of squares that are accounted for by each successive factor.

Model Details

If you specify the DETAILS option in the PROC PLSMOD statement, the PLSMOD procedure produces tables to display details about the fitted model for each successive factor. These tables include the following:

- "Model Effect Loadings" table, which displays the predictor loadings
- "Model Effect Weights" table, which displays predictor weights
- "Response Variable Weights" table, which displays the response weights

- "Coded Regression Coefficients" tables, which display the coded regression coefficients, if you specify METHOD=SIMPLS, METHOD=PCR, or METHOD=RRR in the PROC PLSMOD statement.

Parameter Estimates

If you specify the SOLUTION option in the MODEL statement, the PLSMOD procedure produces a "Parameter Estimates" table to display the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses that are based on the centered and scaled predictors are displayed, in addition to the coefficients for predicting the raw responses based on the raw predictors.

Timing Information

The "Timing" table displays the elapsed time of each main task of the procedure.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the PLSMOD procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or the Output Delivery System (ODS) statements. These names are listed in Table 27.7.

NOTE: The EFFECT statement also create tables which are not listed in this section. For information about these tables, see "ODS Table Names" on page 33 in Chapter 2, "Shared Concepts."

Table 27.7 ODS Tables Produced by PROC PLSMOD

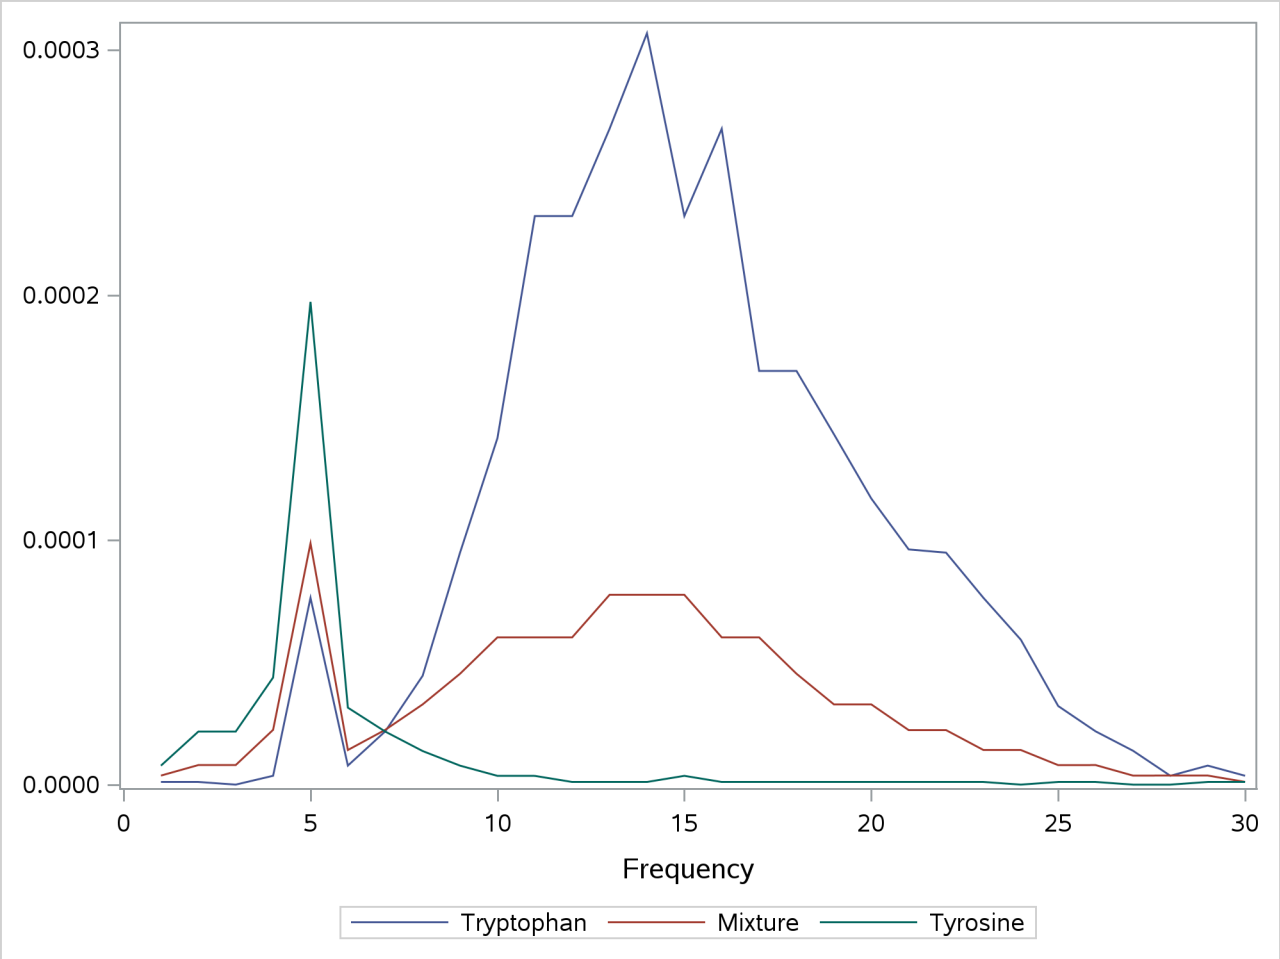
Table Name	Description	Required Statement and Option
CVResults	Results of test set validation	PARTITION statement
CenScaleParms	Parameter estimates for centered and scaled data	SOLUTION option in MODEL statement
ClassInfo	Level information from the CLASS statement	CLASS statement
CodedCoef	Coded regression coefficients	DETAILS option in PROC PLSMOD statement
Dimensions	Model dimensions	Default output
ModelInfo	Model information	Default output
NObs	Number of observations read and used	Default output
OutputCasTables	See the section "OutputCasTables Table" on page 1411	DISPLAYOUT statement or OUTPUT statement

Table 27.7 *continued*

Table Name	Description	Required Statement and Option
ParameterEstimates	Parameter estimates for raw data	SOLUTION option in MODEL statement
PercentVariation	Predictor and response variation that are accounted for by each factor	Default output
ResidualSummary	Residual summary from test set validation	PARTITION statement
Timing	Absolute and relative times spent by tasks that are performed by the procedure	Default output
XEffectCenScale	Centering and scaling information for predictor effects	CENSCALE option in PROC PLSMOD statement
XLoadings	Loadings for predictor effects	DETAILS option in PROC PLSMOD statement
XPercentVariation	Variation that is accounted for by each factor for predictor effects	VARSS option in PROC PLSMOD statement
XWeights	Weights for predictor effects	DETAILS option in PROC PLSMOD statement
YPercentVariation	Variation that is accounted for by each factor for responses	VARSS option in PROC PLSMOD statement
YVariableCenScale	Centering and scaling information for responses	CENSCALE option in PROC PLSMOD statement
YWeights	Weights for responses	DETAILS option in PROC PLSMOD statement

Examples: PLSMOD Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.



NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 27.1: Choosing a PLS Model by Test Set Validation

(View the complete code for this example (plsmodex1.sas) in the example repository.)

This example demonstrates issues in spectrometric calibration. The data (Umetrics 1995) consist of spectrographic readings on 33 samples that contain known concentrations of two amino acids, tyrosine and tryptophan. The spectra are measured at 30 frequencies across the overall range of frequencies. For example, Output 27.1.1 shows the observed spectra for three samples: one with only tryptophan, one with only tyrosine, and one with a mixture of the two, all at a total concentration of 10^{-6}.

Output 27.1.1 Spectra for Three Samples of Tyrosine and Tryptophan

Of the 33 samples, 18 are used as a training set and 15 as a test set. The data originally appear in McAvoy et al. (1989).

These data were created in a lab, where the concentrations are fixed in order to provide a wide range of applicability for the model. This example uses a linear function of the logarithms of the spectra to predict the logarithms of tyrosine and tryptophan concentration and the logarithm of the total concentration. Actually, because zeros are possible in both the responses and the predictors, slightly different transformations are used. The following statements create a data table named ex1Data for these data. The data table also contains a variable Role that is used to assign samples to the training and testing roles.

```
data ex1Data;
   input obsnam $ Role : $5. tot tyr f1-f30 @@;
   try = tot - tyr;
   if (tyr) then tyr_log = log10(tyr); else tyr_log = -8;
   if (try) then try_log = log10(try); else try_log = -8;
   tot_log = log10(tot);

The following statements fit a PLS model that has 10 factors:

```
proc plsmod data=mylib.ex1Data nfac=10;
   model tot_log tyr_log try_log = f1-f30;
run;
```

The "Model Information" table in Output 27.1.2 shows that no validation method is used. The "Number of Observations" table confirms that all 33 sample observations are used in the analysis.

Output 27.1.2 Model Information and Number of Observations

The PLSMOD Procedure

Model Information	
Data Source	EX1DATA
Factor Extraction Method	Partial Least Squares
PLS Algorithm	NIPALS
Validation Method	None

Number of Observations Read	33
Number of Observations Used	33

The table in Output 27.1.3 indicates that only four or five factors are required to explain almost all the variation in both the predictors and the responses.

Output 27.1.3 Amount of Variation Explained

Percentage Variation Accounted for by Partial Least Squares Factors

	Model Effects		Response Variables	
Number of Extracted Factors	**Current**	**Total**	**Current**	**Total**
1	77.67903	77.67903	47.80217	47.80217
2	20.62719	98.30622	38.96826	86.77043
3	1.00143	99.30766	6.89262	93.66305
4	0.24930	99.55696	1.77222	95.43528
5	0.13077	99.68773	1.71763	97.15290
6	0.08970	99.77742	0.58619	97.73909
7	0.05684	99.83426	0.29079	98.02988
8	0.06730	99.90156	0.13857	98.16845
9	0.01521	99.91676	0.68214	98.85059
10	0.02627	99.94304	0.14388	98.99447

In order to choose the optimal number of PLS factors, you can explore how well models that are based on data in training roles and have different numbers of factors fit the data in testing roles. To do so, you can use the PARTITION statement to assign observations to training and testing roles based on the values of the input variable named Role, as follows:

```
proc plsmod data=mylib.ex1Data nfac=10 cvtest(stat=press seed=12345);
   model tot_log tyr_log try_log = f1-f30;
   partition roleVar = Role(train='TRAIN' test='TEST');
run;
```

Output 27.1.4 shows the "Model Information" table and the "Number of Observations" table. The "Model Information" table indicates that test set validation is used, and it displays information about the options that are used in the model comparison test. The "Number of Observations" table confirms that there are 18 observations for the training role and 15 for the testing role.

Output 27.1.4 Model Information and Number of Observations with Test Set Validation

The PLSMOD Procedure

Model Information	
Data Source	EX1DATA
Factor Extraction Method	Partial Least Squares
PLS Algorithm	NIPALS
Validation Method	Test Set Validation
Validation Testing Criterion	Prob PRESS > 0.1
Number of Random Permutations	1000
Random Number Seed for Permutation	12345

Number of Observations Read	33
Number of Observations Used	33
Number of Observations Used for Training	18
Number of Observations Used for Testing	15

Output 27.1.5 displays the results of the test set validation. They indicate that although five PLS factors produce the minimum predicted residual sum of squares, the residuals for four factors are insignificantly different from the residuals for five factors. Thus, the smaller model is preferred.

Output 27.1.5 Test Set Validation for the Number of PLS Factors

The PLSMOD Procedure

Overview: QTRSELECT Procedure

The QTRSELECT procedure fits and performs model selection for quantile regression models in SAS Viya.

Quantile regression uses a linear function model to fit the quantiles of a response variable conditional on the explanatory variables. The model does not assume a particular parametric distribution for the response. The models that PROC QTRSELECT supports can contain main effects that consist of both continuous and classification variables and interaction effects of these variables. The models can also include constructed effects such as splines. The procedure offers a number of effect-selection methods, including stepwise methods. It also offers extensive capabilities for customizing the model selection by using a wide variety of selection and stopping criteria, including significance-level-based criteria, information criteria, and modern validation-based criteria. PROC QTRSELECT also provides a variety of quantile regression diagnostics that are conditional on the selected model.

PROC QTRSELECT Features

The main features of the QTRSELECT procedure are as follows:

- **Model specification**
  - supports quantile regression for single or multiple quantile levels
  - supports multiple parameterizations for classification effects
  - supports any degree of interactions (crossed effects) and nested effects
  - supports hierarchical model selection strategy among effects that have a containment relationship
  - supports partitioning of data into training, validation, and testing roles
  - provides a WEIGHT statement for weighted analysis
- **Selection control**
  - provides multiple effect-selection methods
  - offers selection of individual levels of classification effects
  - provides effect selection based on a variety of selection criteria
  - provides stopping rules based on a variety of model evaluation criteria
  - supports stopping and selection rules based on external validation
- **Display and output**
  - provides a CODE statement to produce SAS code that can score a new data set
  - produces output data tables that contain predicted values, residuals, and confidence limits
  - uses ODS Graphics to create model selection plots as part of its output. For more information about ODS Graphics, see the section "ODS Graphics" on page 1460

The QTRSELECT procedure supports the following effect-selection methods. For a more detailed description of these methods, see the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

- Forward selection starts with no effects in the model and adds effects.
- Backward elimination starts with all effects in the model and deletes effects.
- Stepwise regression is similar to forward selection, except that effects already in the model do not necessarily stay there.

Because the QTRSELECT procedure runs on CAS, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode on CAS
- exploits all the available cores and concurrent threads. For information about how PROC QTRSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC QTRSELECT Compared with Other SAS Procedures

The QTRSELECT procedure provides quantile regression functionality that is comparable to that of the HPQUANTSELECT, QUANTSELECT, and QUANTREG procedures in SAS/STAT software.

PROC QTRSELECT Compared with the HPQUANTSELECT Procedure

The functionality of the QTRSELECT procedure closely resembles that of the HPQUANTSELECT procedure, which is a high-performance procedure. The QTRSELECT procedure is the next generation of the HPQUANTSELECT procedure, and it was developed specifically for SAS Viya. Both procedures are designed to run on a cluster of machines that distribute the data and the computations.

Both the QTRSELECT and HPQUANTSELECT procedures fit and perform effect selection for quantile regression models. The models can contain main effects that consist of both continuous and classification variables and interaction effects of these variables. The QTRSELECT procedure is additionally capable of constructing complex effects including univariate spline and polynomial expansions, and producing effect-selection plots by using ODS Graphics.

With the QTRSELECT and HPQUANTSELECT procedures, you request model selection by using the SELECTION statement. Both procedures offer the same methods of effect selection.

PROC QTRSELECT Compared with the QUANTSELECT Procedure

Both the QTRSELECT and QUANTSELECT procedures fit and perform model selection for quantile regression models. The models can contain main effects that consist of both continuous and classification variables and interaction effects of these variables. Both procedures support the forward, backward, and stepwise effect-selection methods and the ability to use separate validation and test data as specified in the PARTITION statement.

PROC QTRSELECT provides confidence limits and Wald tests for parameters, and prediction limits for quantiles.

PROC QUANTSELECT provides LASSO and adaptive LASSO effect-selection methods and effect selection for quantile process regression.

PROC QTRSELECT Compared with the QUANTREG Procedure

The QTRSELECT procedure chooses and fits quantile regression models. The QUANTREG procedure fits quantile regression models, but it does not offer model selection.

PROC QTRSELECT provides a variety of effect-selection methods, fit statistics, graphical effect-selection summary, and a cloud-enabled interior-point algorithm. It also supports partitioning the data into training, validation, and testing roles.

PROC QUANTREG provides simplex and smoothing algorithms, a rank-score test, a likelihood test, Markov-chain-marginal-bootstrap covariance estimation, many diagnostic and fit plots, and quantile process regression.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: QTRSELECT Procedure

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/qtrselgs.sas.)

The following example is modeled on the example in the section "Getting Started: QUANTSELECT Procedure" in the *SAS/STAT User's Guide*. The Sashelp.baseball data set contains salary and performance information for Major League Baseball (MLB) players, excluding pitchers, who played in at least one game in both the 1986 and 1987 seasons. The salaries (Time Inc. 1987) are for the 1987 season, and the performance measures are for the 1986 season (Reichler 1987).

The following statements display the variables in the data set. Figure 28.1 shows the results.

```
proc contents varnum data=sashelp.baseball;
   ods select position;
run;
```

Figure 28.1 Sashelp.Baseball Data Set

The CONTENTS Procedure

Variables in Creation Order

#	Variable	Type	Len	Label
1	Name	Char	18	Player's Name
2	Team	Char	14	Team at the End of 1986
3	nAtBat	Num	8	Times at Bat in 1986
4	nHits	Num	8	Hits in 1986
5	nHome	Num	8	Home Runs in 1986
6	nRuns	Num	8	Runs in 1986
7	nRBI	Num	8	RBIs in 1986
8	nBB	Num	8	Walks in 1986
9	YrMajor	Num	8	Years in the Major Leagues
10	CrAtBat	Num	8	Career Times at Bat
11	CrHits	Num	8	Career Hits
12	CrHome	Num	8	Career Home Runs
13	CrRuns	Num	8	Career Runs
14	CrRbi	Num	8	Career RBIs
15	CrBB	Num	8	Career Walks
16	League	Char	8	League at the End of 1986
17	Division	Char	8	Division at the End of 1986
18	Position	Char	8	Position(s) in 1986
19	nOuts	Num	8	Put Outs in 1986
20	nAssts	Num	8	Assists in 1986
21	nError	Num	8	Errors in 1986
22	Salary	Num	8	1987 Salary in $ Thousands
23	Div	Char	16	League and Division
24	logSalary	Num	8	Log Salary

You can load the Sashelp.Baseball data set into your CAS session by specifying your CAS engine libref in the first statement in the following DATA step:

```
data mylib.baseball;
   set sashelp.baseball;
run;
```

These statements assume that your CAS engine libref is named mylib, as in the section "Using CAS Sessions and CAS Engine Librefs" on page 1422, but you can substitute any appropriately defined CAS engine libref.

Suppose you want to investigate how the MLB players' salaries for the 1987 season depend on performance measures for the players' previous season and MLB career. You might worry that some players who are outliers could dominate your least squares analysis. To address this concern, you can use the following statements to obtain a median regression model, which is equivalent to the 50th conditional percentile or the quantile regression model at quantile level 0.5:

```
proc qtrselect data=mylib.baseball;
   class league division;
   model Salary = nAtBat nHits nHome nRuns nRBI nBB
                  yrMajor crAtBat crHits crHome crRuns crRbi
                  crBB league division nOuts nAssts nError;
```

```
run;
```

If you do not use the SELECTION statement, the QTRSELECT procedure fits the full model that is specified by the MODEL statement without any effect selection.

Figure 28.2 Number of Observations, Class Level Information, and Dimensions Tables

The QTRSELECT Procedure

Number of Observations Read	322
Number of Observations Used	263

Class Level Information

Class	Levels	Values
League	2	American National
Division	2	East West

Dimensions

Description	Value
Number of Effects	19
Number of Parameters	21

Figure 28.2 displays the "Number of Observations," "Class Level Information," and "Dimensions" tables.

The "Number of Observations" table shows that, of the 322 observations, PROC QTRSELECT uses only 263 observations for model fitting and ignores 59 incomplete observations.

The "Class Level Information" table shows level information for two CLASS effects that the CLASS statement identifies: League and Division. League has two levels: American League and National League. Division also has two levels: East Division and West Division.

The "Dimensions" table shows that the MODEL statement identifies 19 effects for model fitting besides the intercept effect. Because the 19 effects include two CLASS effects and each level of a CLASS effect corresponds to a parameter, the 19 effects contain a total of 21 parameters.

YrMajor	1	6.61877	6.61798	1.00	0.3182
CrAtBat	1	-0.04463	0.15485	-0.29	0.7734
CrHits	1	0.07896	0.73594	0.11	0.9146
CrHome	1	3.78231	1.90065	1.99	0.0477
CrRuns	1	1.23105	0.77137	1.60	0.1118
CrRbi	1	-0.70695	0.76888	-0.92	0.3588
CrBB	1	-0.68911	0.41382	-1.67	0.0971
League American	1	-34.39136	24.37175	-1.41	0.1595
League National	0	0	.	.	.
Division East	1	60.30856	27.28730	2.21	0.0280
Division West	0	0	.	.	.
nOuts	1	0.23273	0.12110	1.92	0.0558
nAssts	1	0.09824	0.18888	0.52	0.6035
nError	1	-0.81574	3.51436	-0.23	0.8166

Figure 28.4 displays the "Parameter Estimates" table, which shows the parameter estimates of the fitted median model. You can see that, of the 19 effective parameters whose degrees of freedom are not zero, the fitted model contains 13 insignificant parameters whose 95% confidence intervals cover zeros. Because more than half of the 19 effective parameters are insignificant, you might worry that the model is overfitted.

It is well known that both overfitting and underfitting harm the prediction performance of a model. You can prevent overfitting and underfitting by using a good effect-selection technique. The following statements apply the forward selection method and the SL (significance level) criterion to choose a parsimonious model for the mylib.baseball data table:

```
proc qtrselect data=mylib.baseball;
   class league division;
   model Salary = nAtBat nHits nHome nRuns nRBI nBB
                  yrMajor crAtBat crHits crHome crRuns crRbi
                  crBB league division nOuts nAssts nError
         / clb;
   selection method=forward(select=sl sle=0.1);
run;
```

The CLB option in the MODEL statement requests 95% confidence limits for the parameter estimates. The SLE=0.1 option in the SELECTION statement specifies the significance level for entry. A candidate effect can enter the model at a certain selection step only if the following conditions are met:

- Its *p*-value is the smallest among all the valid candidate effects.

- Its p-value is smaller than 0.1 (the significance level for entry).

For more information about using significance levels in effect selection, see the section "Statistical Tests for Significance Level" on page 1449.

Figure 28.5 Selection Information

The QTRSELECT Procedure

Selection Information	
Selection Method	Forward
Select Criterion	Significance Level
Stop Criterion	Significance Level
Effect Hierarchy Enforced	None
Entry Significance Level (SLE)	0.1
Stop Horizon	1

Figure 28.5 displays the "Selection Information" table. The "Selection Information" provides details about the method and criteria used to perform the model selection. The requested selection method is the forward selection method where the decisions about what effects to add at any step and when to terminate the selection are both based on the significance level criterion.

Figure 28.6 Selection Summary

The QTRSELECT Procedure

Quantile Level = 0.5
Selection Details

Selection Summary			
Step	**Effect Entered**	**Number Effects In**	**p Value**
0	**Intercept**	1	.

Parameter Estimates

Parameter	DF	Estimate	Standard Error	95% Confidence Limits		t Value	Pr > |t|
Intercept	1	-130.65536	33.04546	-195.73336	-65.57735	-3.95	<.0001
nAtBat	1	-1.20522	0.41690	-2.02624	-0.38419	-2.89	0.0042
nHits	1	7.76667	1.81045	4.20127	11.33207	4.29	<.0001
nRuns	1	-3.92180	1.87567	-7.61566	-0.22795	-2.09	0.0375
nBB	1	3.92049	1.04341	1.86565	5.97532	3.76	0.0002
CrHits	1	0.17697	0.06856	0.04195	0.31198	2.58	0.0104
CrHome	1	1.66939	0.73083	0.23012	3.10866	2.28	0.0232
Division East	1	65.14327	24.48038	16.93289	113.35364	2.66	0.0083
Division West	0	0	.	.	.	.	.
nOuts	1	0.23719	0.11403	0.01261	0.46176	2.08	0.0385

The "Fit Statistics" and "Parameter Estimates" tables in Figure 28.8 give details of the final selected model. You can see that all nine effective parameters (excluding Division West) are significant at the 5% significance level, corresponding to the 95% confidence limits.

Like the sample median, a median regression model is robust to extreme observations, because it depends only on a small middle subset of all the observations in the data table. However, it is less representative of the entire conditional distribution of the response variable. You might want to further investigate the mylib.baseball data table at other quantile levels. The following statements select quantile regression models at the quantile levels 0.1 and 0.9, which correspond to the 10% and 90% conditional percentiles of the players' salaries:

```
proc qtrselect data=mylib.baseball alpha=0.1;
   class league division;
   model Salary = nAtBat nHits nHome nRuns nRBI nBB
                  yrMajor crAtBat crHits crHome crRuns crRbi
                  crBB league division nOuts nAssts nError
         / quantile=0.1 0.9 stb clb;
   selection method=backward(select=sl sls=0.1);
run;
```

The ALPHA=0.1 option in the PROC statement sets the significance level to 0.1. Combined with the CLB option in the MODEL statement, the ALPHA=0.1 option requests 90% confidence limits for parameter estimates. The QUANTILE= option in the MODEL statement specifies two quantile levels, 0.1 and 0.9, for fitting quantile regression models. The METHOD=BACKWARD option in the SELECTION statement specifies the backward elimination method for effect selection.

Division West	0	0	0	.	.	.	.	.
nOuts	1	0.39766	0.24676	0.12820	0.18601	0.60931	3.10	0.0021

Figure 28.9 displays the "Selected Effects" and "Parameter Estimates" tables at quantile level 0.9.

You might want to compute the 90th percentile predictions for players' salaries and find out which players were overpaid based on the quantile regression model at quantile level 0.9. The following statements repeat the backward elimination method at quantile level 0.9, compute and sort the overpaid players' salaries, and output the observations for the top 10 overpaid players in the mylib.baseball data table:

```
proc qtrselect data=mylib.baseball alpha=0.1;
   class league division;
   model Salary = nAtBat nHits nHome nRuns nRBI nBB
                  yrMajor crAtBat crHits crHome crRuns crRbi
                  crBB league division nOuts nAssts nError
         / quantile=0.9 clb;
   selection method=backward(select=sl sls=0.1);
   output out=mylib.BaseballOverpaid copyvar=(Name Salary) r=Overpaid
          p=PredictedSalary lclm uclm;
run;

data BaseballOverpaid;
   set mylib.BaseballOverpaid;
run;

proc sort data=BaseballOverpaid;
   by descending Overpaid;
run;

proc print data=BaseballOverpaid(obs=10);
   var Name Salary Overpaid PredictedSalary lclm uclm;
run;
```

The LCLM and UCLM options, respectively, request lower and upper bounds of $100(1-\alpha)\%$ confidence intervals for the expected conditional quantile predictions of players' salaries at quantile level 0.9.

Figure 28.11 Top 10 Overpaid Baseball Players at Quantile Level 0.9

Obs	Name	Salary	Overpaid	PredictedSalary	LCLM	UCLM
1	Smith, Ozzie	1940.0	1084.54	855.46	611.09	1099.83
2	Wiggins, Alan	700.0	220.74	479.26	345.93	612.60
3	Murray, Eddie	2460.0	213.10	2246.90	1982.06	2511.74
4	Strawberry, Darryl	1220.0	187.64	1032.36	914.99	1149.72
5	Gibson, Kirk	1300.0	177.24	1122.76	1011.97	1233.56
6	Trevino, Alex	512.5	149.70	362.80	273.17	452.43
7	Ramirez, Rafael	875.0	141.09	733.91	599.52	868.31
8	Romero, Ed	375.0	128.71	246.29	144.88	347.70
9	Mattingly, Don	1975.0	124.82	1850.18	1557.81	2142.55
10	Puhl, Terry	900.0	104.34	795.66	625.51	965.81

Output 28.11 shows the information about the top 10 overpaid players according to the final selected quantile regression model at quantile level 0.9. Ozzie Smith is in first place. This might be because, although Smith was known for his defensive brilliance, the model weights offensive performance measures much more than defensive performance measures.

Syntax: QTRSELECT Procedure

The following statements are available in the QTRSELECT procedure:

PROC QTRSELECT < *options* > ;
  BY *variables* ;
  CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > ;
  CODE < *options* > ;
  DISPLAY < *table-list* > < / *options* > ;
  DISPLAYOUT *table-spec-list* < / *options* > ;
  EFFECT *name***=***effect-type***(***variables* < / *options* >**)** ;
  MODEL *dependent* **=** < *effects* > < / *model-options* > ;
  OUTPUT OUT=*libref.data-table* < *keyword* < **=***name* > >. . . < *keyword* < **=***name* > > < / *options* > ;
  PARTITION *partition-options* ;
  SELECTION < **METHOD=***method* < **(***method-options***)** > >< *options* > ;
  STORE < **OUT=** >*libref.data-table* ;
  WEIGHT *variable* ;

The PROC QTRSELECT statement and a single MODEL statement are required. All other statements are optional. The CLASS statement can appear multiple times. If a CLASS statement is specified, it must precede the MODEL statement.

The rest of this section provides detailed syntax information about each of the preceding statements, beginning with the PROC QTRSELECT statement. The remaining statements are described in alphabetical order.

PROC QTRSELECT Statement

PROC QTRSELECT < *options* > **;**

The PROC QTRSELECT statement invokes the procedure. Table 28.1 summarizes the options in the PROC QTRSELECT statement by function.

Table 28.1 PROC QTRSELECT Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data table
Other Options	
ALPHA=	Sets the significance level to be used for the construction of confidence intervals
COV=SPARSITY	Specifies the sparsity-function method for estimating the covariance matrix of the parameter estimates
NOCLPRINT	Limits or suppresses the display of class levels

You can specify the following *options*:

ALPHA=*number*
sets the significance level to be used for the construction of confidence intervals. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the keywords LCLM, UCLM, and STDP in the OUTPUT statement and the CLB option in the MODEL statement.

COV=SPARSITY< (BF | HS) >
specifies the sparsity-function bandwidth method for estimating the covariance matrix of the parameter estimates. You can specify the following suboptions:

BF uses the Bofinger bandwidth method.

HS uses the Hall-Sheather bandwidth method.

By default, COV=SPARSITY(HS). For more information, see the section "Details: QTRSELECT Procedure" on page 1445.

DATA=*libref.data-table*
names the input data table for PROC QTRSELECT to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1422.

data-table specifies the name of the input data table.

NOCLPRINT<**=***number*>
suppresses the display of the "Class Level Information" table if you do not specify *number*. If you specify *number*, the values of the classification variables are displayed for only those variables whose number of levels is less than *number*. Specifying *number* helps reduce the size of the "Class Level Information" table if some classification variables have a large number of levels.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC QTRSELECT to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CLASS Statement

CLASS *variable* <**(***options***)**>. . . <*variable* <**(***options***)**>> </ *global-options*> **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. You can list the response variable for binary models in the CLASS statement, but this is not required. Table 28.2 summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section "CLASS Statement" on page 9 in Chapter 2, "Shared Concepts."

Table 28.2 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable
SPLIT	Splits levels of CLASS variables into independent effects

CODE Statement

CODE < *options* > **;**

The CODE statement writes SAS DATA step code for computing predicted values of the fitted model to a file or to a table. To score new data, you can then include the file in a DATA step, or you can specify the table in the **runCodeTable** action in the **dataStep** action set (for more information, see *SAS Viya: System Programming Guide*).

Table 28.3 summarizes the *options* available in the CODE statement.

Table 28.3 CODE Statement Options

Option	Description
COMMENT	Adds comments to the generated code
FILE=	Names the file in which to save the generated code
FORMATWIDTH=	Specifies the numeric format width for the regression coefficients
INDENTSIZE=	Specifies the number of spaces to indent the generated code
LABELID=	Specifies a number used to construct names and labels
LINESIZE=	Specifies the line size for the generated code
NOTRIM	Compares formatted values, including blank padding
OUT=	Names an output table in which to save the generated code

For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

The predicted values in the SAS DATA step code are computed based on the parameter estimates for the selected models. If you specify multiple quantile levels by using the QUANTILES option in the MODEL statement, then one variable of the predicted values is generated for each specified quantile level.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1459. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

key=value specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1459. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

EFFECT Statement

EFFECT *name*=*effect-type* **(***variables* < / *options* >**) ;**

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 67 in Chapter 2, "Shared Concepts."

You can specify the following *effect-types*:

COLLECTION specifies a collection effect that defines one or more variables as a single effect that has multiple degrees of freedom. The variables in a collection are considered as a unit for purposes of estimation and inference.

MULTIMEMBER | MM specifies a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.

POLYNOMIAL | POLY specifies a multivariate polynomial effect in the specified numeric variables.

SPLINE specifies a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 28.4 summarizes the *options* available in the EFFECT statement.

Table 28.4 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect

Table 28.4 *continued*

Option	Description
Multimember Effects Options	
DETAILS	Displays the levels of the multimember effect
NOEFFECT	Specifies that observations whose levels are all missing for the multimember variables should have 0 values in the corresponding design matrix columns
STDIZE	Standardizes the design matrix entries so that each observation has a sum of 1
WEIGHT=	Specifies the weight variable for the contributions of each classification effect
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect with multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots starting at the variables' maximum and ending at the KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots starting at the KNOTMIN= value and ending at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect
SEPARATE	Treats the spline basis for each variable as a separate effect when multiple variables are specified
SPLIT	Treats each design matrix column as a separate effect for selection methods

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 18 in Chapter 2, "Shared Concepts."

MODEL Statement

MODEL *dependent*=< *effects* > / < *model-options* > **;**

The MODEL statement names the dependent variable and the explanatory effects, including covariates, main effects, interactions, and nested effects. If you omit the explanatory effects, the procedure fits an intercept-only model.

After the keyword MODEL, the dependent (response) variable is specified, followed by an equal sign. The explanatory effects follow the equal sign.

For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

The *model-options* control other aspects of model formation and inference. Table 28.5 summarizes these options.

Table 28.5 MODEL Statement Options

Option	Description
Model Options	
CLB	Requests confidence limits
INCLUDE=	Includes effects in all models for model selection
INFORMATIVE	Models missing values by using extra indicator variables
NOINT	Suppresses the intercept
QUANTILES	Specifies quantile levels for the quantile regression
START=	Includes effects in the initial model for model selection
STB	Displays standardized estimates

Model Options

You can specify the following *options* in the MODEL statement after a slash (/):

CLB

requests the $100(1-\alpha)\%$ upper and lower confidence limits for the parameter estimates. By default, the 95% limits are computed; you can use the ALPHA= option in the PROC QTRSELECT statement to change the α level.

INCLUDE=*n*

INCLUDE=*single-effect*

INCLUDE=(*effects***)**

forces effects to be included in all models. If you specify INCLUDE=*n*, then the first *n* effects listed in the MODEL statement are included in all models. If you specify INCLUDE=*single-effect* or INCLUDE=(*single-effect*), then the specified effects are forced into all models.

INFORMATIVE

models missing values by using extra model effects. These effects consist of dummy variables that take the value 1 when the value of a continuous model variable involved in the effect is missing, and take the value 0 otherwise. The missing value in the original model effect is replaced by the average value of the effect for the nonmissing values. For continuous-by-class effects, such as A*x, where A is a classification variable and x is a continuous variable, informative missingness creates multiple dummy columns and substitutes the effect mean of x that corresponds to the respective level of A. Missing values for classification variables are treated as valid levels. For more information about informative missingness, see the section "Informative Missingness" on page 99 in Chapter 2, "Shared Concepts."

NOINT

suppresses the intercept term that is otherwise included in the model.

QUANTILES< (*quantile-level-options*) **>< =***number-list* **>**

QUANTILE< (*quantile-level-options*) **>< =***number-list* **>**

Q< (*quantile-level-options*) **>< =***number-list* **>**

specifies the quantile levels for the quantile regression. You can request any values of quantile levels in $(0, 1)$ by specifying a *number-list*. By default, the QTRSELECT procedure uses QUANTILES=0.5, which corresponds to median regression.

You can also specify the following *quantile-level-options*:

NTAU=*n*

NQ=*n*

specifies the following *n* quantile levels for the quantile regression:

$$\left\{ \frac{1}{n+1}, \ldots, \frac{n}{n+1} \right\}$$

If you specify both a QUANTILES=*number-list* and NTAU=*n*, the QTRSELECT procedure uses all the specified quantile levels.

SORT

sorts all the specified quantile levels in ascending order. This option affects the order of the prediction variables in the SAS DATA step code that is created by the CODE statement, and the order of the appropriate keyword variables in the SAS data set that is created by the OUTPUT statement.

START=*n*

START=*single-effect*

START=(*effects***)**

begins the selection process in the FORWARD and STEPWISE selection methods from the initial model that you designate. If you specify START=*n*, then the starting model consists of the first *n* effects listed in the MODEL statement. If you specify START=*single-effect* or START=(*single-effect*), then the starting model consists of these specified effects.

STB

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor. If you use the INCLUDE= option to force some effects to be in the model, then the QTRSELECT procedure computes the sample standard deviation against all the effects that are forced in, as follows. Let $\mathbf{X}_1$ denote the design submatrix of p_1 regressors that consists of all the effects that are forced in, and let $\mathbf{z}$ denote the dependent variable or any regressor. Then the sample standard deviation of $\mathbf{z}$ is computed as

$$s_z = \sqrt{\frac{\mathbf{z}'\left[\mathbf{I} - \mathbf{X}_1(\mathbf{X}_1{}'\mathbf{X}_1)^{-1}\mathbf{X}_1{}'\right]\mathbf{z}}{n - p_1}}$$

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < *=name* > >. . . < *keyword* < *=name* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics, which are computed after the model is fitted. The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option are included.

The output statistics are computed based on the parameter estimates for the selected model. If you specify multiple quantile levels by using the QUANTILES option in the MODEL statement, then for each appropriate keyword that is specified in the OUTPUT statement, one variable is generated for each specified quantile level. For observations in which only the response variable is missing, predicted values are computed even though these observations do not affect the model fit. This enables, for example, predicted values to be computed for new observations.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC QTRSELECT to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1422.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

COPYVAR=*variable*

COPYVARS=(*variables***)**

transfers one or more *variables* from the input data table to the output data table.

keyword **<=***name***>**

specifies the statistics to include in the output data table and optionally names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign and a variable to contain the statistic.

If you specify *keyword=name*, the new variable that contains the requested statistic has the specified name. If you omit the optional *=name* after a *keyword*, then a default name is used.

You can specify the following values for *keyword* to request statistics that are available with all selection methods:

PREDICTED<=*name***>**

PRED<=*name***>**

P<=*name***>**

requests predicted values for the response variable. The default *name* is Pred.

RESIDUAL<=*name***>**

RESID<=*name***>**

R<=*name***>**

requests the residual, calculated as ACTUAL – PREDICTED. The default *name* is Residual.

ROLE<=*name***>**

requests a numeric variable that indicates the role played by each observation in fitting the model. The default *name* is _ROLE_. For each observation, the interpretation of this variable is shown in Table 28.6.

Table 28.6 Role Interpretation

Value	Observation Role
0	Not used
1	Training
2	Validation
3	Testing

If you do not partition the input data by using a PARTITION statement, then the role variable value is 1 for observations used in fitting the model, and 0 for observations that have at least one missing or invalid value for the response, regressor, frequency, or weight variables.

If you specify multiple quantile levels by using the QUANTILES option in the MODEL statement, then for each appropriate keyword that is specified in the OUTPUT statement, one variable is generated for each specified quantile level. These variables appear in the same order as the specified quantile levels. For example, the following statements generate the mylib.out data table, which contains the two predicted quantile variables p1 and p2:

```
proc qtrselect data=mylib.one;
   model y = x1-x4 /quantiles=0.5 0.3;
   output out=mylib.out pred=p;
run;
```

The variable p1 is for quantile level 0.5, and the variable p2 is for quantile level 0.3.

By using the SORT suboption in the QUANTILES option, the following statements generate the mylib.out data table in sorted order:

```
proc qtrselect data=mylib.one;
   model y = x1-x4 /quantiles(sort)=0.5 0.3;
   output out=mylib.out pred=p;
run;
```

The variable p1 is for quantile level 0.3, and the variable p2 is for quantile level 0.5, because the sorted quantile levels are (0.3 0.5).

In addition to the preceding statistics, you can also use the *keywords* listed in Table 28.7 in the OUTPUT statement to obtain additional statistics. For computational formulas, see the section "Diagnostic Statistics" on page 1450. All the statistics available in the OUTPUT statement are conditional on the selected model and do not take into account the variability introduced when you do model selection.

Table 28.7 Keywords for OUTPUT Statement

Keyword	Description
LCLM	Lower bound of a $100(1-\alpha)\%$ confidence interval for the quantile prediction variable
STDP	Standard error of the quantile prediction variable
UCLM	Upper bound of a $100(1-\alpha)\%$ confidence interval for the quantile prediction variable

PARTITION Statement

PARTITION *partition-option* **;**

The PARTITION statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. For more information, see the section "Using Validation and Test Data" on page 101 in Chapter 2, "Shared Concepts." Either you can designate a variable in the input data table and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for randomly assigning observations to each role.

You must specify exactly one of the following *partition-options*:

FRACTION(< TEST=*fraction* **> < VALIDATE=***fraction* **> < SEED=***number* **>)**
randomly assigns specified proportions of the observations in the input data table to the roles. You specify the proportions for testing and validation by using the TEST= and VALIDATE= suboptions. If you specify both the TEST= and VALIDATE= suboptions, then the sum of the specified fractions must be less than 1 and the remaining fraction is the proportion of the observations assigned to the training role. The SEED= option specifies an integer that is used to start the pseudorandom number generator for random partitioning of data for training, testing, and validation. If you do not specify SEED=*number* or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

ROLE=*variable* **(< TEST='***value***' > < TRAIN='***value***' > < VALIDATE='***value***' >)**

ROLEVAR=*variable* **(< TEST='***value***' > < TRAIN='***value***' > < VALIDATE='***value***' >)**
names the *variable* in the input data table whose values are used to assign roles to each observation. This *variable* cannot also appear as an analysis variable in other statements or options. The TEST=, TRAIN=, and VALIDATE= suboptions specify the formatted values of this variable that are used to assign observation roles. If you do not specify the TRAIN= suboption, then all observations whose role is not determined by the TEST= or VALIDATE= suboption are assigned to the training role.

SELECTION Statement

SELECTION < **METHOD=***method* < **(***method-options***)** > >< *options* > **;**

The SELECTION statement performs model selection by examining whether effects should be added to or removed from the model according to rules that are defined by model selection methods. The statement is fully documented in the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

The QTRSELECT procedure supports the following values of the METHOD= option in the SELECTION statement:

BACKWARD specifies the backward elimination method, which starts with all effects in the model and deletes effects.

FORWARD specifies the forward selection method, which starts with no effects in the model and adds effects.

NONE specifies no model selection.

STEPWISE specifies the stepwise regression method, which is similar to the forward selection method except that effects already in the model do not necessarily stay there.

By default, METHOD=STEPWISE.

The DETAILS=ALL and DETAILS=STEPS options produce the "Fit Statistics," and "Parameter Estimates" tables, which provide information about the model that is selected at each step of the selection process.

By default, the QTRSELECT procedure displays the stop horizon steps in the "Selection Summary" table, and uses these steps for choosing the final model of the model selection process. Therefore, it is possible that the final model occurs after the step that has the best stop criterion value. To exclude the stop horizon steps for choosing the final model, you can specify the following option:

HIDESTOPSTEPS

HSS

hides the stop horizon steps in the "Selection Summary" table, and excludes these steps in choosing the final model.

If you specify the PLOTS=CRITERIA or PLOTS=ALL option, then a plot of the fit criteria by the selection step is created for the AIC, AICC, SBC, R1, and adjusted R1 statistics. If you also specify a PARTITION statement, then the same type of plot is created for the ACL criteria for training, validation, and testing roles. If you specify the PLOTS=FITBYROLE option and a PARTITION statement, then a plot of the ACL criterion by the selection step for each role is created.

STORE Statement

STORE < **OUT=** >*libref.data-table* **;**

The STORE statement saves the context and results of the statistical analysis. The resulting analytic store has a binary file format that cannot be modified. An example of analytic store technology is to perform a time-consuming analysis and to store its results by using the STORE statement. Later you can perform specific statistical analysis tasks based on the saved results of the previous analysis, without having to fit the model again. The contents of the analytic store can be processed by the ASTORE procedure and the **`score`** action in the **`aStore`** action set.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1422.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

The QTRSELECT procedure uses each valid weight as the scale factor of its relevant observation. Let $\mathbf{X}$ denote the design matrix before weights are used, and let $\mathbf{W}$ denote the diagonal matrix whose diagonal elements are the weights. Then PROC QTRSELECT uses the weighted design matrix $\mathbf{WX}$ for its computation. For example, the weighted version of $\mathbf{X}'\mathbf{X}$ is $\mathbf{X}'\mathbf{WWX}$ but not $\mathbf{X}'\mathbf{WX}$.

Details: QTRSELECT Procedure

Quantile Regression

This section describes the basic concepts and notations for quantile regression and quantile regression model selection.

Let $\{(y_i, \mathbf{x}_i) : i = 1, \ldots, n\}$ denote a data set of observations, where y_i are responses and $\mathbf{x}_i$ are regressors. Koenker and Bassett (1978) define the *regression quantile* at quantile level $\tau \in (0, 1)$ as any solution to the minimization problem

$$\min_{\boldsymbol{\beta} \in \mathbf{R}^p} \sum_{i=1}^{n} \rho_\tau \left(y_i - \mathbf{x}_i{}' \boldsymbol{\beta} \right)$$

where $\rho_\tau(r) = \tau r^+ + (1 - \tau) r^-$ is a check loss function in which $r^+ = \max(r, 0)$ and $r^- = \max(-r, 0)$.

If you specify weights $w_i, i = 1, \ldots, n$, in the WEIGHT statement, then weighted quantile regression is carried out by solving

$$\min_{\boldsymbol{\beta} \in \mathbf{R}^p} \sum_{i=1}^{n} \rho_\tau \left(w_i (y_i - \mathbf{x}_i{}' \boldsymbol{\beta}) \right)$$

The QTRSELECT procedure fits a quantile regression model by using a predictor-corrector interior point algorithm, which was originally designed to solve support vector machine classifiers for large data sets (Gertz and Griffin 2005, 2010).

Linear Model with Independent and Identically Distributed Errors

A linear model with independent and identically distributed (iid) errors assumes that the distribution of the response Y_i conditional on $\mathbf{x}_i$ follows the linear model,

$$Y_i = \mathbf{x}_i{}' \boldsymbol{\beta} + \epsilon_i$$

where ϵ_i for $i = 1, \ldots, n$ are iid in the distribution function F. General linear regression uses this model for deriving its statistical inferences and model selection criteria. Although quantile regression can analyze heterogeneous data without the iid errors assumption, this model is helpful for deriving some quantile regression model selection criteria. For more information about using a linear model with iid errors in deriving the quasi-likelihood information criteria, see the section "Criteria Used in Model Selection" on page 1447.

Linear-in-Parameter Model with Non-iid Settings

The more general form of a linear quantile regression model is

$$Q_Y(\tau|\mathbf{x}) = \mathbf{x}'\boldsymbol{\beta}(\tau)$$

where the iid assumption is not necessary.

Let $s_i(\tau) = 1/f_i(F_i^{-1}(\tau))$ denote the sparsity function of the ith observation. Under some regularity conditions, the asymptotic distribution of the general form of quantile regression estimates is

$$\sqrt{n}(\hat{\boldsymbol{\beta}}(\tau) - \boldsymbol{\beta}(\tau)) \rightarrow N(0, \tau(1-\tau)\mathbf{H}^{-}\boldsymbol{\Omega}\mathbf{H}^{-})$$

where $\mathbf{H} = \lim_{n\rightarrow\infty} n^{-1}\sum \mathbf{x}_i\mathbf{x}_i'/s_i(\tau)$ and $\boldsymbol{\Omega} = \lim_{n\rightarrow\infty} n^{-1}\sum \mathbf{x}_i\mathbf{x}_i'$.

The sparsity function of the ith observation, $s_i(\tau)$, can be estimated as

$$\hat{s}_i(\tau) = \frac{\hat{F}_i^{-1}(\tau + h_n) - \hat{F}_i^{-1}(\tau - h_n)}{2h_n}$$

where $\hat{F}_i^{-1}(\tau \pm h_n) = \mathbf{x}_i'\hat{\boldsymbol{\beta}}(\tau \pm h_n)$ are the quantile predictions of the ith observation at quantile levels $(\tau \pm h_n)$.

Accordingly, the covariance matrix of $\hat{\boldsymbol{\beta}}(\tau)$ can be estimated as

$$\widehat{\mathrm{COV}}\left(\hat{\boldsymbol{\beta}}(\tau)\right) = n^{-1}\tau(1-\tau)\hat{\mathbf{H}}_n^{-}\hat{\boldsymbol{\Omega}}_n\hat{\mathbf{H}}_n^{-}$$

where $\hat{\mathbf{H}}_n = n^{-1}\sum(\mathbf{x}_i\mathbf{x}_i'/\hat{s}_i(\tau))$ and $\hat{\boldsymbol{\Omega}}_n = n^{-1}\sum \mathbf{x}_i\mathbf{x}_i'$.

You can specify the bandwidth method for computing h_n by using either the COV=SPARSITY(BF) option for the Bofinger bandwidth method or the COV=SPARSITY(HF) option for the Hall-Sheather bandwidth method:

- The Bofinger bandwidth optimizes the mean square error for standard density estimation:

  $$h_n = n^{-1/5}\left(4.5v^2(\tau)\right)^{1/5}$$

- The Hall-Sheather bandwidth is based on Edgeworth expansions for studentized quantiles:

  $$h_n = n^{-1/3}{z_\alpha}^{2/3}(1.5v(\tau))^{1/3}$$

  z_α satisfies $T(z_\alpha, df) = 1 - \alpha/2$ for the construction of $1-\alpha$ confidence intervals, where T is the cumulative distribution function for the t distribution and df is the residual degrees of freedom.

The quantity

$$v(\tau) = \frac{s(\tau)}{s^{(2)}(\tau)} = \frac{f^2}{2(f^{(1)}/f)^2 + [(f^{(1)}/f)^2 - f^{(2)}/f]}$$

is not sensitive to f and can be estimated by assuming f is Gaussian as

$$\hat{v}(\tau) = \frac{\exp(-q^2)}{2\pi(q^2+1)}$$

where $q = \Phi^{-1}(\tau)$.

More Statistics for Parameter Estimates

Let $\hat{\beta}_j(\tau)$ denote the jth parameter estimate, and let $\hat{\boldsymbol{\beta}}(\tau) = \left(\hat{\beta}_1(\tau), \ldots, \hat{\beta}_p(\tau)\right)$ denote the vector of the parameter estimates.

PROC QTRSELECT outputs the standard error, t value, and Pr > $|t|$ probability for each $\hat{\beta}_j(\tau)$ in the parameter estimates table. If you specify the CLB option in the MODEL statement, PROC QTRSELECT also outputs confidence limits in the parameter estimates table. Table 28.8 summarizes these statistics for $\hat{\beta}_j(\tau)$.

Table 28.8 More Statistics for $\hat{\beta}_j(\tau)$

Statistic	Definition
Standard error: $\hat{\sigma}_j$	$\sqrt{\widehat{\mathrm{COV}}\left(\hat{\boldsymbol{\beta}}(\tau)\right)_{jj}}$
$(1-\alpha)\%$ confidence limits	$\left(\hat{\beta}_j(\tau) \pm t_{1,1-\frac{\alpha}{2}}\hat{\sigma}_j\right)$
t value	$\hat{\beta}_j(\tau)/\hat{\sigma}_j$
Pr > $\lvert t\rvert$ probability	p-value of the t value

Here $\widehat{\mathrm{COV}}\left(\hat{\boldsymbol{\beta}}(\tau)\right)_{jj}$ is the (j, j) element of $\widehat{\mathrm{COV}}\left(\hat{\boldsymbol{\beta}}(\tau)\right)$, and $t_{1,1-\frac{\alpha}{2}}$ denotes the $\left(1-\frac{\alpha}{2}\right)$-level student's t score with 1 degree of freedom.

Criteria Used in Model Selection

The QTRSELECT procedure supports the following fit statistics that you can use as criteria for the CHOOSE=, SELECT=, and STOP= options in the SELECTION statement:

ADJR1	specifies the adjusted R1 statistic.
AIC	specifies Akaike's information criterion (Akaike 1969; Koenker 2005).
AICC	specifies the corrected Akaike's information criterion (Hurvich and Tsai 1989).
BIC | SBC	specifies the Schwarz Bayesian information criterion (Schwarz 1978; Koenker 2005).
R1	specifies the R1 statistic (Koenker and Machado 1999). The R1 statistic is not valid for the STOP= or CHOOSE= option.
SL	specifies the significance level that is used to assess an effect's contribution to the fit when it is added to or removed from a model. SL is not valid for the CHOOSE= option.
VALIDATE	specifies the average check loss over the validation data.

Table 28.9 provides formulas and definitions for these fit statistics.

Table 28.9 Formulas and Definitions for Model Fit Summary Statistics for Single Quantile Effect Selection

Statistic	Definition or Formula
n	Number of observations
p	Number of parameters, including the intercept
$r_i(\tau)$	Residual for the ith observation; $r_i(\tau) = y_i - \mathbf{x}_i'\hat{\boldsymbol{\beta}}(\tau)$
$D(\tau)$	Total sum of check losses; $D(\tau) = \sum_{i=1}^{n} \rho_\tau(r_i)$. $D(\tau)$ is labeled as Objective Function in the "Fit Statistics" table.
$D_0(\tau)$	Total sum of check losses for intercept-only model if the intercept is a forced-in effect; otherwise for empty model.
$\mathrm{ACL}(\tau)$	Average check loss; $\mathrm{ACL}(\tau) = \dfrac{D(\tau)}{n}$
$\mathrm{R1}(\tau)$	Counterpart of linear regression R square for quantile regression; $\mathrm{R1}(\tau) = 1 - \dfrac{D(\tau)}{D_0(\tau)}$
$\mathrm{ADJR1}(\tau)$	Adjusted R1; $1 - \dfrac{(n-1)D(\tau)}{(n-p)D_0(\tau)}$ if intercept is a forced-in effect; otherwise $1 - \dfrac{nD(\tau)}{(n-p)D_0(\tau)}$.
$\mathrm{AIC}(\tau)$	$2n \ln(\mathrm{ACL}(\tau)) + 2p$
$\mathrm{AICC}(\tau)$	$2n \ln(\mathrm{ACL}(\tau)) + \dfrac{2pn}{n-p-1}$
$\mathrm{SBC}(\tau)$	$2n \ln(\mathrm{ACL}(\tau)) + p \ln(n)$

The $\mathrm{ADJR1}(\tau)$ criterion is equivalent to the generalized approximate cross validation (GACV) criterion for quantile regression (Yuan 2006). The GACV criterion is defined as

$$\mathrm{GACV}(\tau) = D(\tau)/(n-p)$$

which is proportional to $1 - \mathrm{ADJR1}(\tau)$.

Quasi-likelihood Information Criteria

Given the quantile level τ, assume that the distribution of Y_i conditional on $\mathbf{x}_i$ follows the linear model

$$Y_i = \mathbf{x}_i'\boldsymbol{\beta} + \epsilon_i$$

where ϵ_i for $i = 1, \ldots, n$ are iid in distribution F. Further assume that F is an asymmetric Laplace distribution whose density function is

$$f_\tau(r) = \frac{\tau(1-\tau)}{\sigma} \exp\left(-\frac{\rho_\tau(r)}{\sigma}\right)$$

where σ is the scale parameter. Then, the negative log-likelihood function is

$$l_\tau(\boldsymbol{\beta}, \sigma) = n \log(\sigma) + \sigma^{-1} \sum_{i=1}^{n} \rho_\tau(y_i - \mathbf{x}_i'\boldsymbol{\beta}) - n \log(\tau(1-\tau))$$

Under these settings, the maximum likelihood estimate (MLE) of $\boldsymbol{\beta}$ is the same as the relevant level-τ quantile regression solution $\hat{\boldsymbol{\beta}}(\tau)$, and the MLE for σ is

$$\hat{\sigma}(\tau) = n^{-1} \sum_{i=1}^{n} \rho_\tau \left(y_i - \mathbf{x}_i' \hat{\boldsymbol{\beta}}(\tau) \right)$$

where $\hat{\sigma}(\tau)$ equals the level-τ average check loss $\mathrm{ACL}(\tau)$ for the quantile regression solution.

Because the general form of Akaike's information criterion (AIC) is $\mathrm{AIC} = (-2l + 2p)$, the quasi-likelihood AIC for quantile regression is

$$\mathrm{AIC}(\tau) = 2n \ln\left(\mathrm{ACL}(\tau)\right) + 2p$$

where p is the degrees of freedom for the fitted model.

Similarly, the quasi-likelihood AICC (corrected AIC) and SBC (Schwarz Bayesian information criterion) can be formulated as follows:

$$\mathrm{AICC}(\tau) = 2n \ln\left(\mathrm{ACL}(\tau)\right) + \frac{2pn}{n - p - 1}$$

$$\mathrm{SBC}(\tau) = 2n \ln\left(\mathrm{ACL}(\tau)\right) + p \ln(n)$$

In fact, the quasi-likelihood AIC, AICC, and SBC are fairly robust, and you can use them to select effects for data sets without the iid assumption in asymmetric Laplace distribution. For a simulation study that applies SBC for effect selection, see "Example 28.1: Simulation Study" on page 1461. The study generates a data table by using a naive instrumental model (Chernozhukov and Hansen 2008).

Statistical Tests for Significance Level

The QTRSELECT procedure supports the significance level (SL) criterion for effect selection. Consider the general form of a quantile regression model:

$$Q_Y(\tau | \mathbf{x}_1, \mathbf{x}_2) = \mathbf{x}_1' \boldsymbol{\beta}_1(\tau) + \mathbf{x}_2' \boldsymbol{\beta}_2(\tau)$$

At each step of an effect-selection process, a candidate effect can be represented as $\mathbf{x}_2$, and the significance level of the candidate effect can be calculated by testing the null hypothesis: $H_0 : \boldsymbol{\beta}_2(\tau) = \mathbf{0}$.

The QTRSELECT procedure supports the Wald test for computing candidate significance levels. Let $\hat{\boldsymbol{\beta}}(\tau) = \left(\hat{\boldsymbol{\beta}}_1'(\tau), \hat{\boldsymbol{\beta}}_2'(\tau) \right)'$ be the parameter estimates for the extended model, and denote the estimated covariance matrix of $\hat{\boldsymbol{\beta}}(\tau)$ as

$$\hat{\Sigma}(\tau) = \begin{bmatrix} \hat{\Sigma}_{11}(\tau) & \hat{\Sigma}_{12}(\tau) \\ \hat{\Sigma}_{21}(\tau) & \hat{\Sigma}_{22}(\tau) \end{bmatrix}$$

where $\hat{\Sigma}_{22}(\tau)$ is the covariance matrix for $\hat{\boldsymbol{\beta}}_2(\tau)$. Then the Wald test score is defined as

$$\hat{\boldsymbol{\beta}}_2'(\tau) \hat{\Sigma}_{22}^{-1}(\tau) \hat{\boldsymbol{\beta}}_2(\tau)$$

Under the null hypothesis that the reduced model is the true model, the Wald score follows a χ^2 distribution with degrees of freedom $df = df_2 - df_1$, where df_1 and df_2 are the degrees of freedom for the reduced model and the extended model, respectively .

When you use SL as a criterion for effect selection, the algorithm for estimating sparsity function depends on whether an effect is being considered as an add or a drop candidate. For testing an add candidate effect, the sparsity values, $\hat{s}_i(\tau)$'s, are estimated by using the reduced model that does not include the add candidate effect. For testing a drop candidate effect, the sparsity values are estimated on the extended model that does not exclude the drop candidate effect. Then, these estimated sparsity function values are used to compute the covariance matrix of the parameter estimates for the extended model. However, for the model that is selected at each step, the sparsity function for estimating standard errors and confidence limits of the parameter estimates is estimated on that model itself, but not on the model that was selected at the preceding step.

Because the null hypotheses usually do not hold, the SLENTRY and SLSTAY values cannot reliably be viewed as probabilities. One way to address this difficulty is to replace hypothesis testing with a means of selecting a model with information criteria or out-of-sample prediction criteria.

Diagnostic Statistics

This section gathers the formulas for the statistics available in the OUTPUT statement. All the statistics available in the OUTPUT statement are conditional on the selected model and do not take into account the variability that is introduced by doing model selection.

The model to be fit is $Q_Y(\tau|\mathbf{x}) = \mathbf{x}'\boldsymbol{\beta}(\tau)$, and the parameter estimate $\hat{\boldsymbol{\beta}}(\tau)$ is the solution that minimizes $\sum_{i=1}^{n} \rho_\tau\left(y_i - \mathbf{x}_i'\boldsymbol{\beta}\right)$. The subscript i is for the ith observation. The subscript j is for the jth quantile level of the specified QUANTILES levels in the MODEL statement. $\hat{\Sigma}(\tau)$ denotes the covariance estimation for $\hat{\boldsymbol{\beta}}(\tau)$.

The ALPHA= option in the PROC QTRSELECT statement sets the α value for the confidence limit statistics. The degrees of freedom for $t_{\frac{\alpha}{2}}$ are $n - p$.

Table 28.10 contains the diagnostic statistics and their formulas. Each statistic is computed for each observation.

Table 28.10 Formulas and Definitions for Diagnostic Statistics

MODEL Option or Statistic	Formula
PREDj	$\widehat{y}_{ji} = \mathbf{x}_i'\hat{\boldsymbol{\beta}}(\tau_j)$
RESj	$y_i - \widehat{y}_{ji}$
STDPj	$\sqrt{\mathbf{x}_i'\hat{\Sigma}(\tau_j)\mathbf{x}_i}$
LCLMj	$\widehat{y}_{ji} - t_{\frac{\alpha}{2}}\mathrm{STDP}j_i$
UCLMj	$\widehat{y}_{ji} + t_{\frac{\alpha}{2}}\mathrm{STDP}j_i$

Classification Variables and the SPLIT Option

PROC QTRSELECT supports the ability to split classification variables when you are doing model selection. You use the SPLIT option in the CLASS statement to specify that the columns of the design matrix that correspond to effects that contain a split classification variable can enter or leave a model independently of the other design columns of that effect. The following statements illustrate the use of the SPLIT option:

```
data mylib.splitExample;
   length c2 $6;
   drop i;
   do i=1 to 1000;
     c1 = 1 + mod(i,6);
     if      i < 200 then c2 = 'low';
     else if i < 500 then c2 = 'medium';
     else                 c2 = 'high';
     x1 = ranuni(1);
     x2 = ranuni(1);
     y = x1+3*(c2 ='low')  + 10*(c1=3) +5*(c1=5) + rannor(1);
     output;
   end;
run;

proc qtrselect data=mylib.splitExample;
   class c1(split) c2(order=freq);
   model y = c1 c2 x1 x2;
   selection method=forward;
run;
```

The "Class Level Information" table shown in Figure 28.12 is produced by default whenever you specify a CLASS statement.

Figure 28.12 Class Levels

The QTRSELECT Procedure

Class Level Information		
Class	**Levels**	**Values**
c1	6	1 2 3 4 5 6
c2	3	high medium low

The SPLIT option has been specified for the classification variable c1. This permits the parameters associated with the effect c1 to enter or leave the model individually. The "Parameter Estimates" table in Figure 28.13 shows that for this example the parameters that correspond only to levels 3 and 5 of c1 are in the selected model.

Figure 28.13 Parameter Estimates

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	2.84133	0.11898	23.88	<.0001
c1_3	1	10.15300	0.10121	100.31	<.0001
c1_5	1	5.02683	0.09847	51.05	<.0001
c2 high	1	-3.10623	0.09550	-32.52	<.0001
c2 medium	1	-2.88624	0.11896	-24.26	<.0001
c2 low	0	0	.	.	.
x1	1	1.23941	0.14059	8.82	<.0001

Using Validation and Test Data

When you have sufficient data, you can subdivide your data into three parts called the training, validation, and test data. The selection process fits models to the training data and uses the validation data to find the prediction errors for the models that are obtained in this way. This prediction error on the validation data can be used to decide when to terminate the selection process or to decide what effects to include as the selection process proceeds. Finally, after a selected model has been obtained, the test data can be used to assess how the selected model generalizes on data that played no role in selecting the model.

In some cases you might want to use only training and test data. For example, you might want to use an information criterion to decide what effects to include and when to terminate the selection process. In this case no validation data are required, but test data can still help you assess the predictive performance of the selected model. In other cases you might decide to use validation data during the selection process but forgo assessing the selected model on test data. Hastie, Tibshirani, and Friedman (2001) note that it is difficult to give a general rule for how many observations you should assign to each role. They state that a typical split might be 50% for training and 25% each for validation and testing.

You use a PARTITION statement to logically subdivide the DATA= data table into separate roles. You can name the fractions of the data that you want to reserve as test data and validation data. For example, the following statements randomly subdivide the mylib.inData data table, reserving 50% for training and 25% each for validation and testing:

```
proc qtrselect data=mylib.inData;
  partition fraction(test=0.25 validate=0.25);
  ...
run;
```

In some cases you might need to exercise more control over the partitioning of the input data table. You can do this by naming both a variable in the input data table and a formatted value of that variable that correspond to each role. For example, the following statements assign roles to the observations in the mylib.inData data table based on the value of the variable group in that data table. Observations in which the value of group is “group 1” are assigned to testing, and those whose value is “group 2” are assigned to training. All other observations are ignored.

```
proc qtrselect data=mylib.inData;
  partition roleVar=group(test='group 1' train='group 2')
  ...
run;
```

After you reserve observations for training, validation, and testing, a model fit of the training data is scored on the validation and test data, and the average check loss (ACL) is computed separately for each of these subsets. The ACL for each data role is the sum of check losses for observations in that role divided by the number of observations in that role.

The following statements illustrate the use of the ROLEVAR= option:

```
%let seed=321;
%let n=600;
%let p=10;

data mylib.roleExample;
   array x{&p} x1-x&p;
   length r $8;
   drop i j k;

   do i=1 to &n;
      do j=1 to &p;
         x{j} = ranuni(&seed);
      end;

      y  = x1 + x2 + x3 + ranuni(&seed);

      k = mod(i,3);
      if      k=0 then r = 'train';
      else if k=1 then r = 'validate';
      else if k=2 then r = 'test';
      output;
   end;
run;

proc qtrselect data=mylib.roleExample;
   model y = x1-x&p;
   selection method=forward(select=validate stop=sbc);
   partition rolevar=r(train='train' validate='validate' test='test');
run;
```

The “Number of Observations” table shown in Figure 28.14 displays the number of observations used for training, validation, and testing.

Figure 28.14 Number of Observations

Figure 28.16 Fit Statistics

The QTRSELECT Procedure

Quantile Level = 0.5
Selected Model

Objective Function	23.74758
R1	0.47615
Adj R1	0.46814
AIC	-844.33471
AICC	-844.12958
SBC	-831.14144
ACL (Train)	0.11874
ACL (Validate)	0.12409
ACL (Test)	0.12282

Using the Validation ACL as the SELECT= Criterion

If you provided observations for validation and specified a model selection method that uses the SELECT= criterion, then you can specify SELECT=VALIDATE as a suboption of the METHOD= option in the SELECTION statement. After each step, the selection process computes the validation ACL values for all the current candidate models. The candidate model that has the smallest validation ACL value usually serves as the model for the next selection step.

Using the Validation ACL as the STOP= Criterion

If you provided observations for validation, then you can specify STOP=VALIDATE as a suboption of the METHOD= option in the SELECTION statement. At step k of the selection process, the best candidate effect to enter or leave the current model is determined. Here, "best candidate" means the effect that gives the best value of the SELECT= criterion; this criterion does not need to be based on the validation data. The validation ACL for the model with this candidate effect added or removed is computed. If this validation ACL is greater than the validation ACL for the model at step k, then the selection process terminates at step k.

Using the Validation ACL as the CHOOSE= Criterion

When you specify the CHOOSE=VALIDATE suboption of the METHOD= option in the SELECTION statement, the validation ACL is computed for the models at each step of the selection process. The smallest model at any step that yields the smallest validation ACL is selected.

Computational Method

Multithreading

The QTRSELECT procedure allocates data to different threads and calculates crossproduct matrices by accumulating the contributions from all threads. PROC QTRSELECT also uses multiple threads to compute matrix inverses and select candidates during model selection. For more information about how PROC QTRSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Displayed Output

The following sections describe the output produced by PROC QTRSELECT. The output is organized into various tables, which are discussed in their order of appearance.

Selection Information

When you specify the SELECTION statement, the QTRSELECT procedure produces by default a series of tables that display information about the model selection. The "Selection Information" table informs you about the model selection method; select, stop, and choose criteria; and other parameters that govern the selection. You can suppress this table by specifying DETAILS=NONE in the SELECTION statement.

Number of Observations

The "Number of Observations" table displays the number of observations read from the input data table and the number of observations used in the analysis. If you use a PARTITION statement, the table also displays the number of observations used for each data role.

Class Level Information

The "Class Level Information" table lists the levels of every variable that you specify in the CLASS statement. You should check this information to make sure that the data are correct. You can adjust the order of the CLASS variable levels by specifying the ORDER= option in the CLASS statement. You can suppress the "Class Level Information" table completely or partially by specifying the NOCLPRINT= option in the PROC QTRSELECT statement.

If the classification variables use a nonsingular parameterization, the "Class Level Information" table also displays the reference value for each variable.

Dimensions

The "Dimensions" table displays the number of effects and the number of parameters from which the selected model is chosen. If you use split classification variables, then this table also displays the number of effects after splitting is taken into account.

Entry and Removal Candidates

When you specify the DETAILS=ALL or DETAILS=STEPS option in the SELECTION statement, the QTRSELECT procedure produces "Entry Candidates" and "Removal Candidates" tables that display the effect names and values of the criterion used to select entering or departing effects at each step of the selection process. The effects are displayed in sorted order from best to worst of the selection criterion.

Selection Summary

When you specify the SELECTION statement, the QTRSELECT procedure produces the "Selection Summary" table, which displays information about the sequence of steps of the selection process. For each step, the effect that was entered or dropped is displayed along with the statistics used to select the effect, stop the selection, and choose the selected model. For all criteria that you can use for model selection, the steps at which the optimal values of these criteria occur are also indicated.

You can suppress the display of the "Selection Summary" table by specifying DETAILS=NONE in the SELECTION statement.

Stop Reason

The "Stop Reason" table displays the reason why the selection stopped. To facilitate programmatic use of this table, an integer code is assigned to each reason and is included if you use an ODS OUTPUT statement or a DISPLAYOUT statement to output this table. The reasons and their associated codes follow:

Code	Stop Reason
1	All eligible effects are in the model.
2	All eligible effects have been removed.
3	Specified maximum number of steps done.
4	The model contains the specified maximum number of effects.
5	The model contains the specified minimum number of effects (for backward selection).
6	The stopping criterion is at a local optimum.
7	No suitable add or drop candidate could be found.
8	Adding or dropping any effect does not improve the selection criterion.
9	No candidate meets the appropriate SLE or SLS significance level.
10	Stepwise selection is cycling.
11	The model is an exact fit.
12	Dropping an effect would result in an empty model.

You can suppress the display of the "Stop Reason" table by specifying DETAILS=NONE in the SELECTION statement.

Selection Reason

When you specify the SELECTION statement, the QTRSELECT procedure produces a simple table that explains why the final model was selected.

You can suppress the display of the "Selection Reason" table by specifying DETAILS=NONE in the SELECTION statement.

Selected Effects

When you specify the SELECTION statement, the QTRSELECT procedure produces a simple table that lists which effects were selected for the final model.

Fit Statistics

The "Fit Statistics" table displays fit statistics for the selected model. The statistics include the following:

- Objective Function, total sum of check losses. Objective Function is denoted as $D(\tau)$ in Table 28.9.
- R1, a measure between 0 and 1 that indicates the portion of the (corrected) total check losses attributed to the fit rather than left to residuals. It is calculated as $1 - \frac{D(\tau)}{D_0(\tau)}$. It is the quantile regression counterpart of the linear regression R square.
- Adj R1, the adjusted R1, a version of R1 that has been adjusted for degrees of freedom. It is calculated as

$$\text{Adj R1} = 1 - \frac{n-i}{n-p}(1 - \text{R1})$$

where $i = 1$ if the intercept is forced in and $i = 0$ otherwise , n is the number of observations used to fit the model, and p is the number of parameters in the model.

- the fit criteria AIC, AICC, and SBC if they are used in the selection process. For the formulas to evaluate these criteria, see Table 28.9.
- the average check loss (ACL) on the training, validation, and test data

You can request the "Fit Statistics" tables for the model at each step of the selection process by specifying the DETAILS= option in the SELECTION statement.

Parameter Estimates

The "Parameter Estimates" table displays the parameters in the selected model and their estimates. The information displayed for each parameter in the selected model includes the following:

- the parameter label that includes the effect name and level information for effects that contain classification variables
- the degrees of freedom (DF) for the parameter. There is one degree of freedom unless the model is not full rank.
- the parameter estimate
- the standard error, which is the estimate of the standard deviation of the parameter estimate
- t Value, the *t* test that the parameter is 0. This is computed as the parameter estimate divided by the standard error.
- the Pr > |t|, the probability that a *t* statistic would obtain a greater absolute value than that observed given that the true parameter is 0. This is the two-tailed significance probability.

  When you do model selection, these *p*-values are usually liberal because they are not adjusted for the fact that the terms in the model have been selected.

You can request a "Parameter Estimates" table for the model at each step of the selection process by specifying the DETAILS= option in the SELECTION statement.

Timing

The "Timing" table displays the amount of time (in seconds) and the percentage of the time that PROC QTRSELECT required to perform different tasks in the analysis.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the QTRSELECT procedure creates has a name associated with it. You must use this name to refer to the table when you use ODS statements. These names are listed in Table 28.11.

NOTE: The EFFECT statement also create tables which are not listed in this section. For information about these tables, see "ODS Table Names" on page 33 in Chapter 2, "Shared Concepts."

Table 28.11 ODS Tables Produced by PROC QTRSELECT

Table Name	Description	Required Statement / Option
Candidates	Swap candidates at step	SELECTION DETAILS=ALL | STEPS
ClassInfo	Level information from the CLASS statement	CLASS
Dimensions	Model dimensions	Default output
EntryCandidates	Candidates for entry at step	SELECTION DETAILS=ALL | STEPS
FitStatistics	Fit statistics	Default output
ModelInfo	Information about the modeling environment	Default output
NObs	Number of observations read and used	Default output
OutputCasTables	See the section "OutputCasTables Table" on page 1458	OUTPUT DISPLAYOUT
ParameterEstimates	Solutions for the parameter estimates associated with effects in the MODEL statement	Default output
RemovalCandidates	Candidates for removal at step	SELECTION DETAILS=ALL | STEPS
SelectedEffects	List of selected effects	SELECTION
SelectionInfo	Information about selection settings	Default output
SelectionReason	Reason for selecting the final model	SELECTION
SelectionSummary	Summary information about the model selection steps	SELECTION
StopReason	Reason selection was terminated	SELECTION
Timing	Timing breakdown by task	SELECTION DETAILS

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

When ODS Graphics is enabled, then the SELECTION statement can produce plots to help evaluate the selection process. For information about these plots, see the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

PROC QTRSELECT assigns a name to each graph that it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 28.12.

Table 28.12 Graphs Produced by PROC QTRSELECT

ODS Graph Name	Plot Description	PLOTS Option
CoefficientPanel	Coefficients and CHOOSE= criterion by step	COEFFICIENTS
ChooseCriterionPlot	CHOOSE= criterion by step	COEFFICIENTS(UNPACK)
CoefficientPlot	Coefficients by step	COEFFICIENTS(UNPACK)
CriterionPanel	Fit criteria by step	CRITERIA
AdjR1Plot	Adjusted R1 by step	CRITERIA(UNPACK)
AICCPlot	Corrected Akaike's information criterion by step	CRITERIA(UNPACK)
AICPlot	Akaike's information criterion by step	CRITERIA(UNPACK)
SBCPlot	Schwarz Bayesian information criterion by step	CRITERIA(UNPACK)
TEST_ACLPlot	Average check loss on testing data by step	CRITERIA(UNPACK)
TRAIN_ACLPlot	Average check loss on training data by step	CRITERIA(UNPACK)
VAL_ACLPlot	Average check loss on validation data by step	CRITERIA(UNPACK)
FitByRolePlot	Progression of average check loss by role	FITBYROLE

Examples: QTRSELECT Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 28.1: Simulation Study

(View the complete code for this example (qtrselex1.sas) in the example repository.)

This example is based on the section "Simulation Study" (Examples: QUANTSELECT Procedure, *SAS/STAT User's Guide*). This simulation study shows how you can use the forward selection method to select quantile regression models for single quantile levels. The following statements simulate a data set from a naive instrumental model (Chernozhukov and Hansen 2008):

```
%let seed=321;
%let p=20;
%let n=3000;

data analysisData;
   array x{&p} x1-x&p;
   do i=1 to &n;
      U  = ranuni(&seed);
      x1 = ranuni(&seed);
      x2 = ranexp(&seed);
      x3 = abs(rannor(&seed));
      y  = x1*(U-0.1) + x2*(U*U-0.25) + x3*(exp(U)-exp(0.9));
      do j=4 to &p;
         x{j} = ranuni(&seed);
      end;
      output;
   end;
run;
```

Variable U in the data set indicates the true quantile level of the response y conditional on $\mathbf{x} = (x_1, \ldots, x_p)'$.

Let $Q_Y(\tau|\mathbf{x}) = \mathbf{x}'\boldsymbol{\beta}(\tau)$ denote the underlying quantile regression model, where $\boldsymbol{\beta}(\tau) = (\beta_1(\tau), \ldots, \beta_p(\tau))'$. Then, the true parameter functions are

$$\begin{aligned}
\beta_1(\tau) &= \tau - 0.1 \\
\beta_2(\tau) &= \tau^2 - 0.25 \\
\beta_3(\tau) &= \exp(\tau) - \exp(0.9) \\
\beta_4(\tau) &= \cdots = \beta_p(\tau) = 0
\end{aligned}$$

It is easy to see that, at $\tau = 0.1$, only $\beta_2(0.1) = -0.24$ and $\beta_3(0.1) = \exp(0.1) - \exp(0.9) \approx -1.354432$ are nonzero parameters. Therefore, an effective effect-selection method should select x2 and x3 and drop all the other effects in this data set at $\tau = 0.1$. By the same rationale, x1 and x3 should be selected at $\tau = 0.5$ with $\beta_1(0.5) = 0.4$ and $\beta_3(0.5) \approx -0.810882$, and x1 and x2 should be selected at $\tau = 0.9$ with $\beta_1(0.9) = 0.8$ and $\beta_2(0.9) = 0.56$.

You can load the analysisData data set into your CAS session by specifying your CAS engine libref in the first statement in the following DATA step:

```
data mylib.analysisData;
   set analysisData;
run;
```

The following statements use PROC QTRSELECT with the forward selection method. The STB option and the CLB option in the MODEL statement request the standardized parameter estimates and the confidence limits of parameter estimates, respectively.

```
proc qtrselect data=mylib.analysisData;
   model y= x1-x&p / quantile=0.1 0.5 0.9 clb;
   selection method=forward;
   output out=mylib.out p=pred;
run;
```

Output 28.1.1 shows that, by default, the CHOOSE= and STOP= options are both set to SBC.

Output 28.1.1 Selection Information

The QTRSELECT Procedure

Selection Information	
Selection Method	Forward
Select Criterion	SBC
Stop Criterion	SBC
Effect Hierarchy Enforced	None
Stop Horizon	3

Output 28.1.2, Output 28.1.3, and Output 28.1.4 display the selected effects and the parameter estimates for $\tau = 0.1$, $\tau = 0.5$, and $\tau = 0.9$, respectively. You can see that the forward selection method correctly selects active effects for all three quantile levels.

Output 28.1.2 Parameter Estimates at $\tau = 0.1$

Selected Effects:	Intercept x2 x3

Intercept	1	-0.00774	0.03292	-0.07228	0.05680	-0.24	0.8142
x1	1	0.78294	0.05134	0.68228	0.88360	15.25	<.0001
x2	1	0.57644	0.03422	0.50935	0.64354	16.85	<.0001

Example 28.2: Growth Charts for Body Mass Index

(View the complete code for this example (qtrselex2.sas) in the example repository.)

This example is modeled on an example in the section "Getting Started: QUANTREG Procedure" in the *SAS/STAT User's Guide*. This example highlights the use of the QTRSELECT procedure for multiple-level quantile regression by creating growth charts for men's body mass index (BMI).

BMI, which is defined as the ratio of weight (kg) to squared height (m^2), is a standard measure for categorizing individuals as overweight or underweight. The percentiles of BMI for specified ages are of particular interest. This example draws smooth BMI quantile curves conditional on Age, which can serve as BMI growth charts in medical diagnoses to identify BMI percentiles for subjects.

The Sashelp.BMIMen data set records 1999–2000 and 2001–2002 survey results for men's BMI. These survey results are published by the National Center for Health Statistics. The data set contains 3,264 observations for two variables, BMI and Age.

The following statements display the variables in the data set. Output 28.2.1 shows the results.

```
proc contents varnum data=sashelp.BMIMen;
   ods select position;
run;
```

Output 28.2.1 Sashelp.BMIMen Data Set

The CONTENTS Procedure

Variables in Creation Order			
#	Variable	Type	Len
1	Age	Num	8
2	BMI	Num	8

You can load the Sashelp.BMIMen data set into your CAS session by specifying your CAS engine libref in the first statement in the following DATA step:

```
data mylib.BMIMen;
   set sashelp.BMIMen;
   SqrtAge = sqrt(Age);
   InveAge = 1/Age;
   LogBMI  = log(BMI);
run;
```

The logarithm of BMI is used as the response. The following statements fit quantile regression models for the mylib.BMIMen data table at 10 quantile levels:

```
%let quantile=0.03 0.05 0.1 0.25 0.5 0.75 0.85 0.90 0.95 0.97;
%let nq=10;

proc qtrselect data=mylib.BMIMen;
   model logBMI = InveAge SqrtAge Age SqrtAge*Age Age*Age Age*Age*Age
         / quantile=&quantile;
   output out=mylib.BMIOut copyvars=(BMI Age) pred=P_LogBMI;
run;
```

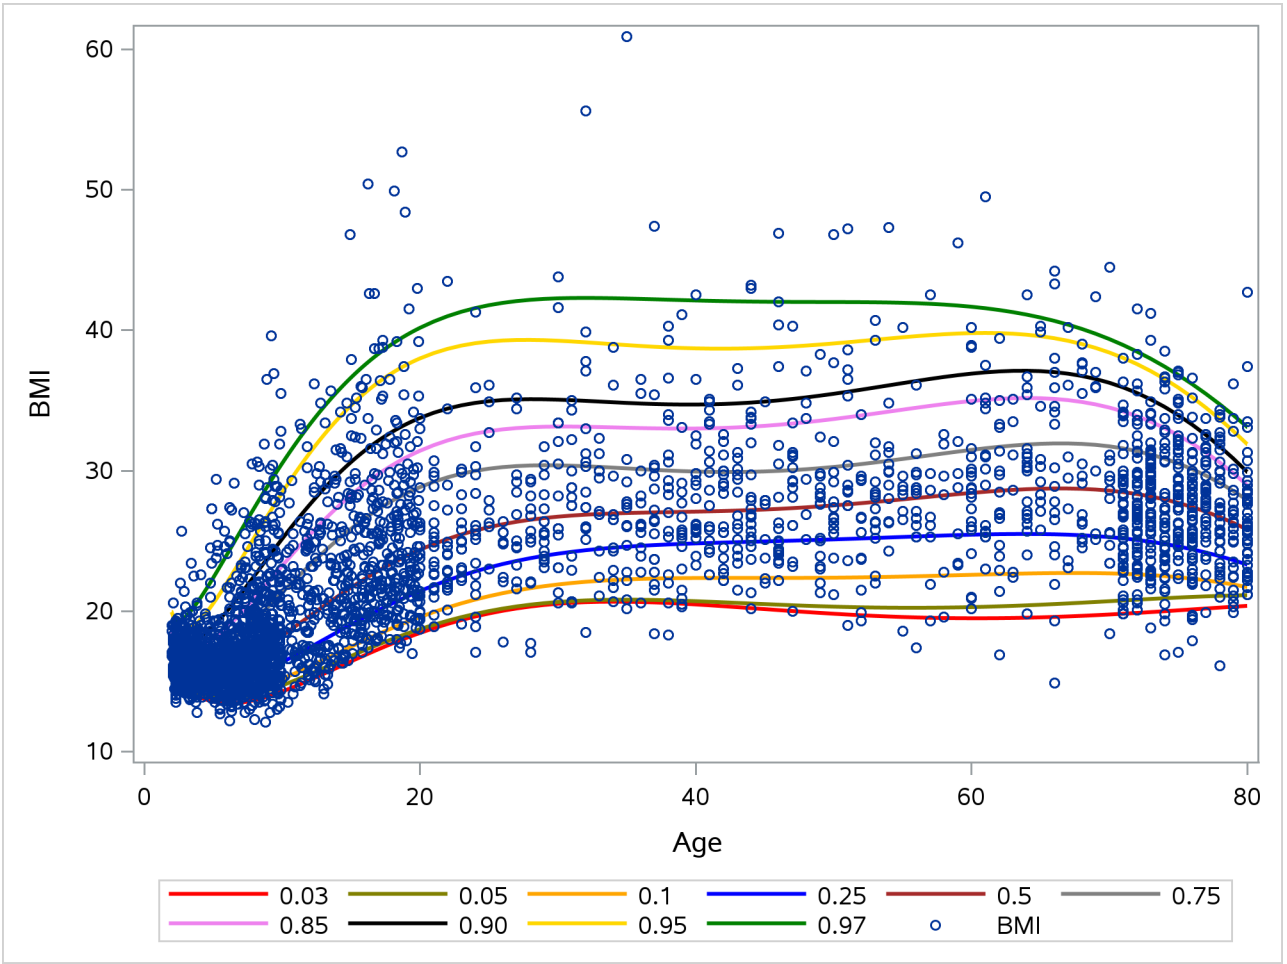
The OUTPUT statement outputs the mean predicted quantiles for the 10 specified quantile levels. The PRED= option in the OUTPUT statement specifies the variable names for the quantile predictions. For example, p1 is for quantile level 0.03, and p2 is for quantile level 0.05.

The following statements define and apply a SAS macro function to create a quantile curves plot for the mylib.BMIOut data table:

```
%let BMIcolor=red olive orange blue brown gray violet black gold green;

%macro plotBMI;
   data BMIPred;
      set mylib.BMIOut;
      %do j=1 %to &nq;
         predBMI&j = exp(P_LogBMI&j);
      %end;
      label %do j=1 %to &nq;
               predBMI&j=%qscan(&quantile,&j,%str( ))
            %end;;
   run;

   proc sort data=BMIPred;
      by Age;
```



```
   run;

   proc sgplot data=BMIPred;
      %do j=1 %to &nq;
         series y=predBMI&j x=Age/lineattrs=(thickness=2
         color=%qscan(&BMIcolor,&j,%str( )));
      %end;
      scatter y=BMI x=Age/markerattrs=(size=5);
   run;
%mend;

%plotBMI;
```

Output 28.2.2 shows the BMI quantile curves, which can serve as BMI growth charts. For example, the percentiles of any observations (small blue circles) that are located between the top 0.95 quantile (gold) curve and the 0.97 quantile (green) curve are between the 95th percentile and the 97th percentile. By using this rule, you can measure the percentile range for any observations of interest.

Output 28.2.2 Growth Chart for Body Mass Index

Example 28.3: Pollution and Mortality

(View the complete code for this example (qtrselex3.sas) in the example repository.)

This example shows how you can produce the ODS graphical summary for the effect selection process, and how you can use the PARTITION statement and other options to control the effect selection process. The data for this example come from a study by McDonald and Schwing (1973). The data set contains 60 observations, 15 covariates, and one response variable. The response variable is the total age-adjusted mortality rate for Standard Metropolitan Statistical Areas in the United States in 1959–1961.

The following DATA step creates the Mortality data set:

```
data mortality;
   input index aap ajant ajult size65 nph nsch25 nfek ppsm snwp nowk nin3k
   hpi nopi sdpi datm DeathRate;
   label index="the index"
      aap="Average Annual Precipitation"
      ajant="Average January Temperature"
      ajult="Average July Temperature"
      size65="Size of Population Older Than 65"
      nph="Number of Members per Household"
      nsch25="Number of Years of Schooling for Persons over 25"
      nfek="Number of Households with Fully Equipped Kitchens"
      ppsm="Population per Square Mile"
      snwp="Size of the Nonwhite Population"
      nowk="Number of Office Workers"
      nin3k="Number of Families with an Income Less Than $3000"
      hpi="Hydrocarbon Pollution Index"
      nopi="Nitric Oxide Pollution Index"
      sdpi="Sulfur Dioxide Pollution Index"
      datm="Degree of Atmospheric Moisture"
      DeathRate="Age-Adjusted Death Rate: Deaths per 100,000 Population";
   datalines;
 1  36  27  71   8.1  3.34  11.4  81.5  3243   8.8  42.6  11.7   21

   ... more lines ...

    11   42  56  1003.502
58  45  24  70  11.8  3.25  11.1  79.8  3678   1.0  44.8  14.0    7
     3    8  56   895.696
59  42  83  76   9.7  3.22   9.0  76.2  9699   4.8  42.2  14.5    8
     8   49  54   911.817
60  38  28  72   8.9  3.48  10.7  79.8  3451  11.7  37.5  13.0   14
    13   39  58   954.442
;
```

The following statements load the mylib.Mortality data set into your CAS session.

```
data mylib.Mortality;
   set Mortality;
run;
```

The following statements fit a median model for mortality rate conditional on a set of climate, demographic, and pollution covariates by using the forward selection method:

```
ods graphics on;
proc qtrselect data=mylib.Mortality;
   partition fraction(validate=0.3 seed=8);
   model DeathRate = aap aap*aap ajant ajant*ajant ajult
      ajult*ajult size65 size65*size65 nph nph*nph nsch25
      nsch25*nsch25 nfek nfek*nfek  ppsm ppsm*ppsm snwp snwp*snwp
      nowk nowk*nowk nin3k nin3k*nin3k hpi hpi*hpi nopi
      nopi*nopi sdpi sdpi*sdpi datm datm*datm
      / quantile=0.5;
   selection method=forward(choose=validate) sh=8 hier=single
      plot=all;
   output out=mylib.OutData copyvar=DeathRate p=Pred role=Role;
run;

proc print data=mylib.OutData(obs=10); run;
```

Because linear terms alone might not be sufficient to fit this model, quadratic terms are also added in the MODEL statement. The FRACTION option of the PARTITION statement requests that 30% of the observations be used for validation and the remaining 70% of the observations be used for training. The SEED suboption in the FRACTION option specifies the random seed for partitioning the data. The HIER=SINGLE option in the MODEL statement forces the effect selection process to ignore quadratic effect candidates if their corresponding main effects are not in the model. The OUTPUT statement creates a SAS data set named mylib.OutData, which contains the variable Role for observation roles and the variable Pred for median prediction conditional on final selected effects.

Output 28.3.1 shows the selection summary. You can see that the best model is at step 10 for validation ACL and step 14 for the SBC.

Output 28.3.1 Selection Summary

Overview: REGSELECT Procedure

The REGSELECT procedure fits and performs model selection for ordinary least squares regression models in SAS Viya.

The models that PROC REGSELECT supports can contain main effects that consist of both continuous and classification variables and interaction effects of these variables. The models can also include constructed effects such as splines. The procedure offers a number of effect-selection methods, including stepwise methods and modern LASSO methods. It also offers extensive capabilities for customizing the model selection by using a wide variety of selection and stopping criteria, from computationally efficient significance-level-based criteria to modern, computationally intensive validation-based criteria. PROC REGSELECT also provides a variety of regression diagnostics that are conditional on the selected model.

PROC REGSELECT Features

The main features of the REGSELECT procedure are as follows:

- **Model specification**
  - supports multiple parameterizations for classification effects
  - supports any degree of interaction (crossed effects) and nested effects
  - supports a hierarchy among effects
  - supports partitioning of data into training, validation, and testing roles
  - provides a FREQ statement for grouped analysis
  - provides a WEIGHT statement for weighted analysis
- **Selection control**
  - provides multiple effect-selection methods
  - offers selection of individual levels of classification effects
  - provides effect selection based on a variety of selection criteria
  - provides stopping rules based on a variety of model evaluation criteria
- **Display and output**
  - produces output data tables that contain predicted values, residuals, studentized residuals, confidence limits, and influence statistics
  - uses ODS Graphics to create model selection plots as part of its output. For more information about ODS Graphics, see the section "ODS Graphics" on page 1517.
  - saves fitted models to analytic stores so that you can use them to make predictions later

The REGSELECT procedure supports the following effect-selection methods. For a more detailed description of these methods, see the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

- Forward selection starts with no effects in the model and adds effects.
- Backward elimination starts with all effects in the model and deletes effects.
- Stepwise regression is similar to forward selection, except that effects already in the model do not necessarily stay there.
- Forward-swap selection is an extension of the forward selection method. Before any addition step, PROC REGSELECT makes all pairwise swaps of one effect in the model and one effect out of the current model that improve the selection criterion. When the selection criterion is R-square, this method is the same as the MAXR method in the REG procedure in SAS/STAT software.
- Least angle regression (LAR), like forward selection, starts with no effects in the model and adds effects. The parameter estimates at any step are "shrunk" when compared to the corresponding least squares estimates.
- LASSO adds and deletes parameters based on a version of ordinary least squares in which the sum of the absolute regression coefficients is constrained. PROC REGSELECT also supports adaptive LASSO selection, in which weights are applied to each of the parameters in forming the LASSO constraint.
- Elastic net is an extension of LASSO that estimates parameters by using a version of ordinary least squares in which both the sum of the absolute regression coefficients and the sum of the squared regression coefficients are constrained.
- Best-subset selection uses the branch-and-bound algorithm (Furnival and Wilson 1974) to efficiently find subsets of model effects that best predict the dependent variable without examining all possible subsets.
- Smoothly clipped absolute deviation (SCAD) and minimax concave penalty (MCP) selection methods use folded concave penalties (FCP) in regularized linear regression to produce shrinkage estimators.

Hybrid versions of the LAR and LASSO are also supported. They use the LAR or LASSO to select the model, but they estimate the regression coefficients by ordinary weighted least squares.

Because the REGSELECT procedure runs on CAS, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode on CAS
- exploits all the available cores and concurrent threads. For information about how PROC REGSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC REGSELECT Compared with Other SAS Procedures

The REGSELECT procedure provides regression modeling functionality that is comparable to that of the HPREG, GLMSELECT, and REG procedures in SAS/STAT software.

PROC REGSELECT Compared with the HPREG Procedure

The functionality of the REGSELECT procedure closely resembles that of the HPREG procedure, which is a high-performance procedure. The REGSELECT procedure is the next generation of the HPREG procedure, and it was developed specifically for SAS Viya. Both procedures are designed to run on a cluster of machines that distribute the data and the computations.

Both the REGSELECT and HPREG procedures fit and perform model selection for ordinary least squares regression models, which you can specify as general linear models that include classification variables. You request model selection by using the SELECTION statement.

The REGSELECT procedure offers all the methods of effect selection that the HPREG procedure supports; in addition, PROC REGSELECT supports the elastic net selection method, the best-subset selection method, the SCAD method, and the MCP method. PROC REGSELECT also produces selection plots by using ODS Graphics. The REGSELECT and HPREG procedures offer the same methods of customizing the model selection, and the same set of regression diagnostics. The main differences in functionality are that the REGSELECT procedure provides the ability to specify constructed effects with the EFFECT statement, and it computes Type 3 tests of effects.

PROC REGSELECT Compared with the GLMSELECT Procedure

The functionality of the REGSELECT procedure also closely resembles that of the GLMSELECT procedure. Both procedures fit and perform model selection for ordinary least squares regression models, which you can specify as general linear models that include classification variables. Both procedures offer the same methods of effect selection (including the LAR, LASSO, and elastic net methods) and extensive options to customize the selection process. The REGSELECT procedure supports the best-subset selection method, the SCAD method, and the MCP method, none of which the GLMSELECT procedure supports. Both procedures provide the ability to specify constructed effects with the EFFECT statement.

Unlike the GLMSELECT procedure, the REGSELECT procedure does not perform model selection by default. If you request model selection by using the SELECTION statement, then the default selection method is stepwise selection based on the Schwarz Bayesian information criterion (SBC). This default matches the default method in PROC GLMSELECT. The REGSELECT procedure does not support using cross validation as a model selection criterion.

With the REGSELECT procedure—but not with the GLMSELECT procedure—you can request observationwise residual and influence diagnostics in the OUTPUT statement and variance inflation and tolerance statistics for the parameter estimates. If the fitted model has been obtained by performing model selection, then these statistics are conditional on the selected model and do not take into account the variability introduced by the selection process.

PROC REGSELECT Compared with the REG Procedure

A major functional difference between the REGSELECT procedure and the REG procedure is that the REGSELECT procedure enables you to specify general linear models that include classification variables. In this respect it is similar to the GLM and GLMSELECT procedures in SAS/STAT.

Unlike the REG procedure, the REGSELECT procedure supports the LAR, LASSO and elastic net methods, the ability to use external validation data as selection criteria, and extensive options to customize the selection process.

Like the REG procedure, PROC REGSELECT does not perform model selection by default. If you request model selection by using the SELECTION statement in PROC REGSELECT, then the default selection method is stepwise selection based on the Schwarz Bayesian information criterion (SBC).

With the REGSELECT procedure, as with the REG procedure, you can request observationwise residual and influence diagnostics in the OUTPUT statement, and variance inflation and tolerance statistics for the parameter estimates. If the fitted model has been obtained by performing model selection, then these statistics are conditional on the selected model and do not take into account the variability introduced by the selection process.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: REGSELECT Procedure

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

(View the complete code for this example at `https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/regselectgs.sas`.)

The following example is closely modeled on the example in the section "Getting Started: GLMSELECT Procedure" in the *SAS/STAT User's Guide*.

The Sashelp.Baseball data set contains salary and performance information for Major League Baseball players who played at least one game in both the 1986 and 1987 seasons, excluding pitchers. The salaries (Time Inc. 1987) are from the 1987 season, and the performance measures are from 1986 (Collier Books 1987). The following step displays (in Figure 29.1) the variables in the data set:

```
proc contents varnum data=sashelp.baseball;
   ods select position;
run;
```

Suppose you want to investigate whether you can model the players' salaries from the 1987 season based on performance measures for the previous season. The aim is to obtain a parsimonious model that does not overfit these particular data, making the model useful for prediction. This example shows how you can use PROC REGSELECT as a starting point for such an analysis. Because the variation of salaries is much greater for the higher salaries, it is appropriate to apply a log transformation to the salaries before you do the model selection.

You can load the Sashelp.Baseball data set into your CAS session by specifying your CAS engine libref in the first statement in the following DATA step:

```
data mylib.baseball;
   set sashelp.baseball;
run;
```

These statements assume that your CAS engine libref is named mylib, as in the section "Using CAS Sessions and CAS Engine Librefs" on page 1479, but you can substitute any appropriately defined CAS engine libref.

Figure 29.1 Sashelp.Baseball Data Set

The CONTENTS Procedure

Variables in Creation Order				
#	Variable	Type	Len	Label
1	Name	Char	18	Player's Name
2	Team	Char	14	Team at the End of 1986
3	nAtBat	Num	8	Times at Bat in 1986
4	nHits	Num	8	Hits in 1986
5	nHome	Num	8	Home Runs in 1986
6	nRuns	Num	8	Runs in 1986
7	nRBI	Num	8	RBIs in 1986
8	nBB	Num	8	Walks in 1986
9	YrMajor	Num	8	Years in the Major Leagues
10	CrAtBat	Num	8	Career Times at Bat
11	CrHits	Num	8	Career Hits
12	CrHome	Num	8	Career Home Runs
13	CrRuns	Num	8	Career Runs
14	CrRbi	Num	8	Career RBIs
15	CrBB	Num	8	Career Walks
16	League	Char	8	League at the End of 1986
17	Division	Char	8	Division at the End of 1986
18	Position	Char	8	Position(s) in 1986
19	nOuts	Num	8	Put Outs in 1986
20	nAssts	Num	8	Assists in 1986
21	nError	Num	8	Errors in 1986
22	Salary	Num	8	1987 Salary in $ Thousands
23	Div	Char	16	League and Division
24	logSalary	Num	8	Log Salary

The following statements select a model by using the default settings for stepwise selection. ODS Graphics must be enabled before you can request plots. For more information about ODS Graphics, see the section "ODS Graphics" on page 1517.

```
ods graphics on;

proc regselect data=mylib.baseball;
   class league division;
   model logSalary = nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB league division nOuts nAssts nError;
   selection method=stepwise plots=all;
run;
```

The output and graphics from this analysis are presented in Figure 29.2 through Figure 29.6.

Figure 29.2 Selection Information, Number of Observations, Class Level Information, and Dimensions

The REGSELECT Procedure

Selection Information	
Selection Method	Stepwise
Select Criterion	SBC
Stop Criterion	SBC
Effect Hierarchy Enforced	None
Stop Horizon	3

Number of Observations Read	322
Number of Observations Used	263

Class Level Information

Class	Levels	Values
League	2	American National
Division	2	East West

Dimensions	
Number of Effects	19
Number of Parameters	21

The "Selection Information" table provides details about the method and criteria used to perform the model selection. The requested selection method is a variant of the traditional stepwise selection in which the decisions about what effects to add or drop at any step and when to terminate the selection are both based on the Schwarz Bayesian information criterion (SBC). The effect in the current model whose removal yields the maximal decrease in the SBC value is dropped, provided that this lowers the SBC value. When no further decrease in the SBC value can be obtained by dropping an effect in the model, the effect whose addition to the model yields the lowest SBC value is added and the whole process is repeated. The method terminates when dropping or adding any effect increases the SBC value.

Figure 29.2 displays the "Number of Observations," "Class Level Information," and "Dimensions" tables. The "Number of Observations" table shows that of the 322 observations in the input data, only 263 observations are used in the analysis because there are observations that contain incomplete data. The "Class Level Information" table lists the levels of the classification variables division and league. When you specify effects that contain classification variables, the number of parameters is usually larger than the number of effects. The "Dimensions" table shows the number of effects and the number of parameters that are considered.

The "Stepwise Selection Summary" table in Figure 29.3 shows the effect that was added or dropped at each step of the selection process together with fit statistics for the model at each step. In this case, both selection and stopping are based on the SBC.

Figure 29.4 displays the "Stop Reason," "Selection Reason," and "Selected Effects" tables. Note that these tables are displayed without any titles. The "Stop Reason" table indicates that selection stopped because adding or removing any effect would worsen the SBC value that is used as the selection criterion. In this case, because no CHOOSE= criterion is specified in the SELECTION statement, the final model is the selected model; this is indicated in the "Selection Reason" table. The "Selected Effects" table lists the effects in the selected model.

The REGSELECT Procedure

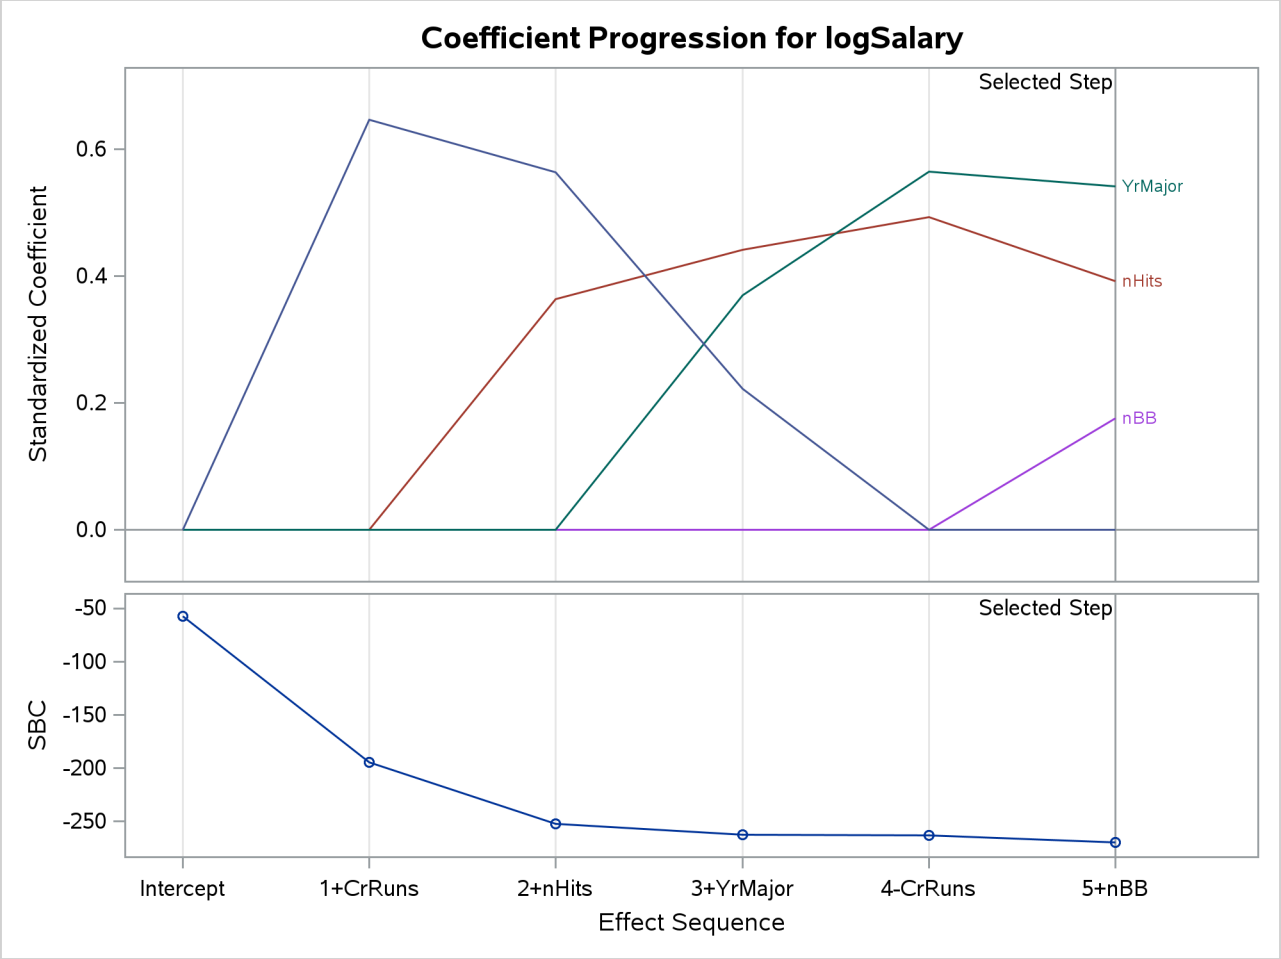
Selection Details

Selection Summary

Step	Effect Entered	Effect Removed	Number Effects In	SBC
0	Intercept		1	-57.2041
1	CrRuns		2	-194.3166
2	nHits		3	-252.5794
3	YrMajor		4	-262.7322
4		CrRuns	3	-262.8353
5	nBB		4	-269.7804*

*** Optimal Value Of Criterion**

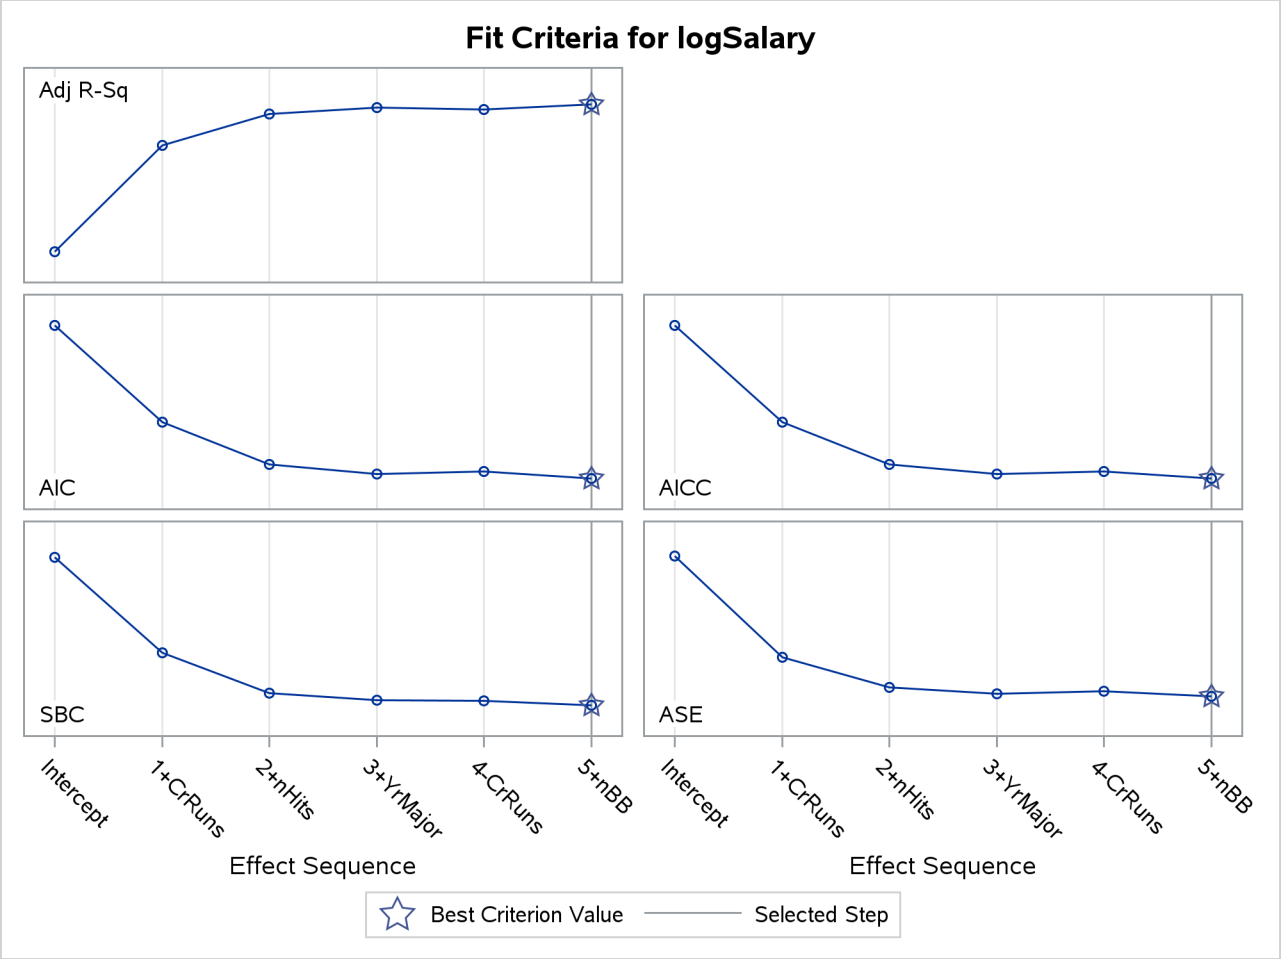
Figure 29.4 Stopping and Selection Reasons



Stepwise selection stopped because adding or removing an effect does not improve the SBC criterion.

The model at step 5 is selected.

Selected Effects: Intercept nHits nBB YrMajor



The coefficient panel in Figure 29.5 enables you to visualize the selection process. In this plot, standardized coefficients of all the effects that are selected at some step of the stepwise method are plotted as a function of the step number. This enables you to assess the relative importance of the effects that are selected at any step of the selection process and to know when effects entered the model. The lower plot in the panel shows how the criterion that is used to choose the selected model changes as effects enter or leave the model.

Figure 29.5 Coefficient Progression

The criterion panel in Figure 29.6 provides a graphical view of the progression of the fit criteria as the selection process evolves.

Figure 29.6 Criterion Panel

The "Analysis of Variance," "Fit Statistics," and "Parameter Estimates" tables shown in Figure 29.7 display details of the selected model.

nHits	1	0.007929	0.000994	7.98	<.0001
nBB	1	0.007280	0.002049	3.55	0.0005
YrMajor	1	0.100663	0.007551	13.33	<.0001

Finally, a table is displayed that shows the amount of time (in seconds) that PROC REGSELECT required to perform the different tasks in the analysis.

Figure 29.8 Procedure Timing

Task Timing

Task	Seconds	Percent
Setup and Parsing	0.03	48.84%
Levelization	0.02	32.62%
Model Initialization	0.00	3.51%
SSCP Computation	0.01	8.02%
Model Selection	0.00	3.65%
Cleanup	0.00	2.49%
Total	0.06	100.00%

You might want to examine regression diagnostics for the selected model to investigate whether collinearity among the selected parameters or the presence of outlying or high-leverage observations might be affecting the fit. The following statements include some options and statements to obtain these diagnostics:

```
proc regselect data=mylib.baseball;
  class league division;
  model logSalary = nAtBat nHits nHome nRuns nRBI nBB
                    yrMajor crAtBat crHits crHome crRuns crRbi
                    crBB league division nOuts nAssts nError / vif clb;
  selection method=stepwise;
  output out=mylib.baseballOut
         p=predictedLogSalary r h cookd rstudent copyvars=(name);
run;
```

The VIF and CLB options in the MODEL statement request variance inflation factors and 95% confidence limits, respectively, for the parameter estimates. Figure 29.9 shows the "Parameter Estimates" table, which displays these requested statistics. The variance inflation factors (VIF) measure the inflation in the variances of the parameter estimates due to collinearities that exist among the regressor (independent) variables.

Although there are no formal criteria for deciding whether a VIF is large enough to affect the predicted values, the VIF values for the selected effects in this example are small enough to indicate that there are no collinearity issues among the selected regressors.

Figure 29.9 Parameter Estimates with Additional Statistics

The REGSELECT Procedure

Selected Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Pr > |t|	Variance Inflation	95% Confidence Limits	
Intercept	1	4.013911	0.111290	36.07	<.0001	0	3.79476	4.23306
nHits	1	0.007929	0.000994	7.98	<.0001	1.49642	0.00597	0.00989
nBB	1	0.007280	0.002049	3.55	0.0005	1.52109	0.00325	0.01131
YrMajor	1	0.100663	0.007551	13.33	<.0001	1.02488	0.08579	0.11553

By default, SAS Viya statistical procedures do not include all variables from the input data table in output data tables. The COPYVARS= option in the OUTPUT statement specifies that the variable name in the input data table be added as an identification variable in the baseballOut data table that is produced by the OUTPUT statement. In addition to this variable, the OUTPUT statement requests that predicted values, raw residuals, leverage values, Cook's D statistics, and studentized residuals be added to the output data table. Note that default names are used for these statistics, except for the predicted values for which a specified name, predictedLogSalary, is supplied. The following statements use PROC PRINT to display five observations in this output data table:

```
proc print data=mylib.baseballOut(obs=5);
run;
```

Figure 29.10 First 5 Observations of the baseballOut Data Set

Obs	predictedLogSalary	Residual	COOKD	H	RSTUDENT	Name
1	4.73980	.	.	0.016087	.	Allanson, Andy

FREQ *variable* **;**
MODEL *dependent* **=** < *effects* > < / *model-options* > **;**
OUTPUT OUT=*libref.data-table* < *keyword* < **=***name* > >. . . < *keyword* < **=***name* > > **;**
PARTITION *partition-options* **;**
SELECTION < **METHOD=***method* < **(***method-options***)** > >< *options* > **;**
STORE < **OUT=** >*libref.data-table* **;**
WEIGHT *variable* **;**

The PROC REGSELECT statement and a single MODEL statement are required. All other statements are optional. The CLASS statement can appear multiple times. If a CLASS statement is specified, it must precede the MODEL statement.

The rest of this section provides detailed syntax information about each of the preceding statements, beginning with the PROC REGSELECT statement. The remaining statements are described in alphabetical order.

PROC REGSELECT Statement

PROC REGSELECT < *options* > **;**

The PROC REGSELECT statement invokes the procedure. Table 29.1 summarizes the options in the PROC REGSELECT statement by function.

Table 29.1 PROC REGSELECT Statement Options

Option	Description
Basic Option	
DATA=	Specifies the input data set
Other Options	
ALPHA=	Sets the significance level to be used for the construction of confidence intervals
NOCLPRINT	Limits or suppresses the display of class levels
PLOTS=	Produces ODS graphical displays

You can specify the following *options*:

ALPHA=*number*

sets the significance level to be used for the construction of confidence intervals. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the keywords LCL, LCLM, UCL, and UCLM in the OUTPUT statement and the CLB option in the MODEL statement.

DATA=*libref.data-table*

names the input data table for PROC REGSELECT to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1479.

data-table specifies the name of the input data table.

NOCLPRINT< =*number* **>**

suppresses the display of the "Class Level Information" table if you do not specify *number*. If you specify *number*, the values of the classification variables are displayed for only those variables whose number of levels is less than *number*. Specifying *number* helps reduce the size of the "Class Level Information" table if some classification variables have a large number of levels.

PLOTS< (UNPACK) > = RIDGE | RIDGEPANEL | RIDGEPLOT < (*ridge-plot-options***) >**

creates panels of variance inflation factor (VIF) values and standardized ridge estimates by ridge values for each coefficient. The VIF values for each coefficient are connected by lines and are displayed in the upper plot in each panel. The points that correspond to the standardized estimates of each coefficient are connected by lines and are displayed in the lower plot in each panel.

You can specify the following *ridge-plot-options*:

COEF

plots the standardized ridge estimates by ridge values for each coefficient.

COMMONAXES

specifies that the same VIF axis and the same standardized estimate axis be used in all panels when multiple panels are needed. By default, these axes are chosen independently for the regressors shown in each panel.

MAXVARS=ALL | *number*

specifies the maximum number of regressors to display in each panel or in each plot if you also specify the UNPACK option. If you specify MAXVARS=ALL, then the VIF values and ridge traces for all regressors are displayed in a single panel. By default, MAXVARS=10.

RIDGEAXIS=LINEAR | LOG

specifies the axis type to use for displaying the ridge parameters. By default, RIDGEAXIS=LINEAR. Note that the point whose ridge parameter value is 0 is not displayed if you specify RIDGEAXIS=LOG.

UNPACK | UNPACKPANEL
suppresses paneling. The traces of the VIF statistics and standardized estimates are shown in separate plots.

VIF
plots the VIF statistics by ridge values for each coefficient.

VIFAXIS=LINEAR | LOG
specifies the axis type to use for displaying the VIF statistics. By default, VIFAXIS=LINEAR.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC REGSELECT to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CLASS Statement

CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. You can list the response variable for binary models in the CLASS statement, but this is not required. Table 29.2 summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section "CLASS Statement" on page 9 in Chapter 2, "Shared Concepts."

Table 29.2 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable
SPLIT	Splits levels of CLASS variables into independent effects

CODE Statement

CODE < *options* > **;**

The CODE statement writes SAS DATA step code for computing predicted values of the fitted model to a file or to a table. To score new data, you can then include the file in a DATA step, or you can specify the table in the **runCodeTable** action in the **dataStep** action set (for more information, see *SAS Viya: System Programming Guide*).

Table 29.3 summarizes the *options* available in the CODE statement.

Table 29.3 CODE Statement Options

Option	Description
COMMENT	Adds comments to the generated code
FILE=	Names the file in which to save the generated code
FORMATWIDTH=	Specifies the numeric format width for the regression coefficients
INDENTSIZE=	Specifies the number of spaces to indent the generated code
LABELID=	Specifies a number used to construct names and labels
LINESIZE=	Specifies the line size for the generated code
NOTRIM	Compares formatted values, including blank padding
OUT=	Names an output table in which to save the generated code

For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

This statement is ignored if you perform best-subset selection.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1515. A path is a table name that is prefixed with dot-separated grouping information. For example, a

SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

key=value specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1515. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

EFFECT Statement

EFFECT *name*=*effect-type* **(***variables* < / *options* >**) ;**

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section "GLM Parameterization of Classification Variables and Effects" on page 67 in Chapter 2, "Shared Concepts."

You can specify the following *effect-types*:

COLLECTION specifies a collection effect that defines one or more variables as a single effect that has multiple degrees of freedom. The variables in a collection are considered as a unit for purposes of estimation and inference.

MULTIMEMBER | MM specifies a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.

POLYNOMIAL | POLY specifies a multivariate polynomial effect in the specified numeric variables.

SPLINE specifies a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 29.4 summarizes the *options* available in the EFFECT statement.

Table 29.4 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect

Table 29.4 *continued*

Option	Description
Multimember Effects Options	
DETAILS	Displays the levels of the multimember effect
NOEFFECT	Specifies that observations whose levels are all missing for the multimember variables should have 0 values in the corresponding design matrix columns
STDIZE	Standardizes the design matrix entries so that each observation has a sum of 1
WEIGHT=	Specifies the weight variable for the contributions of each classification effect
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect with multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots starting at the variables' maximum and ending at the KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots starting at the KNOTMIN= value and ending at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect
SEPARATE	Treats the spline basis for each variable as a separate effect when multiple variables are specified
SPLIT	Treats each design matrix column as a separate effect for selection methods

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section "EFFECT Statement" on page 18 in Chapter 2, "Shared Concepts."

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC REGSELECT treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1.

MODEL Statement

MODEL *dependent*=< *effects* > / < *model-options* > **;**

The MODEL statement names the dependent variable and the explanatory effects, including covariates, main effects, interactions, and nested effects. If you omit the explanatory effects, the procedure fits an intercept-only model.

After the keyword MODEL, the dependent (response) variable is specified, followed by an equal sign. The explanatory effects follow the equal sign.

For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

The *model-options* control other aspects of model formation and inference. Table 29.5 summarizes these options.

Table 29.5 MODEL Statement Options

Option	Description
Model Options	
CLB	Requests confidence limits
INCLUDE=	Includes effects in all models for model selection
INFORMATIVE	Models missing values by using extra indicator variables
NOINT	Suppresses the intercept
RIDGE=	Performs ridge regression analysis
SS3	Displays the Type 3 or joint tests of effects
START=	Includes effects in the initial model for model selection
STB	Displays standardized estimates
TOL	Displays tolerance values for the estimates
VIF	Displays variance inflation factors for the estimates
XPX	Displays sums-of-squares and crossproducts matrix

Model Options

You can specify the following *options* in the MODEL statement after a slash (/):

CLB
requests the $100(1-\alpha)\%$ upper and lower confidence limits for the parameter estimates. By default, the 95% limits are computed; you can use the ALPHA= option in the PROC REGSELECT statement to change the α level. The CLB option is not available when you specify METHOD=LAR, METHOD=LASSO, METHOD=ELASTICNET, or METHOD=BESTSUBSET in the SELECTION statement.

INCLUDE=*n*

INCLUDE=*single-effect*

INCLUDE=(*effects***)**
forces effects to be included in all models. If you specify INCLUDE=*n*, then the first *n* effects that are listed in the MODEL statement are included in all models. If you specify INCLUDE=*single-effect* or INCLUDE=(*single-effect*), then the specified effects are forced into all models. The INCLUDE= option is not available when you specify METHOD=LAR, METHOD=LASSO, or METHOD=ELASTICNET in the SELECTION statement. For METHOD=BESTSUBSET, only the first *n* effects that are listed in the MODEL statement are allowed.

INFORMATIVE
models missing values by using extra model effects. These effects consist of dummy variables that take the value 1 when the value of a continuous model variable involved in the effect is missing, and take the value 0 otherwise. The missing value in the original model effect is replaced by the average value of the effect for the nonmissing values. For continuous-by-class effects, such as A*x, where A is a classification variable and x is a continuous variable, informative missingness creates multiple dummy columns and substitutes the effect mean of x that corresponds to the respective level of A. Missing values for classification variables are treated as valid levels. For more information about informative missingness, see the section "Informative Missingness" on page 99 in Chapter 2, "Shared Concepts."

NOINT
suppresses the intercept term that is otherwise included in the model.

RIDGE=*value(s)*
performs a ridge regression analysis and specifies the values of the ridge constant *k*. Each value of *k* produces a set of ridge regression estimates that are displayed in the RidgeParmEst table and a set of ridge fit statistics that are displayed in the RidgeFitStats table. You can specify only nonnegative numbers in this option. Ridge regression is ignored when you perform model selection.

SS3
displays a "Model Anova" table that contains tests computed with Type III sums of squares for each effect. For more information, see the section "Joint Tests and Type 3 Tests" on page 1509. This option is not available when you specify METHOD=BESTSUBSET in the SELECTION statement.

START=*n*

START=*single-effect*

START=(*effects***)**

is used to begin the selection process in the FORWARD, FORWARDSWAP, and STEPWISE selection methods from the initial model that you designate. If you specify START=*n*, then the starting model consists of the first *n* effects that are listed in the MODEL statement. If you specify START=*single-effect* or START=(*single-effect*), then the starting model consists of these specified effects. The START= option is not available when you specify METHOD=BACKWARD, METHOD=LAR, METHOD=LASSO, METHOD=ELASTICNET, or METHOD=BESTSUBSET in the SELECTION statement.

STB

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor. This option is not available when you specify METHOD=BESTSUBSET in the SELECTION statement.

TOL

produces tolerance values for the estimates. Tolerance for a parameter is defined as $1 - R^2$, where R^2 is obtained from the regression of the parameter on all other parameters in the model. This option is not available when you specify METHOD=LAR, METHOD=LASSO, METHOD=ELASTICNET, or METHOD=BESTSUBSET in the SELECTION statement.

VIF

produces variance inflation factors along with the parameter estimates. Variance inflation is the reciprocal of tolerance. This option is not available when you specify METHOD=LAR, METHOD=LASSO, METHOD=ELASTICNET, or METHOD=BESTSUBSET in the SELECTION statement.

XPX

displays the $X'X$ crossproducts matrix for the model. The crossproducts matrix is bordered by the $X'Y$ and $Y'Y$ matrices.

OUTPUT Statement

OUTPUT OUT=*libref.data-table*
< **COPYVARS=***(variables)* >
< *keyword* < *=name* > >. . . < *keyword* < *=name* > > **;**

The OUTPUT statement creates a data table that contains observationwise statistics, which are computed after the model is fitted. The variables in the input data table are *not* included in the output data table, in order to avoid data duplication for large data tables; however, variables that you specify in the COPYVARS= option are included.

The output statistics are computed based on the parameter estimates for the selected model. For observations in which only the response variable is missing, predicted values are computed even though these observations do not affect the model fit. This enables, for example, predicted values to be computed for new observations.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC REGSELECT to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1479.

data-table specifies the name of the output data table.

You can also specify the following syntax elements:

COPYVAR=*variable*

COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table.

keyword **<** **=***name* **>**
specifies the statistics to include in the output data table and optionally names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign and a variable to contain the statistic.

If you specify *keyword=name*, the new variable that contains the requested statistic has the specified name. If you omit the optional *=name* after a *keyword*, then a default name is used.

You can specify the following values for *keyword* to request statistics that are available with all selection methods:

PREDICTED
PRED
P
requests predicted values for the response variable. The default is Pred.

RESIDUAL
RESID
R
requests the residual, calculated as ACTUAL – PREDICTED. The default is Residual.

ROLE
requests a numeric variable that indicates the role played by each observation in fitting the model. The default is _ROLE_. For each observation, the interpretation of this variable is shown in Table 29.6.

Table 29.6 Role Interpretation

Value	Observation Role
0	Not used
1	Training
2	Validation
3	Testing

If you do not partition the input data by using a PARTITION statement, then the role variable value is 1 for observations used in fitting the model, and 0 for observations that have at least one missing or invalid value for the response, regressor, frequency, or weight variables.

In addition to the preceding statistics, you can also use the *keywords* listed in Table 29.7 in the OUTPUT statement to obtain additional statistics. These statistics are not available if you specify METHOD=LAR or METHOD=LASSO or METHOD=ELASTICNET in the SELECTION statement. For computational formulas, see the section "Diagnostic Statistics" on page 1505. All the statistics available in the OUTPUT statement are conditional on the selected model and do not take into account the variability introduced when you do model selection.

Table 29.7 Keywords for OUTPUT Statement

Keyword	Description
COOKD	Cook's D influence statistic
COVRATIO	Standard influence of observation on covariance of betas
DFFIT	Standard influence of observation on predicted value
H	Leverage, $\mathbf{x}_i(\mathbf{X}'\mathbf{X})^{-}\mathbf{x}_i'$
LCL	Lower bound of a $100(1-\alpha)\%$ confidence interval for an individual prediction. This includes the variance of the error and the variance of the parameter estimates.
LCLM	Lower bound of a $100(1-\alpha)\%$ confidence interval for the expected value (mean) of the dependent variable
LIKEDIST	Likelihood displacement, which measures the change in the error sum of squares when the current observation is deleted
PRESS	ith residual divided by $(1-h)$, where h is the leverage and where the model has been refit without the ith observation
RSTUDENT	A studentized residual with the current observation deleted
STDI	Standard error of the individual predicted value
STDP	Standard error of the mean predicted value
STDR	Standard error of the residual
STUDENT	Studentized residuals, which are the residuals divided by their standard errors
UCL	Upper bound of a $100(1-\alpha)\%$ confidence interval for an individual prediction
UCLM	Upper bound of a $100(1-\alpha)\%$ confidence interval for the expected value (mean) of the dependent variable

This statement is ignored if you perform best-subset selection.

PARTITION Statement

PARTITION *partition-option* **;**

The PARTITION statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. For more information, see the section "Using Validation and Test Data" on page 101 in Chapter 2, "Shared Concepts." Either you can designate a variable in the input data table and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for randomly assigning observations to each role.

You must specify exactly one of the following *partition-options*:

FRACTION(<TEST=*fraction***> <VALIDATE=***fraction***> <SEED=***number***>)**
randomly assigns specified proportions of the observations in the input data table to the roles. You specify the proportions for testing and validation by using the TEST= and VALIDATE= suboptions. If you specify both the TEST= and VALIDATE= suboptions, then the sum of the specified fractions must be less than 1 and the remaining fraction is the proportion of the observations assigned to the training role. The SEED= option specifies an integer that is used to start the pseudorandom number generator for random partitioning of data for training, testing, and validation. If you do not specify SEED=*number* or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

ROLE=*variable* **(<TEST='***value***'> <TRAIN='***value***'> <VALIDATE='***value***'>)**
ROLEVAR=*variable* **(<TEST='***value***'> <TRAIN='***value***'> <VALIDATE='***value***'>)**
names the *variable* in the input data table whose values are used to assign roles to each observation. This *variable* cannot also appear as an analysis variable in other statements or options. The TEST=, TRAIN=, and VALIDATE= suboptions specify the formatted values of this variable that are used to assign observation roles. If you do not specify the TRAIN= suboption, then all observations whose role is not determined by the TEST= or VALIDATE= suboption are assigned to the training role.

SELECTION Statement

SELECTION <**METHOD=***method* <**(***method-options***)**> >< *options* > **;**

The SELECTION statement performs model selection by examining whether effects should be added to or removed from the model according to rules that are defined by model selection methods. The statement is fully documented in the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

The REGSELECT procedure supports the following values of the METHOD= option in the SELECTION statement:

BACKWARD specifies the backward elimination method, which starts with all effects in the model and deletes effects.

BESTSUBSET specifies the best-subset selection method, which uses the branch-and-bound algorithm (Furnival and Wilson 1974) to efficiently search candidate models without examining all possible subsets.

ELASTICNET specifies the elastic net method, which is an extension of LASSO that estimates parameters by using a version of ordinary least squares in which both the sum of the absolute regression coefficients and the sum of the squared regression coefficients are constrained.

FORWARD specifies the forward selection method, which starts with no effects in the model and adds effects.

FORWARDSWAP specifies forward-swap selection, which is an extension of the forward selection method. Before any addition step, PROC REGSELECT makes all pairwise swaps of one effect in the model and one effect out of the current model that improve the selection criterion. When the selection criterion is R-square, this method is the same as the MAXR method in the REG procedure in SAS/STAT software.

LAR specifies the least angle regression method. Like forward selection, this method starts with no effects in the model and adds effects. The parameter estimates at any step are "shrunk" when compared to the corresponding least squares estimates. If the model contains classification variables, then these classification variables are split. For more information about split classification variables, see the section "Classification Variables and the SPLIT Option" on page 1506.

LASSO specifies the LASSO method, which adds and deletes parameters based on a version of ordinary least squares in which the sum of the absolute regression coefficients is constrained. If the model contains classification variables, then these classification variables are split. For more information about split classification variables, see the section "Classification Variables and the SPLIT Option" on page 1506.

MCP specifies the MCP method (Zhang 2010), which uses the minimax concave penalty as the penalty function in penalized least squares estimation.

NONE specifies no model selection.

SCAD specifies the SCAD method (Fan and Li 2001), which uses smoothly clipped absolute deviation as the penalty function in penalized least squares estimation.

STEPWISE specifies the stepwise regression method, which is similar to the forward selection method except that effects already in the model do not necessarily stay there. ??citation??

By default, METHOD=STEPWISE.

The SELECT=, CHOOSE=, and STOP= *method-options* default to the Schwarz Bayesian information criterion (SBC) except in best-subset selection. For the best-subset selection method, the default SELECT= criterion is ADJRSQ. These defaults differ from their corresponding defaults in the HPLOGISTIC procedure in SAS/STAT software.

The DETAILS=ALL and DETAILS=STEPS options produce the "ANOVA," "Fit Statistics," and "Parameter Estimates" tables, which provide information about the model that is selected at each step of the selection process.

If you specify the PLOTS=CRITERIA or PLOTS=ALL option, then a plot of the fit criteria by the selection step is created. The default fit criteria that are shown in this plot are the ADJRSQ, AIC, AICC, ASE, and SBC statistics. If you also specify a PARTITION statement, then the ASE statistics for all roles that are defined in the PARTITION statement are included. If you use the CP or PRESS statistic as the SELECT=, STOP=, or CHOOSE= criterion in the SELECTION statement, then these statistics are also added to the criterion panel.

If you specify the PLOTS=FITBYROLE or PLOTS=ALL option and a PARTITION statement, then a plot of the ASE by the selection step for each role is created.

For best-subset selection, only a plot of the fit criteria is created if you specify the PLOTS=CRITERIA or PLOTS=ALL option. The fit criteria that are shown in the plot are the ADJRSQ, AIC, BIC, CP, RSQUARE, and SBC statistics.

For SCAD and MCP selection, no plot is produced in this release.

STORE Statement

STORE < **OUT=** >*libref.data-table* **;**

The STORE statement saves the context and results of the statistical analysis. The resulting analytic store has a binary file format that cannot be modified. An example of analytic store technology is to perform a time-consuming analysis and to store its results by using the STORE statement. Later you can perform specific statistical analysis tasks based on the saved results of the previous analysis, without having to fit the model again. The contents of the analytic store that PROC REGSELECT produces can be processed by the ASTORE procedure, the **`glmScore`** action in the **`regression`** action set, and the **`score`** action in the **`aStore`** action set.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1479.

This statement is ignored if you perform best-subset selection.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

Details: REGSELECT Procedure

Criteria Used in Model Selection

The REGSELECT procedure supports a variety of fit statistics that you can specify as criteria for the CHOOSE=, SELECT=, and STOP= options in the SELECTION statement, *method-options*. The following statistics are available:

ADJRSQ	Adjusted R-square statistic (Darlington 1968; Judge et al. 1985)
AIC	Akaike's information criterion (Akaike 1969; Judge et al. 1985)
AICC	Corrected Akaike's information criterion (Hurvich and Tsai 1989)
BIC | SBC	Schwarz Bayesian information criterion (Schwarz 1978; Judge et al. 1985)
CP	Mallows' C_p statistic (Mallows 1973; Hocking 1976)
PRESS	Predicted residual sum of squares statistic
RSQUARE	R-square statistic (Darlington 1968; Judge et al. 1985)
SL	Significance used to assess the contribution of an effect to the fit when it is added to or removed from a model
VALIDATE	Average square error over the validation data

NOTE: The RSQUARE statistic is supported only in the SELECT= option.

When you use SL as a criterion for effect selection, the definition depends on whether an effect is being considered as a drop candidate or an add candidate. Assume that the current model has p parameters, excluding the intercept. If you denote its residual sum of squares by RSS_p, add an effect with k degrees of freedom, and denote the residual sum of squares of the resulting model by RSS_{p+k}, then the F statistic for entry with k numerator degrees of freedom and $n-(p+k)-1$ denominator degrees of freedom is given by

$$F = \frac{(\mathrm{RSS}_p - \mathrm{RSS}_{p+k})/k}{\mathrm{RSS}_{p+k}/(n-(p+k)-1)}$$

where n is number of observations used in the analysis. The significance level for adding an effect is the p-value of this F statistic, and the effect is deemed significant if it is smaller than the SLENTRY limit. (For more information about the SLENTRY= option, see the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts.") Among several such add candidates, the effect with the smallest p-value (most significant) is deemed best.

If you drop an effect that has k degrees of freedom and denote the residual sum of squares of the resulting model by RSS_{p-k}, then the F statistic for removal with k numerator degrees of freedom and $n-p-k$ denominator degrees of freedom is given by

$$F = \frac{(\mathrm{RSS}_{p-k} - \mathrm{RSS}_p)/k}{\mathrm{RSS}_p/(n-p-k)}$$

where n is number of observations used in the analysis. The significance level for removal of an effect is the p-value of this F statistic, and the effect is deemed not significant if this p-value is larger than the

SLSTAY limit. (For more information about the SLSTAY= option, see the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts.") Among several such removal candidates, the effect with the largest p-value (least significant) is deemed the best removal candidate.

It is known that the "F-to-enter" and "F-to-delete" statistics do not follow an F distribution (Draper, Guttman, and Kanemasu 1971). Hence the SLENTRY and SLSTAY values cannot reliably be viewed as probabilities. One way to address this difficulty is to replace hypothesis testing as a means of selecting a model with information criteria or out-of-sample prediction criteria. Although Harrell (2001) points out that information criteria were developed for comparing only prespecified models, Burnham and Anderson (2002) note that AIC criteria have routinely been used for several decades to perform model selection in time series analysis.

Table 29.8 provides formulas and definitions for these fit statistics.

Table 29.8 Formulas and Definitions for Model Fit Summary Statistics

Statistic	Definition or Formula
n	Number of observations
p	Number of parameters, including the intercept
$\hat{\sigma}^2$	Estimate of pure error variance from fitting the full model
SST	Total sum of squares corrected for the mean for the dependent variable
SSE	Error sum of squares
ASE	$\frac{\text{SSE}}{n}$
MSE	$\frac{\text{SSE}}{n-p}$
R^2	$1-\frac{\text{SSE}}{\text{SST}}$
ADJRSQ	$1-\frac{(n-1)(1-R^2)}{n-p}$
AIC	$n\log\left(\frac{\text{SSE}}{n}\right)+2p+n+2$
AICC	$n\log\left(\frac{\text{SSE}}{n}\right)+\frac{n(n+p)}{n-p-2}$
CP (C_p)	$\frac{\text{SSE}}{\hat{\sigma}^2}+2p-n$
PRESS	$\sum_{i=1}^{n}\frac{r_i^2}{(1-h_i)^2}$ where r_i = residual at observation i and h_i = leverage of observation $i = \mathbf{x}_i(\mathbf{X}'\mathbf{X})^{-}\mathbf{x}_i'$
RMSE	$\sqrt{\text{MSE}}$
SBC	$n\ln\left(\frac{\text{SSE}}{n}\right)+p\ln(n)$

Diagnostic Statistics

This section gathers the formulas for the statistics available in the OUTPUT statement. All the statistics available in the OUTPUT statement are conditional on the selected model and do not take into account the variability introduced by doing model selection.

The model to be fit is $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$, and the parameter estimate is denoted by $\mathbf{b} = (\mathbf{X}'\mathbf{X})^{-}\mathbf{X}'\mathbf{Y}$. The subscript i denotes values for the ith observation, and the parenthetical subscript (i) means that the statistic is computed by using all observations except the ith observation.

The ALPHA= option in the PROC REGSELECT statement is used to set the α value for the confidence limit statistics.

Table 29.9 contains the diagnostic statistics and their formulas. Each statistic is computed for each observation.

Table 29.9 Formulas and Definitions for Diagnostic Statistics

MODEL Option or Statistic	Formula
PRED ($\widehat{\mathbf{Y}}_i$)	$\mathbf{X}_i\mathbf{b}$
RES (r_i)	$\mathbf{Y}_i - \widehat{\mathbf{Y}}_i$
H (h_i)	$\mathbf{x}_i(\mathbf{X}'\mathbf{X})^{-}\mathbf{x}_i'$
STDP	$\sqrt{h_i\widehat{\sigma}^2}$
STDI	$\sqrt{(1+h_i)\widehat{\sigma}^2}$
STDR	$\sqrt{(1-h_i)\widehat{\sigma}^2}$
LCL	$\widehat{Y}_i - t_{\frac{\alpha}{2}}\text{STDI}$
LCLM	$\widehat{Y}_i - t_{\frac{\alpha}{2}}\text{STDP}$
UCL	$\widehat{Y}_i + t_{\frac{\alpha}{2}}\text{STDI}$
UCLM	$\widehat{Y}_i + t_{\frac{\alpha}{2}}\text{STDP}$
STUDENT	$\dfrac{r_i}{\text{STDR}_i}$
RSTUDENT	$\dfrac{r_i}{\hat{\sigma}_{(i)}\sqrt{1-h_i}}$
COOKD	$\dfrac{1}{p}\text{STUDENT}^2\dfrac{\text{STDP}^2}{\text{STDR}^2}$
COVRATIO	$\dfrac{\det(\hat{\sigma}^2_{(i)}(\mathbf{x}'_{(i)}\mathbf{x}_{(i)})^{-1}}{\det(\hat{\sigma}^2(\mathbf{X}'\mathbf{X})^{-1})}$
DFFITS	$\dfrac{(\widehat{\mathbf{Y}}_i - \widehat{\mathbf{Y}}_{(i)})}{(\hat{\sigma}_{(i)}\sqrt{h_i})}$
PRESS(predr$_i$)	$\dfrac{r_i}{1-h_i}$
LIKEDIST	$(n-p)\log\left(\dfrac{\hat{\sigma}^2_{(i)}}{\text{MSE}}\right) + \dfrac{r_i^2}{(1-h_i)^2\hat{\sigma}^2_{(i)}} - 1$

Classification Variables and the SPLIT Option

(View the complete code for this example (regselectdt.sas) in the example repository.)

PROC REGSELECT supports the ability to split classification variables when you are doing model selection. You use the SPLIT option in the CLASS statement to specify that the columns of the design matrix that correspond to effects that contain a split classification variable can enter or leave a model independently of the other design columns of that effect. The following statements illustrate the use of the SPLIT option:

```
data mylib.splitExample;
   length c2 $6;
   drop i;
   do i=1 to 1000;
     c1 = 1 + mod(i,6);
     if      i < 200 then c2 = 'low';
     else if i < 500 then c2 = 'medium';
     else                 c2 = 'high';
     x1 = ranuni(1);
     x2 = ranuni(1);
     y = x1+3*(c2 ='low')  + 10*(c1=3) +5*(c1=5) + rannor(1);
     output;
   end;
run;

proc regselect data=mylib.splitExample;
   class c1(split) c2(order=freq);
   model y = c1 c2 x1 x2;
   selection method=forward;
run;
```

The "Class Level Information" table shown in Figure 29.11 is produced by default whenever you specify a CLASS statement.

Figure 29.11 Class Levels

The REGSELECT Procedure

Class Level Information		
Class	**Levels**	**Values**
c1	6	1 2 3 4 5 6
c2	3	high medium low

The SPLIT option has been specified for the classification variable c1. This permits the parameters associated with the effect c1 to enter or leave the model individually. The "Parameter Estimates" table in Figure 29.12 shows that for this example the parameters that correspond only to levels 3 and 5 of c1 are in the selected model.

Figure 29.12 Parameter Estimates

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	2.827805	0.094738	29.85	<.0001
c1_3	1	10.161378	0.087606	115.99	<.0001
c1_5	1	5.018482	0.087593	57.29	<.0001
c2 high	1	-3.134740	0.084808	-36.96	<.0001
c2 medium	1	-2.923335	0.092537	-31.59	<.0001
c2 low	0	0	.	.	.
x1	1	1.315202	0.109440	12.02	<.0001

Using Validation and Test Data

When you have sufficient data, you can subdivide your data into three parts called the training, validation, and test data. The selection process fits models to the training data and uses the validation data to find the prediction errors for the models that are obtained in this way. This prediction error on the validation data can be used to decide when to terminate the selection process or to decide what effects to include as the selection process proceeds. Finally, after a selected model has been obtained, the test data can be used to assess how the selected model generalizes on data that played no role in selecting the model.

In some cases you might want to use only training and test data. For example, you might want to use an information criterion to decide what effects to include and when to terminate the selection process. In this case no validation data are required, but test data can still help you assess the predictive performance of the selected model. In other cases you might decide to use validation data during the selection process but forgo assessing the selected model on test data. Hastie, Tibshirani, and Friedman (2001) note that it is difficult to give a general rule for how many observations you should assign to each role. They state that a typical split might be 50% for training and 25% each for validation and testing.

You use a PARTITION statement to logically subdivide the DATA= data table into separate roles. You can name the fractions of the data that you want to reserve as test data and validation data. For example, the following statements randomly subdivide the inData data table, reserving 50% for training and 25% each for validation and testing:

```
proc regselect data=mylib.inData;
  partition fraction(test=0.25 validate=0.25);
  ...
run;
```

In some cases you might need to exercise more control over the partitioning of the input data table. You can do this by naming both a variable in the input data table and a formatted value of that variable that correspond to each role. For example, the following statements assign roles to the observations in the inData data table based on the value of the variable group in that data table. Observations in which the value of group is "group 1" are assigned to testing, and those whose value is "group 2" are assigned to training. All other observations are ignored.

```
proc regselect data=mylib.inData;
  partition roleVar=group(test='group 1' train='group 2')
  ...
run;
```

After you reserve observations for training, validation, and testing, a model fit of the training data is scored on the validation and test data, and the average squared error (ASE) is computed separately for each of these subsets. The ASE for each data role is the error sum of squares for observations in that role divided by the number of observations in that role.

Using the Validation ASE as the STOP= Criterion

If you have provided observations for validation, then you can specify STOP=VALIDATE as a suboption of the METHOD= option in the SELECTION statement. At step k of the selection process, the best candidate effect to enter or leave the current model is determined. Here, "best candidate" means the effect that gives the best value of the SELECT= criterion; this criterion does not need to be based on the validation data. The validation ASE for the model with this candidate effect added or removed is computed. If this validation ASE is greater than the validation ASE for the model at step k, then the selection process terminates at step k.

Using the Validation ASE as the CHOOSE= Criterion

When you specify the CHOOSE=VALIDATE suboption of the METHOD= option in the SELECTION statement, the validation ASE is computed for the models at each step of the selection process. The smallest model at any step that yields the smallest validation ASE is selected.

Computational Method

Multithreading

The REGSELECT procedure allocates data to different threads and calculates crossproduct matrices by accumulating the contributions from all threads. PROC REGSELECT also uses multiple threads to compute matrix inverses and select candidates during model selection. For more information about how PROC REGSELECT uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

Ridge Regression

Ridge regression is a technique for analyzing multiple regression data that suffer from multicollinearity. In ridge regression analysis, the crossproduct matrix for the independent variables is centered (the NOINT option is ignored if it is specified) and scaled to one on the diagonal elements. The ridge constant k (which you specify in the RIDGE= option) is then added to each diagonal element of the crossproduct matrix. The ridge regression estimates are the least squares estimates that are obtained by using the new crossproduct matrix. More specifically, let $\mathbf{X} = (x_1, x_2, \ldots, x_p)$ denote the matrix of covariates, and let $\mathbf{Y}$ denote the response, where the x_i have been centered and scaled to have unit standard deviation and mean 0 and $\mathbf{Y}$ has mean 0. Then for a particular parameter k, the ridge regression coefficients $\boldsymbol{\beta} = (\beta_1, \beta_2, \ldots, \beta_p)$ are obtained by solving

$$\left(\mathbf{X}'\mathbf{X} + k\mathbf{I}\right)\boldsymbol{\beta} = \mathbf{X}'\mathbf{Y}$$

For information about ridge regression and variance inflation factors, see Rawlings, Pantula, and Dickey (1998); Neter, Wasserman, and Kutner (1990); Marquardt and Snee (1975).

Joint Tests and Type 3 Tests

Linear hypotheses for $\boldsymbol{\beta}$ are expressed in matrix form as

$$H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

where $\mathbf{L}$ is a matrix of coefficients for the linear hypotheses and $\mathbf{c}$ is a vector of constants. The vector of regression coefficients $\boldsymbol{\beta}$ includes slope parameters and intercept parameters. The F statistic for testing H_0 is computed as

$$F = (\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})'[\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}']^{-1}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})/r$$

where $\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}}) = \hat{\sigma}^2(X'WX)^{-1}$ is the estimated covariance matrix of $\widehat{\boldsymbol{\beta}}$, with $\hat{\sigma}^2$ being the weighted residual sum of squares divided by the residual degrees of freedom d. Under H_0, F has an asymptotic F distribution with r and d degrees of freedom, where r is the rank of $\mathbf{L}$.

For models that use less-than-full-rank parameterization (as specified by the PARAM=GLM option in the CLASS statement), a Type 3 test of an effect of interest (main effect or interaction) is a test of the Type III estimable functions that are defined for that effect. When the model contains no missing cells, the Type 3 test of a main effect is equivalent to testing the hypothesis of equal marginal means. For more information about Type III estimable functions, see the chapter "The GLM Procedure" and the section "The Four Types of Estimable Functions" in *SAS/STAT User's Guide*. Also see Littell, Freund, and Spector (1991).

For models that use full-rank parameterization, all parameters are estimable when there are no missing cells, so it is unnecessary to define estimable functions. The standard test of an effect of interest in this case is the joint test that the values of the parameters associated with that effect are 0. For a model that uses effects parameterization (as specified by the PARAM=EFFECT option in the CLASS statement), the joint test for a main effect is equivalent to testing the equality of marginal means. For a model that uses reference parameterization (as specified by the PARAM=REF option in the CLASS statement), the joint test is equivalent to testing the equality of cell means at the reference level of the other model effects. For more information about the coding scheme and the associated interpretation of results, see Muller and Fetterman (2002, Chapter 14).

If there is no interaction term, the Type 3 test of an effect for a model that uses GLM parameterization is the same as the joint test of the effect for the model that uses full-rank parameterization. In this situation, the joint test is also called the Type 3 test. For a model that contains an interaction term and no missing cells, the Type 3 test of a component main effect under GLM parameterization is the same as the joint test of the component main effect under effect parameterization. Both test the equality of cell means. But this Type 3 test differs from the joint test under reference parameterization, which tests the equality of cell means at the reference level of the other component main effect. If some cells are missing, you can obtain meaningful tests only by testing a Type III estimation function, so in this case you should use GLM parameterization.

The results of a Type 3 test or a joint test do not depend on the order in which you specify the terms in the MODEL statement.

Displayed Output

The following sections describe the output produced by PROC REGSELECT. The output is organized into various tables, which are discussed in their order of appearance.

Selection Information

When you specify the SELECTION statement, the REGSELECT procedure produces by default a series of tables that display information about the model selection. The "Selection Information" table informs you about the model selection method; select, stop, and choose criteria; and other parameters that govern the selection. You can suppress this table by specifying DETAILS=NONE in the SELECTION statement.

Number of Observations

The "Number of Observations" table displays the number of observations read from the input data table and the number of observations used in the analysis. If you specify a FREQ statement, this table also displays the sum of frequencies read and used. If you use a PARTITION statement, the table also displays the number of observations used for each data role.

Class Level Information

The "Class Level Information" table lists the levels of every variable that you specify in the CLASS statement. You should check this information to make sure that the data are correct. You can adjust the order of the CLASS variable levels by specifying the ORDER= option in the CLASS statement. You can suppress the "Class Level Information" table completely or partially by specifying the NOCLPRINT= option in the PROC REGSELECT statement.

If the classification variables use a nonsingular parameterization, the "Class Level Information" table also displays the reference value for each variable.

Dimensions

The "Dimensions" table displays the number of effects and the number of parameters from which the selected model is chosen. If you use split classification variables, then this table also displays the number of effects after splitting is taken into account.

Entry and Removal Candidates

When you specify the DETAILS=ALL or DETAILS=STEPS option in the SELECTION statement, the REGSELECT procedure produces "Entry Candidates" and "Removal Candidates" tables that display the effect names and values of the criterion used to select entering or departing effects at each step of the selection process. The effects are displayed in sorted order from best to worst of the selection criterion.

Elastic Net Summary

When you specify METHOD=ELASTICNET without specifying an L2 value in the SELECTION statement, the REGSELECT procedure produces the "Elastic Net Summary" table, which displays the ridge regularization parameter L2 (in the ratio scaling) and CHOOSE criterion values in each L2 search step.

Relaxed LASSO Summary

When you specify METHOD=LASSO(RELAXED), the REGSELECT procedure produces the "Relaxed LASSO Summary" table, which displays the mixing parameter kappa and CHOOSE criterion values in each kappa search step.

Selection Summary

When you specify the SELECTION statement, the REGSELECT procedure produces the "Selection Summary" table, which displays information about the sequence of steps of the selection process. For each step, the effect that was entered or dropped is displayed along with the statistics used to select the effect, stop the selection, and choose the selected model. For all criteria that you can use for model selection, the steps at which the optimal values of these criteria occur are also indicated.

When you specify the METHOD=SCAD or METHOD=MCP option in the SELECTION statement, the "Selection Summary" table produces the information from each selection step. This information includes current regularization parameters, number of effects, CHOOSE criterion value, value of the objective function, and optimization convergence status.

You can suppress the display of the "Selection Summary" table by specifying DETAILS=NONE in the SELECTION statement.

Subset Selection Summary

When you specify the METHOD=BESTSUBSET option in the SELECTION statement, the REGSELECT procedure produces the "Subset Selection Summary" table, which displays information about the selected subset models that are found by the best-subset selection method. For each model, the model comparison criteria and selected parameters are displayed. You can request other model statistics and parameter estimates for each model by specifying appropriate suboptions in the METHOD=BESTSUBSET option.

Stop Reason

The "Stop Reason" table displays the reason why the selection stopped. To facilitate programmatic use of this table, an integer code is assigned to each reason and is included if you use an ODS OUTPUT statement or a DISPLAYOUT statement to output this table. The reasons and their associated codes follow:

Code	Stop Reason
1	All eligible effects are in the model.
2	All eligible effects have been removed.
3	Specified maximum number of steps done.
4	The model contains the specified maximum number of effects.
5	The model contains the specified minimum number of effects (for backward selection).
6	The stopping criterion is at a local optimum.
7	No suitable add or drop candidate could be found.
8	Adding or dropping any effect does not improve the selection criterion.
9	No candidate meets the appropriate SLE or SLS significance level.
10	Stepwise selection is cycling.
11	The model is an exact fit.
12	Dropping an effect would result in an empty model.

You can suppress the display of the "Stop Reason" table by specifying DETAILS=NONE in the SELECTION statement.

Selection Reason

When you specify the SELECTION statement, the REGSELECT procedure produces a simple table that explains why the final model was selected.

You can suppress the display of the "Selection Reason" table by specifying DETAILS=NONE in the SELECTION statement.

Selected Effects

When you specify the SELECTION statement, the REGSELECT procedure produces a simple table that lists which effects were selected for the final model.

ANOVA

The "ANOVA" table displays an analysis of variance for the selected model. This table includes the following:

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean. The Uncorrected Total Variation is produced when you specify the NOINT option.
- the degrees of freedom (DF) associated with the source
- the Sum of Squares for the term
- the Mean Square, which is the sum of squares divided by the degrees of freedom
- the *F* Value for testing the hypothesis that all parameters are 0 except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.
- the Prob>*F*, which is the probability of getting a greater *F* statistic than that observed if the hypothesis is true. When you do model selection, these *p*-values are usually liberal because they are not adjusted for the fact that the terms in the model have been selected.

You can request an "ANOVA" table for the model at each step of the selection process by specifying the DETAILS= option in the SELECTION statement.

Fit Statistics

The "Fit Statistics" table displays fit statistics for the selected model. The statistics include the following:

- Root MSE, an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- R-square, a measure between 0 and 1 that indicates the portion of the (corrected) total variation attributed to the fit rather than left to residual error. It is calculated as SS(Model) divided by SS(Total) and is also called the *coefficient of determination*. It is the square of the multiple correlation—in other words, the square of the correlation between the dependent variable and the predicted values.
- Adj R-Sq, the adjusted R-square, which is a version of R-square that has been adjusted for degrees of freedom. It is calculated as

$$\bar{R}^2 = 1 - \frac{(n-i)(1-R^2)}{n-p}$$

  where i is equal to 1 if there is an intercept and 0 otherwise, n is the number of observations used to fit the model, and p is the number of parameters in the model.
- the fit criteria AIC, AICC, BIC, CP, and PRESS if they are used in the selection process. See Table 29.8 for the formulas to evaluate these criteria.
- the average square errors (ASE) on the training, validation, and test data

You can request a "Fit Statistics" table for the model at each step of the selection process by specifying the DETAILS= option in the SELECTION statement.

Parameter Estimates

The "Parameter Estimates" table displays the parameters in the selected model and their estimates. The information displayed for each parameter in the selected model includes the following:

- the parameter label that includes the effect name and level information for effects that contain classification variables
- the degrees of freedom (DF) for the parameter. There is one degree of freedom unless the model is not full rank.
- the parameter estimate
- the standard error, which is the estimate of the standard deviation of the parameter estimate
- t Value, the t test that the parameter is 0. This is computed as the parameter estimate divided by the standard error.

- the Pr > |t|, the probability that a t statistic would obtain a greater absolute value than that observed given that the true parameter is 0. This is the two-tailed significance probability.

  When you do model selection, these p-values are usually liberal because they are not adjusted for the fact that the terms in the model have been selected.

You can request a "Parameter Estimates" table for the model at each step of the selection process by specifying the DETAILS= option in the SELECTION statement.

Model Analysis of Variance (Type III)

When you specify the SS3 option in the MODEL statement, the REGSELECT procedure produces the "Model Analysis of Variance (Type III)" table. This table displays tests that all parameters for a particular effect are equal to zero. These tests are computed by using a Type III sum of squares, which yields a balanced test of each effect, adjusted for every other effect. For more information, see the section "Joint Tests and Type 3 Tests" on page 1509.

Model Crossproducts $X'XX'YY'Y$

When you specify the XPX option in the MODEL statement, the REGSELECT procedure produces the "Model Crossproducts $X'XX'YY'Y$" table. This table displays the $X'X$ crossproducts matrix for the model. The crossproducts matrix is bordered by the $X'Y$ and $Y'Y$ matrices. In addition, if you specify a selection method by using the SELECTION statement and obtain a model that contains a subset of effects, the table displays the $X'X$ crossproducts matrix for the selected model effects.

Ridge Regression Parameter Estimates

When you specify the RIDGE= option in the MODEL statement, the REGSELECT procedure produces the "Ridge Regression Parameter Estimates" table. This table displays the parameters and their estimates from ridge regression. The information that is displayed for each parameter includes the following:

- values of the ridge constant k
- the parameter label, which includes the effect name and level information for effects that contain classification variables
- the parameter estimates
- values of variance inflation factors and tolerance along with the parameter estimates when you specify the VIF and TOL options in the MODEL statement.

Ridge Regression Fit Statistics

When you specify the RIDGE= option in the MODEL statement, the REGSELECT procedure produces the "Ridge Regression Fit Statistics" table. This table displays fit statistics for the ridge regression models. The statistics include root MSE, R-square, Adj R-Sq, AIC, AICC, SBC, and ASE.

Timing

The "Timing" table displays the amount of time (in seconds) and the percentage of the time that PROC REGSELECT required to perform different tasks in the analysis.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the REGSELECT procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or ODS statements. These names are listed in Table 29.10.

NOTE: The EFFECT statement also create tables which are not listed in this section. For information about these tables, see "ODS Table Names" on page 33 in Chapter 2, "Shared Concepts."

Table 29.10 ODS Tables Produced by PROC REGSELECT

Table Name	Description	Required Statement / Option
ANOVA	Selected model ANOVA table	Default output
BSplineDetails	B-spline basis details	EFFECT SPLINE BASIS=BSPLINE and DETAILS
Candidates	Swap candidates at step	SELECTION DETAILS=ALL | STEPS
ClassInfo	Level information from the CLASS statement	CLASS

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

When ODS Graphics is enabled, the SELECTION statement can produce plots to help evaluate the selection process. For information about these plots, see the section "SELECTION Statement" on page 42 in Chapter 2, "Shared Concepts."

PROC REGSELECT assigns a name to each graph that it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 29.11.

Table 29.11 Graphs Produced by PROC REGSELECT

ODS Graph Name	Plot Description	PLOTS= Option

Examples: REGSELECT Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 29.1: Stepwise Selection with Validation

(View the complete code for this example (regselectex1.sas) in the example repository.)

This example is based on the example "Using Validation and Cross Validation" in the documentation for the GLMSELECT procedure in SAS/STAT software. The current example shows how you can use validation data to monitor and control variable selection. It also demonstrates the use of split classification variables.

The following DATA step produces analysis data that contain a variable that you can use to assign observations to the training, validation, and testing roles. In this case, each role has 5,000 observations.

```
%let nTotalObs=15000;
%let seed=1;
   data mylib.analysisData;
    drop i j c3Num nObsPerThread nExtras rew;
    length c3$ 7;

    array x{20} x1-x20;
    call streamInit(&seed);
    nObsPerThread  = int(&nTotalObs/_nthreads_);
    nExtras        = mod(&nTotalObs,_nthreads_);
    if _threadid_ <= nExtras then nObsPerThread =  nObsPerThread + 1;
```

```
   do i=1 to nObsPerThread;
      id = (_threadid_-1)*nObsPerThread +i;
      if _threadid_ > nExtras then id=id+nExtras;
      rew = rand('rewind', id);

      do j=1 to 20;
         x{j} = rand('UNIFORM');
      end;

      if  rand('UNIFORM') < 0.4 then byVar='A';
      else                           byVar='B';

      c1 = 1 + mod(id,8);
      c2 = rand('BERNOULLI',0.6);

      if      id < (0.001 * &nTotalObs) then do; c3 = 'tiny';     c3Num=1;end;
      else if id < (0.3   * &nTotalObs) then do; c3 = 'small';    c3Num=1;end;
      else if id < (0.7   * &nTotalObs) then do; c3 = 'average';  c3Num=2;end;
      else if id < (0.9   * &nTotalObs) then do; c3 = 'big';      c3Num=3;end;
      else                                   do; c3 = 'huge';     c3Num=5;end;

      yTrue = 10 + x1 + 2*x5 + 3*x10 + 4*x20  + 3*x1*x7 + 8*x6*x7
                 + 5*c3Num   + 8*(c1=7) + 8*(c1=3)*c2;
      error = 5*rand('NORMAL');
      y = yTrue + error;

           if mod(id,3)=1 then Role = 'TRAIN';
      else if mod(id,3)=2 then Role = 'VAL';
      else                     Role = 'TEST';

      output;
    end;
   run;
```

By construction, the true model consists of the main effects x1, x5, x10, x20, and c1 and the interaction effects x1*x7, x6*x7, and c1*c3. Furthermore, you can see that only levels 3 and 7 of the classification variable c1 are systematically related to the response.

Because the error term for each observation is five times a value drawn from a standard normal distribution, the expected error variance is 25. For the data in each role, you can compute an estimate of this error variance by forming the average square error (ASE) for the observations in the role. Output 29.1.1 shows the ASE for each role that you can compute with the following statements:

```
proc summary data=mylib.analysisData;
   class role;
   ways 1;
   var error;
   output out=ASE uss=uss n=n;
data ASE; set ASE;
   OracleASE = uss / n;
   label OracleASE = 'Oracle ASE';
   keep Role OracleASE;
proc print data=ASE label noobs;
run;
```

```
proc print data=ASE label noobs;
run;
```

Output 29.1.1 Oracle ASE Values by Role

Role	Oracle ASE
TEST	26.0510
TRAIN	25.0375
VAL	24.9843

The ASE values shown Output 29.1.1 are labeled as "Oracle ASE" because you need to know the true underlying model if you want to compute these values from the response and underlying regressors.

In a modeling context, a good predictive model produces values that are close to these oracle values. An overfit model produces a smaller ASE for the training data but higher values for the validation and test data. An underfit model exhibits higher values for all data roles.

Suppose you suspect that the dependent variable depends on both main effects and two-way interactions. You can use the following statements to select a model:

```
ods graphics on;
proc regselect data=mylib.analysisData;
   partition roleVar=role(train='TRAIN' validate='VAL' test='TEST');
   class c1 c2 c3;
   model y =  c1|c2|c3|x1|x2|x3|x4|x5|x5|x6|x7|x8|x9|x10
              |x11|x12|x13|x14|x15|x16|x17|x18|x19|x20 @2 /stb;
   selection method = stepwise(select=sl sle=0.1 sls=0.15 choose=validate)
                      hierarchy=single details=steps plots(startstep=5)=all;
run;
```

A PARTITION statement assigns observations to training, validation, and testing roles based on the values of the input variable named role. The SELECTION statement requests stepwise selection based on significance level (SL), where the SLE and SLS values are set to use the defaults of PROC REGSELECT. The CHOOSE=VALIDATE option selects the model that yields the smallest ASE value for the validation data.

The "Number of Observations" table in Output 29.1.2 confirms that there are 5,000 observations for each data role. The "Dimensions" table shows that the selection is from 278 effects with a total of 593 parameters.

Output 29.1.2 Number of Observations, Class Levels, and Dimensions

The REGSELECT Procedure

Number of Observations Read	15000
Number of Observations Used	15000
Number of Observations Used for Training	5000
Number of Observations Used for Validation	5000
Number of Observations Used for Testing	5000

Output 29.1.2 *continued*

Class Level Information		
Class	**Levels**	**Values**
c1	8	1 2 3 4 5 6 7 8
c2	2	0 1
c3	5	average big huge small tiny

Dimensions	
Number of Effects	278
Number of Parameters	593

Output 29.1.3 shows the "Selection Summary" table. You see that 17 steps are done, at which point all effects in the model are significant at the SLS value of 0.15 and all the remaining effects if added individually would not be significant at the SLE significance level of 0.1. However, because you specified the CHOOSE=VALIDATE option, the model at step 17 is not used as the selected model. Instead the model at step 11 (where the validation ASE achieves a local minimum value) is selected. The "Stop Reason," "Selection Reason," and "Selected Effects" in Output 29.1.4 tables provide this information.

Output 29.1.3 Selection Summary

The REGSELECT Procedure

Selection Details

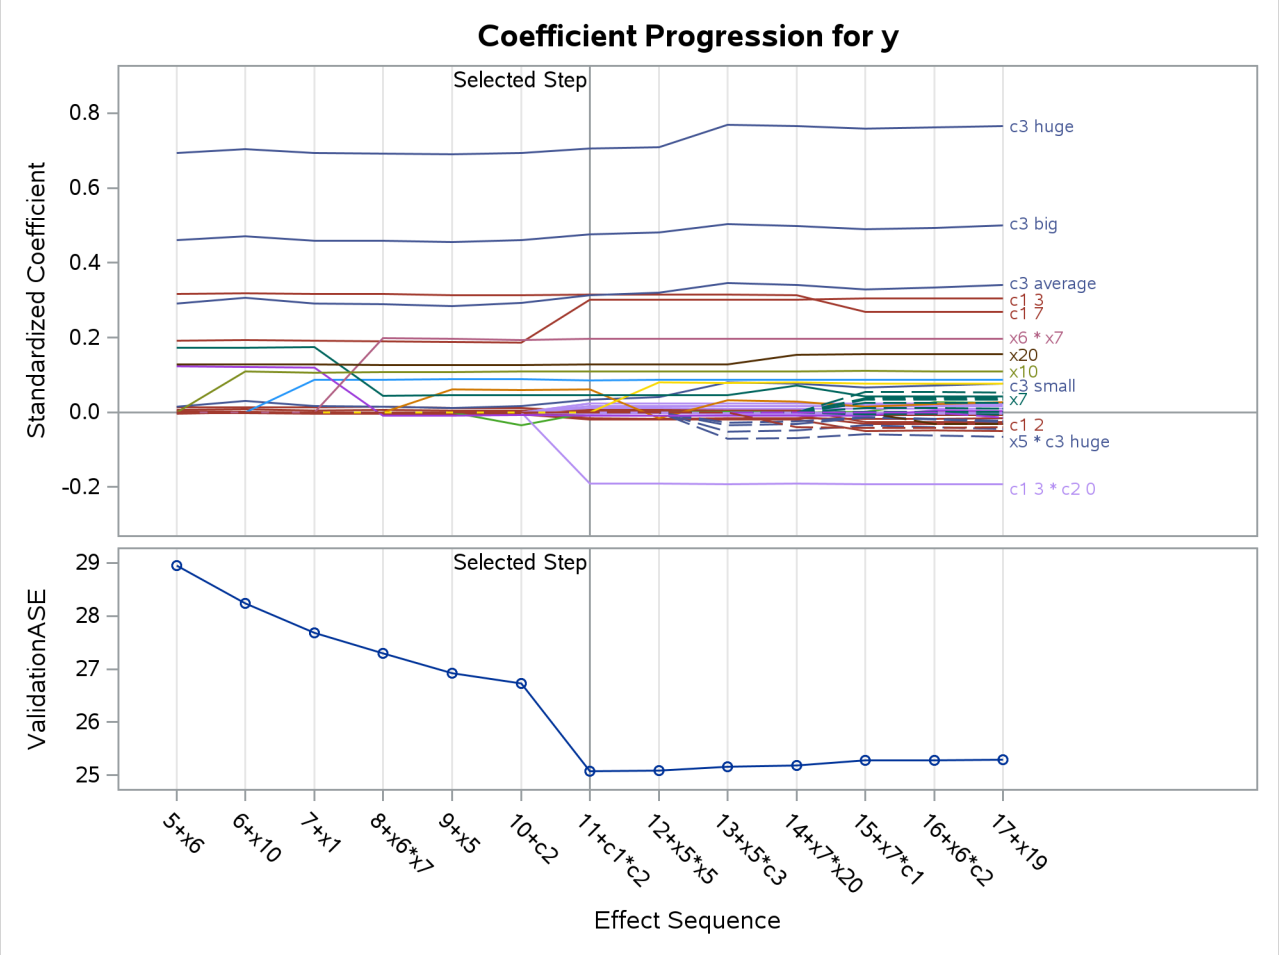
17	**x19**	18	25.2945	0.0748
* Optimal Value Of Criterion				

Output 29.1.4 Stopping and Selection Reasons

Selection stopped because all candidates for removal are significant at the 0.15 level and no candidate for entry is significant at the 0.1 level.

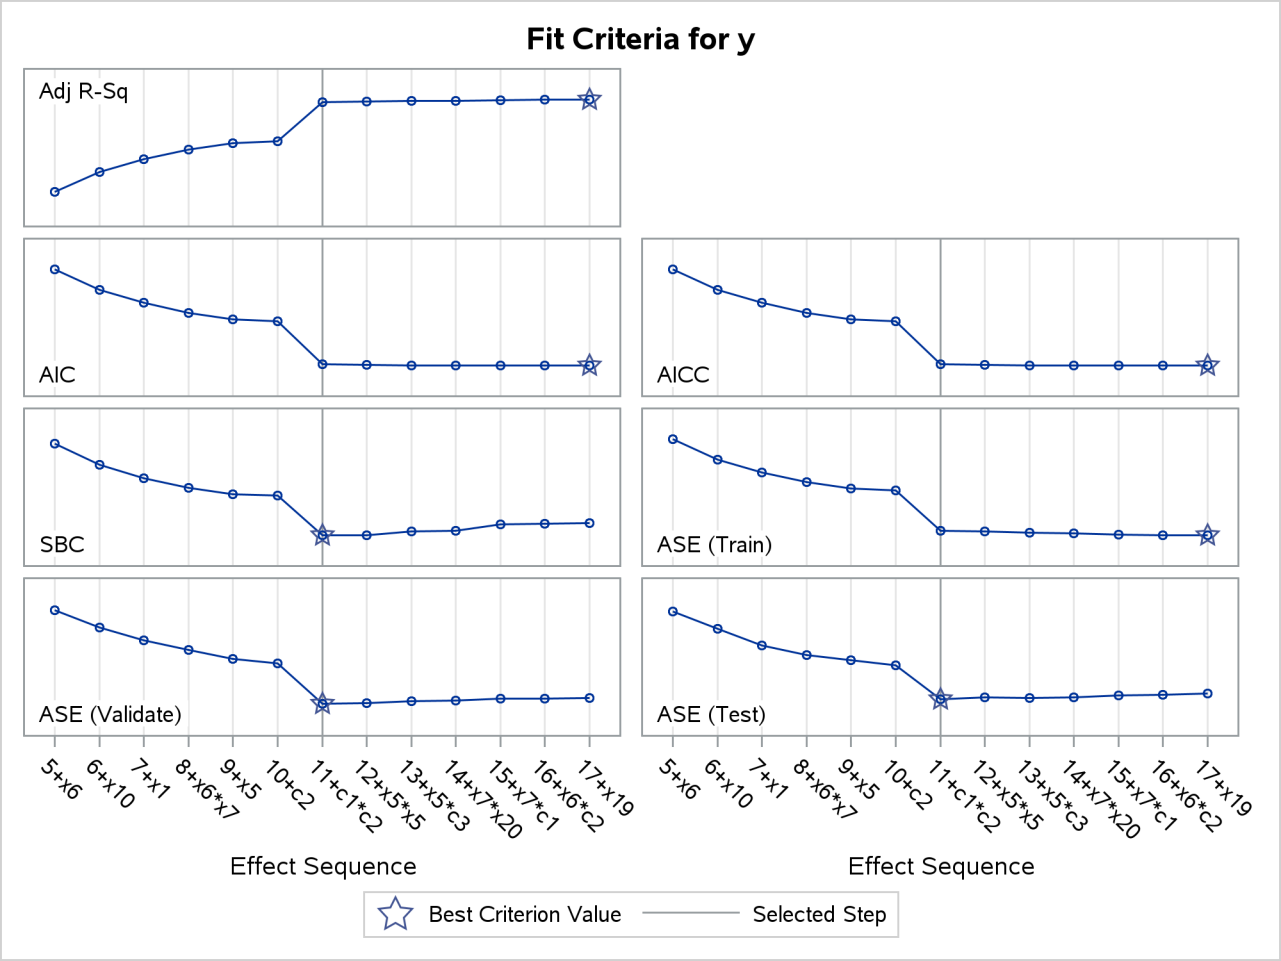
The model at step 11 is selected where Validation ASE is 25.07093.



Selected Effects: Intercept c1 c2 c1*c2 c3 x1 x5 x6 x7 x6*x7 x10 x20

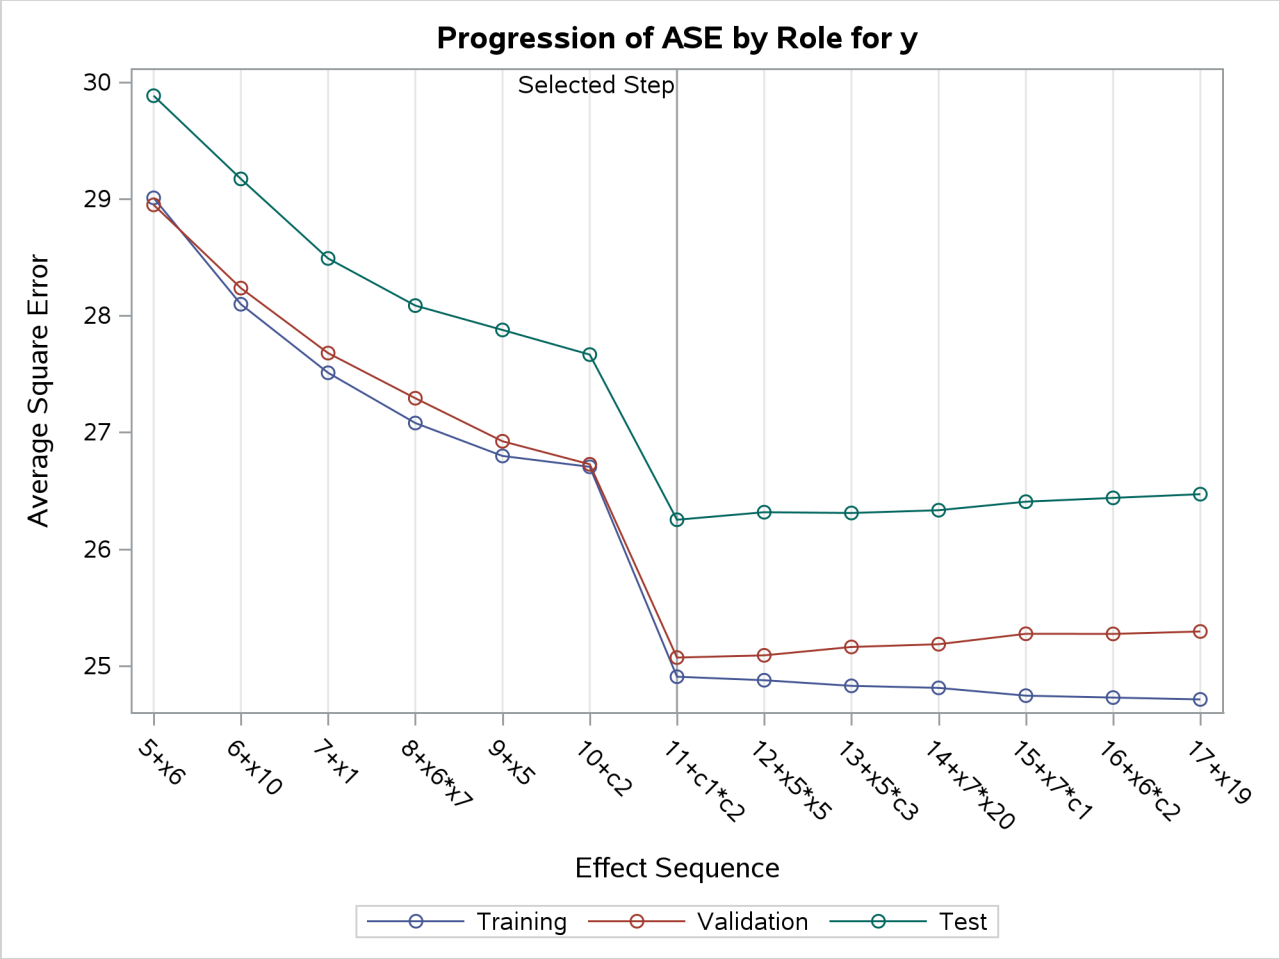
You can see that the selected effects include all the main effects in the true model and two of the three true interaction terms. Furthermore, the selected model does not include any variables that are not in the true model. Note that these statements are not true of the larger model at the final step of the selection process.

When you enable ODS Graphics, the PLOTS=ALL option in the SELECTION statement produces plots that illuminate the selection process. The STARTSTEP=5 suboption in the PLOTS= option requests that only steps 5 and beyond be displayed in the plots. This enables you to more easily assess how the fit criteria change near the selected step.



The upper plot in the coefficient panel in Output 29.1.5 shows how the standardized parameter estimates change with the selection step after step 5. The lower plot in the panel shows how the average square error on the validation data, which you specified as the CHOOSE= criterion, changes with the selection step.

Output 29.1.5 Coefficient Panel



The criterion panel in Output 29.1.6 shows how the various fit criteria change as the stepwise selection method proceeds. This plot shows that if you had used the SBC statistic as the CHOOSE= criterion, then the selected model would still be the model at step 11 However, the AIC or AICC statistic continues to decline for all steps of the selection process. If you had used either of these criteria as the CHOOSE= criterion, then the final model at step 17 would have been selected.

Output 29.1.6 Criterion Panel

Output 29.1.7 shows how the average square error compares for the training, test, and validation data. You see that the average square error on both the test and validation data starts to increase beyond the selected step. This indicates that the selected model does not overfit the training data.

Output 29.1.7 Average Square Error Plot

Output 29.1.8 shows the fit statistics of the selected model. You can see that the ASE values for the training, validation, and test data are all similar, indicating a reasonable predictive model. In this case, where the true model is known, you can see that all three ASE values are close to the oracle values for the true model, as shown in Output 29.1.1.

Output 29.1.8 Fit Statistics for the Selected Model

Root MSE	5.00421
R-Square	0.67654
Adj R-Sq	0.67485
AIC	21132
AICC	21132
SBC	16306
ASE (Train)	24.90688
ASE (Validate)	25.07093
ASE (Test)	26.25177

Because you specified the DETAILS=STEPS option in the SELECTION statement, you can see the fit statistics for the model at each step of the selection process. Output 29.1.9 shows these fit statistics for the

final model at step 17. You see that for this model, the ASE value for the training data is smaller than the ASE values for the validation and test data. This indicates an overfit model that might not generalize well to new data. You see that the ASE values for the validation and test data are now worse in comparison to the oracle values than the values for the selected model at step 11.

Output 29.1.9 Fit Statistics for the Model at Step 17

Root MSE	4.99218
R-Square	0.67907
Adj R-Sq	0.67641
AIC	21123
AICC	21123
SBC	16394
ASE (Train)	24.71247
ASE (Validate)	25.29450
ASE (Test)	26.47078

Output 29.1.10 shows part of the "Parameter Estimates" table for the selected model at step 11 that includes the estimates for the main effect c1. Because you specified the STB option in the MODEL statement, this table includes standardized estimates.

Output 29.1.10 Part of the Parameter Estimates Table for the Selected Model

Parameter Estimates

Parameter	DF	Estimate	Standardized Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	13.672688	0	2.283909	5.99	<.0001
c1 1	1	-0.427892	-0.016127	0.369633	-1.16	0.2471
c1 2	1	-0.511935	-0.019294	0.365942	-1.40	0.1619
c1 3	1	7.970490	0.300395	0.363361	21.94	<.0001
c1 4	1	-0.248256	-0.009356	0.367053	-0.68	0.4989
c1 5	1	0.051535	0.001942	0.366794	0.14	0.8883
c1 6	1	0.170392	0.006422	0.363975	0.47	0.6397
c1 7	1	8.342768	0.314426	0.366337	22.77	<.0001
c1 8	0	0	0	.	.	.

The magnitudes of the standardized estimates and the *t* statistics of the parameters of the effect c1 reveal that only levels 3 and 7 of this effect contribute appreciably to the model. This suggests that you might obtain a more parsimonious model with similar or better predictive power if parameters that correspond to the levels of c1 can enter or leave the model independently. You request this by specifying the SPLIT option in the CLASS statement, as shown in the following statements:

```
proc regselect data=mylib.analysisData;
   partition roleVar=role(train='TRAIN' validate='VAL' test='TEST');
   class c1(split) c2 c3;
   model y = c1|c2|c3|x1|x2|x3|x4|x5|x5|x6|x7|x8|x9|x10
             |x11|x12|x13|x14|x15|x16|x17|x18|x19|x20 @2 /stb;
   selection method = stepwise(select=sl sle=0.1 sls=0.15 choose=validate)
             hierarchy=single details=steps;
run;
```

Output 29.1.11 shows the "Dimensions" table. You can see that because the columns in the design matrix that correspond to the levels of c1 are treated as separate effects, the selection is now from 439 effects, even though the number of parameters is unchanged.

Output 29.1.11 Dimensions with c1 Split

The REGSELECT Procedure

Dimensions	
Number of Effects	439
Number of Parameters	593

Output 29.1.12 shows the selected effects. You can see that, as anticipated, the selected model now depends on only levels 3 and 7 of c1.

Output 29.1.12 Selected Effects with c1 Split

Selected Effects:	Intercept c1_3 c1_7 c2 c1_3*c2 c3 x1 x5 x6 x7 x6*x7 x10 x20

Finally, the fit statistics for the selected model are shown in Output 29.1.13.

Output 29.1.13 Fit Statistics for the Selected Model with c1 Split

Root MSE	5.00424
R-Square	0.67582
Adj R-Sq	0.67485
AIC	21121
AICC	21121
SBC	16223
ASE (Train)	24.96224
ASE (Validate)	25.06729
ASE (Test)	26.21366

If you compare the ASE values for this model in Output 29.1.13 with the oracle values in Output 29.1.1 and the values for the model without splitting c1 in Output 29.1.8, you see that this more parsimonious model produces the best predictive performance for the test data of all the models considered in this example.

Example 29.2: LASSO and Elastic Net Selection

(View the complete code for this example (regselectEx2.sas) in the example repository.)

This example continues the investigation of the baseball data set that were introduced in the section "Getting Started: REGSELECT Procedure" on page 1480. That example uses the default stepwise selection method, which is based on the SBC criterion to select a model. This example explores model selection by using LASSO and elastic net selection methods with validation.

You can load the Sashelp.Baseball data set into your CAS session by specifying your CAS engine libref in the first statement in the following DATA step:

```
data mylib.baseball;
   set sashelp.baseball;
run;
```

The following statements perform LASSO selection with validation for the baseball data:

```
ods graphics on;
proc regselect data=mylib.baseball;
   partition roleVar = league(train='National' validate = 'American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = lasso(choose=validate) plots=all;
run;
```

The PARTITION statement assigns observations to training and validation roles on the basis of the values of the input variable league. The CHOOSE=VALIDATE option in the SELECTION statement selects the model that yields the smallest average square error (ASE) value for the validation data.

Output 29.2.1 shows that 124 observations are used for model training, 139 observations are used for model validation, and the number of effects is 19.

Output 29.2.1 Basic Information about LASSO Selection for baseball Data

The REGSELECT Procedure

Selection Information	
Selection Method	LASSO
Choose Criterion	Validation ASE
Stop Criterion	SBC
Effect Hierarchy Enforced	None
Stop Horizon	3

Number of Observations Read	322
Number of Observations Used	263
Number of Observations Used for Training	124
Number of Observations Used for Validation	139
Number of Observations Used for Testing	0

Output 29.2.1 *continued*

Dimensions	
Number of Effects	19
Number of Parameters	19

The "Selection Summary" table in Output 29.2.2 shows the effect that was added or dropped at each step of the selection process together with the SBC and validation ASE for the model at each step. You see that the local minimum of SBC occurs at step 11 and that three more steps are completed before the procedure stops (because STOPHORIZON=3). The model that has lowest SBC is not used as the selected model because CHOOSE=VALIDATE. Instead, the model at step 14 (where the validation ASE achieves a local minimum value) is selected. Details of this selected model are shown in Output 29.2.3.

Output 29.2.2 Selection Summary of LASSO Selection for baseball Data

The REGSELECT Procedure

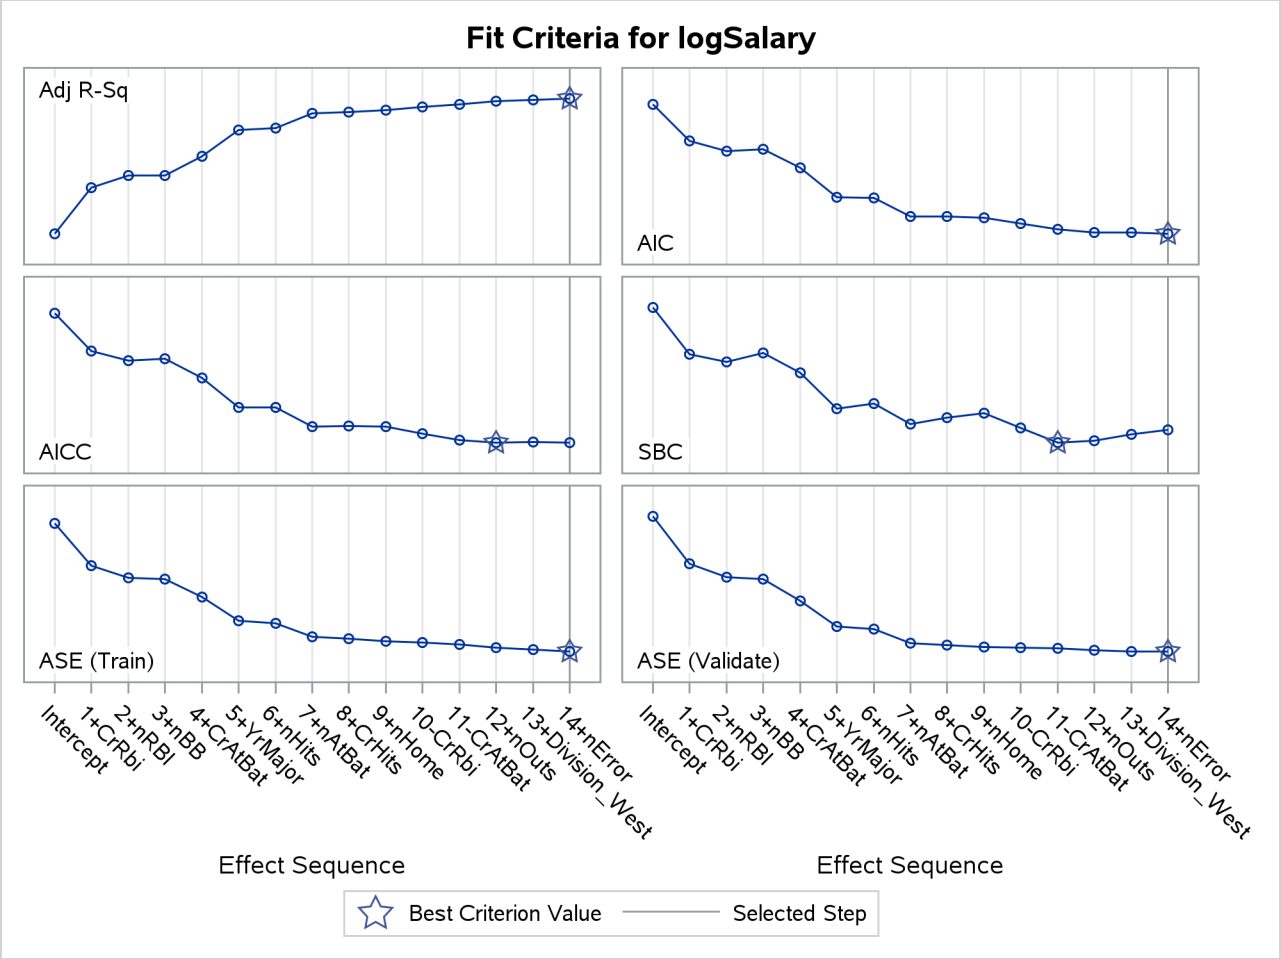
The coefficient panel in Output 29.2.4 enables you to visualize the selection process. In this plot, standardized coefficients of all the effects that are selected at some step of the LASSO method are plotted as a function of the step number. The panel's lower plot shows how the criterion that is used to choose the selected model changes as effects enter or leave the model.



Output 29.2.4 LASSO Coefficient Progression

The criterion panel in Output 29.2.5 shows how the various fit criteria change as the LASSO selection method proceeds. This plot shows that if you had used the SBC statistic as the CHOOSE= criterion, then the selected model would be the model at step 11. However, the AIC and validation ASE continue to decline for all steps of the selection process.

The "Parameter Estimates" table in Output 29.2.3 shows that the coefficients of the parameters are in different scales. In this case, you can use the adaptive LASSO, in which adaptive weights are used for penalizing different coefficients in the L1 penalty. For more information about this selection method, see the section "Adaptive LASSO Selection" on page 82 in Chapter 2, "Shared Concepts."

Output 29.2.5 Criterion Panel

The following statements perform adaptive LASSO selection with validation for the baseball data:

```
proc regselect data=mylib.baseball;
   partition roleVar = league(train='National' validate = 'American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = lasso(adaptive choose=validate);
run;
```

The results of adaptive LASSO selection are shown in Output 29.2.6. You can see that the model that is chosen by adaptive LASSO selection has fewer parameters and a lower validation ASE than the model chosen by LASSO selection.

Output 29.2.6 Details of Model Selected by Adaptive LASSO for baseball Data

The REGSELECT Procedure

Selected Model

Analysis of Variance

As shown in the previous example, adaptive LASSO selection can improve model fit by adaptively penalizing regression parameters. Relaxed LASSO can also achieve this goal by mixing least squares estimates with LASSO estimates. A noteworthy feature of relaxed LASSO is that you can use the least square estimates for model evaluation after variables are chosen by LASSO selection. You can use the LSCOEFFS suboption to perform the analysis. The following statements perform relaxed LASSO selection with ordinary least squares (OLS) coefficients for the baseball data:

```
proc regselect data=mylib.baseball;
   partition roleVar = league(train='National' validate = 'American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = lasso(lscoeffs choose=validate);
run;
```

The results of LASSO selection with OLS coefficients are shown in Output 29.2.7. You can see that the selected model has fewer parameters and a lower validation ASE than the model chosen by original LASSO selection.

Output 29.2.7 Details of Model Selected by LASSO with OLS Coefficients for baseball Data

The REGSELECT Procedure

Selected Model

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	6	52.57372	8.76229	23.57	<.0001
Error	117	43.49438	0.37175		
Corrected Total	123	96.06810			

Root MSE	0.60971
R-Square	0.54725
Adj R-Sq	0.52404
AIC	10.09142
AICC	11.34360
SBC	-96.16661
ASE (Train)	0.35076
ASE (Validate)	0.34000

Parameter Estimates

Parameter	DF	Estimate
Intercept	1	4.130463
nHits	1	0.003124
nRBI	1	0.007459
nBB	1	0.009771
YrMajor	1	0.095590
CrAtBat	1	0.000025438
CrRbi	1	-0.000177

Instead of directly using the least squares estimates to evaluate candidate models, you can use a weighted combination of LASSO estimates and least squares estimates for this purpose. The following statements use this combination to perform relaxed LASSO selection with validation for the baseball data:

```
proc regselect data=mylib.baseball;
   partition roleVar = league(train='National' validate = 'American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = lasso(relaxed choose=validate);
run;
```

The results are shown in Output 29.2.8. You can see that the model that is chosen by relaxed LASSO selection has fewer parameters and a lower validation ASE than the model chosen by LASSO selection.

The "Relaxed LASSO Selection Summary" table in Output 29.2.9 shows that the selected kappa value is 0.1. It also shows that the minimal validation ASE shown in Output 29.2.8 is lower than both the one in original LASSO selection and the one in LASSO selection with the LSCOEFFS suboption. Note that relaxed LASSO selection uses the mixing parameter kappa to control the balance between LASSO solution and

OLS solution. By comparing Output 29.2.3 with Output 29.2.9, you can see that the validation ASE from relaxed LASSO selection with a kappa value of 1 is the same as the validation ASE from original LASSO selection. By comparing Output 29.2.7 with Output 29.2.9, you can see that the validation ASE from relaxed LASSO selection with a kappa value of 0 is the same as the validation ASE from LASSO selection with OLS coefficients. For more information about this selection method, see the section "Relaxed LASSO Selection" on page 83 in Chapter 2, "Shared Concepts."

* Optimal Value of Criterion			

You might be able to further improve the selection by specifying a finer grid near the current optimal kappa value 0.1, as shown in the following statements:

```
proc regselect data=mylib.baseball;
   partition roleVar = league(train='National' validate = 'American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = lasso(relaxed(kappa=0.05 to 0.15  by 0.001) choose=validate);
run;
```

The "Relaxed LASSO Selection Summary" table in Output 29.2.10 shows that the new optimal kappa value is 0.117. Output 29.2.11 shows that the minimal validation ASE is further improved.

Output 29.2.10 Relaxed LASSO Selection Summary for baseball Data

From the previous examples of relaxed LASSO selection, you can see that relaxed LASSO usually produces sparser models with equal or lower prediction error than ordinary LASSO selection produces.

If you are interested only in the catchers' salaries, you can use the following statements to perform LASSO selection for the baseball_C data:

```
proc regselect data = mylib.baseball(where=(Position='C'));
   partition roleVar = league(train='National' validate = 'American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = lasso(choose=validate);
run;
```

Output 29.2.12 shows that 15 observations were used for training and the number of effects is 19. This implies that you cannot obtain a good result by using LASSO selection because the number of effects is greater than the number of observations. In this case, you can use elastic net selection instead of LASSO selection. For more information about this selection method, see the section "Elastic Net Selection" on page 83 in Chapter 2, "Shared Concepts."

   selection method = elasticnet(choose=validate);
   ods output ElasticNetSummary=ElasticNetSummary;
run;
```

You can specify the L2= suboption of the METHOD option in the SELECTION statement if you have a good estimate of the ridge regression parameter. If not, you can leave the L2= suboption unspecified; in this case, PROC REGSELECT estimates this regression parameter according to the criterion that is specified in the CHOOSE= option, by trying a series of candidate values for the ridge regression parameter. The optimal regression parameter is set to the value that achieves the minimum validation ASE.

The "Elastic Net Selection Summary" table in Output 29.2.15 shows that the optimal L2 value is 0.14677993 and the minimal validation ASE is 0.17967. Output 29.2.14 shows the details of the model that is selected by elastic net method with optimal L2 value. If you compare the ASE values for the model in Output 29.2.14 and the model in Output 29.2.13, you see that the elastic net method selects a model that has a lower validation ASE than the LASSO method does in this case.

Similar to the previous analysis, which used the adaptive LASSO selection, you can also perform adaptive elastic net selection on the data when parameter estimates has different scales. The following statements perform adaptive elastic net selection for the baseball_C data:

```
proc regselect data=mylib.baseball(where=(Position='C'));
   partition roleVar = league(train='National' validate = 'American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = elasticnet(adaptive choose=validate);
run;
```

The "Adaptive Elastic Net Selection Summary" table in Output 29.2.16 shows that the optimal L2 value is 0.0215 and the minimal validation ASE is 0.1661. Output 29.2.17 shows that adaptive elastic net selection can produce better results in the sense of a lower validation ASE and a sparser model. For more information about this method, see the section "Adaptive Elastic Net Selection" on page 86 in Chapter 2, "Shared Concepts."

Example 29.3: SCAD and MCP Selection

(View the complete code for this example (regselectEx3.sas) in the example repository.)

This example continues the investigation of the baseball data set that was introduced in the section "Getting Started: REGSELECT Procedure" on page 1480 and in "Example 29.2: LASSO and Elastic Net Selection" on page 1528. That example uses convex penalized selection—the LASSO and elastic net methods—to select an optimal model. In comparison, this example explores model selection by using folded concave penalized selection—the smoothly clipped absolute deviation (SCAD) and minimax concave penalty (MCP)—to select an optimal model.

The following statements perform SCAD selection for the baseball data:

```
proc regselect data=mylib.baseball;
   partition roleVar = league(train='National' validate='American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = scad(choose=validate) details=all;
run;
```

The PARTITION statement assigns observations to training and validation roles on the basis of the values of the input variable league. The METHOD=SCAD option requests SCAD selection, and the CHOOSE=VALIDATE suboption in the SELECTION statement selects the model that yields the lowest average square error (ASE) value for the validation data.

The "Selection Information" table in Output 29.3.1 shows the information that is relevant to SCAD selection, including the solver type (mixed integer linear programming, or MILP) and the ranges of the regularization parameters.

Output 29.3.1 Basic Information about SCAD Selection with MILP Solver

Selection Information	
Selection Method	SCAD
Solver	MILP
Choose Criterion	Validation ASE
Maximum Alpha	5.7
Minimum Alpha	2.7
Alpha Steps	4
Maximum Lambda	0.354142
Minimum Lambda	0.0104153
Lambda Steps	10
Lambda Grid	LOGSPACE

Recall that the SCAD estimator $\hat{\boldsymbol{\beta}}^{\text{scad}}$ solves the following minimization problem:

$$\hat{\boldsymbol{\beta}}^{\text{scad}} = \arg\min_{\boldsymbol{\beta}} \left\{ \frac{1}{2}\|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|_2^2 + n\sum_{j=1}^{m} P_{\lambda,\alpha}^{\text{scad}}(|\beta_j|) \right\}$$

where the $P_{\lambda,\alpha}(\cdot)$ takes the form

$$P_{\lambda,\alpha}^{\text{scad}}(\theta) = \begin{cases} \lambda\theta & \text{if} \quad 0 \le \theta \le \lambda \\ \frac{-1}{2(\alpha-1)}\left(\theta^2 - 2\alpha\lambda\theta + \lambda^2\right) & \text{if} \quad \lambda < \theta < \alpha\lambda \\ \frac{\alpha+1}{2}\lambda^2 & \text{if} \quad \theta > \alpha\lambda \end{cases}$$

This section explains in detail how PROC REGSELECT computes the reported regularization parameter ranges. The values of the grid points of α are $\{2.7, 3.7, 4.7, 5.7\}$ by default. In addition, the number of nonintercept parameters is $19-1 = 18$. Based on this information and the standard deviation of the response variable, the maximum and minimum values of λ are computed in the following way by using the formulas in the section "Folded Concave Penalized Selection" on page 89 in Chapter 2, "Shared Concepts":

$$\lambda_{\max} = y_{\text{std}} \times \sqrt{\frac{\log p}{p}} = 0.8837655 \times \sqrt{\frac{\log 18}{18}} = 0.354142$$

$$\lambda_{\min} = \frac{y_{\text{std}}}{20 \times \sqrt{\log p}} = \frac{0.8837655}{20 \times \sqrt{\log 18}} = 0.0104153$$

The default pattern of the λ grid is such that the values of the grid are evenly spaced on the logarithmic scale, based on the computed $\lambda_{\max}$ and $\lambda_{\min}$ values.

The "Selection Summary" table in Output 29.3.2 shows the values of α and λ together with the validation ASE and objective value at each step. The model that has the lowest validation ASE value is chosen as the final model.

Output 29.3.3 shows the details of this selected model, including fit statistics and parameter estimates. Notice that the model selected by the SCAD method has lower training and validation ASE values than the models selected by the LASSO method (Output 29.2.3) and the adaptive LASSO method (Output 29.2.6). This example demonstrates the advantages of nonconvex penalties over convex penalties.

Furthermore, you can find that for each fixed α, the number of effects increases as the value of λ decreases to zero.

Output 29.3.2 Summary of SCAD Selection with MILP Solver

Selection Summary

Step	Alpha	Lambda	Number of Effects	Validation ASE	Objective Value	Convergence Status

You can also directly supply your own choice of regularization parameters to obtain a model fit. The following program produces an equivalent final model by taking the selected α and λ values from the previous analysis:

```
proc regselect data=mylib.baseball;
   partition roleVar = league(train='National' validate='American');
   class division;
   model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB nOuts nAssts nError;
   selection method = scad(alpha=2.7  lambda=0.0154112628
                           solver=MILP  choose=validate);
run;
```

Suppose you have a good estimate of the regularization parameter α, and you want to use the nonlinear programming (NLP) solver instead of the default MILP solver to search for the best regularization parameter λ. You can perform SCAD selection in the following way:

```
proc regselect data=mylib.baseball;
       partition roleVar = league(train='National' validate='American');
       class division;
       model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                         yrMajor crAtBat crHits crHome crRuns crRbi
                         crBB nOuts nAssts nError;
       selection method = scad(alpha=2.7 solver=NLP choose=validate)
                 details=all;
run;
```

The "Selection Summary" table in Output 29.3.4 shows the optimal validation ASE as well as the value of the objective function for the SCAD selection with the NLP solver. Both values are larger than the ones that are produced by using the MILP solver, shown in Output 29.3.2. In general, the NLP solver is faster but more prone to return local minima because of possible nonconvexity of the reformulated objective function.

Output 29.3.4 Summary of SCAD Selection with NLP Solver

*** Optimal Value of Criterion**

The model at Step 5, where Alpha = 2.7 and Lambda = 0.0738767763, is selected.
Selected model converged. All regularization parameters succeeded.

Selected Effects: Intercept nAtBat nHome nBB YrMajor

Like SCAD selection, MCP selection also applies a nonconvex penalty to the penalized least squares objective function. The penalty function $P_{\lambda,\alpha}(\cdot)$ takes the following form:

$$P^{\text{mcp}}_{\lambda,\alpha}(\theta) = \begin{cases} \lambda\theta - \frac{1}{2\alpha}\theta^2 & \text{if} \quad 0 \le \theta \le \alpha\lambda \\ \frac{\alpha}{2}\lambda^2 & \text{if} \quad \theta > \alpha\lambda \end{cases}$$

The following statements perform MCP selection with a fixed α value of 1.7. The default solver is MILP.

```
proc regselect data=mylib.baseball;
       partition roleVar = league(train='National' validate='American');
       class division;
       model logSalary = division nAtBat nHits nHome nRuns nRBI nBB
                         yrMajor crAtBat crHits crHome crRuns crRbi
                         crBB nOuts nAssts nError;
       selection method = mcp(alpha=1.7 choose=validate) details=all;
run;
```

Output 29.3.6 shows that the model selected by MCP method also has lower training and validation ASE values than those produced by the LASSO method (Output 29.2.3) and the adaptive LASSO method (Output 29.2.6).

Output 29.3.5 Summary of MCP Selection with MILP Solver

Overview: SANDWICH Procedure

The SANDWICH procedure analyzes linear models by using the classical robust sandwich variance estimator. This estimator is constructed by wrapping the inverse of the information matrix by the corrected sum of squares of the residuals. It is commonly used to protect against model misspecifications.

PROC SANDWICH uses algorithms that are specialized for distributed and multicore environments. It also takes advantage of sparse matrix techniques to reduce both memory and time requirements for problems that have classification effects with large numbers of levels. By taking advantage of distributed environments and sparse techniques, PROC SANDWICH can handle data that have large numbers of clusters, observations, and predictor variables.

PROC SANDWICH Features

The main features of the SANDWICH procedure are as follows:

- It computes the between-cluster variance-covariance matrix.
- It uses sparse matrix techniques in analytic computations.

Because the SANDWICH procedure runs on SAS Cloud Analytic Services (CAS; see the section "Using CAS Sessions and CAS Engine Librefs" on page 1556), it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode on CAS
- exploits all the available cores and concurrent threads. For information about how the SANDWICH procedure uses threads, see the section "Multithreading" on page 102 in Chapter 2, "Shared Concepts."

PROC SANDWICH Compared with Other SAS Procedures

The SANDWICH procedure in SAS Visual Statistics produces a robust covariance estimator for linear models, as do several procedures in SAS/STAT. These procedures are compared with PROC SANDWICH in Table 30.1.

Table 30.1 Robust Covariance Estimation Compared between Various SAS/STAT Procedures and PROC SANDWICH

Procedure	Procedure Overview	PROC SANDWICH Comparison
SURVEYREG	Performs regression analysis for sample survey data; provides a sandwich estimator in addition to several other estimators for the covariance matrix. Two important features of the complex survey sample designs—clustering and stratification—are accounted for in the sandwich estimator.	Addresses clustering in the computation of the sandwich estimator; is suitable for analyzing data that are clustered.
GENMOD	Fits generalized linear models and generalized estimating equations (GEE) models. The GEE approach extends independent estimating equations to correlated data. For correlated data, the GEE approach assumes a working correlation matrix from which the covariance matrix of the responses is constructed.	Assumes an independent correlation structure in estimating the weighted least squares regression coefficients, but accounts for correlation in estimating the covariance of these estimated coefficients.
GLIMMIX	Fits generalized linear mixed models; enables you to model the covariance structure of clustered data through random effects and residuals. Random effects, as well as the fixed effects and the parameters of the covariance structure, are estimated using the maximum likelihood method. PROC GLIMMIX computes the sandwich estimator after the mixed model is estimated. The estimation of a mixed model requires iterative optimization. It is a much more involved process than the estimation of a cluster-adjusted empirical covariance estimator.	Does not model the covariance structure of clustered data through random effects; accounts for the covariance structure while estimating the variance and covariance of the estimated parameters.

In addition, both the SANDWICH and LMIXED procedures in SAS Visual Statistics handle correlated data. These procedures are compared in Table 30.2.

Table 30.2 Correlated Data in the LMIXED and SANDWICH Procedures

Procedure	Procedure Overview	PROC SANDWICH Comparison
LMIXED	Fits linear mixed models to Gaussian data. The mean of the data and the variance and covariance of the data are modeled separately. The mean structure is a linear function of both fixed effects and random effects. The variance and covariance structure can arise from both marginal covariance and random effects. The inclusion of random effects and the variance and covariance parameters makes linear mixed models computationally more challenging. An iterative optimization algorithm is required in order to estimate the parameters.	Assumes an independent covariance structure and models the mean structure as a linear function of fixed effects; accounts for correlation in the computation of the covariance of the estimated fixed-effects coefficients. The estimation of fixed-effects coefficients and the robust variance and covariance structure does not require iterative optimization.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: SANDWICH Procedure

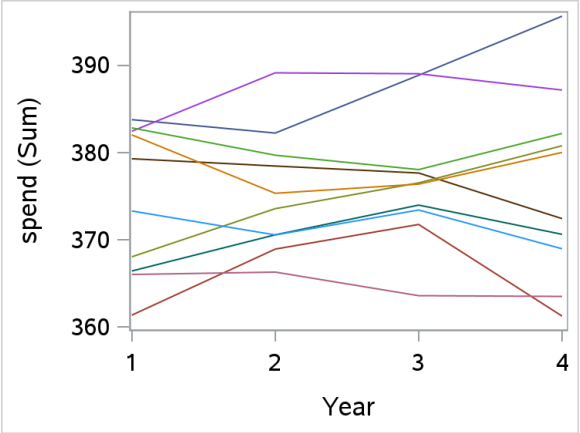
(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/sandgs.sas.)

In health economics, large correlated data are common. These data usually contain information that is observed about large numbers of individuals, hospitals, or employers. The observations within individuals, hospitals, or employers are assumed to be correlated. There are two approaches to modeling such correlated data. One approach is to use random effects to introduce correlation in model estimation. Another approach is to use a robust variance estimator to adjust for correlation after the model is estimated. PROC SANDWICH provides a tool for analyzing large correlated data by using a robust variance estimator.

This example analyzes simulated health-care spending data by using a robust variance estimator. Suppose a number of health insurance choices are provided to 20,000 individuals each year over a period of four years. The goal of this analysis is to study the effect of choices of deductible and out-of-pocket payments on health care spending.

The following DATA step simulates 80,000 observations of annual health care spending from a linear model. The predictor variables are Individual, Year, Income, FamilySize, and choices of deductible and out-of-pocket payments for individual and family. DeductibleInd and DeductibleFam denote the five tiers of deductibles for an individual and a family, respectively. OutOfPocketInd and OutOfPocketFam denote the six tiers of out-of-pocket payments for an individual and a family, respectively. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."



```
%let nDeductibleInd=5;
%let nDeductibleFam=5;
%let nOutOfPocketInd=6;
%let nOutOfPocketFam=6;
%let nFamSize=5;

data mylib.insure;
   call streaminit(1234);
   do Individual = 1 to 20000;
      rInd = 5 *rand("normal");
      Income = 3 + 2 *rand("normal");
      FamilySize = ceil(&nFamSize * rand("uniform"));
      do Year = 1 to 4;
         DeductibleInd = ceil(&nDeductibleInd * rand("uniform"));
```

```
            DeductibleFam = ceil(&nDeductibleFam * rand("uniform"));
            OutOfPocketInd= ceil(&nOutOfPocketInd * rand("uniform"));
            OutOfPocketFam= ceil(&nOutOfPocketFam * rand("uniform"));
            err   = 2*rand("normal");
            spend = 350 + Year + rInd + 3.2*Income + FamilySize +
                    DeductibleInd + DeductibleFam + OutOfPocketInd + OutOfPocketFam + err;
            output;
         end;
      end;
   run;
```

Figure 30.1 below shows the spaghetti plot of health-care spending of 10 individuals over the four-year period. You can see that the intercepts of the trajectories of health-care spending vary from individual to individual. The variability from individual to individual is an indication of correlation within individuals.

Figure 30.1 Spaghetti Plot of 10 Individuals

The following SANDWICH procedure statements fit a linear regression model to the annual health-care spending data:

```
ods select ModelInfo Dimensions ModelAnova;
proc sandwich data=mylib.insure sparse;
   class individual year familysize DeductibleInd DeductibleFam
         OutOfPocketInd OutOfPocketFam;
   clusters individual;
   model spend =  Year Income|DeductibleInd|OutOfPocketInd
                  Income|FamilySize|OutOfPocketFam|DeductibleFam/ss3;
run;
```

In the preceding statements, the cluster effect, Individual, accounts for correlations among observations from the same individual. The SPARSE option tells PROC SANDWICH to invoke sparse matrix methods. All two-way and the three-way interaction effects among Income, DeductibleInd, and OutOfPocketInd are included to study how the effects of individual deductible, out-of-pocket payment, and income change with each other. Also, all two-way, all three-way, and the four-way interaction effects among Income, FamilySize, OutOfPocketFam, DeductibleFam are included to account for the interaction between family deductible, family out-of-pocket payment, family size, and income.

These interaction effects in addition to the main effects add up to a total number of 590 parameters, leading to a sum of squares and crossproducts matrix $\mathbf{X}'\mathbf{X}$ that is of dimension 590×590. Analyzing these data in

PROC SURVEYREG requires the product $\mathbf{X}'\mathbf{X}$ for all 20,000 clusters. It takes about 2 GB of memory to store these matrices and a great deal of time to manipulate them. Such time-consuming and resource-draining problems can benefit from the parallel computing algorithms that are implemented in PROC SANDWICH.

	.	.	.	.	.
	.	.	.	.	.

In the "Parameter Estimates" table, the *t* statistics of the parameters are computed using the sandwich variance estimator, which accounts for clustering. The degrees of freedom for the *t* test is the number of clusters minus one. The *t* test results of five individual deductibles categories indicate that they are significant. The estimates of these five individual categories show how annual health-care spending decreases with the increase of the individual deductible.

Part of the "Type III Model ANOVA" table is shown in Figure 30.5. By construction, the true model consists of the main effects Year, Income, FamilySize, DeductibleInd, DeductibleFam, OutOfPocketInd, and OutOfPocketFam. *F* test results in Figure 30.5 show that only the effects in the true model are significant. The *F* statistics of the parameters are computed using the sandwich variance estimator that accounts for clustering. The degrees of freedom for the *F* test is the number of clusters minus one.

Syntax: SANDWICH Procedure

The following statements are available in the SANDWICH procedure:

PROC SANDWICH < *options* > **;**
BY *variables* **;**
CLASS *variable* < **(***options***)** >. . . < *variable* < **(***options***)** > > < / *global-options* > **;**
CLUSTER *variables* **;**
DISPLAY < *table-list* > < / *options* > **;**
DISPLAYOUT *table-spec-list* < / *options* > **;**
FREQ *variable* **;**
MODEL *dependent* **=** < *effects* > < / *model-options* > **;**
WEIGHT *variable* **;**

The PROC SANDWICH and MODEL statements are required.

If your model contains classification effects, the classification variables must be listed in the CLASS statement.

The following section describes the PROC SANDWICH statement and then describes the other statements in alphabetical order.

PROC SANDWICH Statement

PROC SANDWICH < *options* > **;**

The PROC SANDWICH statement invokes the SANDWICH procedure. Table 30.3 summarizes the options available in the PROC SANDWICH statement.

Table 30.3 PROC SANDWICH Statement Options

Option	Description
DATA=	Names the input data table that the SANDWICH procedure uses
SPARSE	Invokes sparse matrix techniques

You can specify the following *options* in the PROC SANDWICH statement.

DATA=*libref.data-table*
names the input data table for PROC SANDWICH to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1556.

data-table specifies the name of the input data table.

SPARSE

invokes the sparse matrix techniques in the analytic computations. These techniques provide efficient ways to store sparse matrices and to solve sparse linear systems. For problems whose $\mathbf{X}'\mathbf{X}$ matrix is sparse, these techniques can reduce the time and memory requirements for solving the normal equation and computing the sandwich estimator.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC SANDWICH to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

CLASS Statement

CLASS *variable* <**(***options***)**>. . . <*variable* <**(***options***)**>> </ *global-options*> **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. These variables enter the analysis not through their values, but through levels to which the unique values are mapped.

Table 30.4 summarizes the values that you can use as either an *option* or a *global-option*. The options are fully documented in the section "CLASS Statement" on page 9 in Chapter 2, "Shared Concepts."

Table 30.4 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable

CLUSTER Statement

CLUSTER *variables* **;**

The CLUSTER statement specifies one or more *variables* in the DATA= input data table that identify the clusters. These variables must be specified as classification variables in the CLASS statement; they can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. When you specify more than one variable in the CLUSTER statement, the combinations of categories of these variables define the clusters. You can use multiple CLUSTER statements to specify cluster variables. PROC SANDWICH uses variables from all CLUSTER statements to create clusters.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section "ODS Table Names" on page 1573. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying "/tions/" selects all pathnames that contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value*	specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.
key	specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1573. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC SANDWICH treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1. The FREQ statement is supported only when the CLUSTER statement is specified.

MODEL Statement

MODEL *dependent*=< *effects* > / < *model-options* > **;**

The MODEL statement names the dependent variable and the explanatory effects, including covariates, main effects, interactions, and nested effects.

You must specify the following argument:

dependent
specifies the dependent (response) variable.

You can also specify the following argument:

effects
specify the explanatory effects, including covariates, main effects, interactions, and nested effects. If you omit the explanatory effects, PROC SANDWICH fits an intercept-only model. For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

You can also specify the following *model-options* after a slash (/); these *model-options* control other aspects of model formation and inference:

NOINT
suppresses the intercept term that is otherwise included in the model.

SS3
displays a "Model Anova" table that contains tests that are computed by using Type III sums of squares for each effect. For more information, see the section "Type III Tests" on page 1570.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

Details: SANDWICH Procedure

Computational Details

PROC SANDWICH uses the Taylor series (linearization) method to estimate the variance-covariance matrix of estimators. This method is introduced in Huber (1967), White (1980), and MacKinnon and White (1985). It is also well discussed in the context of survey analysis. For more information see Fuller (1975), Särndal, Swensson, and Wretman (1992), Wolter (2007), and Rust (1985). The Taylor series method assumes an independent correlation structure in estimating the weighted least squares regression coefficients, but it accounts for correlations in estimating the covariance of the estimated coefficients. This section includes explicit formulas for estimating the regression coefficients and their covariance.

Notation

In PROC SANDWICH, the data are denoted as

$$(\mathbf{w}, \mathbf{y}, \mathbf{X}) = (w_{ij}, y_{ij}, \mathbf{x}_{ij})$$

where

- $\mathbf{w}$ denotes the weight vector
- $\mathbf{y}$ denotes the dependent variable
- $\mathbf{X}$ denotes the $N \times p$ design matrix
- $i = 1, 2, \ldots, n$ is the cluster index
- $j = 1, 2, \ldots, m_i$ is the unit index within cluster i
- $N = \sum_{i=1}^{n} m_i$

Regression Coefficients

PROC SANDWICH solves the normal equations $\mathbf{X}'\mathbf{W}\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{y}$ by using a modified sweep routine that produces a generalized (g2) inverse $(\mathbf{X}'\mathbf{W}\mathbf{X})^{-}$ and a solution (Pringle and Rayner 1971),

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-}\mathbf{X}'\mathbf{W}\mathbf{y}$$

where $\mathbf{W}$ is the diagonal matrix that is constructed from $\mathbf{w}$.

Because $\mathbf{X}'\mathbf{W}\mathbf{X}$ and $\mathbf{X}'\mathbf{W}\mathbf{y}$ can be decomposed into the corresponding matrices within each of the clusters

$$\mathbf{X}'\mathbf{W}\mathbf{X} = \sum_{i=1}^{n} \mathbf{X}_\mathbf{i}'\mathbf{W}_\mathbf{i}\mathbf{X}_\mathbf{i}$$

$$\mathbf{X}'\mathbf{W}\mathbf{y} = \sum_{i=1}^{n} \mathbf{X}_\mathbf{i}'\mathbf{W}_\mathbf{i}\mathbf{y}_\mathbf{i}$$

Because PROC SANDWICH shuffles the clusters to distinct threads, parallel processing can be leveraged to accumulate these matrices efficiently in parallel. Furthermore, for problems that have many classification effects, the components $\mathbf{X}_\mathbf{i}'\mathbf{W}_\mathbf{i}\mathbf{X}_\mathbf{i}$ and the overall $\mathbf{X}'\mathbf{W}\mathbf{X}$ could be handled as sparse matrices, making matrix storage and computation much more efficient.

Variance Estimation

Using the notation described in the section "Notation" on page 1566, the residuals from the linear regression can be written as

$$\mathbf{r} = \mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}$$

with r_{ij} as its elements. Let the $p \times p$ matrix $\mathbf{G}$ be defined as

$$\mathbf{G} = \frac{n}{n-1} \sum_{i=1}^{n} (\mathbf{e}_{i+} - \bar{\mathbf{e}}_{..})'(\mathbf{e}_{i+} - \bar{\mathbf{e}}_{..})$$

where

$$\begin{aligned} \mathbf{e}_{i+} &= \sum_{j=1}^{m_i} \mathbf{e}_{ij} \\ \mathbf{e}_{ij} &= w_{ij} r_{ij} \mathbf{x}_{ij} \\ \bar{\mathbf{e}}_{..} &= \frac{1}{n} \sum_{i=1}^{n} \mathbf{e}_{i+} \end{aligned}$$

If there is no CLUSTER statement, then the data can be denoted as

$$(\mathbf{w}, \mathbf{y}, \mathbf{X}) = (w_i, y_i, \mathbf{x}_i)$$

where $i = 1, 2, \ldots, N$ is the observation index. The $\mathbf{G}$ matrix becomes

$$\mathbf{G} = \frac{N}{N-1} \sum_{i=1}^{N} (\mathbf{e}_i - \bar{\mathbf{e}})'(\mathbf{e}_i - \bar{\mathbf{e}})$$

where

$$\begin{aligned} \mathbf{e}_i &= w_i r_i \mathbf{x}_i \\ \bar{\mathbf{e}} &= \frac{1}{N} \sum_{i=1}^{N} \mathbf{e}_i \end{aligned}$$

Given $\mathbf{G}$, the sandwich estimator of the covariance matrix of $\hat{\boldsymbol{\beta}}$ is

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-}\mathbf{G}(\mathbf{X}'\mathbf{W}\mathbf{X})^{-}$$

In this formula, the first matrix factor, $(\mathbf{X}'\mathbf{W}\mathbf{X})^{-}$, would be an appropriate estimate for $\mathbf{V}(\hat{\boldsymbol{\beta}})$ if all observations were uncorrelated. Thus, the product of the last two factors effectively creates an adjustment that accounts for the within-cluster covariance.

Computational Methods

In order to perform linear regression with sandwich variance estimation efficiently, PROC SANDWICH uses distributed computing and sparse matrix techniques. The following two subsections discuss these techniques in detail.

Distributed Computing and Multithreading

Distributed computing refers to the use of multiple autonomous computers that communicate through a secure network. Distributed computing solves computational problems by dividing them into many tasks, each of which is solved by one or more computers. Multithreading divides the tasks on each computer so they can be completed in parallel by multiple threads.

PROC SANDWICH uses the following distributed computing and multithreading techniques:

- accumulating the components of weighted normal equations $(\mathbf{X}'\mathbf{W}\mathbf{X})$ and $(\mathbf{X}'\mathbf{W}\mathbf{Y})$
- accumulating the components of the within-cluster residual covariance $\mathbf{G}$
- solving the weighted normal equations
- computing the sandwich variance-covariance estimate

Regular weighted least squares regression depends on matrix quantities such as $\mathbf{X}'\mathbf{W}\mathbf{X}$ and $\mathbf{X}'\mathbf{W}\mathbf{y}$, which can be accumulated in any order and in parallel. Because clusters are independent of each other, these quantities can be processed in parallel by threads across the nodes. Hence, to efficiently compute the cluster components of the matrix $\mathbf{G}$ that forms the "meat" of the sandwich variance estimate, correlated observations

within the same cluster should be processed together. PROC SANDWICH shuffles input data to ensure that observations from the same cluster are on the same node so that they can be assigned to the same thread.

PROC SANDWICH divides the following computational tasks by clusters:

- Using the following decomposition, PROC SANDWICH assigns the task of computing $\mathbf{X_i'W_iX_i}$ and $\mathbf{X_i'W_iy_i}$ to the thread where the observations for cluster i are located. These pieces are then accumulated to give the overall $\mathbf{X'WX}$ and $\mathbf{X'Wy}$.

$$\mathbf{X'WX} = \sum_{i=1}^{n} \mathbf{X_i'W_iX_i}$$

$$\mathbf{X'Wy} = \sum_{i=1}^{n} \mathbf{X_i'W_iy_i}$$

- Similarly, the cluster components of matrix $\mathbf{G}$, $\mathbf{e}_{i\cdot}$, are computed in parallel and then accumulated.

In addition, operations such as sweeping and matrix solving are multithreaded to realize performance benefits for matrices of sufficient sizes.

Distributed computing enables PROC SANDWICH to handle large number of clusters that possibly have large number of observations.

Sparse Matrix Techniques

PROC SANDWICH uses the following sparse matrix techniques:

- storing and accumulating $(\mathbf{X'WX})$ and $(\mathbf{X'WY})$
- obtaining $\hat{\boldsymbol{\beta}}$ and the sandwich estimate $\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$ through sparse Cholesky solvers

A common component in the formula for $\hat{\boldsymbol{\beta}}$ and $\widehat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$ is the matrix product $\mathbf{X'WX}$. The size of this product increases quadratically with the row dimension of $\mathbf{X}$. However, $(\mathbf{X'WX})$ would be relatively sparse if $\mathbf{X}$ is sparse. In such a case, PROC SANDWICH stores both of them in sparse format and computes $(\mathbf{X'WX})$ accordingly.

Furthermore, instead of computing the inversion of $\mathbf{X'WX}$ directly, PROC SANDWICH applies sparse Cholesky solvers to compute $(\mathbf{X'WX})^{-}\mathbf{X'Wy}$ and $(\mathbf{X'WX})^{-}\mathbf{G}(\mathbf{X'WX})^{-}$. In general, for a positive definite matrix $\mathbf{A}$, you can solve $\mathbf{Ax} = \mathbf{b}$ for $\mathbf{x}$ by first performing the Cholesky decomposition $\mathbf{A} = \mathbf{LL}'$, and then applying forward and backward substitution. For general matrices $\mathbf{A}$, the computational cost of this approach is still of order n^3, which is no better than solving $\mathbf{Ax} = \mathbf{b}$ directly. However, if $\mathbf{A}$ is sparse, $\mathbf{L}$ is often sparse too, and forward and backward substitution have much lower cost than of order n^3.

Type III Tests

Linear hypotheses for $\boldsymbol{\beta}$ are expressed in matrix form as

$$H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

where $\mathbf{L}$ is a matrix of coefficients for the linear hypotheses and $\mathbf{c}$ is a vector of constants. The vector of regression coefficients $\boldsymbol{\beta}$ includes slope parameters and intercept parameters. The F statistic for testing H_0 is computed as

$$F = (\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})'[\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}']^{-1}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})/r$$

where $\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})$ is the robust covariance estimator of $\widehat{\boldsymbol{\beta}}$ and r is the rank of $\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}'$. Under H_0, it is common to assume that F follows an F distribution with the numerator degrees of freedom equal to r and the denominator degrees of freedom equal to the number of clusters minus one. If there is no CLUSTER statement, then the denominator degrees of freedom is equal to the number of observations minus the rank of the design matrix. For more information about Type III estimable functions, see the chapter "The GLM Procedure" and the section "The Four Types of Estimable Functions" in *SAS/STAT User's Guide*. Also see Littell, Freund, and Spector (1991).

Displayed Output

The following sections describe the output that the SANDWICH procedure produces. The output is organized into various tables, which are described in the order of their appearance.

Model Information

The "Model Information" table displays basic information about the model, including the data source, the response variable, and the design matrix method.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis. If you specify a FREQ statement, this table also displays the sum of frequencies that are read and used.

Class Level Information

The "Class Level Information" table lists the levels of each variable that is specified in the CLASS statement. You can adjust the order of the CLASS variable levels by specifying the ORDER= option in the CLASS statement.

Dimensions

The "Dimensions" table displays the number of effects, the number of parameters, and the number of clusters in the model. This table can be useful in determining the requirements for CPU time and memory.

Fit Statistics

The "Fit Statistics" table displays fit statistics for the model. These statistics include the following:

- Root MSE, an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- R-square, a measure between 0 and 1 that indicates the portion of the (corrected) total variation that is attributed to the fit rather than left to residual error. It is calculated as SS(Model) divided by SS(Total) and is also called the *coefficient of determination*. It is the square of the multiple correlation—in other words, the square of the correlation between the dependent variable and the predicted values.
- Adj R-Sq, the adjusted R-square, which is a version of R-square that has been adjusted for the number of parameters in the model. It is calculated as

$$\bar{R}^2 = 1 - \frac{(n-i)(1-R^2)}{n-p}$$

  where i is equal to 1 if there is an intercept and 0 otherwise, n is the number of observations that are used to fit the model, and p is the number of parameters in the model.

ANOVA

The "ANOVA" table displays the analysis of variance for the model. This table includes the following:

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean.
- the degrees of freedom (DF) that are associated with the source
- the Sum of Squares for the term
- the Mean Square, which is the sum of squares divided by the degrees of freedom
- the F Value for testing the hypothesis that all parameters are 0 except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.
- the Prob>F, which is the probability of getting a greater F statistic than that observed if the hypothesis is true. The degrees of freedom for the F test is the number of clusters minus one. If there is no CLUSTER statement, the degrees of freedom is the number of observations minus the rank of the design matrix.

Parameter Estimates

The "Parameter Estimates" table displays the parameters in the model and their estimates. The information displayed for each parameter in the model includes the following:

- the parameter label, which includes the effect name and level information for effects that contain classification variables
- the degrees of freedom (DF) for the parameter. There is usually one degree of freedom, except when the model is not of full rank.
- the parameter estimate
- the standard error of the parameter estimate
- t Value, which is computed as the parameter estimate divided by the standard error.
- the Pr > |t|, which the probability of getting a t statistic that has a greater absolute value than that observed if the true parameter is 0. The degrees of freedom for the t test is the number of clusters minus one. If there is no CLUSTER statement, the degrees of freedom is the number of observations minus the rank of the design matrix. This is the two-tailed significance probability.

Type III Model ANOVA

When you specify the SS3 option in the MODEL statement, the SANDWICH procedure produces the "Type III Model ANOVA" table. This table displays tests that all parameters for a particular effect are equal to 0. These tests are computed by using a Type III sum of squares, which yields a balanced test of each effect, adjusted for every other effect. For more information, see the section "Type III Tests" on page 1570.

Timing

The "Timing" table displays the amount of time (in seconds) and the percentage of the time that PROC SANDWICH required to perform different tasks in the analysis.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table. Because this table is not a typical ODS table that contains analytical results, you cannot include it in the *table-spec-list* in the DISPLAYOUT statement.

ODS Table Names

Each table that the SANDWICH procedure creates has a name associated with it. You must use this name to refer to the table when you use the DISPLAY statement, the DISPLAYOUT statement, or ODS statements. These names are listed in Table 30.5.

Table 30.5 ODS Tables Produced by PROC SANDWICH

Table Name	Description	Required Statement / Option
ANOVA	Model ANOVA table	Default output
ClassInfo	Level information from the CLASS statement	CLASS
Dimensions	Model dimensions	Default output
FitStatistics	Fit statistics	Default output

Examples: SANDWICH Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

Example 30.1: Analysis of Microarray Data

(View the complete code for this example (sandex1.sas) in the example repository.)

Gene expression profiling is a technology that monitors differences in gene expression levels. It can be used to discover relationships between gene expression levels and a condition or treatment. Microarray experiments allow simultaneous gene expression profiling of hundreds to thousands of genes. In a microarray experiment, a collection of microscopic DNA spots are attached to a glass slide or silicon cassette. Each DNA spot contains a high density of a specific DNA sequence or gene. These genes are then bound with a mixture of cDNA samples from an experimental group and a reference group. Each group of cDNA samples are labeled with a fluorescent dye. You can measure the intensity of fluorescence to quantify the amount of binding of DNA molecules with cDNA samples from each group. The analysis of microarray data enables you to study genomic response to a particular condition or treatment.

PROC SANDWICH is a suitable tool for the analysis of microarray data. You can specify the microarray variable as the cluster effect to accommodate correlations among the observations from the same array. You can also take advantage of sparse techniques to handle the large number of genes on each array.

The following SAS statements simulate a experiment that includes six arrays:

```
%let nArray  = 6;
%let nDye    = 2;
%let nGene   = 500;
%let nTrt    = 2;

data mylib.microarray;
   keep  Microarray Array Gene Trt Dye Density;
   array GeneDist{&ngene};
   array ArrayEffect{&narray};
   do i = 1 to &nGene;
       GeneDist{i} = 1 + int(&nGene*ranuni(12345));
   end;
   do i = 1 to &nArray;
      ArrayEffect{i} = sqrt(0.014)*rannor(12345);
   end;

   do Microarray = 1 to &nArray;
      do Dye = 1 to &nDye;
         do k = 1 to &nGene;
            Trt   = 1 + int(&nTrt*ranuni(12345));
            Gene  = GeneDist{k};
            Array = ArrayEffect{Microarray};

            Density  = 1 +
                     + Dye
                     + Trt
                     + Gene/1000.0
                     + Gene*Dye/1000.0
                     + Gene*Trt/1000.0
                     + Array
                     + sqrt(0.02)*rannor(12345);
            output;
```

```
         end;
      end;
   end;
run;
```

In these simulated data, each of the six arrays is spotted with the same 500 genes. The cDNA samples are labeled with two dyes, one for the treatment group and one for the reference group. Littell et al. (2006) suggests using gene and dye interaction, Gene*Dye, to control for the fact that dyes incorporate into different target cDNA with different efficiency. Also, it is important to use the gene and treatment interaction, Gene*Trt, to account for the fact that the response to treatment might vary with genes. The cluster effect, Microarray, controls the fact that observations from the same microarray are correlated. With 500 genes, the gene effect and these two interaction effects account for 1,500 parameters of the total 1,600 parameters. A sparse problem of this size can benefit from the sparse techniques that PROC SANDWICH implements.

The following SANDWICH procedure fits a linear regression to the simulated data. The SPARSE option in the PROC statement requests that PROC SANDWICH use sparse matrix techniques.

```
ods select Dimensions ModelAnova ModelInfo;
proc sandwich data=mylib.microarray sparse;
   class Microarray Gene Trt Dye;
   model Density = Gene Trt Dye Gene*Trt Gene*Dye/ss3;
   cluster Microarray;
run;
```

The "Model Information" table (Output 30.1.1) shows that the sparse method was used in the model estimation.

Output 30.1.1 Model Information

The SANDWICH Procedure

Model Information	
Data Source	MICROARRAY
Response Variable	Density
Design Matrix Method	Sparse

The "Dimensions" table (Output 30.1.2) shows that this is a sparse problem with 6 effects, 6 clusters, and 1,600 parameters.

Output 30.1.2 Dimensions

Dimensions	
Number of Effects	6
Number of Parameters	1600
Number of Clusters	6

The "Type III Model ANOVA" table (Output 30.1.3) shows the Type III analysis of model effects. The degrees of freedom for the F test is the number of clusters minus one. The covariance of the estimates of model effects are adjusted for the correlation among the measurements from the same array.

Output 30.1.3 Type III Model ANOVA

Type III Model ANOVA

Effect	DF	Sum of Squares	Mean Square	F Value	Pr > F
Gene	5	3576.51442	715.30288	715.30	<.0001
Trt	1	248839	248839	248839	<.0001
Dye	1	166548	166548	166548	<.0001
Gene*Trt	5	256.35404	51.27081	51.27	0.0003
Gene*Dye	5	228.99388	45.79878	45.80	0.0004

The denominator degrees of freedom for the F tests is 5.

Overview: SIMSYSTEM Procedure

The SIMSYSTEM procedure simulates continuous univariate data from distributions in the Pearson and Johnson systems. You request these distributions by directly specifying their measures of skewness and kurtosis rather than their distribution names and mathematical parameters. This makes it convenient to simulate data from a series of distributions whose degrees of asymmetry and tail weight vary over a grid of skewness-kurtosis combinations.

A property of the Pearson and Johnson systems is that there is a unique distribution in each system for any feasible skewness-kurtosis combination. This generality, together with the convenience of specifying skewness and kurtosis, enables you to design simulation studies that have a greater variety of distributional shapes and to reach conclusions that are more reliable than is possible with smaller families of distributions—such as the lognormal and Weibull—that are traditionally used in simulation.

Simulation from Probability Distributions

Simulation is a powerful method for understanding and predicting the behavior of a complex system under different conditions when it is not feasible to experiment with the system and measure how the output changes in response to variation in the inputs. See Ross (2006) for an introduction to the design and analysis of simulation studies.

Probabilistic simulation—often referred to as Monte Carlo simulation—is based on a probability model that assumes distributions for the input variables and assumes a functional relationship between the input variables and the output. By sampling a large number of values from the input distributions, you can simulate the distribution of the output and compute probabilities that quantify uncertainty in the performance of the system.

Simulation based on probability distributions is essential for assessing and managing risk in many fields of business, government, and research where actual data for unusual events are limited or unavailable. These fields include banking (market and credit risk), insurance (actuarial risk), fraud prevention, cybersecurity risk assessment, reliability engineering, national defense, climate modeling, environmental analysis, and epidemiology. In the field of statistics, simulation is a standard approach for evaluating the performance and robustness of statistical methods when applied to data that cannot be represented by standard modeling distributions such as the normal distribution.

Simulation from Families of Distributions

Because the actual distribution of an input variable is generally unknown, the reliability of a simulation study rests on sampling from distributions that represent a broad set of realistic scenarios. Well-designed simulation studies sample from a range of parametric distributions that have different means, standard deviations, and shapes. In studies of this type, you typically select several families of distributions to sample from, and then you specify the mathematical parameters for particular distributions within each family.

For example, if your goal is to model the effects of nonnormality on a statistical method, you might simulate data from various lognormal distributions to allow for different degrees of skewness, and you might simulate data from various *t* distributions to allow for distribution tails that are heavier than those of the normal distribution. The following statements illustrate how you carry this out with the RAND function in the DATA step:

```
data SimNonNormal(drop=i);
   call streaminit(15531);
   do i=1 to 10000;
      normal        = rand('NORMAL');
      t_4           = rand('T', 4);
      t_10          = rand('T', 10);
      lognormal_0_2 = rand('LOGNORMAL', 0, 0.2);
      lognormal_0_4 = rand('LOGNORMAL', 0, 0.4);
      output;
   end;
run;
```

Note that for each distribution in the *t* family you must specify its degrees of freedom (in this case, the values 4 and 10). Likewise, for each distribution in the lognormal family you must specify a shape parameter σ (in this case, the values 0.2 and 0.4).

When using the RAND function you must choose both a distribution family and the mathematical parameters for the distributions in that family. This approach has three major disadvantages:

- The choice of a family is generally not obvious. In some applications the choice is well established; for example, the lognormal and Weibull families are commonly chosen for simulating lifetime distributions in reliability analysis. However, in most applications the family is chosen in an ad hoc manner.
- The parameter choices are nonintuitive. Generally, the most useful descriptors of a distribution—in particular, its mean, standard deviation, skewness, and kurtosis—are complicated mathematical functions of the parameters. For example, the skewness of a lognormal distribution with parameter σ is $\sqrt{\beta_1} = \sqrt{\exp(\sigma^2) - 1}(\exp(\sigma^2) + 2)$. This makes it difficult to simulate data by specifying the descriptors of this distribution.
- It is computationally challenging to simulate data from distributions with a broad combinations of skewness and kurtosis because the families available in the RAND function—and distribution families in general—cover only a subset of the combinations that are feasible.

You can avoid these disadvantages by using the SIMSYSTEM procedure.

Simulation from the Pearson and Johnson Systems of Distributions

In contrast to the traditional approach of simulating from families of distributions, the SIMSYSTEM procedure simulates values from the Pearson system of distributions (Pearson 1895, 1901, 1916) and the Johnson system of distributions (Johnson 1949). You request a range of distributions simply by specifying combinations of skewness and kurtosis, also referred to as moment ratios, rather than names and parameters of distributions, as illustrated in the following statements:

```
proc simsystem system=pearson n=10000 seed=15531;
   moments skewness = 0  0  0  0.5  1.0
           kurtosis = 3  2  4  3.5  4.5;
   output out=mylib.MySimulation;
run;
```

In this example, the procedure simulates 10,000 values from each of five Pearson distributions. The first distribution, with a skewness of 0 and a kurtosis of 3, is the normal distribution. The next two distributions are also symmetric (with a skewness of 0) but differ from the normal distribution in their values of kurtosis. The final two distributions are skewed (with skewness values of 0.5 and 1.0) and have different values of kurtosis (3.5 and 4.5).

Benefits of the SIMSYSTEM Procedure

The SIMSYSTEM procedure provides three major benefits in practice:

- You can request a range of distributions just by specifying their combinations of mean, standard deviation, skewness, and kurtosis. These descriptors control the location, scale, and shapes of the distributions—aspects that are intuitive to understand and can be visualized in graphical displays created by the procedure.
- You can specify any feasible combination of skewness and kurtosis, because there is a unique distribution in each system whose theoretical skewness and kurtosis match that combination. By comparison, families of better-known distributions, which are smaller than these systems, cover only a limited set of combinations.
- By specifying a grid of evenly spaced combinations of skewness and kurtosis, you can explore their effects more thoroughly and form conclusions that are more general than those you would obtain from an ad hoc selection of distributions.

Features of the SIMSYSTEM Procedure

Key features of the SIMSYSTEM procedure are as follows:

- The procedure provides three convenient ways to specify combinations of mean, standard deviation, skewness, and kurtosis for the distributions to be sampled: the MOMENTS statement, the MOMENTGRID statement, and the DATA= option in the PROC SIMSYSTEM statement.
- The procedure produces summary tables and graphical displays for the distributions that you specify. When a specified Pearson distribution also happens to be a well-known parametric distribution, such as a beta distribution or an exponential distribution, the summary table identifies the well-known distribution in addition to the Pearson type.
- The procedure produces moment-ratio diagrams, which map the specified skewness and kurtosis values in the skewness-kurtosis plane.
- The procedure produces summary tables and histograms for the values that are sampled from each specified distribution.
- The procedure provides the ability to create replicate samples.
- The procedure creates a data table in which to save the values that are sampled from specified distributions.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the

CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: SIMSYSTEM Procedure

ANOVA for Nonnormal Data

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/ssy_gs.sas.)

This example demonstrates a basic application of the SIMSYSTEM procedure in which the MOMENTS statement is used to simulate samples from a small number of nonnormal distributions with specified skewness (denoted by $\sqrt{\beta_1}$) and kurtosis (denoted by β_2); see "Moments and Moment Ratios" on page 1597. The example concludes by explaining the use of the MOMENTGRID statement to simulate samples from a large number of nonnormal distributions whose skewness and kurtosis, also referred to as moment ratios, vary evenly over a grid.

An industrial engineer in a manufacturing facility is investigating the effect of five operators with different levels of training on a critical functional parameter of a product. The engineer obtains 100 measurements of the parameter, 20 for each operator. A one-way analysis of variance (ANOVA) seems like an appropriate method for testing the hypothesis of no training effect, because if there is an effect the level of training would shift the expected (mean) value of the parameter.

However, it cannot be assumed that the measurements are normally distributed. The distribution of measurements taken previously was found to be skewed and heavy-tailed, with a skewness of 1.5 and a kurtosis of 7. There is concern that ANOVA F tests might not be valid for this type of data. You can use PROC SIMSYSTEM to simulate data with this particular combination of skewness and kurtosis, and with combinations that depart from the observed combination (including a skewness of 0 and a kurtosis of 3, which correspond to the normal distribution). You can then use the simulated data to study the behavior of ANOVA tests.

To start, consider how to simulate data from a single distribution with the observed combination of skewness and kurtosis. The following statements use PROC SIMSYSTEM to simulate 100 values from the Pearson distribution that has mean 0, standard deviation 1, skewness 1.5, and kurtosis 7:

```
ods graphics on;
proc simsystem system=pearson n=100 seed=12345;
   moments skewness=1.5 kurtosis=7;
   output out=mylib.sim;
run;
```

The SYSTEM= option specifies the system of distributions to sample from. The N= option specifies the number of simulated values, and the SEED= option specifies the seed for the random number generator in order to make the results reproducible. The MOMENTS statement specifies the values of skewness and kurtosis. Note that skewness and kurtosis are defined somewhat differently for theoretical distribution in the statistics literature and in SAS; see "Definitions and Interpretations of Skewness and Kurtosis" on page 1598 for the definitions used by the SIMSYSTEM procedure. Because no values are specified for the mean and standard deviation, default values of 0 and 1 are used, respectively. The OUTPUT statement requests a CAS table named SIM that contains the simulated values.

Figure 31.1 Pearson Distribution with Specified Skewness and Kurtosis

The SIMSYSTEM Procedure

Simulation Information

1	1.500	7	Type VI	F(DF1=6.777,DF2=38)	-1.641	1.555

Distribution Moments

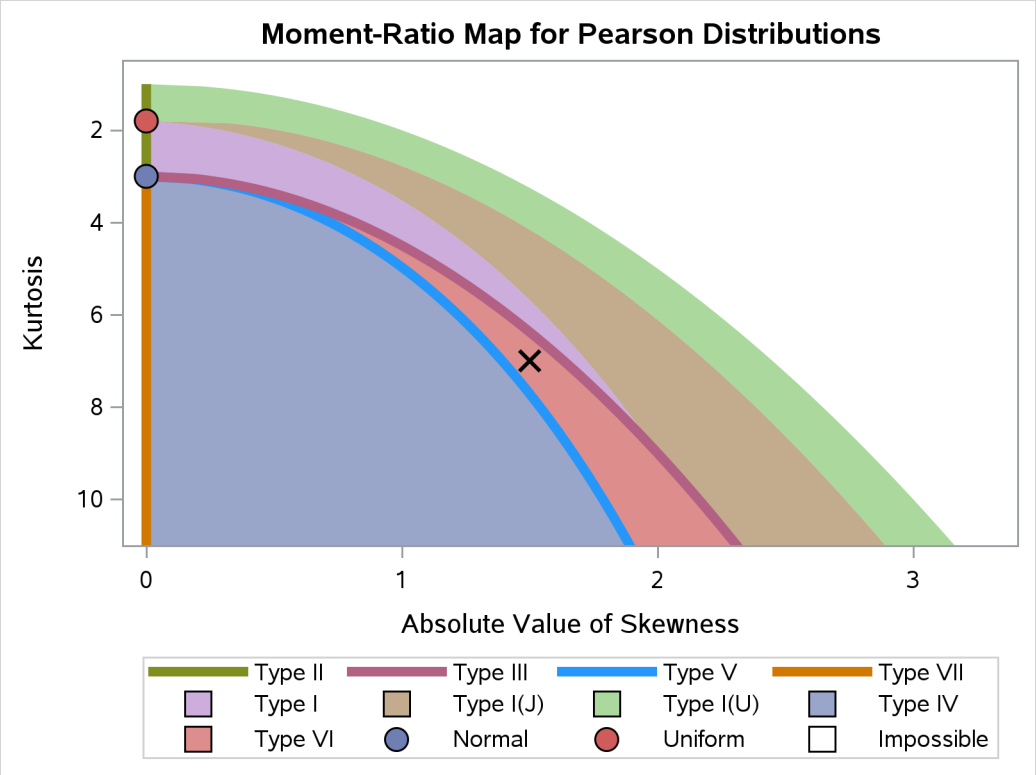
	Specified Moments				Sample Moments			
	Mean	Std Dev	Skewness	Kurtosis	Mean	Std Dev	Skewness	Kurtosis
1	0	1	1.500	7	0.0029	0.980	0.977	3.515

The SIMSYSTEM procedure determines the unique distribution in the Pearson system that has the specified skewness, kurtosis, mean, and standard deviation. Distributions in the Pearson system are classified into families, also referred to as Pearson types, which are designated by Roman numerals; see "Pearson System of Distributions" on page 1600. The procedure determines both the Pearson type and the mathematical parameters for the distribution, as displayed by the Parameters for Pearson Distributions table in Figure 31.1. The specified moments and the sample moments for the simulated values are displayed in the Distribution Moments table.

As shown in Figure 31.1, the Pearson distribution determined by the procedure belongs to the Type VI family, which corresponds to a shifted and scaled F distribution with 6.777 and 38 degrees of freedom; see "Pearson Type VI Family" on page 1604. Because the sample size is relatively small, the sample skewness and especially the sample kurtosis in the Distribution Moments table are not all that close to the specified values.

In addition to these tables, if ODS Graphics is enabled, PROC SIMSYSTEM displays a graphical map of the Pearson system of distributions in which the specified distribution is marked. The procedure also displays the theoretical density for the distribution and a histogram for the 100 sampled values. These plots are shown in Figure 31.2 and Figure 31.3.

Figure 31.2 Pearson Distributions



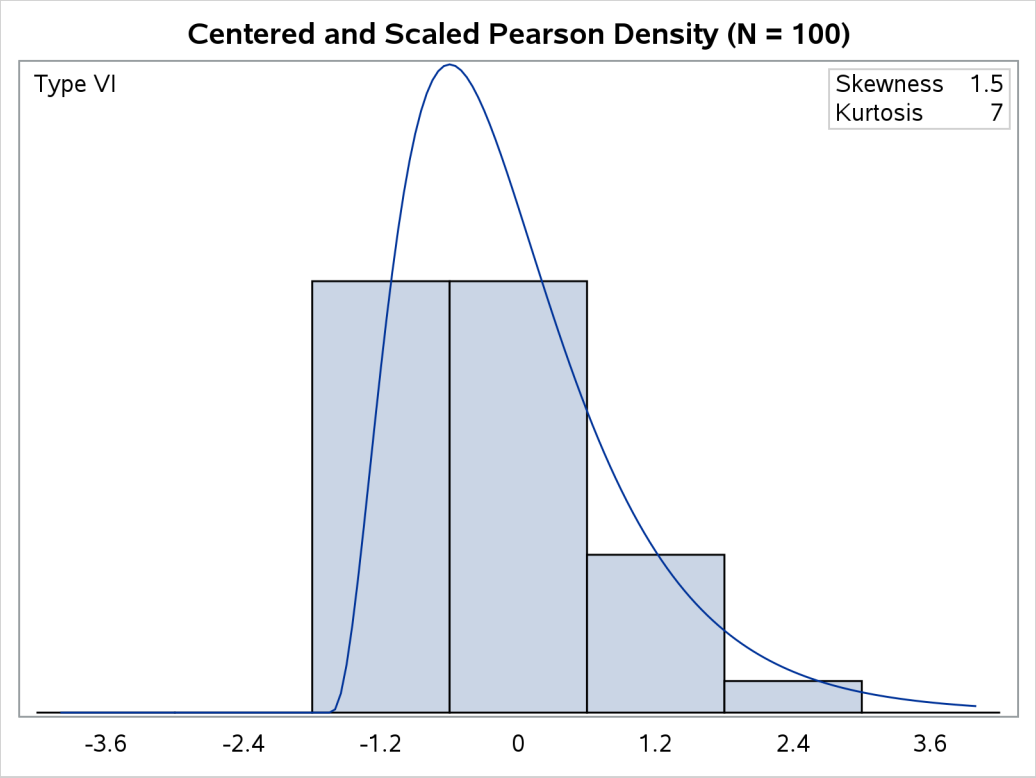


Figure 31.3 Density of Selected Distribution and Histogram of Simulated Values

To carry out an F test with the simulated data, you can create a categorical variable (named A) that randomly groups the measurements by operator and run PROC REGSELECT, as follows:

```
data mylib.sim; set mylib.sim;
   a = mod(iObs-1,5)+1;
   y = variate;
run;

proc regselect data=mylib.sim;
   class a;
   model y = a;
run;
```

Because all the measurements come from a distribution with the same mean, you expect that the F test will fail to reject the hypothesis of no operator effect. Figure 31.4 shows that this is what you get.

Figure 31.4 ANOVA F Test on Data from Distribution with Skewness=1.5 and Kurtosis=7

The REGSELECT Procedure

Analysis of Variance

Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	3.18986	0.79746	0.82	0.5132
Error	95	91.96079	0.96801		
Corrected Total	99	95.15065			

However, one F test does not say anything about the general characteristics of ANOVA on such data. One way to explore this is to generate many replicates of such null data and see how often the F test is rejected. In addition, because you cannot be certain that the distribution of the functional parameter has a precise skewness of 1.5 and a kurtosis of 7, you need to study how well ANOVA works for a variety of skewness-kurtosis combinations.

For a valid analysis of variance, the F test on null data should be rejected about 5% of the time at the 0.05 level, and likewise 1% and 10% of the time at the 0.01 and 0.10 levels, respectively. The following code checks this by using PROC SIMSYSTEM with the NREP= option to generate 1,000 samples of size 100, and by using multiple skewness and kurtosis pairs in the MOMENTS statement to draw these samples from a selection of six Pearson distributions whose skewness ranges from 0 to 1.5 and whose kurtosis ranges from 3 to 7.

```
proc simsystem system=pearson n=100 seed=12345 nrep=1000;
   moments skewness = 0 0 0.75 0.75 0.75 1.5
           kurtosis = 3 5 3    5    7    7  ;
   output out=mylib.sim;
run;
```

The Parameters table in Figure 31.5 displays the Pearson family types and parameters determined by the procedure for these six distributions. The first distribution is the standard normal distribution, which is the Pearson distribution with a skewness of 0 and a kurtosis of 3. The second distribution is a Pearson Type VII distribution, also known as a t distribution, with 7 degrees of freedom; see "Pearson Type VII Family" on page 1605. The third distribution is a Pearson Type I distribution, also known as a beta distribution, with shape parameters 1.342 and 3.769; see "Pearson Type I Family" on page 1601. The fourth and fifth distributions are Pearson Type IV distributions, which do not correspond to any well-known family of distributions; see

"Pearson Type IV Family" on page 1603. The sixth distribution is the Pearson Type VI distribution, also known as an *F* distribution, that was determined at the beginning of this example; see "Pearson Type VI Family" on page 1604.

For each of these distributions, the Distribution Moments table in Figure 31.5 displays the specified moments and the sample moments averaged over the 1,000 replicate samples.

Figure 31.6 locates the specified skewness-kurtosis combinations for the six distributions in a moment-ratio map of the Pearson system. Figure 31.7 shows the shapes of the six corresponding density functions.

Figure 31.5 Parameters and Average Moments for 1,000 Samples

The SIMSYSTEM Procedure

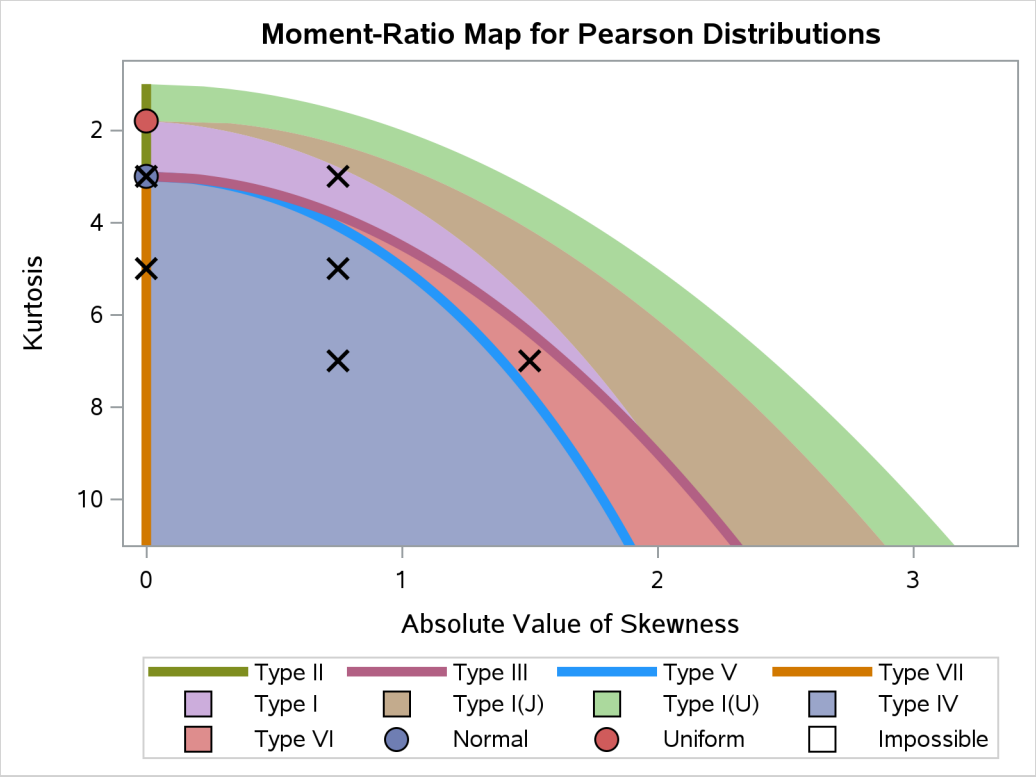
5	0	1	0.750	7	-0.006	0.992	0.568	5.252
6	0	1	1.500	7	-0.001	0.989	1.330	5.722

Figure 31.6 Selected Pearson Distributions



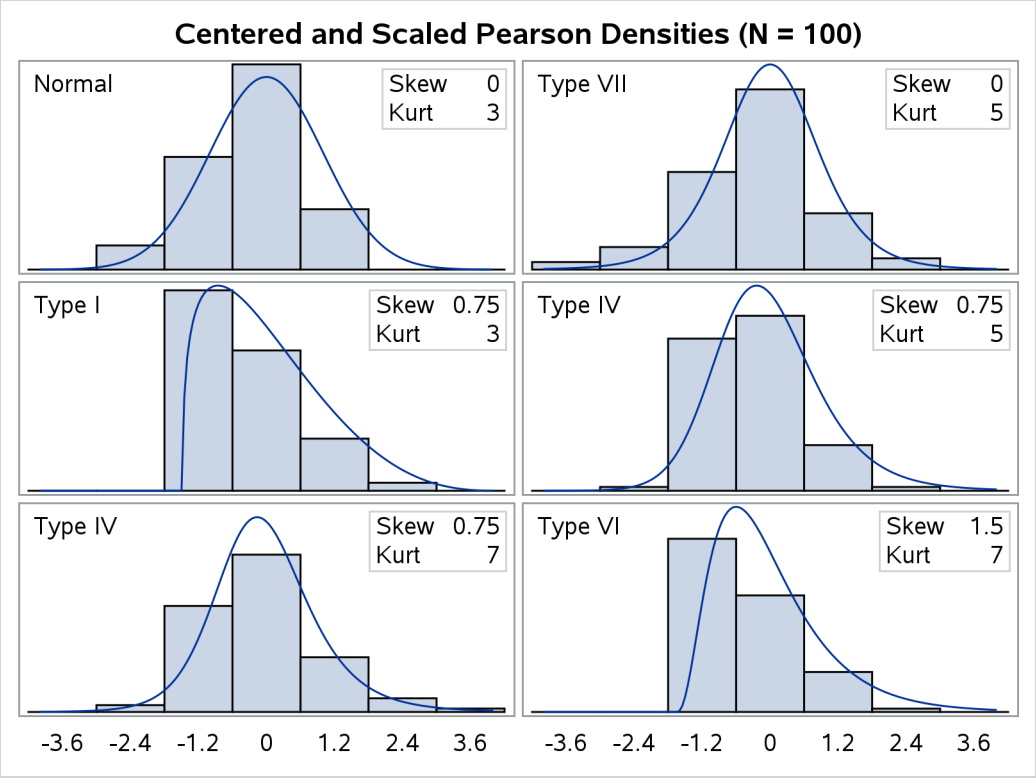


Figure 31.7 Densities and Histograms of Selected Pearson Distributions

Notice how the Pearson system provides all of the distribution shapes necessary to match the entire set of skewness-kurtosis combinations specified in the MOMENTS statement. This could not be accomplished with a single family of distributions.

The average sample moments in Figure 31.5 are all close to the specified values, but there are noticeable discrepancies for the standard deviation, for the skewness, and especially for the kurtosis. This is because these sample moments are biased estimates of the specified population moments, with a bias that can be rather high even for moderately large samples if the kurtosis is large.

In the following statements, the PROC REGSELECT step shown earlier is performed on each of the 1,000 samples of size 100, for each combination of skewness and kurtosis values, and the DATA step and PROC MDSUMMARY are used to compute how often the F test is rejected at the 10%, 5%, and 1% levels. The ODS SELECT NONE statement suppresses printed output for all the ANOVA analyses.

```
data mylib.sim; set mylib.sim;
   a = mod(iObs-1,5)+1;
   y = variate;
run;

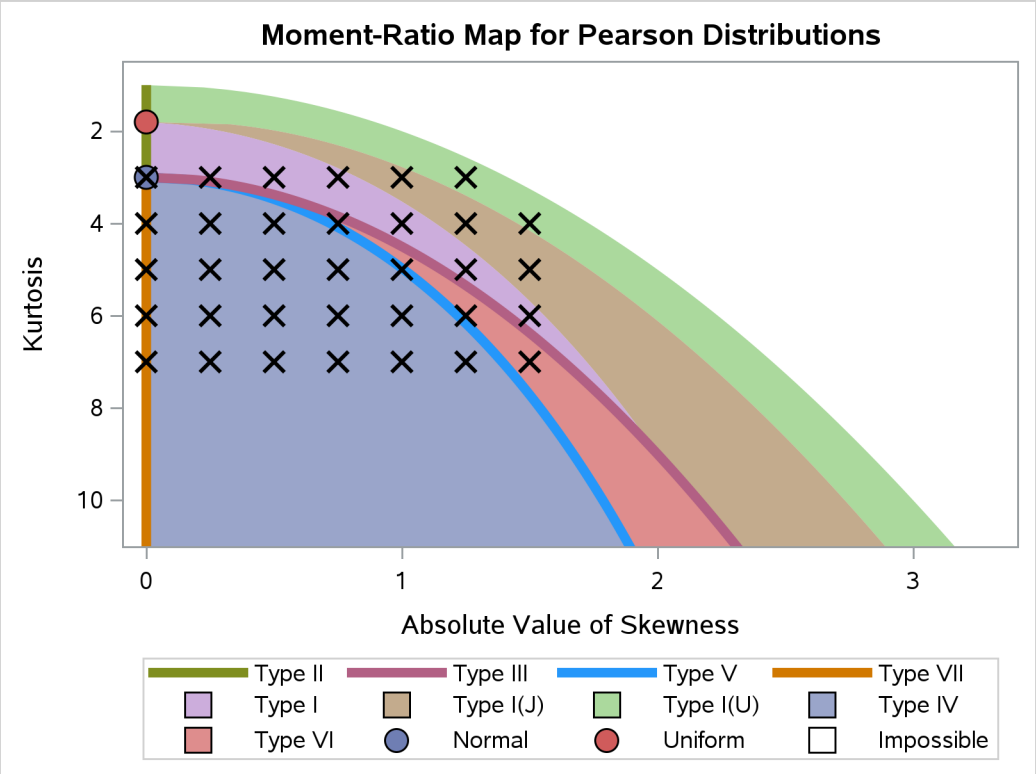
ods select none;
proc regselect data=mylib.sim;
   by Skewness Kurtosis Rep;
   class a;
   model y = a;
   displayout ANOVA=AOV;
run;
ods select all;

data mylib.AOV; set mylib.AOV;
   where (Source = "Model");
   Rej10 = (ProbF < 0.10);
   Rej05 = (ProbF < 0.05);
   Rej01 = (ProbF < 0.01);
proc mdsummary data=mylib.AOV;
   groupby Skewness Kurtosis;
   var Rej:;
   output out=mylib.AOV_summary;
proc transpose data=mylib.AOV_summary(rename=(_Column_=_Name_)) out=summary;
   by notsorted Skewness Kurtosis;
   var _Mean_;
proc sort data=summary;
   by Skewness Kurtosis;
proc print data=summary noobs;
   var Skewness Kurtosis Rej01 Rej05 Rej10;
   format Rej01 Rej05 Rej10 5.3;
run;
```

The results, shown in Figure 31.8, indicate that the simulated rejection rates are reasonably close to the nominal levels over the entire set of skewness-kurtosis combinations. The conclusion is that you can be confident in using ANOVA with these nonnormal data.

Figure 31.8 Simulated Rejection Rates for ANOVA F Test on Nonnormal Data

Skewness	Kurtosis	Rej01	Rej05	Rej10
0.00	3	0.013	0.066	0.124
0.00	5	0.005	0.050	0.101
0.75	3	0.011	0.050	0.100
0.75	5	0.009	0.051	0.105
0.75	7	0.012	0.047	0.090
1.50	7	0.009	0.039	0.098



This example demonstrates how easy it is to simulate data from a variety of distributions with a single invocation of the SIMSYSTEM procedure. In practice, you will often want to simulate data from a larger number of distributions whose moment ratios lie on an evenly spaced grid of skewness-kurtosis combinations. The MOMENTGRID statement is useful for this purpose, as shown in the following statements.

```
proc simsystem system=pearson n=100 seed=12345 nrep=1000 plot(only)=mrmap;
   momentgrid skewness = 0 to 1.5 by 0.25
              kurtosis = 3 to 7   by 1;
   output out=mylib.sim;
run;
```

When you use the MOMENTGRID statement, each value of $\sqrt{\beta_1}$ that you specify in the SKEWNESS= option is paired with all the values of β_2 that you specify in the KURTOSIS= option to form a grid of combinations of $\sqrt{\beta_1}$ and β_2.

The Pearson distributions determined by these combinations are mapped in Figure 31.9.

Figure 31.9 Selected Pearson Distributions

Although the preceding MOMENTGRID statement requests Pearson distributions for a grid of $6 \times 7 = 35$ moment ratio combinations, the combination with skewness 1.5 and kurtosis 3 is not feasible because it does not satisfy the condition $\beta_2 > 1 + \beta_1$.

In general, you can use the MOMENTGRID statement to simulate data from distributions specified by a comprehensive grid of evenly spaced combinations of skewness and kurtosis. This enables you to explore the effects of a wide variety of distributional shapes and to form conclusions that are framed in terms of skewness and kurtosis.

Syntax: SIMSYSTEM Procedure

The following statements are available in the SIMSYSTEM procedure:

PROC SIMSYSTEM < *options* > **;**
  MOMENTGRID SKEWNESS=*values* **KURTOSIS=***values* < **MEAN=***values* **STDDEV=***values* > **;**
  MOMENTS SKEWNESS=*values* **KURTOSIS=***values* < **MEAN=***values* **STDDEV=***values* > **;**
  OUTPUT OUT=*libref.data-table* < *keyword*=*name* . . . *keyword*=*name* > **;**

The following sections describe the PROC SIMSYSTEM statement and then describe the other statements in alphabetical order. You must specify the moments of the distributions to be sampled by specifying only one of the following: the DATA= option in the PROC SIMSYSTEM statement; the MOMENTGRID statement; or the MOMENTS statement. The OUTPUT statement is required if you want to save the sample in a data table.

PROC SIMSYSTEM Statement

PROC SIMSYSTEM < *options* > **;**

The PROC SIMSYSTEM statement invokes the SIMSYSTEM procedure. Table 31.1 summarizes the *options* available in the PROC SIMSYSTEM statement.

Table 31.1 PROC SIMSYSTEM Statement Options

Option	Description
CDF=	Specifies values at which to compute the cumulative probability
DATA=	Specifies an input CAS data table
MOMENTREPS	Displays moments of individual sample replicates
N=	Specifies the number of values to sample
NOPRINT	Suppresses the normal display of results
NREP=	Specifies the number of sample replicates
PDF=	Specifies values at which to compute the probability density
PLOTS	Controls the plots that are produced through ODS Graphics
QUANTILE=	Specifies quantiles of the distribution to be computed
SEED=	Specifies the seed for pseudorandom number generation
SIMPLETOL=	Specifies the tolerance value for choosing a simpler distribution
SYSTEM=	Specifies the system of distributions to sample from

You can specify the following *options*:

CDF=*values*
specifies values at which to compute the exact cumulative probability for each distribution. The computed cumulative probabilities are included as nonprinting columns in the table of distribution parameters.

DATA=*libref.data-table*
names the input data table for PROC SIMSYSTEM to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1581.

data-table specifies the name of the input data table.

This data table must contain a numeric variable named Skewness and a numeric variable named Kurtosis. The data table can also contain the following numeric variables:

- Mean, which contains the mean values of the distributions to be simulated
- StdDev, which contains the standard deviation values of the distributions to be simulated
- SimIndex, which contains simulation indexes that identify the distributions in output tables and data tables

If you specify this option, then you cannot use the MOMENTS statement or the MOMENTGRID statement.

MOMENTREPS
MREPS
displays sample moments for individual samples when multiple replicates are computed by using the NREP= option.

N=*value*
specifies the number of simulated values to compute for each distribution. By default, N=0; that is, if you omit this option, then no samples are computed.

NOPRINT
suppresses the normal display of results. This option temporarily disables the Output Delivery System (ODS).

NREP=*value*
specifies the number of sample replicates to compute for each distribution. If you specify a value larger than 1, then PROC SIMSYSTEM displays the sample moments averaged over the replicates instead of displaying the sample moments. If you still want to see the moments for individual samples, use the MOMENTREPS option.

By default, NREP=1.

PDF=*values*
specifies values at which to compute the exact probability density function for each distribution. The computed PDF values are included as nonprinting columns in the table of distribution parameters.

QUANTILE=*values*
specifies probability values at which to compute the exact quantiles for each distribution, where each of the specified *values* must be between 0 and 1, inclusive. The computed quantiles are included as nonprinting columns in the table of distribution parameters.

PLOTS <(*global-plot-options***)> <=***plot-request* **<(***options***)>>**

PLOTS <(*global-plot-options***)> <=(***plot-request* **<(***options***)> <...** *plot-request* **<(***options***)>>)>**
controls the plots produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. The following examples show a variety of ways that you can specify this option:

```
PLOTS=NONE
PLOTS=(MRMAP HISTOGRAM)
PLOTS(UNPACK)=HISTOGRAM
PLOT=MRMAP(SKEWSCALE=SQUARE)
```

ODS Graphics must be enabled before plots can be requested, as shown in the following example:

```
ods graphics on;
proc simsystem n=100 seed=12345;
   momentgrid skew=1.5 kurt=7;
   output out=mylib.sim;
run;
ods graphics off;
```

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC SIMSYSTEM produces a moment-ratio map (PLOT=MRMAP) by default and also a histogram of the centered and scaled sample values. If multiple distributions are being sampled, then the histogram for each one is displayed by default in a lattice.

You can specify the following *global-plot-options*:

ONLY
suppresses the default plots. Only plots that you specifically request are displayed.

UNPACKPANEL

UNPACK
suppresses paneling. By default, multiple histograms can appear in an output panel. Specify this option to display each plot in a separate panel.

You can specify the following individual *plot-requests* and their *plot-options*. If you specify only one *plot-request*, then you can omit the parentheses.

ALL
produces all appropriate plots. You can specify other options by using ALL; for example, to request all plots and unpack only the histogram lattices, specify PLOTS=(ALL HISTOGRAM(UNPACK)).

HISTOGRAM< (UNPACK) >
modifies the histograms of sampled values. By default, histograms of multiple distributions are displayed together in a panel. The UNPACK suboption suppresses their display in a panel and instead produces the series of individual plots that form the paneled display.

MRMAP< (INDEXLABELS) >
modifies the moment-ratio map. The specified distributions are marked on the map by using their simulation index values instead of the default marker.

MRMAP< (KURTSCALE=DIRECT | REVERSE) >
modifies the moment-ratio map. You can specify the following values for the KURTSCALE= suboption:

DIRECT displays the kurtosis values in increasing order from bottom to top.

REVERSE displays the kurtosis values in reverse order, increasing from top to bottom.

By default, KURTSCALE=REVERSE.

MRMAP< (SKEWSCALE=ABS | SKEWNESS | SQUARE) >
modifies the moment-ratio map. You can specify the following values for the SKEWSCALE= suboption:

ABS displays the absolute value of skewness.

SKEWNESS displays the skewness.

SQUARE displays the square of the skewness.

By default, SKEWSCALE=ABS.

NONE
suppresses all graphics.

SEED=*n*
specifies an integer to use to start the pseudorandom number generator for drawing samples. If you do not specify a seed or if you specify a value less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

SIMPLETOL=*n*
specifies a tolerance value to use in choosing to map input skewness and kurtosis values to those of a simpler distribution. For more information about how this value is used, see "Specifying Boundary Widths for Transition Families" on page 1610. The default value for n is 10^{-4}.

SYSTEM=PEARSON | JOHNSON
specifies the system to use to simulate data. You can specify the following values:

JOHNSON uses the Johnson system (Johnson 1949).

PEARSON uses the Pearson system (Pearson 1895, 1901, 1916).

By default, SYSTEM=PEARSON. For more information about the Johnson and Pearson systems, see "Details: SIMSYSTEM Procedure" on page 1597.

MOMENTGRID Statement

MOMENTGRID SKEWNESS=*values* **KURTOSIS=***values* < **MEAN=***values* **STDDEV=***values* > **;**

The MOMENTGRID statement specifies a grid of combinations of skewness ($\sqrt{\beta_1}$) and kurtosis (β_2) for the distributions that you want to sample. Each value of $\sqrt{\beta_1}$ that you specify in the SKEWNESS= option is paired with all the values of β_2 that you specify in the KURTOSIS= option to form a series of combinations $(\sqrt{\beta_1}, \beta_2)$. Distributions are produced and sampled for all the combinations.

The moment values that you specify should be the values that you believe might be relevant to the process that you intend to study with the simulation. They might be suggested by sample moments computed from historical data or by the shape of the corresponding distributions, as indicated by surveys such as those in "Shapes of Pearson and Johnson Density Functions" on page 1611.

The MOMENTGRID statement is recommended for situations in which you want to conduct a simulation study for a rectangular grid of moment ratio combinations, so that you can draw conclusions about the systematic effects of skewness and kurtosis. If you use the MOMENTGRID statement, then you cannot also use the MOMENTS statement or the DATA= option in the PROC SIMSYSTEM statement.

You must specify the following options:

KURTOSIS=*values*
specifies values of kurtosis, denoted by β_2. Kurtosis values must be greater than $1 + \beta_1$, where $\sqrt{\beta_1}$ is the associated value of skewness that you specify in the SKEWNESS= option.

SKEWNESS=*values*
specifies the skewness values. Any numeric value is valid in principle, although extremely heavily skewed distributions might be numerically unstable.

You can also specify the following options:

MEAN=*values*
specifies the mean values. By default, MEAN=0 for all distributions.

STDDEV=*values*
specifies the standard deviation values. By default, STDDEV=1 for all distributions.

You can specify any number of values in any of these options. The number of combinations that are defined will be the product of the number of values in each specification.

MOMENTS Statement

MOMENTS SKEWNESS=*values* **KURTOSIS=***values* < **MEAN=***values* **STDDEV=***values* > **;**

The MOMENTS statement specifies parallel lists of skewness and kurtosis for the distributions that you want to sample. Each value of $\sqrt{\beta_1}$ that you specify in the SKEWNESS= option is paired with the corresponding value of β_2 that you specify in the KURTOSIS= option to form a list of combinations $(\sqrt{\beta_1}, \beta_2)$. A distribution is produced and sampled for each combination in the list.

The moment values that you specify should be the values that you believe might be relevant to the process that you intend to study with the simulation. They might be suggested by sample moments computed from historical data or by the shape of the corresponding distributions, as indicated by surveys such as those in "Shapes of Pearson and Johnson Density Functions" on page 1611.

If you use the MOMENTS statement, then you cannot also use the MOMENTGRID statement or the DATA= option in the PROC SIMSYSTEM statement.

You must specify the following options:

KURTOSIS=*values*
specifies values of kurtosis, denoted by β_2. Kurtosis values must be greater than $1 + \beta_1$, where $\sqrt{\beta_1}$ is the associated value of skewness that you specify in the SKEWNESS= option.

SKEWNESS=*values*
specifies values of skewness, denoted by $\sqrt{\beta_1}$. Any numeric value is valid in principle, although extremely heavily skewed distributions might be numerically unstable.

You can also specify the following options:

MEAN=*values*
specifies the mean values. By default, MEAN=0 for all distributions.

STDDEV=*values*
specifies values of the standard deviation, which must be positive. By default, STDDEV=1 for all distributions.

If you specify $n > 1$ values in any of the four options (SKEWNESS=, KURTOSIS=, MEAN=, and STDDEV=), then in each of the remaining options you must specify either exactly n values or one value. The procedure will create exactly n combinations of moments by using values from each option in the order specified and by reusing single values.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *keyword*=*name* . . . *keyword*=*name* > **;**

The OUTPUT statement creates a new data table in which to save the values that are sampled from all specified distributions.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC SIMSYSTEM to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1581.

data-table specifies the name of the output data table.

You can also specify one or more of the following *keyword=name* pairs:

IOBS=*name*
assigns a *name* to the variable that indexes the observation within a replicate of the distribution being sampled.

KURT=*name*
assigns a *name* to the variable that contains the kurtosis values.

MEAN< =*name* **>**
adds the mean of the distribution being sampled to the output data table and optionally assigns a *name* to it. If you do not specify a *name*, the name Mean is used by default.

REPIDX=*name*
assigns a *name* to the variable that indexes the replicate of the distribution being sampled.

SIMIDX=*name*
assigns a *name* to the variable that indexes the distribution being sampled.

SIMVALUE=*name*
assigns a *name* to the variable that contains the sampled values.

SKEW=*name*
assigns a *name* to the variable that contains the skewness values.

STDDEV< =*name* **>**
adds the standard deviation of the distribution being sampled to the output data table and optionally assigns a *name* to it. If you do not specify a *name*, the name StdDev is used by default.

By default, the output data table contains the variables Skewness and Kurtosis, which define the distribution that is being sampled; the variable Variate, which contains the sampled values; and the variable SimIndex, which indexes the distribution being sampled. If you specify the MEAN or STDDEV keyword, the output data table also contains the mean (Mean) or standard deviation (StdDev), respectively, of the distribution being sampled.

Details: SIMSYSTEM Procedure

Moments and Moment Ratios

For a random variable X, the first moment (expected value) is denoted by

$$\mu = E[X]$$

The rth uncorrected moment (rth moment about zero) is denoted by

$$\mu'_r(X) = \mu'_r = E[X^r], \quad r = 2, 3, \ldots$$

The rth central moment (rth moment about the mean) is denoted by

$$\mu_r(X) = \mu_r = E[(X - E[X])^r], \quad r = 2, 3, \ldots$$

The central moments can be expressed in terms of the uncorrected moments. In particular,

$$\begin{aligned} \mu_2 &= \mu'_2 - \mu^2 \\ \mu_3 &= \mu'_3 - 3\mu'_2\mu + 2\mu^3 \\ \mu_4 &= \mu'_4 - 4\mu'_3\mu + 6\mu'_2\mu^2 - 3\mu^4 \end{aligned}$$

For $r = 3, 4, \ldots$, the ratio $\mu_r/\mu_2^{r/2}$ is referred to as the rth moment ratio (rth standardized moment). Moment ratios are denoted as

$$\beta_{r-2}^{(r-2)/2} = \mu_r/\mu_2^{r/2}, \quad r = 3, 4, \ldots$$

For any two constants a and b, the moment ratios for $aX + b$ are identical to the moment ratios for X. In other words, moment ratios are invariant with respect to the location and scale of a distribution. Moment ratios vary with the shape of a distribution, and for this reason they are often called shape factors.

Moment ratios do not uniquely determine the shape of a distribution (or more precisely, its density function). In fact, they do not even exist for some distributions, such as the Cauchy distribution. However, for continuous distributions whose first four moments exist, the first two moment ratios, β_1 (or $\sqrt{\beta_1}$) and β_2, are useful measures of the skewness and kurtosis.

Definitions and Interpretations of Skewness and Kurtosis

When you run the SIMSYSTEM procedure, you specify the Pearson and Johnson distributions to use for simulation by their shapes—as quantified by their measures of skewness and kurtosis—rather than by their mathematical parameters. Unfortunately, the definitions and interpretations of skewness and kurtosis are slightly inconsistent in the statistics literature and in SAS. This section explains subtle differences that you should be aware of when running the procedure and reporting your results.

In the context of the SIMSYSTEM procedure, the terms skewness and kurtosis refer to the shape characteristics of probability distributions that are used to simulate data. Elsewhere in SAS, these terms typically apply to shape characteristics of data distributions. For example, several summarization procedures, such as PROC UNIVARIATE, compute sample skewness and sample kurtosis among the descriptive statistics that they provide for univariate data.

Skewness measures the asymmetry of a distribution about its median or mean. It is important to consider various degrees of skewness when you select the distributions for a simulation study. Typically, a distribution is positively skewed (right skewed) if the tail of high values is longer than the tail of low values, and it is negatively skewed (left skewed) if the tail of low values is longer than the tail of high values.

In the statistics literature, different authors use $\sqrt{\beta_1}$ and β_1 to measure the skewness of a probability distribution. The sign of $\sqrt{\beta_1}$ can be either positive or negative, and the sign is often included with $\sqrt{\beta_1}$. This can lead to confusion, so it is important to understand and indicate which measure is being used when you are specifying or reporting values of skewness.

The SIMSYSTEM procedure consistently uses $\sqrt{\beta_1}$ as the measure for skewness in its syntax and output. Note the following points:

- You must specify values of $\sqrt{\beta_1}$ in the SKEWNESS= option in the MOMENTS and MOMENTGRID statements.
- Values of $\sqrt{\beta_1}$ are displayed in the Specified Skewness column in the parameters and moments tables.
- In moment-ratio diagrams produced by the procedure, the axis labeled "Skewness" refers to $\sqrt{\beta_1}$.

Also note that values of sample skewness in moments tables are computed using the square root version of the formula for sample skewness. The UNIVARIATE and MEANS procedures also use this version.

Kurtosis measures the heaviness of the tails of a distribution relative to that of the normal distribution. The degree of kurtosis—like the degree of skewness—is a consideration in selecting distributions for simulation.

Kurtosis is sometimes said to measure the peakedness of a distribution as opposed to its flatness. However, Westfall (2014) and other authors have pointed out that this interpretation is incorrect. Westfall makes the following distinction:

> Kurtosis tells you virtually nothing about the shape of the peak—its only unambiguous interpretation is in terms of tail extremity, that is, either existing outliers (for the sample kurtosis) or propensity to produce outliers (for the kurtosis of a probability distribution).

For additional discussion of the interpretation of kurtosis, see Darlington (1970), Moors (1986), Ruppert (1987), and Balanda and MacGillivray (1988).

In the statistics literature, different authors use β_2 and $\beta_2 - 3$ (referred to as *excess kurtosis*) to measure the kurtosis of a probability distribution. The reason for adjusting β_2 by 3 is that the kurtosis for the normal distribution is then 0, which seems like a more natural baseline for comparisons with the kurtosis of other distributions. This can lead to confusion, so it is important to understand and indicate which measure is being used when you are specifying or reporting values of kurtosis.

The SIMSYSTEM procedure consistently uses β_2 as the measure for kurtosis in its syntax and output. Note the following points:

- You must specify values of β_2 in the KURTOSIS= option in the MOMENTS and MOMENTGRID statements.
- Values of β_2 are displayed in the Specified Kurtosis column in the parameters and moments tables.
- In moment-ratio diagrams produced by the procedure, the axis labeled "Kurtosis" refers to β_2.

Also note that values of sample kurtosis in moments tables are computed using a sample estimate of β_2. In contrast, the UNIVARIATE and MEANS procedures report a sample estimate of $\beta_2 - 3$.

Moment Ratio Coverage

For any distribution whose first four moments exist, $\sqrt{\beta_1}$ and β_2 satisfy the feasibility condition

$$\beta_2 - \beta_1 - 1 \geq 0$$

Moment-ratio diagrams such as those in Figure 31.10 and Figure 31.11 represent the skewness and kurtosis values of all feasible distributions by the region of the $(\sqrt{\beta_1}, \beta_2)$ plane that lies above the curve $\beta_2 = 1 + \beta_1$. Within this region, the skewness and kurtosis values of familiar parametric families of distributions are represented by points, curves, or subregions, depending on whether the number of shape parameters for the distribution is 0, 1, or 2, respectively.

For example, consider the subregions that correspond to the normal, lognormal, and beta families. The normal distribution, which lacks a shape parameter, is represented by the point at $\sqrt{\beta_1} = 0$ and $\beta_2 = 3$. The lognormal family of distributions is represented by the parametric curve whose coordinates are

$$\begin{aligned} \sqrt{\beta_1} &= (\omega - 1)^{\frac{1}{2}}(\omega + 2) \\ \beta_2 &= \omega^4 + 2\omega^3 + 3\omega^2 - 3 \end{aligned}$$

where $\omega = \exp(\sigma^2)$ and σ is the lognormal shape parameter ($\sigma > 0$). The beta family of distributions is represented by the subregion whose coordinates are

$$\begin{aligned} \sqrt{\beta_1} &= 2(\beta - \alpha)\frac{\sqrt{\alpha^{-1} + \beta^{-1} + (\alpha\beta)^{-1}}}{\alpha + \beta + 2} \\ \beta_2 &= 3(\alpha + \beta + 1)\frac{2(\alpha + \beta)^2 + \alpha\beta(\alpha + \beta - 6)}{\alpha\beta(\alpha + \beta + 2)(\alpha + \beta + 3)} \end{aligned}$$

where α and β are the shape parameters ($\alpha > 0$ and $\beta > 0$).

Unlike families of distributions that are commonly used for simulation, the Pearson and Johnson systems of distributions completely span the feasible region of the $(\sqrt{\beta_1}, \beta_2)$ plane. For any combination of skewness and kurtosis within this region, there is exactly one distribution in each of the Pearson and Johnson systems whose values of $\sqrt{\beta_1}$ and β_2 match that combination. Furthermore, a number of familiar distributions that are used for simulation (such as the normal, lognormal, and beta) are special cases of the Pearson and Johnson systems. Consequently, simulating data from these two systems makes it possible to synthesize data that have a much broader range of distributional shapes that vary evenly and systematically. Using the SIMSYSTEM procedure, you can request a comprehensive set of shapes simply by specifying a grid of values of skewness and kurtosis, as opposed to specifying particular families and parameters.

Pearson System of Distributions

The Pearson system of continuous distributions was introduced by Karl Pearson beginning in the 1890s (Pearson 1895, 1901, 1916). For an explanation of Pearson's derivation, see Chapter 4 of Elderton and Johnson (1969) and Chapter 12 of Johnson, Kotz, and Balakrishnan (1994). Rodriguez (2006) and Ord (2006) provide overviews of the Pearson system.

Each probability density function $p(y)$ in the Pearson system is a solution of the differential equation

$$\frac{d \log p(y)}{dy} = \frac{a + y}{c_0 + c_1 y + c_2 y^2}$$

The location, scale, and shape parameters of the density function depend on the constants a, c_0, c_1, and c_2. Solving the equation for various combinations of these constants gives rise to different families of distributions, which Pearson designated by using roman numerals. As pointed out by Johnson, Kotz, and Balakrishnan (1994), this numbering scheme does not have a clear basis, but it is well established in the statistical literature.

Subsequent to Pearson's work, most families in the Pearson system were re-derived in other contexts, where they received other names that are familiar in modern statistical work. For instance, the distributions in the Pearson Type III family are now commonly known as the gamma distributions. The parameters table that is produced by the SIMSYSTEM procedure identifies each Pearson distribution used for simulation by its Pearson type and its common name (if there is one). This table also provides the location, scale, and shape parameter(s) for each distribution.

There are three main types of distributions in the Pearson system:

- the Type I family, known as beta distributions
- the Type IV family, which has no familiar counterpart
- the Type VI family, known as F distributions

Each of these three families has two shape parameters. Their regions in the $(\sqrt{\beta_1}, \beta_2)$ plane complement each other and completely cover the feasible region.

The Pearson system also includes families of distributions that are limiting forms of the main types and are referred to as transition types:

- the normal distribution (no associated type number)

- the Type II family, known as symmetric beta distributions
- the Type III family, known as gamma distributions
- the Type V family, known as inverse gamma distributions
- the Type VII family, known as Student's *t* distributions

Finally, the Pearson system also includes families of distributions that are special cases of the more important types:

- Type VIII, known as power distributions
- Type IX, known as power distributions
- Type X, known as exponential distributions
- Type XI, known as power distributions
- Type XII, a special case of Type I

These additional types are not required for defining distributions that cover the full skewness/kurtosis range, so they are not included in the PROC SIMSYSTEM results.

The following subsections provide the probability density function for each Pearson family. The parameter notation matches that of the parameters table produced by the procedure.

Pearson Normal Family

The family of normal distributions belongs to the Pearson system in the sense that it is a limiting form of each of the three main types of Pearson distributions. Pearson did not assign a roman numeral to the normal family, but it could be referred to as the "Type 0 family."

The probability density function for the normal family is

$$p(y) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2}\left(\frac{y-\mu}{\sigma}\right)^2\right], \quad \sigma > 0$$

For normal distributions, $\sqrt{\beta_1} = 0$ and $\beta_2 = 3$.

Pearson Type I Family

Pearson Type I probability density functions are obtained as solutions to Pearson's differential equation when the roots of $c_0 + c_1 y + c_2 y^2 = 0$ are real and have opposite signs.

The Type I family is composed of the beta distributions, whose probability density functions are of the form

$$p(y) = \frac{1}{B(\alpha, \beta)} \frac{(y-a)^{\alpha-1}(b-y)^{\beta-1}}{(b-a)^{\alpha+\beta-1}}, \quad a \le y \le b$$

where a is the location parameter, $b - a$ is the scale parameter, and α and β are shape parameters ($\alpha > 0$ and $\beta > 0$). The range of the distribution is bounded below by a and above by b.

The standard form of the beta distribution is obtained by setting $a = 0$ and $b = 1$, and the standard beta density function is

$$p(y) = \frac{1}{B(\alpha, \beta)} y^{\alpha-1}(1-y)^{\beta-1}, \quad 0 \le y \le 1$$

Beta density functions come in a variety of shapes:

- unimodal (bell-shaped) when $\alpha > 1$ and $\beta > 1$
- unimodal and symmetric when $\alpha > 1$, $\beta > 1$, and $\alpha = \beta$
- rectangular when $\alpha = \beta = 1$ (uniform distributions)
- bimodal (U-shaped) when $\alpha < 1$ and $\beta < 1$
- U-shaped and symmetric when $\alpha < 1$, $\beta < 1$, and $\alpha = \beta$
- J-shaped or reverse J-shaped when $(\alpha - 1)(\beta - 1)$ is not positive

For more information about beta distributions, see Chapter 25 of Johnson, Kotz, and Balakrishnan (1995).

Pearson Type II Family

The Pearson Type II family is a limiting form of the Type I family. It is composed of the symmetric beta distributions, which have identical shape parameters $\alpha = \beta$, and its probability density functions are of the general form

$$p(y) = \frac{1}{B(\alpha, \alpha)} \frac{(y-a)^{\alpha-1}(b-y)^{\alpha-1}}{(b-a)^{2\alpha-1}}, \quad a \le y \le b$$

where a is the location parameter, $b - a$ is the scale parameter, and $\alpha > 0$. The range of the distribution is bounded below by a and above by b.

Setting $a = -1$ and $b = 1$ gives the particular form

$$p(y) = \frac{1}{B(\alpha, \alpha)} \frac{(1+y)^{\alpha-1}(1-y)^{\alpha-1}}{2^{2\alpha-1}}, \quad -1 \le y \le 1$$

which can be rewritten as

$$p(y) = \frac{1}{B(\alpha, \alpha)} \frac{\left(1-y^2\right)^{\alpha-1}}{2^{2\alpha-1}}, \quad -1 \le y \le 1$$

Some references present this as the standard form of the Type II density function.

For distributions in the Type II family, $\sqrt{\beta_1} = 0$ and $\beta_2 < 3$. The uniform distribution is a special case of the Type II family.

Pearson Type III Family

The Pearson Type III family is composed of the gamma distributions, whose probability density functions are of the form

$$p(y) = \frac{[(y-\xi)/\lambda]^{\alpha-1} \exp[-(y-\xi)/\lambda]}{\lambda\Gamma(\alpha)}, \quad y > \xi$$

where ξ is the location parameter, λ is the scale parameter, and α is the shape parameter ($\alpha > 0$). The range of the distribution is bounded below by ξ.

For distributions in the Type III family,

$$2\beta_2 - 3\beta_1 - 6 = 0$$

The standard form of the gamma distribution is obtained by setting $\xi = 0$ and $\lambda = 1$:

$$p(y) = \frac{y^{\alpha-1} \exp(-y)}{\Gamma(\alpha)}, \quad y > 0$$

Gamma density functions come in a variety of shapes:

- unimodal (bell-shaped) when $\alpha > 1$
- reverse J-shaped and finite at $y = 0$ when $\alpha = 1$ (exponential distributions)
- reverse J-shaped and tending to infinity as y tends to 0

Within the gamma family, three subfamilies are particularly well-known by other names:

- Gamma distributions where $\alpha = 1$ are referred to as exponential distributions and form the Pearson Type X family.
- Gamma distributions for which α is an integer are referred to as Erlang distributions.
- Standard gamma distributions where $\lambda = 2$ and $\alpha = \nu/2$ for $\nu > 0$ are referred to as chi-square distributions with ν degrees of freedom.

For more information about gamma distributions, see Chapter 17 of Johnson, Kotz, and Balakrishnan (1994).

Pearson Type IV Family

Pearson Type IV probability density functions are obtained as solutions to Pearson's differential equation when the roots of $c_0 + c_1 y + c_2 y^2 = 0$ are complex.

The Pearson Type IV family is composed of distributions whose probability density functions are of the form

$$p(y) = K\left(1 + \left(\frac{y-\xi}{\lambda}\right)^2\right)^{-m} \exp\left(-\nu \tan^{-1}\left(\frac{y-\xi}{\lambda}\right)\right), \quad -\infty < y < \infty$$

where ξ is the location parameter, λ is the scale parameter, m and ν are shape parameters ($m > 5/2$), and K is the constant of integration.

Elderton and Johnson (1969, pp. 58–66) explain how to compute K and the parameters given μ, μ_2, $\sqrt{\beta_1}$, and β_2. Johnson, Kotz, and Balakrishnan (1994, pp. 18–19) note that integrating the expression for $p(y)$ to obtain the cumulative distribution function leads to intractable mathematics. The SIMSYSTEM procedure uses specialized numerical techniques to compute K, the distribution function, and the corresponding quantile function.

Type IV distributions are unimodal and bell-shaped. No common statistical distributions are of the Type IV form.

Pearson Type V Family

Pearson Type V probability density functions are obtained as solutions to Pearson's differential equation when $c_1^2 = 4c_0c_2$.

The Pearson Type V family includes the inverse gamma distributions, whose probability density functions are of the form

$$p(y) = \frac{\lambda^\alpha}{\Gamma(\alpha)} \left(\frac{y-\xi}{\lambda}\right)^{-\alpha-1} \exp\left(-\left(\frac{y-\xi}{\lambda}\right)^{-1}\right), \quad y > \xi$$

where ξ is the location parameter, λ is the scale parameter ($\lambda > 0$), and α is the shape parameter ($\alpha > 0$). Inverse gamma densities are unimodal and either bell-shaped or skewed.

The Type V family is a transition family; its values of skewness and kurtosis lie on a curve in the $(\sqrt{\beta_1}, \beta_2)$ plane that separates the regions of the Type IV and Type VI families. The equation for this curve is

$$\beta_1 (\beta_2 + 3)^2 = 4 (4\beta_2 - 3\beta_1) (2\beta_2 - 3\beta_1 - 6)$$

Pearson Type VI Family

Pearson Type VI probability density functions are obtained as solutions to Pearson's differential equation when the roots of $c_0 + c_1 y + c_2 y^2 = 0$ are real and have the same sign. If the roots a_1 and a_2 are both negative and $a_1 < a_2 < 0$, then the densities have the general form

$$p(y) = K(y - a_1)^{m_1} (y - a_2)^{m_2}$$

where K is a constant of integration, $m_2 < -1$, and $m_1 + m_2 < 0$. For more information, see Johnson, Kotz, and Balakrishnan (1994, chap. 12).

Pearson Type VI probability density functions can be expressed as

$$p(y) = \frac{1}{B(\nu_1/2, \nu_2/2)} \frac{\left(\frac{y-\xi}{\lambda}\right)^{(\nu_1/2)-1}}{\left(1 + \frac{y-\xi}{\lambda}\right)^{(\nu_1+\nu_2)/2}}, \quad y > \xi$$

where ξ is the location parameter, λ is the scale parameter ($\lambda > 0$), and ν_1 and ν_2 are shape parameters ($\nu_1 > 0$, $\nu_2 > 0$). For $\xi = 0$ and $\lambda = 1$, this reduces to the standard form

$$p_G(y) = \frac{1}{B(\nu_1/2, \nu_2/2)} \frac{y^{(\nu_1/2)-1}}{1 + y^{(\nu_1+\nu_2)/2}}, \quad y > 0$$

which is the density function of $G = X_1/X_2$, the ratio of two independent variables X_1 and X_2 with chi-square distributions whose degrees of freedom are ν_1 and ν_2, respectively (Johnson, Kotz, and Balakrishnan 1995, chap. 27). Pearson Type VI distributions are also known as beta distributions of the second kind (Johnson, Kotz, and Balakrishnan 1995, chap. 25).

Pearson Type VI distributions are closely related to F distributions (Johnson, Kotz, and Balakrishnan 1995, chap. 27). The ratio

$$F = \frac{X_1/\nu_1}{X_2/\nu_2}$$

has the F distribution with degrees of freedom ν_1 and ν_2. The density function of F is

$$p_F(y) = \frac{(\nu_1/\nu_2)^{\nu_1/2}}{B(\nu_1/2, \nu_2/2)} \frac{y^{(\nu_1/2)-1}}{(1+\nu_1 y/\nu_2)^{(\nu_1+\nu_2)/2}}, \quad y > 0$$

Pearson Type VII Family

Pearson Type VII probability density functions are obtained as solutions to Pearson's differential equation when $c_1 = a = 0$, $c_0 > 0$, and $c_2 > 0$.

Pearson Type VII densities have the general form

$$p(y) = K(c_0 + c_2 y^2)^{-1/(2c_2)}$$

where K is a constant of integration.

For distributions in the Type VII family, $\sqrt{\beta_1} = 0$ and $\beta_2 > 3$.

Pearson Type VII distributions are closely related to Student's t distributions, which have the form

$$p_{t_\nu}(y) = \frac{\Gamma\left((\nu+1)/2\right)}{\Gamma(\nu/2)} \left(1 + \frac{y^2)}{2}\right)^{-(\nu+1)/2} \qquad y > 0$$

Note that ν must be positive but does not need to be an integer. The t distributions have skewness $\sqrt{\beta_1} = 0$ and kurtosis $\beta_2 = 3(\nu-2)/(\nu-4)$, which exist if $\nu > 4$. For more information about the t family, see Johnson, Kotz, and Balakrishnan (1995, chap. 28) .

Parameter Values for Pearson Distributions

The purpose of this subsection is to explain how parameter values that the SIMSYSTEM procedure computes for the well-known distributions that underlie most of the Pearson system are related to the parameters used by the other functions in SAS to work with these distributions. These distributions are special cases of the Pearson system, and they are identified in the parameters table when the combination of skewness and kurtosis specified matches the theoretical skewness and kurtosis for these cases. The tables that are provided are helpful for understanding what the procedure is computing in each particular case, and they are also helpful if you want to reuse parameter values from the procedure to compute your own simulations in DATA step code by using the RAND function.

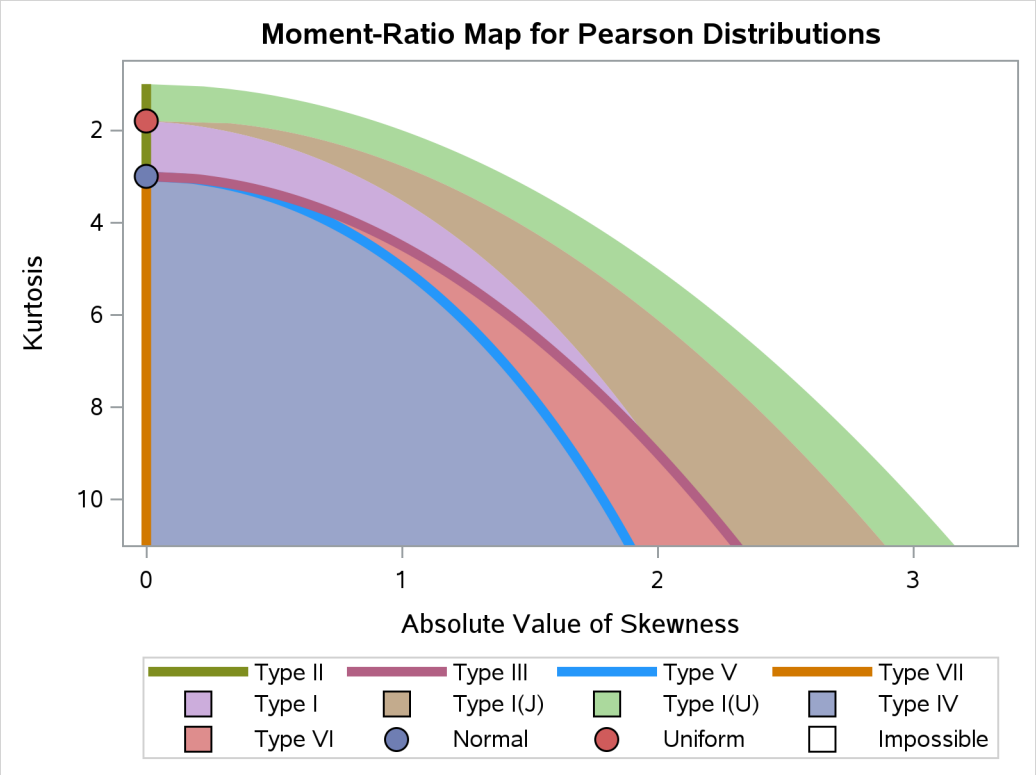
Table 31.2 summarizes the Pearson types, their corresponding standard distributions, and the mathematical form of the density for these standard distributions in terms of the parameters displayed in the "Parameters for Pearson Distributions" table. In Table 31.2, $\Gamma(\alpha)$ denotes the gamma function, and $B(\alpha, \beta) = \Gamma(\alpha)\Gamma(\beta)/\Gamma(\alpha+\beta)$ denotes the beta function. The one exception is Type IV, which is essentially a skewed version of Student's t distribution. There is no closed form for the constant C in the Type IV density; internally, it is computed by using specialized methods.

Table 31.2 Pearson Distributions for $y = (x - \xi)/\lambda$

Type	Standard Distribution	Probability Density Function	Constant C
Type I	Beta(α,β)	$Cy^{\alpha-1}(1-y)^{\beta-1}$	$1/B(\alpha,\beta)$
Type II	Beta(α,α)	$Cy^{\alpha-1}(1-y)^{\alpha-1}$	$1/B(\alpha,\alpha)$
Type III	Gamma(α)	$Cy^{\alpha-1}\exp(-y)$	$1/\Gamma(\alpha)$
Type IV		$C(1+y^2)^{-m}\exp(-\alpha\tan^{-1}(y))$	No closed form
Type V	Inverse gamma(α)	$C(1/y)^{\alpha+1}\exp(-1/y)$	$1/\Gamma(\alpha)$
Type VI	F_{d_1,d_2}	$Cy^{d_1/2-1}(d_2+d_1y)^{-(d_1+d_2)/2}$	$d_1^{d_1/2}d_2^{d_2/2}/B(d_1/2,d_2/2))$
Type VII	Student's t_d	$C(1+y^2/d)^{(d+1)/2}$	$\sqrt{d}\,B(d/2,1/2)$

The precise numeric values of these parameters are available as hidden columns named Shap1Val and Shap2Val in the underlying ODS object for this table. For illustration, Table 31.3 shows DATA step code that is equivalent to how PROC SIMSYSTEM generates random variates for these distributions, after it determines the appropriate values of these shape parameters.

Table 31.3 Pearson Sampling for $y = (x - \xi)/\lambda$



Type	Standard Distribution	Standard Random Variate
Type I	Beta(α,β)	`rand('beta',Shap1Val,Shap2Val)`
Type II	Beta(α,α)	`rand('beta',Shap1Val,Shap1Val)`
Type III	Gamma(α)	`rand('gamma',Shap1Val)`
Type IV		
Type V	Inverse gamma(α)	`1/rand('gamma',Shap1Val)`
Type VI	F_{d_1,d_2}	`rand('f',Shap1Val,Shap2Val)`
Type VII	Student's t_d	`rand('t',Shap1Val)`

Again, the standard random variate for the Type IV distribution is blank because there is no standard distribution that corresponds to this type.

In order to achieve the specified mean and standard deviation, the argument for these standard distributions is further shifted by a value ξ and scaled by a value λ; these values are displayed as the Shift and Scale columns in the "Parameters for Pearson Distributions" table. If the specified value of skewness is negative, then internally, the procedure solves for a distribution that has a mean and skewness of the opposite sign, and it adjusts the sign of ξ and λ values to produce a distribution that has the specified moments.

The manner in which the distributions in the Pearson system partition the space of possible skewness/kurtosis values is shown in Figure 31.10.

Figure 31.10 Pearson Distributions

Johnson System of Distributions

The Johnson system of continuous distributions was introduced in 1949 by Norman L. Johnson, who referred to it as the translation system (Johnson 1949). Johnson derived the system by constructing a set of transformations (translations) to normality. For more information about the derivation, see Chapter 7 of Elderton and Johnson (1969) and Chapter 12 of Johnson, Kotz, and Balakrishnan (1994). Rodriguez (2006) and Bowman and Shenton (2006) provide overviews of the Johnson system.

There are four families of distributions in the Johnson system, each corresponding to a transformation $f(X)$ of a random variable X such that

$$Z = \gamma + \delta f\left(\left(Y - \xi\right)/\lambda\right)$$

has a standard normal distribution.

- The S_N family is generated by the identity transformation $f(X) = X$ and is simply the family of normal distributions with mean ξ and standard deviation λ.
- The S_L family is generated by the transformation

  $$f(X) = \log\left(X\right)$$

  and is the family of lognormal distributions with the shape parameter $1/\delta$.

- The S_B family is generated by the transformation

$$f(X) = \log\left(X + \sqrt{1 + X^2}\right) = \sinh^{-1}(X)$$

and has the shape parameters γ and δ.

- The S_U family is generated by the transformation

$$f(X) = \log\left(\frac{X}{1 - X}\right)$$

and has the shape parameters γ and δ.

Johnson S_N Family

The probability density function for the S_N family, which consists of the normal distributions, is

$$p(y) = \frac{1}{\sqrt{2\pi}\lambda} \exp\left[-\frac{1}{2}\left(\frac{y - \xi}{\lambda}\right)^2\right], \quad -\infty < y < \infty$$

where $\lambda > 0$.

For S_N distributions, $\sqrt{\beta_1} = 0$ and $\beta_2 = 3$.

Johnson S_L Family

The probability density function of the S_L family is

$$p(y) = \frac{\delta}{(y - \xi)\sqrt{2\pi}} \exp\left(-\left(\gamma + \delta \log(y - \xi)\right)^2 / 2\right), \quad y > \xi$$

Johnson S_U Family

The probability density function of the S_U family is

$$p(y) = \frac{\delta}{\lambda\sqrt{2\pi}\sqrt{1 + ((y - \xi)/\lambda)^2}} \exp\left(-\frac{1}{2}\left(\gamma + \delta \sinh^{-1}\left(\frac{y - \xi}{\lambda}\right)\right)^2\right), \quad -\infty < y < \infty$$

Johnson S_B Family

The probability density function of the S_B family is

$$p(y) = \frac{\delta\lambda}{\sqrt{2\pi}\,(y - \xi)\,(\xi + \lambda - y)} \exp\left(-\frac{1}{2}\left(\gamma + \delta \log\left(\frac{y - \xi}{\xi + \lambda - y}\right)\right)^2\right), \quad \xi < y < \xi + \lambda$$

The S_B distribution is bounded below by the parameter ξ and above by the value $\xi + \lambda$.

Parameter Values for Johnson Distributions

The purpose of this section is to explain in detail how parameter values and transformation families that the procedure computes for the Johnson system can be used to transform the normal distribution into variates that have the specified moments. The tables that are provided are helpful for understanding what the procedure is computing in each particular case, and they are also helpful if you want to reuse parameter values from the procedure to compute your own simulations in DATA step code by using the RAND function.

The density functions for the Johnson distributions are shown in Table 31.4. As indicated, the SB and SU types (which PROC SIMSYSTEM uses to denote the S_B and S_U families) do not correspond to any familiar distribution.

Table 31.4 Johnson Distributions for $y = (x - \xi)/\lambda$

Type	Standard Distribution	Probability Density Function
SB		$(\delta/\sqrt{2\pi})\exp(-(\gamma + \delta\log(y/(1-y))/2)^2)/(y(1-y))$
SL	Lognormal	$(\delta/\sqrt{2\pi})\exp(-(\gamma + \delta\log(y)/2)^2)/y$
SU		$(\delta/\sqrt{2\pi})\exp(-(\gamma + \delta\sinh^{-1}(y)/2)^2)/\sqrt{1+y^2}$

PROC SIMSYSTEM displays the specific δ and γ parameter values for achieving the values of skewness and kurtosis that you specify in the "Parameters for Johnson Distributions" table. For illustration, Table 31.5 shows DATA step code that is equivalent to how PROC SIMSYSTEM generates random variates for these distributions, after it determines the appropriate values of δ and γ.

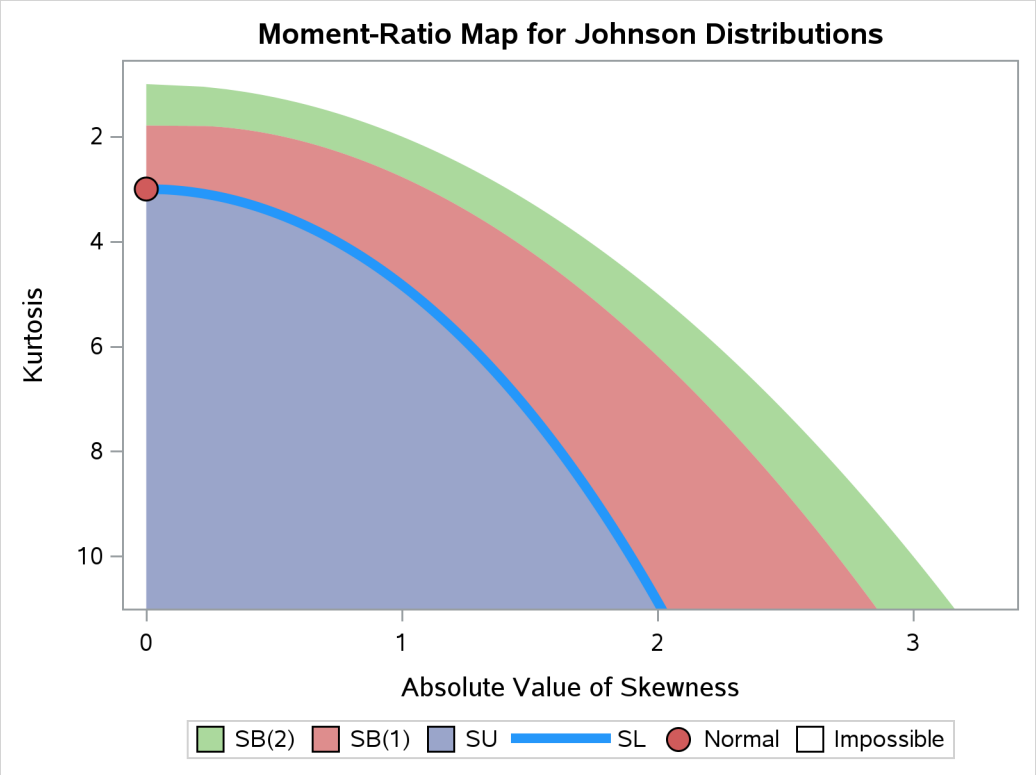


Table 31.5 Johnson Sampling for $y = (x - \xi)/\lambda$

Type	Standard Random Variate
SB	`1/(1 + exp(-(rand('Normal') - Gamma)/Delta))`
SL	`exp(rand('Normal')/Delta)`
SU	`sinh((rand('Normal') - Gamma)/Delta)`

In order to achieve the specified mean and standard deviation, the results of the computations in Table 31.5 are further scaled by a value λ and shifted by a value ξ; these values are displayed as the Shift and Scale columns in the "Parameters for Johnson Distributions" table. If the specified value of skewness is negative, then internally, the procedure solves for a distribution that has a mean and skewness of the opposite sign, and it adjusts the sign of ξ and λ to produce a distribution that has the specified moments.

The way that the distributions in the Johnson system partition the space of possible skewness/kurtosis values is shown in Figure 31.11.

Figure 31.11 Johnson Distributions

Specifying Boundary Widths for Transition Families

Most distributions in both the Pearson and Johnson systems have two parameters on which the skewness and kurtosis depend. The nature of these two parameters depends on the particular distribution family. However, the distributions on the boundaries between the skewness/kurtosis regions of different families can be characterized in a simpler fashion, using only a single parameter. These simpler families are as follows:

- Pearson Type V, between Pearson Types IV and VI
- Pearson Type III, between Pearson Types VI and I
- Johnson SL, between Johnson SB and Johnson SU

Moreover, near these boundaries, the underlying distributional parameters for the more complicated families can grow without bound and calculations can be unstable.

For these reasons, when you specify skewness and kurtosis values that are within a certain tolerance τ of one of these boundaries, PROC SIMSYSTEM generates and samples from a nearby distribution that is actually on the boundary. By default, $\tau = 10^{-4}$; you can adjust this value by using the SIMPLETOL= option in the PROC SIMSYSTEM statement.

Shapes of Pearson and Johnson Density Functions

This section discusses the variety of distribution shapes that both the Pearson and Johnson systems can cover. Figure 31.12 shows the shapes of selected distributions with a skewness of 0, for which the distributions in both systems are symmetric. Pearson distributions move smoothly from the limiting case of a fair-coin binary at a kurtosis of 1, through uniform at kurtosis 1.8 and normal at kurtosis 3, to t distributions with DF $\rightarrow 4$ as the kurtosis goes to ∞. Johnson distributions look similar, but they do not have precisely the same shapes as the familiar distributions in the Pearson system.

Figure 31.12 Centered and Scaled Densities for Skewness 0

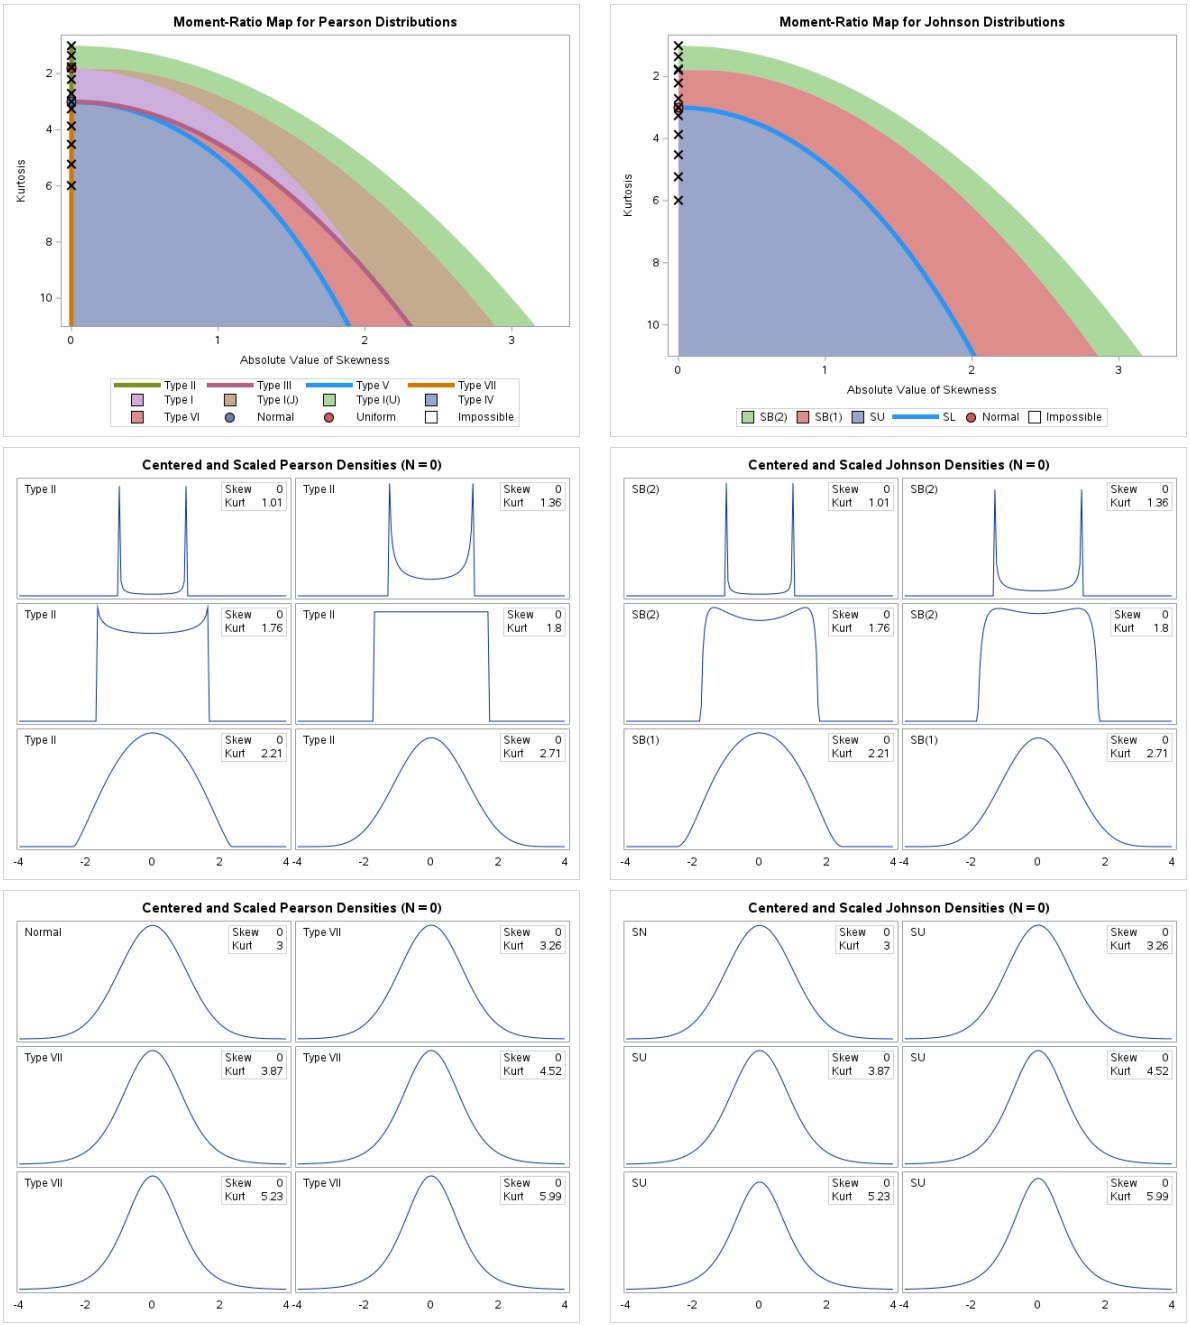

Figure 31.13 shows the shapes of selected distributions with skewness 1. When skewness is nonzero, the shapes in Figure 31.12 are all tilted to the left. For both systems, the fair-coin binary becomes the distribution of a biased coin flip, the uniform becomes approximately a triangular distribution, and for larger kurtosis you essentially get skewed t distributions.

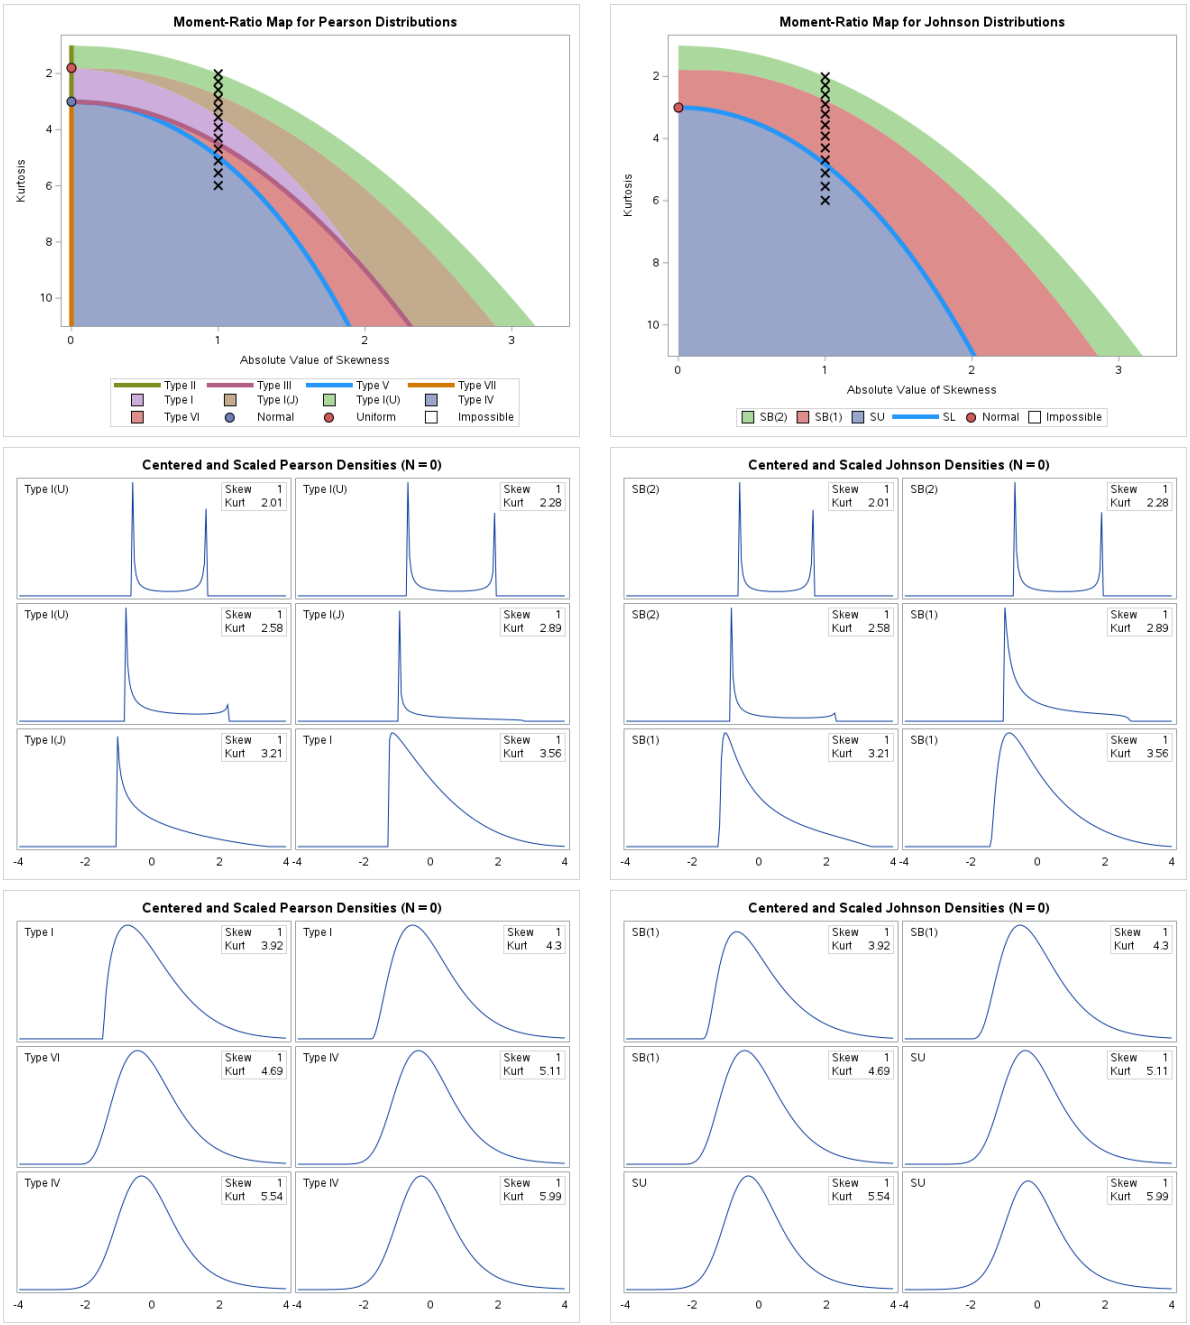
Figure 31.13 Centered and Scaled Densities for Skewness 1



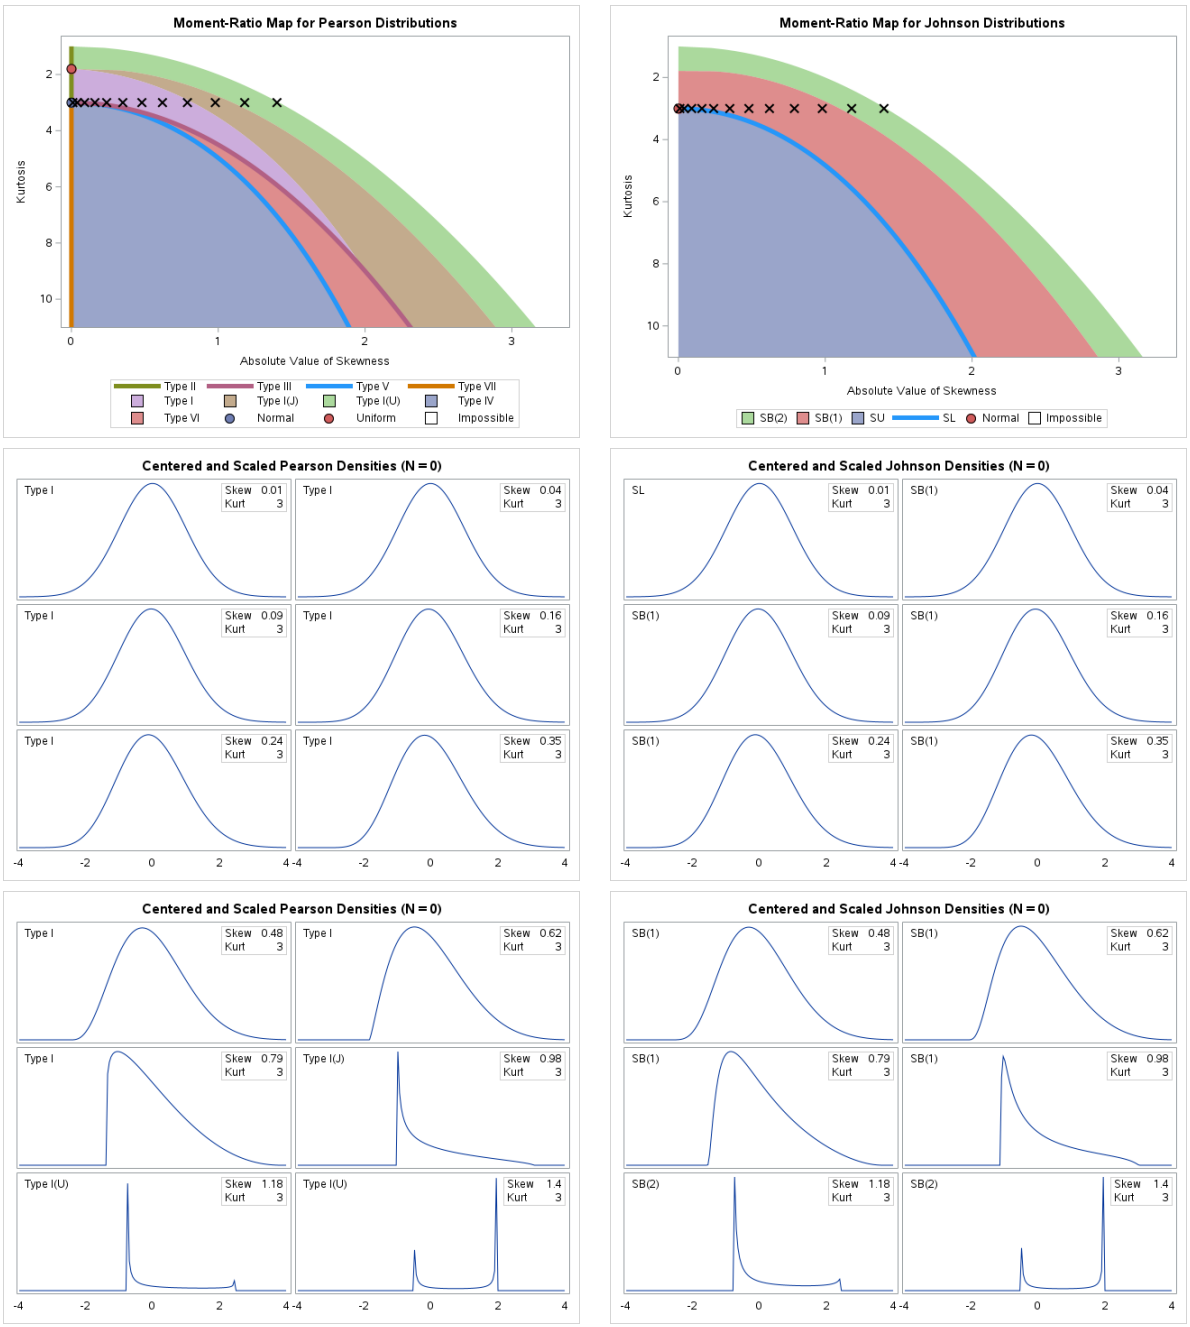


Figure 31.14 shows the shapes of selected distributions with kurtosis 3. At skewness 0, you get the normal distribution for both the Pearson and Johnson systems. As skewness increases to its maximum value of $\sqrt{3-1} \sim 1.4$, the distributions tilt more and more to the left, until they again approximate an unfair-coin binary.

Figure 31.14 Centered and Scaled Densities for Kurtosis 3

Output Data Table

The OUTPUT statement produces a CAS data table that contains simulated values from distributions in the specified system that have the specified moments. The data table contains the following variables:

- SimIndex, a numerical index for the distribution being sampled. You can use the SIMIDX= option in the OUTPUT statement to change the name of this variable.
- Rep, a numerical index for a replicate of the distribution being sampled. This variable is included in the data table only when you specify the NREP= option in the PROC statement. You can use the REPIDX= option in the OUTPUT statement to change the name of this variable.
- iObs, the observation number of a simulated value within the distribution being sampled. If you specify the NREP= option in the PROC statement, this is the number of an observation within a replicate of the distribution. You can use the IOBS= option in the OUTPUT statement to change the name of this variable.
- Mean, the mean value for the distribution being sampled. This variable is included in the output data table only when one or more of the following conditions is true:
  - The MEAN= option is specified in a MOMENTS or MOMENTGRID statement.
  - The variable Mean is included in the data table that is specified in the DATA= option.
  - The MEAN option is specified in the OUTPUT statement.

  You can use the MEAN= option in the OUTPUT statement to change the name of this variable.
- StdDev, the standard deviation for the distribution being sampled. This variable is included in the data table only when one or more of the following conditions is true:
  - The STDDEV= option is specified in a MOMENTS or MOMENTGRID statement.
  - The variable StdDev is included in the data table that is specified in the DATA= option.
  - The STDDEV option is specified in the OUTPUT statement.

  You can use the STDDEV= option in the OUTPUT statement to change the name of this variable.
- Skewness, the skewness value for the distribution being sampled. You can use the SKEW= option in the OUTPUT statement to change the name of this variable.
- Kurtosis, the kurtosis value for the distribution being sampled. You can use the KURT= option in the OUTPUT statement to change the name of this variable.
- Variate, a sampled values from the distribution. You can use the SIMVALUE= option in the OUTPUT statement to change the name of this variable.

Displayed Output

For each set of valid input moments that you specify, PROC SIMSYSTEM displays a table that contains the parameters of the distribution in the specified system that has those moments. The table of parameters includes the specified skewness and kurtosis values, the distribution family within the specified system, and the values Shift and Scale by which to transform the sampled values of the distribution in that family in order to achieve the specified mean and standard deviation. The table also includes columns for the underlying parameters of the distribution family. For the default Pearson system, a column of distribution notes displays these values along with the name of the common distribution for the family, except for the Pearson Type IV distribution, which corresponds to no common distribution. For the Johnson system, PROC SIMSYSTEM displays the values of the parameters δ and γ that define the translation of the underlying normal variate. For more information about the two systems, see "Details: SIMSYSTEM Procedure" on page 1597.

If you use the N= option to specify a number of simulated values to sample for each distribution, then PROC SIMSYSTEM also displays a table of specified and computed moments for those samples.

ODS Table Names

PROC SIMSYSTEM assigns a name to each table that it creates. You can use these names to refer to the tables when you use the Output Delivery System (ODS) to select tables and create output data tables. These names are listed in Table 31.6.

Table 31.6 ODS Tables Produced by PROC SIMSYSTEM

ODS Table Name	Description	Statement
Parameters	Type and parameters of specified distributions	Default
Moments	Specified and observed moments for random sample	Default

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in the "Statistical Graphics Using ODS" chapter in *SAS/STAT User's Guide*.

Before you create graphs, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

PROC SIMSYSTEM assigns a name to each graph that it creates using ODS. You can use these names to refer to the graphs when you use ODS. The names are listed in Table 31.7. ODS Graphics must be enabled before you request plots.

Table 31.7 Graphs Produced by PROC SIMSYSTEM

ODS Graph Name	Plot Description	Option
DensityPlot	Expected density and the observed histogram	Default
JohnsonMap	Moment-ratio map for Johnson system	SYSTEM=JOHNSON
PearsonMap	Moment-ratio map for Pearson system	SYSTEM=PEARSON (default)

Examples: SIMSYSTEM Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

Example 31.1: Estimating the Parameters of Johnson Distributions

(View the complete code for this example (ssyex1.sas) in the example repository.)

The UNIVARIATE procedure in Base SAS software can fit the parameters of all three distribution families in the Johnson system. This example demonstrates how to use PROC SIMSYSTEM in conjunction with PROC UNIVARIATE to study these fits.

Suppose you want to work with data from a Johnson SB distribution that has true moments as given in Table 31.8.

Table 31.8 Moments for a Johnson SB Distribution

Mean	5
Standard deviation	2
Skewness	1
Kurtosis	4.5

The following statements use PROC SIMSYSTEM to generate 10,000 observations of such data and to store them in a data table named SB:

```
proc simsystem system=Johnson n=10000 seed=12345;
   moments mean=5 stddev=2 skew=1 kurt=4.5;
   output out=mylib.SB;
run;
```

The SIMSYSTEM procedure displays the parameters of this distribution in the table shown in Output 31.1.1 and the observed moments of the 10,000 sampled values in the table shown in Output 31.1.2.

Output 31.1.1 Parameters for a Johnson Distribution with Specified Skewness and Kurtosis

The SIMSYSTEM Procedure

Parameters for Johnson Distributions							
	Skewness	Kurtosis	Family	Delta	Gamma	Shift	Scale
1	1	4.500	SB(1)	2.124	4.192	0.120	37.31

Output 31.1.2 Moments for a Johnson Distribution with Specified Skewness and Kurtosis

Distribution Moments								
	Specified Moments				Sample Moments			
	Mean	Std Dev	Skewness	Kurtosis	Mean	Std Dev	Skewness	Kurtosis
1	5	2	1	4.500	5.016	2.007	0.957	4.283

The following statements use PROC UNIVARIATE with the SB option in the HISTOGRAM statement to fit the parameters of a Johnson SB distribution to these data. The default method of fitting an SB distribution uses the percentiles of the data, but in this case, because the moments of the distribution are of particular interest, you use the method of moments to fit the distribution.

```
proc univariate data=mylib.SB;
   var variate;
   histogram / sb(theta=est sigma=est fitmethod=moments) noplot;
run;
```

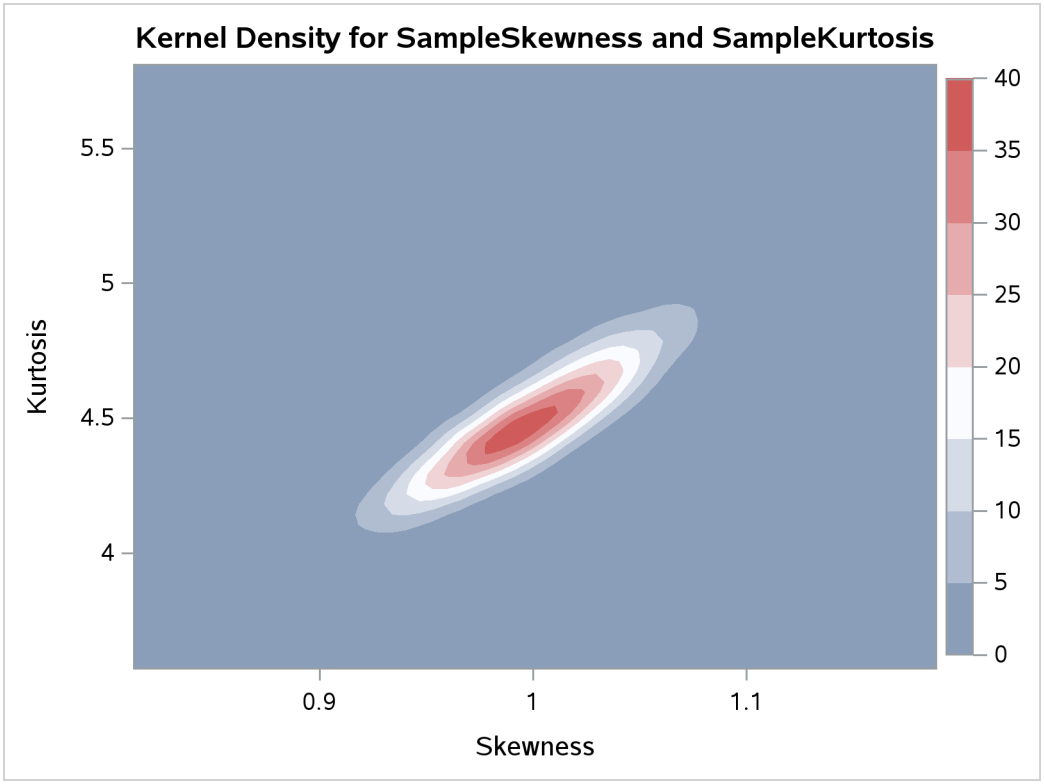
The part of the PROC UNIVARIATE output that shows the fitted parameters for the SB distribution is shown in Output 31.1.3.

Output 31.1.3 Fitted Parameters for a Johnson SB Distribution

The UNIVARIATE Procedure
Fitted SB Distribution for Variate (Random Variate)

Parameters for Johnson SB Distribution		
Parameter	Symbol	Estimate
Threshold	Theta	0.210058
Scale	Sigma	30.82224
Shape	Delta	2.007138
Shape	Gamma	3.555699
Mean		5.016387
Std Dev		2.006555
Skewness		0.956928
Kurtosis		1.283402
Mode		4.021034

As expected from a fit that uses the method of moments, the values of the moments in Output 31.1.3 match those for the sample in Output 31.1.2. The caveat is that PROC SIMSYSTEM works with the direct or raw kurtosis, whereas PROC UNIVARIATE prints the excess kurtosis, which is the raw value minus 3. The values of the four fitted parameters of the distribution match up reasonably well with the true values that they



correspond to in the PROC SIMSYSTEM output, with PROC UNIVARIATE's Theta corresponding to PROC SIMSYSTEM's Shift and Sigma corresponding to Scale. Delta and Gamma denote the same parameters in both procedures.

It is not at all surprising that, although the sample moments in Output 31.1.2 are fairly close to the specified moments, they do not match very precisely, and the sample skewness and kurtosis are a good deal less precise than the mean and standard deviation. You can explore how far off they are likely to be by using the following statements to simulate 10,000 replicates of this 10,000-observation sample, by using the NREP=10000 option in the PROC SIMSYSTEM code discussed earlier. What you want to look at in this case is a summary analysis of the 10,000 skewness and kurtosis values for each sample, so you specify the MOMENTREPS option to include all the sample moments in the "Distribution Moments" table, instead of just the default averages, and you also use the ODS SELECT NONE statement to suppress printing this table, instead using the ODS OUTPUT statement to direct it to a data set named Moments. Finally, PROC KDE is used to create a contour plot of the distribution of skewness and kurtosis values.

```
ods select none;
proc simsystem system=johnson n=10000 seed=12345 nrep=10000 momentreps;
   moments mean=5 stddev=2 skew=1 kurt=4.5;
   ods output Moments=Moments;
run;
ods select all;

proc kde data=Moments;
   bivar SampleSkewness SampleKurtosis / plots=contour;
run;
```

Output 31.1.4 Observed Distribution of Sample Skewness and Kurtosis

The resulting density is shown in Output 31.1.4. Perhaps the most notable feature is that, even though the replicated samples are quite large, containing 10,000 observations each, there is considerable variability in the sample skewness and kurtosis values. This explains the magnitude of the default value for the SIMPLETOL= option. When this option comes into play, PROC SIMSYSTEM does not return a sample that has precisely the expected skewness and kurtosis that you specify, but the difference is undetectable in samples of any reasonable size.

Example 31.2: Exploring the Coverage of Three-Sigma Limits

(View the complete code for this example (ssyex2.sas) in the example repository.)

In statistical process control, the three-sigma limits for a random distribution are defined as the mean plus three times the standard deviation and the mean minus three times the standard deviation—symbolically, $\mu \pm 3\sigma$. Three-sigma limits are very commonly used as a rule of thumb for where the vast majority of values from a process should lie; conversely, they are used to say which outlying values might indicate that the process is not in control. Precisely how much of any given distribution is actually covered by the three-sigma limits varies, although by Chebychev's inequality this actual coverage is bounded below by $1 - 1/3^2 \sim 89\%$. This example is patterned after a study of three-sigma coverage by Wheeler (2010).

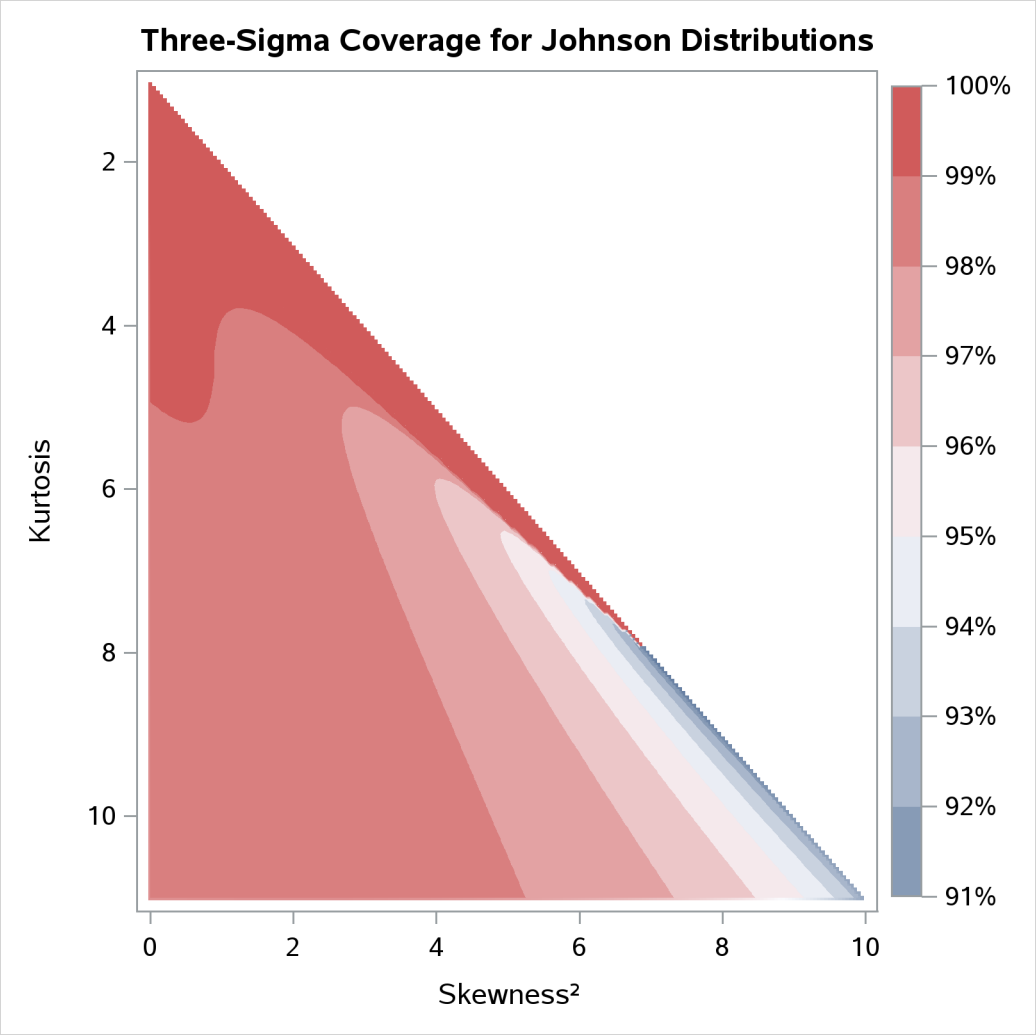
The following statements use PROC SIMSYSTEM to compute the theoretical three-sigma coverage for a wide variety of distributions. The key element is the CUMPROB= option in the PROC SIMSYSTEM statement, which computes cumulative probabilities.

```
data mylib.Grid;
   do s2 = 0 to 10 by 0.05;
      do Kurtosis = 1 to 11 by 0.05;
         Skewness = sqrt(s2);
         output;
         end;
      end;
run;

ods select none;
proc simsystem data=mylib.Grid system=johnson cumprob=-3 3 plot=none;
   ods output Parameters=SKProbJ;
run;
ods select all;

data SKProbJ; set SKProbJ;
   Coverage = P2 - P1;
   s2 = Skewness*Skewness;
   format Coverage percent6.;
run;
```

The first step creates a fine grid of skewness and kurtosis values. The skewness values are created on a squared scale, to match the results of Wheeler (2010). There are over 40,000 pairs of values in all, although about half of them have kurtosis $\leq$ skewness$^2 + 1$ and thus lie in the "impossible region" for which no distribution is possible. Still, you probably do not want to display all 20,000 of those values, so the subsequent ODS SELECT NONE and ODS SELECT ALL statements suppress this display for the duration of the PROC SIMSYSTEM run, using an ODS OUTPUT statement to save the distribution parameters to a data set named SKProbJ.



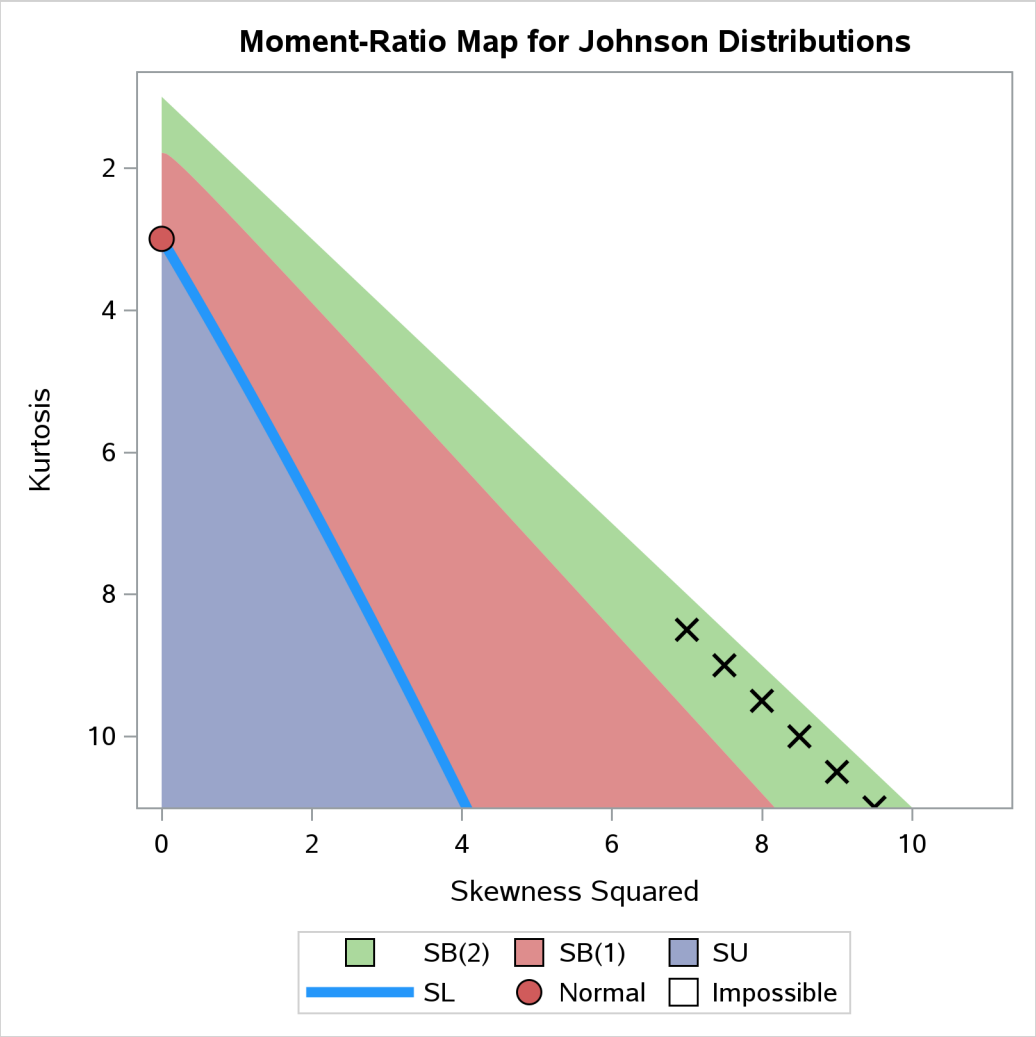
This grid of values is provided as input to PROC SIMSYSTEM. No number of simulations or output data table is specified for the procedure, because you are using the procedure to study the underlying distributions themselves. The SYSTEM=JOHNSON option specifies that this study concerns distributions in the Johnson system; very similar results are obtained using SYSTEM=PEARSON. The CUMPROB= option computes the cumulative probabilities for –3 and 3. Because no value for standard deviation is specified, its value is assumed to be 1 for all distributions, and thus the difference between these two cumulative probabilities is the expected coverage rate. A final DATA step computes this coverage value for each distribution and also recovers the squared skewness values for plotting.

The following statements use PROC SGRENDER to create a plot of the three-sigma coverages computed using the previous statements. They use a predefined graphical template that is specifically designed for plotting the contours of a continuous variable against kurtosis and squared skewness.

```
proc sgrender data=SKProbJ template=acas.simsystem.Graphics.S2KContourMap;
   dynamic _Title = "Three-Sigma Coverage for Johnson Distributions"
           _XVar  = "s2"
           _YVar  = "Kurtosis"
           _ZVar  = "Coverage";
run;
```

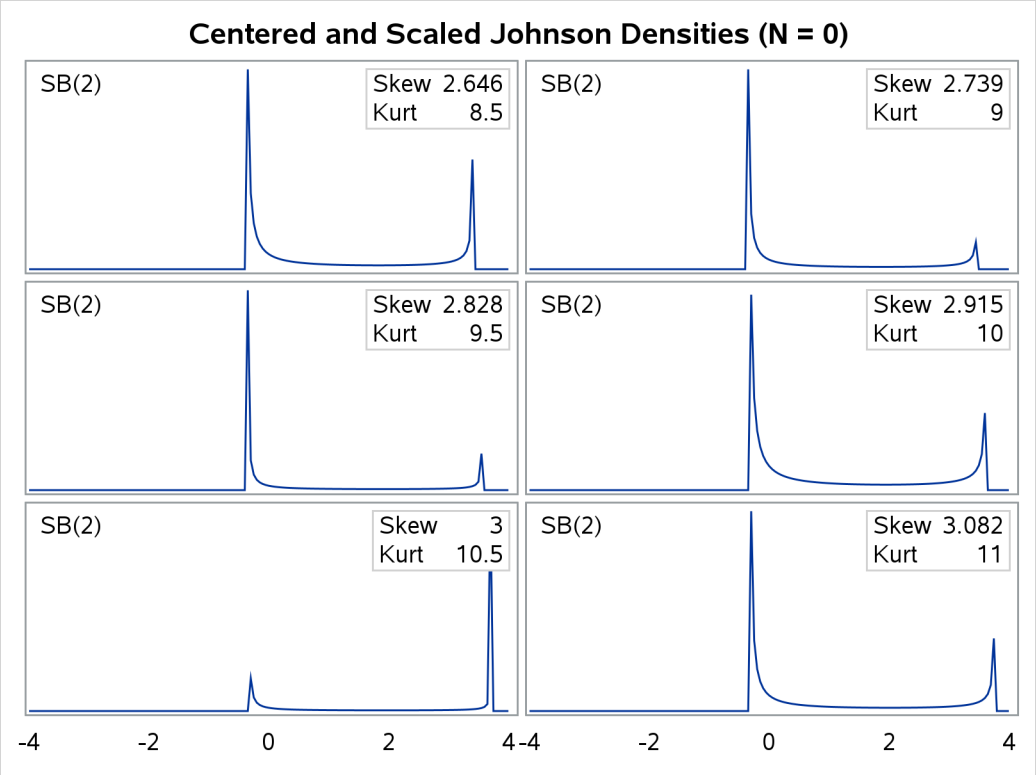
The resulting plot is shown in Output 31.2.1.

Output 31.2.1 Exploring the Coverage of Three-Sigma Limits



Compare this plot to Figure 3 in Wheeler (2010). As noted there, the coverage is quite high for most of the distributions; only for highly skewed distributions very near the boundary of the "impossible region" does the coverage approach the lower bound of 89%. You can use PROC SIMSYSTEM as follows to see what these distributions look like:

```
data mylib.LowCoverage;
   do s2 = 7 to 10 by 0.5;
      do Kurtosis = 8 to 11 by 0.5;
         Skewness = sqrt(s2);
         if (1 + s2 < Kurtosis <= 1 + s2 + 0.5) then
            output;
         end;
      end;
run;



proc simsystem data=mylib.LowCoverage system=johnson
               plots=mrmap(skewscale=square);
run;
```

The DATA step creates another grid of skewness and kurtosis values, which are filtered to lie in the small area of low-coverage distributions shown in Output 31.2.1. The plots that this PROC SIMSYSTEM code produces are shown in Output 31.2.2 and Output 31.2.3.

Output 31.2.2 Low-Coverage Johnson Distribution Map

Output 31.2.3 Low-Coverage Johnson Distribution Densities

Output 31.2.2 confirms that these distributions do indeed lie in the low-coverage region of interest. From Output 31.2.3 you can see that they are all quite extreme. Technically they are "U-shaped" distributions in Johnson's SB family, but in all cases at least one of the two modes is very sharp. As noted by Wheeler (2010), if your process really does have a distribution like this, then it probably indicates an underlying mixture distribution.

Example 31.3: Simulating Portfolio Values

(View the complete code for this example (ssyex3.sas) in the example repository.)

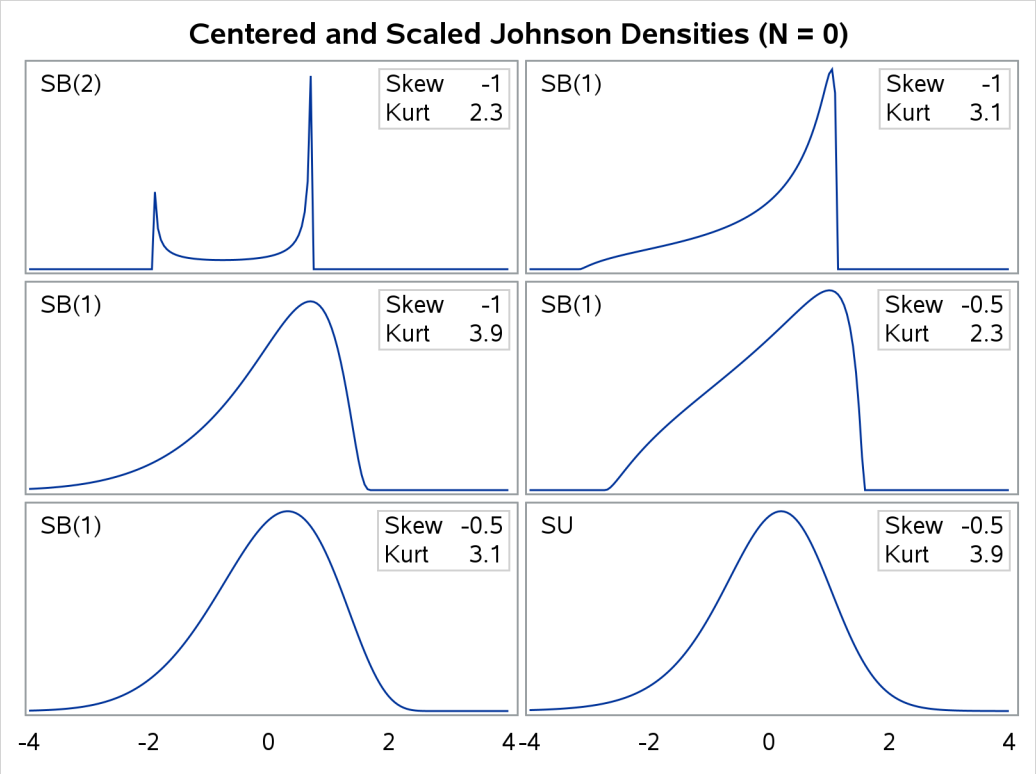
This example demonstrates how you can use PROC SIMSYSTEM to perform an experimental simulation over a grid of potential distributions. The procedure plays two different roles in this application: screening the shapes of potential distributions and simulating samples from selected distributions. Other SAS tools (the DATA step, PROC SUMMARY, and PROC RSREG) are used to complete and analyze the simulation.

You are interested in studying the likely performance over the next 30 years of a $1,000,000 portfolio that is managed to track the performance of the S&P 500 stock index. Of course, key information that you are missing is the future performance of the S&P 500, but you can simulate it for a variety of potential distributions.

Your first question is, What are the potential shapes for the true distribution of total annual returns of the S&P 500? You can use PROC SIMSYSTEM to get an idea of this, by specifying several potential values for skewness and kurtosis that seem feasible according to historical data and reviewing the density plots for them, as shown in the following code:

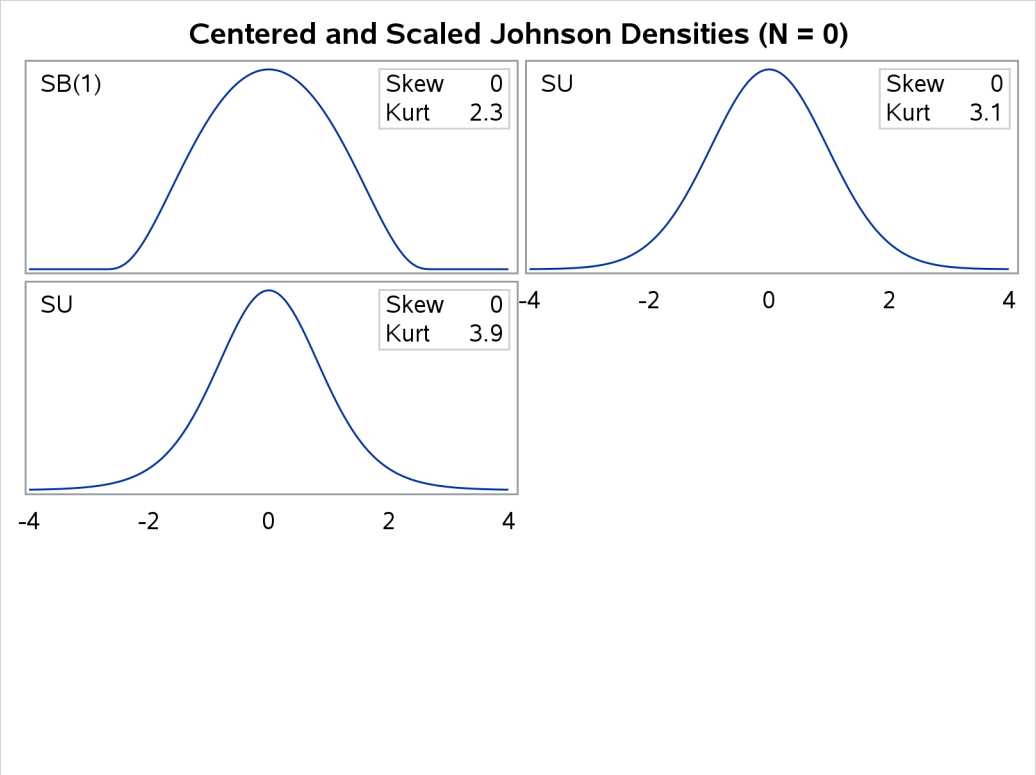
```
proc simsystem system=johnson;
   momentgrid Skewness = -1.0 -0.5 0.0
              Kurtosis =  2.3  3.1 3.9;
run;
```

The table of parameters for these distributions, shown in Output 31.3.1, indicates that they are mostly of the bounded type. Also, as you can see in Output 31.3.2, most of the densities seem reasonable, except for the first one, with the lowest values of both skewness and kurtosis.



Output 31.3.1 Parameters of Representative Distributions for S&P 500 Returns

The SIMSYSTEM Procedure



Parameters for Johnson Distributions

	Skewness	Kurtosis	Family	Delta	Gamma	Shift	Scale
1	-1	2.300	SB(2)	0.190	0.627	0.739	-2.674
2	-1	3.100	SB(1)	0.647	0.931	1.146	-4.311
3	-1	3.900	SB(1)	1.259	1.779	1.730	-7.785
4	-0.500	2.300	SB(1)	0.799	0.565	1.598	-4.346
5	-0.500	3.100	SB(1)	2.109	1.917	3.109	-10.49
6	-0.500	3.900	SU	2.931	-1.378	1.276	-2.469
7	0	2.300	SB(1)	1.225	19E-15	-2.796	5.592
8	0	3.100	SU	6.441	0	0	6.363
9	0	3.900	SU	2.417	0	0	2.213

Output 31.3.2 Representative Densities for S&P 500 Returns

Output 31.3.2 *continued*

The extreme density in Output 31.3.2 is omitted by a PROC DS2 step after the PROC SIMSYSTEM code, as shown in the following statements. The grid discussed earlier is expanded with typical values for the mean and standard deviation of annual S&P 500 returns. The code creates, for each set of moment values, 1,000 replicates of potential sequences of N=30 years of total annual returns, using the Johnson system of distributions. You will use these potential sequences of returns to explore the success rate of your portfolio for each distribution, as defined by the moments.

```
proc simsystem n=30 system=johnson seed=12345 noprint nrep=1000;
   momentgrid
      Mean     =   7.5 12.0 16.5
      StdDev   =  17.0 20.0 23.0
      Skewness =  -1.0 -0.5  0.0
      Kurtosis =   2.3  3.1  3.9;
   output out=mylib.Sim_raw Mean=Mean Std=StdDev;
run;

proc ds2 sessref=mysess;
   data Sim / overwrite=yes;
      rename Variate=AnnualReturn;
      method run();
         set Sim_raw;
         if ^((Skewness = -1) & (Kurtosis = 2.3)) then output;
      end;
   enddata;
run;
quit;
```

The resulting data table has over 2,000,000 observations. These observations will be processed in groups defined by the simulation index SimIndex and the replicate number Rep, each group being a potential sequence of returns for the hypothetical 30 years of interest. The value of your portfolio for any particular sequence of returns is adjusted annually by the simulated return and also by a fixed withdrawal of $40,000 per year. The sequence is successful for your portfolio if its value never falls below $0. The following PROC DS2 code evaluates the success of each simulated sequence of 30 returns, using a thread block to process different replicates in parallel. A subsequent PROC MDSUMMARY step computes the mean of these 0/1 success values, which is thus the observed success rate for each set of moment values that are defined by the MOMENTGRID statement.

```
%let Start    = 1000000;
%let Withdraw =   40000;
proc ds2 sessref=mysess;
   thread Success_thd / overwrite=yes;
      dcl double Value minVal;
      dcl int Success;
      retain Value minVal;
      keep SimIndex Mean StdDev Skewness Kurtosis Rep Success;
      method run();
         set Sim;  /*being parallelized*/
         by SimIndex Rep;
         /*BY statement takes the BY-groups as batches in threads*/
         if FIRST.Rep then do;        /* First year in a sequence: */
            Value  = 1000000;         /* Initialize the portfolio  */
            minVal = Value;           /* value.                    */
         end;
         /*
         /  The value at the end of the year is the sum of the
         /  original value and the annual return, minus the amount
         /  withdrawn.
         /-----------------------------------------------------*/
         if Value then do;
            Value  = Value + (AnnualReturn/100)*Value - 40000;
            minVal = min(minVal, Value);
         end;
         if LAST.Rep then do;         /* Last year in a sequence:  */
            Success = (minVal > 0);   /* Evaluate success and      */
            output;                   /* output.                   */
         end;
      end;
   endthread;
   data Success / overwrite=yes;
      dcl thread Success_thd Success_thd_instance;
      method run();
         set from Success_thd_instance threads=1;
      end;
   enddata;
run;
quit;

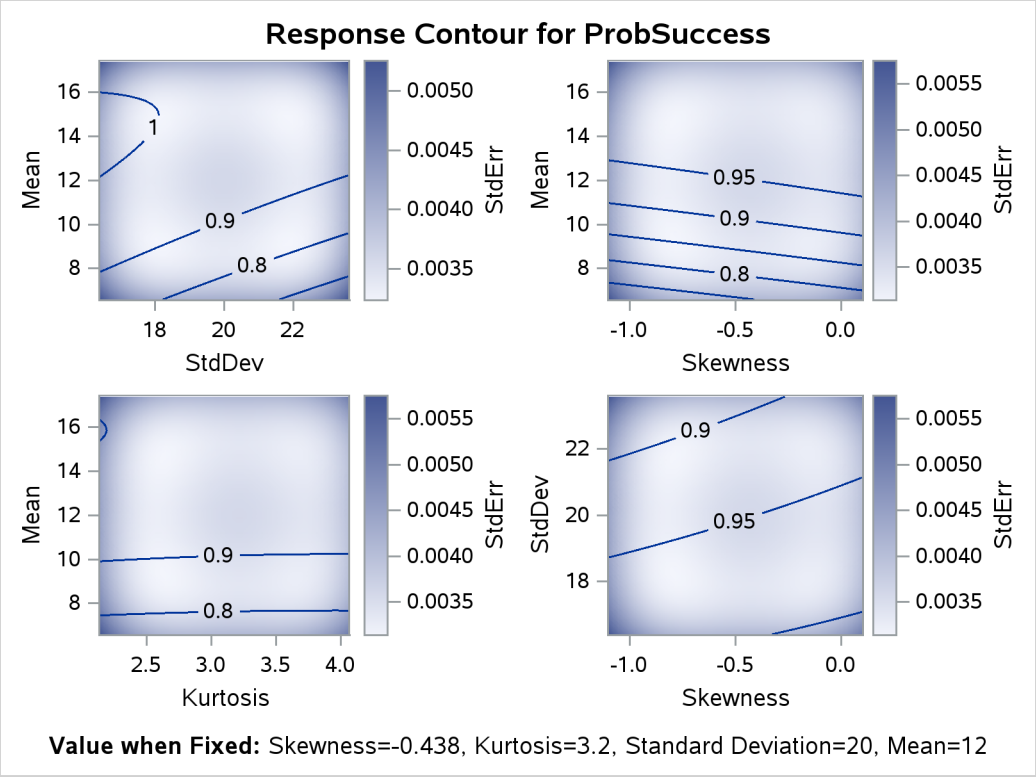
proc mdsummary data=mylib.Success;
   groupby Mean StdDev Skewness Kurtosis SimIndex;
```

```
   var Success;
   output out=mylib.ProbSuccess;
run;

proc cas;
   session mysess;
   table.alterTable /
      name="ProbSuccess"
      columns={{name="_Mean_" rename="ProbSuccess" label=""}};
quit;
```

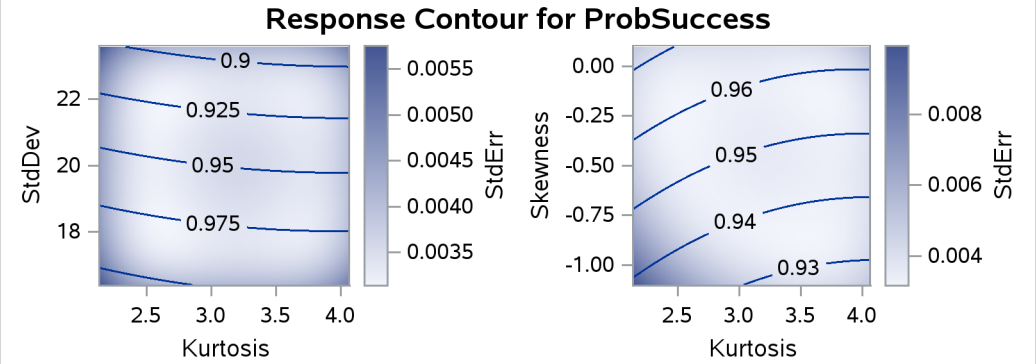
Finally, you use PROC RSREG, as in the following statements, to apply response surface analysis methods to the simulated success rates. PROC RSREG fits a quadratic function to these values and plots the predicted surfaces.

```
proc rsreg data=mylib.ProbSuccess plots=contour(nodesign);
   model ProbSuccess = Mean StdDev Skewness Kurtosis;
   ods select FactorANOVA Contour;
run;
```



Selected PROC RSREG results are shown in Output 31.3.3 and Output 31.3.4. The ANOVA for individual factors shows that although the mean rate of return is the most influential factor in portfolio success, all four moments of the return distribution have some effect. In the plots of predicted success rates, you can see that a $40,000 withdrawal gives your portfolio about a 95% probability of success in the center of the experimental region, near the historical estimates for the moments of the return distribution. This is encouraging, but the predicted probability of success drops off precipitously as the moments of the return distribution change.

Output 31.3.3 Response Surface Analysis of Simulated S&P 500 Returns



The RSREG Procedure

Factor	DF	Sum of Squares	Mean Square	F Value	Pr > F	Label
Mean	5	0.564070	0.112814	1597.15	<.0001	Mean

Output 31.3.4 Predicted S&P 500 Returns

Value when Fixed: Skewness=-0.438, Kurtosis=3.2, Standard Deviation=20, Mean=12

Value when Fixed: Mean=12, Skewness=-0.438, Standard Deviation=20

Example 31.4: Simulating Estimation of Value at Risk

(View the complete code for this example (ssyex4.sas) in the example repository.)

The *value at risk* (VaR_τ) of an investment is the most that you can expect to lose in a given future time frame, with a given probability $1 - \tau$. One way to think of this is that if you have $X = \text{VaR}_\tau$ cash on hand, then you can be $100 \times (1 - \tau)\%$ confident that you will be able to cover a loss in that investment. This example uses PROC SIMSYSTEM to explore the accuracy of a common method of estimating the VaR_τ when the assumptions of the method break down.

A popular way to model the periodic returns of an investment is to use a GARCH (generalized autoregressive conditional heteroscedasticity) model, in which, conditional on past returns, future returns are distributed as independent normal values, with a variance that also depends autoregressively on the past. The following code for simulating and fitting a GARCH process is modeled on the first example in SAS Institute Inc. (2019):

```
data Index;
   call streaminit(12345);
   do t = 1 to 10000;
      e = normal(2);
      output;
      end;
run;

data Index; set Index;
   retain ReturnRate Var eLag varLag;
   if (_N_ = 1) then do;
      eLag   = 1;
      VarLag = 1;
      end;
   Var = 0.4 + 0.8 * eLag**2  + 0.1 * VarLag;
   ReturnRate = sqrt(Var) * e;
   output;
   eLag   = ReturnRate;
   varLag = Var;
run;

proc autoreg data=Index;
   model ReturnRate = / noint garch=(p=1, q=1) dist=t;
   output out=o1 alphacli=%sysevalf(2*0.05) lcl=lcl;
run;
```

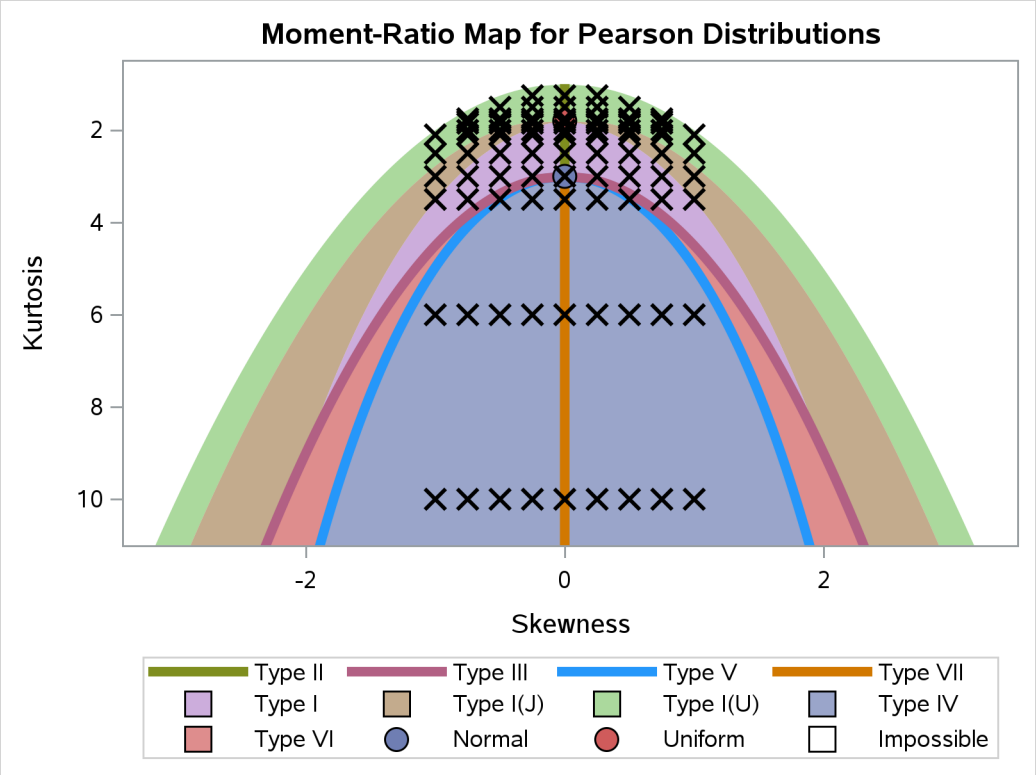
The OUTPUT statement for PROC AUTOREG computes $-\text{VaR}_{0.05}$ for this sequence of returns as the 95% lower confidence limit for the forecasted returns, and if you use PROC MEANS as follows to count up the proportion of returns that are less than this (that is, that have greater loss than this), you see that this indeed accounts for about 5% of them, as shown in Output 31.4.1:

```
data o1; set o1;
   AtRisk = (ReturnRate < lcl);
proc means data=o1 mean;
   var AtRisk;
run;
```

Output 31.4.1 In-Sample Coverage Rate for GARCH Estimation with Normal Errors

The MEANS Procedure

Analysis Variable : AtRisk
Mean
0.0491000



The PROC AUTOREG code given earlier for estimating $-\text{VaR}_{0.05}$ depends on the assumption that the conditional returns are normally distributed, corresponding to the use of the NORMAL() random number generating function in the first DATA step shown previously. How important is this assumption? The following code uses PROC SIMSYSTEM to simulate the random part of 10,000 conditional returns from each of a systematic grid of mostly nonnormal distributions. A subsequent call of the **alterTable** action renames the output variables for convenience.

```
proc simsystem n=10000 system=pearson seed=1 plot(only)=mrmap(skewscale=skewness);
   momentgrid skew=-1 -0.75 -0.5 -0.25 0 0.25 0.5 0.75 1
              kurt=1.25  1.5
                   1.75  1.8
                   1.85  2.0
                   2.1   2.5
                   3     3.5
                   6    10;
   output out=mylib.GARCHSim_error;
run;

proc cas;
   session mysess;
   table.alterTable /
      name="GARCHSim_error"
      columns={
         {name="iObs"    rename="t" label=""},
         {name="Variate" rename="e" label=""}
      };
quit;
```

These statements specify negative as well as positive skewness values and kurtosis values that run from appreciably platykurtic (kurtosis less than 3, the kurtosis of the normal distribution) to appreciably leptokurtic (kurtosis greater than 3). The MOMENTGRID statement specifies a distribution for every pair of these values, although some are ignored because of the constraint that the kurtosis for a random distribution must always be greater than or equal to $1 + \text{skewness}^2$. The SKEWSCALE=SKEWNESS option produces a moment-ratio map that shows both negative and positive skewness values. The placement of this grid of skewness and kurtosis values within the moment-ratio map for the Pearson system is shown in Output 31.4.2.

Output 31.4.2 Systematic Grid of Sampled Errors

The following PROC DS2 code uses these simulated values in the same way that the previous DATA step code used random normal values: to produce many samples of returns. A thread block in the PROC DS2 step processes different samples in parallel. The subsequent code performs the PROC AUTOREG analysis discussed earlier for each sample of 10,000 simulated returns, as indexed by the specified skewness and kurtosis values, and similarly uses PROC SUMMARY to count up the proportion whose loss exceeds the computed $\text{VaR}_{0.05}$.

```
/*using THREAD to parallelize the set statement*/
proc ds2 sessref=mysess;
thread GARCHSim_thd / overwrite=yes;
   dcl double ReturnRate Var eLag VarLag;
   retain ReturnRate Var eLag VarLag;
   method run();
      set GARCHSim_error;
      by SimIndex;
      if FIRST.SimIndex then do;
         eLag   = 1;
         VarLag = 1;
      end;
      Var = 0.4 + 0.8 * eLag**2 + 0.1 * VarLag;
      ReturnRate = sqrt(Var) * e;
      output;
      eLag   = ReturnRate;
      VarLag = Var;
   end;
endthread;
```

```
data GARCHSim / overwrite=yes;
   dcl thread GARCHSim_thd GARCHSim_thd_instance;
   method run();
      set from GARCHSim_thd_instance;
   end;
enddata;
run;
quit;

proc autoreg data=mylib.GARCHSim noprint;
   by notsorted Skewness Kurtosis;
   model ReturnRate = / noint garch=(p=1, q=1);
   output out=mylib.g11 alphacli=%sysevalf(2*0.05) lcl=lcl;
run;

data g11; set mylib.g11;
   AtRisk = (ReturnRate < lcl);
proc summary data=g11 mean;
   class Kurtosis Skewness;
   ways 2;
   var AtRisk;
   output out=AtRisk mean=pAtRisk;
run;
```

Finally, the following code prints these simulated actual coverage values for the nominal $\mathrm{VaR}_{0.05}$, arranging them in a fashion similar to that of the moment-ratio map in Output 31.4.2. The results are shown in Output 31.4.3.

```
proc sort data=AtRisk;
   by Kurtosis Skewness;
proc transpose data=AtRisk(rename=(Skewness=_NAME_)) out=AtRisk;
   by Kurtosis;
   var pAtRisk;
proc print data=AtRisk(drop=_NAME_) noobs label;
   var N1 N0D75 N0D5 N0D25 _0 _0D25 _0D5 _0D75 _1;
   id Kurtosis;
   format _: N: 6.3;
   label
      N1    = "-1"
      N0D75 = "-0.75"
      N0D5  = "-0.5"
      N0D25 = "-0.25"
      _0    =  "0"
      _0D25 =  "0.25"
      _0D5  =  "0.5"
      _0D75 =  "0.75"
      _1    =  "1";
run;
```

Output 31.4.3 In-Sample Coverage Rate for GARCH Estimation with Nonnormal Errors

Kurtosis	-1	-0.75	-0.5	-0.25	0	0.25	0.5	0.75	1
1.25	.	.	.	0.039	0.028	0.017	.	.	.

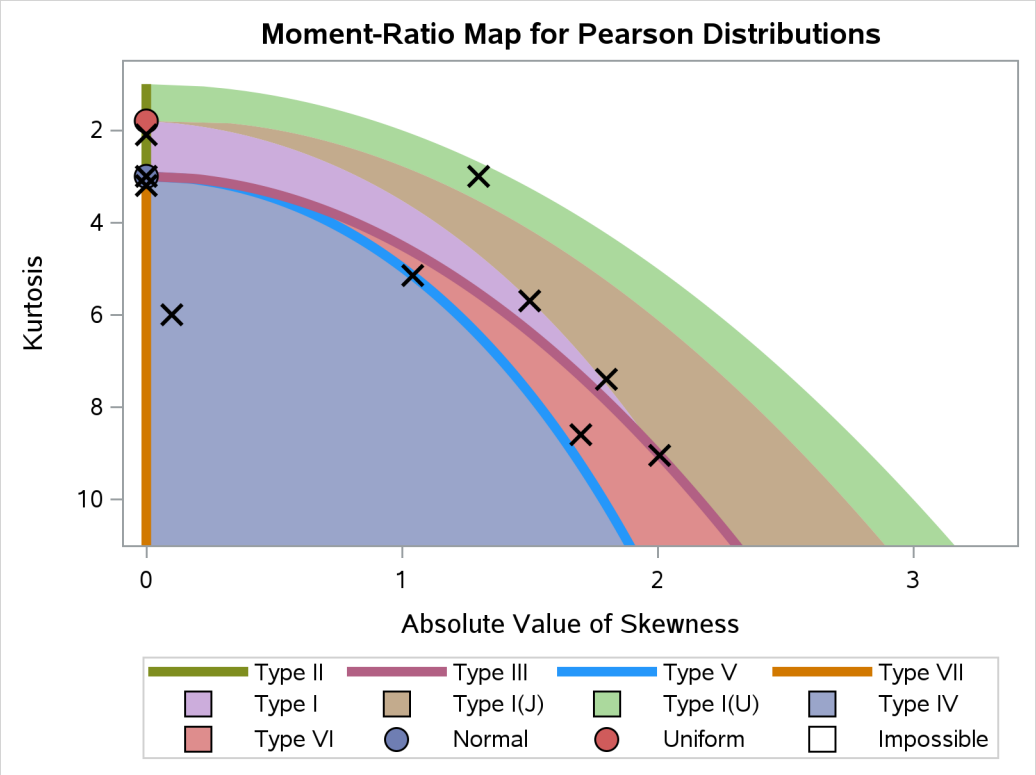
2.50	0.054	0.044	0.043	0.041	0.039	0.032	0.034	0.026	0.017
3.00	0.032	0.035	0.034	0.026	0.036	0.035	0.030	0.029	0.025
3.50	0.037	0.042	0.020	0.033	0.040	0.034	0.035	0.033	0.026
6.00	0.031	0.042	0.039	0.030	0.039	0.032	0.035	0.032	0.037
10.00	0.036	0.022	0.030	0.027	0.035	0.036	0.036	0.035	0.037

In Output 31.4.3, you can see that the simulated $\text{VaR}_{0.05}$ coverage is reasonably accurate for distributions near skewness 0 and kurtosis 3 of the normal, but the coverage can be severely liberal or conservative for negatively or positively skewed errors, respectively. This fact motivated Koenker and Zhao (1996) to use quantile regression to construct a distribution-free estimate of VaR that is less sensitive to skewness and kurtosis in the underlying error distribution for the returns, as discussed in Rodriguez and Yao (2017).



Example 31.5: Interpreting Distribution Parameters

(View the complete code for this example (ssyex5.sas) in the example repository.)

This example demonstrates how to use the table of parameters that PROC SIMSYSTEM displays to reconstruct in DATA step code random variates that have the specified moments for each distribution. Starting with the Pearson system, the moment combinations that are specified for PROC SIMSYSTEM in the following code are chosen to span the families of distributions in the Pearson family, plus the normal distribution, as the parameters table (Output 31.5.2) that PROC SIMSYSTEM produces for these moment combinations confirms:

```
%let Mean   = -4.5 -3.5 -2.5 -1.5 -0.5  0.5        1.5  2.5        3.5  4.5;
%let Stddev =  1    2    3    4    5    6          7    8          9   10;
%let Skew   =  0   -1.5  1.8 -1.3  0   -2.00831604 0.1 -1.04235831 1.7  0;
%let Kurt   =  3    5.7  7.4  3    2.1  9.05       6    5.15       8.6  3.2;

Output 31.5.1 Selected Pearson Distributions

Output 31.5.2 Parameters for Selected Pearson Distributions

Parameters for Pearson Distributions

	Skewness	Kurtosis	Family	Distribution Notes	Shift	Scale
1	0	3	Normal		-4.500	1
2	-1.500	5.700	Type I	Beta(1.012,9.877)	-1.292	-23.75
3	1.800	7.400	Type I(J)	Beta(0.932,19.68)	-5.535	67.11
4	-1.300	3	Type I(U)	Beta(0.083,0.284)	1.021	-11.20
5	0	2.100	Type II	Beta(1.833,1.833)	-11.30	21.60
6	-2.008	9.050	Type III	Gamma, shape parameter = 0.992	6.475	-6.025
7	0.100	6	Type IV	Alpha = -0.189, m = 3.5075	0.972	14.02
8	-1.042	5.150	Type V	Inverse gamma, shape parameter = 18.67	35.16	-577.0
9	1.700	8.600	Type VI	F(DF1=8.262,DF2=24.34)	-11.41	13.69
10	0	3.200	Type VII	Students t, DF = 34	4.500	9.701

The ODS OUTPUT statement in the preceding PROC SIMSYSTEM code saves the parameters for this sequence of distributions in a data set named Parm. The following PROC PRINT code produces the selected contents of this data set shown in Output 31.5.3. As you can see, the exact numeric values of the parameters that describe each distribution in the Notes column are available in the Shap1Val and Shap2Val variables.

```
proc print data=Parm noobs;
   var Family Notes Shap: Shift Scale;
run;
```

Output 31.5.3 Displayed and Hidden Pearson Distribution Parameters

Family	Notes	Shap1Lab	Shap1Val	Shap2Lab	Shap2Val	Shift	Scale
Normal			.		.	-4.500	1
Type I	Beta(1.012,9.877)	Alpha	1.012230	Beta	9.876659	-1.292	-23.75
Type I(J)	Beta(0.932,19.68)	Alpha	0.931965	Beta	19.676731	-5.535	67.11

As discussed in "Parameter Values for Pearson Distributions" on page 1605, you can use the values of the Shap1Val and Shap2Val variables in DATA step code with the formulas given in Table 31.3 to compute random samples that have the specified moments, as shown in the following DATA step code:

```
%let N = 1000000;
data mylib.Parm; set Parm; run;
proc ds2 sessref=mysess;
data Sim / overwrite=yes;
   dcl int i;
   dcl double y;
   method run();
      set Parm;
      streaminit(15531);
      do i=1 to &N;
         select (trim(left(Family)));
            when ('Type I'   )
            when ('Type I(J)')
            when ('Type I(U)') y =   rand('beta'  ,Shap1Val,Shap2Val);
            when ('Type II'  ) y =   rand('beta'  ,Shap1Val,Shap1Val);
            when ('Type III' ) y =   rand('gamma' ,Shap1Val);
            when ('Type IV'  ) y = .;
            when ('Type V'   ) y = 1/rand('gamma' ,Shap1Val);
            when ('Type VI'  ) y =   rand('f'     ,Shap1Val,Shap2Val);
            when ('Type VII' ) y =   rand('t'     ,Shap1Val);
            when ('Normal'   ) y =   rand('normal');
         end;
         y = Scale*y + Shift;
         output;
      end;
   end;
enddata;
run;
quit;
```

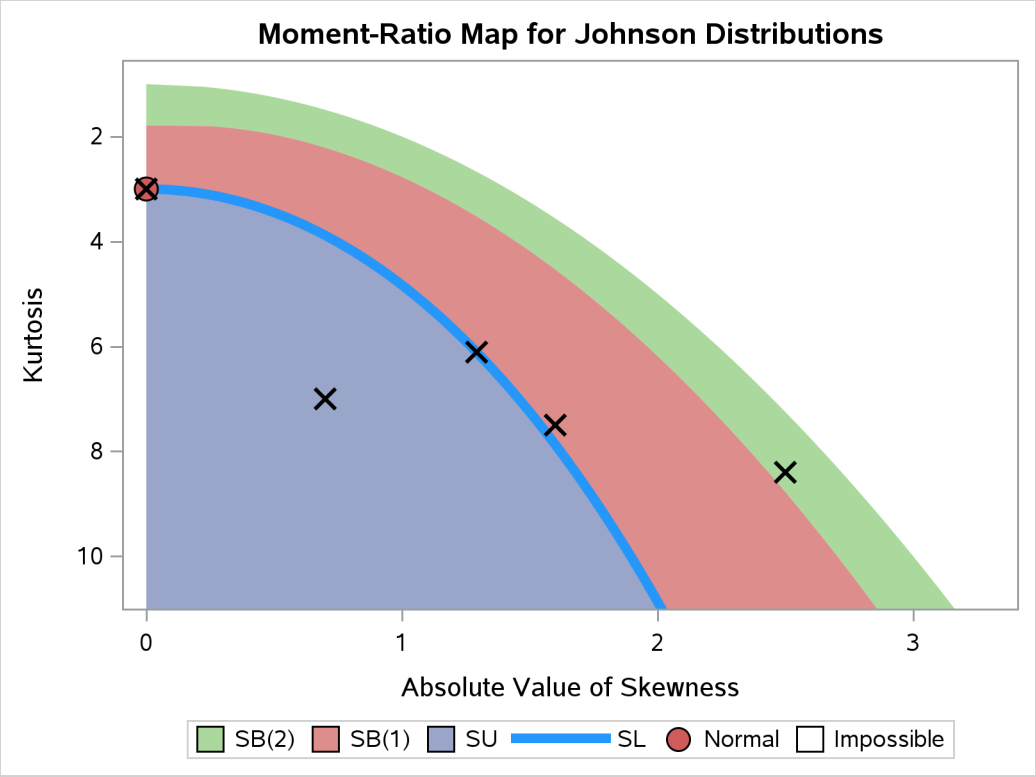
The following code computes and displays (in Output 31.5.4) the first four moments for each distribution sampled by the preceding PROC DS2 code. These moments match the specified ones reasonably well.

```
proc mdsummary data=mylib.Sim;
   var y;
   groupby Family Notes Mean StdDev Skewness Kurtosis;
   output out=mylib.Sim_summary;
run;

proc cas;
   session mysess;
   table.alterTable /
      name="Sim_summary"
      columns={
         {name="_Mean_"       rename="sMean"},
         {name="_Std_"        rename="sStdDev"},
         {name="_Skewness_"   rename="sSkewness"},
         {name="_Kurtosis_"   rename="sKurtosis"}
      };
   table.update /
      table="Sim_summary"
      set={{var="sKurtosis" value="sKurtosis + 3"}};
quit;

proc sort data=mylib.Sim_summary out=Sim_summary; by Family; run;
proc print data=Sim_summary noobs;
   var Family Mean sMean StdDev sStdDev Skewness sSkewness Kurtosis sKurtosis;
   format _NUMERIC_ 6.3;
run;
```

Output 31.5.4 Moments for PROC DS2 Samples



Family	Mean	sMean	StdDev	sStdDev	Skewness	sSkewness	Kurtosis	sKurtosis
Normal	-4.500	-4.501	1.000	1.000	0.000	0.002	3.000	2.997
Type I	-3.500	-3.498	2.000	2.000	-1.500	-1.503	5.700	5.709
Type I(J)	-2.500	-2.505	3.000	2.995	1.800	1.799	7.400	7.389
Type I(U)	-1.500	-1.504	4.000	4.003	-1.300	-1.297	3.000	2.990

Finally, for the Johnson system, the following code performs steps precisely like those shown earlier for the Pearson system, except that the moment combinations are chosen to represent the families of the Johnson system, as shown in Output 31.5.5 and Output 31.5.6:

```
%let Mean   =  -2   -1    0            1  2  ;
%let Stddev =   1    2    3            4  5  ;
%let Skew   =  -1.6  2.5 -1.2922847983 0 -0.7;
%let Kurt   =   7.5  8.4  6.1093660061 3  7  ;
proc simsystem system=johnson;
   moments mean=&Mean StdDev=&Stddev skew=&Skew kurt=&Kurt;
   ods output Parameters=Parm;
```

```
run;
```

Output 31.5.5 Selected Johnson Distributions

Output 31.5.6 Parameters for Selected Johnson Distributions

Parameters for Johnson Distributions							
	Skewness	Kurtosis	Family	Delta	Gamma	Shift	Scale
1	-1.600	7.500	SB(1)	1.852	6.017	-0.151	-43.59
2	2.500	8.400	SB(2)	0.282	1.375	-1.975	8.885
3	-1.292	6.109	SL	2.548		7.351	-6.806
4	0	3	SN			1	4
5	-0.700	7	SU	1.571	-0.390	3.876	-6.099

Turning to the Johnson system, as discussed in "Parameter Values for Johnson Distributions" on page 1609, you can use the values of the Gamma and Delta columns of the "Parameters for Johnson Distributions" table in DATA step code with the formulas given in Table 31.5 to compute random samples that have the specified moments, as shown in the following code:

```
%let N = 1000000;
data mylib.Parm; set Parm; run;
proc ds2 sessref=mysess;
data Sim / overwrite=yes;
   dcl int i;
   dcl double y z;
   method run();
      set Parm;
```

```
      streaminit(15531);
      do i = 1 to &N;
         z = rand('normal');
         select (trim(left(Family)));
            when ('SB(1)')
            when ('SB(2)') y = 1/(1 + exp(-(z - Gamma)/Delta));
            when ('SL'   ) y =        exp(  z         /Delta) ;
            when ('SU'   ) y =       sinh( (z - Gamma)/Delta) ;
            when ('SN'   ) y =              z                 ;
         end;
         y = Scale*y + Shift;
         output;
      end;
   end;
enddata;
run;
quit;

proc mdsummary data=mylib.Sim;
   var y;
   groupby Family Mean StdDev Skewness Kurtosis;
   output out=mylib.Sim_summary;
run;

proc cas;
   session mysess;
   table.alterTable /
      name="Sim_summary"
      columns={
         {name="_Mean_"       rename="sMean"},
         {name="_Std_"        rename="sStdDev"},
         {name="_Skewness_"   rename="sSkewness"},
         {name="_Kurtosis_"   rename="sKurtosis"}
      };
   table.update /
      table="Sim_summary"
      set={{var="sKurtosis" value="sKurtosis + 3"}};
quit;

proc sort data=mylib.Sim_summary out=Sim_summary; by Family; run;
proc print data=Sim_summary noobs;
   var Family Mean sMean StdDev sStdDev Skewness sSkewness Kurtosis sKurtosis;
   format _NUMERIC_ 6.3;
run;
```

As was the case with the Pearson system shown earlier, the moments for the samples that the PROC DS2 code computes, shown in Output 31.5.7, match the specified moments reasonably well.

Output 31.5.7 Moments for PROC DS2 Samples

Family	Mean	sMean	StdDev	sStdDev	Skewness	sSkewness	Kurtosis	sKurtosis

Overview: SPC Procedure

The SPC procedure performs control chart analysis.

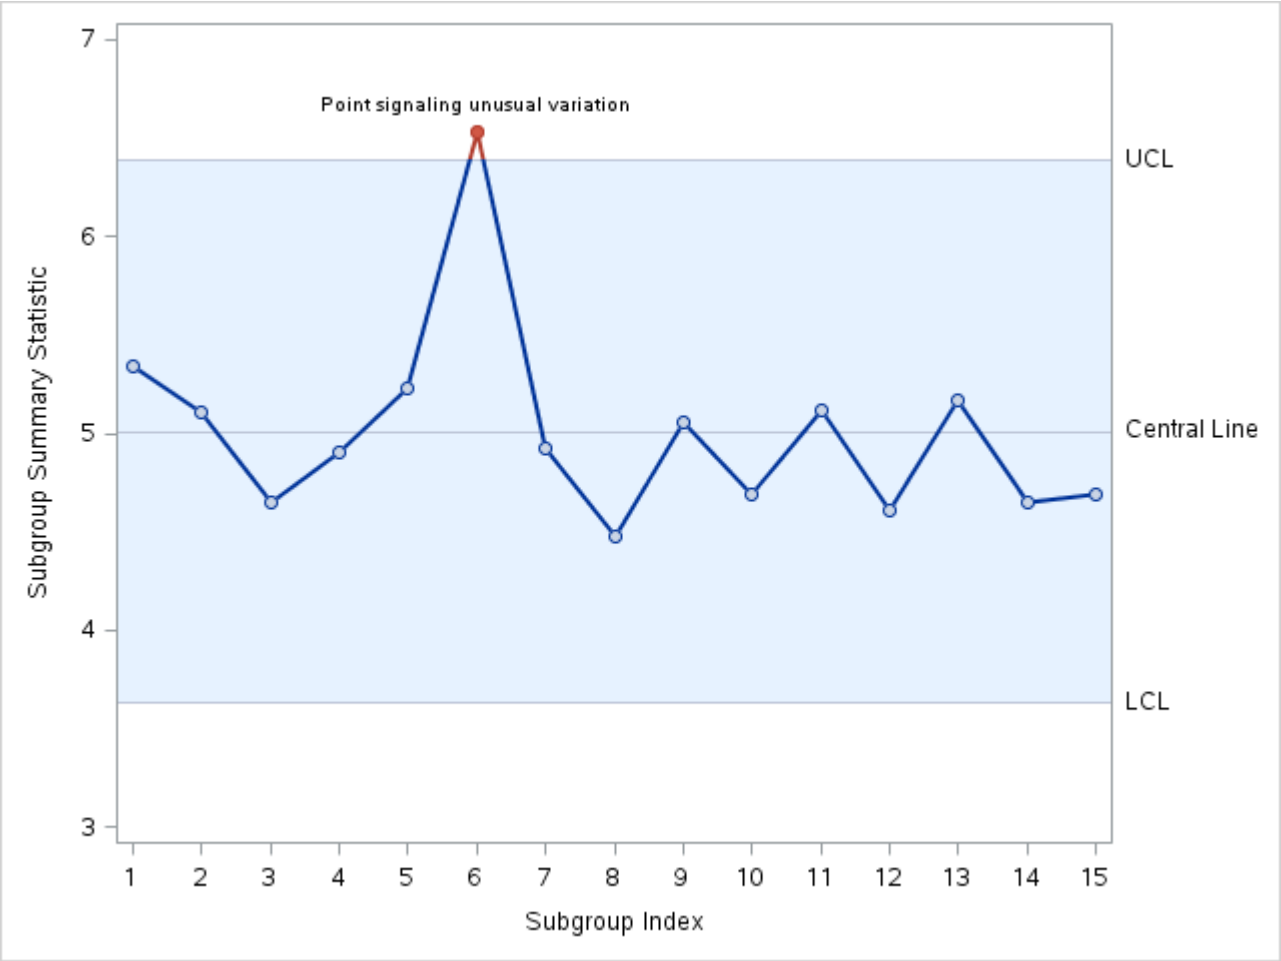
A control chart is a graphical and analytical tool for determining whether a process is in a state of statistical control. You can use the SPC procedure to compute many different types of control charts, including all commonly used Shewhart charts and moving average charts. In addition, you can use PROC SPC to do the following:

- analyze multiple process variables and produce a table that identifies processes that are out of statistical control
- adjust control limits to compensate for unequal subgroup sizes
- estimate control limits from the data, compute control limits from specified values for population parameters (known standards), or read limits from an input data table
- perform tests for special causes based on runs patterns (Western Electric rules)
- estimate the process standard deviation by using various methods
- specify process specification limits and compute capability indices for processes that are in statistical control
- save chart statistics and control limits in output data tables that you can use as input for the SHEWHART or MACONTROL procedure in SAS/QC software to display the control charts graphically

Uses of Control Charts

The control chart was invented by Walter A. Shewhart (1891–1967), a physicist at Bell Telephone Laboratories, who introduced the method in 1924 and elaborated on it in his book *Economic Control of Quality of Manufactured Product* (1931). Many varieties of control chart have been developed in the years since, but the original types of control chart are called Shewhart charts. The concepts that underlie the control chart are that the natural variability in any process can be quantified by using a set of control limits and that variation exceeding these limits signals a change in the process. Although control charts were developed to improve manufacturing processes, they are used in many other fields, including finance and health care.

In industry, the Shewhart chart is the most commonly applied statistical quality control method of studying the variation in output from a manufacturing process. Shewhart charts are typically used to distinguish variation due to *special causes* from variation due to *common causes*. Special causes, also referred to as *assignable causes*, are local, sporadic problems such as the failure of a particular machine or a mistakenly recorded measurement. Common causes are problems inherent in the system as a whole, such as inadequate product design, inherited defective material, and excessive humidity.



After the special causes have been identified and eliminated, the process is said to be in *statistical control*. When statistical control has been established, Shewhart charts can be used to monitor the process for the occurrence of future special causes and to measure and reduce the effects of common causes.

Deming (1982) emphasized that the improvement of a process can begin only after statistical control has been established. Deming also noted that control chart techniques are applicable to quality improvement in service industries as well as manufacturing industries.

Characteristics of Shewhart Charts

Figure 32.1 illustrates a typical Shewhart chart.

Figure 32.1 A Shewhart Control Chart

All Shewhart charts have the following characteristics:

- Each point represents a *summary statistic* that is computed from a sample of measurements of a quality characteristic. For example, the summary statistic might be the average value of a critical dimension of five items selected at random, or it might be the proportion of nonconforming items in a sample of 100 items.
- The samples from which the summary statistics are computed are referred to as *rational subgroups* or *subgroup samples*. The organization of the data into subgroups is critical to the interpretation of a Shewhart chart. Shewhart (1931) advocated selecting rational subgroups so that variation within subgroups is minimized and variation among subgroups is maximized; this makes the chart more sensitive to shifts in the process level. Various approaches to subgrouping are discussed by Grant and Leavenworth (1988), Montgomery (1996), and Kume (1985).
- The *horizontal axis* of a Shewhart chart identifies the subgroup samples. Frequently, the samples are indexed according to the order in which they were taken or the time at which they were taken. Subgroup samples can also be assigned labels that indicate some other type of classification (such as lot number).

- The *central line* on a Shewhart chart indicates the average (expected value) of the summary statistic when the process is in statistical control.

- The *upper and lower control limits*, labeled UCL and LCL, respectively, indicate the range of variation to be expected in the summary statistic when the process is in statistical control. The control limits are commonly computed as 3σ limits,[1] which represent three standard errors[2] of variation in the summary statistic above and below the central line. However, the limits can also be determined using a multiple of the standard error other than three.

  The control limits are also determined by the subgroup sample size, because the standard error of the summary statistic is a function of sample size. If the sample size is constant across subgroups, the control limits are typically horizontal lines, as in Figure 32.1. However, if the sample size varies from subgroup to subgroup, the limits are usually adjusted to compensate for the effect of sample size, resulting in steplike boundaries.

  Control limits can be estimated from the data that you are analyzing, or they can be standard, previously determined values. Estimated limits are often used when you are establishing statistical control, and standard limits are often used when you are maintaining statistical control.

- *A point outside the control limits* signals the presence of a special cause of variation. In addition, *tests for special causes* (also referred to as *Western Electric rules* and *runs tests*) can signal an out-of-control condition if a statistically unusual pattern of points is observed in the control chart. For example, one pattern that is commonly used to diagnose the existence of a trend is seven consecutive steadily increasing points.

  When the process is in statistical control, a point can fall outside the control limits purely by chance, resulting in a false out-of-control signal. However, when the Shewhart chart correctly signals the presence of a special cause, you must take additional action to determine the nature of the problem and eliminate it.

Classification of Control Charts

PROC SPC calculates control charts that can be broadly classified as follows:

- Shewhart charts for *variables* are used when you are measuring the quality characteristic of a process on a continuous scale.

- Shewhart charts for *attributes* are used when you are measuring the quality characteristic of a process by counting the number of nonconformities (defects) in an item or the number of nonconforming (defective) items in a sample.

- Moving average charts are used to detect small shifts in the average of a quality characteristic measured on a continuous scale.

[1] In this context, σ always stands for the standard error of the subgroup summary statistic that is plotted on the chart. Elsewhere in this chapter, σ is also used to denote the standard deviation of a process, also referred to as the population standard deviation. This dual usage is standard practice.

[2] The term *standard deviation* is also used by some authors to refer to this quantity; see, for example, Montgomery (1996). This chapter uses the term *standard error* for the dispersion of the distribution of a statistic and the term *standard deviation* for the dispersion of a distribution of individual measurements.

Shewhart charts for variables are further classified according to the subgroup summary statistic that is plotted on the chart:

- $\bar{X}$ and R charts display subgroup means (averages) and ranges. You usually present the two charts on the same page, aligning the $\bar{X}$ chart above the R chart to facilitate the simultaneous analysis of the central tendency and variability of the process.
- $\bar{X}$ and s charts display subgroup means (averages) and standard deviations. You usually present the two charts on the same page, aligning the $\bar{X}$ chart above the s chart.
- Median and range charts display subgroup medians and ranges. You usually present the two charts on the same page, aligning the median chart above the R chart.
- Charts for individual measurements and moving ranges display individual measurements and moving ranges of two of more successive measurements. In this case the subgroup sample consists of a single observation.
- Box charts display a box plot (box-and-whisker plot) for each subgroup and control limits for the subgroup means or medians. This type of chart facilitates detailed analysis of the subgroup distributions and is applicable to large subgroup sample sizes (10 or more).

Likewise, Shewhart charts for attributes are classified according to the subgroup summary statistic that is plotted on the chart:

- A p chart displays the proportion of nonconforming (defective) items in a subgroup sample.
- An np chart displays the number of nonconforming (defective) items in a subgroup sample.
- A u chart displays the number of nonconformities (defects) per unit in a subgroup sample that consists of an arbitrary number of units.
- A c chart displays the number of nonconformities (defects) in a unit (here, a subgroup sample typically consists of one unit).

In contrast to a Shewhart chart, in which each point is based on information from a single subgroup sample, each point on a moving average chart combines information from the current sample and past samples. Moving average charts are classified by how the moving averages are computed:

- A uniformly weighted moving average chart (commonly called a moving average chart) computes the average of the w most recent subgroup means, including the present subgroup mean. The constant w is referred to as the *span* of the moving average.
- An exponentially weighted moving average (EWMA) chart computes a weighted average of all previous subgroup means, including the mean of the present subgroup sample. The weights decrease exponentially going backward in time.

PROC SPC Compared with SAS/QC Procedures

The SPC procedure performs univariate control chart analysis that is comparable to that of the SHEWHART and MACONTROL procedures in SAS/QC. Whereas the SAS/QC procedures produce graphical control charts, PROC SPC produces tables that summarize signals of process instability. PROC SPC also produces output data tables that you can read into SAS data sets and use as input to PROC SHEWHART and PROC MACONTROL. See Example 32.5 for an illustration.

PROC SPC is intended to perform control chart analysis on many process variables in parallel. Its input data format and syntax are more conducive to processing large numbers of processes than those of the SAS/QC procedures. You can use PROC SPC to produce concise summaries of process health for a large number of processes. After you identify potential problems, you can use PROC SHEWHART or PROC MACONTROL to produce control chart graphs of selected processes.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “Introduction to Shared Concepts” on page 6 in Chapter 2, “Shared Concepts.”

Getting Started: SPC Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/spcgs.sas.)

A brewery monitors its bottling process to ensure that each bottle is filled with the proper amount of beer. The following statements create a SAS data set named Beer that contains the amount of beer, recorded in fluid ounces, for 23 sample batches:

```
data Beer;
   input Batch size @;
   do i=1 to size;
      input Amount @@;
      output;
   end;
   drop i size;
   label Batch  ='Batch Number';
   datalines;
 1  5  12.01 11.97 11.93 11.98 12.00
 2  5  11.88 11.98 11.93 12.03 11.92
 3  5  11.93 11.99 12.00 12.03 11.95
 4  5  11.98 11.94 12.02 11.90 11.97
 5  5  12.02 12.02 11.98 12.04 11.90
 6  4  11.98 11.98 12.00 11.93
 7  5  11.93 11.95 12.02 11.91 12.03
 8  5  12.00 11.98 12.02 11.89 12.01
 9  5  11.98 11.93 11.99 12.02 11.91
10  5  11.97 12.02 12.05 12.01 11.97
11  5  12.02 12.01 11.97 12.02 11.94
12  5  11.93 11.83 11.99 12.02 12.01
13  5  12.01 11.98 11.94 12.04 12.01
14  5  11.98 11.96 12.02 12.00 12.00
15  5  11.97 11.99 12.03 11.95 11.96
16  5  11.99 11.95 11.96 12.03 12.01
17  4  11.99 11.97 12.03 12.01
18  5  11.94 11.96 11.98 12.03 11.97
19  5  11.97 11.87 11.90 12.01 11.95
20  5  11.96 11.94 11.96 11.98 12.05
21  3  12.06 12.07 11.98
22  5  12.01 11.98 11.96 11.97 12.00
23  5  12.00 12.02 12.03 11.99 11.96
;
```

The format of the Beer data set makes it suitable for analysis by PROC SHEWHART. The process variable is Amount, and the subgroup variable is Batch. Figure 32.2 shows a partial listing of the data set.

Figure 32.2 Data Set Beer (PROC SHEWHART Format)

Batch	Amount
1	12.01
1	11.97
1	11.93
1	11.98
1	12.00
2	11.88
2	11.98
2	11.93
2	12.03
2	11.92
3	11.93
3	11.99
3	12.00
3	12.03
3	11.95

The following DATA step modifies Beer so that it is suitable for analysis by PROC SPC:

```
data Beer;
   length processname $16 subgroupname $8;
   processname='Amount';
   subgroupname='Batch';
   set Beer(rename=(Amount=process Batch=subgroup));
run;
```

The modified data set is shown in Figure 32.3.

Figure 32.3 Data Set Beer (PROC SPC Format)

processname	subgroupname	subgroup	process
Amount	Batch	1	12.01
Amount	Batch	1	11.97
Amount	Batch	1	11.93
Amount	Batch	1	11.98
Amount	Batch	1	12.00
Amount	Batch	2	11.88
Amount	Batch	2	11.98
Amount	Batch	2	11.93
Amount	Batch	2	12.03
Amount	Batch	2	11.92
Amount	Batch	3	11.93
Amount	Batch	3	11.99
Amount	Batch	3	12.00
Amount	Batch	3	12.03
Amount	Batch	3	11.95

The PROC SPC data format is more conducive than the PROC SHEWHART format to analyzing many processes at once. Because process names are recorded in the process name variable, you do not have to list the processes to be analyzed in the procedure syntax.

The following statements create a data table called mylib.AllProcesses that contains the beer bottle data along with data from seven other SAS data sets (not shown here) that appear in the SHEWHART procedure chapter of *SAS/QC User's Guide*. These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.AllProcesses;
   set Beer Detergent Disks Partgaps Times Turbine Wafers Wire;
   format subgroup;
run;
```

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The following statements use PROC SPC to perform a means and ranges chart analysis of the eight processes.

```
proc spc data=mylib.AllProcesses;
   xrchart;
run;
```

The XRCHART statement performs an $\bar{X}$ and R chart analysis on the process data, calculating control charts for subgroup means and subgroup ranges. By default, control limits are calculated from the data. Figure 32.4 shows the resulting output.

Figure 32.4 PROC SPC Output

The SPC Procedure

Means and Ranges Chart Summary for ALLPROCESSES

			Means		Ranges	
processname	subgroupname	Number of Subgroups	Number > UCL	Number < LCL	Number > UCL	Number < LCL
Amount	Batch	23	0	0	0	0
Breakstrength	Sample	25	0	0	0	0
Delay	Day	11	3	1	2	2
Diameter	Batch	45	0	1	0	0
KWatts	Day	40	0	0	0	0
Partgap	Sample	41	0	0	0	0
Time	Lot	25	0	0	0	0
Weight	Lot	28	0	0	0	0

The default output from PROC SPC is an exception summary table. For each process, the table shows the number of subgroups that were analyzed and the number of subgroup summary statistics that fell outside the control limits of each chart.

The table in Figure 32.4 shows signals of unusual variation in process Delay (from the Times data set) and process Diameter (from the Wafers data set). When unusual variation is signaled in a process, you should investigate to find and correct any special causes of variation.

Syntax: SPC Procedure

PROC SPC < *options* > ;
BY *variables* ;
BOXCHART < / *options* > ;
CCHART < / *options* > ;
EWMACHART < / *options* > ;
IRCHART < / *options* > ;
MACHART < / *options* > ;
MCHART < / *options* > ;
MRCHART < / *options* > ;
NPCHART < / *options* > ;
PCHART < / *options* > ;
RCHART < / *options* > ;
SCHART < / *options* > ;
UCHART < / *options* > ;
XCHART < / *options* > ;
XRCHART < / *options* > ;
XSCHART < / *options* > ;

The PROC SPC statement invokes the procedure.

You use the chart statements to perform control chart analysis. You can specify a BY statement to obtain separate analyses for each BY group.

PROC SPC Statement

PROC SPC < *options* > ;

The PROC SPC statement is required in order to invoke the SPC procedure. By itself, it does not perform any statistical process control analysis.

You can specify the following options in the PROC SPC statement:

DATA=*libref.data-table*
names the input data table for PROC SPC to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1647.

data-table specifies the name of the input data table.

For more information, see the section "DATA= Data Table" on page 1702.

LIMITS=*libref.data-table*
names an input data table that contains preestablished control limits or the parameters from which control limits can be computed. Each observation in a LIMITS= data table provides control limit information for a process. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1647.

You can create this data table as an OUTLIMITS= data table in a previous run of PROC SPC. For more information, see the section "LIMITS= Data Table" on page 1702.

NTHREADS=*n*
specifies the number of threads per node to be used to perform the analysis. You can specify a number between 1 and 64, inclusive. By default, *n* is the maximum number of threads available on each node.

PROCESSNAME=*variable*
specifies the variable in the input data table that contains the names of processes to be analyzed. Each unique combination of process name and subgroup name in the input data table identifies the data for one control chart. By default, PROC SPC looks for a variable named ProcessName that contains the process names.

PROCESSVALUE=*variable*
specifies the variable in the input data table that contains the process measurements to be analyzed. By default, PROC SPC looks for a variable named Process that contains the process measurements.

SUBGROUPNAME=*variable*
specifies the variable in the input data table that contains the names of subgroup variables. Each unique combination of process name and subgroup name in the input data table identifies the data for one control chart. By default, PROC SPC looks for a variable named SubgroupName that contains the subgroup variable names.

SUBGROUPVALUE=*variable*
specifies the variable in the input data table that contains the subgroup values. Subgroup values identify rational subgroups for control chart analysis. By default, PROC SPC looks for a variable named Subgroup that contains the subgroup values.

BY Statement

BY *variables* **;**

You can specify a BY statement in PROC SPC to obtain separate analyses of observations in groups that are defined by the values of the BY variables. If you specify more than one BY statement, only the last one specified is used. For more information, see the discussion of BY-group processing in the "Grouping Data" section of *SAS Programmers Guide: Essentials*.

BOXCHART Statement

BOXCHART < */ options* > **;**

The BOXCHART statement produces control charts for subgroup means or medians, along with statistics that describe the distribution of data within each subgroup. Table 32.1 lists the options that you can specify in a BOXCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.1 BOXCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits
CONTROLSTAT=	Specifies whether control limits are computed for subgroup means or subgroup medians
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
MEDCENTRAL=	Specifies the method of estimating the process mean μ when control limits are computed for subgroup medians
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
PCTLDEF=	Specifies the percentile definition for box-and-whisker computation
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the box chart

CCHART Statement

CCHART < */ options* > **;**

The CCHART statement produces *c* charts for the numbers of nonconformities (defects) in subgroup samples. Table 32.2 lists the options that you can specify in a CCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.2 CCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SUBGROUPN=	Specifies a variable in the input data table that contains subgroup sample sizes
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the *c* chart

EWMACHART Statement

EWMACHART < */ options* > **;**

The EWMACHART statement produces exponentially weighted moving average (EWMA) charts of subgroup means. Table 32.3 lists the options that you can specify in an EWMACHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.3 EWMACHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
ASYMPTOTIC	Requests constant control limits
EXCHART	Produces results only for charts in which exceptions occur

Table 32.3 *continued*

Option	Description
LIMITN=	Specifies the nominal sample size for fixed control limits
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limit parameters
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
RESET	Resets the value of the EWMA after each point outside the control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the EWMAs
SMETHOD=	Specifies the method of estimating the process standard deviation σ
WEIGHT=	Specifies the weight to assign to the most recent subgroup mean in the computation of the EWMA

IRCHART Statement

IRCHART < */ options* > **;**

The IRCHART statement produces control charts for individual measurements and moving ranges. Table 32.4 lists the options that you can specify in an IRCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.4 IRCHART Statement Options

Option	Description
CIINDICES	Computes capability index confidence limits
EXCHART	Produces results only for charts in which exceptions occur
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the individual measurements chart

MACHART Statement

MACHART < */ options* > **;**

The MACHART statement produces uniformly weighted moving average charts of subgroup means. Table 32.5 lists the options that you can specify in an MACHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.5 MACHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
ASYMPTOTIC	Requests constant control limits
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limit parameters
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the moving averages
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPAN=	Specifies the number of subgroup means in the moving average

MCHART Statement

MCHART < */ options* > **;**

The MCHART statement produces control charts for subgroup medians. Table 32.6 lists the options that you can specify in an MCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.6 MCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
MEDCENTRAL=	Specifies the method of estimating the process mean μ
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits

Table 32.6 *continued*

Option	Description
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the median chart

MRCHART Statement

MRCHART < */ options* > **;**

The MRCHART statement produces control charts for subgroup medians and ranges. Table 32.7 lists the options that you can specify in an MRCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.7 MRCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
MEDCENTRAL=	Specifies the method of estimating the process mean μ
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3

Table 32.7 *continued*

Option	Description
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the median chart
TESTS2=	Requests tests for special causes for the *R* chart

NPCHART Statement

NPCHART < */ options* > **;**

The NPCHART statement produces control charts for the numbers of nonconforming items in subgroup samples. Table 32.8 lists the options that you can specify in an NPCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.8 NPCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SUBGROUPN=	Specifies a variable in the input data table that contains subgroup sample sizes
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the *np* chart

PCHART Statement

PCHART < */ options* > **;**

The PCHART statement produces control charts for the proportions of nonconforming items in subgroup samples. Table 32.9 lists the options that you can specify in a PCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.9 PCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SUBGROUPN=	Specifies a variable in the input data table that contains subgroup sample sizes
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the *p* chart

RCHART Statement

RCHART < */ options* > **;**

The RCHART statement produces control charts for subgroup ranges. Table 32.10 lists the options that you can specify in an RCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.10 RCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits
EXCHART	Produces results only for charts in which exceptions occur

Table 32.10 *continued*

Option	Description
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS2=	Requests tests for special causes for the *R* chart

SCHART Statement

SCHART < */ options* > **;**

The SCHART statement produces control charts for subgroup standard deviations. Table 32.11 lists the options that you can specify in an SCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.11 SCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ

Table 32.11 *continued*

Option	Description
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS2=	Requests tests for special causes for the *s* chart

UCHART Statement

UCHART < */ options* > **;**

The UCHART statement produces control charts for the numbers of nonconformities per inspection unit in subgroup samples. Table 32.12 lists the options that you can specify in a UCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.12 UCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SUBGROUPN=	Specifies a variable in the input data table that contains subgroup sample sizes
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the *u* chart

XCHART Statement

XCHART < */ options* > **;**

The XCHART statement produces control charts for subgroup means. Table 32.13 lists the options that you can specify in an XCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.13 XCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the $\bar{X}$ chart

XRCHART Statement

XRCHART < */ options* > **;**

The XRCHART statement produces control charts for subgroup means and ranges. Table 32.14 lists the options that you can specify in an XRCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.14 XRCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits

Table 32.14 *continued*

Option	Description
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the $\bar{X}$ chart
TESTS2=	Requests tests for special causes for the R chart

XSCHART Statement

XSCHART < */ options* > **;**

The XSCHART statement produces control charts for subgroup means and standard deviations. Table 32.15 lists the options that you can specify in an XSCHART statement. For detailed descriptions of these options, see the section "Dictionary of Options" on page 1664.

Table 32.15 XSCHART Statement Options

Option	Description
ALLN	Includes all subgroups in the analysis, regardless of sample size
CIINDICES	Computes capability index confidence limits
EXCHART	Produces results only for charts in which exceptions occur
LIMITN=	Specifies the nominal sample size for fixed control limits
NO3SIGMACHECK	Enables tests for special causes to be applied when control limits other than 3σ limits are in effect
NOPRINT	Suppresses ODS output
OUTLIMITS=	Creates an output data table that contains control limits
OUTTABLE=	Creates an output data table that contains subgroup summary statistics and control limits

Table 32.15 *continued*

Option	Description
SIGMAS=	Specifies the width of the control limits in terms of a multiple of the standard error of the subgroup summary statistic
SMETHOD=	Specifies the method of estimating the process standard deviation σ
SPECS=	Specifies an input data table that contains process specification limits and computes process capability indices
TEST2RUN=	Specifies the length of the pattern for Test 2
TEST3RUN=	Specifies the length of the pattern for Test 3
TESTNSTD	Applies tests for special causes to standardized chart statistics
TESTOVERLAP	Performs tests for special causes on overlapping patterns of points
TESTS=	Requests tests for special causes for the $\bar{X}$ chart
TESTS2=	Requests tests for special causes for the s chart

Dictionary of Options

The following entries provide detailed descriptions of options that are available in the BOXCHART, CCHART, EWMACHART, IRCHART, MACHART, MCHART, MRCHART, NPCHART, PCHART, RCHART, SCHART, UCHART, XCHART, XRCHART, and XSCHART statements. An option is available in all the chart statements unless otherwise noted.

ALLN

includes all subgroups in the analysis, regardless of whether the subgroup sample size equals the nominal control limit sample size n that you specify in the LIMITN= option or the variable _LIMITN_ in the LIMITS= data table. Use the ALLN option in conjunction with the LIMITN= option or the variable _LIMITN_.

ASYMPTOTIC

requests constant lower and upper control limits for all subgroups in a moving average chart.

In a uniformly weighted moving average chart, asymptotic limits have the following values:

$$\text{LCL} = \overline{\overline{X}} - \frac{k\hat{\sigma}}{\sqrt{nw}}$$

$$\text{UCL} = \overline{\overline{X}} + \frac{k\hat{\sigma}}{\sqrt{nw}}$$

Here w is the span of the moving average, and n is the nominal sample size associated with the control limits. When you do not specify this option, the control limits are computed using the exact formulas in Table 32.35.

In an exponentially weighted moving average chart, asymptotic limits have the following values:

$$\text{LCL} = \overline{\overline{X}} - k\hat{\sigma}\sqrt{r/n(2-r)}$$

$$\text{UCL} = \overline{\overline{X}} + k\hat{\sigma}\sqrt{r/n(2-r)}$$

Here r is the weight parameter ($0 < r \leq 1$), and n is the nominal sample size associated with the control limits. When you do not specify the ASYMPTOTIC option, the control limits are computed using the exact formulas in Table 32.37.

Use the ASYMPTOTIC option only if all the subgroup sample sizes are the same or if you specify a nominal subgroup sample size by using the LIMITN= option or by including the _LIMITN_ column in a LIMITS= data table.

This option is available only in the EWMACHART and MACHART statements.

CIINDICES <(< TYPE=LOWER | UPPER | TWOSIDED > < ALPHA=*value* >) >
requests capability index confidence limits that are based on subgroup summary data and are calculated using "effective degrees of freedom," as described by Bissell (1990). These confidence limits are approximate. When you specify the CIINDICES option, the calculated confidence limits are displayed in the "CapabilityIndices" table and are included in the OUTLIMITS= data table, if one is produced.

TYPE=*keyword*
specifies the type of confidence limit. Valid *keywords* are LOWER, UPPER, and TWOSIDED. By default, TYPE=TWOSIDED.

ALPHA=*value*
specifies the default confidence level to compute confidence limits. The percentage for the confidence limits is $(1 - \textit{value}) * 100$. For example, ALPHA=.05 results in a 95% confidence limit. The default value is .05, and the possible range of values is from 0 to 1.

The CIINDICES option is ignored unless you also specify the SPECS= option. These options are available only in the chart statements that produce Shewhart charts for variables: BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHART, XCHART, XRCHART, and XSCHART. For more information about capability indices, see the section "Capability Indices" on page 1700.

CONTROLSTAT=MEAN | MEDIAN
specifies whether the control limits that are displayed in a box chart are computed for subgroup means or for subgroup medians. By default, CONTROLSTAT=MEAN. This option is available only in the BOXCHART statement.

EXCHART
includes a control chart in the results only when exceptions occur—specifically, when the control limits are exceeded or when any tests that you request by using the TESTS= or TESTS2= option are positive.

LIMITN=*n*
specifies a nominal sample size for the control limits, where *n* is a whole number.

If you specify LIMITN=*n*, the control limits are computed for the fixed value *n*, and they do not vary with the subgroup sample sizes. Moreover, only those subgroups whose sample size is equal to *n* are included in the analysis. You can specify the ALLN option in conjunction with LIMITN=*n* to force all subgroups to be included, regardless of subgroup sample size.

Note that control limits for EWMA and moving average charts vary according to the number of subgroup means that are included in the moving average, not only because of varying subgroup sample sizes.

If you do not specify LIMITN=*n* and the subgroup sample sizes are constant, the default value of *n* is the constant subgroup sample size.

Depending on which chart statement you use, there are restrictions on the value of n that you can specify in the LIMITN= option:

- For the MRCHART, RCHART, and XRCHART statements, $2 \leq n \leq 25$.
- For the EWMACHART, MACHART, SCHART, and XSCHART statements, $n \geq 2$.
- For the BOXCHART, MCHART, and XCHART statements, $n \geq 1$. If the estimate of the process standard deviation is based on subgroup ranges (see the SMETHOD= option and the section "Methods of Estimating the Standard Deviation" on page 1672), $n \leq 25$.
- For the CCHART, NPCHART, PCHART, and UCHART statements, $n \geq 1$.

This option is not available in the IRCHART statement.

Notice the difference between the LIMITN= option and the SUBGROUPN= option that is available in the CCHART, NPCHART, PCHART, and UCHART statements. The LIMITN= option specifies a nominal sample size for the *control limits*, whereas the SUBGROUPN= option provides the sample sizes for the *data*.

NOTE: As an alternative to specifying the LIMITN= option, you can read the nominal control limit sample size from the variable _LIMITN_ in a LIMITS= data table.

MEDCENTRAL=AVGMEAN | AVGMED | MEDMED

identifies a method of estimating the process mean μ, which is represented by the central line on a median chart. The method that corresponds to each keyword is shown in Table 32.16.

Table 32.16 Methods of Estimating the Process Mean

Keyword	Method
AVGMEAN	Average of subgroup means
AVGMED	Average of subgroup medians
MEDMED	Median of subgroup medians

By default, MEDCENTRAL=AVGMED. This option is available only in the MCHART and MRCHART statements, and in the BOXCHART statement when you specify the CONTROLSTAT=MEDIAN option.

NO3SIGMACHECK

suppresses the check for 3σ limits when you request tests for special causes. This enables tests for special causes to be applied when you use SIGMAS= option to specify control limits other than the default 3σ limits. You should not use the NO3SIGMACHECK option for standard control chart applications, because the standard tests for special causes assume 3σ limits.

This option is not available in the EWMACHART and MACHART statements.

NOPRINT

suppresses the display of ODS output.

OUTLIMITS=*libref.data-table*

creates an output data table that saves the control limits and/or control limit parameters. You can use an OUTLIMITS= data table as an input LIMITS= data table in a subsequent run of the procedure. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1647.

For more information about OUTLIMITS= data tables, see the section "OUTLIMITS= Data Table" on page 1704.

OUTTABLE=*libref.data-table*

creates an output data table that saves the information plotted on the chart, including the subgroup variable values and their corresponding summary statistics and control limits. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1647.

For more information about OUTTABLE= data tables, see the section "OUTTABLE= Data Table" on page 1710.

PCTLDEF=*index*

specifies one of five definitions that are used to calculate percentiles in the construction of box-and-whisker plots that you request in the BOXCHART statement. The *index* can be 1, 2, 3, 4, or 5. The five corresponding percentile definitions are discussed in the section "Percentile Definitions" on page 1693. By default, PCTLDEF=5. This option is available only in the BOXCHART statement.

RESET

resets the value of the EWMA after each out-of-control point. Specifically, when a point exceeds the control limits, the EWMA for the next subgroup is computed as the weighted average of the subgroup mean and the overall mean. By default, the EWMA values are not reset. This option is available only in the EWMACHART statement.

SIGMAS=*k*

specifies the width of the control limits in terms of the multiple k of the standard error of the subgroup summary statistic. The value of k must be positive. By default, $k = 3$, and the control limits are 3σ limits.

SMETHOD=MAD | MMR<(*n*)> | MVGRANGE<(*n*)> | RMSDF | RMVLUE | RNOWEIGHT | SMVLUE | SNOWEIGHT

specifies the method of estimating the process standard deviation, σ, as summarized in Table 32.17.

Table 32.17 Methods of Estimating the Process Standard Deviation

Keyword	Method
MAD	Calculates a median absolute deviation estimate of σ
MMR	Calculates a median moving range estimate of σ
MVGRANGE	Estimates σ based on a moving range of n subgroup means
RMSDF	Calculates a root mean square estimate of σ
RMVLUE	Calculates a minimum variance linear unbiased estimate of σ based on subgroup ranges
RNOWEIGHT	Estimates σ as an unweighted average of unbiased subgroup estimates of σ based on subgroup ranges
SMVLUE	Calculates a minimum variance linear unbiased estimate of σ based on subgroup standard deviations
SNOWEIGHT	Estimates σ as an unweighted average of unbiased subgroup estimates of σ based on subgroup standard deviations

Table 32.18 lists the SMETHOD= option values that are valid for each chart statement. The default value for each statement is shown in bold.

Table 32.18 Valid SMETHOD= Values by Chart Statement

Chart Statement	Methods
BOXCHART	RMSDF, RMVLUE, RNOWEIGHT, SMVLUE, **SNOWEIGHT**
EWMACHART	RMSDF, SMVLUE, **SNOWEIGHT**
IRCHART	MAD, MMR, **MVGRANGE**
MACHART	RMSDF, SMVLUE, **SNOWEIGHT**
MCHART	RMSDF, RMVLUE, **RNOWEIGHT**, SMVLUE, SNOWEIGHT
MRCHART	RMVLUE, **RNOWEIGHT**
RCHART	RMVLUE, **RNOWEIGHT**
SCHART	RMSDF, SMVLUE, **SNOWEIGHT**
XCHART	RMSDF, RMVLUE, **RNOWEIGHT**, SMVLUE, SNOWEIGHT
XRCHART	MVGRANGE, RMVLUE, **RNOWEIGHT**
XSCHART	MVGRANGE, RMSDF, SMVLUE, **SNOWEIGHT**

When you use the MMR or MVGRANGE method, you can specify the number n of consecutive subgroup summary statistics from which moving ranges are computed by appending the number in parentheses to the keyword. For example, you can specify SMETHOD=MVGRANGE(4) to use moving ranges of four subgroup statistics. Values in the range $2 \leq n \leq 25$ are valid. By default, $n = 2$.

This option is not available in the following statements that produce Shewhart charts for attributes: CCHART, NPCHART, PCHART, and UCHART.

For more information about the different methods of estimating the process standard deviation, see the section "Methods of Estimating the Standard Deviation" on page 1672.

SPAN=*w*

specifies the number of terms to use in calculating the moving average for a uniformly weighted moving average chart, where *w* is an integer greater than 1. This option is required in an MACHART statement unless you specify span values in a column named _SPAN_ in a LIMITS= data table.

This option is available only in the MACHART statement.

SPECS=*libref.data-table*

specifies an input data table that contains process specification limits. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1647. PROC SPC calculates capability indices for processes whose specifications are given in *data-table*.

This option is available only in the statements that produce Shewhart charts for variables: BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHART, XCHART, XRCHART, and XSCHART. For more information, see the sections "SPECS= Data Table" on page 1703 and "Capability Indices" on page 1700.

SUBGROUPN=*variable*

specifies a variable in the input data table whose values specify the subgroup sample sizes. This option is available only in the CCHART, NPCHART, PCHART, and UCHART statements. You must specify this option in the NPCHART, PCHART, and UCHART statements. For the CCHART statement, the default subgroup sample size is 1.

TEST2RUN=*run-length*

specifies the length of the pattern for Test 2 that you request in the TESTS= and TESTS2= options. The *run-length* values that you can specify are 7, 8, 9, 11, 14, and 20. The form of the test for each *run-length* value is shown in the following table. By default, TEST2RUN=9. For more information, see the section "Tests for Special Causes" on page 1694.

run-length	**Number of Points on One Side of the Central Line**
7	7 in a row
8	8 in a row
9	9 in a row
11	At least 10 out of 11 in a row
14	At least 12 out of 14 in a row
20	At least 16 out of 20 in a row

This option is not available in the EWMACHART and MACHART statements.

TEST3RUN=*run-length*

specifies the length of the pattern for Test 3 that you request in the TESTS= and TESTS2= options. Test 3 searches for a pattern of steadily increasing or decreasing values, where the length of the pattern is at least the value of *run-length*. The values that you can specify for *run-length* are 6, 7, and 8. By default, TEST3RUN=6. For more information, see the section "Tests for Special Causes" on page 1694.

This option is not available in the EWMACHART and MACHART statements.

TESTNSTD

applies the tests for special causes that you request in the TESTS= and TESTS2= options to standardized test statistics when the subgroup sample sizes are not constant. This method was suggested by Nelson (1994). For more information, see the section "Tests for Special Causes" on page 1694. By default, the tests are not applied to data that have varying subgroup sample sizes.

This option is not available in the EWMACHART and MACHART statements.

TESTOVERLAP

applies tests for special causes (which you request in the TESTS= or TESTS2= option) to overlapping patterns of points.

This option modifies the way in which the search for a subsequent pattern is done when a pattern is encountered. If you omit this option, the search begins with the first subgroup after the current pattern ends. If you specify this option, the search begins with the second subgroup in the current pattern.

The following statements request Test 3, which detects six subgroup means in a row that steadily increase or decrease:

```
proc spc;
   xrchart / test=3;
   xrchart / test=3 testoverlap;
run;
```

Suppose that the subgroup means are steadily increasing for subgroups 5, 6, 7, 8, 9, 10, and 11. The first XRCHART statement signals that Test 3 is positive at subgroup 10 but not at subgroup 11, because the search for the next pattern begins with subgroup 11. The second XRCHART statement signals that Test 3 is positive at subgroup 10 and subgroup 11, because the search for the next pattern begins with subgroup 6 and thus finds a second pattern that ends with subgroup 11. For more information, see the section "Tests for Special Causes" on page 1694.

CAUTION: Specifying TESTOVERLAP affects the interpretation of the standard tests for special causes, because a particular point can contribute to more than one positive test. Typically, you should not use this option.

This option is not available in the EWMACHART and MACHART statements.

TESTS=*index-list*

requests one or more tests for special causes, which are also known as *runs tests*, *pattern tests*, and *Western Electric rules*. These tests detect particular nonrandom patterns in the points that are plotted on the primary control chart. The occurrence of a pattern, referred to as a *signal*, suggests the presence of a special cause of variation.

Each pattern is defined in terms of Zones A, B, and C, which are constructed by dividing the interval between the control limits into six equally spaced subintervals. Zone A is the union of the subintervals immediately below the upper control limit and immediately above the lower control limit. Zone C is the union of the subintervals immediately above and below the central line. Zone B is the union of the subintervals between Zones A and C. For an illustration of test zones, see Figure 32.9.

Table 32.19 lists the standard tests that you can request by specifying this option. The tests are indexed according to the sequence used by Nelson (1984, 1985).

Table 32.19 Standard Tests for Special Causes

Index	Pattern Description
1	One point beyond Zone A (outside the control limits)
2	Nine points in a row in Zone C or beyond on one side of the central line (see the TEST2RUN= option)
3	Six points in a row that steadily increase or decrease (see the TEST3RUN= option)
4	Fourteen points in a row that alternate up and down
5	Two out of three points in a row in Zone A or beyond
6	Four out of five points in a row in Zone B or beyond
7	Fifteen points in a row in Zone C on either or both sides of the central line
8	Eight points in a row on either or both sides of the central line, with no points in Zone C

You can specify any combination of the eight *indices* by using an explicit list or an implicit list, as in the following example:

```
proc spc;
   xrchart / tests=1 2 3 4;
   xrchart / tests=1 to 4;
run;
```

The TESTS= option is available in all chart statements except the RCHART and SCHART statements. Use only tests 1, 2, 3, and 4 in the CCHART, NPCHART, PCHART, and UCHART statements. By default, the TESTS= option is not applied in any chart statement unless the control limits are 3σ limits. You can use the NO3SIGMACHECK option to request tests for special causes when you use the SIGMAS= option to specify control limits other than 3σ limits.

For more information about the TESTS= option, see the section "Tests for Special Causes" on page 1694. Related options include TEST2RUN=, TEST3RUN=, TESTNSTD, TESTOVERLAP, and TESTS2=.

This option is not available in the EWMACHART and MACHART statements.

TESTS2=*index-list*

requests one or more tests for special causes for *R* charts or *s* charts. The syntax for the TESTS2= option is identical to the syntax for the TESTS= option. The TESTS2= option is available in the MRCHART, RCHART, SCHART, XRCHART, and XSCHART statements. For more information about the TESTS2= option, see the section "Tests for Special Causes" on page 1694. Related options include TEST2RUN=, TEST3RUN=, TESTNSTD, TESTOVERLAP, and TESTS=.

WEIGHT=*r*

specifies the weight r ($0 < r \leq 1$) assigned to the most recent subgroup mean in the computation of the exponentially weighted moving average in an EWMA chart. The WEIGHT= option is required in an EWMACHART statement unless you specify weight values in a column named _WEIGHT_ in a LIMITS= data table.

This option is available only in the EWMACHART statement.

Details: SPC Procedure

Methods of Estimating the Standard Deviation

You can specify the SMETHOD= option to choose among several methods of estimating the process standard deviation for Shewhart charts for variables and moving average charts. The following sections describe the methods in detail.

MAD Method

If you specify SMETHOD=MAD, a median absolute deviation estimator is computed for σ. This method is described by Boyles (1997) and computed as

$$\hat{\sigma} = \text{median}\{|X_i - \tilde{X}|, 1 \leq i \leq N\}/0.6745$$

where $\tilde{X}$ is the sample median.

The MAD method is available only in the IRCHART statement.

MMR Method

If you specify SMETHOD=MMR, a median moving range estimator is computed for σ. This estimator is described by Boyles (1997) and computed as

$$\hat{\sigma} = \tilde{R}/0.954$$

where $\tilde{R}$ is the median of the nonmissing moving ranges.

The MMR method is available only in the IRCHART statement.

MVGRANGE Method

If you specify SMETHOD=MVGRANGE, σ is estimated by using a moving range of subgroup averages (or individual measurements in an IRCHART statement). The estimate of σ is

$$\hat{\sigma} = \bar{R}/d_2(n)$$

where $\bar{R}$ is the average of the moving ranges; n is the number of consecutive subgroup averages that are used to compute each moving range; and the unbiasing factor $d_2(n)$ is defined so that if the subgroup averages are normally distributed, the expected value of R_i is

$$E(R_i) = d_2(n_i)\sigma$$

This method is described by the American Society for Testing and Materials (1976).

The method is appropriate for constructing the three-way control chart that Wheeler (1995) advocated for this situation. A three-way control chart is useful when sampling (*within-group*) variation is not the only source of variation. A three-way control chart contains a chart of subgroup means, a moving range chart of the subgroup means, and a chart of subgroup ranges. When you specify the SMETHOD=MVGRANGE option, the XRCHART statement produces the appropriate charts of subgroup means and subgroup ranges, and the XSCHART statement produces the appropriate charts of subgroup means and subgroup standard deviations.

The MVGRANGE method is available in the IRCHART, XRCHART, and XSCHART statements. It is the default in the IRCHART statement.

RMSDF Method

If you specify SMETHOD=RMSDF, a weighted root mean square estimate is computed for σ,

$$\hat{\sigma} = \frac{\sqrt{(n_1 - 1)s_1^2 + \cdots + (n_N - 1)s_N^2}}{c_4(n)\sqrt{n_1 + \cdots + n_N - N}}$$

where $n = n_1 + \cdots + n_N - (N - 1)$. The weights are the degrees of freedom $n_i - 1$. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$.

If the unknown standard deviation σ is constant across subgroups, the root mean square estimate is more efficient than the minimum variance linear unbiased estimate (MVLUE). However, in process control applications, it is generally not assumed that σ is constant, and if σ varies across subgroups, the root mean square estimate tends to be more inflated than the MVLUE.

The RMSDF method is available in the BOXCHART, EWMACHART, MACHART, MCHART, SCHART, XCHART, and XSCHART statements.

RMVLUE Method

If you specify SMETHOD=RMVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ; see Burr (1969, 1976) and Nelson (1989, 1994). The MVLUE is a weighted average of N unbiased estimates of σ of the form $R_i/d_2(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{f_1 R_1/d_2(n_1) + \cdots + f_N R_N/d_2(n_N)}{f_1 + \cdots + f_N}$$

where

$$f_i = \frac{[d_2(n_i)]^2}{[d_3(n_i)]^2}$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The unbiasing factor $d_3(n_i)$ is defined so that, if the observations are normally distributed, the expected value of σ_{R_i} is $d_3(n_i)\sigma$. The MVLUE assigns greater weight to estimates of σ from subgroups that have larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the RMVLUE estimate reduces to the RNOWEIGHT estimate.

The RMVLUE method is available in the BOXCHART, MCHART, MRCHART, RCHART, XCHART, and XRCHART statements.

RNOWEIGHT Method

If you specify SMETHOD=RNOWEIGHT, the estimate of σ is

$$\hat{\sigma} = \frac{R_1/d_2(n_1) + \cdots + R_N/d_2(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, and R_i is the sample range of the observations x_{i1}, $\ldots$, x_{in_i} in the ith subgroup:

$$R_i = \max_{1 \leq j \leq n_i}(x_{ij}) - \min_{1 \leq j \leq n_i}(x_{ij})$$

A subgroup range R_i is included in the calculation only if $n_i \geq 2$. The unbiasing factor $d_2(n_i)$ is defined so that, if the observations are normally distributed, the expected value of R_i is $d_2(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ. This method is described by the American Society for Testing and Materials (1976).

The RNOWEIGHT method is available in the BOXCHART, MCHART, MRCHART, RCHART, XCHART, and XRCHART statements. It is the default in the MCHART, MRCHART, RCHART, XCHART, and XRCHART statements.

SMVLUE Method

If you specify SMETHOD=SMVLUE, a minimum variance linear unbiased estimate (MVLUE) is computed for σ; see Burr (1969, 1976) and Nelson (1989, 1994). This estimate is a weighted average of N unbiased estimates of σ of the form $s_i/c_4(n_i)$, and it is computed as

$$\hat{\sigma} = \frac{h_1 s_1/c_4(n_1) + \cdots + h_N s_N/c_4(n_N)}{h_1 + \cdots + h_N}$$

where

$$h_i = \frac{[c_4(n_i)]^2}{1 - [c_4(n_i)]^2}$$

A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$, and N is the number of subgroups for which $n_i \geq 2$. The MVLUE assigns greater weight to estimates of σ from subgroups with larger sample sizes, and it is intended for situations where the subgroup sample sizes vary. If the subgroup sample sizes are constant, the SMVLUE estimate reduces to the SNOWEIGHT estimate.

The SMVLUE method is available in the BOXCHART, EWMACHART, MACHART, MCHART, SCHART, XCHART, and XSCHART statements.

SNOWEIGHT Method

If you specify SMETHOD=SNOWEIGHT, the estimate for σ is

$$\hat{\sigma} = \frac{s_1/c_4(n_1) + \cdots + s_N/c_4(n_N)}{N}$$

where N is the number of subgroups for which $n_i \geq 2$, s_i is the sample standard deviation of the ith subgroup,

$$s_i = \sqrt{\frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{X}_i)^2}$$

and

$$c_4(n_i) = \frac{\Gamma(n_i/2)\sqrt{2/(n_i - 1)}}{\Gamma((n_i - 1)/2)}$$

Here $\Gamma(\cdot)$ denotes the gamma function, and $\bar{X}_i$ denotes the ith subgroup mean. A subgroup standard deviation s_i is included in the calculation only if $n_i \geq 2$. If the observations are normally distributed, the expected value of s_i is $c_4(n_i)\sigma$. Thus, $\hat{\sigma}$ is the unweighted average of N unbiased estimates of σ. This method is described by the American Society for Testing and Materials (1976).

The SNOWEIGHT method is available in the BOXCHART, EWMACHART, MACHART, MCHART, SCHART, XCHART, and XSCHART statements. It is the default in the BOXCHART, EWMACHART, MACHART, SCHART, and XSCHART statements.

Constructing Charts for Individual Measurements and Moving Ranges

You produce control charts for individual measurements and moving ranges by using the IRCHART statement. The following notation is used in this section:

μ	Process mean (expected value of the population of measurements)
σ	Process standard deviation (standard deviation of the population of measurements)
X_i	The ith individual measurement
$\bar{X}$	Mean of the individual measurements, computed as $(X_1 + \cdots + X_N)/N$, where N is the number of individual measurements
n	Number of consecutive measurements that are used to calculate the moving ranges (by default, $n = 2$)
R_i	Moving range that is computed for the ith subgroup (corresponding to the ith individual measurement). If $i < n$, then R_i is assigned a missing value. Otherwise, $R_i = \max(X_i, X_{i-1}, \ldots, X_{i-n+1}) - \min(X_i, X_{i-1}, \ldots, X_{i-n+1})$ This formula assumes that $X_i, X_{i-1}, \ldots, X_{i-n+1}$ are nonmissing.
$\bar{R}$	Average of the nonmissing moving ranges, computed as $\frac{R_n + R_{n+1} + \cdots + R_N}{N + 1 - n}$
$d_2(n)$	Expected value of the range of n independent normally distributed variables with unit standard deviation
$d_3(n)$	Standard error of the range of n independent observations from a normal population with unit standard deviation

Subgroup Summary Statistics

Each point on an individual measurements chart indicates the value of a measurement (X_i).

Each point on a moving range chart indicates the value of a moving range (R_i). For $n = 2$, for example, if the first three measurements are 3.4, 3.7, and 3.6, then the first moving range is missing, the second moving range is $|3.7 - 3.4| = 0.3$, and the third moving range is $|3.6 - 3.7| = 0.1$.

Central Lines

By default, the central line on an individual measurements chart indicates an estimate for μ, which is computed as $\bar{X}$. If you specify a known value (μ_0) for μ, the central line indicates the value of μ_0.

The central line on a moving range chart indicates an estimate for the expected moving range, which is computed as $d_2(n)\hat{\sigma}$, where $\hat{\sigma} = \bar{R}/d_2(n)$. If you specify a known value ($\hat{\sigma}_0$) for σ, the central line indicates the value of $d_2(n)\sigma_0$.

Control Limits

The control limits are computed as a specified multiple (k) of the standard errors of X_i and R_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

Table 32.21 provides the formulas for the limits.

Table 32.21 Limits for Individual Measurements and Moving Range Charts

Individual Measurements Chart
LCL = lower control limit = $\bar{X} - k\hat{\sigma}$ UCL = upper control limit = $\bar{X} + k\hat{\sigma}$
Moving Range Chart
LCL = lower control limit = $\max(d_2(n)\hat{\sigma} - kd_3(n)\hat{\sigma}, 0)$ UCL = upper control limit = $d_2(n)\hat{\sigma} + kd_3(n)\hat{\sigma}$

The formulas assume that the measurements are normally distributed. If the standard values μ_0 and σ_0 are available for μ and σ, replace $\bar{X}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 32.21.

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify n by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify μ_0 by using the variable _MEAN_ in the LIMITS= data table.
- Specify σ_0 by using the variable _STDDEV_ in the LIMITS= data table.

Constructing Charts for Means

You produce control charts for means by using the BOXCHART, XCHART, XRCHART, or XSCHART statement. The following notation is used in this section:

μ	Process mean (expected value of the population of measurements)
σ	Process standard deviation (standard deviation of the population of measurements)
$\bar{X}_i$	Mean of measurements in ith subgroup
n_i	Sample size of ith subgroup
R_i	Range of measurements in ith subgroup
n_i	Sample size of ith subgroup
N	Number of subgroups
$\overline{\overline{X}}$	Weighted average of subgroup means

Subgroup Summary Statistics

Each point on an $\bar{X}$ chart indicates the value of a subgroup mean ($\bar{X}_i$). For example, if the 10th subgroup contains the values 12, 15, 19, 16, and 14, the subgroup summary statistic is

$$\bar{X}_{10} = \frac{12 + 15 + 19 + 16 + 14}{5} = 15.2$$

Central Line

By default, the central line on an $\bar{X}$ chart indicates an estimate for μ, which is computed as

$$\hat{\mu} = \overline{\overline{X}} = \frac{n_1\bar{X}_1 + \cdots + n_N\bar{X}_N}{n_1 + \cdots + n_N}$$

If you specify a known value (μ_0) for μ, the central line indicates the value of μ_0.

Control Limits

The limits are computed as a specified multiple (k) of the standard error of $\bar{X}_i$ above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

Table 32.23 provides the formulas for the limits.

Table 32.23 Limits for $\bar{X}$ Charts

LCL = lower limit = $\overline{\overline{X}} - k\hat{\sigma}\sqrt{n_i}$
UCL = upper limit = $\overline{\overline{X}} + k\hat{\sigma}\sqrt{n_i}$

Note that the limits vary with n_i. If the standard values μ_0 and σ_0 are available for μ and σ, respectively, replace $\overline{\overline{X}}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 32.23.

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify μ_0 by using the variable _MEAN_ in a LIMITS= data table.
- Specify σ_0 by using the variable _STDDEV_ in a LIMITS= data table.

Constructing Charts for Medians

You produce control charts for medians by using the MCHART or MRCHART statement, and by using the BOXCHART statement when you specify CONTROLSTAT=MEDIAN. The following notation is used in this section:

μ	Process mean (expected value of the population of measurements)
σ	Process standard deviation (standard deviation of the population of measurements)
n_i	Sample size of ith subgroup
N	Number of subgroups
x_{ij}	jth measurement in the ith subgroup, $j = 1, 2, 3, \ldots, n_i$
$x_{i(j)}$	jth-largest measurement in the ith subgroup. Then $$x_{i(1)} \leq x_{i(2)} \leq \cdots \leq x_{i(n_i)}$$
$\overline{\overline{X}}$	Weighted average of subgroup means
M_i	Median of the measurements in the ith subgroup: $$M_i = \begin{cases} x_{i((n_i+1)/2)} & \text{if } n_i \text{ is odd} \\ (x_{i(n_i/2)} + x_{i((n_i/2)+1)})/2 & \text{if } n_i \text{ is even} \end{cases}$$
$\bar{M}$	Average of the subgroup medians: $$\bar{M} = (n_1 M_1 + \cdots + n_N M_N)/(n_1 + \cdots + n_N)$$
$\tilde{M}$	Median of the subgroup medians. Denote the jth-largest median by $M_{(j)}$ so that $M_{(1)} \leq M_{(2)} \leq \cdots \leq M_{(N)}$. Then $$\tilde{M} = \begin{cases} M_{((N+1)/2)} & \text{if } N \text{ is odd} \\ (M_{(N/2)} + M_{(N/2)+1})/2 & \text{if } N \text{ is even} \end{cases}$$
$e_M(n)$	Standard error of the median of n independent, normally distributed variables with unit standard deviation (the value of $e_M(n)$ can be calculated using the STDMED function in a DATA step)

Subgroup Summary Statistics

Each point on a median chart indicates the value of a subgroup median (M_i). For example, if the 10th contains the values 12, 15, 19, 16, and 14, the subgroup summary statistic is $M_{10} = 15$.

Central Line

The value of the central line indicates an estimate of μ, which is computed as follows:

- $\bar{M}$ by default
- $\overline{\overline{X}}$ when you specify MEDCENTRAL=AVGMEAN
- $\tilde{M}$ when you specify MEDCENTRAL=MEDMED

Control Limits

The control limits are computed as a specified multiple (k) of the standard error of M_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

Table 32.25 provides the formulas for the limits.

Table 32.25 Limits for Median Charts

LCL = lower limit = $\bar{M} - k\hat{\sigma}e_M(n_i)$
UCL = upper limit = $\bar{M} + k\hat{\sigma}e_M(n_i)$

Note that the limits vary with n_i. In Table 32.25, replace $\bar{M}$ with $\overline{\overline{X}}$ if you specify MEDCENTRAL=AVGMEAN, and replace $\bar{M}$ with $\tilde{M}$ if you specify MEDCENTRAL=MEDMED. The formulas assume that the data are normally distributed.

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify μ_0 by using the variable _MEAN_ in the LIMITS= data table.
- Specify σ_0 by using the variable _STDDEV_ in the LIMITS= data table.

Constructing Charts for Ranges

You produce control charts for ranges by using the MRCHART, RCHART, or XRCHART statement. The following notation is used in this section:

σ	Process standard deviation (standard deviation of the population of measurements)
R_i	Range of measurements in ith subgroup
n_i	Sample size of ith subgroup
$d_2(n)$	Expected value of the range of n independent normally distributed variables with unit standard deviation
$d_3(n)$	Standard error of the range of n independent observations from a normal population with unit standard deviation

Subgroup Summary Statistics

Each point on an R chart indicates the value of a subgroup range (R_i). For example, if the 10th subgroup contains the values 12, 15, 19, 16, and 14, the subgroup summary statistic is $R_{10} = 19 - 12 = 7$.

Central Line

By default, the central line for the ith subgroup indicates an estimate of the expected value of R_i, which is computed as $d_2(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of σ. If you specify a known value (σ_0) for σ, the central line indicates the value of $d_2(n_i)\sigma_0$. Note that the central line varies with n_i.

Control Limits

The control limits are computed as a specified multiple (k) of the standard error of R_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

Table 32.27 provides the formulas for the limits.

Table 32.27 Control Limits for R Charts

LCL = lower limit = $\max(d_2(n_i)\hat{\sigma} - k d_3(n_i)\hat{\sigma}, 0)$
UCL = upper limit = $d_2(n_i)\hat{\sigma} + k d_3(n_i)\hat{\sigma}$

The formulas assume that the data are normally distributed. Note that the control limits vary with n_i. If a standard value σ_0 is available for σ, replace $\hat{\sigma}$ with σ_0 in Table 32.27.

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify σ_0 by using the variable _STDDEV_ in a LIMITS= data table.

Constructing Charts for Standard Deviations

You produce control charts for standard deviations by using the SCHART or XSCHART statement. The following notation is used in this section:

σ	Process standard deviation (standard deviation of the population of measurements)
s_i	Standard deviation of measurements in ith subgroup

$$s_i = \sqrt{(1/(n_i - 1))((x_{i1} - \bar{X}_i)^2 + \cdots + (x_{in_i} - \bar{X}_i)^2)}$$

n_i	Sample size of ith subgroup
$c_4(n)$	Expected value of the standard deviation of n independent normally distributed variables with unit standard deviation
$c_5(n)$	Standard error of the standard deviation of n independent observations from a normal population with unit standard deviation

Subgroup Summary Statistics

Each point on an s chart indicates the value of a subgroup standard deviation (s_i). For example, if the 10th subgroup contains the values 12, 15, 19, 16, and 13, the subgroup summary statistic is

$$s_{10} = \sqrt{((12-15)^2 + (15-15)^2 + (19-15)^2 + (16-15)^2 + (13-15)^2)/4} = 2.739$$

Central Line

By default, the central line for the ith subgroup indicates an estimate for the expected value of s_i, which is computed as $c_4(n_i)\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of σ. If you specify a known value (σ_0) for σ, the central line indicates the value of $c_4(n_i)\sigma_0$. Note that the central line varies with n_i.

Control Limits

The control limits are computed as a specified multiple (k) of the standard error of s_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

Table 32.29 provides the formulas for the limits.

Table 32.29 Control Limits for s Charts

LCL = lower limit = $\max(c_4(n_i)\hat{\sigma} - kc_5(n_i)\hat{\sigma}, 0)$
UCL = upper limit = $c_4(n_i)\hat{\sigma} + kc_5(n_i)\hat{\sigma}$

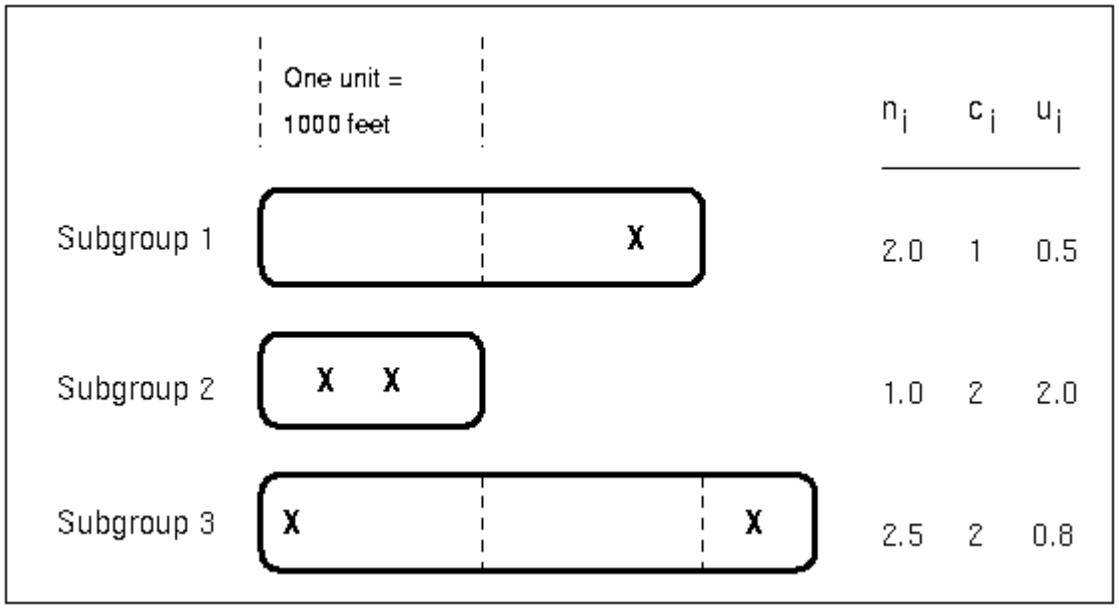
The formulas assume that the data are normally distributed. If a standard value σ_0 is available for σ, replace $\hat{\sigma}$ with σ_0 in Table 32.29. Note that the upper and lower limits vary with n_i.

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify σ_0 by using the variable _STDDEV_ in a LIMITS= data table.

Constructing Charts for Numbers of Nonconformities (c Charts)

You produce control charts for numbers of nonconformities by using the CCHART statement.



The following notation is used in this section:

u	Expected number of nonconformities per unit that the process produces
u_i	Number of nonconformities per unit in the ith subgroup
c_i	Total number of nonconformities in the ith subgroup
n_i	Number of inspection units in the ith subgroup. Typically, $n_i = 1$ and $u_i = c_i$ for c charts. In general, $u_i = c_i / n_i$.
$\bar{u}$	Average number of nonconformities per unit taken across subgroups. The quantity $\bar{u}$ is computed as a weighted average: $$\bar{u} = \frac{n_1 u_1 + \cdots + n_N u_N}{n_1 + \cdots + n_N} = \frac{c_1 + \cdots + c_N}{n_1 + \cdots + n_N}$$
N	Number of subgroups

Subgroup Summary Statistics

Each point on a c chart represents the total number of nonconformities (c_i) in a subgroup. For example, Figure 32.5 displays three sections of pipeline that are inspected for defective welds (indicated by an X). Each section represents a *subgroup* that consists of a number of *inspection units*, which are 1,000-foot sections. The number of units in the ith subgroup is denoted by n_i, which is the subgroup sample size. The value of n_i can be fractional; Figure 32.5 shows $n_3 = 2.5$ units in the third subgroup.

Figure 32.5 Terminology for c Charts and u Charts

The *number of nonconformities* in the ith subgroup is denoted by c_i. The *number of nonconformities per unit* in the ith subgroup is denoted by $u_i = c_i / n_i$. In Figure 32.5, the number of welds per inspection unit in the third subgroup is $u_3 = 2/2.5 = 0.8$.

A u chart that is created by the UCHART statement plots the quantity u_i for the ith subgroup (see the section "Constructing Charts for Nonconformities per Unit (u Charts)" on page 1687). An advantage of a u chart is that the value of the central line at the ith subgroup does not depend on n_i. This is not the case for a c chart, so a u chart is often preferred when the number of units n_i is not constant across subgroups.

Central Line

On a c chart, the central line indicates an estimate for $n_i u$, which is computed as $n_i \bar{u}$. If you specify a known value (u_0) for u, the central line indicates the value of $n_i u_0$.

Note that the central line varies with subgroup sample size n_i. When $n_i = 1$ for all subgroups, the central line has the constant value $\bar{c} = (c_1 + \cdots + c_N)/N$.

Control Limits

The control limits are computed as a specified multiple (k) of the standard error of c_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

The lower and upper control limits, LCL and UCL, respectively, are given by

$$\begin{aligned} \text{LCL} &= \max\left(n_i \bar{u} - k\sqrt{n_i \bar{u}}\ , 0\right) \\ \text{UCL} &= n_i \bar{u} + k\sqrt{n_i \bar{u}} \end{aligned}$$

The lower and upper control limits vary with the number of inspection units per subgroup n_i. If $n_i = 1$ for all subgroups, the control limits have constant values, as follows:

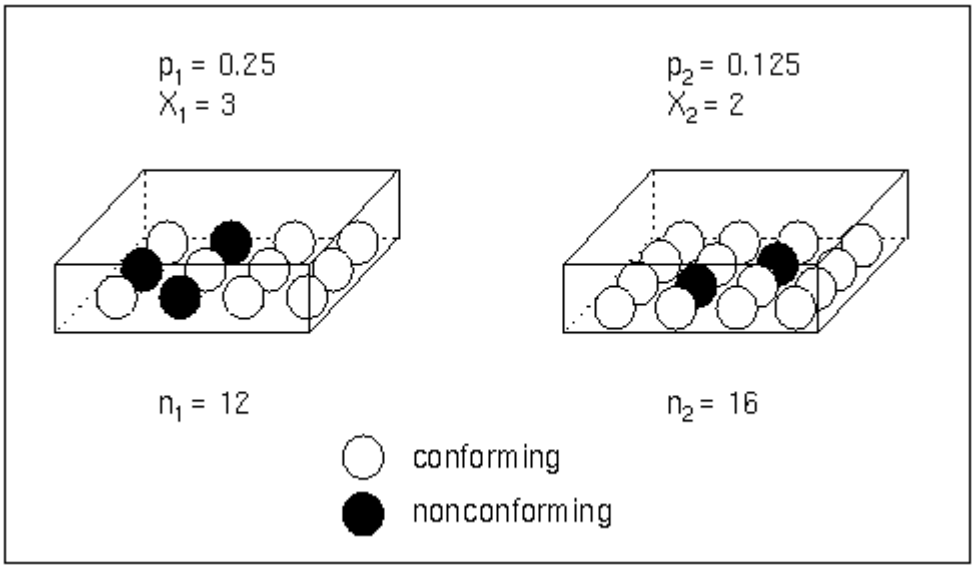
$$\begin{aligned} \text{LCL} &= \max\left(\bar{c} - k\sqrt{\bar{c}}\,, 0\right) \\ \text{UCL} &= \bar{c} + k\sqrt{\bar{c}} \end{aligned}$$

If a standard value u_0 is available for u, replace $\bar{u}$ with u_0 in the formulas for the control limits. You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify u_0 by using the variable _U_ in a LIMITS= data table.

Constructing Charts for Number Nonconforming (np Charts)

You produce control charts for number nonconforming by using the NPCHART statement.



The following notation is used in this section:

p	Expected proportion of nonconforming items that the process produces
p_i	Proportion of nonconforming items in the ith subgroup
X_i	Number of nonconforming items in the ith subgroup
n_i	Number of items in the ith subgroup
$\bar{p}$	Average proportion of nonconforming items taken across subgroups: $\bar{p} = \frac{n_1 p_1 + \cdots + n_N p_N}{n_1 + \cdots + n_N} = \frac{X_1 + \cdots + X_N}{n_1 + \cdots + n_N}$
N	Number of subgroups

Subgroup Summary Statistics

Each point on an np chart represents the observed number (X_i) of nonconforming items in a subgroup. For example, in Figure 32.6 the first subgroup contains 12 items, of which 3 are nonconforming. The summary statistic for the first subgroup is $X_1 = 3$.

Figure 32.6 Proportions versus Counts

Note that a p chart displays the proportion of nonconforming items p_i. You can use the PCHART statement to create p charts; for more information, see the section "Constructing Charts for Proportion Nonconforming (p Charts)" on page 1686.

Central Line

By default, the central line on an np chart indicates an estimate for $n_i\, p$, which is computed as $n_i\, \bar{p}$. If you specify a known value (p_0) for p, the central line indicates the value of $n_i\, p_0$. Note that the central line varies with n_i.

Control Limits

The control limits are computed as a specified multiple (k) of the standard error of X_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

The lower and upper control limits, LCL and UCL, respectively, are computed as

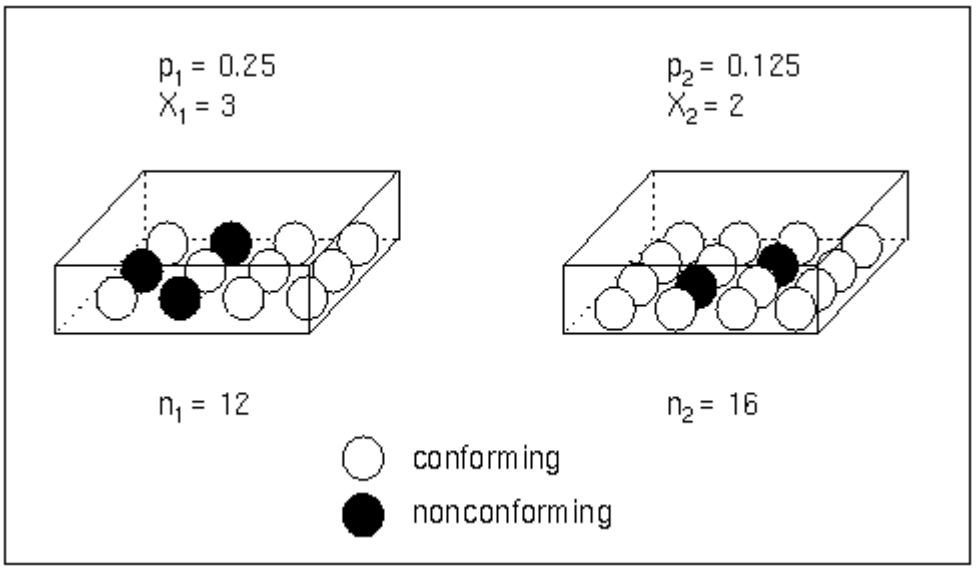
$$\text{LCL} = \max\left(n_i\,\bar{p} - k\sqrt{n_i\,\bar{p}(1-\bar{p})}\,, 0\right)$$
$$\text{UCL} = \min\left(n_i\,\bar{p} + k\sqrt{n_i\,\bar{p}(1-\bar{p})}\,, n_i\right)$$

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify p_0 by using the variable _P_ in the LIMITS= data table.

Constructing Charts for Proportion Nonconforming (p Charts)

You produce control charts for proportion nonconforming by using the PCHART statement.



The following notation is used in this section:

p	Expected proportion of nonconforming items that the process produces
p_i	Proportion of nonconforming items in the ith subgroup
X_i	Number of nonconforming items in the ith subgroup
n_i	Number of items in the ith subgroup
$\bar{p}$	Average proportion of nonconforming items taken across subgroups: $\bar{p} = \frac{n_1 p_1 + \cdots + n_N p_N}{n_1 + \cdots + n_N} = \frac{X_1 + \cdots + X_N}{n_1 + \cdots + n_N}$
N	Number of subgroups

Subgroup Summary Statistics

Each point on a p chart represents the observed proportion ($p_i = X_i/n_i$) of nonconforming items in a subgroup. For example, in Figure 32.7 the second subgroup contains 16 items, of which 2 are nonconforming. The summary statistic for the second subgroup is $p_2 = 2/16 = 0.125$.

Figure 32.7 Proportions versus Counts

Note that an np chart displays the number (count) of nonconforming items X_i. You can use the NPCHART statement to create np charts; for more information, see the section "Constructing Charts for Number Nonconforming (np Charts)" on page 1684.

Central Line

By default, the central line on a p chart indicates an estimate of p that is computed as $\bar{p}$. If you specify a known value (p_0) for p, the central line indicates the value of p_0.

Control Limits

The control limits are computed as a specified multiple (k) of the standard error of p_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

The lower and upper control limits, LCL and UCL, respectively, are computed as

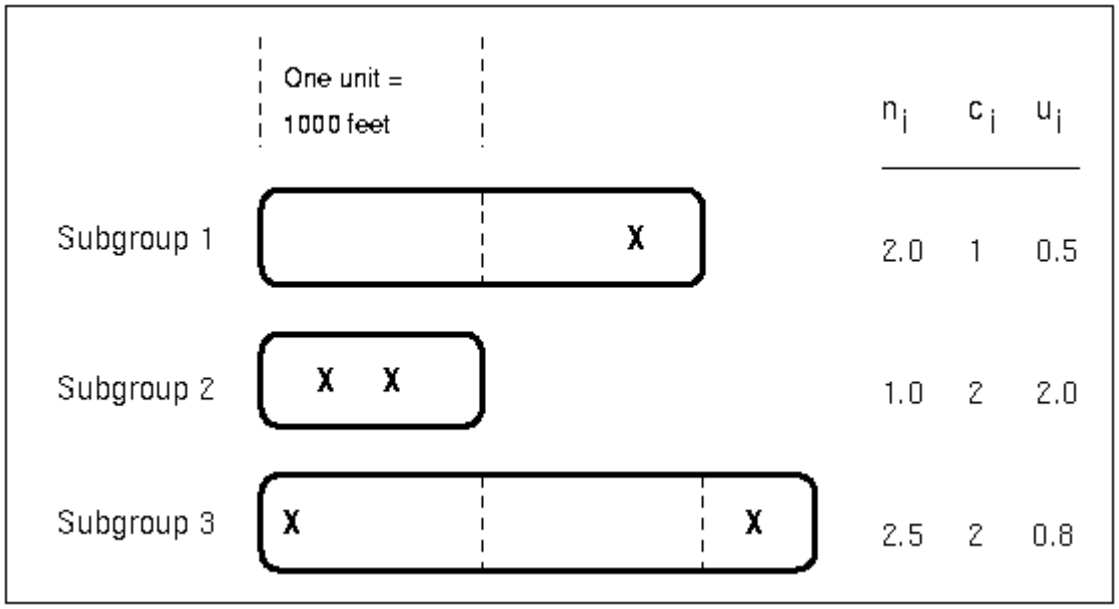
$$\begin{aligned} \text{LCL} &= \max\left(\bar{p} - k\sqrt{\bar{p}(1-\bar{p})/n_i}\ , 0\right) \\ \text{UCL} &= \min\left(\bar{p} + k\sqrt{\bar{p}(1-\bar{p})/n_i}\ , 1\right) \end{aligned}$$

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify p_0 by using the variable _P_ in a LIMITS= data table.

Constructing Charts for Nonconformities per Unit (u Charts)

You produce control charts for nonconformities per unit by using the UCHART statement.



The following notation is used in this section:

u	Expected number of nonconformities per unit that the process produces
u_i	Number of nonconformities per unit in the ith subgroup. In general, $u_i = c_i/n_i$.
c_i	Total number of nonconformities in the ith subgroup
n_i	Number of inspection units in the ith subgroup
$\bar{u}$	Average number of nonconformities per unit taken across subgroups. The quantity $\bar{u}$ is computed as a weighted average: $\bar{u} = \frac{n_1u_1 + \cdots + n_Nu_N}{n_1 + \cdots + n_N} = \frac{c_1 + \cdots + c_N}{n_1 + \cdots + n_N}$
N	Number of subgroups

Subgroup Summary Statistics

Each point on a u chart indicates the number of nonconformities per unit (u_i) in a subgroup. For example, Figure 32.8 displays three sections of pipeline that are inspected for defective welds (indicated by an X). Each section represents a *subgroup* that consists of a number of *inspection units*, which are 1,000-foot sections. The number of units in the ith subgroup is denoted by n_i, which is the subgroup sample size.

Figure 32.8 Terminology for c Charts and u Charts

The *number of nonconformities* in the ith subgroup is denoted by c_i. The *number of nonconformities per unit* in the ith subgroup is denoted by $u_i = c_i/n_i$. In Figure 32.8, the number of defective welds per unit in the third subgroup is $u_3 = 2/2.5 = 0.8$.

A u chart plots the quantity u_i for the ith subgroup. A c chart plots the quantity c_i for the ith subgroup (for more information, see the section "Constructing Charts for Numbers of Nonconformities (c Charts)" on page 1682). An advantage of a u chart is that the value of the central line at the ith subgroup does not depend on n_i. This is not the case for a c chart, so a u chart is often preferred when the number of units n_i is not constant across subgroups.

Central Line

On a u chart, the central line indicates an estimate of u, which is computed as $\bar{u}$ by default. If you specify a known value (u_0) for u, the central line indicates the value of u_0.

Control Limits

The control limits are computed as a specified multiple (k) of the standard error of u_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

The lower and upper control limits, LCL and UCL, respectively, are given by

$$\begin{aligned} \text{LCL} &= \max\left(\bar{u} - k\sqrt{\bar{u}/n_i}\ , 0\right) \\ \text{UCL} &= \bar{u} + k\sqrt{\bar{u}/n_i} \end{aligned}$$

The limits vary with n_i.

You can specify parameters for the limits as follows:

- Specify k by using the SIGMAS= option or the variable _SIGMAS_ in a LIMITS= data table.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or the variable _LIMITN_ in a LIMITS= data table.
- Specify u_0 by using the variable _U_ in a LIMITS= data table.

Constructing Uniformly Weighted Moving Average Charts

The following notation is used in this section:

A_i	Uniformly weighted moving average for the ith subgroup
w	Span parameter (number of terms in the moving average)
μ	Process mean (expected value of the population of measurements)
σ	Process standard deviation (standard deviation of the population of measurements)
x_{ij}	jth measurement in the ith subgroup, where j =1, 2, 3, . . . , n_i
n_i	Sample size of the ith subgroup
$\overline{X}_i$	Mean of measurements in the ith subgroup. If $n_i = 1$, then the subgroup mean reduces to the single observation in the subgroup.
$\overline{\overline{X}}$	Weighted average of subgroup means
$\Phi^{-1}(\cdot)$	Inverse standard normal function

Subgroup Summary Statistics

Each point on the chart indicates the value of the uniformly weighted moving average for that subgroup. The moving average for the ith subgroup (A_i) is defined as

$$A_i = (\overline{X}_1 + \cdots + \overline{X}_i)/i \qquad \text{if } i < w$$

$$A_i = (\overline{X}_i + \cdots + \overline{X}_{i-w+1})/w \quad \text{if } i \geq w$$

where w is the span, or number of terms, of the moving average. You can specify the span by using the SPAN= option in the MACHART statement or by including the value of the variable _SPAN_ in a LIMITS= data set.

Central Line

By default, the central line on a moving average chart indicates an estimate of μ, which is computed as

$$\hat{\mu} = \overline{\overline{X}} = \frac{n_1 \bar{X}_1 + \cdots + n_N \bar{X}_N}{n_1 + \cdots + n_N}$$

If you specify a known value (μ_0) for μ, the central line indicates the value of μ_0.

Control Limits

The limits are computed as a specified multiple (k) of the standard error of A_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ limits).

Table 32.35 provides the formulas for the limits:

Table 32.35 Limits for Moving Average Charts

$\text{LCL} = \overline{\overline{X}} - k(\hat{\sigma}/\min(i,w))\sqrt{(1/n_i) + (1/n_{i-1}) + \cdots + (1/n_{1+\max(i-w,0)})}$
$\text{UCL} = \overline{\overline{X}} + k(\hat{\sigma}/\min(i,w))\sqrt{(1/n_i) + (1/n_{i-1}) + \cdots + (1/n_{1+\max(i-w,0)})}$

These formulas assume that the data are normally distributed. If the standard values μ_0 and σ_0 are available for μ and σ, respectively, replace $\overline{\overline{X}}$ with μ_0 and replace $\hat{\sigma}$ with σ_0 in Table 32.35. Note that the limits vary with both n_i and i.

If the subgroup sample sizes are constant ($n_i = n$), the formulas for the control limits simplify to

$$\begin{aligned} \text{LCL} &= \overline{\overline{X}} - \frac{k\hat{\sigma}}{\sqrt{n \min(i,w)}} \\ \text{UCL} &= \overline{\overline{X}} + \frac{k\hat{\sigma}}{\sqrt{n \min(i,w)}} \end{aligned}$$

See Montgomery (1996) for more information. When the subgroup sample sizes are constant, the width of the control limits for the first w moving averages decreases monotonically, because each of the first w moving averages includes one more term than the preceding moving average.

If you specify the ASYMPTOTIC option, constant control limits that have the following values are computed:

$$\begin{aligned} \text{LCL} &= \overline{\overline{X}} - \frac{k\hat{\sigma}}{\sqrt{nw}} \\ \text{UCL} &= \overline{\overline{X}} + \frac{k\hat{\sigma}}{\sqrt{nw}} \end{aligned}$$

You can specify parameters for the moving average limits as follows:

- Specify k by using the SIGMAS= option or by including the variable _SIGMAS_ in a LIMITS= data set.

- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or by including the variable _LIMITN_ in a LIMITS= data set.
- Specify w by using the SPAN= option or by including the variable _SPAN_ in a LIMITS= data set.
- Specify μ_0 by including the variable _MEAN_ in a LIMITS= data set.
- Specify σ_0 by including the variable _STDDEV_ in a LIMITS= data set.

Constructing Exponentially Weighted Moving Average Charts

You produce exponentially weighted moving average (EWMA) charts by using the EWMACHART statement.

The following notation is used in this section:

E_i	Exponentially weighted moving average for the ith subgroup
r	EWMA weight parameter ($0 < r \leq 1$)
μ	Process mean (expected value of the population of measurements)
σ	Process standard deviation (standard deviation of the population of measurements)
x_{ij}	jth measurement in the ith subgroup, where j =1, 2, 3, ..., n_i
n_i	Sample size of the ith subgroup
$\overline{X}_i$	Mean of measurements in the ith subgroup. If $n_i = 1$, then the subgroup mean reduces to the single observation in the subgroup.
$\overline{\overline{X}}$	Weighted average of subgroup means
$\Phi^{-1}(\cdot)$	Inverse standard normal function

Subgroup Summary Statistics

Each point on the chart indicates the value of the exponentially weighted moving average (EWMA) for that subgroup. The EWMA for the ith subgroup (E_i) is defined recursively as

$$E_i = r\overline{X}_i + (1-r)E_{i-1}, \quad i > 0$$

where r is a weight parameter ($0 < r \leq 1$). Some authors (such as Hunter 1986 and Crowder 1987a,b) use the symbol λ instead of r for the weight. You can specify the weight by using the WEIGHT= option in the EWMACHART statement or by including the variable _WEIGHT_ in a LIMITS= data table. If you specify a known value (μ_0) for μ, then $E_0 = \mu_0$; otherwise, $E_0 = \overline{\overline{X}}$.

The preceding equation can be rewritten as

$$E_i = E_{i-1} + r(\overline{X}_i - E_{i-1})$$

which expresses the current EWMA as the previous EWMA plus the weighted error in the prediction of the current mean based on the previous EWMA.

The EWMA for the ith subgroup can also be written as

$$E_i = r\sum_{j=0}^{i-1}(1-r)^j\overline{X}_{i-j} + (1-r)^i E_0$$

which expresses the EWMA as a weighted average of past subgroup means, where the weights decline exponentially and the heaviest weight is assigned to the most recent subgroup mean.

Central Line

By default, the central line on an EWMA chart indicates an estimate of μ, which is computed as

$$\hat{\mu} = \overline{\overline{X}} = \frac{n_1\bar{X}_1 + \cdots + n_N\bar{X}_N}{n_1 + \cdots + n_N}$$

If you specify a known value (μ_0) for μ, the central line indicates the value of μ_0.

Control Limits

The limits are computed as a specified multiple (k) of the standard error of E_i above and below the central line. The default limits are computed using $k = 3$ (these are referred to as 3σ *limits*).

Table 32.37 provides the formulas for the limits.

Table 32.37 Limits for EWMA Charts

LCL = lower limit = $\overline{\overline{X}} - k\hat{\sigma}r\sqrt{\sum_{j=0}^{i-1}(1-r)^{2j}/n_{i-j}}$
UCL = upper limit = $\overline{\overline{X}} + k\hat{\sigma}r\sqrt{\sum_{j=0}^{i-1}(1-r)^{2j}/n_{i-j}}$

These formulas assume that the data are normally distributed. If the standard values μ_0 and σ_0 are available for μ and σ, respectively, replace $\overline{\overline{X}}$ with μ_0 and $\hat{\sigma}$ with σ_0 in Table 32.37. Note that the limits vary with both n_i and i.

If the subgroup sample sizes are constant ($n_i = n$), the formulas for the control limits simplify to

$$\text{LCL} = \overline{\overline{X}} - k\hat{\sigma}\sqrt{r(1-(1-r)^{2i})/n(2-r)}$$

$$\text{UCL} = \overline{\overline{X}} + k\hat{\sigma}\sqrt{r(1-(1-r)^{2i})/n(2-r)}$$

Consequently, when the subgroup sample sizes are constant, the width of the control limits increases monotonically with i. See Roberts (1959) and Montgomery (1996).

As i becomes large, the upper and lower control limits approach constant values:

$$\text{LCL} = \overline{\overline{X}} - k\hat{\sigma}\sqrt{r/n(2-r)}$$

$$\text{UCL} = \overline{\overline{X}} + k\hat{\sigma}\sqrt{r/n(2-r)}$$

Some authors base the control limits for EWMA charts on the asymptotic expressions in the two previous equations. You can display asymptotic limits by specifying the ASYMPTOTIC option.

Uniformly weighted moving average charts and exponentially weighted moving average charts have similar properties, and their asymptotic control limits are identical, provided that

$$r = 2/(w+1)$$

where w is the weight factor for uniformly weighted moving average charts. See Wadsworth, Stephens, and Godfrey (1986) and the American Society for Quality Control (1983).

You can specify parameters for the EWMA limits as follows:

- Specify k by using the SIGMAS= option or by including the variable _SIGMAS_ in a LIMITS= data set.
- Specify a constant nominal sample size $n_i \equiv n$ for the control limits by using the LIMITN= option or by including the variable _LIMITN_ in a LIMITS= data set.
- Specify r by using the WEIGHT= option or by including the variable _WEIGHT_ in a LIMITS= data set.
- Specify μ_0 by including the variable _MEAN_ in a LIMITS= data set.
- Specify σ_0 by including the variable _STDDEV_ in a LIMITS= data set.

Percentile Definitions

You can use the PCTLDEF= option in the BOXCHART statement to specify one of five definitions for computing quantile statistics (percentiles). Let n equal the number of nonmissing values for a variable, and let $x_1, x_2, \ldots, x_n$ represent the ordered values of the process variable. For the tth percentile, set $p = t/100$, and express np as

$$np = j + g$$

where j is the integer part of np, and g is the fractional part of np.

The tth percentile (call it y) can be defined in five ways, as described in the next five sections.

PCTLDEF=1

This definition uses the weighted average at x_{np},

$$y = (1 - g)x_j + gx_{j+1}$$

where x_0 is taken to be x_1.

PCTLDEF=2

This definition uses the observation numbered closest to np,

$$y = x_i$$

where i is the integer part of $np + 1/2$.

PCTLDEF=3

This definition uses the empirical distribution function:

$$y = x_j \quad \text{if } g = 0$$
$$y = x_{j+1} \quad \text{if } g > 0$$

PCTLDEF=4

This definition uses the weighted average aimed at $x_{p(n+1)}$,

$$y = (1 - g)x_j + gx_{j+1}$$

where $(n + 1)p = j + g$, and where x_{n+1} is taken to be x_n.

PCTLDEF=5

This definition uses the empirical distribution function with averaging:

$$y = (x_j + x_{j+1})/2 \quad \text{if } g = 0$$
$$y = x_{j+1} \quad \text{if } g > 0$$

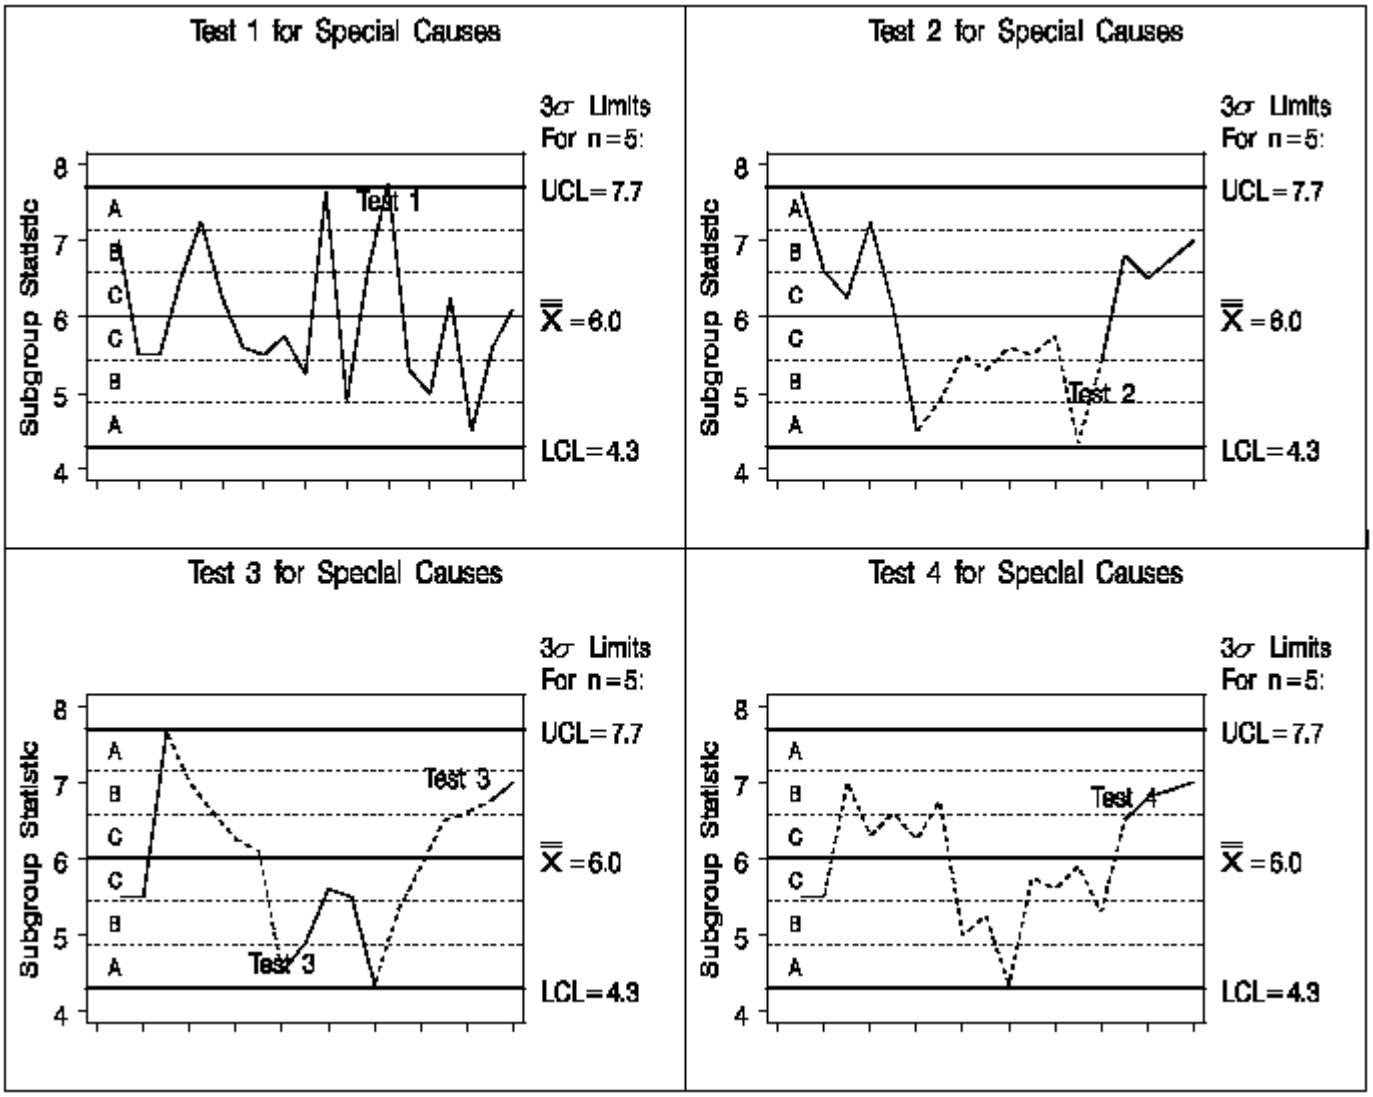
Tests for Special Causes

This section provides details about tests for special causes that you can apply by using the SPC procedure. These tests are not applicable to moving average charts that you compute by using the EWMACHART and MACHART statements.

The SPC procedure provides eight standard *tests for special causes*, also referred to as *rules for lack of control*, *supplementary rules*, *runs tests*, *runs rules*, *pattern tests*, and *Western Electric rules*. These tests improve the sensitivity of a Shewhart chart to small changes in the process. You can also improve the sensitivity of the chart by increasing the rate of sampling, increasing the subgroup sample size, and using control limits that represent less than three standard errors of variation from the central line. However, increasing the sampling rate and sample size is often impractical, and tightening the control limits increases the chances of falsely signaling an out-of-control condition. By detecting particular nonrandom patterns in the subgroup summary statistics, the tests can provide greater sensitivity and useful diagnostic information while incurring a reasonable probability of a false signal.

The patterns that the eight standard tests detect are defined in Table 32.38 and Table 32.39 and illustrated in Figure 32.9 and Figure 32.10. All eight tests were developed for use with fixed 3σ limits. The tests are indexed according to the numbering sequence used by Nelson (1984, 1985). You can request any combination of the eight tests by specifying the test *indices* in the TESTS= option in the BOXCHART, CCHART, IRCHART, MCHART, MRCHART, NPCHART, PCHART, UCHART, XCHART, XRCHART, and XSCHART statements.

The following restrictions apply to the tests:



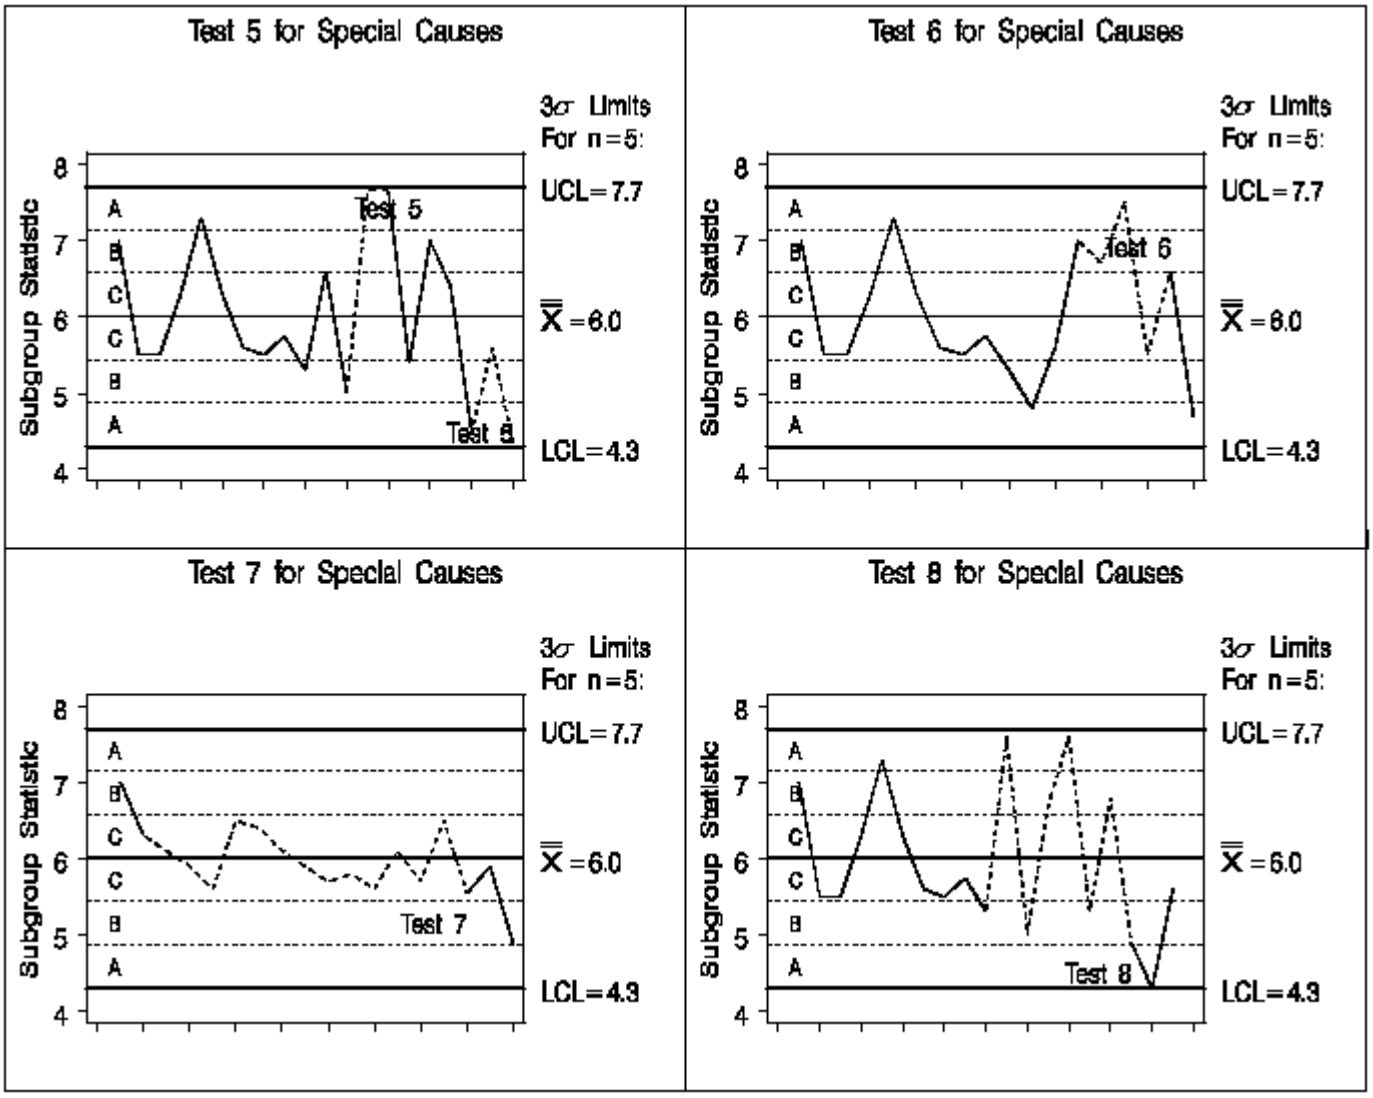
- Only Tests 1, 2, 3, and 4 are recommended for *c* charts, *np* charts, *p* charts, and *u* charts that you create using the CCHART, NPCHART, PCHART, and UCHART statements, respectively. In these four cases, you should not use Test 2 unless the process distribution is symmetric or nearly symmetric.

- By default, the TESTS= option is not applied when the control limits are not 3σ limits or vary with subgroup sample size. You can use the NO3SIGMACHECK option to request tests for special causes when the SIGMAS= option specifies control limits other than 3σ limits. This is not recommended for standard control chart applications, because the standard tests for special causes are based on 3σ limits. You can apply tests for special causes when control limits vary with subgroup sample size by using the LIMITN= or TESTNSTD option (for more information, see the section "Applying Tests with Varying Subgroup Sample Sizes" on page 1699).

Table 32.38 Definitions of Tests 1 to 4

Test Index	Pattern Description
1	One point beyond Zone A (outside the control limits)
2	Nine points in a row in Zone C or beyond on one side of the central line (see Note 1 after Figure 32.9)
3	Six points in a row that steadily increase or steadily decrease (see Note 2 after Figure 32.9)
4	Fourteen points in a row that alternate up and down

Figure 32.9 Examples of Tests 1 to 4



Notes:

1. You can specify the number of points in Test 2 as 7, 8, 9, 11, 14, or 20 in the TEST2RUN= option.
2. You can specify the number of points in Test 3 as 6, 7, or 8 in the TEST3RUN= option.

Table 32.39 Definitions of Tests 5 to 8

Test Index	Pattern Description
5	Two out of three points in a row in Zone A or beyond
6	Four out of five points in a row in Zone B or beyond
7	Fifteen points in a row in Zone C on either or both sides of the central line
8	Eight points in a row on either or both sides of the central line, with no points in Zone C

Figure 32.10 Examples of Tests 5 to 8

Interpreting Tests for Special Causes

Nelson (1984, 1985) makes the following comments about interpreting the tests for special causes:

- When a process is in statistical control, the chance of a false signal for each test is less than 5 in 1,000.
- Test 1 is positive if there is a shift in the process mean, if there is an increase in the process standard deviation, or if there is a "single aberration in the process such as a mistake in calculation, an error in measurement, bad raw material, a breakdown of equipment, and so on" (Nelson 1985).
- Test 2 signals a shift in the process mean. The use of nine points (rather than seven, as in Grant and Leavenworth 1988 for the pattern that defines Test 2 makes the chance of a false signal comparable to that of Test 1. (To control the number of points for the pattern in test 2, use the TEST2RUN= option in the chart statement.)
- Test 3 signals a drift in the process mean. Nelson (1985) states that causes can include "tool wear, depletion of chemical baths, deteriorating maintenance, improvement in skill, and so on."
- Test 4 signals "a systematic effect such as produced by two machines, spindles, operators or vendors used alternately" (Nelson 1985).
- Tests 1, 2, 3, and 4 should be applied routinely; the combined chance of a false signal from one or more of these tests is less than 1 in 100. Nelson (1985) describes these tests as "a good set that will react to many commonly occurring special causes."
- In the case of charts for variables, the first four tests should be augmented by Tests 5 and 6 when earlier warning is desired. The chance of a false signal increases to 2 in 100.
- Tests 7 and 8 indicate stratification (observations in a subgroup have multiple sources with different means). Test 7 is positive when the observations in the subgroup always have multiple sources. Test 8 is positive when the subgroups are taken from one source at a time.

Nelson (1985) also comments that "the probabilities quoted for getting false signals should not be considered to be very accurate" because the probabilities are based on assumptions of normality and independence that might not be satisfied. Consequently, he recommends that the tests "should be viewed as simply practical rules for action rather than tests having specific probabilities associated with them." Nelson cautions that "it is possible, though unlikely, for a process to be out of control yet not show any signals from these eight tests."

Modifying Standard Tests for Special Causes

Some textbooks and references present slightly different versions of Tests 2 and 3. You can use the following options to request these modifications:

- TEST2RUN=*run-length* specifies the length of the pattern for Test 2. The form of the test for each *run-length* is shown in the following table. The default *run-length* is 9.

run-length	**Number of Points on One Side of the Central Line**
7	7 in a row
8	8 in a row
9	9 in a row
11	At least 10 out of 11 in a row
14	At least 12 out of 14 in a row
20	At least 16 out of 20 in a row

- TEST3RUN=*run-length* specifies the length of the pattern for Test 3. The *run-length* values that you can specify are 6, 7, and 8. The default *run-length* is 6.

The Western Electric Company (now AT&T) *Statistical Quality Control Handbook* (1956) and Montgomery (1996) discuss a test that is signaled by eight points in a row in Zone C or beyond (on one side of the central line). You can request this test by specifying TESTS=2 and TEST2RUN=8. The *Handbook* also discusses tests that correspond to Tests 1, 5, 6, 7, and 8.

Kume (1985) recommends a number of tests for special causes that can be regarded as modifications of Tests 2 and 3:

- seven points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=7.
- at least 10 out of 11 points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=11.
- at least 12 out of 14 points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=14.
- at least 16 out of 20 points in a row on one side of the central line. Specify TESTS=2 and TEST2RUN=20.
- seven points in a row that steadily increase or decrease. Specify TESTS=3 and TEST3RUN=7.

Applying Tests with Varying Subgroup Sample Sizes

Nelson (1989, 1994) describes the use of standardization to apply the tests for special causes to data that involve varying subgroup samples. This approach applies the tests to the standardized subgroup statistics, setting the control limits at ± 3 and the zone boundaries at ± 1 and ± 2. For example, for an $\bar{X}$ chart with subgroup means $\bar{X}_i$ and varying subgroup sample sizes n_i, the tests are applied to the standardized values $z_i = (\bar{X}_i - \overline{\overline{X}})/(s/\sqrt{n_i})$, where $\overline{\overline{X}}$ estimates the process mean and s estimates the process standard deviation. You can request this method by using the TESTNSTD option.

Alternatively, you can handle varying subgroup sample sizes by specifying a nominal sample size in the LIMITN= option. If you specify LIMITN=*n*, the control limits are computed for the fixed value n, and they do not vary with the subgroup sample sizes. Moreover, subgroup summary statistics are computed only for those subgroups whose sample size is equal to n; only those subgroups are included in the results. You can specify the ALLN option in conjunction with the LIMITN= option to force subgroup summary statistics to be computed for all subgroups, regardless of subgroup sample size.

Capability Indices

This section provides formulas for process capability indices, which are computed for stable processes when you use the SPECS= option to specify a data table that contains process specification limits. The estimate $\hat{\sigma}$ is computed as described in the section "Methods of Estimating the Standard Deviation" on page 1672.

NOTE: You can specify the SPECS= option to compute capability indices only in the following chart statements that produce Shewhart charts for variables: BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHART, XCHART, XRCHART, and XSCHART.

The Index C_p

The process capability index C_p is computed as

$$C_p = (\mathrm{USL} - \mathrm{LSL})/6\hat{\sigma}$$

If you do not specify both LSL and USL, the variable _CP_ is assigned a missing value.

The Index CPL

The process capability index CPL is computed as

$$\mathrm{CPL} = (\overline{\overline{X}} - \mathrm{LSL})/3\hat{\sigma}$$

If you do not specify LSL, the variable _CPL_ is assigned a missing value.

The Index CPU

The process capability index CPU is computed as

$$\mathrm{CPU} = (\mathrm{USL} - \overline{\overline{X}})/3\hat{\sigma}$$

If you do not specify USL, the variable _CPU_ is assigned a missing value.

The Index C_{pk}

The process capability index C_{pk} is computed as

$$C_{pk} = \min(\mathrm{USL} - \overline{\overline{X}}, \overline{\overline{X}} - \mathrm{LSL})/3\hat{\sigma}$$

If you specify only USL, the index C_{pk} is computed as

$$C_{pk} = (\mathrm{USL} - \overline{\overline{X}})/3\hat{\sigma}$$

and if you specify only LSL, the index C_{pk} is computed as

$$C_{pk} = (\overline{\overline{X}} - \mathrm{LSL})/3\hat{\sigma}$$

The Index C_{pm}

The process capability index C_{pm} is computed as

$$C_{pm} = \frac{\min(T - \mathrm{LSL}, \mathrm{USL} - T)}{3\sqrt{\hat{\sigma}^2 + (\overline{\overline{X}} - T)^2}}$$

where T is the target value that is specified in the Target variable in the SPECS= data table.

When you specify a single specification limit (SL) and target, C_{pm} is computed as

$$C_{pm} = \frac{|T - \mathrm{SL}|}{3\sqrt{\hat{\sigma}^2 + (\overline{\overline{X}} - T)^2}}$$

You should verify that a process is in statistical control before interpreting its capability indices, and you should verify that the data are normally distributed. A process must be stable and predictable before you can effectively address its ability to produce output within specifications. PROC SPC computes capability indices only for processes that do not show signs of being out of statistical control.

Some references use different notation and names for capability indices. For example, the manual ASQC Automotive Division/AIAG (1990) uses the term "process capability indices" for the indices that are computed by PROC SPC, and it uses the term "process performance indices" for indices that are computed by using the overall sample standard deviation as the estimate of $\hat{\sigma}$.

Input Data Tables

DATA= Data Table

The SPC procedure accepts a primary input data table that you specify in the DATA= option in the PROC SPC statement. This data table contains measurements of one or more process quality characteristics. Data to be analyzed by using the CCHART, IRCHART, NPCHART, PCHART, or UCHART statement should contain one observation per subgroup. Data to be analyzed by using other chart statements usually contain multiple observations per subgroup.

The DATA= data table must contain the following variables:

- the process name variable, which contains the names of the process variables. You specify it in the PROCESSNAME= option in the PROC SPC statement.
- the process value variable, which contains the process measurements. You specify it in the PROCESSVALUE= option in the PROC SPC statement.
- the subgroup name variables, which contains the names of the subgroup variables. You specify it in the SUBGROUPNAME= option in the PROC SPC statement.
- the subgroup value variable, which contains the subgroup values. You specify it in the SUBGROUPVALUE= option in the PROC SPC statement.

An input data table that contains attribute data (see the section "Classification of Control Charts" on page 1645) can also include a variable that contains the number of inspection units per subgroup. You specify this variable in the SUBGROUPN= option in the chart statement. It is required in the NPCHART, PCHART, and UCHART statements and optional in the CCHART statement.

The DATA= data table can also contain BY variables (see the section "BY Statement" on page 1652).

LIMITS= Data Table

You can read preestablished control limits or parameters from which the control limits can be calculated from a LIMITS= data table that you specify by using the LIMITS= option in the PROC SPC statement. The LIMITS= data table can be an OUTLIMITS= data table that was created in a previous run of the SPC procedure. Such data tables always contain the variables that a LIMITS= data table requires. For more information about the variables that are included in an OUTLIMITS= data table, see the section "OUTLIMITS= Data Table" on page 1704.

The LIMITS= data table must contain the following variables:

- the process name variable, which contains the names of the process variables. You specify it in the PROCESSNAME= option in the PROC SPC statement.
- the subgroup name variable, which contains the names of the subgroup variables. You specify it in the SUBGROUPNAME= option in the PROC SPC statement.

For each control chart type, Table 32.40 lists the variables that are required to specify parameters from which control limits are calculated and the variables that contain preestablished control limits.

Table 32.40 Variables in the LIMITS= Data Table

Chart Type	Parameters	Limits
c	_U_	_LCLC_, _C_, _UCLC_
EWMA	_MEAN_, _STDDEV_, _WEIGHT_	N/A
Individual measurements	_MEAN_, _STDDEV_	_LCLI_, _MEAN_, _UCLI_
Moving average	_MEAN_, _STDDEV_, _SPAN_	N/A
Moving range	_STDDEV_	_LCLR_, _R_, _UCLR_
Medians	_MEAN_, _STDDEV_	_LCLM_, _MEAN_, _UCLM_
np	_P_	_LCLNP_, _NP_, _UCLNP_
p	_P_	_LCLP_, _P_, _UCLP_
R	_STDDEV_	_LCLR_, _R_, _UCLR_
s	_STDDEV_	_LCLS_, _S_, _UCLS_
u	_U_	_LCLU_, _U_, _UCLU_
$\bar{X}$	_MEAN_, _STDDEV_	_LCLX_, _MEAN_, _UCLX_

Notes:

1. You can include the variable _LIMITN_, with or without parameters and limits variables, to specify different nominal subgroup sizes for different processes.
2. The special missing value *V* indicates variables that vary with subgroup sample size. Their values are calculated from the data. Table 32.42 identifies the variables that are assigned the missing value *V* in an OUTLIMITS= data table when subgroup sample sizes vary.
3. The variables _SIGMAS_ and _TYPE_ are optional, but they are recommended to maintain a complete set of control limit information. The variable _TYPE_ must be a character variable of length 8; valid values are 'ESTIMATE', 'STANDARD', 'STDMU', and 'STDSIGMA'.
4. For the EWMA and moving average charts, the LIMITS= data table contains only control limit parameters, not the control limits themselves.
5. If you specify a BY statement, the LIMITS= data table must also contain the specified BY variables.

SPECS= Data Table

You can provide process specification limits in a data table by using the SPECS= option. PROC SPC uses specification limits to calculate capability indices for processes. This option is available only in the following statements that produce Shewhart charts for variables: BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHART, XCHART, XRCHART, and XSCHART.

The SPECS= data table must include the process name variable, which, as the name suggests, contains the names of the process variables. You specify it in the PROCESSNAME= option in the PROC SPC statement. Table 32.41 lists the specification limit variables that the data table can include.

Table 32.41 SPECS= Data Table Variables

Variable	Description
LSL	Lower specification limit
Target	Target value
USL	Upper specification limit

PROC SPC computes capability indices for each process that is included in the DATA= data table and whose specification limits are provided in the SPECS= data table. For more information about how capability indices are computed, see the section "Capability Indices" on page 1700.

Output Data Tables

OUTLIMITS= Data Table

An OUTLIMITS= data table contains control limits and control limit parameters. It contains one observation for each process. The following variables are always included in an OUTLIMITS= data table:

- the process name variable, which contains the names of the process variables. You specify it in the PROCESSNAME= option in the PROC SPC statement.
- the subgroup name variable, which contains the names of the subgroup variables. You specify it in the SUBGROUPNAME= option in the PROC SPC statement.

In addition, if you specify any BY variables, they are included in the OUTLIMITS= data table.

The other variables that are included in an OUTLIMITS= data table depend on which chart statement produced that data table. Table 32.42 lists the variables that are always included in OUTLIMITS= data tables for the different chart statements.

Table 32.42 Variables in the OUTLIMITS= Data Table

Variable	Varying	Description
BOXCHART Statement		
LCLM	✓	Lower control limit for subgroup median
LCLR	✓	Lower control limit for subgroup range
LCLS	✓	Lower control limit for subgroup standard deviation
LCLX	✓	Lower control limit for subgroup mean
LIMITN	✓	Nominal sample size associated with the control limits
MEAN		Process mean (value of central line on box chart)
_R_	✓	Value of central line on R chart
_S_	✓	Value of central line on s chart
SIGMAS		Multiple (k) of standard error of $\bar{X}_i$ or M_i
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLM	✓	Upper control limit for subgroup median

Table 32.42 *continued*

Variable	Varying	Description
UCLR	✓	Upper control limit for subgroup range
UCLS	✓	Upper control limit for subgroup standard deviation
UCLX	✓	Upper control limit for subgroup mean
CCHART Statement		
_C_	✓	Value of central line on c chart ($n_i\bar{u}$ or $n_i u_0$)
LCLC	✓	Lower control limit for number of nonconformities
LIMITN	✓	Sample size associated with the control limits
SIGMAS		Multiple (k) of standard error of c_i
TYPE		Type (estimate or standard value) of _U_
_U_		Average number of nonconformities per unit ($\bar{u}$ or u_0)
UCLC	✓	Upper control limit for number of nonconformities
EWMACHART Statement		
LIMITN	✓	Sample size associated with the control limits
MEAN		Process mean
SIGMAS		Multiple (k) of standard error of exponentially weighted moving averages
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
WEIGHT		Weight parameter used to compute the EWMA
IRCHART Statement		
LCLI		Lower control limit for individual measurements
LCLR		Lower control limit for moving ranges
LIMITN		Number of consecutive measurements that are used to compute moving ranges
MEAN		Process mean
_R_		Value of central line on moving range chart
SIGMAS		Multiple (k) of standard error of individual measurement or moving range
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLI		Upper control limit for individual measurements
UCLR		Upper control limit for moving ranges
MACHART Statement		
LIMITN	✓	Sample size associated with the control limits
MEAN		Process mean
SIGMAS		Multiple (k) of standard error of moving averages
SPAN		Number of terms in the moving average
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_

Table 32.42 *continued*

Variable	Varying	Description
MCHART Statement		
LCLM	✓	Lower control limit for subgroup median
LCLR	✓	Lower control limit for subgroup range
LCLS	✓	Lower control limit for subgroup standard deviation
LIMITN	✓	Sample size associated with the control limits
MEAN		Value of central line on median chart ($\bar{M}$, $\tilde{M}$, $\overline{\overline{X}}$, or μ_0)
_R_	✓	Value of central line on R chart
_S_	✓	Value of central line on s chart
SIGMAS		Multiple (k) of standard error of M_i
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLM	✓	Upper control limit for subgroup median
UCLR	✓	Upper control limit for subgroup range
UCLS	✓	Upper control limit for subgroup standard deviation
MRCHART Statement		
LCLM	✓	Lower control limit for subgroup median
LCLR	✓	Lower control limit for subgroup range
LIMITN	✓	Sample size associated with the control limits
MEAN		Estimate of process mean ($\bar{M}$, $\tilde{M}$, $\overline{\overline{X}}$, or μ_0)
_R_	✓	Value of central line on range chart
SIGMAS		Multiple (k) of standard error of M_i or R_i
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLM	✓	Upper control limit for subgroup median
UCLR	✓	Upper control limit for subgroup range
NPCHART Statement		
LCLNP	✓	Lower control limit for number of nonconforming items
LIMITN	✓	Sample size associated with the control limits
_NP_	✓	Average number of nonconforming items ($n_i\,\bar{p}$ or $n_i\,p_0$)
_P_		Average proportion of nonconforming items ($\bar{p}$ or p_0)
SIGMAS		Multiple (k) of standard error of X_i
TYPE		Type (standard or estimate) of _NP_
UCLNP	✓	Upper control limit for number of nonconforming items
PCHART Statement		
LCLP	✓	Lower control limit for proportion of nonconforming items
LIMITN	✓	Nominal sample size associated with the control limits
_P_		Average proportion of nonconforming items ($\bar{p}$ or p_0)
SIGMAS		Multiple (k) of standard error of p_i
TYPE		Type (standard or estimate) of _P_
UCLP	✓	Upper control limit for proportion of nonconforming items

Table 32.42 *continued*

Variable	Varying	Description
RCHART Statement		
LCLR	✓	Lower control limit for subgroup range
LCLX	✓	Lower control limit for subgroup mean
LIMITN	✓	Sample size associated with the control limits
MEAN		Process mean ($\overline{\overline{X}}$)
_R_	✓	Value of central line on R chart
SIGMAS		Multiple (k) of standard error of R_i
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLR	✓	Upper control limit for subgroup range
UCLX	✓	Upper control limit for subgroup mean
SCHART Statement		
LCLS	✓	Lower control limit for subgroup standard deviation
LCLX	✓	Lower control limit for subgroup mean
LIMITN	✓	Sample size associated with the control limits
MEAN		Process mean ($\overline{\overline{X}}$ or μ_0)
_S_	✓	Value of central line on s chart
SIGMAS		Multiple (k) of standard error of $\bar{X}_i$ or s_i
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLS	✓	Upper control limit for subgroup standard deviation
UCLX	✓	Upper control limit for subgroup mean
UCHART Statement		
LCLU	✓	Lower control limit for number of nonconformities per unit
LIMITN	✓	Sample size associated with the control limits
SIGMAS		Multiple (k) of standard error of u_i
TYPE		Type (estimate or standard value) of _U_
_U_		Value of central line of u chart ($\bar{u}$ or u_0)
UCLU	✓	Upper control limit for number of nonconformities per unit
XCHART Statement		
LCLR	✓	Lower control limit for subgroup range
LCLS	✓	Lower control limit for subgroup standard deviation
LCLX	✓	Lower control limit for subgroup mean
LIMITN	✓	Sample size associated with the control limits
MEAN		Process mean ($\overline{\overline{X}}$ or μ_0)
_R_	✓	Value of central line on R chart
_S_	✓	Value of central line on s chart
SIGMAS		Multiple (k) of standard error of $\bar{X}_i$
STDDEV		Process standard deviation

Table 32.42 *continued*

Variable	Varying	Description
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLR	✓	Upper control limit for subgroup range
UCLS	✓	Upper control limit for subgroup standard deviation
UCLX	✓	Upper control limit for subgroup mean
XRCHART Statement		
LCLR	✓	Lower control limit for subgroup range
LCLX	✓	Lower control limit for subgroup mean
LIMITN	✓	Nominal sample size associated with the control limits
MEAN		Process mean ($\overline{\overline{X}}$ or μ_0)
_R_	✓	Value of central line on R chart
SIGMAS		Multiple (k) of standard error of $\bar{X}_i$ or R_i
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLR	✓	Upper control limit for subgroup range
UCLX	✓	Upper control limit for subgroup mean
XSCHART Statement		
LCLS	✓	Lower control limit for subgroup standard deviation
LCLX	✓	Lower control limit for subgroup mean
LIMITN	✓	Nominal sample size associated with the control limits
MEAN		Process mean ($\overline{\overline{X}}$ or μ_0)
_S_	✓	Value of central line on s chart
SIGMAS		Multiple (k) of standard error of $\bar{X}_i$ or s_i
STDDEV		Process standard deviation
TYPE		Type (estimate or standard value) of _MEAN_ and _STDDEV_
UCLS	✓	Upper control limit for subgroup standard deviation
UCLX	✓	Upper control limit for subgroup mean

Notes:

1. If the control limits vary with subgroup sample size, the special missing value V is assigned to the variables that are indicated by a check mark (✓) in the Varying column of Table 32.42.

2. For all Shewhart charts for variables, the OUTLIMITS= data table includes control limits for means or medians and for ranges or standard deviations. This enables you to use the OUTLIMITS= data table as a LIMITS= data table for different charts for variables.

3. For the BOXCHART statement, the variables _LCLM_ and _UCLM_ are included if you specify CONTROLSTAT=MEDIAN; otherwise, the variables _LCLX_ and _UCLX_ are included. The variables _LCLR_, _R_, and _UCLR_ are included if you specify SMETHOD=RMVLUE or RNOWEIGHT; otherwise, the variables _LCLS_, _S_, and _UCLS_ are included.

4. For the MCHART and XCHART statements, the variables _LCLS_, _S_, and _UCLS_ are included if you specify SMETHOD=RMSDF, SMVLUE, or SNOWEIGHT; otherwise, the variables _LCLR_, _R_, and _UCLR_ are included.

5. For the EWMACHART and MACHART statements, OUTLIMITS= data tables contain only control limit parameters, not the control limits themselves.

If you specify the SPECS= option, the OUTLIMITS= data table also includes the variables that are listed in Table 32.43.

Table 32.43 Additional OUTLIMITS= Data Table Variables

Variable	Description
LSL	Lower specification limit
TARGET	Target value
USL	Upper specification limit
_CP_	Process capability index C_p
CPL	Process capability index CPL
CPU	Process capability index CPU
CPK	Process capability index C_{pk}
CPM	Process capability index C_{pm}

NOTE: Capability indices are computed only for processes that are in statistical control.

If you specify both the SPECS= and CIINDICES options, the OUTLIMITS= data table includes the additional variables that are listed in Table 32.44.

Table 32.44 Additional OUTLIMITS= Data Table Variables

Variable	Description
_CP_LCL_	Lower confidence limit for C_p
_CP_UCL_	Upper confidence limit for C_p
_CPL_LCL_	Lower confidence limit for CPL
_CPL_UCL_	Upper confidence limit for CPL
_CPU_LCL_	Lower confidence limit for CPU
_CPU_UCL_	Upper confidence limit for CPU
_CPK_LCL_	Lower confidence limit for C_{pk}
_CPK_UCL_	Upper confidence limit for C_{pk}
_CPM_LCL_	Lower confidence limit for C_{pm}
_CPM_UCL_	Upper confidence limit for C_{pm}

NOTE: Confidence limits are computed for C_{pm} only when both an LSL and a USL are specified and when the target value is halfway between the LSL and the USL.

OUTTABLE= Data Table

An OUTTABLE= data table contains subgroup summary statistics, control limits, and related information. The following variables are always included in an OUTTABLE= data table:

- _VAR_, which contains the process variable name
- the subgroup name variable, which contains subgroup variable names. You specify the name of the subgroup name variable in the SUBGROUPNAME= option in the PROC statement.
- the subgroup variable, which contains subgroup variable values. You specify the name of the subgroup variable in the SUBGROUPVALUE= option in the PROC statement.

In addition, if you specify any BY variables, they are included in the OUTTABLE= data table.

The other variables that are included in an OUTTABLE= data table depend on which chart statement produced that data table. Table 32.45 lists the variables that are included in OUTTABLE= data tables for the different chart statements.

Table 32.45 Variables in the OUTTABLE= Data Table

Variable	Description
BOXCHART Statement	
EXLIM	Control limit exceeded on box chart
LCLM	Lower control limit for median
LCLX	Lower control limit for mean
LIMITN	Nominal sample size associated with the control limits
MEAN	Process mean
SIGMAS	Multiple (k) of the standard error associated with the control limits
STDDEV	Process standard deviation ($\hat{\sigma}$ or σ_0)
SUBMAX	Subgroup maximum
SUBMED	Subgroup median
SUBMIN	Subgroup minimum
SUBN	Subgroup sample size
SUBQ1	Subgroup first quartile (25th percentile)
SUBQ3	Subgroup third quartile (75th percentile)
SUBX	Subgroup mean
TESTS	Tests for special causes signaled on box chart
UCLM	Upper control limit for median
UCLX	Upper control limit for mean
CCHART Statement	
_C_	Average number of nonconformities
EXLIM	Control limit exceeded on c chart
LCLC	Lower control limit for number of nonconformities
LIMITN	Nominal sample size associated with the control limits
SIGMAS	Multiple (k) of the standard error associated with the control limits
SUBC	Subgroup number of nonconformities
SUBN	Subgroup sample size

Table 32.45 *continued*

Variable	Description
TESTS	Tests for special causes signaled on c chart
UCLC	Upper control limit for number of nonconformities
EWMACHART Statement	
EWMA	Exponentially weighted moving average
EXLIM	Control limit exceeded on EWMA chart
LCLE	Lower control limit for EWMA
LIMITN	Nominal sample size associated with control limits
MEAN	Process mean
SIGMAS	Multiple (k) of the standard error associated with control limits
SUBN	Subgroup sample size
SUBS	Subgroup standard deviation
SUBX	Subgroup mean
UCLE	Upper control limit for EWMA
WEIGHT	Weight parameter used to compute EWMA
IRCHART Statement	
EXLIM	Control limit exceeded on individual measurements chart
EXLIMR	Control limit exceeded on moving range chart
LCLI	Lower control limit for individual measurements
LCLR	Lower control limit for moving range
LIMITN	Number of consecutive measurements that are used to compute moving ranges
MEAN	Process mean
_R_	Average range
SIGMAS	Multiple (k) of the standard error associated with the control limits
STDDEV	Process standard deviation ($\hat{\sigma}$ or σ_0)
SUBI	Individual measurement
SUBR	Moving range
TESTS	Tests for special causes signaled on individual measurements chart
UCLI	Upper control limit for individual measurements
UCLR	Upper control limit for moving range
MACHART Statement	
EXLIM	Control limit exceeded on moving average chart
LCLA	Lower control limit for moving average
LIMITN	Nominal sample size associated with control limits
MEAN	Process mean
SIGMAS	Multiple (k) of the standard error associated with control limits
SPAN	Number of terms in moving average
SUBN	Subgroup sample size
SUBS	Subgroup standard deviation
SUBX	Subgroup mean
UCLA	Upper control limit for moving average

Table 32.45 *continued*

Variable	Description
UWMA	Uniformly weighted moving average
MCHART Statement	
EXLIM	Control limit exceeded on median chart
LCLM	Lower control limit for median
LIMITN	Nominal sample size associated with the control limits
MEAN	Estimate of process mean ($\bar{\tilde{M}}$, $\tilde{\tilde{M}}$, $\overline{\overline{X}}$, or μ_0)
SIGMAS	Multiple (k) of the standard error associated with the control limits
STDDEV	Process standard deviation ($\hat{\sigma}$ or σ_0)
SUBMED	Subgroup median
SUBN	Subgroup sample size
TESTS	Tests for special causes signaled on median chart
UCLM	Upper control limit for median
MRCHART Statement	
EXLIM	Control limit exceeded on median chart
EXLIMR	Control limit exceeded on range chart
LCLM	Lower control limit for median
LCLR	Lower control limit for range
LIMITN	Nominal sample size associated with the control limits
MEAN	Estimate of process mean ($\bar{\tilde{M}}$, $\tilde{\tilde{M}}$, $\overline{\overline{X}}$, or μ_0)
_R_	Average range
SIGMAS	Multiple (k) of the standard error associated with the control limits
STDDEV	Process standard deviation ($\hat{\sigma}$ or σ_0)
SUBM	Subgroup median
SUBN	Subgroup sample size
SUBR	Subgroup range
TESTS	Tests for special causes signaled on median chart
TESTS2	Tests for special causes signaled on range chart
UCLM	Upper control limit for mean
UCLR	Upper control limit for range
NPCHART Statement	
EXLIM	Control limit exceeded on np chart
LCLNP	Lower control limit for number of nonconforming items
LIMITN	Nominal sample size associated with the control limits
_NP_	Average number of nonconforming items
SIGMAS	Multiple (k) of the standard error of X_i associated with the control limits
SUBNP	Subgroup number of nonconforming items
SUBN	Subgroup sample size
TESTS	Tests for special causes signaled on np chart
UCLNP	Upper control limit for number of nonconforming items

Table 32.45 *continued*

Variable	Description
PCHART Statement	
EXLIM	Control limit exceeded on p chart
LCLP	Lower control limit for proportion of nonconforming items
LIMITN	Nominal sample size associated with the control limits
_P_	Average proportion of nonconforming items
SIGMAS	Multiple (k) of the standard error of p_i associated with the control limits
SUBP	Subgroup proportion of nonconforming items
SUBN	Subgroup sample size
TESTS	Tests for special causes signaled on p chart
UCLP	Upper control limit for proportion of nonconforming items
RCHART Statement	
EXLIM	Control limit exceeded on R chart

SUBX	Subgroup mean
TESTS	Tests for special causes signaled on $\bar{X}$ chart
TESTS2	Tests for special causes signaled on s chart
UCLS	Upper control limit for standard deviation
UCLX	Upper control limit for mean

Notes:

1. The variable _TESTS_ is saved if you specify the TESTS= option. The kth character of a value of _TESTS_ is k if Test k is positive at that subgroup. For example, if you request all eight tests and Tests 2 and 8 are positive for a given subgroup, the value of _TESTS_ has a 2 for the second character, an 8 for the eighth character, and blanks for the other six characters.
2. The variable _TESTS2_ is saved if you specify the TESTS2= option.
3. The variables _EXLIM_, _EXLIMR_, _EXLIMS_, _TESTS_, and _TESTS2_ are character variables of length 8. All other variables are numeric.

ODS Table Names

Each table that the SPC procedure creates has a name associated with it. You must use this name to refer to the table when you use ODS statements. The name of this table and a short description of its contents are listed in Table 32.46.

Table 32.46 ODS Table Produced by PROC SPC

Table Name	Description	Statements	Option
BoxchartExceptionSummary	Summary of exceptions	BOXCHART	Default output
CapabilityIndices	Specification limits and capability indices	BOXCHART, IRCHART, MCHART, MRCHART, RCHART, SCHART, XCHART, XRCHART, XSCHART	SPECS=
CChartExceptionSummary	Summary of exceptions	CCHART	Default output
EWMAChartExceptionSummary	Summary of exceptions	EWMACHART	Default output
IRChartExceptionSummary	Summary of exceptions	IRCHART	Default output
MAChartExceptionSummary	Summary of exceptions	MACHART	Default output
MChartExceptionSummary	Summary of exceptions	MCHART	Default output
MRChartExceptionSummary	Summary of exceptions	MRCHART	Default output

Table 32.46 *continued*

Table Name	Description	Statement	Option
NPChartExceptionSummary	Summary of exceptions	NPCHART	Default output
PChartExceptionSummary	Summary of exceptions	PCHART	Default output
RChartExceptionSummary	Summary of exceptions	RCHART	Default output
SChartExceptionSummary	Summary of exceptions	SCHART	Default output
UChartExceptionSummary	Summary of exceptions	UCHART	Default output
XChartExceptionSummary	Summary of exceptions	XCHART	Default output
XRChartExceptionSummary	Summary of exceptions	XRCHART	Default output
XSChartExceptionSummary	Summary of exceptions	XSCHART	Default output

Examples: SPC Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 32.1: Saving Results in Output Data Tables

(View the complete code for this example (spcex1.sas) in the example repository.)

The following statements perform $\bar{X}$ and R chart analysis on the data table mylib.AllProcesses that is created in the section "Getting Started: SPC Procedure" on page 1648 and save the results in OUTTABLE= and OUTLIMITS= data tables:

```
proc spc data=mylib.AllProcesses;
   xrchart / noprint
             outtable  = mylib.AllTable
             outlimits = mylib.AllLimits;
run;
```

The NOPRINT option suppresses the display of the exception summary table. Output 32.1.1 shows a partial listing of the mylib.AllTable data table.

Output 32.1.1 Partial Listing of the mylib.AllTable Data Table

Note that limits variables for three of the processes have the special missing value *V*, because the data for those processes have varying subgroup sample sizes.

The mylib.AllLimits data table has the same format as a LIMITS= data table, so it could provide limits for these processes in a later run of PROC SPC.

Example 32.2: Computing Process Capability Indices

(View the complete code for this example (spcex2.sas) in the example repository.)

You can use the SPC procedure to compute process capability indices for stable processes. The following statements create a data table that contains process specification limits for the processes in the data table mylib.AllProcesses:

```
data mylib.AllSpecs;
   length processname $16;
   input processname LSL Target USL;
   datalines;
Amount           11.95   12.00   12.05
Breakstrength    52.0    60.0      .
Delay              .      0      30
Diameter         34.98   35.00   35.01
KWatts         3400    3500    4000
Partgap         250     260     270
Time              7.85    8.0     8.15
Weight           23.0    24.0    25.0
;
```

Not all processes have both lower and upper specification limits. For example, the Breakstrength process variable measures the breaking strength of metal wire and has no upper specification limit.

The following statements read the specification limits and compute capability indices for processes that the $\bar{X}$ and *R* chart analysis indicates are in statistical control:

```
proc spc data=mylib.AllProcesses;
   xrchart / exchart specs=mylib.AllSpecs;
run;
```

The EXCHART option includes only processes whose exceptions are signaled in the exception summary table. The resulting output is shown in Output 32.2.1.

Output 32.2.1 Exception Summary and Capability Indices

The SPC Procedure

Means and Ranges Chart Summary for ALLPROCESSES

			Means		Ranges	
processname	subgroupname	Number of Subgroups	Number > UCL	Number < LCL	Number > UCL	Number < LCL
Delay	Day	11	3	1	2	2
Diameter	Batch	45	0	1	0	0

Output 32.2.1 *continued*

Specification Limits and Capability Indices for ALLPROCESSES									
processname	subgroupname	LSL	Target	USL	Cp	CPL	CPU	Cpk	Cpm
Amount	Batch	11.950000	12.000000	12.050000	0.379318	0.228958	0.529679	0.228958	0.345768
Breakstrength	Sample	52.000000	60.000000	.	.	1.259258	.	1.259258	1.262873
KWatts	Day	3400.000000	3500.000000	4000.000000	0.495204	0.161038	0.829369	0.161038	0.165056
Partgap	Sample	250.000000	260.000000	270.000000	0.247761	0.247640	0.247882	0.247640	0.247761
Time	Lot	7.850000	8.000000	8.150000	1.021941	1.042834	1.001048	1.001048	1.019939
Weight	Lot	23.000000	24.000000	25.000000	0.143037	0.230790	0.055284	0.055284	0.138324

When you use the EXCHART option in combination with the SPECS= option, each process is listed in either the exception summary table or the capability indices table, but not both.

Example 32.3: Reading Preestablished Control Limits

(View the complete code for this example (spcex3.sas) in the example repository.)

You can apply the control limits that are saved in the data table mylib.AllLimits to new data for those processes. The exception summary table in the section "Getting Started: SPC Procedure" on page 1648 shows unusual variation in the processes Delay and Diameter, whereas the other six processes are stable. The data table mylib.StableProcesses contains additional data for the stable processes. The following statements read the control limits that are saved in the mylib.AllLimits data table and apply them to these new data:

```
proc spc data=mylib.StableProcesses limits=mylib.AllLimits;
   xrchart;
run;
```

The resulting exception summary table is shown in Output 32.3.1.

Output 32.3.1 Exception Summary of Additional Process Data

The SPC Procedure

Means and Ranges Chart Summary for STABLEPROCESSES						
			Means		Ranges	
processname	subgroupname	Number of Subgroups	Number > UCL	Number < LCL	Number > UCL	Number < LCL
Amount	Batch	35	0	0	0	0
Breakstrength	Sample	28	0	0	0	0
KWatts	Day	55	0	0	0	0
Partgap	Sample	36	0	0	1	0
Time	Lot	19	0	0	0	0
Weight	Lot	40	0	0	0	0

The analysis of the additional process data shows unusual variation in the Partgap process.

Example 32.4: Applying Tests for Special Causes

(View the complete code for this example (spcex4.sas) in the example repository.)

The following statements produce a data table for 100 simulated process measurements, called Process001 through Process100:

```
data mylib.Random;
   length processname $16 subgroupname $16;
   do i = 1 to 100;
      processname  = 'Process'  || left( put( i, z3. ) );
      subgroupname = 'Subgroup' || left( put( i, z3. ) );
      do subgroup = 1 to 30;
         do j = 1 to 5;
            process = rannor(123);
            output;
         end;
      end;
   end;
   drop i j;
run;
```

The following statements use PROC SPC to do an $\bar{X}$ chart analysis of the simulated data and apply the first through fourth tests for special causes:

```
proc spc data=mylib.Random;
   xchart / exchart
            tests    = 1 to 4
            outtable = mylib.RandomTests;
run;
```

The TESTS= option requests the tests for special causes. Output 32.2 shows the resulting exception summary table.

Output 32.4.1 Results of Tests for Special Causes

The SPC Procedure

Means Chart Summary for RANDOM

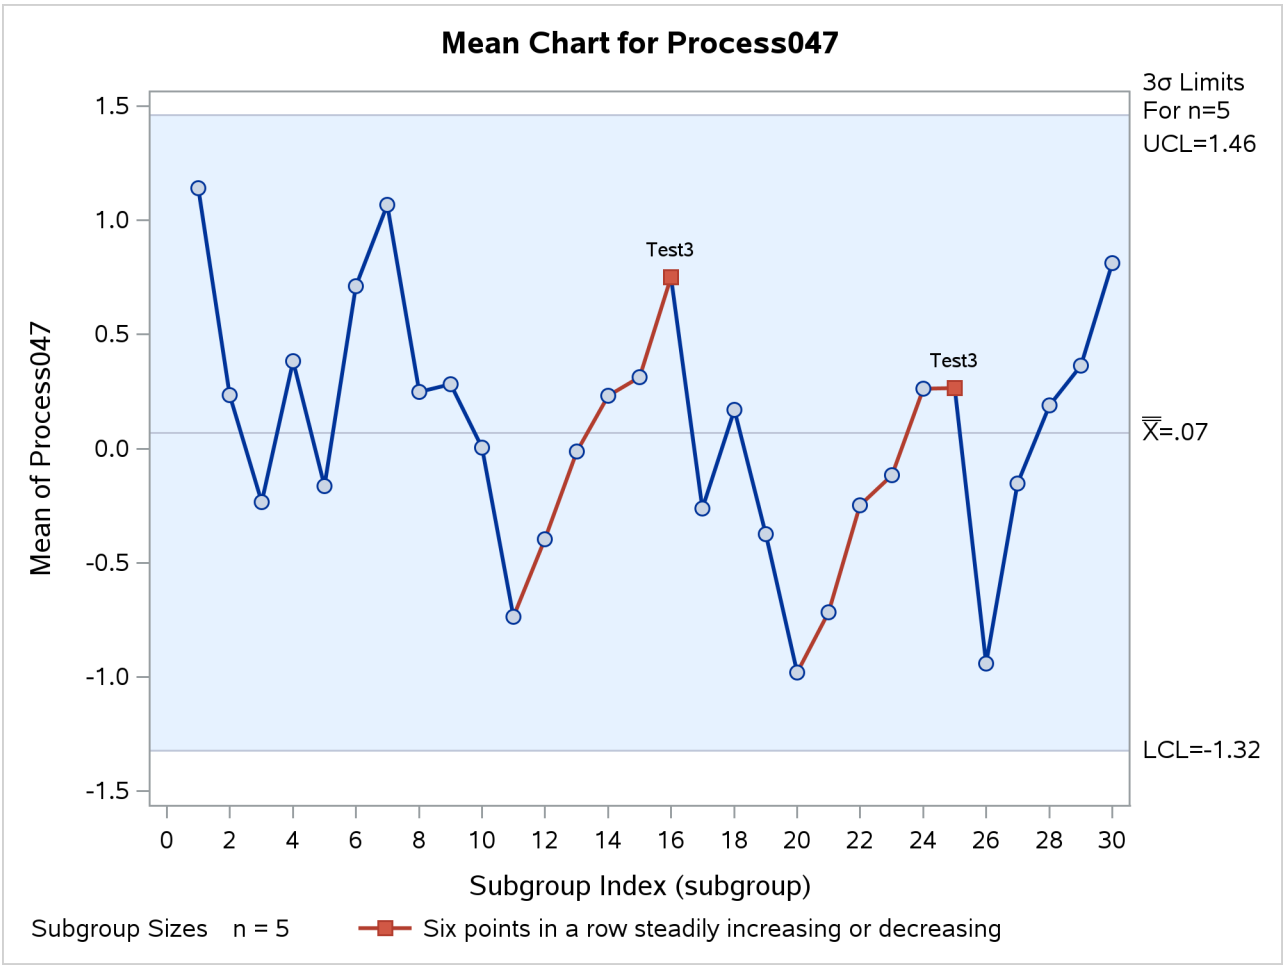
processname	subgroupname	Number of Subgroups	Number > UCL	Number < LCL	Test 1 Signals	Test 2 Signals	Test 3 Signals	Test 4 Signals
Process006	Subgroup006	30	0	1	1	0	0	0
Process011	Subgroup011	30	1	0	1	0	1	0
Process015	Subgroup015	30	0	1	1	0	0	0
Process021	Subgroup021	30	1	0	1	0	0	0
Process031	Subgroup031	30	0	0	0	1	0	0
Process032	Subgroup032	30	1	0	1	0	0	0
Process034	Subgroup034	30	0	0	0	0	1	0
Process047	Subgroup047	30	0	0	0	0	2	0
Process048	Subgroup048	30	0	0	0	0	0	1
Process066	Subgroup066	30	0	0	0	0	0	1
Process069	Subgroup069	30	0	0	0	0	1	0
Process074	Subgroup074	30	0	0	0	0	0	1
Process078	Subgroup078	30	0	1	1	0	0	0
Process079	Subgroup079	30	0	0	0	0	1	0
Process080	Subgroup080	30	0	1	1	0	0	0
Process081	Subgroup081	30	0	0	0	0	1	0
Process089	Subgroup089	30	1	0	1	0	0	0
Process092	Subgroup092	30	1	0	1	0	0	0
Process099	Subgroup099	30	0	0	0	0	1	0

Nineteen of the 100 processes are flagged for at least one exception: a subgroup mean outside the control limits or a positive test result. Because these data were simulated from a normal distribution, they represent processes that are in statistical control. Therefore, you should regard all these exceptions as false positives.

The combined chance of a false signal when Tests 1–4 are applied together is less than 1 in 100 (see the section "Interpreting Tests for Special Causes" on page 1698). Therefore, finding 21 positive tests in an analysis of 3,000 total subgroups is not unexpected.

Example 32.5: Displaying Control Charts by Using SAS/QC Procedures

(View the complete code for this example (spcex5.sas) in the example repository.)



You can use data tables that are produced by the OUTTABLE= option in the SPC procedure's chart statements as input to SAS/QC procedures that can display control charts graphically. You can use PROC SHEWHART to display Shewhart charts that are computed by PROC SPC's BOXCHART, CCHART, IRCHART, MCHART, MRCHART, NPCHART, PCHART, RCHART, SCHART, UCHART, XCHART, XRCHART, and XSCHART statements. You can use PROC MACONTROL to display moving average charts that are computed by PROC SPC's EWMACHART and MACHART statements.

The exception summary table that is displayed in Output 32.5.1 shows that the process variable Process047 had two signals of Test 3, indicating a drift in the process mean. The following statements copy the data for Process047 from the data table mylib.RandomTests to a SAS data set and run PROC SHEWHART to produce an $\bar{X}$ chart of the Process047 data:

```
data RandomTests;
   set mylib.RandomTests;
proc shewhart table=RandomTests(where=(_VAR_ eq 'Process047'));
   xchart Process047 * Subgroup /
            tests = 1 to 4
            markers;
run;
```

The $\bar{X}$ chart for Process047 is shown in Output 32.5.1.

Output 32.5.1 $\bar{X}$ Chart for Process047 Data

The sawtooth pattern of points in Output 32.5.1 indicates an alternating instability in the process. However, it is known that the simulated data are stable, and therefore this must be a random effect. Control chart analysis detects unusual variation in a process measurement, but if you analyze enough data, you will find unusual variation even in a stable process.

Overview: SUPERLEARNER Procedure

The SUPERLEARNER procedure implements the super learner model in SAS Viya (Van der Laan and Rose 2011; Phillips et al. 2023; Naimi and Balzer 2018). In the terminology of machine learning, super learner models are predictive models. The super learner model constructs a predictive model by combining predictions from other models. You can use PROC SUPERLEARNER to train and score predictive models for continuous and binary response variables and to compute predictive margins.

There is no single best machine learning model for all data sets and prediction problems. Given a specific prediction task, it is often difficult to choose a predictive model a priori that will perform best. Wolpert (1992) proposed an approach to increase prediction accuracy by combining multiple models into a single model. Later, this approach became known as "stacking." Breiman (1996) demonstrated additional improvements to predictive performance by using nonnegative least squares for stacking. Van der Laan and colleagues proved the theoretical optimality of stacking in large samples and coined an additional name, "super learner" (Van der Laan and Dudoit 2003; Dudoit and van der Laan 2005; Van der Vaart, Dudoit, and van der Laan 2006; Van der Laan, Polley, and Hubbard 2007). Van der Laan and Rose (2011) provided a detailed description of the super learner model and conducted simulation studies to evaluate its finite sample performance. Phillips et al. (2023) provided practical recommendations for specifying super learner models. The super learner model considers a collection of candidate models, or base learners, and systematically chooses the best combination of them. Optimality theory shows that in large samples, the super learner model performs at least as well as the best base learner model in the ensemble, where predictive performance is defined in terms of a bounded loss function (Van der Laan, Polley, and Hubbard 2007).

When you train a super learner model, you must specify a list of predictive models (also called base learners), a cross-validation scheme, and a meta-learner model. The base learners that make up the ensemble can range from parametric regressions to nonparametric machine learning algorithms. The super learner model uses cross-validation, a sample splitting technique, to assess each base learner's performance. This is an iterative process in which each base learner is trained on a portion of the input data and predicted responses are generated for observations that were not used in the training process. The meta-learner model then computes the best weighted combination of base learners. The output of the training process is an ensemble predictive model that uses a vector of input variables (also called predictor variables) to predict the value of a response variable (also called a target variable). The purpose of a predictive model is to use a set of input variables

to predict a target variable. You create a predictive model by using training data in which the target values are known. If the model is able to accurately predict the value of the target for observations that were not included in the training data, then the model is said to generalize well. Good generalization is an important property of a predictive model. Internally, the super learner model uses cross-validation to mitigate overfitting of the training data and obtain good generalization. The internal cross-validation estimates the out-of-sample performance of each base learner. Base learners that demonstrate better out-of-sample performance tend to receive larger coefficients and generally contribute more to the final predictions.

For more information about super learner models, see the section "Details: SUPERLEARNER Procedure" on page 1759.

PROC SUPERLEARNER Features

PROC SUPERLEARNER has the following basic features:

- trains super learner models for continuous response variables and binary response variables
- specifies and customizes base learner models
- controls the details of cross-validation
- creates an item store for the model and saves it as a binary object in a data table
- produces a data table that contains predicted values
- supports meta-learning methods such as convex-constrained least squares and binomial likelihood maximization
- supports fitting a cross-validated selector (discrete super learner model)

Because PROC SUPERLEARNER runs on SAS Cloud Analytic Services (CAS), it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode
- exploits available cores and concurrent threads

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “Introduction to Shared Concepts” on page 6 in Chapter 2, “Shared Concepts.”

Getting Started: SUPERLEARNER Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/superlearnergs.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

This example demonstrates how you can use the SUPERLEARNER procedure to train a super learner model.

The Sashelp.Baseball data table contains salary and performance information for Major League Baseball players (excluding pitchers) who played at least one game in both the 1986 and 1987 seasons (Time Inc. 1987). You can load the Sashelp.Baseball data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step:

```
data mylib.baseball;
  set sashelp.baseball;
run;
```

The following statements train a super learner model:

```
proc superlearner data=mylib.baseball seed=24893;
   target logSalary / level=interval;
   input nAtBat nHits nHome nRuns nRBI nBB
         yrMajor crAtBat crHits crHome
         crRuns crRbi crBB nOuts nAssts nError
         / level=interval;
   input league division / level=nominal;
   baselearner 'lm' regselect;
   baselearner 'dtree' treesplit;
   baselearner 'bart' bart;
   crossvalidation kfold=6;
   output out=mylib.predout copyvar=logSalary;
run;
```

When you use PROC SUPERLEARNER for training, you must specify the TARGET statement, at least one INPUT statement, and at least two BASELEARNER statements.

You use the TARGET statement to specify the target variable. You use the LEVEL= option to specify that the target variable is treated as a continuous (interval) variable for the analysis. You specify two INPUT statements in this example; one statement contains continuous predictors, and the other statement contains categorical predictors. You specify whether the variables in each INPUT statement are treated as interval (continuous) or nominal (categorical) variables by using the LEVEL= option.

When you use the BASELEARNER statement to specify a base learner model, you begin by specifying a name of the base learner in single quotes. After the name, you must specify a model type. The BASELEARNER statement supports various model types that you can use to build a base learner. It also supports a large number of options that you can use to customize each base learner. For more information, see the BASELEARNER statement.

In this example, you specify three base learners by using three BASELEARNER statements. You use the REGSELECT, TREESPLIT, and BART model types to specify a linear regression model, a decision tree, and a Bayesian additive regression trees model, respectively.

You split the input data into five folds for cross-validation by specifying the KFOLD= option in the CROSSVALIDATION statement. If you omit this statement, cross-validation is still conducted, and the number of folds is computed on the basis of the size of the input data set. For more information, see the section "*K*-Fold Cross-Validation" on page 1761.

To form the final predictive model, PROC SUPERLEARNER uses a meta-learning step to form a weighted combination of the predictions from the base learners. In this example, the target variable is continuous, so the meta-learning step uses the convex-constrained least squares method by default. For more information, see the section "Meta-learning Methods" on page 1760.

Finally, you use the OUTPUT statement to create an output data table named predout that contains predicted response values from the super learner. You use the OUT= option to specify the name of the output data table. You use the COPYVAR= option to copy the target variable from the input data table to the output data table.

The output from this analysis is presented in Figure 33.1 and Figure 33.2. The "Model Information" table in Figure 33.1 summarizes important information about the input data and primary analysis options. Information includes the input data source, response (target) variable and its type, number of folds used in cross-validation, number of base learners, loss function, meta-learning method, and random number seed.

The second table in Figure 33.1 shows the number of observations in the input data table. PROC SUPERLEARNER uses only complete cases in the input data for training, so an observation is excluded from training if any analysis variable contains a missing value. For more information, see the section "Missing Values" on page 1766.

Figure 33.1 Model Information and Number of Observations

Model Information	
Data Source	BASEBALL
Target Variable	logSalary
Target Variable Type	INTERVAL
Number of Folds	6
Number of Base Learners	3
Loss Function	Quadratic Loss
Meta-learning Method	Convex-constrained Least Squares
Random Number Seed	24893

Number of Observations Read	322
Number of Observations Used for Training	263
Number of Observations Used for Scoring	322

Figure 33.2 displays information about the super learner model coefficients, which describe the contribution of each base learner model in the super learner model ensemble. The cross-validated risk measures each base learner's predictive performance in cross-validation. (For more information about cross-validated risk, see the section "Cross-Validated Risk" on page 1762.) In this example, the "bart" base learner model has the smallest cross-validated risk and therefore shows the best out-of-sample performance. It receives the largest super learner model coefficient.

Figure 33.2 Super Learner Model Coefficients

Super Learner Model Coefficients

Name	Model Type	Coefficient	Cross-Validated Risk
lm	Ordinary Linear Least Squares	0.06908	0.35223
dtree	Decision Tree	0.12885	0.26394
bart	Bayesian Additive Regression Trees	0.80207	0.17854

The following PROC PRINT statements print the first 10 observations of the predicted and observed response values. The results are shown in Figure 33.3.

```
proc print data=mylib.predout(obs=10);
run;
```

Figure 33.3 First 10 Observations in the Output Data Table

Obs	P_logSalary	logSalary
1	6.76028	6.65286
2	5.72326	5.70378
3	5.99384	.
4	6.06349	5.76832
5	4.59300	4.70048
6	6.72476	.
7	5.95649	5.95324
8	6.62632	6.74524
9	4.92826	4.38203
10	4.34254	4.31749

Syntax: SUPERLEARNER Procedure

PROC SUPERLEARNER < *options* > **;**
BASELEARNER '*name*' *model-type* **<(***model-options***)>** < *input-options* > **;**
CROSSVALIDATION < *options* > **;**
INPUT *variables* < */option* > **;**
MARGIN '*name*' *variable*='*value*' < . . . *variable*='*value*' > **;**
OUTPUT OUT=*libref.data-table* < *options* > **;**
STORE < **OUT=** >*libref.data-table* **;**
TARGET *variable* < */option* > **;**

The PROC SUPERLEARNER statement, INPUT statement, TARGET statement, and at least two BASELEARNER statements are required. You can specify the BASELEARNER, INPUT, and MARGIN statements multiple times. You can specify all other statements only once. The following sections describe the PROC SUPERLEARNER statement and then describe the other statements in alphabetical order.

PROC SUPERLEARNER Statement

PROC SUPERLEARNER < *options* > **;**

The PROC SUPERLEARNER statement invokes the procedure. Table 33.1 summarizes the available options in this statement.

Table 33.1 PROC SUPERLEARNER Statement Options

Option	Description
APPLYROWORDER	Uses group and order information from the input data table
DATA=	Specifies the input data table
METHOD=	Specifies the method to use for fitting the meta-learner model
RESTORE=	Specifies the input item store
SEED=	Specifies the seed for the pseudorandom number generator

You can specify the following *options*:

APPLYROWORDER
uses group and order information from the input data table. You can add this information to the input table by using the `partition` action in the `table` action set. For more information, see the section "The APPLYROWORDER Option" on page 107 in Chapter 2, "Shared Concepts." This option is applicable to models that require the simulation of latent variables; by default, it is not enabled. If you specify this option but the table does not contain group and order information, the procedure terminates with an error.

DATA=*libref.data-table*
names the input data table for PROC SUPERLEARNER to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1728.

data-table specifies the name of the input data table.

METHOD=*method* **<(***method-option***)>**
specifies the meta-learning method to be used to estimate the coefficients of the super learner model. By specifying a meta-learning method, you specify an algorithm that is used to combine the individual base learner models in the library. For more information, see the section "Meta-learning Methods" on page 1760. You can specify one of the following *methods*:

CCAUC estimates the coefficients by maximizing the convex-constrained area under the ROC curve (AUC). This option is available only if the response variable is binary.

CCLOGLIK estimates the coefficients by maximizing the convex-constrained binomial log likelihood. This option is available only if the response variable is binary.

CCLS estimates the coefficients by fitting a convex-constrained least squares regression with no intercept.

CVSELECTOR estimates the coefficients by assigning a coefficient of 1 to a single base learner model on the basis of cross-validated performance and setting coefficients of all other base learner models to 0.

By default, METHOD=CCLS if the response variable is continuous and METHOD=CCLOGLIK if the response variable is binary.

You can specify the following *method-option* when METHOD=CVSELECTOR:

LOSS=*keyword*
specifies the loss function to use for computing cross-validated risks. You can specify the following *keywords*:

AUC uses the area under the ROC curve loss function. This option is available only if the response variable is binary.

LOG uses the log loss function. This option is available only if the response variable is binary.

QUADRATIC uses the quadratic loss function.

By default, LOSS=QUADRATIC if the response variable is continuous and LOSS=LOG if the response variable is binary.

RESTORE=*libref.data-table*
specifies the name of the item store that contains a model that is fitted and stored from a previous analysis. The item store is created by a STORE statement from a previous PROC SUPERLEARNER call or by a **`store`** parameter that is specified in a previous **`slTrain`** action call. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1728.

You can use the previously fitted model to either score data or compute predictions at fixed values of the predictors. For each task, you use the DATA= option to specify the input data table to be used. To score the input data, you specify the OUTPUT statement to create a data table that contains the observationwise predictions. To compute predictions at fixed values of the predictors, you specify one or more MARGIN statements and specify the MARGINPRED option in the OUTPUT statement. You can also request observationwise predictions from each base learner model that you use to train the super learner model. To do so, specify the LEARNERPRED option in the OUTPUT statement.

Because the previously fitted model is stored and retrieved for the analysis, you cannot include statements and options that are specific to training a model. In particular, the BASELEARNER, CROSSVALIDATION, INPUT, STORE, and TARGET statements are not available when you specify the RESTORE= option.

SEED=*n*

specifies the initial seed to start the pseudorandom number generator for *k*-fold partitioning and base learner model building, where *n* is an integer. If you omit the SEED= option or if *n* is negative or 0, the procedure uses the time of day from the computer's clock to obtain the initial seed.

BASELEARNER Statement

BASELEARNER '*name*' *model-type* **<(***model-options***)>** < *input-options* > **;**

The BASELEARNER statement provides options for you to specify and customize a base learner model. Here *name* represents a label that you assign to the base learner model. It is enclosed in quotes and must be a valid variable name. Every base learner that you specify in a BASELEARNER statement must have a unique label. The labels for base learners are not case-sensitive.

You use the *model-type* to specify the type of a base learner model. You can specify the following *model-types*:

BART specifies a Bayesian additive regression trees model. For a list of available *model-options* and *input-options*, see the BART section.

BNET specifies a Bayesian network model. This model is available only if you specify a binary response variable. For a list of available *model-options* and *input-options*, see the BNET section.

FACTMAC specifies a factorization machine model. This model is available only if you specify a continuous response variable. For a list of available *model-options* and *input-options*, see the FACTMAC section.

FOREST specifies a forest model. For a list of available *model-options* and *input-options*, see the FOREST section.

GAMMOD specifies a generalized additive model based on low-rank regression splines. For a list of available *model-options* and *input-options*, see the GAMMOD section.

GAMSELECT specifies a generalized additive model with model selection. For a list of available *model-options* and *input-options*, see the GAMSELECT section.

GPCLASS specifies a Gaussian process classification model. This model is available only if you specify a binary response variable. For a list of available *model-options* and *input-options*, see the GPCLASS section.

GPREG specifies a Gaussian process regression model. This model is available only if you specify a continuous response variable. For a list of available *model-options* and *input-options*, see the GPREG section.

GRADBOOST specifies a gradient boosting model. For a list of available *model-options* and *input-options*, see the GRADBOOST section.

LIGHTGRADBOOST specifies a light gradient boosting machine model. For a list of available *model-options* and *input-options*, see the LIGHTGRADBOOST section.

LOGSELECT specifies a logistic regression model with model selection. This model is available only if you specify a binary response variable. For a list of available *model-options* and *input-options*, see the LOGSELECT section.

NNET specifies an artificial neural network model. For a list of available *model-options* and *input-options*, see the NNET section.

REGSELECT specifies an ordinary least squares regression model with model selection. This model is available only if you specify a continuous response variable. For a list of available *model-options* and *input-options*, see the REGSELECT section.

SVMACHINE specifies a support vector machine model. For a list of available *model-options* and *input-options*, see the SVMACHINE section.

TREESPLIT specifies a tree-based statistical model. For a list of available *model-options* and *input-options*, see the TREESPLIT section.

Depending on the SAS software product that you have, some of these model types might not be available. For more information, see the section "Supported Base Learner Model Types" on page 1762.

Depending on which model type you choose, different *model-options* and *input-options* might be available to you. The following sections describe the relevant *model-options* and *input-options* for each base learner model.

BART

The BART model fits a Bayesian additive regression trees model. For more information, see Chapter 4, "BART Procedure."

The *model-options* for the BART model cover only a subset of the options in PROC BART. You can specify any of the following BART-specific *model-options* by enclosing them in parentheses after the BART keyword:

MINLEAFSIZE=*number*
specifies the minimum number of observations that each child of a split must contain in the training data in order for the split to be considered. By default, MINLEAFSIZE=5.

NBI=*number*
specifies the number of burn-in iterations to perform before the procedure starts to save samples for prediction. By default, NBI=100.

NBINS=*number*
specifies the number of bins to use for binning the continuous input variables. By default, NBINS=50.

NMC=*number*
specifies the number of iterations in the main simulation loop. By default, NMC=200.

NTHIN=*number*
specifies the thinning rate of the simulation. By default, NTHIN=1.

NTREE=*number*
specifies the number of trees in a sample of the sum-of-trees ensemble. By default, NTREE=50.

For full descriptions of these *model-options* and the BART model, see the PROC BART documentation. Note that the default values for the NMC= and NTREE= options differ from those of the corresponding options in PROC BART.

You can specify *input-options* to customize the set of predictor variables for the BART model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements

are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

If the response variable is nominal, then a binary response model is used. If the response variable is interval, then a Gaussian response model is used.

BNET

The BNET model creates a Bayesian network model. For more information, see Chapter 5, "BNET Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the BNET model cover only a subset of the options in PROC BNET. You can specify any of the following BNET-specific *model-options* by enclosing them in parentheses after the BNET keyword:

ALPHA=*number*
specifies the significance level for independence tests by using the chi-square or G-square statistics, where *number* is between 0 and 1, inclusive. By default, ALPHA=0.05.

INDEPTEST=*keyword*
specifies the method to use for independence tests. You can specify the following *keywords*:

ALL	uses the chi-square statistics, the G-square statistics, and the normalized mutual information for independence tests.
CHIGSQUARE	uses both the chi-square and G-square statistics for independence tests.
CHISQUARE	uses the chi-square statistics for independence tests.
GSQUARE	uses the G-square statistics for independence tests.
MI	uses the normalized mutual information for independence tests.

By default, INDEPTEST=CHIGSQUARE.

MAXPARENTS=*integer*
specifies the maximum number of parents that are allowed for each node in the network structure, where *integer* is a value between 1 and 16, inclusive. By default, MAXPARENTS=5.

MIALPHA=*number*
specifies the threshold for independence tests by using mutual information, where *number* is a value between 0 and 1, inclusive. By default, MIALPHA=0.05.

NUMBIN=*integer*
specifies the number of binning levels for all interval variables, where *integer* is a value between 2 and 1,024, inclusive. By default, NUMBIN=5.

PARENTING=*keyword*
specifies the algorithm to use for orienting the network structure. You can specify the following *keywords*:

BESTONE uses a greedy approach to determine the parents of each node.

BESTSET determines the best set of variables among possible candidate sets as the parents of each node.

By default, PARENTING=BESTSET.

PRESCREENING=*keyword*
specifies the initial screening for the input variables. You can specify the following *keywords*:

0 uses all the input variables.

1 uses only the input variables that are dependent on the target.

By default, PRESCREENING=1.

STRUCTURE=*keyword*
specifies the network structure. You can specify the following *keywords*:

GENERAL learns a general Bayesian network over the target and input variables.

MB learns the Markov blanket of the target variable.

NAIVE assumes a naive Bayesian network structure.

PC learns the parent-child Bayesian network structure.

TAN learns the tree-augmented naive Bayesian network structure.

By default, STRUCTURE=PC.

VARSELECT=*keyword*
specifies how input variables are selected beyond the prescreening. You can specify the following *keywords*:

0 uses all input variables that remain after the initial screening is performed as specified in the PRESCREENING= option.

1 tests each input variable for conditional independence of the target variable, given any other input variable.

2 tests each input variable further for conditional independence of the target variable, given any subset of other input variables.

3 determines the Markov blanket of the target variable and uses only the variables in the Markov blanket.

By default, VARSELECT=1.

For full descriptions of these *model-options* and the BNET model, see the PROC BNET documentation. Note that in contrast with PROC BNET, you can specify a single number only when you specify the ALPHA= or MAXPARENTS= option. Also in contrast with PROC BNET, you can specify a single keyword only when you specify the PARENTING=, PRESCREENING=, STRUCTURE=, or VARSELECT= option.

You can specify *input-options* to customize the set of predictor variables for the BNET model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

FACTMAC

The FACTMAC model fits a factorization machine model. For more information, see Chapter 8, "FACTMAC Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the FACTMAC model cover only a subset of the options in PROC FACTMAC. You can specify any of the following FACTMAC-specific *model-options* by enclosing them in parentheses after the FACTMAC keyword:

LEARNSTEP=*number*
specifies the learning step size for the stochastic gradient descent algorithm, where *number* is a positive real number. By default, LEARNSTEP=0.001.

MAXITER=*number*
specifies the maximum number of iterations for the algorithm to perform, where *number* is an integer greater than or equal to 1. By default, MAXITER=1.

NFACTORS=*number*
specifies the number of factors to estimate for the model, where *number* is an integer greater than or equal to 1. By default, NFACTORS=1.

For full descriptions of these *model-options* and the FACTMAC model, see the PROC FACTMAC documentation. Note that you must specify at least two nominal input variables. You can also specify any number of interval input variables.

You can specify *input-options* to customize the set of predictor variables for the FACTMAC model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

FOREST

The FOREST model creates a predictive model called a forest (which consists of several decision trees). For more information, see Chapter 11, "FOREST Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the FOREST model cover only a subset of the options in PROC FOREST. You can specify any of the following FOREST-specific *model-options* by enclosing them in parentheses after the FOREST keyword:

INBAGFRACTION=*number*
specifies the fraction of the random bootstrap sample of the training data to be used to grow each tree in the forest, where *number* is a value between 0 and 1, inclusive. By default, INBAGFRACTION=0.6.

MAXDEPTH=*number*
specifies the maximum depth of the tree to be grown. By default, MAXDEPTH=20.

MINLEAFSIZE=*number*
specifies the minimum number of observations that each child of a split must contain in the training data table in order for the split to be considered. By default, MINLEAFSIZE=5.

NTREES=*number*
specifies the number of trees to grow in the forest model. By default, NTREES=100.

NUMBIN=*number*
specifies the number of bins to use for binning the interval input variables. By default, NUMBIN=50.

VARS_TO_TRY=*m*
specifies the number of input variables to consider splitting on in a node, where *m* ranges from 1 to the number of input variables. By default, *m* is the square root of the number of input variables.

For full descriptions of these *model-options* and the FOREST model, see the PROC FOREST documentation.

You can specify *input-options* to customize the set of predictor variables for the FOREST model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables*)
specifies the nominal input *variables* for the base learner model.

GAMMOD

The GAMMOD model fits a generalized additive model that is based on low-rank regression splines. For more information, see Chapter 12, "GAMMOD Procedure."

There are no available *model-options* that you can specify when using a base learner of the GAMMOD model type.

You can specify *input-options* to customize the set of predictor variables for the GAMMOD model type. If you omit *input-options* for this base learner model, then the nominal variables that you specify in the INPUT statements enter the base learner as main parametric effects, and each interval variable that you specify in the INPUT statement enters the base learner as a univariate spline effect. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

CLASS=(*variables*)
names the classification variables to be used as explanatory variables in the analysis if they are also used in the PARAM(*effects*) option. You can include the response variable, but this is not required.

PARAM(*effects*)
specifies parametric effects that are constructed from variables in the input data; this option can appear multiple times. For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

SPLINE(*variable*...<*variable*><*/spline-options*>)
specifies nonparametric spline effects that are constructed from variables in the input data. You can specify only continuous variables (not classification variables) in spline effects. You can specify this option any number of times. For information about constructing spline effects, see the section "MODEL Statement" on page 596 in Chapter 12, "GAMMOD Procedure."

You can specify the following *spline-options* after a slash:

DF=*n*
specifies a fixed degrees of freedom. When you specify this option, no smoothing parameter selection is performed on the spline term. If *n* is not an integer, then it is truncated to an integer.

M=*n*
specifies the order of the derivative in the penalty term, where *n* is a positive integer. The default is described in the section

"MODEL Statement" on page 596 in Chapter 12, "GAMMOD Procedure."

For a binary response variable, the response distribution for the GAMMOD model is the binary distribution function. For an interval response variable, the response distribution for the GAMMOD model is the normal distribution function.

For example, you can use the following syntax to specify a base learner by using the GAMMOD model type that includes a mixture of parametric and spline effects:

```
baselearner 'lrnr' GAMMOD class=(z) param(z x1) spline(x2) spline(x3);
```

This is equivalent to the following specification that uses PROC GAMMOD:

```
proc gammod data=mylib.data;
   class z;
   model y=param(z x1) spline(x2) spline(x3);
run;
```

GAMSELECT

The GAMSELECT model fits a generalized additive model and performs model selection. For more information, see Chapter 13, "GAMSELECT Procedure."

You can specify any of the following GAMSELECT-specific *model-options* by enclosing them in parentheses after the GAMSELECT keyword:

PARTBYFRAC(VALIDATE=*fraction***)**
randomly assigns specified proportions of the observations in the input data table to the validation role. You specify the proportions for validation by using the VALIDATE= suboption.

PARTBYVAR=*variable***(VALIDATE='***value***')**
names the variable in the input data table whose values are used to assign the validation role to each observation. You cannot use this variable as an analysis variable for this base learner model. The VALIDATE= suboption specifies the formatted value of this variable that is used to assign observations to the validation role. All observations that are not assigned to the validation role are assigned to the training role.

SELECTION=*method***< (***method-options***) >**
specifies the method to be used to select the model. You can specify the following *methods*. You can also specify *method-options* to apply to the specified method by enclosing them in parentheses after the *method*.

BOOSTING specifies the boosting method.

SHRINKAGE specifies the shrinkage method.

By default, SELECTION=BOOSTING.

Because of the intrinsic difference between the boosting method and the shrinkage method, the two selection methods have two different sets of options that enable you to control the selection process. You can specify the following *method-options* when SELECTION=BOOSTING:

CHOOSE=VALIDATE
specifies the criterion to use in selecting the final model.

You can specify the following value:

VALIDATE specifies the average square error for the validation data.

If you omit the CHOOSE= option, the average square error for the training data is used to select the final model.

MAXITER=*number*
specifies the maximum number of iterations for the boosting method. By default, MAXITER=500.

STEPSIZE=*number*
specifies the step size to use for the boosting algorithm, where *number* is a value between 0 and 1. By default, STEPSIZE=0.1.

You can specify the following *method-options* when SELECTION=SHRINKAGE:

LAMBDA1=*number*
sets a fixed nonnegative value to control the sparsity penalty.

LAMBDA2=*number*
sets a fixed nonnegative value to control the smoothness penalty.

MAXITER=*number*
specifies the maximum number of iterations that generalized additive model fitting can perform by solving reweighted additive models at each iteration. By default, MAXITER=500.

You can specify *input-options* to customize the set of predictor variables for the GAMSELECT model type. If you omit *input-options* for this base learner model, then the nominal variables that you specify in the INPUT statements enter the base learner as main parametric effects, and each interval variable that you specify in the INPUT statement enters the base learner as a univariate spline effect. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

CLASS=(*variables***)**
names the classification variables to be used as explanatory variables in the analysis if they are also used in the PARAM(*effects*) option. You can include the response variable, but this is not required.

PARAM(*effects***)**
specifies parametric effects that are constructed from variables in the input data; you can specify this option multiple times. For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

SPLINE(*variable***<** *variable***><** */ *spline-options***>)**
specifies nonparametric spline effects that are constructed from variables in the input data. You can specify only continuous variables (not classification variables) in spline effects. You can specify one or two variables in this option when SELECTION=BOOSTING. You can specify only one variable when SELECTION=SHRINKAGE. You can specify this option any number of times. For information about constructing spline effects, see the section "MODEL Statement" on page 656 in Chapter 13, "GAMSELECT Procedure."

When SELECTION=BOOSTING, you can specify the following *spline-options* after a slash:

DEGREE=*n*
specifies the degree of the spline transformation, where *n* is a nonnegative integer. By default, DEGREE=3.

DF=*n*
specifies the fixed degrees of freedom for the spline at each boosting iteration. By default, DF=4 for univariate spline terms and DF=6 for bivariate spline terms.

For a binary response variable, the response distribution for the GAMSELECT model is the binary distribution function. For an interval response variable, the response distribution for this model is the normal distribution function.

For example, you can use the following syntax to specify a base learner model by using the GAMSELECT model type that includes a mixture of parametric and spline effects with boosting model selection based on partitioned data:

```
baselearner 'lrnr' gamselect(selection=boosting partbyfrac(validate=0.2))
   class=(z) param(z x1) spline(x2) spline(x3);
```

This is equivalent to the following specification that uses PROC GAMSELECT:

```
proc gamselect data=mylib.data;
   partition fraction(validate=0.2);
   selection method=boosting;
   class z;
   model y=param(z x1) spline(x2) spline(x3);
run;
```

GPCLASS

The GPCLASS model fits a Gaussian process classification model. For more information, see Chapter 15, "GPCLASS Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the GPCLASS model cover only a subset of the options in PROC GPCLASS. You can specify any of the following GPCLASS-specific *model-options* by enclosing them in parentheses after the GPCLASS keyword:

KERNEL=*keyword***<(***kernel-options***)>**
specifies the kernel-related parameters to use in the Gaussian process. You can specify the following *keywords*:

CHIGSQUARE uses a linear kernel.

GAUSSIAN uses a Gaussian kernel.

By default, KERNEL=GAUSSIAN.

You can also specify the following *kernel-options* by enclosing them in parentheses after the *keyword*:

CONSTANT=*n*
specifies the constant in the linear kernel function. By default, CONSTANT=0.

SIGMA=*n*
specifies the bandwidth in the Gaussian kernel function. By default, SIGMA=1.

MAXITER=*number*
specifies the maximum number of Newton iterations. By default, MAXITER=100.

MINLEAFSIZE=*number*
specifies the minimum change of the loss function between consecutive Newton iterations. By default, THRESHOLD=1.0E–10.

For full descriptions of these *model-options* and the GPCLASS model, see the PROC GPCLASS documentation.

You can specify *input-options* to customize the set of predictor variables for the GPCLASS model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-option*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

GPREG

The GPREG model performs Gaussian process regression. For more information, see Chapter 16, "GPREG Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the GPREG model cover only a subset of the options in PROC GPREG. You can specify any of the following GPREG-specific *model-options* by enclosing them in parentheses after the GPREG keyword:

ALGORITHM=*keyword*
specifies the optimization-algorithm to use during training. You can specify the following *keywords*:

ADAM specifies the adaptive moments algorithm.

SGD specifies the plain stochastic gradient descent algorithm.

By default, ALGORITHM=ADAM.

AUTORELEVANCEDETERMINATION
uses automatic relevance determination in the kernel function.

JITTERMAXITERS=*number*
specifies the maximum number of iterations for jitter Cholesky decomposition. By default, JITTERMAXITERS=10.

KERNEL=*keyword*
specifies the kernel-related parameters to be used in the Gaussian process. You can specify the following *keywords*:

LINEAR specifies a linear kernel.

MATERN32 specifies a Matern 3/2 kernel.

MATERN52 specifies a Matern 5/2 kernel.

PERIODIC specifies a periodic kernel.

RBF specifies a radial basis function kernel.

By default, KERNEL=RBF.

LEARNINGRATE=*number*
specifies the learning rate parameter for the adam or SGD algorithm. By default, LEARNINGRATE=0.001.

MINIBATCHSIZE=*number*
specifies the size of the minibatches to use in the adam or SGD algorithm. By default, MINIBATCHSIZE=10.

MOMENTUM=*number*
specifies the momentum, where *number* is a value between 0 and 1, inclusive. By default, MOMENTUM=0.

NINDUCINGPOINTS=*number*
specifies the number of inducing points to use in the sparse Gaussian process, where *number* is a positive integer. By default, NINDUCINGPOINTS=100.

For full descriptions of these *model-options* and the GPREG model, see the PROC GPREG documentation.

You can specify *input-options* to customize the set of predictor variables for the GPREG model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-option*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

GRADBOOST

The GRADBOOST model specifies a gradient boosting model. For more information, see Chapter 17, "GRADBOOST Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the GRADBOOST model cover only a subset of the options in PROC GRADBOOST. You can specify any of the following GRADBOOST-specific *model-options* by enclosing them in parentheses after the GRADBOOST keyword:

LASSO=*number*
specifies the L1 norm regularization parameter, where *number* must be nonnegative. By default, LASSO=0.

LEARNINGRATE=*number*
specifies the learning rate for the gradient boosting algorithm, where *number* is a value between 0 and 1, inclusive. By default, LEARNINGRATE=0.1.

MAXDEPTH=*number*
specifies the maximum depth of the tree to be grown. By default, MAXDEPTH=4.

MINLEAFSIZE=*number*
specifies the minimum number of observations that each child of a split must contain in the training data table in order for the split to be considered. By default, MINLEAFSIZE=5.

NTREES=*number*
specifies the *number* of trees to grow in the gradient boosting model. By default, NTREES=100.

NUMBIN=*number*
specifies the number of bins to use for binning the interval input variables. By default, NUMBIN=50.

RIDGE=*number*
specifies the L2 norm regularization parameter, where *number* must be nonnegative. By default, RIDGE=1.

SAMPLINGRATE=*number*
specifies the fraction of the training data to be used to grow each tree in the boosting model. By default, SAMPLINGRATE=0.5.

VARS_TO_TRY=*m*
specifies the number of input variables to consider splitting on in a node, where *m* ranges from 1 to the number of input variables. By default, *m* is the number of input variables

For full descriptions of these *model-options* and the GRADBOOST model, see the PROC GRADBOOST documentation.

You can specify *input-options* to customize the set of predictor variables for the GRADBOOST model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

LIGHTGRADBOOST

The LIGHTGRADBOOST model fits a light gradient boosting machine model. For more information, see Chapter 20, "LIGHTGRADBOOST Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the LIGHTGRADBOOST model cover only a subset of the options in PROC LIGHTGRADBOOST. You can specify any of the following LIGHTGRADBOOST-specific *model-options* by enclosing them in parentheses after the LIGHTGRADBOOST keyword:

BAGGINGFRACTION=*number*
randomly selects a portion of the observations without resampling. By default, BAGGINGFRACTION=1.0.

BAGGINGFREQUENCY=*number*
specifies the frequency of bagging. By default, BAGGINGFREQUENCY=0.

INPUTFRACTION=*number*
randomly selects a subset of features on each iteration or tree. By default, INPUTFRACTION=1.0.

LASSO=*number*
specifies the L1-norm regularization parameter, where *number* must be nonnegative. You cannot use this option for categorical responses. By default, LASSO=0.

LEAFSIZE=*number*
specifies the minimum number of observations that each child of a split must contain in the training data table in order for the split to be considered. By default, LEAFSIZE=20.

LEARNINGRATE=*number*
specifies the learning rate for each tree, where *number* must be greater than 0. By default, LEARNINGRATE=0.1.

MAXDEPTH=*number*
limits the maximum depth of the tree model. A *number* less than or equal to 0 means no limit. By default, MAXDEPTH=–1.

MAXITERS=*number*
specifies the maximum number of iterations for the boosting. By default, MAXITERS=100.

NUMBIN=*number*
specifies the number of bins to use for binning the interval input variables. By default, NUMBIN=255.

RIDGE=*number*
specifies the L2-norm regularization parameter, where *number* must be nonnegative. You cannot use this option for categorical responses. By default, RIDGE=1.

For full descriptions of these *model-options* and the LIGHTGRADBOOST model, see the PROC LIGHTGRADBOOST documentation.

You can specify *input-options* to customize the set of predictor variables for the LIGHTGRADBOOST model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

LOGSELECT

The LOGSELECT model specifies a logistic regression model with model selection. For more information, see Chapter 18, "LOGSELECT Procedure."

The *model-options* for the LOGSELECT model cover only a subset of the options in PROC LOGSELECT. You can specify any of the following LOGSELECT-specific *model-options* by enclosing them in parentheses after the LOGSELECT keyword:

LASSORHO=*r*
specifies the base regularization parameter for the LASSO model selection method. The regularization parameter for step i is r^i. By default, LASSORHO=0.8.

LASSOSTEPS=*n*
specifies the maximum number of steps for LASSO model selection. By default, LASSOSTEPS=20.

LASSOTOL=*r*
specifies the convergence tolerance for the optimization algorithm that solves for the LASSO parameter estimates at each step of LASSO model selection. By default, LASSOTOL=1E–6.

LINK=*keyword*
specifies the link function for the model. The default link is the logit. You can specify the following *keywords*:

LOGIT	specifies the logit link function.
PROBIT	specifies the probit link function.

PARTBYFRAC(VALIDATE=*fraction***)**
randomly assigns specified proportions of the observations in the input data table to the validation role. You specify the proportions for validation by using the VALIDATE= suboption.

PARTBYVAR=*variable***(VALIDATE='***value***')**
names the variable in the input data table whose values are used to assign the validation role to each observation. You cannot use this variable as an analysis variable for this base learner model. The VALIDATE= suboption specifies the formatted value of this variable that is used to assign observations to the validation role. All observations that are not assigned to the validation role are assigned to the training role.

SELECTION=*method***<(***method-options***)>**
specifies the method to be used to select the model. You can specify the following selection *methods*:

BACKWARD	performs backward elimination. This method starts with all effects in the model and deletes effects.
ELASTICNET	performs elastic net selection. This method selects effects by fitting a sequence of candidate models with a grid of regularization parameters.
FORWARD	performs forward selection. This method starts with no effects in the model and adds effects.

LASSO performs model selection by the group LASSO method. This method adds and removes effects by using a sequence of LASSO steps.

NONE specifies no model selection. This method fits the full model.

STEPWISE performs stepwise selection. This method is similar to the FORWARD selection method, except that effects already in the model do not necessarily stay there.

By default, SELECTION=NONE. You can also specify *method-options* to apply to the specified method by enclosing them in parentheses after the method. For more information about the available *method-options*, see the section "Supported Model Selection Suboptions" on page 1762.

You can specify *input-options* to customize the model effects for the LOGSELECT model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as main model effects for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

CLASS=(*variables***)**
names the classification variables to be used as explanatory variables in the analysis if you also specify them in the EFFECT= option. You can include the response variable, but this is not required.

EFFECT=(*effects***)**
specifies model effects that are constructed from variables in the input data table. For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

For example, you can use the following syntax to specify a base learner model by using the LOGSELECT model type with LASSO model selection, where the regularization parameter is chosen on the basis of the partitioned data:

```
baselearner 'lrnr'
   logselect(selection=lasso(choose=validate) partbyfrac(validate=0.2))
   class=(z) effect=(z x1-x3);
```

This is equivalent to the following specification that uses PROC LOGSELECT:

```
proc logselect data=mylib.data;
   partition fraction(validate=0.2);
   selection method=lasso(choose=validate);
   class z;
   model y=z x1-x3;
run;
```

NNET

The NNET model trains an artificial neural network model. For more information, see Chapter 25, "NNET Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the NNET model cover only a subset of the options in PROC NNET. You can specify any of the following NNET-specific *model-options* by enclosing them in parentheses after the NNET keyword:

ALGORITHM=*keyword*

specifies the optimization algorithm to use during training. You can specify the following *keywords*:

ADAM	specifies the adaptive moments algorithm.
HF	specifies the Hessian-free algorithm.
LBFGS	specifies the limited-memory Broyden-Fletcher-Goldfarb-Shanno algorithm.
SGD	specifies the plain stochastic gradient descent algorithm.

By default, ALGORITHM=LBFGS.

ANNEALINGRATE=*number*

specifies the annealing parameter, where *number* is a nonnegative value. You can use this option when you specify the adaptive moments algorithm (ALGORITHM=ADAM) or the stochastic gradient descent algorithm (ALGORITHM=SGD). By default, ANNEALINGRATE=1.0E–6.

HIDDEN(*number* **<** */ layer-options* **>)**

specifies the number of neurons or units in a hidden layer. You must specify a *number*, which must be a positive integer. Multiple HIDDEN options are allowed. Each additional HIDDEN option adds a new hidden layer that connects sequentially to the previous layer. If you omit this option, the NNET base learner model has no hidden layer and is equivalent to a generalized linear model.

You can specify the following *layer-options* after a slash:

ACT=*keyword*

specifies the activation function for the neurons on each hidden layer. You can specify the following *keywords*:

EXP	specifies the exponential function.
IDENTITY	specifies the identity function.
LOGISTIC	specifies the logistic function.
RECTIFIER	specifies the rectifier activation function.
SIN	specifies the sine function.
TANH	specifies the hyperbolic tangent function.

By default, ACT=TANH.

COMB=*keyword*

specifies the combination function for the neurons in each hidden layer. You can specify the following *keywords*:

ADD	specifies the additive combination function.
LINEAR	specifies the linear combination function.

By default, COMB=LINEAR.

LEARNINGRATE=*number*
specifies the learning rate parameter, where *number* is a nonnegative value. You can use this option when you specify the adaptive moments algorithm (ALGORITHM=ADAM) or the stochastic gradient descent algorithm (ALGORITHM=SGD). By default, LEARNINGRATE=0.001.

MINIBATCHSIZE=*number*
specifies the size of the minibatches to use in the algorithm, where *number* is a positive value. You can use this option when you specify the adaptive moments algorithm (ALGORITHM=ADAM) or the stochastic gradient descent algorithm (ALGORITHM=SGD). By default, MINIBATCHSIZE=10.

MOMENTUM=*number*
specifies the momentum, where *number* is a value between 0 and 1, inclusive. You can use this option when you specify the adaptive moments algorithm (ALGORITHM=ADAM) or the stochastic gradient descent algorithm (ALGORITHM=SGD). By default, MOMENTUM=0.

REGL1=*number*
specifies the L1 regularization parameter for the model loss function, where *number* is a nonnegative value. By default, REGL1=0.

REGL2=*number*
specifies the L2 regularization parameter, where *number* is a nonnegative value. By default, REGL2=0.

For full descriptions of these *model-options* and the NNET model, see the PROC NNET documentation.

You can specify *input-options* to customize the set of predictor variables for the NNET model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

REGSELECT

The REGSELECT model specifies an ordinary least squares regression model with model selection. For more information, see Chapter 29, "REGSELECT Procedure."

The *model-options* for the REGSELECT model cover only a subset of the options in PROC REGSELECT. You can specify any of the following REGSELECT-specific *model-options* by enclosing them in parentheses after the REGSELECT keyword:

PARTBYFRAC(VALIDATE=*fraction***)**
randomly assigns specified proportions of the observations in the input data table to the validation role. You specify the proportions for validation by using the VALIDATE= suboption.

PARTBYVAR=*variable***(VALIDATE='***value***')**
names the variable in the input data table whose values are used to assign the validation role to each observation. You cannot use this variable as an analysis variable for this base learner model. The VALIDATE= suboption specifies the formatted value of this variable that is used to assign observations to the validation role. All observations that are not assigned to the validation role are assigned to the training role.

SELECTION=*method***< (***method-options***) >**
specifies the method to be used to select the model. You can specify the following *methods*:

BACKWARD performs backward elimination. This method starts with all effects in the model and deletes effects.

ELASTICNET performs elastic net selection. This method selects effects by fitting a sequence of candidate models with a grid of regularization parameters.

FORWARD performs forward selection. This method starts with no effects in the model and adds effects.

FORWARDSWAP specifies forward-swap selection, which is an extension of the forward selection method.

LAR specifies the least angle regression method. Like forward selection, this method starts with no effects in the model and adds effects. The parameter estimates at any step are "shrunk" when compared to the corresponding least squares estimates. If the model contains classification variables, then these classification variables are split.

LASSO specifies the LASSO method, which adds and deletes parameters on the basis of a version of ordinary least squares in which the sum of the absolute regression coefficients is constrained. If the model contains classification variables, then these classification variables are split.

MCP specifies the MCP method, which uses the minimax concave penalty as the penalty function in penalized least squares estimation.

NONE specifies no model selection.

SCAD specifies the SCAD method, which uses smoothly clipped absolute deviation as the penalty function in penalized least squares estimation.

STEPWISE performs stepwise selection. This method is similar to the forward selection method, except that effects already in the model do not necessarily stay there.

By default, SELECTION=NONE. You can also specify *method-options* to apply to the specified method by enclosing them in parentheses after the *method*. For more information about the available *method-options*, see the section "Supported Model Selection Suboptions" on page 1762.

You can specify *input-options* to customize the model effects for the REGSELECT model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as main model effects for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

CLASS=(*variables***)**
names the classification variables to be used as explanatory variables in the analysis if you also specify them in the EFFECT= option. You can include the response variable, but this is not required.

EFFECT=(*effects***)**
specifies model effects that are constructed from variables in the input data table. For information about constructing the model effects, see the section "Specification and Parameterization of Model Effects" on page 64 in Chapter 2, "Shared Concepts."

For example, you can use the following syntax to specify a base learner model by using the REGSELECT model type with LASSO model selection, where the regularization parameter is chosen on the basis of the partitioned data:

```
baselearner 'lrnr'
   regselect(selection=lasso(choose=validate) partbyfrac(validate=0.2))
   class=(z) effect=(z x1-x3);
```

This is equivalent to the following specification that uses PROC REGSELECT:

```
proc regselect data=mylib.data;
   partition fraction(validate=0.2);
   selection method=lasso(choose=validate);
   class z;
   model y=z x1-x3;
run;
```

SVMACHINE

The SVMACHINE model fits a support vector machine model. For more information, see Chapter 39, "SVMACHINE Procedure" (*SAS Viya: Machine Learning Procedures*).

The *model-options* for the SVMACHINE model cover only a subset of the options in PROC SVMACHINE. You can specify any of the following SVMACHINE-specific *model-options* by enclosing them in parentheses after the SVMACHINE keyword:

C=*number*
specifies the penalty value, where *number* is a real number greater than 0. By default, C=1.0.

DEGREE=*number*
specifies the degree that is used in a polynomial kernel. By default, DEGREE=2.

EPSILON=*number*
specifies the insensitive loss value, where *number* is a nonnegative real number. By default, EPSILON=0.01.

KERNEL=*keyword*
specifies the type of kernel. You can specify the following *keywords*:

LINEAR	uses a linear kernel.
POLYNOMIAL	uses a polynomial kernel.
RBF	uses a radial basis function kernel.
SIGMOID	uses a sigmoid kernel.

By default, KERNEL=LINEAR.

METHOD=*keyword*
specifies the optimization method. You can specify the following *keywords*:

ACTIVESET	uses the active-set method.
CD	uses the coordinate descent method.
IPOINT	uses the interior point method.

By default, METHOD=IPOINT.

RBFPARAMETER=*number*
specifies the K_PAR parameter that is used in an RBF kernel, where *number* is greater than or equal to 0.0001. By default, the *number* is the square root of the number of features.

REGL2=*number*
specifies the L2 penalty value when METHOD=CD, where *number* is a real number greater than 0.

SCALE
scales the input variables to between 0 and 1, inclusive, during training when the response variable is continuous. By default, the input variables are not scaled when the response variable is continuous.

SIGMOIDPARAMETER1=*number*
specifies the K_PAR1 parameter that is used in a sigmoid kernel, where *number* is a positive number. By default, SIGMOIDPARAMETER1=1.

SIGMOIDPARAMETER2=*number*
specifies the K_PAR2 parameter that is used in a sigmoid kernel, where *number* is a real number. By default, SIGMOIDPARAMETER2=–1.

For full descriptions of these *model-options* and the SVMACHINE model, see the PROC SVMACHINE documentation.

You can specify *input-options* to customize the set of predictor variables for the SVMACHINE model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

TREESPLIT

The TREESPLIT model fits a decision tree model. For more information, see Chapter 34, "TREESPLIT Procedure."

The *model-options* for the TREESPLIT model cover only a subset of the options in PROC TREESPLIT. You can specify any of the following TREESPLIT-specific *model-options* by enclosing them in parentheses after the TREESPLIT keyword:

CRITERION=*keyword*
specifies the criterion by which to split a parent node into child nodes. You can specify the following *keywords*:

CHAID uses the chi-square automatic interaction detector (CHAID) criterion.

CHISQUARE uses a chi-square statistic to split each variable, and then uses the p-values that correspond to the resulting splits to determine the splitting variable. This *keyword* is available only for categorical responses.

ENTROPY uses the gain in information to split each variable, and then to determine the split. This *keyword* is available only for categorical responses.

GINI uses the decrease in the Gini index to split each variable and then to determine the split. This *keyword* is available only for categorical responses.

IGR uses the entropy metric to split each variable, and then uses the information gain ratio to determine the split. This *keyword* is available only for categorical responses.

FTEST uses an F statistic to split each variable, and then uses the resulting p-value to determine the split variable. This *keyword* is available only for continuous responses.

RSS uses the change in response variance to split each variable and then to determine the split. This *keyword* is available only for continuous responses.

By default, CRITERION=IGR for categorical responses and CRITERION=RSS for continuous responses.

DEGREE=*number*
specifies the maximum depth of the tree to be grown. For the default, see Chapter 34, "TREESPLIT Procedure."

MINLEAFSIZE=*number*
specifies the minimum number of observations per child node. By default, MINLEAFSIZE=5.

NUMBIN=*number*
specifies the number of bins to use for binning interval predictor variables. By default, NUMBIN=50.

For full descriptions of these *model-options* and the TREESPLIT model, see the PROC TREESPLIT documentation. Note that in contrast with PROC TREESPLIT, no pruning is done when you use the TREESPLIT base learner model.

You can specify *input-options* to customize the set of predictor variables for the TREESPLIT model type. If you omit *input-options* for this base learner model, then the variables that you specify in the INPUT statements are used as predictor variables for this base learner. If you specify at least one *input-option*, then the variables that you specify in the INPUT statements do not apply to this base learner. You can specify the following *input-options*:

INTINPUT=(*variables***)**
specifies the interval input *variables* for the base learner model.

NOMINPUT=(*variables***)**
specifies the nominal input *variables* for the base learner model.

CROSSVALIDATION Statement

CROSSVALIDATION < *options* > **;**

The CROSSVALIDATION statement controls details about the *k*-fold cross-validation process. If you omit this statement, PROC SUPERLEARNER uses an internal algorithm to determine the number of folds. For more information about the internal algorithm, see the section "*K*-Fold Cross-Validation" on page 1761.

You can specify the following *options*:

KFOLD=*n*
specifies the number of partition folds in cross-validation, where *n* is an integer between 2 and the number of observations that are used for training, inclusive. If you omit this option, the value of *n* is determined by the process described in the section "*K*-Fold Cross-Validation" on page 1761.

STRATVAR=*variable*
specifies a categorical *variable* for stratified cross-validation. This option is valid only if the number of observations in each class of the *variable* is larger than the number of folds. For more information about stratified cross-validation, see the section "*K*-Fold Cross-Validation" on page 1761.

INPUT Statement

INPUT *variables* < */option* > **;**

The INPUT statement specifies one or more predictor variables for the super learner model that share a common variable type. If your analysis has predictor variables of different types (for example, interval variables and nominal variables), you must specify multiple INPUT statements, one for each type. If you specify multiple INPUT statements, the union of variables that you specify in all the INPUT statements is used as predictor variables for each base learner model. However, if you specify any *input-options* in a BASELEARNER statement, then that base learner no longer uses variables that you specify in the INPUT statements as predictors.

You can specify the following *option* after a slash (/):

LEVEL=*value*
specifies the variable type. You can specify the following *values*:

INTERVAL specifies that the variables are interval, which must be numeric.

NOMINAL specifies that the variables are nominal, also known as classification variables, which can be numeric or character.

By default, LEVEL=INTERVAL for numeric variables and LEVEL=NOMINAL for categorical character variables.

MARGIN Statement

MARGIN '*name*' *variable*='*value*' < . . . *variable*='*value*' > **;**

The MARGIN statement computes a predictive margin (Lane and Nelder 1982). A predictive margin is obtained by fixing the *value* of one or more input *variables* and averaging the predicted response values over the distribution of predictor variables in an input data table.

The MARGIN statement has the following elements:

name
identifies the predictive margin. The *name* is used to name a variable in an output data table that is created by a OUTPUT statement. It must be a valid variable name.

variable=**'***value***'**
identifies an input *variable* and the *value* that it is set to when the predictive margin is computed. The *variable* can be either continuous or categorical. For a categorical variable, you must specify the *value* in quotes. You must specify a raw (not formatted) value. You can specify multiple input *variables* and the *values* that they are set to when computing the predictive margin.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *options* > **;**

The OUTPUT statement creates a data table that contains observationwise predicted values that PROC SUPERLEARNER computes after fitting the model. To avoid data duplication when you have large data tables, the variables in the input data table are not included in the output data table unless you specify them in the COPYVARS= option.

You must specify the following option:

OUT=*libref.data-table*
names the output data table for PROC SUPERLEARNER to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1728.

data-table specifies the name of the output data table.

You can also specify the following *options*:

COPYVAR=*variable*

COPYVARS=(*variables***)**
transfers one or more *variables* from the input data table to the output data table.

LEARNERPRED
computes predicted response values by using each trained base learner model. The default name of the computed variable in the output data table is the name of the base learner that you specify in the BASELEARNER statement. You can use this option to compare base learner and super learner model predictions.

MARGINPRED
outputs the predicted response values under each intervening scenario that you specify in a MARGIN statement. The default name of the computed variable in the output data table is the name that you specify in the MARGIN statement.

STORE Statement

STORE < **OUT=** >*libref.data-table* **;**

The STORE statement saves the context and results of the statistical analysis. The resulting item store has a binary file format that you cannot modify. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1728.

An example of item store technology is to perform a time-consuming analysis and to store its results by using the STORE statement. Later you can perform specific statistical analysis tasks that are based on the saved results of the previous analysis, without having to fit the model again. You can process the contents of the item store by using the RESTORE= option or the **`slScore`** action in the **`superLearner`** action set. Currently, processing the contents of the item store by using the ASTORE procedure or the **`score`** action in the **`aStore`** action set is not supported.

TARGET Statement

TARGET *variable* < */option* > **;**

The TARGET statement specifies the response variable for the super learner model.

You can specify the following *option* after a slash (/):

LEVEL=*value*
specifies the variable type. You can specify the following *values*:

INTERVAL	specifies that the response variable is interval, which must be numeric.
NOMINAL	specifies that the response variable is nominal, also known as a classification variable, which can be numeric or character.

By default, LEVEL=INTERVAL for numeric variables and LEVEL=NOMINAL for categorical character variables.

Details: SUPERLEARNER Procedure

The super learner model is a cross-validation-based approach that combines predictive algorithms into an ensemble model. Asymptotically, it generates predictions that are at least as good as those of the best-performing algorithm.

Super Learner Algorithm

Given an input data set with a vector of predictors $\mathbf{x}$ and a response variable y, the super learner model consists of two layers of models that are used to describe the relationship between $\mathbf{x}$ and y.

The first layer includes a library of B individual base learner models:

$$f_b\left(\mathbf{x} \mid \boldsymbol{\beta}_b\right) \text{ for } b \in \{1, \ldots, B\}$$

where $\boldsymbol{\beta}_1, \boldsymbol{\beta}_2, \ldots, \boldsymbol{\beta}_B$ are the model parameters for base learners *1* through B.

The second layer contains the meta-learner model m, which is a function of the individual base learners in the first layer:

$$m\left(f_1\left(\mathbf{x} \mid \boldsymbol{\beta}_1\right), f_2\left(\mathbf{x} \mid \boldsymbol{\beta}_2\right), \ldots, f_B\left(\mathbf{x} \mid \boldsymbol{\beta}_B\right) \mid \boldsymbol{\alpha}\right)$$

where $\boldsymbol{\alpha}$ is the vector of meta-learner model parameters, also known as the super learner model coefficients.

Training a super learner amounts to estimating the model parameters in the base learner models and the meta-learner model. You estimate the base learner model parameters $\boldsymbol{\beta}_1, \boldsymbol{\beta}_2, \ldots, \boldsymbol{\beta}_B$ by fitting each base learner to the entire input data set. You estimate the super learner model coefficients $\boldsymbol{\alpha}$ by following these general steps:

1. Randomly split all observations in the input data set into K disjoint blocks.
2. Train each base learner by using only data in blocks *2* through K, excluding block *1*.
3. For each trained base learner, generate predictions for block *1*.
4. Repeat steps 2 and 3 $(K-1)$ times, each time leaving out block $k = 2, 3, \ldots, K$ for predictions. This step is known as k-fold cross-validation.
5. Across all blocks, fit a regression of the observed responses on the out-of-sample predictions from step 3. This is known as the meta-learning step.

For more information about k-fold cross-validation, see the section "*K*-Fold Cross-Validation" on page 1761. For more information about estimating the super learner model coefficients $\boldsymbol{\alpha}$, see the section "Meta-learning Methods" on page 1760.

Meta-learning Methods

Let $K_i \in \{1, \ldots, K\}$ denote the block of input data that contains observation i; let n_k denote the number of observations in block k; and let $\hat{\boldsymbol{\beta}}_b^{\sim k}$ denote the parameter estimates of base learner model b by training it on the input data, excluding block k. Let $\hat{f}_{b,i}^{\sim k} = f_b\left(\mathbf{x}_i \mid \hat{\boldsymbol{\beta}}_b^{\sim k}\right)$ denote the out-of-sample predicted response that is made by base learner b, given the inputs $\mathbf{x}_i$.

The meta-learner model m is defined as a linear combination of the base learner models:

$$m\left(f_1, \ldots, f_B \mid \boldsymbol{\alpha}\right) = \boldsymbol{\alpha}_1 f_1 + \boldsymbol{\alpha}_2 f_2 + \cdots + \boldsymbol{\alpha}_B f_B$$

Continuous Response

For a continuous response, you estimate the super learner coefficients $\boldsymbol{\alpha}$ by minimizing the following cross-validated empirical risk that is based on the squared loss function:

$$\sum_{k=1}^{K} \sum_{i:K_i=k} \left\{ y_i - m\left(\hat{f}_{1,i}^{\sim k}, \ldots, \hat{f}_{B,i}^{\sim k} \mid \boldsymbol{\alpha}\right)\right\}^2$$

Solving this minimization problem is equivalent to fitting a linear regression model (without the intercept) that regresses the observed responses on the base learner out-of-sample predictions. In addition, it is theoretically advantageous to restrict the search for the coefficients $\boldsymbol{\alpha}_1, \ldots, \boldsymbol{\alpha}_B$ to the convex combination (Van der Laan, Polley, and Hubbard 2007); that is, $\boldsymbol{\alpha}_1 + \cdots + \boldsymbol{\alpha}_B = 1$ and $\boldsymbol{\alpha}_b \geq 0$ for all $b \in \{1, \ldots, B\}$. Solving the cross-validated empirical risk minimization with this convex constraint is the default meta-learning method for a continuous response.

Binary Response

For a binary response $y_i \in \{0, 1\}$, now $\hat{f}_{b,i}^{\sim k}$ denotes the out-of-sample predicted probability of $y_i = 1$ that is made by base learner b, given the inputs $\mathbf{x}_i$. Three meta-learning approaches are available for a binary response.

The first approach is to estimate the super learner coefficients $\boldsymbol{\alpha}$ by minimizing the cross-validated empirical risk that is based on the squared loss function.

The second approach is to estimate $\boldsymbol{\alpha}$ by maximizing the following binomial log likelihood:

$$\sum_{k=1}^{K} \sum_{i:K_i=k} \left\{ y_i \log\left(m\left(\hat{f}_{1,i}^{\sim k}, \ldots, \hat{f}_{B,i}^{\sim k} \mid \boldsymbol{\alpha}\right)\right) + (1 - y_i) \log\left(1 - m\left(\hat{f}_{1,i}^{\sim k}, \ldots, \hat{f}_{B,i}^{\sim k} \mid \boldsymbol{\alpha}\right)\right)\right\}$$

As in the continuous response case, the coefficients $\boldsymbol{\alpha}$ are restricted so that $\boldsymbol{\alpha}_1 + \cdots + \boldsymbol{\alpha}_B = 1$ and $\boldsymbol{\alpha}_b \geq 0$ for all $b \in \{1, \ldots, B\}$.

The third approach is to maximize the area under the ROC curve (AUC). This approach is effective when the response variable is highly imbalanced or when classification performance is the primary objective (LeDell, van der Laan, and Petersen 2016). To maximize the AUC in the meta-learning step, you estimate the super learner coefficients $\boldsymbol{\alpha}$ by maximizing the following:

$$\sum_{i:y_i=1} \sum_{j:y_j=0} I\left(m\left(\hat{f}_{1,i}^{\sim K_i}, \ldots, \hat{f}_{B,i}^{\sim K_i} \mid \boldsymbol{\alpha}\right) > m\left(\hat{f}_{1,j}^{\sim K_j}, \ldots, \hat{f}_{B,j}^{\sim K_j} \mid \boldsymbol{\alpha}\right)\right)$$

where $I(\cdot)$ is the indicator function. As in the continuous response case, the search for coefficients $\boldsymbol{\alpha}$ is restricted to the convex combination. The AUC optimization problem is solved by using the black-box solver. For more information about the black-box solver, see the discussion in the section "Black-Box Optimization Solver" in *SAS Optimization: Mathematical Optimization Procedures*. Because the objective function is nonconvex and piecewise constant, the black-box solver converges to a local optimum. The availability of AUC maximization is limited by the SAS software product that you are using. PROC SUPERLEARNER displays an error message and stops the analysis if METHOD=CCAUC is not available with your product license.

Discrete Super Learner

The discrete super learner model (also known as a cross-validated selector) is a variation of the super learner that selects a single base learner model that has the smallest cross-validated risk instead of searching for the optimal combination of all base learners. The base learner that has the smallest cross-validated risk receives a super learner coefficient of *1*, and the remaining base learners receive coefficients of *0*. You can train a discrete super learner by specifying the METHOD=CVSELECTOR option in the PROC SUPERLEARNER statement.

K-Fold Cross-Validation

K-fold cross-validation is a required step for training a super learner model. To strike a balance between computation time and predictive performance, you compute the default number of folds by using the recommendation of Phillips et al. (2023). In their approach, the number of folds is determined on the basis of the effective sample size. If the response is binary and $\bar{p}$ is its prevalence in the entire input data set, the effective sample size is computed as $n_{\text{eff}} = \min(n, 5n_{\text{rare}})$, where $n_{\text{rare}} = n \times \min(\bar{p}, 1 - \bar{p})$ is the number of rare events in the response. For a continuous response, the effective sample size is equal to the number of observations in the input data. The default number of folds K is computed as follows:

$$K = \begin{cases} n_{\text{eff}} & \text{if } n_{\text{eff}} < 30 \\ 20 & \text{if } 30 \le n_{\text{eff}} < 500 \\ 10 & \text{if } 500 \le n_{\text{eff}} < 5{,}000 \\ 5 & \text{if } 5{,}000 \le n_{\text{eff}} < 10{,}000 \\ 2 & \text{if } n_{\text{eff}} \ge 10{,}000 \end{cases}$$

You can also set the number of folds by specifying the KFOLD= option in the CROSSVALIDATION statement.

When the response variable or an important predictor is categorical, it can be beneficial to preserve its prevalence in each partitioned block of the input data, so that each partitioned block contains the same number of cases in each class of the variable. You can achieve this through stratified cross-validation. To do so, you specify the variable in the STRATVAR= option of the CROSSVALIDATION statement.

Cross-Validated Risk

The cross-validated (CV) risk of a base learner model is an estimate of its true out-of-sample predictive performance that is based on its performance in cross-validation. For a continuous response, the CV risk of base learner b is computed on the basis of the squared loss function:

$$\text{CVrisk}_b = \frac{1}{n}\sum_{i=1}^{n}\left(\hat{y}_{i,b} - y_i\right)^2$$

where n is the number of observations in the input data set, $\hat{y}_{i,b}$ is the out-of-sample predicted value of observation i from base learner b, and y_i is the observed response value of observation i.

For a binary response $y_i \in \{0, 1\}$, the CV risk of base learner b can be computed on the basis of the squared loss, the log loss function, or the AUC loss function. For the log loss function, the CV risk is

$$\text{CVrisk}_b = -\frac{1}{n}\sum_{i=1}^{n}\left[y_i \log\left(\hat{p}_{i,b}(y_i = 1)\right) + (1 - y_i)\log\left(\hat{p}_{i,b}(y_i = 0)\right)\right]$$

where n is the number of observations and $\hat{p}_{i,b}(y_i = 1)$ is base learner b's out-of-sample predicted probability that $y_i = 1$. The CV risk can be undefined if $\hat{p}_{i,b}(y_i = 1)$ is exactly 1 or 0.

For the AUC loss function, the CV risk is

$$\text{CVrisk}_b = 1 - \frac{1}{n_1 n_0}\sum_{i:y_i=1}\sum_{j:y_j=0} I(\hat{p}_{i,b}(y_i = 1) > \hat{p}_{j,b}(y_j = 1))$$

where n_1 and n_0 denote the number of observations for $y = 1$ and $y = 0$, respectively, and $I(\cdot)$ denotes the indicator function.

Supported Base Learner Model Types

The available base learner model types are limited by the SAS software product that you are using. If you attempt to use a base learner model type that is not available with your product license, PROC SUPERLEARNER displays an error message and stops the analysis.

Supported Model Selection Suboptions

This section provides more details about the model selection methods and suboptions that are available for the LOGSELECT and REGSELECT base learner model types. For these base learner model types, you can use the SELECTION= option in the BASELEARNER statement to specify a model selection method.

The SELECTION= option in the BASELEARNER statement is similar to the METHOD= option in the SELECTION statement of the LOGSELECT and REGSELECT procedures. When you use these procedures, you can choose to specify suboptions for each model selection method to further customize the model selection process. PROC SUPERLEARNER supports a subset of the suboptions in these procedures. Table 33.2 lists the applicable suboptions for each selection method.

Table 33.2 Applicable Suboptions by Selection Method

Suboption	BACKWARD	ELASTICNET	FORWARD	LAR	LASSO	MCP/SCAD	STEPWISE
ADAPTIVE		x			x		
ALPHA=						x	
BIGM=						x	
CHOOSE=	x	x	x	x	x	x	x
COMPETITIVE							x
CRITERION=	x		x				x
ENSCALE		x					
FAST	x						
L2=		x					
LAMBDA=		x				x	
LSCOEFFS				x	x		
MAXEFFECTS=		x	x	x	x		x
MINEFFECTS=	x						
MIXING=		x					
NLAMBDA=		x					
RELAXED					x		
SELECT=	x		x				x
SLENTRY=		x	x	x	x		x
SLSTAY=	x	x			x		x
SOLVER=		x				x	
STOP=	x	x	x	x	x		x

The following list includes a short description of each supported suboption:

ADAPTIVE
applies adaptive weights to each of the coefficients when SELECTION=LASSO or ELASTICNET.

ALPHA=*value*
specifies the regularization parameter α to use when you specify SELECTION=MCP or SCAD.

BIGM=*value*
specifies the constant $\mathcal{M}$ when you specify SOLVER=MILP.

CHOOSE=*criterion*
chooses from the list of models (at each step of the selection process) the model that yields the best value of the specified criterion. For the supported criteria, see the chapters for the relevant procedures.

COMPETITIVE
If you specify this option, then the SELECT= criterion is evaluated for all models in which an effect currently in the model is removed or an effect not yet in the model is added. The effect whose removal from or addition to the model yields the maximum improvement to the SELECT= criterion is removed or added.

CRITERION=*criterion*
is an alias for the SELECT= option.

ENSCALE
scales the results of the elastic net method to offset bias from the double shrinkage inherent in this method (Zou and Hastie 2005).

FAST
implements the computational algorithm of Lawless and Singhal (1978) to compute a first-order approximation to the remaining slope estimates for each subsequent elimination of a variable from the model.

L2=*value*
specifies the ridge regularization parameter to use when you specify SELECTION=ELASTICNET.

LAMBDA=*value*
specifies the regularization parameter λ to use when you specify SELECTION=ELASTICNET, MCP, or SCAD.

LSCOEFFS
requests a hybrid version of the LAR and LASSO methods, in which the sequence of models is determined by the LAR or LASSO algorithm but the coefficients of the parameters for the model at any step are determined by using ordinary least squares.

MAXEFFECTS=*n*
specifies the maximum number of effects in any model that is considered during the selection process.

MINEFFECTS=*n*
specifies the minimum number of effects in any model that is considered during backward selection.

MIXING=*value*
specifies the mixing parameter that controls the balance between the L_1 penalty and the L_2 penalty in elastic net selection. The *value* must be between 0 and 1, inclusive. If you specify 0, elastic net selection fits ridge regression models. If you specify 1, elastic net selection fits LASSO regression models. By default, MIXING=0.5.

NLAMBDA=*n*
specifies the number of regularization parameters to use in fitting candidate models. By default, NLAMBDA=1.

RELAXED
specifies relaxed LASSO selection, in which each candidate is determined by the LASSO algorithm but the coefficients of the parameters for each candidate at any step are determined by using a linear combination of LASSO coefficients and least squares estimates.

SELECT=*criterion*
specifies the criterion that the procedure uses to determine the order in which effects enter or leave at each step of the selection method. For supported criteria, see the chapter for the relevant procedure.

SLENTRY=*value*
specifies the significance level for entry when STOP=SL or SELECT=SL. By default, SLENTRY=0.05.

SLSTAY=*value*
specifies the significance level for staying in the model when STOP=SL or SELECT=SL. By default, SLSTAY=0.05.

SOLVER=*solver-value*
specifies the optimization solver when you specify SELECTION=ELASTICNET, MCP, or SCAD. You can specify the following *solver-values*:

ADMM	specifies the alternating direction methods of multipliers (ADMM) as the solver.
BFGS	specifies the Broyden-Fletcher-Goldfarb-Shanno (BFGS) method as the solver.
LBFGS	specifies the limited-memory BFGS method as the solver.
MILP	specifies the mixed integer linear programming (MILP) solver.
NLP	specifies the nonlinear programming (NLP) solver.

For the MCP and SCAD selection methods, by default SOLVER=MILP.

STOP=SL | NONE | *criterion*
specifies a criterion that is used to stop the selection process. The criteria that are supported depend on the type of model that you are fitting. For information about the supported criteria, see the chapter for the relevant procedure.

You can specify the following values:

NONE	stops the selection process if no suitable candidates for addition or removal are found or if a size-based limit is reached.
SL	stops the selection process at the step where the significance level of the candidate for entry is greater than the SLENTRY= option value for addition steps and where the significance level of the candidate for removal is greater than the SLSTAY= option value.
criterion	stops the selection process if the selection process produces a local extremum of this *criterion* or if a size-based limit is reached.

For more information about the supported model selection methods, see the section "Model Selection Methods" on page 75 and the LOGSELECT and REGSELECT procedure documentation. For more information about the supported suboptions, see the section "SELECTION Statement" on page 42.

For example, the following code specifies a linear regression model with adaptive LASSO model selection:

```
baselearner 'adaptivelasso' regselect(selection=lasso(adaptive));
```

Missing Values

When you are training a super learner model, any observation that has missing values for an input variable, the response variable, or a variable that is used for stratified cross-validation is excluded from the analysis. For the purpose of deciding which observations are used, the input variables are the union of the set of variables that you specify in each INPUT statement and the set of variables that you specify in each *input-option* of a BASELEARNER statement. If you use the APPLYROWORDER option, any observation that has missing values for a partition or orderBy variable is not used for training. When you are scoring or computing predictive margins, any observation that has missing values for an input variable that is used for training is excluded from the analysis.

Displayed Output

The following sections describe the output that PROC SUPERLEARNER produces. The output is organized into various tables, which are discussed in order of their appearance.

Model Information

The "Model Information" table displays basic information about the super learner model, such as the input data, response variable, type of response variables, number of folds, number of base learner models, and meta-learning method.

Number of Observations

The "Number of Observations" table displays the number of observations that are read from the input data table and the number of observations that are used in the analysis. If you specify a BASELEARNER statement, the table displays the number of observations that are used for training. If you specify a MARGIN statement, the table displays the number of observations that are used for computing predictive margins. If you specify an OUTPUT statement, the table displays the number of observations that are used for scoring.

Super Learner Coefficients

The "Super Learner Coefficients" table displays the name, model type, super learner coefficient estimate, and cross-validated risk of each base learner model. Each row of the table corresponds to a base learner that you define in a BASELEARNER statement.

Scoring Information

The "Scoring Information" table displays the name of the data table that is used for scoring, the name of the item store, and the response variable.

Margins

The "Margins" table displays predictive margin estimates. Each row of the table corresponds to a predictive margin that you define in a MARGIN statement.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table.

ODS Table Names

Each table that PROC SUPERLEARNER creates has a name that is associated with it. You must use this name to refer to the table when you use ODS statements. Table 33.3 lists the name of each table and a short description of its contents.

Table 33.3 ODS Tables Produced by PROC SUPERLEARNER

Table Name	Description	Statements	Option
Margins	Predictive margins	MARGIN	
ModelInfo	Information about the modeling environment	Default output	
NObs	Number of observations read and used	Default output	
OutputCasTables	See the section "OutputCasTables Table" on page 1767	OUTPUT STORE	OUT=
ScoreInfo	Information about the stored model used for scoring	PROC SUPERLEARNER	RESTORE=
SLCoefficients	Information about the super learner coefficients	Default output	

Examples: SUPERLEARNER Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

Example 33.1: Storing and Scoring

(View the complete code for this example (superlearnerex1.sas) in the example repository.)

When you use the SUPERLEARNER procedure to train a predictive model, you can save the model by using the STORE statement. You can then use the saved model to score new observations or compute predictive margins by fixing the values of one or more predictor variables. To do so, you use the RESTORE= option in the PROC SUPERLEARNER statement for subsequent scoring.

The following statements generate the data table inputData, which consists of 5,000 observations on a continuous response variable (y), five continuous predictor variables (x1–x5), and two binary predictor variables (z1,z2), in your CAS session:

```
data mylib.dataForTrain / single=yes;
   drop i;
   array x{5};
   array z{2};
   call streaminit(6520);
   pi=constant("pi");

   do i=1 to 5000;
     x1=rand("Normal");
     x2=rand("Uniform");
     z1=rand("Bernoulli",0.7);
     x3=rand("Normal",x1*z1,0.6*z1);
     z2=rand("Bernoulli",logistic(z1*x3));
     x4=rand("Normal",0,0.8*z2);
     if (x4 - z1) > 0 then x5 = x4 - z1;
     else x5 = (x4 - z1)**2;

     y=2+x1+x1*z1+sin(pi/2*x2)+x3**2+z2+x4**3+x5+rand("Normal");
   output;

   end;
run;
```

Note that the response variable y is generated on the basis of x1–x5, z1, and z2.

The following program trains a super learner ensemble model on the simulated data:

```
proc superlearner data=mylib.dataForTrain seed=2324;
   target y / level=interval;
   input z1 z2 / level=nominal;
   input x1-x5 / level=interval;
   baselearner 'lm' regselect;
```

```
    baselearner 'lasso_2way' regselect(selection=elasticnet(lambda=5 mixing=1))
      class=(z1 z2) effect=(z1|z2|x1|x2|x3|x4|x5 @2);
    baselearner 'gam' gammod class=(z1 z2) param(z1 z2 x1 x2)
      spline(x3) spline(x4) spline(x5);
    baselearner 'bart' bart(nTree=10 nMC=100);
    baselearner 'forest' forest;
    baselearner 'svm' svmachine;
    baselearner 'factmac' factmac(nfactors=4 learnstep=0.15);
    store out=mylib.slmodel;
run;
```

When you use PROC SUPERLEARNER for training, you must specify the TARGET statement, one or more INPUT statements, and two or more BASELEARNER statements.

You use the TARGET statement to specify y as the response variable. You indicate that it should be treated as a continuous variable by using the LEVEL= option. You specify two INPUT statements: the first one contains two variables, which are treated as categorical predictor variables; the second one contains five variables, which are labeled as continuous predictor variables.

When you use the BASELEARNER statement to specify a base learner model, you must first provide a name for the base learner in single quotes and then a model type. This statement supports various model types and options that you can choose for building a base learner. For more information, see the BASELEARNER statement.

In this example, you specify seven base learners by using seven BASELEARNER statements. For the first base learner, 'lm', you use the REGSELECT model type to specify a linear regression model.

You specify the second base learner, 'lasso_2way', again by using the REGSELECT model type. For this base learner, you use the SELECTION= option to specify the elastic net model selection method. You use the LAMDBA= and MIXING= suboptions to specify the lambda and mixing parameters, respectively. You use the EFFECT= option to specify that all the main effects and two-way interactions among the seven predictor variables are to be used as constructed effects for this base learner. When you specify the EFFECT= option, nominal predictor variables that you specify in the INPUT statement are no longer automatically considered as classification variables for this base learner. You include z1 and z2 in the CLASS= option so that the procedure treats them as classification variables for this base learner.

For the third base learner, you use the GAMMOD model type to specify a generalized additive model. You use the CLASS=, PARAM, and SPLINE input options to specify the model effects of the base learner. You require that z1 and z2 be treated as classification variables by including them in the CLASS= option. You include the main effects of z1, z2, x1, and x2 in the base learner by specifying the PARAM option. You include univariate spline effects of x3, x4, and x5 in the base learner by using the SPLINE option.

The remaining four base learners are defined by using the BART, FOREST, SVMACHINE, and FACTMAC model types, which correspond to specifying a Bayesian additive regression tree model, a forest model, a support vector machine model, and a factorization machine model, respectively. For the base learner 'bart', you customize the number of trees and the number of MCMC iterations by using the NTREE= and NMC= options, respectively. For the base learner 'factmac', you customize the number of factors and learning steps by using the NFACTORS= and LEARNSTEP= options, respectively.

You use the STORE statement to save the trained super learner ensemble model as an item store. You can use the saved item store to score new observations without having to retrain the model again. This is illustrated later in this example.

Output 33.1.1 displays basic information about the super learner ensemble specification, and Output 33.1.2 displays the estimated coefficient for each base learner.

Output 33.1.1 Model Information and Number of Observations

The SUPERLEARNER Procedure

Model Information	
Data Source	DATAFORTRAIN
Target Variable	y
Target Variable Type	INTERVAL
Number of Folds	5
Number of Base Learners	7
Loss Function	Quadratic Loss
Meta-learning Method	Convex-constrained Least Squares
Random Number Seed	2324

Number of Observations Read	5000
Number of Observations Used	5000

Output 33.1.2 Super Learner Coefficients

Super Learner Model Coefficients

Name	Model Type	Coefficient	Cross-Validated Risk
lm	Ordinary Linear Least Squares	0	4.35073
lasso_2way	Ordinary Linear Least Squares	0.21575	1.40477
gam	Generalized Additive Model	0.71463	1.15176
bart	Bayesian Additive Regression Trees	0.06962	1.69381
forest	Forest	0	1.78765
svm	Support Vector Machine	0	4.52188
factmac	Factorization Machine	0	2.60129

By default, based on the input data sample size, the input data are divided into five folds for cross-validation. Because the target variable is continuous, by default the convex-constrained least squares meta-learning method is used to estimate the weight of each base learner in the super learner ensemble, and the quadratic loss is used to compute the cross-validated risk of each base learner.

The following DATA step code uses the same data-generating process to create new observations to be used for scoring:

```
data mylib.dataForScore / single=yes;
   drop i;
   array x{5};
   array z{2};
   call streaminit(2456);
   pi=constant("pi");

   do i=1 to 1000;
     x1=rand("Normal");
```

```
      x2=rand("Uniform");
      z1=rand("Bernoulli",0.7);
      x3=rand("Normal",x1*z1,0.6*z1);
      z2=rand("Bernoulli",logistic(z1*x3));
      x4=rand("Normal",0,0.8*z2);
      if (x4 - z1) > 0 then x5 = x4 - z1;
      else x5 = (x4 - z1)**2;

      y=2+x1+x1*z1+sin(pi/2*x2)+x3**2+z2+x4**3+x5+rand("Normal");
   output;

   end;
run;
```

The following statements show how to use PROC SUPERLEARNER to score the new data by using the previously fitted model:

```
proc superlearner data=mylib.dataForScore restore=mylib.slmodel;
   output out=mylib.scoredData1 learnerpred;
run;
```

You specify the fitted model in the RESTORE= option. You use the DATA= option to specify the data table of observations to score, and you use the OUTPUT statement to designate the output data table to contain the predicted responses. The LEARNERPRED option includes the predicted values from each base learner in the output data table, in addition to the predicted responses from the super learner ensemble. The RESTORE= option and OUTPUT statement are both required when you use PROC SUPERLEARNER to score data by using a previously saved model.

The following statements print the first 10 observations of the scored data table. The results are shown in Output 33.1.3.

```
proc print data=mylib.scoredData1(obs=10);
run;
```

Output 33.1.3 First 10 Observations in the Output Data Table

Obs	P_y	lm	lasso_2way	gam	bart	forest	svm	factmac
1	6.65683	6.54213	6.50964	6.71963	6.46835	6.50313	6.86751	4.30350
2	1.98392	1.85226	2.49392	1.79935	2.29800	2.18953	1.91218	2.03633

4	4.42276	5.64113	4.70199	4.32795	4.53066	4.32606	5.15384	4.35422
5	2.23673	2.88074	2.44980	2.22783	1.66777	2.56502	2.54407	3.13678
6	5.53240	7.17779	6.03486	5.29490	6.41315	5.92846	6.63275	6.20529
7	2.86278	3.19713	3.02958	2.86950	2.27690	2.76490	2.82833	3.28876
8	8.03762	7.80369	8.38578	7.90433	8.32684	8.12643	7.62153	7.72098
9	3.34112	4.96500	3.41055	3.36905	2.83928	3.39109	4.51414	5.07560
10	4.26333	3.58532	3.94204	4.35639	4.30383	4.30255	3.20928	3.13718

The P_y column contains super learner predictions, and the other columns contain predictions from each individual base learner.

You can also use the saved model to compute predictive margins. To compute a predictive margin, you use the MARGIN statement to specify a fixed value for one or more variables. Then the procedure scores each

observation in an input data table that you specify in the DATA= option, but the values of the variable(s) that you specify in the MARGIN statement are replaced by the specified value(s). By default, PROC SUPERLEARNER prints the means of the predicted responses. You can also directly access the predicted response values for each set of interventions by specifying the MARGINPRED option in the OUTPUT statement to include them in the output data table.

The following code shows how to compute predictive margins and the predicted response values under interventions by using PROC SUPERLEARNER and the trained model that you saved earlier in this example:

```
proc superlearner data=mylib.dataForScore restore=mylib.slmodel;
   margin "Scenario1" z1=0 x1=0.25;
   margin "Scenario2" x1=0.25;
   margin "Scenario3" x1=0.5;
   margin "Scenario4" x1=0.75;
   output out=mylib.scoredData2 marginpred;
run;
```

You specify the saved model mylib.slmodel in the RESTORE= option, and you specify the data table that contains new observations to be scored in the DATA= option. Four predictive margins are specified using the MARGIN statement. The first scenario fixes the values of z1 and x1 to 0 and 0.25, respectively. The remaining three predictive margins fix the value of x1 to 0.25, 0.5, and 0.75, respectively.

The "Scoring Information" table in Output 33.1.4 displays the names of the saved model, the data table that is used for training, the data table of scored observations, and the target variable. The "Number of Observations" table displays the number of observations that are used to score and compute the predictive margins.

Output 33.1.4 Scoring Information and Number of Observations

The SUPERLEARNER Procedure

Scoring Information

Scenario4	6.00051

The following statements print the first 10 observations of the scored data table that contain predicted responses without intervention and predicted responses under each intervening scenario. The results are shown in Output 33.1.6.

```
proc print data=mylib.scoredData2(obs=10);
run;
```

Output 33.1.6 First 10 Observations in the Output Data Table

Obs	P_y	Scenario1	Scenario2	Scenario3	Scenario4
1	6.65683	5.55252	7.11563	7.41870	7.75641
2	1.98392	3.85930	3.85930	4.15335	4.48204
3	2.61899	3.56465	3.89671	4.24107	4.62008
4	4.42276	4.22765	4.57249	4.93537	5.33288
5	2.23673	3.57691	3.92740	4.25761	4.62246
6	5.53240	4.30642	4.33119	4.69125	5.08595
7	2.86278	4.11930	4.46090	4.77948	5.13271
8	8.03762	6.60072	7.11505	7.51966	7.94006
9	3.34112	4.40659	4.38477	4.71462	5.07911
10	4.26333	4.92668	5.26729	5.56103	5.88941

The P_y column again contains super learner predictions, and the other columns contain predictions from each intervening scenario.

Example 33.2: Causal Effect Estimation

(View the complete code for this example (superlearnerex2.sas) in the example repository.)

This example illustrates how you can use the SUPERLEARNER procedure for causal effect estimation.

This example uses the SmokingWeight data set available in the examples for the CAUSALTRT procedure in *SAS/STAT User's Guide*. These data are a subset of data from the NHANES I Epidemiologic Follow-Up Study (NHEFS) in Hernán and Robins (2020). For the study, medical and behavioral information was collected during an initial physical examination and again at follow-up interviews about 10 years later. As in the PROC CAUSALTRT examples, the question of interest here is what effect does quitting smoking, as recorded in the variable Quit, have on an individual's change in weight (measured in kilograms), as recorded in the variable Change.

To create the data table SmokingWeight in your CAS session, you can modify the DATA step that is used to create the data set in PROC CAUSALTRT to create the data table in your CAS engine library . For this example, it is assumed that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

In addition to the treatment variable Quit and outcome variable Change, the data include the following variables:

- Activity: level of daily activity, with values 0, 1, and 2
- Age: age in 1971

- BaseWeight: weight in kilograms in 1971
- Education: level of education, with values 0, 1, 2, 3, and 4
- Exercise: amount of regular recreational exercise, with values 0, 1, and 2
- PerDay: number of cigarettes smoked per day in 1971
- Race: 0 for white; 1 otherwise
- Sex: 0 for male; 1 for female
- Weight: weight in kilograms at the follow-up interview
- YearsSmoke: number of years an individual has smoked

For this example, it is assumed that the variables Activity, Age, BaseWeight, Education, Exercise, PerDay, Race, Sex, and YearsSmoke make up a valid adjustment set that you can use to obtain unbiased estimates of the potential outcome means.

Targeted maximum likelihood estimation (TMLE) is a doubly robust method that combines modeling of both the treatment and outcome variable to estimate the potential outcome means and causal effects. This example uses the super learner to model the treatment and outcome variables, because it has been proven effective when combined with TMLE for causal effect estimation.

The following statements use PROC SUPERLEARNER to fit a super learner model for the treatment variable Quit and create an output data table that contains the predictions from the fitted model:

```
proc superlearner data=mylib.SmokingWeight seed=2324;
   target Quit / level=nominal;
   input Sex Race Education Exercise Activity / level=nominal;
   input Age YearsSmoke PerDay / level=interval;
   baselearner 'logistic' logselect;
   baselearner 'logistic_2way' logselect
      class=(Sex Race Education Exercise Activity)
      effect=(Age|YearsSmoke|PerDay|Sex|Race|Education|Exercise|Activity @ 2);
   baselearner 'logistic_ridge' logselect(selection=ELASTICNET(lambda=5 mixing=0))
      class=(Sex Race Education Exercise Activity)
      effect=(Age|YearsSmoke|PerDay|Sex|Race|Education|Exercise|Activity @ 2);
   baselearner 'gam' gammod;
   baselearner 'bart' bart(nTree=10 nMC=100);
   output out=mylib.swTrtEstData copyvars=(_ALL_);
run;
```

When you use PROC SUPERLEARNER, you must specify the TARGET statement, at least one INPUT statement, and at least two BASELEARNER statements. You specify the input data table to use for training the super learner model in the DATA= option. The TARGET statement specifies information about the target variable. Each INPUT statement specifies predictor variables of the same type. Each BASELEARNER statement specifies a base learner model to be included in the super learner model.

In the TARGET statement, you use the LEVEL= option to indicate that you want to treat the treatment variable Quit as a categorical variable. You specify the categorical predictor variables in one INPUT statement and the continuous predictor variables in another.

In this example, five base learners are specified. For the first base learner, 'logistic', you specify a logistic regression model by using the LOGSELECT model type. The second base learner, 'logistic_2way', also specifies a logistic regression model but includes different model effects. You use the CLASS= option to specify the classification variables for this base learner. You use the EFFECT= option to construct main and two-way interaction effects that are based on the eight input variables and to include them in this base learner. The third base learner, 'logistic_ridge', adds a ridge penalty to the second base learner specification. You do this by using the SELECTION= option to apply the elastic net model selection method to this base learner. You set the lambda parameter to 5 by using the LAMDBA= option, and you set the mixing parameter to 0 by using the MIXING= option. For the fourth base learner, 'gam', you use the GAMMOD model type to specify a nonparametric logistic regression. You specify a Bayesian additive regression trees model by using the BART model type. You set the number of trees to 10 and the number of MCMC iterations to 100 by using the NTREES= and NMC= options, respectively.

In the OUTPUT statement, you use the COPYVARS= option to copy all variables from the input data table to the output data table.

The "Model Information" table in Output 33.2.1 summarizes important information, including the input data source, response (target) variable and its type, number of folds that are used in cross-validation, number of base learners, loss function, meta-learning method, and random number seed.

Output 33.2.1 Model Information

The SUPERLEARNER Procedure

Model Information	
Data Source	SMOKINGWEIGHT
Target Variable	Quit
Target Variable Type	NOMINAL
Number of Folds	10
Number of Base Learners	5
Loss Function	Log Loss
Meta-learning Method	Convex-constrained Binomial Likelihood Maximization
Random Number Seed	2324

By default, based on the sample size used for training, the input data are divided into 10 folds for cross-validation. Because the response variable is categorical, the CCLOGLIK meta-learning method is used by default to compute the super learner coefficients, and the log loss function is used to compute the cross-validated risks of base learners.

Output 33.2.2 displays the "Number of Observations" table. In this analysis, a number of observations are not used for training, because there are missing values in the predictor variables and the response variable. A number of observations are not used for scoring, because there are missing predicted treatment assignment probabilities from the base learners. These probabilities are missing because there are missing values in the predictor variables.

Output 33.2.2 Number of Observations

Number of Observations Read	1746
Number of Observations Used for Training	1629
Number of Observations Used for Scoring	1629

Output 33.2.3 displays the super learner coefficient estimates and the cross-validated risks of the base learners. The base learner 'logistic' has the smallest cross-validated risk and the largest coefficient in the ensemble.

Output 33.2.3 Super Learner Coefficients

Super Learner Model Coefficients

Name	Model Type	Coefficient	Cross-Validated Risk
logistic	Logistic Regression	0.54565	0.55602
logistic_2way	Logistic Regression	0.01448	0.59092
logistic_ridge	Logistic Regression	0.05880	0.56960
gam	Generalized Additive Model	0	0.56010
bart	Bayesian Additive Regression Trees	0.38106	0.55771

By default, PROC SUPERLEARNER models the probability that the variable Quit takes the value 0. The name of the variable in the output data table that contains the predicted probability is P_Quit0. The following DATA step creates the variable P_Quit1, which contains the predicted probability of being assigned to the treatment condition, Quit=1:

```
data mylib.swTrtEstData;
  set mylib.swTrtEstData;
  P_Quit1 = 1 - P_Quit0;
run;
```

The following statements use PROC SUPERLEARNER to fit a super learner model for the outcome variable Change and create an output data table that contains the predictions from the fitted model:

```
proc superlearner data=mylib.swTrtEstData seed=2324;
   baselearner 'linear' regselect;
   baselearner 'linear_2way' regselect
      class=(Sex Race Education Exercise Activity Quit)
      effect=(Age|YearsSmoke|PerDay|Sex|Race|Education|Exercise|Activity|Quit @ 2);
   baselearner 'linear_ridge' regselect(selection=ELASTICNET(lambda=5 mixing=0))
      class=(Sex Race Education Exercise Activity Quit)
      effect=(Age|YearsSmoke|PerDay|Sex|Race|Education|Exercise|Activity|Quit @ 2);
   baselearner 'gam' gammod;
   baselearner 'bart' bart(nTree=10 nMC=100);
   margin 'quitsmoking' Quit=1;
   margin 'noquitsmoking' Quit=0;
   target Change / level=interval;
   input Sex Race Education Exercise Activity Quit / level=nominal;
   input Age YearsSmoke PerDay / level=interval;
   output out=mylib.swDREstData marginpred copyvars=(Quit Change P_Quit1 P_Quit0);
run;
```

The syntax is almost identical to the syntax that is used to model the treatment probability. The first three base learners are specified using the REGSELECT model instead of the LOGSELECT model for modeling a continuous response variable. Also, the treatment variable Quit is added as a predictor variable. You use two MARGIN statements to intervene and set the Quit variable to two different values. You use the MARGINPRED option in the OUTPUT statement to include predictions that are based on the intervened values of the Quit variable in the output data table.

The "Model Information" table in Output 33.2.4 again summarizes important information about the fitted outcome mean model.

Output 33.2.4 Model Information

The SUPERLEARNER Procedure

Model Information	
Data Source	SWTRTESTDATA
Target Variable	Change
Target Variable Type	INTERVAL
Number of Folds	10
Number of Base Learners	5
Loss Function	Quadratic Loss
Meta-learning Method	Convex-constrained Least Squares
Random Number Seed	2324

By default, based on the sample size used for training, the input data are divided into 10 folds for cross-validation. Because the response variable is continuous, CCLS is used as the default meta-learning method to compute the super learner coefficients.

Output 33.2.5 displays the "Number of Observations" table. In this analysis, a number of observations are not used for training, because there are missing values in the predictor variables and the response variable. A number of observations are not used for scoring and computing the predictive margins, because there are missing predicted responses from the base learners. These predicted responses are missing because there are missing values in the predictor variables.

Output 33.2.5 Number of Observations

Number of Observations Read	1746
Number of Observations Used for Training	1566
Number of Observations Used for Computing Predictive Margins	1629
Number of Observations Used for Scoring	1629

Output 33.2.6 displays the super learner coefficient estimates and the cross-validated risks of the base learners. The base learner 'gam' has the smallest cross-validated risk and the largest coefficient in the ensemble.

Output 33.2.6 Super Learner Coefficients

Super Learner Model Coefficients			
Name	**Model Type**	**Coefficient**	**Cross-Validated Risk**
linear	Ordinary Linear Least Squares	0	57.31210
linear_2way	Ordinary Linear Least Squares	0.18160	59.30354
linear_ridge	Ordinary Linear Least Squares	0.15837	57.85823
gam	Generalized Additive Model	0.40464	56.70110
bart	Bayesian Additive Regression Trees	0.25539	56.93869

The following statements use the CAEFFECT procedure to estimate potential outcome means and their difference by using the doubly robust TMLE method:

```
proc caeffect data=mylib.swDREstData inference method=TMLE;
   treatvar Quit;
   outcomevar Change;
   pom treatLev=1 treatProb=P_Quit1 predout=quitsmoking;
   pom treatLev=0 treatProb=P_Quit0 predout=noquitsmoking;
   difference evtLev=1;
run;
```

For this example, you use the TREATVAR and OUTCOMEVAR statements to specify the treatment and outcome variables, respectively. You use two POM statements to specify the potential outcomes of interest under the two treatment levels. In each POM statement, you supply the variables in the input data table that contains the predicted treatment assignment probabilities and outcome means that the TMLE analysis requires. You do this by specifying the TREATPROB= and PREDOUT= options, respectively. The variable names of the predicted outcome means correspond to the names that you specify in the MARGIN statements earlier. You use the DIFFERENCE statement to request a difference between the potential outcome mean estimates.

Output 33.2.7 displays the potential outcome mean estimates and their difference. The "POM Estimates" table indicates the level of treatment that defines the potential outcome and the estimate of its mean.

Output 33.2.7 Potential Outcome Mean and Difference Estimates

The CAEFFECT Procedure

POM Estimates

Treatment Level	Estimate	Standard Error	95% Confidence Limits		Z	Pr > |Z|
1	5.06841	0.43041	4.22482	5.91201	11.78	<.0001
0	1.81793	0.21516	1.39622	2.23964	8.45	<.0001

POM Differences

Treatment Levels							
Event	Reference	Difference	Standard Error	95% Confidence Limits		Z	Pr > |Z|
1	0	3.2505	0.47196	2.32545	4.17552	6.89	<.0001

The "POM Differences" table shows the requested difference in potential outcome mean estimates. With the proper causal assumptions, the difference in potential outcome mean estimates corresponds to an estimate of the average treatment effect (ATE) of a weight change that is approximately 3.2 kilograms greater because the subjects quit smoking.

Overview: TREESPLIT Procedure

The TREESPLIT procedure builds tree-based statistical models for classification and regression in SAS Viya. The procedure produces a classification tree, which models a categorical response, or a regression tree, which models a continuous response. Both types of trees are called decision trees, because the model is expressed as a series of if-then statements. For each type of tree, you specify a response variable (also called a target variable), whose values you want PROC TREESPLIT to predict, and one or more input variables (called predictor variables), whose values the procedure uses to predict the values of the target variable.

The predictor variables for tree models can be categorical or continuous. The set of all possible combinations of the predictor variables is called the predictor space. The model is based on partitioning the predictor space into nonoverlapping segments, which correspond to the terminal nodes (called leaves) of the tree. Partitioning is done repeatedly, starting with the root node, which contains all the data, and continuing until a stopping criterion is met. At each step, the parent node is split into child nodes by selecting a predictor variable and a split value for that variable that minimize the variability, according to a specified measure (or the default measure), in the response variable across the child nodes. Various measures, such as the Gini index, entropy, and residual sum of squares, can be used to assess candidate splits for each node. The selected predictor variable and its split value are called the splitting rule.

Tree models are built from training data for which the response values are known, and these models are subsequently used to score (classify or predict) response values for new data. For classification trees, the most frequent response level of the training observations in a leaf is used to classify observations in that leaf. For regression trees, the average response of the training observations in a leaf is used to predict the response for observations in that leaf. The splitting rules that define the leaves provide the information that is needed to score new data; these rules consist of the splitting rules and default rules for each node.

The process of building a decision tree begins with growing a large, full tree. The full tree can overfit the training data, resulting in a model that does not adequately generalize to new data. To prevent overfitting, the full tree is often pruned back to a smaller subtree that balances the goals of fitting training data and predicting new data. Two commonly applied approaches for finding the best subtree are cost-complexity pruning (Breiman et al. 1984) and C4.5 pruning (Quinlan 1993). For more information, see the section "Building a Decision Tree" on page 1826.

Compared with other regression and classification methods, tree models have the advantage that they are easy to interpret and visualize, especially when the tree is small. Tree-based methods scale well to large data, and they offer various methods of handling missing values.

However, tree models have limitations. Regression tree models fit response surfaces that are constant over rectangular regions of the predictor space, so they often lack the flexibility needed to capture smooth relationships between the predictor variables and the response. Another limitation of tree models is that small

changes in the data can lead to very different splits, and this undermines the interpretability of the model (Hastie, Tibshirani, and Friedman 2009; Kuhn and Johnson 2013).

PROC TREESPLIT Features

The main features of the TREESPLIT procedure are as follows:

- provides a computationally efficient strategy for generating candidate splits
- provides the cost-complexity, C4.5, and reduced-error methods of pruning trees
- supports the use of validation data for selecting the best subtree during pruning
- supports the use of *k*-fold cross validation for cost-complexity pruning when validation data are not present
- provides various methods of handling missing values
- creates tree diagrams and plots for pruning analysis
- computes statistics for assessing model fit
- computes measures of variable importance
- produces a file that contains SAS DATA step code for scoring new data
- provides an output data table that contains leaf assignments and predicted values for observations

The TREESPLIT procedure uses ODS Graphics to create plots as part of its output. For information about the statistical graphics available with the TREESPLIT procedure, see the PLOTS options in the PROC TREESPLIT statement and the section "ODS Graphics" on page 1854.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: TREESPLIT Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/treesplgs1.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

This example explains basic features of the TREESPLIT procedure for building a classification tree. The data contain measurements of 13 chemical attributes for 178 samples of wine. Each wine is derived from one of three cultivars that are grown in the same area of Italy, and the goal of the analysis is a model that classifies samples into cultivar groups. The data are available from the UCI Irvine Machine Learning Repository (Lichman 2013). [1]

The following statements create a data set named Wine that contains the measurements:

```
data Wine;
   %let url = http://archive.ics.uci.edu/ml/machine-learning-databases;
   infile "&url/wine/wine.data" url delimiter=',';
   input Cultivar Alcohol Malic Ash Alkan Mg TotPhen
         Flav NFPhen Cyanins Color Hue ODRatio Proline;
   label Cultivar = "Cultivar"
         Alcohol  = "Alcohol"
         Malic    = "Malic Acid"
         Ash      = "Ash"
```

```
            Alkan    = "Alkalinity of Ash"
            Mg       = "Magnesium"
            TotPhen  = "Total Phenols"
            Flav     = "Flavonoids"
            NFPhen   = "Nonflavonoid Phenols"
            Cyanins  = "Proanthocyanins"
            Color    = "Color Intensity"
            Hue      = "Hue"
            ODRatio  = "OD280/OD315 of Diluted Wines"
            Proline  = "Proline";
run;
```

The following DATA step loads the mylib.Wine data into your CAS session. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.Wine;
   set Wine;
run;
```

The following statements print the first 10 observations of Wine, as shown in Figure 34.1:

```
proc print data=Wine(obs=10); run;
```

Figure 34.1 Partial Listing of mylib.Wine

Obs	Cultivar	Alcohol	Malic	Ash	Alkan	Mg	TotPhen	Flav	NFPhen	Cyanins	Color	Hue	ODRatio	Proline
1	1	14.23	1.71	2.43	15.6	127	2.80	3.06	0.28	2.29	5.64	1.04	3.92	1065
2	1	13.20	1.78	2.14	11.2	100	2.65	2.76	0.26	1.28	4.38	1.05	3.40	1050
3	1	13.16	2.36	2.67	18.6	101	2.80	3.24	0.30	2.81	5.68	1.03	3.17	1185
4	1	14.37	1.95	2.50	16.8	113	3.85	3.49	0.24	2.18	7.80	0.86	3.45	1480
5	1	13.24	2.59	2.87	21.0	118	2.80	2.69	0.39	1.82	4.32	1.04	2.93	735
6	1	14.20	1.76	2.45	15.2	112	3.27	3.39	0.34	1.97	6.75	1.05	2.85	1450
7	1	14.39	1.87	2.45	14.6	96	2.50	2.52	0.30	1.98	5.25	1.02	3.58	1290

9	1	14.83	1.64	2.17	14.0	97	2.80	2.98	0.29	1.98	5.20	1.08	2.85	1045
10	1	13.86	1.35	2.27	16.0	98	2.98	3.15	0.22	1.85	7.22	1.01	3.55	1045

The variable Cultivar is a nominal categorical variable that has levels 1, 2, and 3, and the 13 attribute variables are continuous.

The following statements use the TREESPLIT procedure to create a classification tree:

```
ods graphics on;

proc treesplit data=mylib.Wine seed=54321;
   class Cultivar;
   model Cultivar = Alcohol Malic Ash Alkan Mg TotPhen Flav
                            NFPhen Cyanins Color Hue ODRatio Proline;
   grow entropy;
   prune costcomplexity(leaves=SE);
run;
```

The MODEL statement specifies Cultivar as the response variable and the variables to the right of the equals sign as the predictor variables. The inclusion of Cultivar in the CLASS statement designates it as a categorical

response variable and requests a classification tree. All the predictor variables are treated as continuous variables because none are included in the CLASS statement.

The GROW and PRUNE statements control two fundamental aspects of building classification and regression trees: growing and pruning. You use the GROW statement to specify the criterion for recursively splitting parent nodes into child nodes as the tree is grown. For classification trees, the default criterion is entropy; for more information, see the section "Splitting Criteria" on page 1829.

By default, the growth process continues until the tree reaches a maximum depth of 10 (you can specify a different limit by using the MAXDEPTH= option). The result is often a large tree that overfits the data and is likely to perform poorly in predicting future data. A recommended strategy for avoiding this problem is to prune the tree to a smaller subtree that minimizes prediction error. You can use the PRUNE statement to specify the method of pruning. The default method is cost complexity.

The default output includes several informational tables, which are shown in Figure 34.2 through Figure 34.7. The "Model Information" table in Figure 34.2 provides information about the model and the methods that are used to grow and prune the tree.

Figure 34.2 Model Information

The TREESPLIT Procedure

Model Information	
Split Criterion	Entropy
Pruning Method	Cost Complexity
Max Branches per Node	2
Max Tree Depth	10
Tree Depth Before Pruning	3
Tree Depth After Pruning	2
Number of Leaves Before Pruning	7
Number of Leaves After Pruning	3

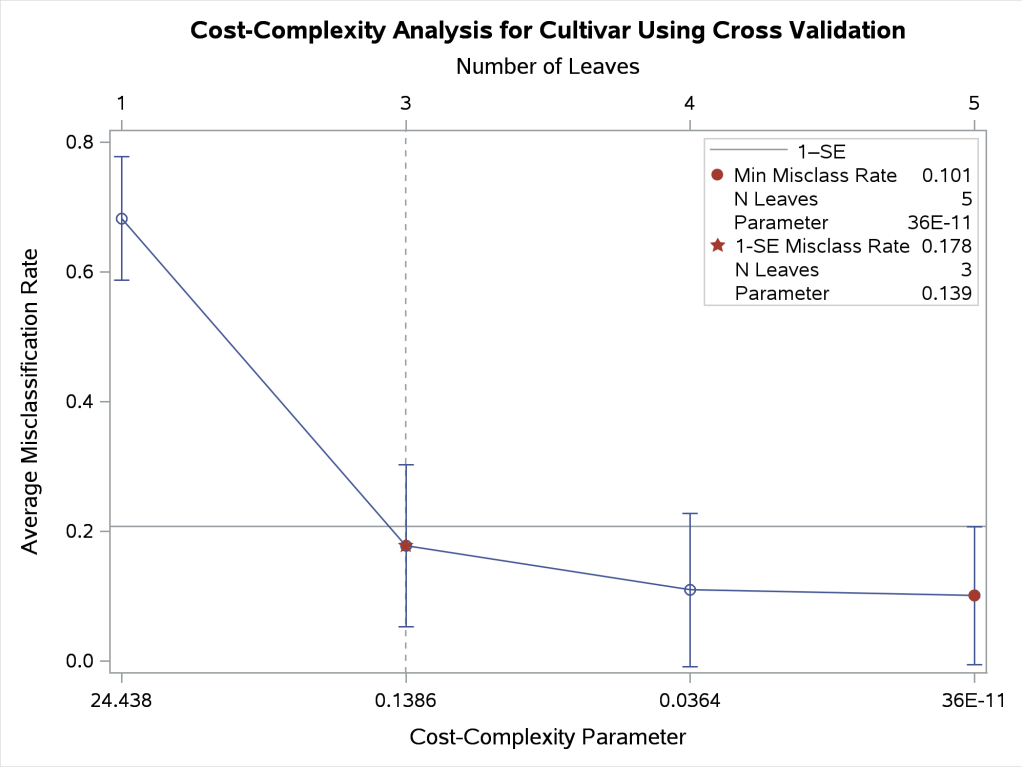
The "Observation Information" table in Figure 34.3 provides the numbers of observations that are read and used. These numbers are the same in this example because there are no missing values in the predictor variables and the ASSIGNMISSING= option is not set to NONE.

Figure 34.3 Observation Information

	Training
Number of Observations Read	178
Number of Observations Used	178

The plot in Figure 34.4 is a tool for selecting the tuning parameter for cost-complexity pruning. The parameter (indicated on the lower horizontal axis) indexes a sequence of progressively smaller subtrees that are nested within the large tree. The parameter value 0 corresponds to the fully grown tree, and positive values control the trade-off between complexity (number of leaves) and fit to the training data, as measured by average misclassification rate.

Figure 34.4 Misclassification Rate as a Function of Cost Complexity



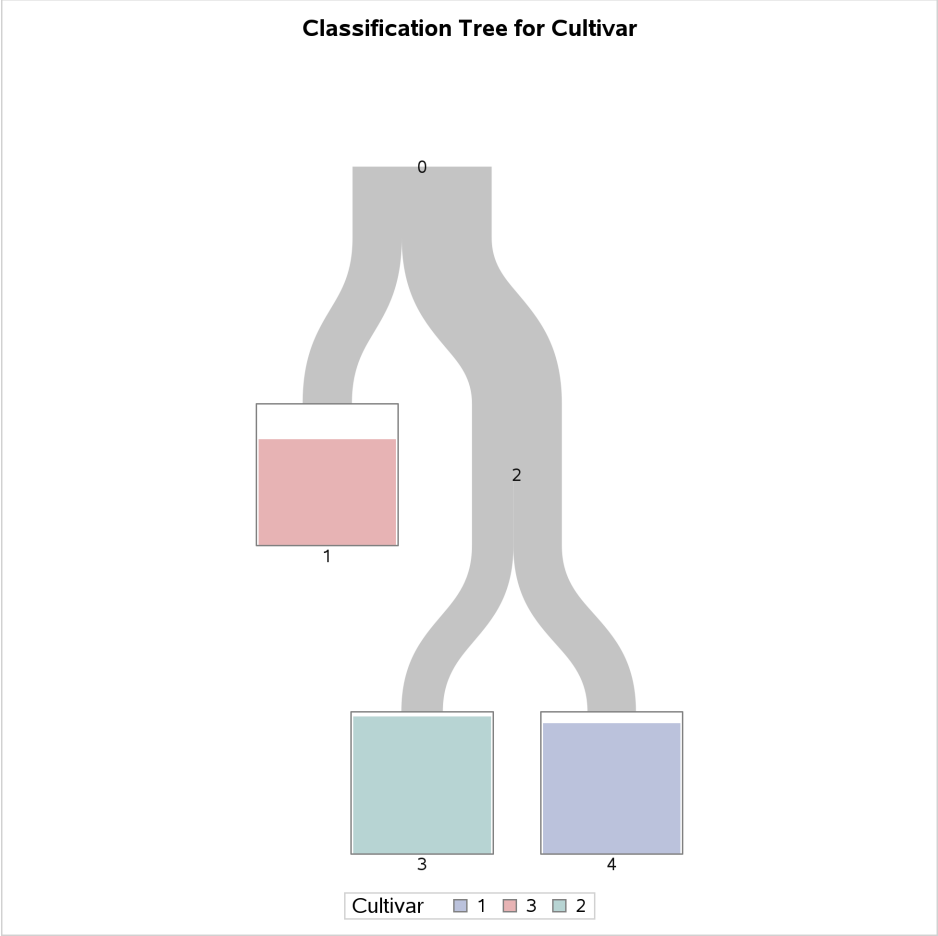


Figure 34.4 shows the minimum average misclassification rate, which is obtained by 10-fold cross validation. In the plot, this value is indicated by a filled-in circle. Information about the 1-SE misclassification rate is also included because the LEAVES=SE suboption was specified.

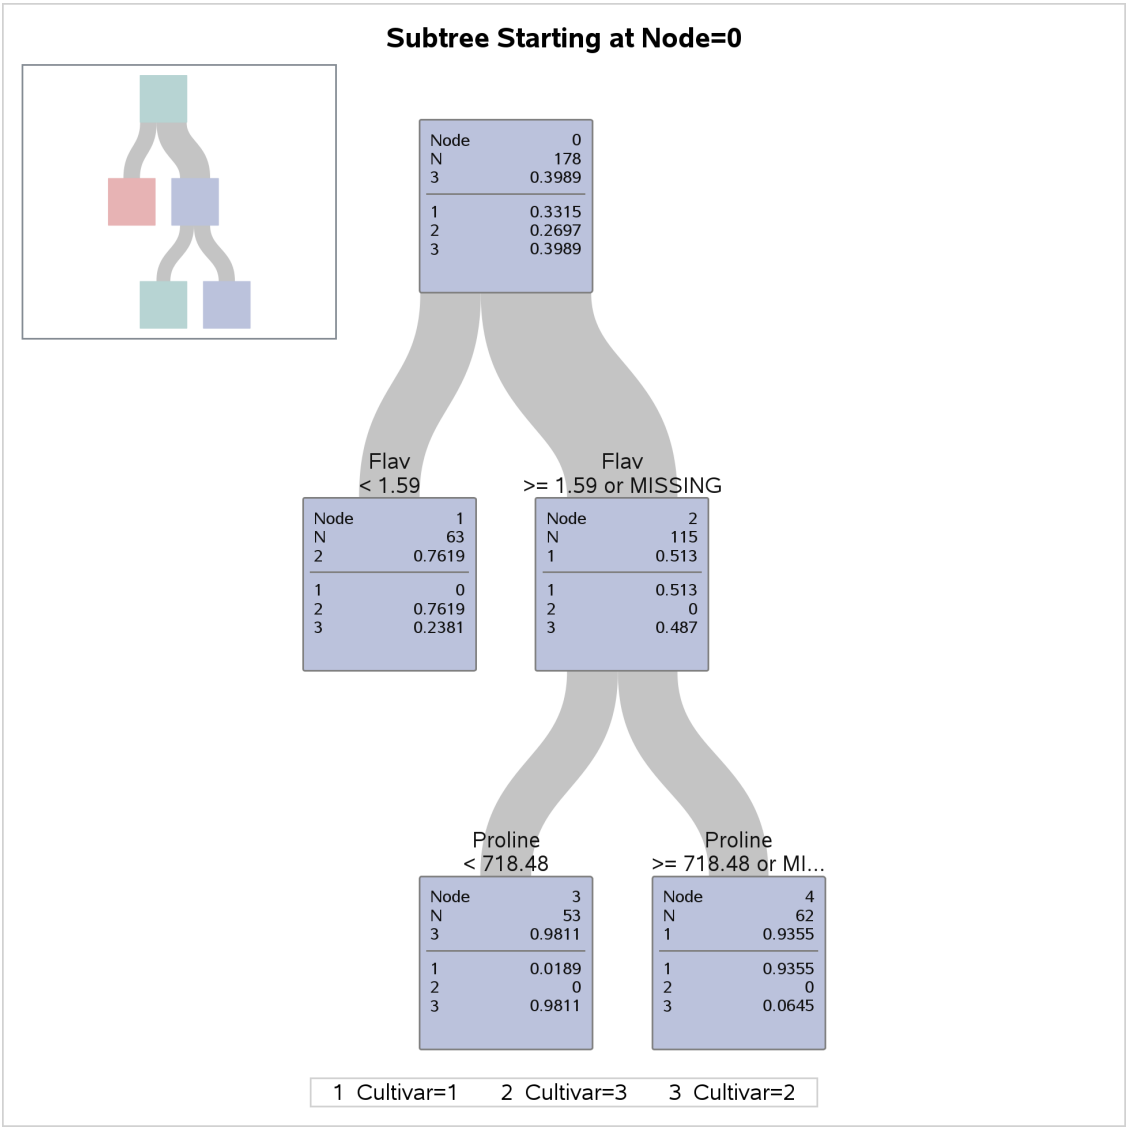
Breiman's 1-SE rule chooses the parameter that corresponds to the smallest subtree for which the misclassification rate is less than one standard error above the minimum misclassification rate (Breiman et al. 1984). The parameter value that corresponds to the 1-SE rule is indicated by a star. The dotted vertical line in Figure 34.4 indicates the chosen tree.

The tree diagram in Figure 34.5, which is produced by default when ODS Graphics is enabled, provides an overview of the tree as a classifier.

Figure 34.5 Overview Diagram of Final Tree



The tree is constructed by starting with all the observations in the root node (labeled 0). This node is split into two internal nodes (1 and 2, respectively). Node 1 is further split into leaf nodes (3 and 4), and node 2 is further split into leaf nodes (5 and 6).

The color of the bar for each leaf node indicates the most frequent level of Cultivar among the observations in that node; this is also the classification level that is assigned to all observations in that node. The height of the bar indicates the proportion of observations in the node that have the most frequent level. The width of the link between parent and child nodes is proportional to the number of observations in the child node.

The diagram in Figure 34.6 provides more detail about the nodes and splits.

Figure 34.6 Detailed Tree Diagram

The detailed tree diagram displays a box for each node; the box contains six lines of information, separated by a horizontal line. The proportion of each level of the predictor variable is shown below the horizontal line, and the level that has the highest proportion is also displayed above the horizontal line. Also displayed above the horizontal line are the node identifier and the number of observations that are assigned to the node.

The root node (node 0) contains 178 samples. Because the MAXBRANCH= option is not specified in the preceding statements, PROC TREESPLIT divides each node into two child nodes (MAXBRANCH=2 by default). At node 0, PROC TREESPLIT determines that the impurity of the root node is maximally decreased (as measured by the entropy criterion, which is the default) by splitting the 178 observations such that all samples for which Flav $\geq$ 1.59 are assigned to node 2 and all samples for which Flav < 1.59 are assigned to node 1. This is the splitting rule for node 0. In this training phase, 63 samples are assigned to node 1 and 115 samples are assigned to node 2.

Figure 34.6 also indicates that node 1 contains 0 samples with level 1. The legend shows that level 1 corresponds to a Cultivar value of 1, so node 1 contains no samples of the first cultivar. Similarly, the diagram

indicates that node 2 contains 0 samples with level 2, and the legend shows that level 2 corresponds to a Cultivar value of 3, so node 2 contains no samples of the third cultivar.

The splitting rule for node 1 consists of the variable Color and the split value 3.8032. All samples for which Color $\geq$ 3.8032 are assigned to node 4 (which then contains 49 samples), and all samples for which Color $<$ 3.8032 are assigned to node 3 (which then contains 14 samples).

The resulting classification tree yields simple rules for predicting the cultivar. For example, a sample for which Flav $<$ 1.59 and Color $<$ 3.8032 is predicted to be from the second cultivar (node 3 indicates that level 3 has the highest proportion of observations, and the legend shows that level 3 corresponds to a Cultivar value of 2).

Figure 34.6 displays the entire tree that begins with the root node and has a depth of three levels. You can use the PLOTS=ZOOMEDTREE option in the PROC TREESPLIT statement to request diagrams that begin with other nodes and have specified depths.

The table in Figure 34.7 displays fit statistics for the tree model.

Figure 34.7 Fit Statistics

The TREESPLIT Procedure

Fit Statistics for Selected Tree

	Number of Leaves	Misclassification Rate
Training	3	0.1124

The misclassification rate is the total proportion of the 178 wine samples that were misclassified. The following numbers of samples were misclassified in the terminal nodes:

- node 3: 0
- node 4: 1
- node 5: 1
- node 6: 4

So the total misclassification rate is $(0 + 1 + 1 + 4)/178 \approx 0.0337$.

Syntax: TREESPLIT Procedure

The following statements and options are available in the TREESPLIT procedure:

PROC TREESPLIT < *options* > ;
  AUTOTUNE < *options* > ;
  CLASS *variables* ;
  CODE < *options* > ;
  CROSSVALIDATION < *options* > ;
  FREQ *variable* ;
  GROW *criterion* < *options* > ;
  MITIGATEBIAS *mitigate-options* ;
  MODEL *response* **=** *variable. . .* ;
  OUTPUT OUT=*libref.data-table output-options* ;
  PARTITION < *partition-options* > ;
  PRUNE *prune-method* < **(***prune-options***)** > ;
  SAVESTATE RSTORE=*libref.data-table* ;
  VIICODE < *options* > ;
  WEIGHT *variable* ;

The PROC TREESPLIT statement and the MODEL statement are required. If any variables are character or are to be treated as categorical, at least one CLASS statement is required. Variables that appear after the equals sign (=) in the MODEL statement are predictor variables that model the *response* variable. By default, all *variables* that appear in the MODEL statement are treated as continuous variables. A CLASS statement causes a *variable* to be treated as categorical. Specifying a *variable* in a CLASS statement but not in a MODEL statement causes the *variable* to be implicitly added to the MODEL statement.

The following sections describe the PROC TREESPLIT statement and then describe the other statements in alphabetical order.

PROC TREESPLIT Statement

PROC TREESPLIT < *options* > ;

The PROC TREESPLIT statement invokes the procedure. Table 34.1 summarizes the options in this statement.

Table 34.1 PROC TREESPLIT Statement Options

Option	Description
Basic Options	
APPLYROWORDER	Specifies that the procedure use a prespecified data distribution
BINMETHOD=	Specifies how to bin interval inputs prior to training
CVCC	Requests a table of the results of the cost-complexity pruning based on cross validation
INMODEL=	Specifies a saved tree model to use to score a new table
NOPRINT	Suppresses ODS output
NTHREADS=	Specifies the number of threads to use in the computation

Table 34.1 *continued*

Option	Description
NUMBIN=	Specifies the number of bins to use for continuous variables
OUTMODEL=	Specifies the data table to which the decision tree model is to be saved
PLOTS=	Specifies options for plots
PRINTTARGET	Create tables that contain information about columns in the output
PRUNINGTABLE	Creates a table that contains the pruning information
RBAIMP	Creates a variable importance table by using random branch assignment
SEED=	Sets the seed for pseudorandom number generation
TREEPLOT	Creates a table that contains the information used to render the tree graphics
VII=	Calculates the importance of the specified types of variable interactions
Splitting Options	
ASSIGNMISSING=	Specifies how to handle missing values in a predictor variable
CLUSTERSPLIT	Requests that an alternative method of determining splits be used
MAXBRANCH=	Specifies the maximum number of child nodes per parent node
MAXDEPTH=	Specifies the maximum tree depth
MINLEAFSIZE=	Specifies the minimum number of observations per child node
MINUSEINSEARCH=	Specifies the minimum number of observations to use with the USEINSEARCH policy for handling missing values
NOMSEARCH=	Specifies the method to use to find a split on a nominal variable
SPLITONCE	Specifies that a variable can be used to split only once per branch

You can specify the following *options*:

APPLYROWORDER
uses a data distribution and row order as determined by a previous **`partition`** action call. For more information, see the section "The APPLYROWORDER Option" on page 107 in Chapter 2, "Shared Concepts."

ASSIGNMISSING=BRANCH | NONE | MACSMALL | POPULAR | SIMILAR | USEINSEARCH
specifies how to handle missing values of predictor variables during training and how to handle missing values and unknown levels of predictor variables. An unknown level of a categorical predictor variable is a level that does not exist in the training data but is encountered during scoring. During scoring, unknown levels are treated as missing values.

You can specify one of the following values:

BRANCH during the training phase, assigns any observation that has a missing value for the predictor variable to a specially created child node (branch). If all observations have nonmissing values for a predictor variable, then no branch is created to contain observations with missing values. In the scoring phase, if an observation has a missing value for a predictor variable and no special branch was created to contain observations with missing values, or if an observation has an unknown level for a

predictor variable, then the observation is assigned to the child node that contains the most training observations.

NONE during the training phase, excludes any observation that has a missing value for any predictor variable. In the scoring phase, if an observation has a missing value or an unknown level for a categorical predictor variable, then the observation is assigned to the child node that contains the most training observations. If an observation has a missing value for a continuous predictor, then the observation is assigned to the child node with the smallest numerical values of the predictor.

MACSMALL during the training phase, treats a missing value in a categorical predictor variable as a separate, legitimate value. If all observations have nonmissing values for a categorical predictor variable, then no branch is selected to contain observations with missing values. In the scoring phase, if an observation has a missing value for a categorical predictor variable and no branch is selected to contain observations with missing values, or if an observation has an unknown level for a predictor variable, then the observation is assigned to the child node that contains the most training observations.

In both the training and the scoring phases, missing values in continuous predictor variables are treated as the smallest possible value.

POPULAR during the training phase, assigns any observation that has a missing value in the predictor variable to the child node that has the most training observations. In the scoring phase, if an observation has a missing value or an unknown level for a predictor variable, then the observation is assigned to the child node that contains the most training observations.

SIMILAR during the training phase, assigns any observation that has a missing value in the predictor variable to the child node whose observations are most similar to it. This similarity is determined using the chi-square criterion for categorical responses or the F-test criterion for continuous responses. If all observations have nonmissing values for a predictor variable, then no branch is selected to contain observations with missing values. In the scoring phase, if an observation has a missing value for a predictor variable and no branch is selected to contain observations with missing values, or if an observation has an unknown level for a predictor variable, then the observation is assigned to the child node that contains the most training observations.

USEINSEARCH during the training phase, treats a missing value in a predictor variable as a separate, legitimate value. If all observations have nonmissing values for a predictor variable, then no branch is selected to contain observations with missing values. In the scoring phase, if an observation has a missing value for a predictor variable and no branch is selected to contain observations with missing values, or if an observation has an unknown level for a predictor variable, then the observation is assigned to the child node that contains the most training observations.

By default, ASSIGNMISSING=USEINSEARCH.

BINMETHOD=BUCKET | QUANTILE

specifies how to bin interval input variables prior to growing the decision tree. The number of bins that are created is determined by the NUMBIN= option.

You can specify one of the following values:

BUCKET bins interval input variables into fixed-width bins. The width of each bin for a particular variable is calculated by subtracting the smallest value among all observations from the largest value among all observations, and then dividing that result by the number of bins.

QUANTILE bins interval input variables into bins according to their quantile. The width of the bins for a particular variable is not fixed, but the number of observations in each bin is approximately equal.

By default, BINMETHOD=QUANTILE.

CLUSTERSPLIT

determines the splits at each node using clustering on each input variable, and then chooses the splitting variable on the basis of which variable and split optimize the criterion that is specified in the GROW statement.

CVCC

CVCOSTCOMPLEXITY

requests a table of the results of cost-complexity pruning based on cross validation. For each penalty parameter in the cross validation, the table provides the penalty parameter, the minimum, the maximum, and the average error. The error is the misclassification rate when the response variable is categorical and is the average square error (ASE) when the response variable is continuous. You can use the PLOTS=CVCC option to request a plot of the information in this table.

DATA=*libref.data-table*

names the input data table for PROC TREESPLIT to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1783.

data-table specifies the name of the input data table.

INMODEL=< *libref.***>***data-table*

specifies the data table that you have previously saved as a tree model by using the OUTMODEL= option in a previous run of PROC TREESPLIT. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1783.

When you use the INMODEL= option, the OUTPUT statement is required and any other options in the PROC TREESPLIT statement, except for NOPRINT and PLOTS, are ignored.

The data table used in the INMODEL= option must include the attributes that are associated with the table produced by the OUTMODEL= option, or PROC TREESPLIT issues an error.

MAXBRANCH=*b*

specifies the maximum number of child nodes per parent node in the tree. PROC TREESPLIT tries to create this number of children unless it is impossible (for example, if a split variable does not have enough levels).

By default, MAXBRANCH=2.

MAXDEPTH=*number*

specifies the maximum depth of the tree to be grown. The number of levels in a tree is equal to the depth plus 1. The default is calculated by the following equation, where b is the value of the MAXBRANCH= option in the PROC TREESPLIT statement:

$$\text{MaxDepth} = \left\lceil \frac{10}{\log_2(b)} \right\rceil$$

This value can be tuned with the AUTOTUNE statement. In the ODS output that corresponds to tables that are generated using the AUTOTUNE statement, the term "MAXLEVEL" is used. The value of MAXLEVEL is equal to the value of the MAXDEPTH= option plus 1.

MINLEAFSIZE=*number*

LEAFSIZE=*number*

specifies the minimum *number* of observations in the training data that each child of a split must contain in order for the split to be considered.

By default, MINLEAFSIZE=5. This value can be tuned with the AUTOTUNE statement.

MINUSEINSEARCH=*number*

specifies a threshold for using missing values in the split search when ASSIGNMISSING=USEINSEARCH as the missing value policy. If the number of observations that have missing values for the splitting variable is greater than or equal to *number*, then PROC TREESPLIT uses the USEINSEARCH policy for missing values.

By default, MINUSERINSEARCH=1.

NOMSEARCH(*suboption* **...)**

specifies search methods for splitting on a nominal variable. For more information, see the section "Splitting Nominal Values" on page 1831.

If you do not specify this option, the default values of the *suboptions* determine the search method. You can specify one or more of the following *suboptions*:

MAXCATEGORIES=*number*

specifies the maximum number of categories to use in a splitting rule. The input is eligible for splitting nodes in which no more than *number* categories appear. The value of *number* must be greater than 1.

By default, MAXCATEGORIES=128.

SHRINKAGE=*number*
specifies how much weight to give the average gradient when you combine it with the average gradient within a category. You use this option only when sorting the categories. The value of *number* must be nonnegative.

By default, SHRINKAGE=10.

SORT=*number*
specifies the minimum cardinality in the node of the nominal variable for using the sort method. The sort method sorts the categories and then examines binary splits that preserve the ordering. The value of *number* must be a nonnegative integer. If *number* is greater than the value of the MAXCATEGORIES=*number* option, then the variable is not used in the node.

By default, SORT=10.

NOPRINT
suppresses the generation of ODS output.

NTHREADS=*number-of-threads*
specifies the number of threads to use in the computation. The default value is the number of CPUs available on the machine.

NUMBIN=*number*
NBINS=*number*
specifies the *number* of bins to use for binning interval predictor variables. PROC TREESPLIT bins continuous predictors to a fixed bin size. This option controls the number of bins and thereby also the size of the bins.

By default, NUMBIN=50. This value can be tuned with the AUTOTUNE statement.

OUTMODEL=*libref.data-table*
specifies the data table to which to save the decision tree model. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1783.

The data table that results from this option contains information about each node in the decision tree model, including the splitting variables, the child nodes, the number of observations at each node, and the predicted response at each node. This table also has attributes attached that contain information about the input variables, the target variable, and the decision tree model.

PLOTS <(*global-plot-option***)> <= *plot-request* <(***options***)>>**
PLOTS <(*global-plot-option***)> <= (***plot-request* <(***options***)> <... *plot-request* <(***options***)>>)>**
controls the plots that are produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around it.

You can specify the following *global-plot-option*:

ONLY
suppresses the default plots. Only plots that you specifically request are displayed.

You can specify the following *plot-requests*:

ALL
produces all appropriate plots.

CVCC
produces a plot that is used to determine the tuning parameter for cost-complexity pruning when *k*-fold cross validation is used. This plot displays the average misclassification rate when the response variable is a classification variable and displays the average square error (ASE) when the response variable is a continuous variable.

NONE
suppresses the default plots. Only plots that you specifically request are displayed.

PRUNEUNTIL
plots the metric that is used to select the final subtree.

This option is enabled by default except when you specify the OFF option in the PRUNE statement (which turns off pruning completely). Specifying the PRUNEUNTIL option has no effect if you also specify the OFF option in the prune statement.

WHOLETREE < (*whole-tree-options*) >
produces a plot to visualize the entire finished (grown and pruned) tree. This option is enabled by default.

You can specify the following values:

LINKSTYLE=CURVED | ORTHOGONAL | STRAIGHT
specifies the style of links between nodes and leaves in the tree. You can specify the following *link-styles*:

CURVED requests curved links between the nodes and their children.

ORTHOGONAL requests that links go straight down partway from a node to its children, create a horizontal line at the base of the vertical line, and then go straight down from that line to each child.

STRAIGHT requests that links go straight from the nodes to their children.

By default, LINKSTYLE=CURVED.

LINKWIDTH=CONSTANT | PROPORTIONAL
specifies the width of links between nodes and leaves in the tree. You can specify the following values:

CONSTANT requests that all links have the same thickness.

PROPORTIONAL requests that links have a thickness proportional to the total number of observations that go between the node and each child.

By default, LINKWIDTH=PROPORTIONAL.

NOLEGEND
turns off the legend.

ZOOMEDTREE < (*zoomed-tree-options*) >
produces a plot to visualize a portion of the finished (grown and pruned) tree. This option is enabled by default.

You can specify the following values:

DEPTH=*depth*
creates a plot down to *depth* for each *node-id* specified in the NODES= option.

By default, DEPTH=2.

LINKSTYLE=CURVED | ORTHOGONAL | STRAIGHT
specifies the style of links between nodes and leaves in the tree. You can specify the following values:

CURVED requests curved links between the nodes and their children.

ORTHOGONAL requests that links go straight down partway from a node to its children, create a horizontal line at the base of the vertical line, and then go straight down from that line to each child.

STRAIGHT requests that links go straight from the nodes to their children.

By default, LINKSTYLE=CURVED.

LINKWIDTH=CONSTANT | PROPORTIONAL
specifies the width of links between nodes and leaves in the tree. You can specify the following values:

CONSTANT requests that all links have the same thickness.

PROPORTIONAL requests that links have a thickness proportional to the total number of observations that go between the node and each child.

By default, LINKWIDTH=PROPORTIONAL.

NODES=(*node-id* **<** *node-id* **< . . . > >)** requests a plot for a subtree that is rooted at each node specified by a *node-id*. The values of *node-id* are alphanumeric strings that are displayed within the nodes in the plot that is created by the WHOLETREE option. PROC TREESPLIT creates one plot for each *node-id* that you specify. The default node ID is "0," the root of the entire tree.

NOLEGEND
suppresses the display of the legend

PRINTTARGET
outputs tables that indicate generated columns in the OUT= table from the OUTPUT statement. For a continuous response, PROC TREESPLIT generates an output table named PredName, which indicates the name of the predicted value column. For a categorical response, PROC TREESPLIT generates an output table named PredIntoName, which indicates the name of the predicted value column, and also an output table named PredProbName, which indicates the names of the predicted probability columns.

PRUNINGTABLE
outputs a table of the pruning results.

RBAIMP
creates a variable importance table by using random branch assignment (RBA). This table is created in addition to the normal variable importance table that is calculated using the residual sum of squares (RSS) error. For more information about RBA and RSS variable importance, see the section "Variable Importance" on page 1839.

SEED=*number*
specifies the initial seed for random number generation. The seed is used in the AUTOTUNE statement, in the CROSSVALIDATION statement, and for *k*-fold cross validation pruning. The value of *number* must be an integer. By default, the seed is generated by reading the time of day from the computer's clock.

SPLITONCE
splits predictor variables only once on a branch. When you specify this option, a variable cannot be split more than once on the path from the root to any particular terminal node. However, a variable can be used more than once across branches.

TREEPLOT
creates a table that contains the information used to create the WholeTree and ZoomedTree ODS graphics.

VII=*n*

INTERACTIONIMP=*n*
calculates the variable interaction importance, which is described in the section "Variable Interaction Importance" on page 1840. *n* can be one of the following values:

0 suppresses the calculation of variable importance.

1 calculates the importance of individual variables without interactions.

2 calculates the importance of two-way interactions and of individual variables.

3 calculates the importance of three-way and two-way interactions and of individual variables.

If you do not specify this option, then only the importance of individual variables without interactions is calculated.

AUTOTUNE Statement

AUTOTUNE < *options* > **;**

The AUTOTUNE statement searches for the best combination of values of the MAXDEPTH=, MINLEAFSIZE=, and NUMBIN= options in the PROC TREESPLIT statement and the criterion in the GROW statement. If you specify the AUTOTUNE statement, then you cannot also specify *k*-fold cross validation with cost-complexity pruning. You cannot specify both the AUTOTUNE statement and the CROSSVALIDATION statement in the same run of PROC TREESPLIT.

Table 34.2 summarizes the *options* that you can specify in the AUTOTUNE statement.

Table 34.2 AUTOTUNE Statement Options

Option	Description
APPENDLOOKUP	Specifies that the table specified in the HISTORYTABLE= option contain the rows from the table specified in the LOOKUPTABLE= option
CONSTRAINTS=	Specifies the constraints on the output metrics
EVALHISTORY=	Specifies how to report the evaluation history of the tuner
FOLDCOLUMN=	Specifies the column in the data table in which the cross validation fold value is indicated
FRACTION=	Specifies the fraction of observations to use for validation
HISTORYTABLE=	Specifies the CAS table that contains the evaluation history
KFOLD=	Specifies the number of folds for *k*-fold cross validation
LIVEUPDATE	Specifies that the table specified in the HISTORYTABLE= option be updated at every evaluation
LOOKUPTABLE=	Specifies the CAS table to use for evaluation lookup
MAXBAYES=	Specifies the maximum number of points in the kriging model
MAXEVALS=	Specifies the maximum number of evaluations
MAXITER=	Specifies the maximum number of iterations when SEARCHMETHOD=GA or SEARCHMETHOD=BAYESIAN
MAXTIME=	Specifies the maximum time for all iterations
MAXTRAINTIME=	Specifies the maximum time for a model training
NCONVITER=	Specifies the number of convergence iterations
NOGRIDSHUFFLE	Requests that the grid points not be shuffled
NOLOCALSEARCH	Disables local search optimization
NPARALLEL=	Specifies the number of parallel sessions
NSUBSESSIONWORKERS=	Specifies the number of workers in parallel sessions
OBJECTIVE=	Specifies the objective function
POPSIZE=	Specifies the population size when SEARCHMETHOD=GA or SEARCHMETHOD=BAYESIAN
SAMPLESIZE=	Specifies the sample size when SEARCHMETHOD=LHS or SEARCHMETHOD=RANDOM
SEARCHMETHOD=	Specifies the search method that the optimizer uses
SECONDOBJECTIVE=	Specifies the second objective to use for tuning
SELECTINITPOINT	Specifies that the tuner select the best evaluation from the lookup table

Table 34.2 *continued*

Option	Description
TARGETEVENT=	Specifies the target event for ROC-based calculations
TRAINFRACTION=	Specifies the fraction of observations to use for training
TUNINGPARAMETERS=	Specifies the custom tuning parameters
USEPARAMETERS=	Specifies how to handle the TUNINGPARAMETERS= option

APPENDLOOKUP
specifies that the rows from the table specified in the LOOKUPTABLE= option be appended to the output table that is created using the HISTORYTABLE= option.

This option is ignored if you do not specify both the HISTORYTABLE= and LOOKUPTABLE= options.

CONSTRAINTS=(*suboption* **| . . . | <** *suboption* **>)**
specifies constraints on output metrics that the tuner will use during tuning.

You can specify one or more of the following *suboptions*:

ASE (LB=*number* **UB=***number***)**
specifies a constraint on the average square error to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the average square error.

UB=*number*
specifies the upper bound for the average square error.

F05 (LB=*number* **UB=***number***)**
specifies a constraint on the F0.5 coefficient to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the F0.5 coefficient.

UB=*number*
specifies the upper bound for the F0.5 coefficient.

F1 (LB=*number* **UB=***number***)**
specifies a constraint on the F1 coefficient to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the F1 coefficient.

UB=*number*
specifies the upper bound for the F1 coefficient.

FNR (LB=*number* **UB=***number***)**
specifies a constraint on the false negative rate to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the false negative rate.

UB=*number*
specifies the upper bound for the false negative rate.

FPR (LB=*number* **UB=***number***)**
specifies a constraint on the false positive rate to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the false positive rate.

UB=*number*
specifies the upper bound for the false positive rate.

GAMMA (LB=*number* **UB=***number***)**
specifies a constraint on the gamma coefficient to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the gamma coefficient.

UB=*number*
specifies the upper bound for the gamma coefficient.

GINI (LB=*number* **UB=***number***)**
specifies a constraint on the Gini coefficient to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the Gini coefficient.

UB=*number*
specifies the upper bound for the Gini coefficient.

KS (LB=*number* **UB=***number***)**
specifies a constraint on the Kolmogorov-Smirnov coefficient to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the Kolmogorov-Smirnov coefficient.

UB=*number*
specifies the upper bound for the Kolmogorov-Smirnov coefficient.

MAE (LB=*number* **UB=***number***)**
specifies a constraint on the mean absolute error to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the mean absolute error.

UB=*number*
specifies the upper bound for the mean absolute error.

MCE (LB=*number* **UB=***number***)**
specifies a constraint on the misclassification rate to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the misclassification rate.

UB=*number*
specifies the upper bound for the misclassification rate.

MCLL (LB=*number* **UB=***number***)**
specifies a constraint on the multiclass log loss to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the multiclass log loss.

UB=*number*
specifies the upper bound for the multiclass log loss.

MISC (LB=*number* **UB=***number***)**
specifies a constraint on the misclassification error percentage to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the misclassification error percentage.

UB=*number*
specifies the upper bound for the misclassification error percentage.

MSE (LB=*number* **UB=***number***)**
specifies a constraint on the mean square error to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the mean square error.

UB=*number*
specifies the upper bound for the mean square error.

MSLE (LB=*number* **UB=***number***)**
specifies a constraint on the mean square logarithmic error to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the mean square logarithmic error.

UB=*number*
specifies the upper bound for the mean square logarithmic error.

RASE (LB=*number* **UB=***number***)**
specifies a constraint on the root average square error to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the root average square error.

UB=*number*
specifies the upper bound for the root average square error.

RMAE (LB=*number* **UB=***number***)**
specifies a constraint on the root mean absolute error to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the root mean absolute error.

UB=*number*
specifies the upper bound for the root mean absolute error.

RMSLE (LB=*number* **UB=***number***)**
specifies a constraint on the root mean square logarithmic error to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the root mean square logarithmic error.

UB=*number*
specifies the upper bound for the root mean square logarithmic error.

SCORETIME (LB=*number* **UB=***number***)**

SCORINGTIME (LB=*number* **UB=***number***)**
specifies a constraint on the model scoring time to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the model scoring time.

UB=*number*
specifies the upper bound for the model scoring time.

TAU (LB=*number* **UB=***number***)**
specifies a constraint on the tau coefficient to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the tau coefficient.

UB=*number*
specifies the upper bound for the tau coefficient.

TNR (LB=*number* **UB=***number***)**
specifies a constraint on the true negative rate to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the true negative rate.

UB=*number*
specifies the upper bound for the true negative rate.

TPR (LB=*number* **UB=***number***)**
specifies a constraint on the true positive rate to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the true positive rate.

UB=*number*
specifies the upper bound for the true positive rate.

TRAINTIME (LB=*number* **UB=***number***)**
TRAININGTIME (LB=*number* **UB=***number***)**
specifies a constraint on the model training time to be used while tuning the model.

You must specify one or both of the following suboptions:

LB=*number*
specifies the lower bound for the model training time.

UB=*number*
specifies the upper bound for the model training time.

EVALHISTORY=ALL | LOG | NONE | TABLE
specifies how to report the evaluation history of the tuner.

You can specify one of the following values:

ALL	reports each evaluation in the log and creates the EvaluationHistory ODS table.
LOG	prints the following information to the log for each evaluation: evaluation number, objective value, best objective value up to that point, evaluation time, and elapsed time since the beginning of the tuning process.
NONE	suppresses reporting of evaluations in the log and does not create the Evaluation-History ODS table.
TABLE	creates the EvaluationHistory ODS table, which contains all evaluated points. The table contains columns for the evaluation number, all tuning parameters, and the objective function value.

By default, EVALHISTORY=TABLE.

FOLDCOLUMN=*string*
specifies the name of the column in the data table in which the cross validation fold value is indicated for all observations. This column must contain integers between 1 and *number*, where *number* is the desired number of folds. This option has an effect similar to that of the KFOLD=*number* option. If you specify this option, the tuner uses the cross validation process to estimate the accuracy of the models. But instead of dividing the data into multiple folds (partitions), as the KFOLD=*number* option does, the tuner reads the fold numbers from the specified column in the data table and assigns each observation to the specified fold. In cross validation, each model evaluation requires *number* of training executions (on *number*–1 data folds) and *number* of scoring executions (on one holdout fold). Thus, the evaluation time is increased by approximately a factor of *number*. For small to medium data tables or for unbalanced data tables, cross validation typically provides a better representation of error across the entire data table (a better generalization error).

If you specify both this option and the KFOLD= option, the value of the KFOLD= option must match the number of folds in the fold column. If you omit this option, the KFOLD= option, and the

FRACTION= option, then the default value of FRACTION=0.3 is used. If you specify a PARTITION statement, the validation partition defined in that statement is used, and the FOLDCOLUMN= option is ignored. You cannot specify the FOLDCOLUMN= option in combination with the FRACTION= option.

FRACTION=*number*

specifies the fraction of all data to use for validation, where *number* must be between 0.01 and 0.99, inclusive. If you specify this option, the tuner uses a single-partition validation for finding the objective value (validation error estimate). Using this option might not be advisable for small or unbalanced data tables, where the random assignment of the validation subset might not provide a good estimate of error. For large, balanced data tables, a single-partition validation is usually sufficient for estimating error; a single partition is more efficient than cross validation in terms of the total execution time.

If you specify a PARTITION statement, the validation partition defined in that statement is used, and this option is ignored. You cannot specify this option in combination with the KFOLD= option.

If you specify the TRAINFRACTION= option, then by default the value of the FRACTION= option is one minus the value of the TRAINFRACTION= option. Otherwise, by default, FRACTION=0.3.

HISTORYTABLE=*libref.data-table* **<(***data-set-options***)>**

specifies the data table created by the tuning process that contains the evaluation history. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1783.

The *data-set-options* are various options that enable you to control how the data table is created. For more information about data set options, see *SAS Data Set Options: Reference*. In the case of the HISTORYTABLE= option, the default value of the REPLACE= data set option is NO. The REPLACE= option specifies whether a new SAS data set can overwrite an existing data set that has the same name. You can override the default value by specifying REPLACE=YES.

KFOLD=*number*

specifies the number of folds (partitions) in the cross validation process, where *number* must be between 2 and 20, inclusive. If you specify this option, the tuner uses cross validation to find the objective value. In cross validation, each model evaluation requires *number* of training executions (on *number*–1 data folds) and *number* of scoring executions (on one holdout fold). Thus, the evaluation time is increased by approximately a factor of *number*. For small to medium data tables or for unbalanced data tables, cross validation typically provides a better representation of error across the entire data table (a better generalization error).

Another option that triggers cross validation is the FOLDCOLUMN= option. If you specify both the KFOLD= option and the FOLDCOLUMN= option, the value of the KFOLD= option must match the number of folds in the fold column.

If you omit the KFOLD= option, the FOLDCOLUMN= option, and the FRACTION= option, then the default value of FRACTION=0.3 is used. If you specify a PARTITION statement, the validation partition defined in that statement is used, and the KFOLD= option is ignored. You cannot specify the KFOLD= option in combination with the FRACTION= option.

LIVEUPDATE
specifies that the table specified in the HISTORYTABLE= option be updated at every evaluation. This option forces the table to be a promoted CAS table so that it can be seen by other sessions.

This option is ignored if you do not specify the HISTORYTABLE= option.

LOOKUPTABLE=*libref.data-table*
specifies the data table previously created by the tuning process that you want to use as the lookup table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1783.

MAXBAYES=*number*
specifies the maximum number of points in the Kriging model. This option is honored only when SEARCHMETHOD=BAYESIAN and when *number* has a minimum value of 10.

By default, MAXBAYES=100.

MAXEVALS=*number*
specifies the maximum number of configuration evaluations allowed for the tuner, where *number* must be an integer greater than or equal to 3. When the *number* of evaluations is reached, the tuner terminates the search and returns the results. To produce a single objective function value (validation error estimate), each configuration evaluation requires either a single model training and scoring execution on a validation partition, or a number of training and scoring executions equal to the value of the KFOLD= option for cross validation. The MAXEVALS= option might lead to termination before the value of the MAXITER= option or the MAXTIME= option is reached.

By default, MAXEVALS=50.

MAXITER=*number*
specifies the maximum number of iterations of the optimization tuner, where *number* must be greater than or equal to 1. Each iteration normally involves a number of objective evaluations up to the value of the POPSIZE= option. The MAXITER= option is used only when SEARCHMETHOD=GA or SEARCHMETHOD=BAYESIAN; it is ignored when SEARCHMETHOD=RANDOM or SEARCHMETHOD=LHS. The MAXITER= option might lead to termination before the value of the MAXEVALS= option or the MAXTIME= option is reached.

By default, MAXITER=5.

MAXTIME=*number*
specifies the maximum time (in seconds) allowed for the tuner, where *number* must be greater than or equal to 1. When this value is reached, the tuner terminates the search and returns results. The actual run time for optimization might be longer because it includes the remaining time needed to finish the current evaluation. For long-running model training (large data tables), the actual run time might significantly exceed *number*. The MAXTIME= option might lead to termination before the value of the MAXEVALS= option or the MAXITER= option is reached.

By default, MAXTIME=36000.

MAXTRAINTIME=*number*
specifies the maximum time allowed for a single model train. The model train is terminated if it exceeds this time, and the objective value is set to missing.

By default, there is no maximum time allowed for a single train.

NCONVITER=*number*
specifies the *number* of convergence iterations after which tuning is terminated.

By default, NCONVITER=4.

NOGRIDSHUFFLE
requests that the points that are generated by the grid search method not be shuffled before execution.

NOLOCALSEARCH
disables local search optimization for the tuning process.

By default, local search optimization is enabled.

NPARALLEL=*number*
specifies the number of evaluations to be performed in parallel, where *number* must be greater than or equal to 0.

By default, NPARALLEL=0, which indicates that the value of *number* is determined as follows:

- If SEARCHMETHOD=GA or SEARCHMETHOD=BAYESIAN, then the number of parallel evaluations is equal to the value of the POPSIZE= option minus 1.
- If SEARCHMETHOD=LHS or SEARCHMETHOD=RANDOM, then the number of parallel evaluations is equal to the value of the SAMPLESIZE= option, with a maximum value of 32.

NSUBSESSIONWORKERS=*number*
specifies the number of workers to use in parallel subsessions. When alternative configurations are evaluated in parallel, a number of subsessions are created by the tuner, and each subsession uses multiple workers. By default, the number of workers that are used in a parallel subsession is determined as described in the section "Determining the Number of Parallel Evaluations" on page 1844.

OBJECTIVE=*function*
specifies which measure of model performance the tuner uses as the objective function.

You can specify one of the following values for *function*. Some values can be specified only when the target variable is of a particular type, as shown in parentheses.

ASE specifies average square error as the objective function.

AUC specifies area under the curve as the objective function (nominal type only).

F05 specifies the F0.5 coefficient as the objective function (nominal type only).

F1 specifies the F1 coefficient as the objective function (nominal type only).

FNR specifies the false negative rate as the objective function (nominal type only).

FPR specifies the false positive rate as the objective function (nominal type only).

GAMMA specifies the gamma coefficient as the objective function (nominal type only).

GINI specifies the Gini coefficient as the objective function (nominal type only).

KS specifies the Kolmogorov-Smirnov coefficient as the objective function (nominal type only).

MAE specifies the mean absolute error as the objective function (interval type only).

MCE specifies the misclassification rate as the objective function (nominal type only).

MCLL specifies the multiclass log loss as the objective function (nominal type only).

MISC specifies the misclassification error percentage as the objective function (nominal type only).

MSE specifies the mean square error as the objective function (interval type only).

MSLE specifies the mean square logarithmic error as the objective function (interval type only).

RASE specifies the root average square error as the objective function.

RMAE specifies the root mean absolute error as the objective function (interval type only).

RMSLE specifies the root mean square logarithmic error as the objective function (interval type only).

SCORETIME specifies the model scoring time as the objective function.

TAU specifies the tau coefficient as the objective function (nominal type only).

TNR specifies the true negative rate as the objective function (nominal type only).

TPR specifies the true positive rate as the objective function (nominal type only).

TRAINTIME specifies the model training time as the objective function.

By default, OBJECTIVE=MISC for nominal targets, and OBJECTIVE=MSE for interval targets.

POPSIZE=*number*

specifies the maximum population size, where population is the number of configuration evaluations in one iteration (population). The *number* must be greater than or equal to 1. In some cases, the tuner algorithm might generate a number of new configurations that is smaller than *number*. The POPSIZE= option is used only when SEARCHMETHOD=GA or SEARCHMETHOD=BAYESIAN; it is ignored when SEARCHMETHOD=RANDOM or SEARCHMETHOD=LHS.

By default, POPSIZE=10.

SAMPLESIZE=*number*

specifies the total number of evaluations, where *number* must be greater than or equal to 1. This option is only used when SEARCHMETHOD=RANDOM or SEARCHMETHOD=LHS; it is ignored when SEARCHMETHOD=GA or SEARCHMETHOD=BAYESIAN.

By default, SAMPLESIZE=50.

SEARCHMETHOD=BAYESIAN | GA | GRID | LHS | RANDOM

specifies the search method to use for tuning. You can specify the following values:

BAYESIAN builds a kriging surrogate model to approximate the objective value and uses this surrogate model to generate new alternative configurations at each iteration. The kriging model is continuously updated during the search process.

GA uses an initial Latin hypercube sample that seeds a genetic algorithm to generate a new population of alternative configurations at each iteration.

GRID uses all combinations of selected values of the hyperparameters.

LHS uses a Latin hypercube to generate a single sample of configurations that is uniform in each tuning parameter but random in combinations.

RANDOM generates a single sample of purely random configurations.

By default, SEARCHMETHOD=GA.

SECONDOBJECTIVE=*function*

specifies the type of the second objective to use for tuning.

You can specify one of the following values for *function*. Some values can be specified only when the target variable is of a particular type, as shown in parentheses.

NONE does not use a second objective for tuning.

ASE specifies average square error as the second objective.

AUC specifies area under the curve as the second objective (nominal type only).

F05 specifies the F0.5 coefficient as the second objective (nominal type only).

F1 specifies the F1 coefficient as the second objective (nominal type only).

FNR specifies the false negative rate as the second objective (nominal type only).

FPR specifies the false positive rate as the second objective (nominal type only).

GAMMA specifies the gamma coefficient as the second objective (nominal type only).

GINI specifies the Gini coefficient as the second objective (nominal type only).

KS specifies the Kolmogorov-Smirnov coefficient as the second objective (nominal type only).

MAE specifies the mean absolute error as the second objective (interval type only).

MCE specifies the misclassification rate as the second objective (nominal type only).

MCLL specifies the multiclass log loss as the second objective (nominal type only).

MISC specifies the misclassification error percentage as the second objective (nominal type only).

MSE specifies the mean square error as the second objective (interval type only).

MSLE specifies the mean square logarithmic error as the second objective (interval type only).

RASE specifies the root average square error as the second objective.

RMAE specifies the root mean absolute error as the second objective (interval type only).

RMSLE specifies the root mean square logarithmic error as the second objective (interval type only).

SCORETIME specifies the model scoring time as the second objective.

TAU specifies the tau coefficient as the second objective (nominal type only).

TNR specifies the true negative rate as the second objective (nominal type only).

TPR specifies the true positive rate as the second objective (nominal type only).

TRAINTIME specifies the model training time as the second objective.

By default, SECONDOBJECTIVE=NONE.

SELECTINITPOINT
specifies that the tuner select the best evaluation from the table specified in the LOOKUPTABLE= option as the initial point for the tuning process.

This option is ignored if you do not specify the LOOKUPTABLE= option.

TARGETEVENT=*string*
specifies the target event to use for calculating the selected objective function. This option is ignored when the value of the OBJECTIVE= option is not AUC, F1, F05, GINI, GAMMA, TAU, or KS.

If you omit the TARGETEVENT= option, the tuner selects one of the target levels and uses it to calculate the specified objective function.

TRAINFRACTION=*number*
specifies the fraction of all data to be used for training, where *number* must be between 0.01 and 0.99, inclusive. If you specify this option, the tuner uses a single-partition validation to find the objective value (validation error estimate). Using this option might not be advisable for small or unbalanced data tables, where the random assignment of the validation subset might not provide a good estimate of error. For large, balanced data tables, a single-partition validation is usually sufficient for estimating error; a single partition is more efficient than cross validation in terms of the total execution time.

If you specify a PARTITION statement, the validation partition defined in that statement is used, and this option is ignored. You cannot specify this option in combination with the KFOLD= option.

If you specify the FRACTION= option, then by default the value of the TRAINFRACTION= option is one minus the value of the FRACTION= option. Otherwise, by default, TRAINFRACTION=0.7.

TUNINGPARAMETERS=(*suboption* **| . . . | <** *suboption* **>)**
TUNEPARMS=(*suboption* **| . . . | <** *suboption* **>)**
specifies which parameters to tune and which ranges to tune over. If USEPARAMETERS=STANDARD, this option is ignored.

You can specify one or more of the following suboptions:

CRITERION (VALUES=*value-list* **INIT=***value* **EXCLUDE)**
specifies information about the splitting criteria to use for tuning the decision tree. For more information about the criteria, see the GROW statement.

You can specify the following additional suboptions:

VALUES=*value-list*
specifies a list of splitting criteria to consider during tuning, where *value-list* is a space separated list that can include one or more of the following values: CHAID, CHISQUARE, FTEST, GAIN, GINI, and VARIANCE.

INIT=*value*
specifies the initial splitting criterion for the tuner to use. You can specify the following *values*: CHAID, CHISQUARE, FTEST, GAIN, GINI, IGR, RSS, or VARIANCE.

By default, INIT=IGR for nominal targets and INIT=VARIANCE for interval targets.

EXCLUDE
excludes the splitting criterion from the tuning process.

MAXDEPTH (LB=*number* **UB=***number* **VALUES=***value-list* **INIT=***number* **EXCLUDE)**
specifies information about the maximum depth to grow the decision tree to use for tuning the decision tree. For more information, see the MAXDEPTH= option.

You can specify the following additional suboptions:

LB=*number*
specifies the minimum depth to consider during tuning. If you specify this suboption, you cannot specify the VALUES= suboption.

By default, LB=1.

UB=*number*
specifies the maximum depth to consider during tuning. If you specify this suboption, you cannot specify the VALUES= suboption.

By default, UB=19.

VALUES=*value-list*
specifies a list of depth values to consider during tuning, where *value-list* is a space-separated list of positive integers. If you specify this suboption, you cannot specify either the LB= or UB= suboption.

INIT=*number*
specifies the initial depth for the tuner to use.

By default, INIT=10.

EXCLUDE
excludes depth from the tuning process.

MINLEAFSIZE (LB=*number* **UB=***number* **VALUES=***value-list* **INIT=***number* **EXCLUDE)**
specifies information about tuning the leaf size option for training the decision tree. This option is not tuned by default. If it is specified without any suboptions, then tuning uses the following values: 1, 5, 10, 20, 40, 80, 160, 320. For more information, see the MINLEAFSIZE= option in the PROC TREESPLIT statement.

You can specify the following additional suboptions:

LB=*number*
specifies the minimum leaf size value to consider during tuning. If you specify this suboption, you cannot specify the VALUES= suboption.

By default, LB=1.

UB=*number*
specifies the maximum leaf size value to consider during tuning. If you specify this suboption, you cannot specify the VALUES= suboption.

By default, UB=320.

VALUES=*value-list*
specifies a list of leaf size values to consider during tuning, where *value-list* is a space-separated list of positive integers. If you specify this suboption, you cannot specify either the LB= or UB= suboption.

INIT=*number*
specifies the initial leaf size for the tuner to use.

By default, INIT=5.

EXCLUDE
excludes the leaf size from the tuning process.

NUMBIN (LB=*number* **UB=***number* **VALUES=***value-list* **INIT=***number* **EXCLUDE)**
specifies information about the number of bins in which to bin the interval inputs while tuning the decision tree. For more information, see the NUMBIN= option.

You can specify the following additional suboptions:

LB=*number*
specifies the minimum number of bins to consider during tuning. If you specify this suboption, you cannot specify the VALUES= suboption.

By default, LB=20.

UB=*number*
specifies the maximum number of bins to consider during tuning. If you specify this suboption, you cannot specify the VALUES= suboption.

By default, UB=200.

VALUES=*value-list*
specifies a list of numbers of bins to consider during tuning, where *value-list* is a space-separated list of positive integers. If you specify this suboption, you cannot specify either the LB= or UB= suboption.

INIT=*number*
specifies the initial number of bins for the tuner to use.

By default, INIT=20.

EXCLUDE
excludes the number of bins from the tuning process.

USEPARAMETERS=*tuning-parameter-option*
specifies which set of parameters to tune.

You can specify the following *tuning-parameter-options*:

STANDARD tunes using the default bounds and initial values for all parameters.

CUSTOM tunes only the parameters that are specified in the TUNINGPARAMETERS= option.

COMBINED tunes the parameters that are specified in the TUNINGPARAMETERS= option and uses default bounds and initial values to tune all other parameters.

CLASS Statement

CLASS *variables* **;**

The CLASS statement causes the specified *variables* to be treated as categorical variables in the analysis. These variables enter the analysis not through their values but through levels to which the unique values are mapped. For more information about these mappings, see the section "Levelization of Classification Variables" on page 62.

You can specify only one CLASS statement.

NOTE: All classification levels are padded or truncated to 32 characters.

CODE Statement

CODE < *options* > **;**

The CODE statement writes SAS DATA step code for computing predicted values of the fitted model to a file or to a table. To score new data, you can then include the file in a DATA step, or you can specify the table in the **runCodeTable** action in the **dataStep** action set (for more information, see *SAS Viya: System Programming Guide*).

Table 34.3 summarizes the *options* available in the CODE statement.

Table 34.3 CODE Statement Options

Option	Description
COMMENT	Adds comments to the generated code
FILE=	Names the file in which to save the generated code
FORMATWIDTH=	Specifies the numeric format width for the regression coefficients
INDENTSIZE=	Specifies the number of spaces to indent the generated code
LABELID=	Specifies a number used to construct names and labels
LINESIZE=	Specifies the line size for the generated code
NOTRIM	Compares formatted values, including blank padding
OUT=	Names an output table in which to save the generated code

For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

CROSSVALIDATION Statement

CROSSVALIDATION < *options* > **;**

The CROSSVALIDATION statement performs *k*-fold cross validation to find the average estimated validation error. You cannot specify this statement if you specify either the AUTOTUNE statement or the PARTITION statement. **NOTE:** The CROSSVALIDATION statement does not support any pruning method. If you specify this statement, you must also disable pruning by specifying the OFF option in the PRUNE statement.

You can specify the following *options*:

KFOLD=*number*
specifies the number of partition folds in the cross validation process, where *number* is between 2 and 20, inclusive. By default, KFOLD=5.

NOPARALLEL
specifies that *k*-fold cross validation not be run in parallel. By default, the process runs in parallel.

NSUBSESSIONWORKERS=*number*
specifies the number of worker nodes to use in parallel subsessions. If you omit this option or if the *number* is 0, the number of worker nodes is determined automatically.

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC TREESPLIT treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1.

GROW Statement

GROW *criterion* **<(***options***)> ;**

The GROW statement specifies the *criterion* by which to split a parent node into child nodes. As it grows the tree, PROC TREESPLIT calculates the specified *criterion* for each predictor variable and then splits on the predictor variable that optimizes the specified *criterion*.

For categorical responses, the available *criteria* are CHAID, CHISQUARE, ENTROPY, GINI, and IGR; the default is IGR. For continuous responses, the available *criteria* are CHAID, FTEST, and RSS; the default is RSS.

For either categorical or continuous responses, you can specify the following *criterion*:

CHAID <(*options***)>**
for categorical predictor variables, CHAID uses the value (as specified in the ALPHA= option) of a chi-square statistic (for a classification tree) or an F statistic (for a regression tree) to merge similar levels of the predictor variable until the number of children in the proposed split reaches the number that you specify in the MAXBRANCH= option. The p-values for the final split determine the variable on which to split.

For continuous predictor variables, CHAID chooses the best single split until the number of children in the proposed split reaches the value that you specify in the MAXBRANCH= option.

You can specify the following *options*:

ALPHA=*value*
specifies the maximum p-value for a split to be considered.

By default, ALPHA=0.3.

BONFERRONI
requests a Bonferroni adjustment to the p-value for a variable after the split has been determined.

By default, no adjustment is made.

For categorical responses only, you can specify the following *criteria*:

CHISQUARE < (*options*) >
uses a chi-square statistic to split each variable and then uses the *p*-values that correspond to the resulting splits to determine the splitting variable.

You can specify the following *options*:

ALPHA=*value*
specifies the maximum *p*-value for a split to be considered.

By default, ALPHA=0.3.

BONFERRONI
requests a Bonferroni adjustment to the *p*-value for a variable after the split has been determined.

By default, no adjustment is made.

ENTROPY < *option* >

GAIN < *option* >
uses the gain in information (decrease in entropy) to split each variable and then to determine the split. You can specify the following *option*:

MINENTROPY=*number*

MINGAIN=*number*
specifies the minimum gain value to validate a split.

GINI
uses the decrease in the Gini index to split each variable and then to determine the split.

IGR
uses the entropy metric to split each variable and then uses the information gain ratio to determine the split.

The default *criterion* for categorical responses is IGR.

For continuous responses only, you can specify the following *criteria*:

FTEST < (*options*) >
uses an *F* statistic to split each variable and then uses the resulting *p*-value to determine the split variable.

You can specify the following *options*:

ALPHA=*value*
specifies the maximum *p*-value for a split to be considered.

By default, ALPHA=0.3.

BONFERRONI
requests a Bonferroni adjustment to the *p*-value for a variable after the split has been determined.

By default, no adjustment is made.

RSS

VARIANCE

uses the change in response variance to split each variable and then to determine the split.

The default *criterion* for continuous responses is RSS.

You can tune the *criterion* by using the AUTOTUNE statement.

MITIGATEBIAS Statement

MITIGATEBIAS SENSITIVEVAR=*variable* **PREDICTEDVARS=(***variable-names***) PREDICTEDEVENTS=***"event-list"* < *options* > **;**

The MITIGATEBIAS statement enables PROC TREESPLIT to iteratively train a model while minimizing the bias metric that you specify. To use this statement, you must also specify the SAVESTATE statement and a categorical response (target) variable. You cannot also specify the AUTOTUNE statement, the CROSSVALIDATION statement, or the KFOLD= suboption in the PRUNE statement.

You must specify the following options:

PREDICTEDEVENTS="*event-list***"**

PEVENTS="*event-list***"**

specifies the events that correspond to each variable in the PREDICTEDVARS= option. You must specify the PREDICTEDEVENTS= and PREDICTEDVARS= options with the same number of items in the same order. Items in the *event-list* must be separated by the delimiter that you specify in the DELIMETER= option.

PREDICTEDVARS=(*variable-names***)**

PVARS=(*variable-names***)**

specifies the names of the variables that contain the posterior probability for each level in model prediction that corresponds to the response (target) variable. You must specify the PREDICTEDVARS= and PREDICTEDEVENTS= options with the same number of items in the same order. Duplicate variables are not allowed.

SENSITIVEVAR=*variable*

specifies the sensitive variable to use in order to reduce the value of the bias measurement that you specify in the BIASMETRIC= option.

You can also specify the following *options*:

BIASMETRIC=*bias-metric*

specifies the type of bias measurement. You can specify the following *bias-metrics*:

DEMOGRAPHICPARITY specifies demographic parity as the bias measurement.

EQUALIZEDODDS specifies equalized odds as the bias measurement.

EQUALOPPORTUNITY specifies equal opportunity as the bias measurement.

PREDICTIVEPARITY specifies predictive parity as the bias measurement.

By default, BIASMETRIC=DEMOGRAPHICPARITY.

BOUND=*number*
specifies the bound value for the exponentiated gradient reduction algorithm.

By default, BOUND=100.

DELIMITER="*character***"**
DLM="*character***"**
specifies the delimiter to be used to separate events that you specify in the PREDICTEDEVENTS= option. A delimiter is used when event names contain embedded spaces (such as "Fuel Oil") or special characters (such as ";" or "*"). You must use quotation marks around *character*. You can specify only one delimiter; combinations of delimiters are not supported. The valid values of the DELIMITER= option are " " (space), ";" (semicolon), "*" (asterisk), "." (period), and "," (comma).

By default, DELIMITER=" " (space).

If you specify a delimiter other than " " (space), PROC TREESPLIT treats any spaces (including empty spaces) as valid characters. You are responsible for mapping events correctly in order to obtain correct results.

LEARNINGRATE=*number*
specifies the step size to use in updating the exponentiated gradient reduction algorithm.

By default, LEARNINGRATE=0.01.

LOGLEVEL=0 | 1 | 2
specifies the level of log information to print.

0 prints only warnings and errors.

1 prints some notes.

2 prints notes for each iteration.

By default, LOGLEVEL=1.

MAXITER=*number*
specifies the maximum number of iterations to run the exponentiated gradient reduction algorithm.

By default, MAXITER=10.

SEED=*number*
specifies the seed for the pseudorandom number generator. By default, the random number stream is based on the time of day from the computer's clock. A 0 or negative seed value also results in random number streams that are based on the time of day from the computer's clock. If you want a reproducible random number sequence between runs, specify a value greater than 0.

By default, SEED=0.

TARGETEVENT="*event***"**
specifies the formatted value of the response (target) variable that represents the event of interest.

By default, *event* is the first level that you specify in the PREDICTEDEVENTS= option.

TOLERANCE=*number*
specifies the parity constraint violation tolerance. If you set *number* to 0, PROC TREESPLIT trains for the maximum number of iterations, which you specify in the MAXITER= option.

By default, TOLERANCE=0.005.

TUNEBOUND
specifies that the bound value must be tuned.

MODEL Statement

MODEL *response* **=** *variable* **;**

The MODEL statement causes PROC TREESPLIT to create a tree model by using *response* as the response variable and one or more *variables* as predictors. By default, *variables* are treated as a continuous predictors if they are numeric variables, or as categorical variables if they also appear in a CLASS statement.

NOTE: Specifying a character variable in a MODEL statement without previously declaring it in a CLASS statement results in an error.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *option* > **;**

The OUTPUT statement creates an output data table that contains the results of PROC TREESPLIT.

You must specify the following argument:

OUT=*libref.data-table*
names the output data table for PROC TREESPLIT to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1783.

data-table specifies the name of the output data table.

You can also specify the following *options*:

COPYVAR=*variable*
COPYVARS=(*variables***)**
lists one or more variables from the input data table to be transferred to the output data table.

ROLE<=*name*>
generates a numeric variable that indicates the role played by each observation in fitting the model. By default, the variable is named _ROLE_. You can add an optional *=name* to change the name of this generated variable. For each observation, the interpretation of this variable is shown in Table 34.4.

Table 34.4 Role Interpretation

Value	Observation Role
0	Not used
1	Training
2	Validation
3	Testing

If you do not partition the input data by using a PARTITION statement, then the value of the role variable is 1 for all observations.

PARTITION Statement

PARTITION *partition-option* **;**

The PARTITION statement specifies how observations in the input data set are logically partitioned into disjoint subsets for model training, validation, and testing. For more information, see the section "Using Validation and Test Data" on page 101 in Chapter 2, "Shared Concepts." Either you can designate a variable in the input data table and a set of formatted values of that variable to determine the role of each observation, or you can specify proportions to use for randomly assigning observations to each role.

You must specify exactly one of the following *partition-options*:

FRACTION(<TEST=*fraction***> <VALIDATE=***fraction***> <SEED=***number***>)**
randomly assigns specified proportions of the observations in the input data table to the roles. You specify the proportions for testing and validation by using the TEST= and VALIDATE= suboptions. If you specify both the TEST= and VALIDATE= suboptions, then the sum of the specified fractions must be less than 1 and the remaining fraction is the proportion of the observations assigned to the training role. The SEED= option specifies an integer that is used to start the pseudorandom number generator for random partitioning of data for training, testing, and validation. If you do not specify SEED=*number* or if *number* is less than or equal to 0, the seed is generated by reading the time of day from the computer's clock.

ROLE=*variable* **(<TEST='***value***'> <TRAIN='***value***'> <VALIDATE='***value***'>)**
ROLEVAR=*variable* **(<TEST='***value***'> <TRAIN='***value***'> <VALIDATE='***value***'>)**
names the *variable* in the input data table whose values are used to assign roles to each observation. This *variable* cannot also appear as an analysis variable in other statements or options. The TEST=, TRAIN=, and VALIDATE= suboptions specify the formatted values of this variable that are used to assign observation roles. If you do not specify the TRAIN= suboption, then all observations whose role is not determined by the TEST= or VALIDATE= suboption are assigned to the training role.

PRUNE Statement

PRUNE < *prune-method* >< (*prune-options*) > **;**

The PRUNE statement specifies the pruning method and related options.

You can specify the following *prune-methods*. The default *prune-method* is COSTCOMPLEXITY.

C45 < (CONFIDENCE=*confidence-level***) >**
requests C4.5 pruning (Quinlan 1993), which is based on the upper confidence limit for the error rate. For more information, see the section "Pruning" on page 1833. This pruning method is available only for classification trees (which have a categorical response). PROC TREESPLIT uses the error rate from the training data only.

You can specify the following *prune-option*:

CONFIDENCE=*confidence-level*
specifies the pruning confidence level, which must be a positive number in the range of [0, 1]. The default confidence level is 0.25.

COSTCOMPLEXITY < (*prune-options***) >**
CC < (*prune-options***) >**
requests cost-complexity pruning (Breiman et al. 1984; Quinlan 1987; Zhang and Singer 2010). You can specify this pruning method both for classification trees (which have a categorical response) and for regression trees (which have a continuous response).

By default, cost-complexity pruning uses k-fold cross validation. If you specify a validation data set by using the PARTITION statement, PROC TREESPLIT uses the validation data for subtree selection and does not perform k-fold cross validation.

You can specify one the following *prune-options*:

ALPHA=*number*
selects the subtree whose cost-complexity value α is equal to *number* instead of using k-fold cross validation. You cannot specify this option with either the KFOLD= or the LEAVES= options.

KFOLD=*number*
specifies the *number* of folds for k-fold cross validation. This option is ignored if you specify the PARTITION statement. You can specify this option and the LEAVES=SE value at the same time.

By default, KFOLD=10.

LEAVES=*number* | **ALL** | **SE**
selects the subtree according to one of the following values:

number	selects the subtree that has the *number* of leaves, or the subtree whose number of leaves is less than and closest to *number* if no subtree with exactly *number* of leaves exists, instead of using k-fold cross validation.
ALL	selects the largest tree after removing splits that do not improve the error instead of using k-fold cross validation.

SE selects the subtree by performing *k*-fold cross validation and using Breiman's 1-SE rule instead of minimum error rate. You can specify this value and the KFOLD= option at the same time.

OFF

NONE

turns off pruning completely. No pruning is performed, and no pruning plots are generated.

REDUCEDERROR <(*prune-options***)>**

REP <(*prune-options***)>**

requests reduced-error pruning (Quinlan 1986). Reduced-error pruning has two stages: subtree sequence generation and subtree selection. The validation data are used for both stages. The PARTITION statement is required. For more information, see the section "Pruning" on page 1833.

PROC TREESPLIT generates a pruning plot that shows the requested error metric as a function of the number of leaves in the subtree.

You can specify the following *prune-options*:

LEAVES=*number* **| ALL**

selects the subtree that has the requested *number* of leaves, or if no subtree with exactly that *number* of leaves is available, selects the subtree whose number of leaves is less than and closest to *number*. LEAVES=ALL selects the largest tree after removing splits that do not improve the error.

By default, PRUNE=COSTCOMPLEXITY.

SAVESTATE Statement

SAVESTATE RSTORE=*libref.data-table* **;**

The SAVESTATE statement creates an analytic store for the model and saves it as a binary object in a data table. You can use the analytic store in the ASTORE procedure to score new data. For more information, see Chapter 4, "ASTORE Procedure" (*SAS Viya: Machine Learning Procedures*).

You must specify the following option:

RSTORE=*libref.data-table*

specifies a data table in which to save the analytic store for the model. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1783.

VIICODE Statement

VIICODE < *options* > **;**

The VIICODE statement writes SAS DATA step code to a file or to a catalog entry. The SAS DATA step code creates new variables on the basis of the detected variable interactions.

You can specify the following *options* in addition to all options in the CODE statement. For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

ADD
requests that the newly created variables be of the form $V + W$.

LIMIT=*number*
specifies the maximum *number* of new variables to create. By default, LIMIT=200.

MISS
requests that the generated code handle missing values.

MULTIPLY
requests that the newly created variables be of the form $V \times W$.

SUBTRACT
requests that the newly created variables be of the form $V - W$.

THRESHOLD=*number*
requests that interactions with an importance less than *number* times the maximum interaction importance be ignored, where *number* must be between 0 and 1. By default, THRESHOLD=0.0001.

If the VII= option is not specified in the PROC TREESPLIT statement, then the VIICODE statement is ignored. For more information about variable interaction importance, see the section "Variable Interaction Importance" on page 1840.

WEIGHT Statement

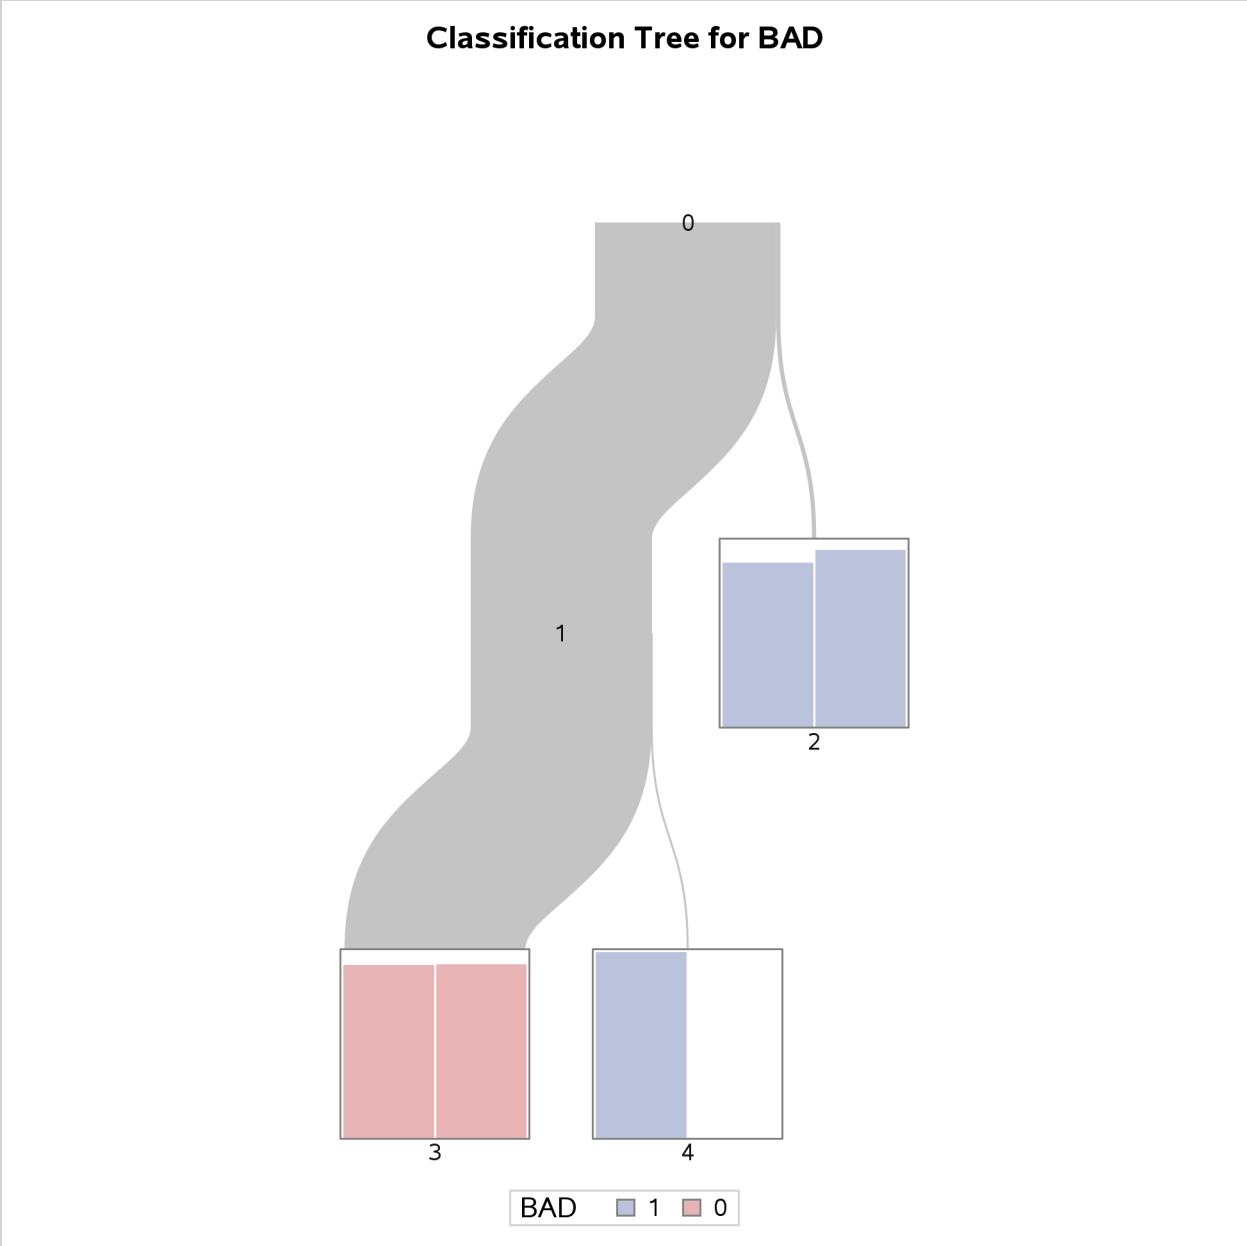
WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

Details: TREESPLIT Procedure

Building a Decision Tree

Algorithms for building a decision tree use the training data to split the predictor space (the set of all possible combinations of values of the predictor variables) into nonoverlapping regions. These regions correspond to the terminal nodes of the tree, which are also known as leaves.



The splitting is done by recursive partitioning, starting with all the observations, which are represented by the node at the top of the tree. The algorithm splits this parent node into two or more child nodes in such a way that the values (or levels) of the response variable within each child region are as similar as possible. The splitting process is then repeated for each of the child nodes, and the recursion continues until a stopping criterion is satisfied. At that point, the tree is considered to be fully built (grown).

At each step, the split is determined by finding the best predictor variable and the best split value (or possibly a set of split values when the value of the MAXBRANCH= option is greater than 2) that optimize a specified criterion in the response variable across the child nodes to which the parent node is split. For more information about the splitting methods available in the TREESPLIT procedure, see the section "Splitting Criteria" on page 1829.

Each region, which corresponds to a terminal node, is described by a set of splitting rules that determine the observations that are assigned to the region. During scoring these rules are applied to determine the predicted values for new observations. For classification trees, the predicted value for a scored observation is the level of the response variable that is most common in the region in which the scored observation exists. For regression trees, the predicted value for a scored observation is the mean of the response variable across training observations values in the region in which the scored observation exists.

Figure 34.8, Figure 34.9, and Figure 34.10 illustrate this process. Figure 34.8 shows a classification tree of depth 2.

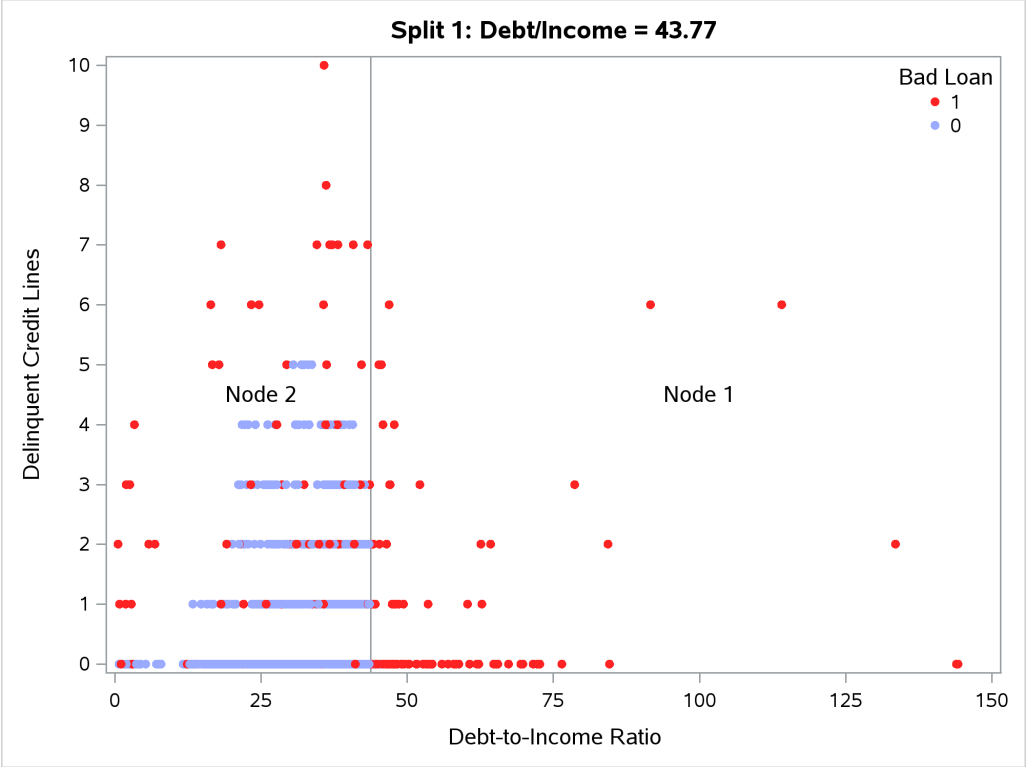


Figure 34.8 First Two Splits for the mylib.hmeq Data Table

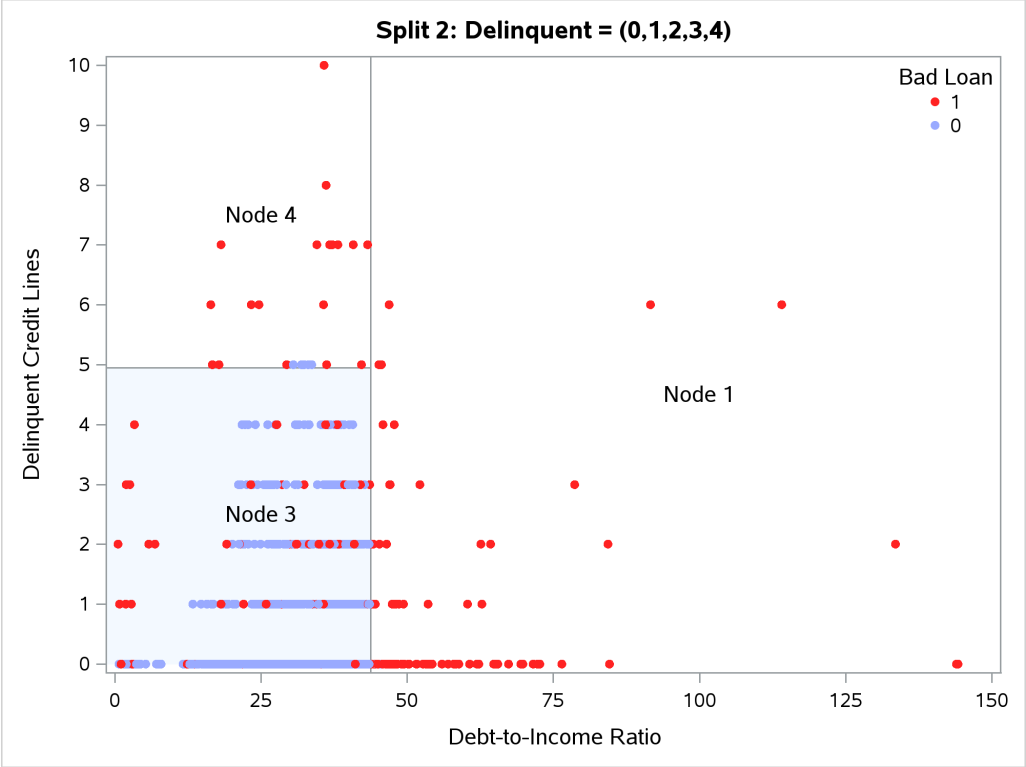
All 4,172 observations in the data are initially assigned to node 0 at the top of the tree, which represents the entire predictor space. PROC TREESPLIT splits this space into two nonoverlapping regions, represented by node 1 and node 2. PROC TREESPLIT determines that the predictor variable and its split value that optimize the growing criterion across the child nodes are Debtinc and 43.77156, respectively. This split variable and split value constitute the splitting rule for node 0. Observations in which Debtinc $<$ 43.77156 are assigned to node 2, and observations in which Debtinc $\geq$ 43.77156 are assigned to node 1.

Figure 34.9 presents a scatter plot of the predictor space for the splitting rule for node 0. The split of the variable Debtinc divides the predictor space into node 1 and node 2; these nodes are represented by the two rectangular regions, which have different ratios of events to nonevents for the response variable.

Figure 34.9 Scatter Plot of the Predictor Space for the First Split



Next, the algorithm determines the splitting rule for node 2 and splits the region that is represented by node 2 into two nonoverlapping regions, represented by node 3 and node 4. PROC TREESPLIT chooses the variable Delinq and its values to optimize the growing criterion. Observations in which values of the categorical predictor variable Delinq are equal to 0, 1, 2, 3, or 4 are assigned to node 3, and observations in which the values of Delinq are equal to 5, 6, 7, 8, or 10 are assigned to node 4.

Figure 34.10 presents a scatter plot of the predictor space for the splitting rule of node 2. The split of the variable Delinq further divides the predictor space of node 2 into two regions: node 3 and node 4, which have different ratios of events to nonevents for the response variable.

Node 3 has a very high proportion of observations for which Bad is equal to 0. In contrast, Bad is equal to 1 for almost all the observations in node 4.

Note that several observations have the same values for Debtinc or Delinq, so the scatter plot gives the perception of fewer observations than there actually are.

Figure 34.10 Scatter Plot of the Predictor Space for the Second Split

This example illustrates recursive binary splitting, in which each parent node is split into two child nodes. By default, the TREESPLIT procedure creates at most two child nodes per split. You can use the MAXBRANCH= option to specify the maximum possible number of child nodes you want per split of a parent node. Based on the splitting criterion you specify, PROC TREESPLIT determines the best number of child nodes up to the value of the MAXBRANCH= option.

Splitting Criteria

The goal of recursive partitioning, as described in the section "Building a Decision Tree" on page 1826, is to subdivide the predictor space in such a way that the values of the response variable for the observations within a terminal node are similar as possible. The TREESPLIT procedure provides two types of criteria for splitting a parent node: criteria that maximize a decrease in node impurity, as defined by an impurity function, and criteria that are defined by a statistical test. You can specify the criterion in the GROW statement. If you do not specify a criterion in the GROW statement, the entropy criterion is used for classification trees and the RSS criterion is used for regression trees.

Criteria Based on Impurity

The entropy, Gini index, and RSS criteria decrease impurity. The impurity of a parent node τ is defined as $i(\tau)$, a nonnegative number that is equal to zero for a pure node (a node in which all the observations have the same value of the response variable). Nodes in which the observations have very different values of the response variable have a large impurity.

The TREESPLIT procedure selects the best split variable and the best split value to produce the highest reduction in impurity,

$$\Delta i(s,\tau) = i(\tau) - \sum_{b=1}^{B} p(\tau_b|\tau) i(\tau_b)$$

where τ_b denotes the bth child node, $p(\tau_b|\tau)$ is the proportion of observations in τ that are assigned to τ_b, and B is the number of branches after splitting τ.

Impurity Reduction Criteria for Classification Trees

The following impurity reduction criteria available for classification trees are based on different impurity functions $i(\tau)$:

- Entropy criterion: The entropy impurity of node τ is defined as

  $$i(\tau) = -\sum_{j=1}^{J} p_j \log_2 p_j$$

  where p_j is the proportion of observations that have the jth response value.

- Gini index criterion: This criterion defines $i(\tau)$ as the Gini index that corresponds to the ASE of a class response and is given by

  $$i(\tau) = -\sum_{j=1}^{J} p_j^2$$

  For more information, see Hastie, Tibshirani, and Friedman (2009).

Impurity Reduction Criterion for Regression Trees

Only one impurity reduction criterion, the RSS criterion, is available for regression trees. This criterion, also called the ANOVA criterion, defines $i(\tau)$ as the residual sum of squares,

$$i(\tau) = \frac{1}{N(\tau)} \sum_{i=1}^{N(\tau)} (Y_i - \overline{Y})^2$$

where $N(\tau)$ is the number of observations in τ, Y_i is the response value of observation i, and $\overline{Y}$ is the average response of the observations in τ.

Criteria Based on Statistical Test

The chi-square, F test, and CHAID criteria are defined by statistical tests. These criteria calculate the worth of a split by testing for a significant difference in the response variable across the branches that are defined by a split. The worth is defined as $-\log(p)$, where p is the p-value of the test. You can adjust the p-values for these criteria by specifying the BONFERRONI option in the GROW statement.

Statistical Criterion for Classification Trees

In the chi-square criterion for categorical response variables, the worth is based on the p-value for the Pearson chi-square test, which compares the frequencies of the levels of the response across the child nodes.

Statistical Criterion for Regression Trees

In the F-test criterion for continuous response variables, the worth is based on the F test for the null hypothesis that the means of the response values are identical across the child nodes. The test statistic is

$$F = \frac{\mathrm{SS}_{\mathrm{between}}/(B-1)}{\mathrm{SS}_{\mathrm{within}}/(N(\tau)-B)}$$

where

$$\mathrm{SS}_{\mathrm{between}} = \sum_{b=1}^{B} N(\tau_b)(\overline{Y}(\tau_b) - \overline{Y}(\tau))^2$$

$$\mathrm{SS}_{\mathrm{within}} = \sum_{b=1}^{B} \sum_{i=1}^{N(\tau_b)} (Y_{bi}) - \overline{Y}(\tau_b))^2$$

Statistical Criterion for Both Classification and Regression Trees

Available for both categorical and continuous response variables, CHAID, first described by Kass (1980), is an approach that regards every possible split as representing a test. CHAID tests the hypothesis of no association between the values of the response (target) variable and the branches of a node. The Bonferroni adjusted probability is defined as $m\alpha$, where α is the significance level of a test and m is the number of independent tests.

Splitting Nominal Values

Methods

PROC TREESPLIT evaluates a nominal variable in a node in one of three ways:

- enumerate: evaluate all possible splits
- sort: evaluate splits that preserve a sort order of the values
- reject: reject the variable without considering any splits

The number of categories K that are present in a node of an input variable X determines the choice. A different choice might be used for a different variable in the same node, or for the same variable in a different node because K might be different in different nodes. Let s denote the value of the SORT= suboption of the NOMSEARCH option, and let c denote the value of the MAXCATEGORIES= suboption. The following rules determine which choice PROC TREESPLIT uses:

- Enumerate when $K \leq \min(15, s, c)$.
- Sort when $\min(s, 16) \leq K < c$.
- Reject the variable when $c \leq K$.

The enumerate choice examines all possible splits. The number of splits grows exponentially with the number of categories K.

The sort choice first sorts the categories and then finds the best split that preserves the sort. The sort is on z_k, which is defined as

$$z_k = \frac{\Sigma_{i \text{ in } k}\ g_i + r\bar{g}}{n_k + r}$$

where

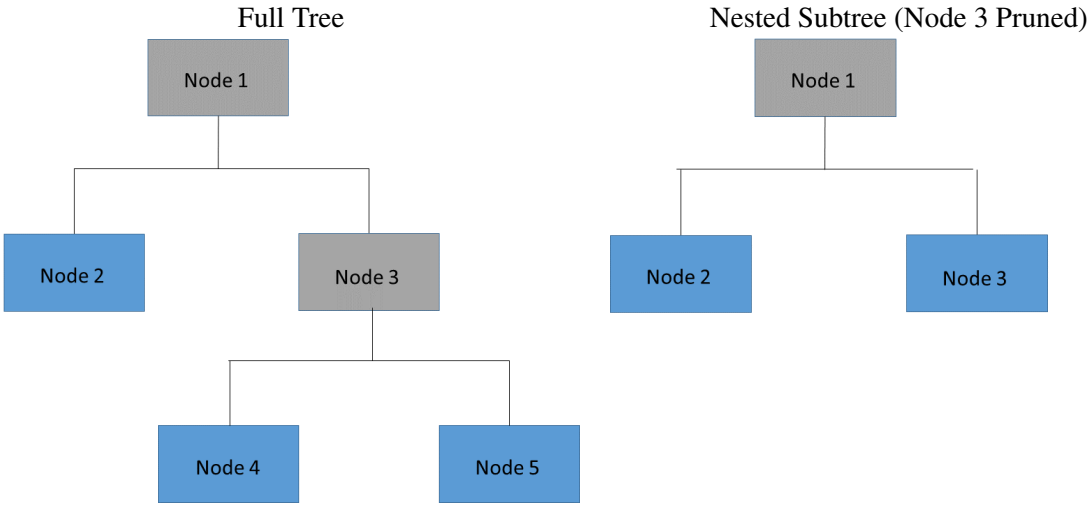
- k is a category
- Σ sums over observations in category k
- g_i is either the interval target value or the majority target class indicator
- r is the NOMSEARCH(SHRINKAGE=) suboption value
- $\bar{g}$ is the average of g_i across all categories
- n_k is the number of observations in category k

For a binary or nominal target, g_i is 1 if observation i is of the majority class in the node, and 0 otherwise.

Risks of Many Categories

Algorithms that search for a splitting rule preferentially select nominal inputs that contain lots of categories because of the large number of ways the categories can be combined to match noise in the training data. Irrelevant nominal inputs commonly supplant predictive inputs, creating spurious splits that can degrade accuracy on new data.

Memory depletion is another risk, especially in the output model table. The branch assignment of every category is stored. The OUTMODEL= table contains a row for every node in the model and a column for every category assigned to that node. The table contains enough columns to accommodate the node with the most category assignments, even if only one node requires it. A single nominal input that contains lots of categories can create a model so large as to exhaust memory. The MAXCATEGORIES=*number* suboption prevents splitting a node with a nominal input that has more than *number* categories in the node. An input with more than *number* categories in one node and fewer than *number* categories in a second node is eligible for splitting the second node but not the first.



Scoring can take noticeably longer when a splitting rules include many categories.

Pruning

The TREESPLIT procedure creates a classification or regression tree by first growing a tree as described in the section "Splitting Criteria" on page 1829. This usually results in a large tree that provides a good fit to the training data. The problem with this tree is its potential for overfitting the data: the tree can be tailored too specifically to the training data and not generalize well to new data. The solution is to find a smaller subtree that results in a low error rate on the validation data.

It is often prohibitively expensive to evaluate the error on all possible subtrees of the full tree. A more practical strategy is to focus on a sequence of nested trees that are obtained by successively pruning leaves from the tree. Figure 34.11 shows an example of pruning in which node 3's leaves (terminal nodes 4 and 5) are removed to create a nested subtree of the full tree. In the nested subtree, node 3 is now a leaf that contains all the observations that were previously in nodes 4 and 5. This process is repeated until only the root node remains.

Figure 34.11 Tree and Pruned Subtree

Many different methods have been proposed for pruning in this manner. These methods address both how to select which nodes to prune to create the sequence of subtrees and how then to select the optimal subtree from this sequence as the final tree. You can use the PRUNE statement in PROC TREESPLIT to specify which pruning method to apply and related options. Several well-known pruning methods, described in this section, are available, and you can override the final selected tree based on your preferences or domain knowledge.

Cost-Complexity Pruning

Cost-complexity pruning is a widely used pruning method that was originally proposed by Breiman et al. (1984). You can request cost-complexity pruning for either a categorical or continuous response variable by specifying the following statement:

```
prune costcomplexity;
```

The cost-complexity pruning method helps prevent overfitting by making a trade-off between the complexity (size) of a tree and the error rate Thus large trees with a low error rate are penalized in favor of smaller trees.

The cost complexity of a tree T is defined as

$$\mathrm{CC}(T) = \mathrm{R}(T) + \alpha|T|$$

where R(T) represents T's error rate, $|T|$ represents the number of leaves on T, and the complexity parameter α represents the cost of each leaf. For a categorical response variable, the misclassification rate is used for the error rate, R(T); for a continuous response variable, the residual sum of squares (RSS), also called the sum of square errors (SSE), is used for the error rate. Only the training data are used to evaluate cost complexity. Breiman et al. (1984) show that for each value of α, there is a subtree of T that minimizes cost complexity. When $\alpha = 0$, this is the full tree, T_0. As α increases, the corresponding subtree becomes progressively smaller, and the subtrees are in fact nested. Then, at some value of α, the root node has the minimal cost complexity for any α greater than or equal to that value. Because there are a finite number of possible subtrees, each subtree corresponds to an interval of values of α; that is,

$$\begin{aligned}
[0, \alpha_1) &= \text{interval where } T_0 \text{ (the full tree) has minimal cost complexity} \\
[\alpha_1, \alpha_2) &= \text{interval where } T_1 \text{ has minimal cost complexity} \\
&\vdots \\
[\alpha_m, \infty) &= \text{interval where } T_m \text{ (the root node) has minimal cost complexity}
\end{aligned}$$

PROC TREESPLIT uses weakest-link pruning, as described by Breiman et al. (1984), to create the sequence of $\alpha_1, \ldots, \alpha_m$ values and the corresponding sequence of nested subtrees, $T_1, \ldots, T_m$.

Finding the optimal subtree from this sequence is then a question of determining the optimal value of the complexity parameter α. This is performed either by using the validation partition (when you use the PARTITION statement to reserve a validation holdout sample) or by using cross validation. In the first case, the subtree in the pruning sequence that has the lowest validation error rate is selected as the final tree. When there is no validation partition, k-fold cross validation can be applied to cost-complexity pruning to select a subtree that generalizes well and does not overfit the training data (Breiman et al. 1984; Zhang and Singer 2010). The algorithm proceeds as follows after creating the sequence of subtrees and α values by using the entire set of training data as described earlier:

1. Randomly divide the training observations into k approximately equal-sized parts, or folds.
2. Define a sequence of β values as the geometric mean of the endpoints of the $[\alpha_i, \alpha_{i+1})$ intervals (that is, $\beta_i = \sqrt{\alpha_i \times \alpha_{i+1}}$) to represent the intervals.
3. For each of the k folds, hold out the current fold for validation and use the remaining $k - 1$ folds for the training data in the following steps:
   a) Grow a tree as is done using the full training data set with the same splitting criterion.
   b) Using the $\beta_1, \ldots, \beta_m$ values that are calculated in step 2, create a sequence of subtrees for each β_i as described in the pruning steps given earlier, but now using β_i as a fixed value for α and minimizing the cost complexity, CC(T), to select a subtree at each pruning step.
   c) For each β_i, set T_{ij} to be the subtree that has the minimum cost complexity from the sequence for the jth fold.
   d) Calculate the error for each T_{ij} by using the current (jth) fold (the one omitted from the training).

4. Now the error rate can be averaged across folds, and the β_i that has the smallest average error is selected. The tree T_i from pruning the complete training data that corresponds to the selected β_i is the final selected subtree.

Because the k-fold cross validation is done sequentially, the process can take a long time for deep trees or for large amounts of data. Consider using the PARTITION statement for pruning large amounts of data.

The TREESPLIT procedure provides two plots that you can use to tune and evaluate the pruning process: the cost-complexity analysis plot and the cost-complexity pruning plot.

When performing cost-complexity pruning with cross validation (that is, no PARTITION statement is specified), it is recommended that you examine the cost-complexity analysis plot that is created by default. This plot displays the error as a function of the complexity parameters β_i, and it uses a vertical reference line to indicate the β_i that minimizes the error. You can use this plot to examine alternative choices for β_i. For example, you might prefer to select a smaller tree that has only a slightly higher error rate. You can specify LEAVES=SE to use the 1-SE rule developed by Breiman et al. (1984).

When you specify validation data by using the PARTITION statement, the cost-complexity pruning plot displays the error rate $R(T)$ as a function of the number of leaves $|T|$ for both the training and validation data. This plot indicates the final selected tree, the tree with the minimum $R(T)$ for the validation data, by using a vertical reference line. Like the cost-complexity analysis plot that is produced when you perform cross validation, this plot can help you identify a smaller tree that has only a slightly higher validation error rate. For an example of this plot, see Output 34.1.5 in "Example 34.1: Creating a Binary Classification Tree with Validation Data" on page 1856.

You can use the LEAVES= option in the PRUNE statement to select a tree that has a specified number of leaves or fewer if a smaller subtree has the same error.

Alternatively, you can use the ALPHA= option in the PRUNE statement to select a tree that has a specified value of the cost-complexity value α.

The computation of the subtree sequence can take a long time when the MAXDEPTH= option value is large. This will be remedied in a future release.

C4.5 Pruning

Quinlan (1987) first introduced pessimistic pruning as a method of pruning classification trees. In this method, the estimate of the true error rate is increased by using a statistical correction in order to prevent overfitting. C4.5 pruning (Quinlan 1993) evolved from pessimistic pruning to employ an even more pessimistic (that is, higher) estimate of the true error rate. An advantage of methods such as pessimistic and C4.5 pruning is that they enable you to use all the data for training instead of requiring a holdout sample. In C4.5 pruning, the upper confidence limit of the true error rate based on the binomial distribution is used to estimate the error rate. PROC TREESPLIT implements a C4.5 algorithm variant that uses the beta distribution in place of the binomial distribution to estimate the upper confidence limit. This pruning method is available only for categorical response variables and it uses only training data for tree pruning. It is implemented by the following statement:

```
prune C45;
```

The C4.5 pruning method follows these steps:

1. Grow a tree from the training data table, and call this full, unpruned tree T_0.

2. Set $i = 0$, and do the following until T_i is only the root node:

   a) For each leaf (terminal node) in the tree T_i, solve the following equation for p_l (which is the adjusted prediction error rate for leaf l):

   $$\alpha = 1 - \frac{\Gamma(N_l + 1)}{\Gamma(F_l + 1)\,\Gamma(N_l - F_l)} \int_0^{p_l} \nu^{F_l} (1 - \nu)^{N_l - F_l + 1}\, \mathrm{d}\nu$$

   Here the confidence level α is the value of the CONFIDENCE= option in the PRUNE statement, F_l is the number of failures (misclassified observations) at leaf l, N_l is the number of observations at leaf l, and the function $\Gamma(x)$ is defined as

   $$\Gamma(x) = \int_0^{\infty} \nu^{x-1} e^{-\nu} \mathrm{d}\nu$$

   b) Given these values of p_l, use the following formula for the prediction error E_i of tree T_i:

   $$E_i = \sum_{l \in T_i} N_l\, p_l$$

   c) For each node in tree T_i that has only leaves as children, create a candidate subtree by pruning those leaves.

   d) For each candidate subtree, use the equations from steps 2 and 3 to calculate its prediction error. Then select the candidate subtree that has the largest decrease (or smallest increase) in prediction error, E_i. Let this be the next subtree in the sequence, T_{i+1}.

   e) Set $i = i + 1$

3. Calculate the change in error between each pair of consecutive subtrees, $\Delta_i = E_i - E_{i-1}$ for each $i = 1, \ldots, m$.

4. Find the smallest integer j such that $\Delta_j > 0$.

5. Select the subtree T_{j-1} as the final subtree.

Reduced-Error Pruning

Quinlan's reduced-error pruning (1987) performs pruning and subtree selection based on minimizing the error rate in the validation partition at each pruning step and then in the overall subtree sequence. The error rate is based on the misclassification rate for a categorical response variable and on the ASE for a continuous response. The following PRUNE statement implements reduced-error pruning:

```
prune reducederror;
```

Reduced-error pruning creates a sequence of subtrees from the largest tree, T_0, to the root node, T_m. The subtree that has the smallest validation error is then selected as the final subtree. Pruning could be stopped as soon as the error begins to increase in the validation data as originally described by Quinlan; continuing to prune to create a subtree sequence back to the root node enables you to select a smaller tree that still has an acceptable error rate, as discussed in the next section.

User Specification of Subtree

You might want to select a different tree from the one selected by default when you use cost-complexity or reduced-error pruning to create the sequence of subtrees. For example, you might have a subtree that has a slightly larger error but is smaller, and thus simpler, than the subtree that has the minimum error according to reduced-error pruning. You can override the selected subtree and instead select the subtree that has *n* leaves and was created by cost-complexity or reduced-error pruning, where *n* is specified in the LEAVES= option in the PRUNE statement. In addition, if you are using cost-complexity pruning, you can override the selected subtree by using the ALPHA= option in the PRUNE statement.

Alternatively, you might want to select the largest tree that is created in one of the following ways:

- Specify LEAVES=ALL in the PRUNE statement to still see the statistics for the sequence of subtrees that are created according to the specified pruning error measure, even though the largest (unpruned) tree is selected as the final subtree.
- Specify the following statement to select the largest tree with no pruning performed:

  ```
  prune none;
  ```

  Statistics are not calculated and plots are not created for a sequence of subtrees.

Scoring

After you create a tree model, you can apply it to training or test data for model assessment or to new data for making predictions. The process of applying a model to a data table is called *scoring*. You can score data as described in the following sections.

Scoring the Input Data Table

Usually, the purpose of scoring training data is to diagnose the model. The training data table is the data table that you specify with the DATA= option. To score the training data, use the OUTPUT statement to create an output data table that contains one observation for each observation in the training data. You can specify the output data table by using the OUT= option in the OUTPUT statement.

In the following example, the input data table (mylib.hmeq) is scored after the tree model has been created:

```
proc treesplit data=mylib.hmeq;
   class Bad Delinq Derog Job Ninq Reason;
   model Bad = Delinq Derog Job Ninq Reason;
   output out=mylib.scored;
run;
```

For classification trees, the scored data table also contains one new variable for each level of the response variable. These new variables have the prefix “P_”; for all observations in the same leaf, these new variables represent the proportion of the training observations in that leaf that have that particular response level. For example, if the name of the categorical response variable is Color and it has two levels, `'Blue'` and `'Green'`, then the scored data table contains the variable P_ColorBlue (which provides the proportion

of training data in this leaf that have the response level `'Blue'`) and the variable P_ColorGreen (which provides the proportion of training data in this leaf that have the response level `'Green'`).

For regression trees, the scored data table contains exactly one new variable with the prefix "P_", which represents the average value of the response variable for all observations in the same leaf. For example, if the name of the continuous response variable is logSalary, then the scored data table contains one new variable, P_logSalary, which represents the average value of the response variable logSalary in the training data for observations in the same leaf.

Scoring Using DATA Step Code

You can use the CODE statement to generate SAS DATA step code that you can use to score new data. The following example uses PROC TREESPLIT to produce SAS DATA step code:

```
proc treesplit data=mylib.hmeq;
   class Bad Delinq Derog Job Ninq Reason;
   model Bad = Delinq Derog Job Ninq Reason;
   code file="treesplit_data_step.sas";
run;
```

Measures of Model Fit

The TREESPLIT procedure measures model fit based on the misclassification rate for classification trees or the average square error for regression trees, as follows:

- The misclassification rate is calculated from the number of incorrectly predicted observations:

$$\text{Misc} = \frac{1}{N_0} \sum \begin{cases} 0 & \text{if prediction is correct} \\ 1 & \text{otherwise} \end{cases}$$

- The average square error (ASE) for regression trees is defined as

$$\text{ASE} = \frac{\text{RSS}}{N_0}$$

Variable Importance

A training data table can contain a large number of predictor variables, some of which are useful for predicting the response variable and others of which are not. You can use the TREESPLIT procedure to select the most useful predictor variables on the basis of variable importance (Breiman et al. 1984). (See "Example 34.3: Assessing Variable Importance" on page 1865.) Variable importance is an indication of which predictor variables are the most useful for predicting the response variable.

The most important variables might not be the ones near the top of the tree. The TREESPLIT procedure implements several methods for computing variable importance, which are described in the following subsections. By default, PROC TREESPLIT calculates the variable importance by three methods (count-based, change in the residual sum of square errors, and relative importance), and outputs the results from these variable importance methods in one table. You can request that the TREESPLIT procedure also calculate the variable importance by random branch assignment (RBA) by specifying the RBAIMP option.

Count-Based Importance Method

The count-based variable importance simply counts the number of times in the tree that a particular variable is used in a split.

Residual Sum of Squares (RSS) Importance Method

This method measures variable importance based on the change of RSS when a split is found at a node. The change for variable v is

$$\Delta_d^v = \mathrm{RSS}_d - \sum_i \mathrm{RSS}_i^d$$

where

- d denotes the node
- i denotes the index of a child that this node includes
- RSS_d is the RSS if the node is treated as a leaf
- RSS_i^d is the RSS of the node after it has been split

If the change in RSS is negative (which is possible when you measure the validation set), then the change is set to 0.

The residual sum of squares for regression trees is defined as

$$\mathrm{RSS} = \sum_\lambda \sum_{i \in \lambda} \left(y_i - \hat{y}_\lambda^T \right)^2$$

where

- i is an observation on leaf λ
- y_i is the predicted value of the response variable of observation i

- $\hat{y}_{\lambda}^{T}$ is the actual value of the response variable on leaf λ

The residual sum of squares for classification trees is defined as

$$\mathrm{RSS} = \sum_{\lambda} \sum_{\Phi} N_{\Phi}^{\lambda} \left[\sum_{\tau \neq \Phi} \left(P_{\tau}^{\lambda} \right)^2 + \left(1 - P_{\Phi}^{\lambda} \right)^2 \right]$$

where

- Φ is the actual response level
- N_{Φ}^{λ} is the number of observations on leaf λ that have response level Φ
- P_{τ}^{λ} is the posterior probability for the response level τ on leaf λ
- P_{Φ}^{λ} is the posterior probability for the actual response level Φ on leaf λ

The RSS-based importance for a single variable, v, is then defined as

$$\sum_{d=1}^{D} \Delta_{d}^{v}$$

where D is the total number of nodes in which v was used as the splitting variable.

Relative Variable Importance Method

The relative variable importance metric is a number between 0 and 1, which is calculated in two steps:

1. PROC TREESPLIT finds the maximum RSS-based variable importance.
2. For each variable, PROC TREESPLIT calculates the relative variable importance as the RSS-based importance of this variable divided by the maximum RSS-based importance among all the variables.

The RSS and relative importance are calculated from the validation data. If no validation data exist, they are calculated instead from the training data.

Variable Interaction Importance

In some cases, interactions of variables are of more interest than a single variable. When you specify the VII= option in the PROC TREESPLIT statement, the procedure computes variable interaction importance as follows.

The two-way interaction importance for the variables v and w is

$$\sum_{d,e} \frac{\Delta_{d}^{v} + \Delta_{e}^{w}}{\Delta_{d}^{v}}$$

where

- d and e denote nodes, where node d is the parent of node e

- v and w are variables, where v is the splitting variable for node d and w is the splitting variable for node e
- this summation is across all parent-child node combinations with respect to the variables v and w

The three-way interaction importance for the variables v, w, and x is

$$\sum_{d,e,f} \frac{\Delta_d^v + \Delta_e^w + \Delta_f^x}{\Delta_d^v + \Delta_e^w}$$

where

- d, e, and f denote nodes, where node d is the parent of node e, which is the parent of node f
- v, w, and x are variables, where v is the splitting variable for node d, w is the splitting variable for node e, and x is the splitting variable for node f
- this summation is across all parent-child-grandchild node combinations with respect to the variables v, w, and x

When comparing variable importance values, you should compare a two-way interaction only with another two-way interaction, or a three-way interaction only with another three-way interaction. Comparing a two-way interaction to a three-way interaction is not meaningful, because the values of the importance are not on the same scale.

In addition to calculating the variable interaction importance, you can also generate SAS DATA step code to create interaction variables and save the code to a file by using the VIICODE statement. When you run the generated SAS DATA step code on the original data or on new data, interaction variables are created.

Created interaction variables are of the form $W + V$, $W - V$, or $W \times V$, where the values that are used in the calculations come from the variables whose interactions are determined to be important. The values that are used are as follows:

- For continuous variables, the raw value of the variable is used.
- For categorical variables, the proportion of observations in the training set that is assigned to a specific branch is used.

Random Branch Assignment Importance Method

The random branch assignment (RBA) method computes the importance of an input variable v by comparing how well the data fit the predictions before and after they are modified. Neville and Tan (2014) motivate and introduce the RBA method of variable importance. To modify the predictions, the TREESPLIT procedure replaces all splitting rules that use variable v by a rule that randomly assigns an observation to a branch. The probability of assigning an observation to a branch is proportional to the number of observations that are assigned to the branch in the current data. The current data are the training data when RBA is computed during training. Otherwise, the current data are those being scored on an existing model.

The RBA importance can be expressed mathematically as

$$I_{\mathrm{RBA}}(v) \propto \sum_{i=1}^{n} \mathrm{Loss}(y_i, \ddot{y}_i) - \sum_{i=1}^{n} \mathrm{Loss}(y_i, \hat{y}_i)$$

where $\ddot{y}_i$ is the modified prediction for observation i and $\hat{y}_i$ is the standard prediction.

For an continuous response, PROC TREESPLIT computes the RBA importance of squared error loss. For a categorical response, PROC TREESPLIT uses the misclassification rate as the loss function.

Neville and Tan (2014) motivate and introduce the RBA method of variable importance.

Hyperparameter Tuning

The quality of the predictive model that a machine learning algorithm creates depends on the values for various options that govern the training process; these options are called *hyperparameters*. The default values of these hyperparameters might not be suitable for all applications. In order to reduce the manual effort in adjusting these hyperparameters, you can use the AUTOTUNE statement to identify the best settings for them.

To tune hyperparameters, the AUTOTUNE statement directs the procedure to engage a search method (tuner) that searches for the best possible combination of values of these hyperparameters while trying to minimize or maximize an objective function. The objective function is a validation error or accuracy estimate—for example, MISC (misclassification error) for nominal targets or ASE (average square error) for interval targets. The tuning process involves multiple evaluations of the objective function (one for each model hyperparameter configuration it evaluates) and might include multiple iterations, depending on the specified search method. The tuning process also requires data partitioning in order to avoid overfitting to training data; models are trained on a training partition and validated on a validation partition to obtain the objective function value for each chosen hyperparameter configuration. The options for data partitioning are described in the next section, followed by descriptions of the default hyperparameter tuning process and determination of sizing for parallel tuning.

Data Partitioning

Each evaluation of the objective function can consist of one or several training and scoring (validation) executions, depending on whether single-partition validation or k-fold cross validation is used. In both cases, the tuner partitions the data unless the PARTITION statement is used (in this case, the tuner does not partition the training data, but instead uses the data roles that are specified in the PARTITION statement for training and validation).

Single-Partition Validation

By default, the tuner uses single-partition validation. In this process, the tuner partitions all the data into two subsets: one subset for model training and one subset for model validation. For each newly generated configuration of hyperparameters, a new model is trained on the training subset and then the validation subset is scored using the trained model to find the resulting objective function value.

The AUTOTUNE statement calls the **`sampling`** action set, which creates the training and validation partitions. The **`stratified`** action in the **`sampling`** action set is used for a target of nominal type (if all target levels can be included in both the training and validation partitions), and the **`srs`** action in the **`sampling`** action

set is used for a target of interval type and for cases in which stratified sampling is not possible. By default, a validation partition of 30% is used and the remaining 70% is used for model training. The validation partition size can be adjusted by specifying the FRACTION= option in the AUTOTUNE statement. For more information about the **sampling** action set, see Chapter 24, "Sampling and Partitioning Action Set" (*SAS Visual Statistics: Programming Guide*).

Cross Validation

If *k*-fold cross validation is specified, the tuner partitions all the data into *k* subsets (folds). For each fold, a new model is trained on all folds except the selected (holdout) fold (that is, it is trained on *k*–1 folds) and then validated using the selected (holdout) fold. The objective function value is averaged over the set of fold validation executions to obtain a single error estimate value. Cross validation is specified using the KFOLD= option in the AUTOTUNE statement.

For efficiency, the cross validation process might be terminated before all *k* folds are evaluated. Cross validation is terminated under the following conditions: the validation score is 2 times worse than the current best score after the first fold, the validation score is 1.75 times worse than the current best score after two folds, or the validation score is 1.5 times worse than the current best score after three or more folds.

Hyperparameter Tuning Process

By default, the tuner chooses the model hyperparameter configurations to evaluate by using a hybrid optimization strategy that is based on a genetic algorithm (GA), which applies principles of natural selection and evolution to find an improved configuration. The tuner performs the following steps:

1. A default model configuration (default values of select model hyperparameters) is evaluated first and designated as Iteration 0. The objective function value is obtained by using either single-partition validation or *k*-fold cross validation and then recorded for comparison.

2. An initial set of hyperparameter configurations, also called a "population," is generated using a technique called Latin hypercube sampling (LHS). Each configuration of hyperparameters in the Latin hypercube sample is evaluated, and the objective function value for each is again recorded for comparison. This set becomes Iteration 1. All or a portion of the sample configurations can be evaluated in parallel, as described in the section "Determining the Number of Parallel Evaluations" on page 1844.

3. The best model configurations from the Iteration 1 are used to generate the next population of model configurations, Iteration 2, which are then evaluated, in parallel when possible (see the section "Determining the Number of Parallel Evaluations" on page 1844). This process is repeated for the remaining iterations, as long as the maximum number of evaluations or the maximum time has not been reached. The default number of iterations is 5, and the default maximum time is 36,000 seconds (10 hours).

4. The best model configuration (the one that minimizes or maximizes the objective function) is reevaluated by executing a single model training and scoring, and information about the model training and scoring for this configuration is returned.

5. All evaluated model configurations are ranked, and the hyperparameter and objective function values of the top 10 configurations are returned in the TunerResults table.

You can specify four alternative search methods: Bayesian, random, LHS, and grid. The preceding steps are performed differently, depending on the search method that you use:

- For the Bayesian search method, the preceding steps are performed in the same sequence, with the following changes. Instead of using genetic operations to generate the new combinations of hyperparameter values, an internal surrogate model is created after the first iteration. This surrogate model is then explored for potential candidate configurations, and the new set of configurations is created and evaluated in parallel. After each iteration, the internal surrogate model is updated with the new data and explored again for new potential configurations.
- For the random, LHS, or grid search method, step 3 in the preceding sequence is eliminated; a single sample of candidate configurations is generated and evaluated in step 2. This single sample of configurations is generated in one of the following ways:
  - randomly, for the random search method
  - by using a Latin hypercube sample, for the LHS search method
  - by creating all possible combinations of hyperparameter levels, for the grid search method. If the VALUELIST= option is specified for any hyperparameter, the levels are taken from that list. Otherwise, the tuner takes the lower bound, the upper bound, and the middle value between the two bounds and uses those values as the grid levels for each hyperparameter. The total number of grid configurations is the product of the numbers of levels for each hyperparameter. If the number of hyperparameters and the number of levels is greater than a very small value, then the total number of combinations can be many hundreds or thousands. If the MAXEVALS= option is specified, the tuner uses it to terminate execution of the grid search method before all grid points are evaluated.

If the tuner had partitioned the data for training and scoring (if the PARTITION statement is not specified), then the final (best) model configuration is trained on all the data and scored on all the data; as a result the final model that is returned and its reported validation score might not match the value that is observed during tuning, when the model was trained to a portion of the data and validated on the remaining validation partition.

Determining the Number of Parallel Evaluations

By default, the number of possible parallel evaluations during step 2 and step 3 (if performed) in the section "Hyperparameter Tuning Process" on page 1843 is determined by the population size for the GA or Bayesian search method or by the sample size for the random or LHS sampling method. The maximum number of parallel evaluations is limited by the total number of worker nodes that are connected to the server divided by the number of worker nodes that are used by the parallel sessions that are created. For example, if the server is configured with 100 worker nodes and four workers are used in the sessions, at most 25 parallel evaluations are performed by default. This limit can be overridden by a factor of 2, resulting in up to 50 parallel evaluations in this example scenario. Because of the data movement that parallel subsessions produce, repeated runs with the same seed can produce different results.

Specifically, the number of parallel evaluations is determined as follows:

1. If you do not specify the number of workers to use in parallel subsessions by using the NSUBSESSIONWORKERS= option in the AUTOTUNE statement, the number of workers is determined using

the size of the data table: NSUBSESSIONWORKERS = 1 + *nDataRows* * *nDataColumns* * 2E–8. If determined on the basis of the data table size, the number of workers in each subsession is fairly aggressively set at one node per 50 million values. The efficiency benefits of tuning in parallel generally outweigh the time savings from distributed training if the data can be managed on fewer nodes. For example, if training a single model on four workers takes 1 minute versus 2 minutes on one worker, then training four models in parallel on one worker each requires only 2 minutes, whereas training four sequential models each on four workers would require 4 minutes.

2. The number of possible parallel evaluations is then determined either as one less than the population size for the GA or Bayesian search method, or as the sampling size for the random or LHS search method.

3. The number of parallel evaluations is then limited by the server configuration:

   - In single-machine mode, if the number of possible parallel evaluations is greater than 4 and not specified in the NPARALLEL= option in the AUTOTUNE statement, it is limited to 4. You can override this limit up to a value of 32 by specifying the NPARALLEL= option (the value of the NPARALLEL= option is reduced if it is greater than 32).
   - In distributed mode, the upper limit for the number of parallel evaluations is calculated as W/n, where W is the number of workers connected to the server and n is the number of workers in the parallel subsessions. You can override this limit by a factor of 2 by specifying the NPARALLEL= option; the new limit is $2W/n$ (the value of the NPARALLEL= option is reduced if it is greater than $2W/n$).

Lookup Table and History Table

Tuning a predictive model often requires multiple runs of a tuning action and various adjustments of the hyperparameter bounds or their initial values. This often means training a large number of model configurations for each new tuning process, some of which might be duplicates of configurations from the previous tuning runs. To avoid rerunning the same configurations, you can use a lookup table, which you specify in the LOOKUPTABLE= option in the AUTOTUNE statement. You can create this lookup table manually, such as by using a DATA step, or you can produce it automatically in any procedure call in which you specify the HISTORYTABLE= option in the AUTOTUNE statement. Before evaluating a new predictive model configuration, the tuner first checks the lookup table for a potential match. The lookup table must contain all the hyperparameter columns and the objective column; if any required columns are not found, the tuner rejects the lookup table. If a matching configuration is found, its objective value is read from the lookup table and the configuration is not evaluated. The tuner matches only the hyperparameter values and ignores all other columns in the lookup table. For convenience, when you do multiple runs of a procedure in which you use autotuning, you can collect the history of all runs in one table by using the APPENDLOOKUP option in the AUTOTUNE statement. This causes the tuner to append all unused configurations from the lookup table to the history table, which can then be used again as the lookup table for the next procedure call in which you use autotuning. It is essential that the lookup table contain only the appropriate data. If any nontuned parameters have changed, or if the data that are used for the predictive model have changed, then the objective values inside the lookup table might no longer be valid for the new tuning process. The tuner is oblivious to any changes in the problem setup between any two runs of the tuning process and will use the objective values from the lookup table as long as the hyperparameter values match the configuration to be evaluated.

You can use the AUTOTUNE statement to tune the following options in the PROC TREESPLIT statement:

- the value of the NUMBIN= option for the number of bins for continuous predictors
- the value of the MAXDEPTH= option for the maximum depth of the decision tree
- the criterion on the GROW statement for how the nodes are split

k-fold Cross Validation

The CROSSVALIDATION statement performs *k*-fold cross validation to assess the accuracy of a model. During cross validation, all data are divided into *k* subsets (folds), where *k* is the value of the KFOLD= option. For each fold, a new model is trained on the (*k*–1) folds and then validated using the selected (holdout) fold. The assessment metrics are then averaged across all the holdout folds. The CROSSVALIDATION statement creates a table that has *k*+1 rows. The first *k* rows contain the assessment metrics for each holdout fold, and the last row contains the average across all the holdout folds. Which metrics the table includes depends on whether the target is nominal or interval. For nominal targets, the table includes the values of square error, mean consequential error, and multiclass log loss. For interval targets, the table includes the values of square error, absolute error, and square logarithmic error.

Determining the Number of Parallel Evaluations

The number of parallel fold evaluations is determined by the following two-step process:

1. The number of worker nodes to use in parallel subsessions is determined as follows:
   a) If you specify a value greater than 0 in the NSUBSESSIONWORKERS= option to indicate the number of workers to use in parallel subsessions, then that value is used for each subsession.
   b) If you do not specify a value in the NSUBSESSIONWORKERS= option, or if you specify a value of 0, then the number of workers for each subsession is the same as the number of workers that are used in the parent session. If the number of workers that are used in the parent session times the number of folds is greater than the number of workers available on the server, then the number of workers for each subsession is reduced to the number of workers on the server divided by the number of folds. The number of workers in each subsession is then increased if necessary, according to the size of the data table, as follows: NSUBSESSIONWORKERS= 1+*Number of Observations***Number of Columns* / 50,000,000 (the number of worker nodes in each subsession is at least one node per 50 million values).
2. The number of parallel evaluations is then limited by the server configuration as follows:
   a) In single-machine mode, if the number of folds is greater than 16, then the number of parallel evaluations is limited to 16. Otherwise, the number of parallel evaluations is equal to the number of folds.
   b) In distributed mode, the upper limit for the number of parallel evaluations is calculated as 2**W*/*n*, where *W* is the number of workers that are connected to the server and *n* is the number of workers in the parallel subsessions.

Bias Mitigation

With the widespread use of AI and machine learning models in decision-making processes, there is concern about the social impacts of these models. Bias can be embedded in both the training data and the trained model, either of which can lead to unfair or biased predictions for certain groups or populations. To reduce bias in the data and models, researchers have developed three main categories of bias mitigation methods:

- Preprocessing methods, which transform the data prior to model training. These methods try to eliminate the correlations between the input features and the sensitive feature while retaining as much information from the input data as possible.
- In-process methods, which consider fairness constraints during the model training process. These methods actively adjust the model parameters during training to create a model that produces fair predictions and classifications.
- Postprocessing methods, which do not directly alter the input data or the model training process. These methods adjust the predictive outputs from the learned models to compensate for the bias in the model.

You can reduce bias in the trained model by specifying the MITIGATEBIAS statement. This statement uses the exponentiated gradient reduction (EGR) algorithm, which is an in-process method of mitigating bias.

Exponentiated Gradient Reduction (EGR) Algorithm

The exponentiated gradient reduction (EGR) algorithm was introduced at ICML 2018 (Agarwal et al. 2018). As an in-process algorithm, it considers fairness constraints during the model training process. The EGR algorithm has three main advantages. First, it is model-agnostic, which means that you can apply it to a wide variety of machine learning models. The EGR algorithm works like a wrapper that is built around existing machine learning models. The wrapper iteratively reweights and possibly relabels the data, and then it trains a new classifier model on the basis of reweighted data in each iteration. By doing so, it reduces the complex optimization problem of training a machine learning model with fairness constraints to a series of standard model training problems without the fairness constraints. Second, the EGR algorithm supports various fairness measurements, such as demographic parity, equal opportunity, and equalized odds. Finally, the algorithm has strong theoretical support in terms of its optimization trade-off between fairness and accuracy. In theory, the EGR algorithm returns solutions that satisfy all the fairness constraints and also achieve the optimal error rate of the best fair solution.

Training a fair machine learning model is in general a nonlinear programming problem. In nonlinear optimization tasks, it is not uncommon to get suboptimal solutions because the constraints are infeasible or because the algorithm is stuck in a local minimum. As with many other machine learning algorithms, the effectiveness of the EGR algorithm depends on many factors, such as the quality of the input data, the selection of fairness constraints, the quality of the machine learning model that it wraps around, and the values of the hyperparameters.

PROC TREESPLIT supports bias mitigation for multilevel nominal target variables and multilevel nominal sensitive variables. Note that when you include a large number of levels in the sensitive variable, the EGR algorithm searches more complex optimization scenarios; this can result in suboptimal solutions. Therefore, the solutions from this algorithm might not always be desirable when the number of levels in the sensitive variable is high. You should review and validate your sensitive variable, training models, and fairness constraints before applying the EGR algorithm.

Fairness Constraints

PROC TREESPLIT supports the following fairness measurements: demographic parity, predictive parity, equal opportunity, and equalized odds. The goal of the EGR algorithm is to bring the fairness metrics of groups as close together as possible, as well as to convert fair machine learning to a sequence of standard cost-sensitive machine learning problems whose solutions yield a randomized classifier with the lowest error rate, subject to the desired constraints. As a result, the EGR algorithm iteratively trains the machine learning models by using different weights to reduce the fairness disparities without significantly increasing the loss of the final machine learning model. For example, when there are two protected groups in the sensitive variable, the fairness constraints that the EGR algorithm requires for demographic parity are as follows:

$$\mu_1^t - \mu_0^t \le c$$
$$\mu_1^t - \mu_0^t \ge -c$$
$$\mu_2^t - \mu_0^t \le c$$
$$\mu_2^t - \mu_0^t \ge -c$$

where μ_1^t is the demographic parity for the first protected group during iteration t; μ_2^t is the demographic parity for the second protected group during iteration t; μ_0^t is the demographic parity for the entire population during iteration t; and c is the predefined violation tolerance threshold.

Exponentiated Gradient Reduction Algorithm Workflow

Two key hyperparameters in the EGR algorithm are specified by the BOUND= option (denoted by B) and the LEARNINGRATE= option (denoted by lr); both are available in the MITIGATEBIAS statement. To derive the fair machine learning algorithm, the fairness constraints (see the section "Fairness Constraints" on page 1848) are added to the loss function of the cost-sensitive machine learning model by introducing the Lagrange multipliers $\lambda_{j,t}$, where j is the index in the constraint set. The multipliers $\lambda_{j,t}$ are updated on the basis of the degree of constraint violations $\gamma_{j,t}$, B, and lr. Then $\lambda_{j,t}$ is used to derive the new weights for each observation in the input data set for the next round of training. Note that the values of B and lr play important roles in the performance of the EGR algorithm, based on experiments. The next section discusses how to come up with appropriate values for B and lr.

Bound Value Recommendation

Because the EGR algorithm is designed to strike a balance between model accuracy and fairness constraint violations, it does not perform well unless you specify appropriate values for the BOUND= and LEARNINGRATE= options in the MITIGATEBIAS statement. The BOUND= option is important for the sample reweighting and relabeling process. It controls how heavily the EGR algorithm penalizes fairness constraint violations, and therefore it determines the trade-off between the fairness constraints and the model accuracy. When the bound is too small, there is not enough momentum to drive the model close enough to the saddle points in the solution sets. In this case, the bias metric values of the different subgroups do not approach each other.

The LEARNINGRATE= option controls how quickly the algorithm reduces fairness constraint violations. If the learning rate is too small, the algorithm converges very slowly, resulting in a long training process; if the learning rate is too large, the algorithm becomes unstable and might not converge. In general, the learning rate and the bound value are coupled, and changing one of these values changes the optimal value of the other.

The MITIGATEBIAS statement offers a built-in bound value recommendation function to automatically search for a good candidate bound value when you request it. To eliminate the coupling effect of the bound

and the learning rate, PROC TREESPLIT fixes the initial learning rate at 0.01 during the tuning process. The procedure runs the bound value recommendation function if you specify the TUNEBOUND option. This function finds the best bound value through multiple iterations by analyzing the convergence patterns of the fairness metrics. PROC TREESPLIT first runs the EGR algorithm with some initial bound value for a few iterations, while monitoring the convergence pattern for signs of stagnation or overshooting to determine whether the bound value is too small or too large. It then adjusts the bound value until it finds an appropriate value or reaches the maximum number of iterations that are allowed. After the recommendation process, PROC TREESPLIT applies the recommended bound value to the EGR algorithm to train a final model. Note that because of the nonlinear nature of the optimization process, the bound value recommendation is also subject to the problem of local minima. This recommendation should be used as a general guideline for setting the bound value; you might find a better solution by further fine-tuning.

Displayed Output

The following sections describe the output that PROC TREESPLIT produces. The output is organized into various tables, which are discussed in the order of appearance.

Model Information

The "Model Information" table contains the settings of the training parameters. This table also contains some basic information about the resulting decision tree. This table is produced by default.

Number of Observations

The "Number of Observations" table contains the number of observations that are read from the input data table and the number of observations that are used in the analysis. When you specify the PARTITION statement, the table also indicates the number of observations that are used in each partition. This table is produced by default.

CV Statistics

The "CV Statistics" table contains information about *k*-fold cross validated cost-complexity pruning, such as the alpha values, the corresponding size of the tree, and the corresponding minimum, average, and maximum error. The table is generated when you specify the CVCC option in the PROC TREESPLIT statement, and you are also using *k*-fold cross validated cost-complexity pruning.

Tree as a Table

The "Tree as a Table" table is used for generating the WholeTreePlot and the ZoomedTreePlot. This table is produced when you specify the TREEPLOT option in the PROC TREESPLIT statement.

Tree Performance

The "Tree Performance" table contains statistics that measure the model's goodness of fit. If you specify the PARTITION statement, the table also indicates these statistics on all partitions of the data.

Variable Importance

The "Variable Importance" table displays variable importance based on residual sum of square errors, which is explained in the section "Residual Sum of Squares (RSS) Importance Method" on page 1839. This table is produced by default.

RBA Variable Importance

The "RBA Variable Importance" table displays variable importance based on the random branch assignment (RBA) method, which is explained in the section "Random Branch Assignment Importance Method" on page 1841. This table is produced by the RBAIMP option in the PROC TREESPLIT statement.

Reduced Error

The "Reduced Error" table contains the pruning results of reduced-error pruning that uses validation data. This is the table of the data shown in the PruningPlot. This table is generated when you specify the PRUNINGTABLE option and are using reduced-error pruning in the PRUNE statement with validation data.

Cost Complexity

The "Cost Complexity" table contains the pruning results of cost-complexity pruning that uses validation data. This is the table of the data shown in the PruningPlot. This table is generated when you specify the PRUNINGTABLE option and are using cost-complexity pruning in the PRUNE statement with validation data.

OutputCasTables Table

The OutputCasTables table is a special table that has information about each CAS table that is created during a CAS action execution. The information for each CAS table consists of the CAS table name, the caslib in which the table resides, and the number of columns and rows in the CAS table.

Tuner Information

The "Tuner Information" table displays the setup values that the tuner uses. This table is produced by the AUTOTUNE statement.

Tuner Summary

The "Tuner Summary" table displays statistics about the tuning process. This table is produced by the AUTOTUNE statement.

Tuner Timing

The "Tuner Timing" table displays the total time spent on different tasks during tuning. This table is produced by the AUTOTUNE statement.

Best Configuration

The "Best Configuration" table displays the hyperparameters and objective function values for the best configuration. This table is produced by the AUTOTUNE statement.

Tuner Results

The "Tuner Results" table displays the values of the hyperparameters, the objective function for the default configuration (Iteration 0), and up to 10 of the best configurations that are found. This table is produced by the AUTOTUNE statement.

Evaluation History

The "Evaluation History" tables displays the values of the hyperparameters and the objective function for all configurations. This table is produced by the AUTOTUNE statement, either by default or when EVALHISTORY=ALL.

Predicted Probability Names

The "Predicted Probability Names" table indicates the names of the created variables in either the score code or the data table that is specified in the OUT= option in the OUTPUT statement. This table is produced when you specify the PRINTTARGET option in the PROC TREESPLIT statement.

Constraint History

The "Constraint History" table lists the values of the various constraints at each iteration of the EGR algorithm. This table is produced by the MITIGATEBIAS statement.

Group Metrics History

The "Group Metrics History" table displays the metrics for accuracy and fairness for each subpopulation over each iteration of the EGR algorithm. This table is produced by the MITIGATEBIAS statement.

Iteration History

The "Iteration History" table displays the values of accuracy and bias metric at each iteration of the EGR algorithm. This table is produced by the MITIGATEBIAS statement.

Mitigation Information

The "Mitigation Information" table displays information about the options that you use for bias mitigation. This table is produced by the MITIGATEBIAS statement.

Timing

The "Timing" table displays the breakdown of how long bias mitigation spent on the various tasks of training models. This table is produced by the MITIGATEBIAS statement.

Weight History

The "Weight History" table displays the weights that are assigned by the EGR algorithm for each level of the response (target) variable and for each subpopulation. This table is produced by the MITIGATEBIAS statement.

ODS Table Names

PROC TREESPLIT assigns a name to each table it creates. You can use these names to refer to the table when you use the Output Delivery System (ODS) to select tables and create output data tables. Table 34.5 lists these names.

Table 34.5 ODS Tables Produced by PROC TREESPLIT

Table Name	Description	Statement	Option
BestConfiguration	Hyperparameters and objective function values for the best configuration	AUTOTUNE	Default
ConstraintHistory	Values of the various constraints at each iteration of the EGR algorithm	MITIGATEBIAS	Default
CostComplexity	Information about the number of leaves and the error for cost-complexity pruning when validation data are used	PROC TREESPLIT	PRUNINGTABLE
CrossValidateMLFitStat	Per-fold and average assessment metrics of *k*-fold cross validation	CROSSVALIDATION	Default
CrossValidationValues	Results for cost-complexity pruning based on cross validation	PROC TREESPLIT	CVCC
EvaluationHistory	Values of the hyperparameters and the objective function for all configurations	AUTOTUNE	Default / EVALHISTORY=ALL
GroupMetricsHistory	Metrics for accuracy and fairness for each subpopulation over each iteration of the EGR algorithm	MITIGATEBIAS	Default
IterationHistory	Values of the model accuracy and bias metric over each iteration of the EGR algorithm	MITIGATEBIAS	Default
MitigationInformation	Information about the options that are used for bias mitigation	MITIGATEBIAS	Default
ModelInfo	Information about the modeling environment	PROC TREESPLIT	Default

Table 34.5 *continued*

Table Name	Description	Statement	Option
NObs	Observation information	PROC TREESPLIT	Default
OutputCasTables	See the section "OutputCasTables Table" on page 1850	PROC TREESPLIT / OUTPUT	OUTMODEL= / Default
PredName	Predicted name information for interval targets	PROC TREESPLIT	PRINTTARGET
PredProbName	Predicted probability name information for nominal targets	PROC TREESPLIT	PRINTTARGET
PredIntoName	Predicted name information for nominal targets	PROC TREESPLIT	PRINTTARGET
RBAImportance	Random branch assignment variable importance	PROC TREESPLIT	RBAIMP
ReducedError	Information about the number of leaves and the error for reduced-error pruning when validation data are used	PROC TREESPLIT	PRUNINGTABLE
Timing	Breakdown of how long bias mitigation spent on the various tasks of training models	MITIGATEBIAS	Default
TreePerformance	Fit statistics for the selected tree	PROC TREESPLIT	Default
TreePlotTable	The table that is used to generate the WholeTreePlot and ZoomedTreePlot	PROC TREESPLIT	TREEPLOT
TunerInfo	Setup values used by the tuner	AUTOTUNE	Default
TunerResults	Values of the hyperparameters and the objective function for the default configuration (Iteration 0) and up to 10 best configurations found	AUTOTUNE	Default
TunerSummary	Statistics about the tuning process	AUTOTUNE	Default
TunerTiming	Total time spent on different tasks while tuning	AUTOTUNE	Default
VariableImportance	Variable importance	PROC TREESPLIT	Default
WeightHistory	Weights that are assigned by the EGR algorithm for each level of the response (target) variable and for each subpopulation	MITIGATEBIAS	Default

ODS Graphics

You can refer to every graph that is produced through ODS Graphics by name. The names of the graphs that PROC TREESPLIT generates are listed in Table 34.6, along with the relevant PLOTS= options.

Table 34.6 Graphs Produced by PROC TREESPLIT

ODS Graph Name	Plot Description	PLOTS= Option
CrossValidationASEPlot	Cross validation cost-complexity ASE plot when the response is continuous	CVCC
CrossValidationMisclassPlot	Cross validation cost-complexity misclassification plot when the response is categorical	CVCC
IterationHistoryPlot	Iteration history of the model accuracy and bias metric when the MITIGATEBIAS statement is used	
PruningPlot	Plot of the error sum of squares, misclassification rate, or cost complexity when it is used for final tree selection	PRUNEUNTIL
WholeTreePlot	Overview plot of final tree	WHOLETREE
ZoomedTreePlot	Detailed plot of portion of final tree	ZOOMEDTREE

INPUT and TARGET Statement Syntax

In addition to the syntax that is described in the CLASS and MODEL statement sections, PROC TREESPLIT supports INPUT/TARGET syntax that you might be familiar with from other procedures. The INPUT/TARGET syntax cannot be used together with the CLASS/MODEL syntax.

This syntax requires one TARGET statement and one or more INPUT statements. If you use this syntax, then the PROC TREESPLIT statement, the TARGET statement, and the INPUT statement are required. Depending on the options in those statements, specified variables can be interval or nominal. By default, numeric INPUT variables are treated as interval (or continuous) predictors, and character INPUT variables are treated as nominal (or categorical) predictors.

INPUT *variables* < / *option* > **;**
TARGET *variable* < / *option* > **;**

INPUT Statement

INPUT *variables* < / *option* > **;**

The INPUT statement specifies predictor *variables* for the decision tree or regression tree. The value of *variable* can be a range such as "var_1–var_1000" or the special "_ALL_" value to include all variables in the data tables. As with CLASS variables, all nominal INPUT variables are padded or truncated to 32 characters.

You cannot use an INPUT statement with a MODEL or CLASS statement.

You can specify the following *option*:

LEVEL=INTERVAL | NOMINAL

specifies whether the specified predictor *variables* are interval or nominal. You can specify the following values:

INTERVAL treats all numeric *variables* as interval predictors.

NOMINAL treats all *variables* as nominal predictors.

By default, numeric *variables* are treated as interval predictors, and character *variables* are treated as nominal predictors. Specifying LEVEL=NOMINAL forces all *variables* in that statement to be treated as nominal. You cannot specify LEVEL=INTERVAL for character variables.

TARGET Statement

TARGET *variable* < / *options* > **;**

The TARGET statement names the *variable* whose values PROC TREESPLIT predicts. Missing values in the target are ignored except during scoring.

You cannot use a TARGET statement with a MODEL or CLASS statement.

You can specify the following *option*:

LEVEL=INTERVAL | NOMINAL

specifies whether the specified response *variable* is interval or nominal. You can specify the following values:

INTERVAL treats the response as an interval variable and creates a regression tree.

NOMINAL treats the response as a nominal variable and creates a decision tree.

By default, LEVEL=INTERVAL for numeric variables and LEVEL=NOMINAL for categorical variables.

Examples: TREESPLIT Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 34.1: Creating a Binary Classification Tree with Validation Data

(View the complete code for this example (treesplex4.sas) in the example repository.)

A common use of classification trees is to predict whether a mortgage applicant will default on a loan. The data table Hmeq, which is in the Sampsio library that SAS provides, contains observations for 5,960 mortgage applicants. A variable named Bad indicates whether the applicant, after being approved for a loan, paid off or defaulted on the loan.

This example uses Hmeq to build a tree model that is used to score the data and can be used to score data about new applicants. Table 34.7 describes the variables in Hmeq.

Table 34.7 Variables in the Home Equity (Hmeq) Data Table

Variable	Role	Level	Description
Bad	Response	Binary	1 = applicant defaulted on the loan or is seriously delinquent 0 = applicant paid off the loan
CLAge	Predictor	Interval	Age of oldest credit line in months
CLNo	Predictor	Interval	Number of credit lines
DebtInc	Predictor	Interval	Debt-to-income ratio
Delinq	Predictor	Interval	Number of delinquent credit lines
Derog	Predictor	Interval	Number of major derogatory reports
Job	Predictor	Nominal	Occupational category
Loan	Predictor	Interval	Requested loan amount
MortDue	Predictor	Interval	Amount due on mortgage
nInq	Predictor	Interval	Number of recent credit inquiries
Reason	Predictor	Binary	`'DebtCon'` = debt consolidation `'HomeImp'` = home improvement
Value	Predictor	Interval	Value of property
YoJ	Predictor	Interval	Years at present job

The response variable for the tree model is Bad, a classification variable that has two values (0 for payment of loan and 1 for default). The other variables are predictor variables for the model. The following statements load mylib.hmeq data into your CAS session and display the first 10 observations of the data table. For this example, the statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
/* Convert variable names to mixed case */
data mylib.hmeq;
   length Bad Loan MortDue Value 8 Reason Job $7
          YoJ Derog Delinq CLAge nInq CLNo DebtInc 8;
   set sampsio.hmeq;
run;

proc print data=mylib.hmeq(obs=10); run;
```

Output 34.1.1 shows the first 10 observations of mylib.hmeq.

Output 34.1.1 Partial Listing of the mylib.hmeq Data

Obs	Bad	Loan	MortDue	Value	Reason	Job	YoJ	Derog	Delinq	CLAge	nInq	CLNo	DebtInc
1	1	1100	25860	39025	HomeImp	Other	10.5	0	0	94.367	1	9	.
2	1	1500	.	.			.	.	.	.	.	.	.
3	1	1800	48649	57037	HomeImp	Other	5.0	3	2	77.100	1	17	.
4	1	2000	.	62250	HomeImp	Sales	16.0	0	0	115.800	0	13	.
5	1	2000	45000	55000	HomeImp	Other	3.0	0	0	86.067	2	25	.
6	1	2200	24280	34687	HomeImp	Other	.	0	1	300.867	0	8	.
7	1	2300	28192	40150	HomeImp	Other	4.5	0	0	54.600	1	16	.
8	1	2400	50000	73395	HomeImp	ProfExe	5.0	1	0	.	1	0	.
9	1	2400	.	17180	HomeImp	Other	.	0	0	14.567	3	4	.
10	1	2500	15000	20200	HomeImp		18.0	0	0	136.067	1	19	.

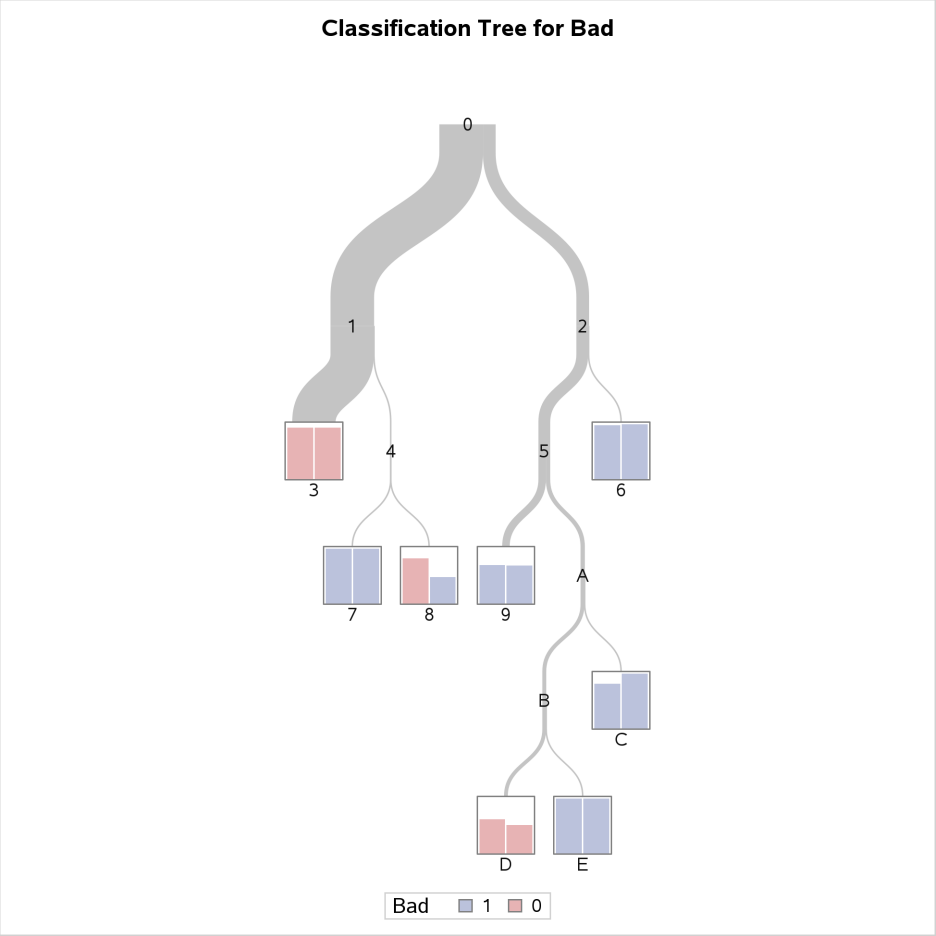
The following statements use the TREESPLIT procedure to create a classification tree:

```
ods graphics on;

proc treesplit data=mylib.hmeq maxdepth=5;
   class Bad Delinq Derog Job nInq Reason;
   model Bad = Delinq Derog Job nInq Reason CLAge CLNo
               DebtInc Loan MortDue Value YoJ;
   prune costcomplexity;
   partition fraction(validate=0.3 seed=123);
   code file='treesplexc.sas';
run;
```

The MAXDEPTH= option specifies that the maximum depth of the tree to be grown is 5.

Specifying Bad to the left of the equals sign in the MODEL statement indicates that it is the response variable.

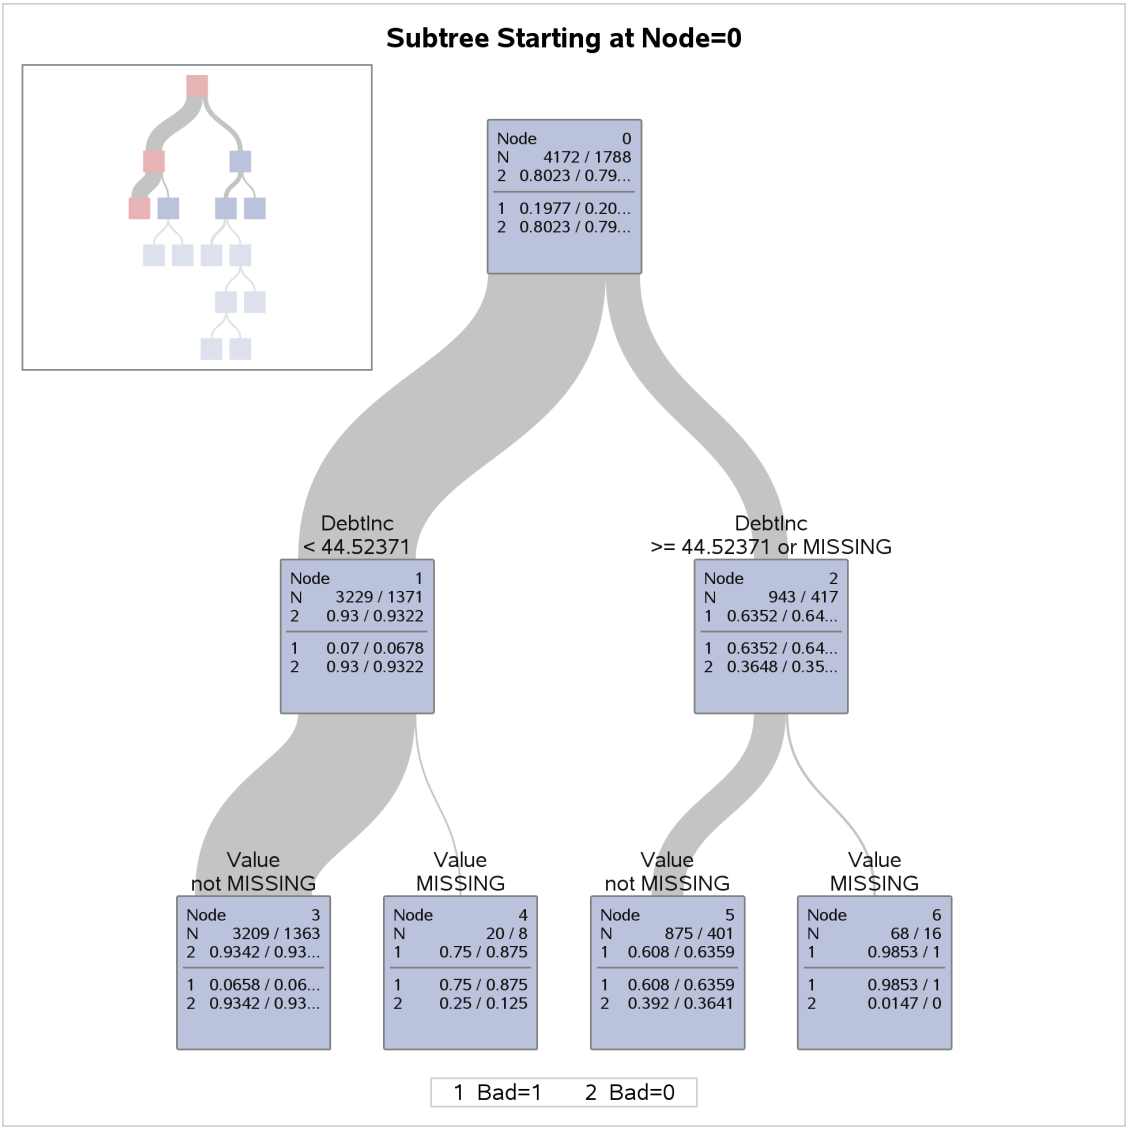


Because no GROW statement is included, PROC TREESPLIT defaults to using the entropy metric, which calculates the gain to grow the tree. The PRUNE statement requests cost-complexity pruning.

The PARTITION statement requests that the observations in Hmeq be partitioned into disjoint subsets for model training and validation. Observations are randomly selected for the validation subset with probability 0.3; the remaining observations are selected for the training subset.

The FILE= option in the CODE statement requests that SAS DATA step score code be saved to a file named *treesplexc.sas*.

The tree diagram in Output 34.1.2 provides an overview of the full tree.



Output 34.1.2 Overview Diagram of Final Tree

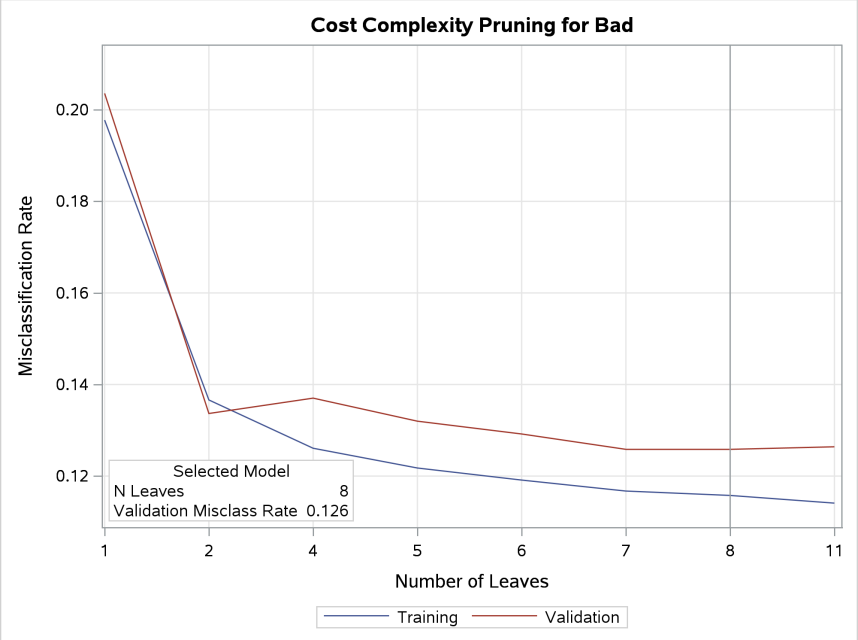
The observations in terminal nodes are assigned a prediction of Bad=0 or Bad=1, as shown by the color in the plot legend. The first bar in a leaf node shows the proportion of the responses that match the prediction of Bad=0 or Bad=1 in the training partition, and the second bar in a leaf node shows the proportion of responses that match in the validation partition. The thickness of the line indicates which nodes have more total observations.

The tree diagram in Output 34.1.3 is a detailed view of the top portion of the tree. You can use the PLOTS= option in the PROC TREESPLIT statement to control which nodes are displayed.

Output 34.1.3 Detailed Tree Diagram

By default, this view provides detailed splitting information about the first three levels of the tree, including the root level. The splitting rule above each node shows the splitting variable and splitting value; the rule determines which observations from the parent node are included in the node. The first row of the table inside the node provides the node identifier. The second row provides the number of training observations, followed by a backslash, and then the number of validation observations. The third row shows the predicted response for observations in that node if classification occurs at that point, along with the proportion of training observations with that observed response. This is separated from the proportion of validation observations by a backslash. Note that the legend shows what actual value of the response variable is represented by the value shown in the node.

Output 34.1.4 displays the fit statistics for the final tree.



Output 34.1.4 Tree Performance

The TREESPLIT Procedure

Fit Statistics for Selected Tree		
	Number of Leaves	Misclassification Rate
Training	8	0.1158
Validation	8	0.1258

Output 34.1.5 displays the pruning plot.

Output 34.1.5 Pruning Plot

This plot displays the misclassification rates for the training and validation data as the tree is pruned. The vertical line shows the selected final tree that has the lowest misclassification rate for the validation data.

Creating Score Code and Scoring New Data

In addition to seeing information about the tree model, you might be interested in applying the model to predict the response variable in other data tables where the response is unknown. You can use the score code file *treesplexc.sas* (which was created by the FILE= option in the CODE statement) to score new data anywhere that you can run SAS DATA step code. The following is an example of using the score code file *treesplexc.sas* to score the data in Hmeq and save the results in a SAS data table named Scored:

```
data scored;
   set sampsio.hmeq;
   %include 'treesplexc.sas';
run;
```

Output 34.1.6 shows a partial listing of Scored.

Output 34.1.6 Partial Listing of the Scored Hmeq Data

Obs	BAD	LOAN	MORTDUE	VALUE	REASON	JOB	YOJ	DEROG	DELINQ	CLAGE	NINQ
1	1	1100	25860	39025	HomeImp	Other	10.5	0	0	94.367	1
2	1	1300	70053	68400	HomeImp	Other	7.0	0	2	121.833	0
3	1	1500	13500	16700	HomeImp	Other	4.0	0	0	149.467	1
4	1	1500	.	.			.	.	.	.	.
5	0	1700	97800	112000	HomeImp	Office	3.0	0	0	93.333	0
6	1	1700	30548	40320	HomeImp	Other	9.0	0	0	101.466	1
7	1	1800	48649	57037	HomeImp	Other	5.0	3	2	77.100	1
8	1	1800	28502	43034	HomeImp	Other	11.0	0	0	88.766	0
9	1	2000	32700	46740	HomeImp	Other	3.0	0	2	216.933	1
10	1	2000	.	62250	HomeImp	Sales	16.0	0	0	115.800	0

Obs	CLNO	DEBTINC	_leaf_id_	I_Bad	P_Bad1	P_Bad0
1	9	.	9	1	0.70916	0.29084
2	14	.	9	1	0.70916	0.29084
3	10	.	9	1	0.70916	0.29084
4	.	.	6	1	0.98529	0.01471
5	14	.	9	1	0.70916	0.29084
6	8	37.1136	3	0	0.06575	0.93425
7	17	.	9	1	0.70916	0.29084
8	8	36.8849	3	0	0.06575	0.93425
9	12	.	13	0	0.36918	0.63082
10	13	.	9	1	0.70916	0.29084

The data table contains the 13 original variables and 4 new variables that are created by the score code. The variable P_BAD1 is the proportion of training observations in this leaf for which BAD=1; this variable can be interpreted as the probability of default. The variable I_BAD indicates the predicted value of BAD for the observation.

You can use the preceding statements to score new data by including the new data table in place of Hmeq in the SET statement. The new data table must contain the same variables as the data that are used to build the tree model, but not the unknown response variable that you now want to predict.

Example 34.2: Creating a Regression Tree

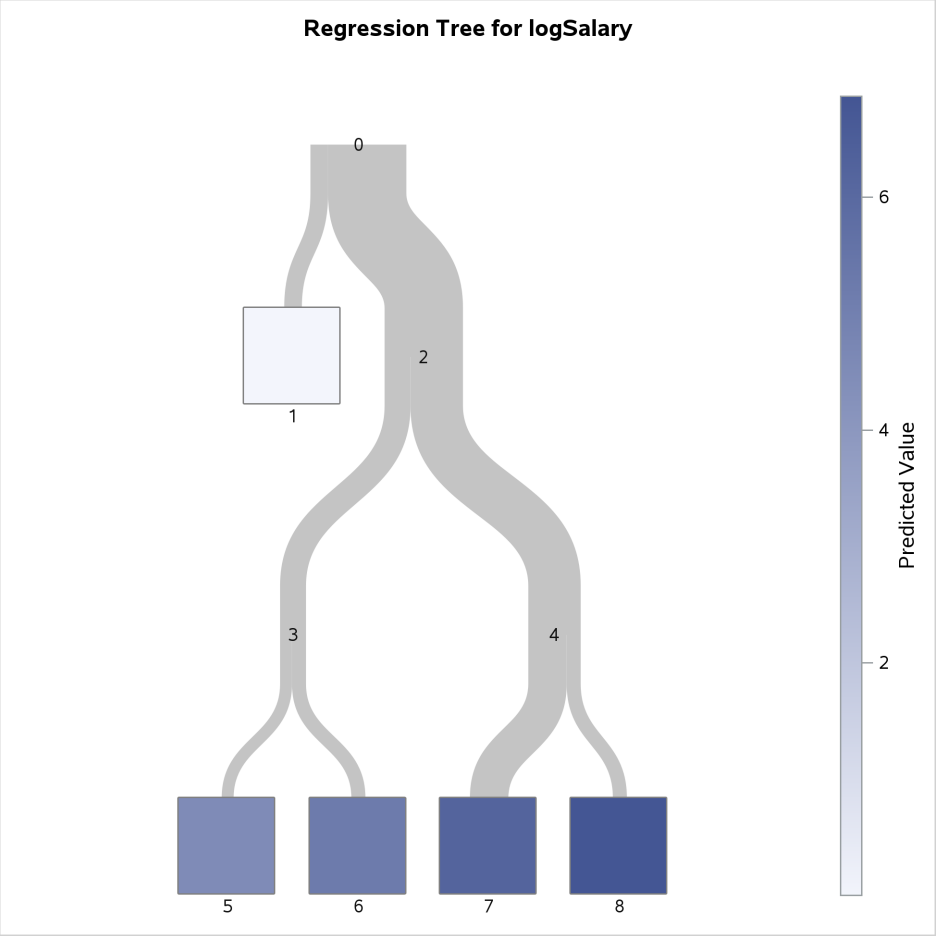
(View the complete code for this example (treesplex3.sas) in the example repository.)

This example performs an analysis in which a linear regression model is fit. You can alternatively fit a regression tree to predict the salaries of Major League Baseball players based on their performance measures from the previous season by using almost identical code. Regression trees are piecewise constant models that, for relatively small data tables such as Sashelp.Baseball, provide succinct summaries of how the predictor variables determine the predictions. These models are usually easier to interpret than linear regression models. The Sashelp.Baseball data table contains salary and performance information for Major League Baseball players (excluding pitchers) who played at least one game in both the 1986 and 1987 seasons (Time Inc. 1987). You can load the Sashelp.Baseball data set into your CAS session by naming your CAS engine libref in the first statement of the following DATA step:

```
data mylib.baseball;
   set sashelp.baseball;
run;
```

The following statements create a regression tree model:

```
ods graphics on;

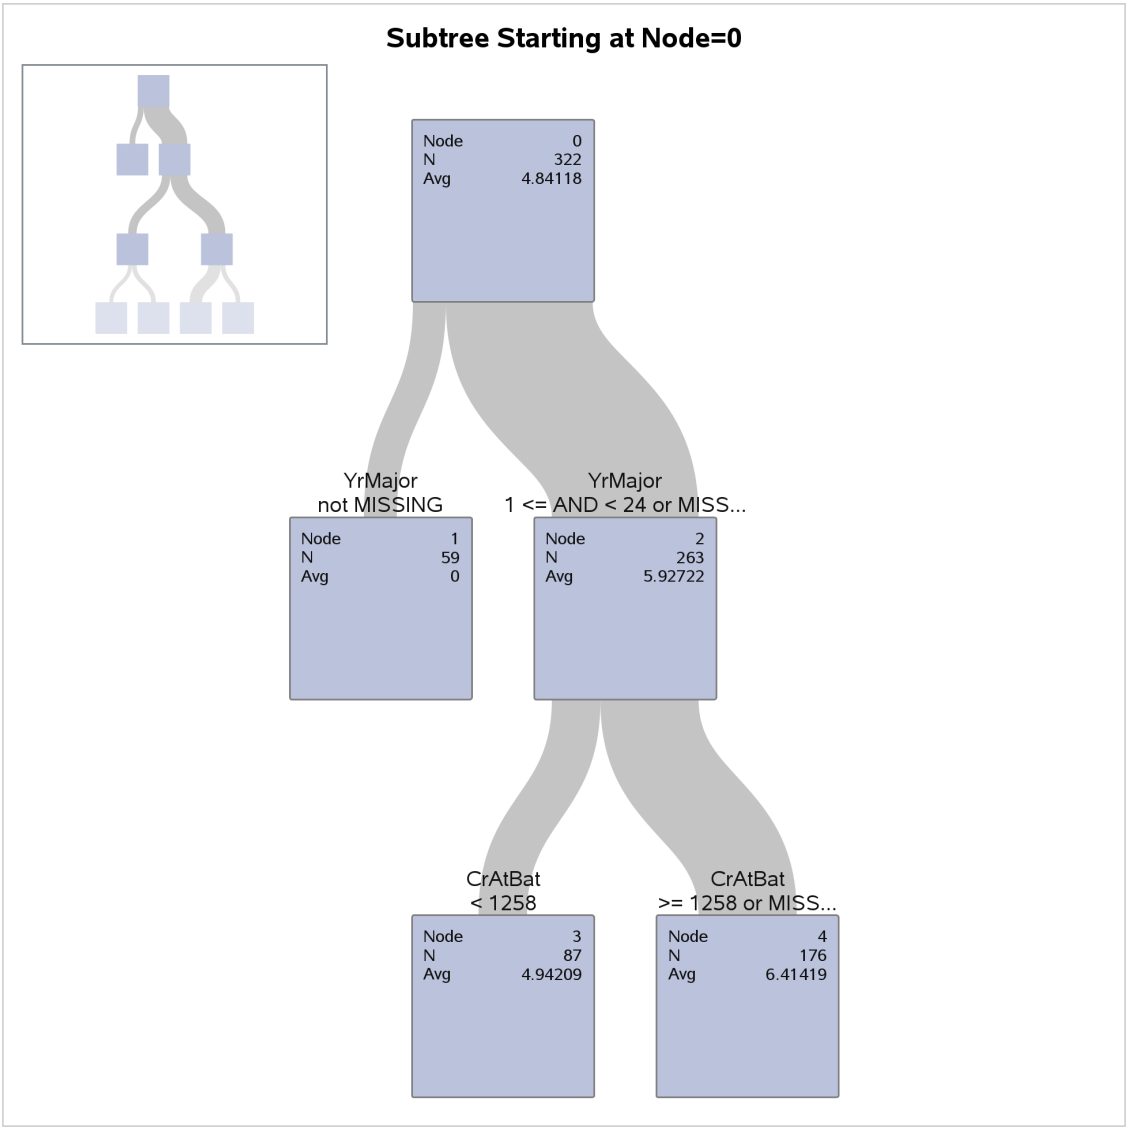


proc treesplit data=mylib.baseball maxdepth=3;
   class league division;
   model logSalary = nAtBat nHits nHome nRuns nRBI nBB
                     yrMajor crAtBat crHits crHome crRuns crRbi
                     crBB league division nOuts nAssts nError;
   output out=mylib.treesplout;
   prune none;
run;
```

Because no GROW statement is specified, the tree is grown using the RSS criterion by default. Because PRUNE none is specified, no pruning is performed. The OUTPUT statement requests generation of the data table mylib.treesplout, which contains the predicted salary from the tree model for each observation.

Much of the output for a regression tree is identical to the output for a classification tree. Where there are differences, tables and plots are displayed and discussed on the following pages.

Output 34.2.1 displays the full regression tree.



Output 34.2.1 Overview Diagram of Regression Tree

The final selected tree has eight leaves. In a regression tree, the shade of the leaves represents the predicted response value, which is the average observed logSalary for the observations in that leaf. Node 7 has the lowest predicted response value, indicated by the lightest shade of blue, and node E has the highest, indicated by the dark shade.

Output 34.2.2 shows details of the first three levels of the tree, including the root node.

Output 34.2.2 Detailed Diagram of Regression Tree

As in Output 34.1.3, this diagram displays split variables and split values for the nodes, along with the exact predicted response value, which is the average observed response, in each node.

Output 34.2.3 displays the fit statistic for the final regression tree (the only fit statistic provided for a regression tree is the ASE).

Output 34.2.3 Regression Tree Performance

The TREESPLIT Procedure

Fit Statistics for Selected Tree		
	Number of Leaves	Average Square Error
Training	5	0.2156

Output 34.2.4 is a partial display of the mylib.treesplout data table that is created when you specify the OUTPUT statement.

Output 34.2.4 Scored Predictor Data Table

Obs	P_logSalary	_DT_PredStd_	_LeafID_	_Residual_
1	4.56042	0.24843	5	.
2	6.24707	0.54820	7	0.03246
3	4.56042	0.24843	5	0.31193
4	6.87289	0.48707	8	-0.13018
5	6.24707	0.54820	7	-0.06285
6	4.56042	0.24843	5	.
7	6.87289	0.48707	8	.
8	4.56042	0.24843	5	-0.18451
9	6.24707	0.54820	7	-0.40794
10	6.24707	0.54820	7	-0.37300

The variable P_logSalary contains the predicted salaries on the log scale. Note that all observations in the same leaf have the same predicted response. The OUT= data table can contain additional variables from the DATA= data table if you specify them by using the COPYVARS= option.

Example 34.3: Assessing Variable Importance

(View the complete code for this example (treesplex5.sas) in the example repository.)

This example creates a classification tree model to determine important variables (parameters) during the manufacture of a semiconductor device. Some of the variables that are involved in the manufacturing process are: gTemp, the growth temperature of substrate; aTemp, the annealing temperature; Rot, rotation speed; Dopant, the atom used during device growth; and Usable, which indicates whether the device is usable.

The following statements create a data table named mylib.MBE_Data, which contains measurements for 20 devices:

```
data mylib.MBE_Data;
   label gTemp  = 'Growth Temperature of Substrate';
   label aTemp  = 'Anneal Temperature';
   label Rot    = 'Rotation Speed';
   label Dopant = 'Dopant Atom';
   label Usable = 'Experiment Could Be Performed';

   input gTemp aTemp Rot Dopant $ 39-40 Usable $ 47-54;
   datalines;
   384.614    633.172    1.01933      C       Unusable
   363.874    512.942    0.72057      C       Unusable
   397.395    671.179    0.90419      C       Unusable
   389.962    653.940    1.01417      C       Unusable
   387.763    612.545    1.00417      C       Unusable
   394.206    617.021    1.07188      Si      Usable
   387.135    616.035    0.94740      Si      Usable
   428.783    745.345    0.99087      Si      Unusable
   399.365    600.932    1.23307      Si      Unusable
```

```
455.502    648.821    1.01703      Si      Unusable
387.362    697.589    1.01623      Ge      Usable
408.872    640.406    0.94543      Ge      Usable
407.734    628.196    1.05137      Ge      Usable
417.343    612.328    1.03960      Ge      Usable
482.539    669.392    0.84249      Ge      Unusable
367.116    564.246    0.99642      Sn      Unusable
398.594    733.839    1.08744      Sn      Unusable
378.032    619.561    1.06137      Sn      Usable
357.544    606.871    0.85205      Sn      Unusable
384.578    635.858    1.12215      Sn      Unusable
;
```

The following statements create the tree model:

```
proc treesplit data=mylib.MBE_Data maxdepth=6;
   class Usable Dopant;
   model Usable = gTemp aTemp Rot Dopant;
   prune none;
run;
```

Output 34.3.1 shows the "Variable Importance" table.

Output 34.3.1 Variable Importance

The TREESPLIT Procedure

Variable Importance

Training

Variable	Importance	Relative Importance	Count
Dopant	2.7000	1.0000	1
aTemp	1.0500	0.3889	1

This table shows that the predictor Dopant has the largest importance value. This means that the atom used during device growth is the most important consideration in determining the usability of the sample. The column Count indicates how many times the variable was used in for splits within the decision tree.

Example 34.4: Mitigating Bias of a Classification Tree

(View the complete code for this example (treesplex6.sas) in the example repository.)

This example creates a classification tree model while minimizing the demographic parity for the Job variable. The response variable for the tree model is Bad, a classification variable that has two values (0 for payment of loan and 1 for default). The other variables are predictor variables for the model.

The following statements load the data table mylib.hmeq into your CAS session. For this example, the statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements use the TREESPLIT procedure to create a classification tree without minimizing the demographic parity:

```
proc treesplit data=mylib.hmeq;
   class Bad Reason;
   model Bad = CLAge CLNo DebtInc Derog
               Loan MortDue Reason Value;
   prune off;
   output out=mylib.scored copyvars=(_ALL_);
   saveState rstore=mylib.treeModel;
run;
```

Specifying Bad to the left of the equals sign in the MODEL statement indicates that it is the response variable. The PRUNE statement specifies no pruning. The OUTPUT statement generates the data table mylib.scored, which contains the predicted mortgage default from the tree model for each observation and all variables from the input data table as copy variables. The SAVESTATE statement creates an analytic store for the model and saves it as a binary object in the data table mylib.treeModel.

Output 34.4.1 displays the fit statistics for the tree model.

Output 34.4.1 Fit Statistics Table

The TREESPLIT Procedure

Fit Statistics for Selected Tree

	Number of Leaves	Misclassification Rate
Training	63	0.1084

After you train a classification tree model, you might want to view the demographic parity of the trained model. You can do this by running the ASSESSBIAS procedure.

The following statements use PROC ASSESSBIAS to assess the bias measurements of the model:

```
proc assessbias data=mylib.scored;
   target bad / event="1" level=nominal;
   var P_Bad1;
   fitstat pvar=P_BAD0 / pevent="0";
   sensitiveVar Job;
run;
```

For more information about PROC ASSESSBIAS, see Chapter 3, "ASSESSBIAS Procedure" (*SAS Viya: Machine Learning Procedures*). Output 34.4.2 displays the bias metric values of the model. PROC ASSESSBIAS also produces other output that is not shown here.

Output 34.4.2 Bias Metrics Table

The ASSESSBIAS Procedure

Bias Metrics					
Bias Statistic	Bias Statistic Label	Bias Statistic Value	Base Level	Compare Level	Note
DemographicParity	Demographic Parity (Statistical Parity)	0.1476	Self		
PredictiveParity	Predictive Parity	0.1265	Self		
EqualAccuracy	Equal Accuracy	0.0804	Office	Sales	
EqualizedOdds	Equalized Odds	0.1534	Self	Sales	The maximum TPR difference is greater than the maximum FPR difference.
EqualOpportunity	Equal Opportunity	0.1534	Self	Sales	

In order to use the MITIGATEBIAS statement to reduce the demographic parity, you must specify the levels of the response (target) variable and the corresponding predicted variables. You can use the DESCRIBE statement in the ASTORE procedure to obtain this information. The following statements use PROC ASTORE to describe the model:

```
proc astore;
   describe rstore=mylib.treeModel;
run;
```

Output 34.4.3 lists the output variables that the model creates. The predicted variables are P_BAD1 and P_BAD0. Their corresponding response (target) levels are 1 and 0, respectively.

Output 34.4.3 Output Variables Table

The ASTORE Procedure

Output Variables			
Name	Length	Type	Label
P_BAD1	8	Num	Predicted: BAD=1
P_BAD0	8	Num	Predicted: BAD=0
I_BAD	12	Character	Into: BAD
WARN	4	Character	Warnings
_leaf_id_	8	Num	_leaf_id_

The following statements use PROC TREESPLIT to create a classification tree, while minimizing the demographic parity for Job by using the MITIGATEBIAS statement:

```
ods graphics on;

proc treesplit data=mylib.hmeq;
   class Bad Reason;
   model Bad = CLAge CLNo DebtInc Derog
               Loan MortDue Reason Value;
   prune off;
   saveState rstore=mylib.treeModel;
   mitigateBias pevents="1 0"
                pvars=(P_BAD1 P_BAD0)
```

```
                    seed=12345
                    sensitivevar=Job
                    targetEvent="1";
run;
```

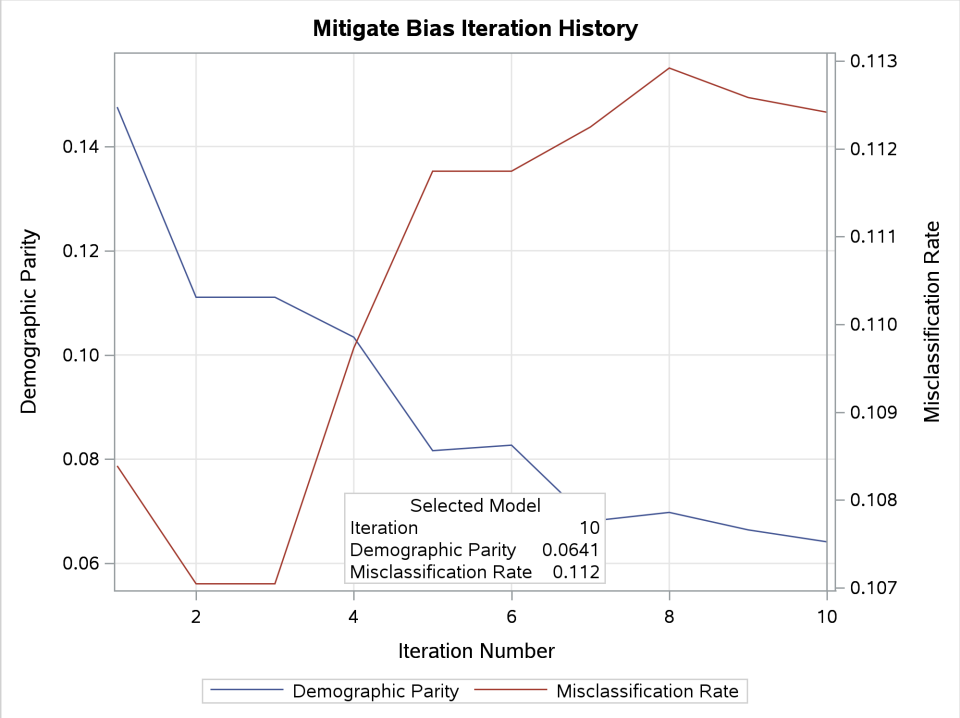
The PEVENTS= option lists the levels of the response (target) variable Bad. The predicted variables correspond to the levels that are listed in the PVARS= option. The PVARS= option lists the predicted variables that contain the posterior probability for each level in model prediction that corresponds to the response (target) variable Bad. The SEED= option specifies the seed for the pseudorandom number generator to be 12345. The SENSITIVEVAR= option names the variable Job as the sensitive variable for the purpose of reducing the value of the bias measurement. The TARGETEVENT= option specifies the value 1 as the event of interest.

Output 34.4.4 displays the information about the options that are used for bias mitigation. Output 34.4.5 displays the model accuracy and bias metric values over each iteration of the EGR algorithm. Output 34.4.6 shows the iteration history, which is a graphical representation of the iteration history table. The MITIGATEBIAS statement also creates other tables, which are not shown here but are listed in the section "ODS Table Names" on page 1852.

Output 34.4.4 Mitigation Information Table

The TREESPLIT Procedure

Mitigation Information



Description	Character Value	Value
Bias Metric	DEMOGRAPHICPARITY	.
Sensitive Variable	JOB	.
Response	BAD	.
Bound Value	100	100
Learning Rate	0.01	0.01
Maximum Iteration	10	10
Tolerance	0.005	0.005
Event Level	1	.

Output 34.4.5 Iteration History Table

EGR Iteration History

Iteration	Demographic Parity (Statistical Parity)	Misclassification Rate	Multi-Class Log Loss
1	0.147566	0.1084	0.2718
2	0.111078	0.1070	0.2698
3	0.111078	0.1070	0.2695
4	0.103414	0.1097	0.2769
5	0.081634	0.1117	0.2799
6	0.082688	0.1117	0.2833
7	0.068110	0.1122	0.2842
8	0.069785	0.1129	0.2895
9	0.066434	0.1126	0.2896
10	0.064139	0.1124	0.2891

Output 34.4.6 Iteration History Plot

Example 34.5: Tuning the Hyperparameters of a Decision Tree

(View the complete code for this example (treesplex7.sas) in the example repository.)

This example illustrates how you can use the AUTOTUNE statement in the TREESPLIT procedure to tune the hyperparameters of a decision tree. It uses the home equity data set Hmeq, which is in the Sampsio library.

The Hmeq data set contains 5,960 observations with 13 variables. The response variable, Bad, is a binary indicator to predict which clients will default on their loan.

The following statements load the data table Hmeq into your CAS session. For this example, the statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements use PROC TREESPLIT with the AUTOTUNE statement to automatically tune the hyperparameters of a decision tree:

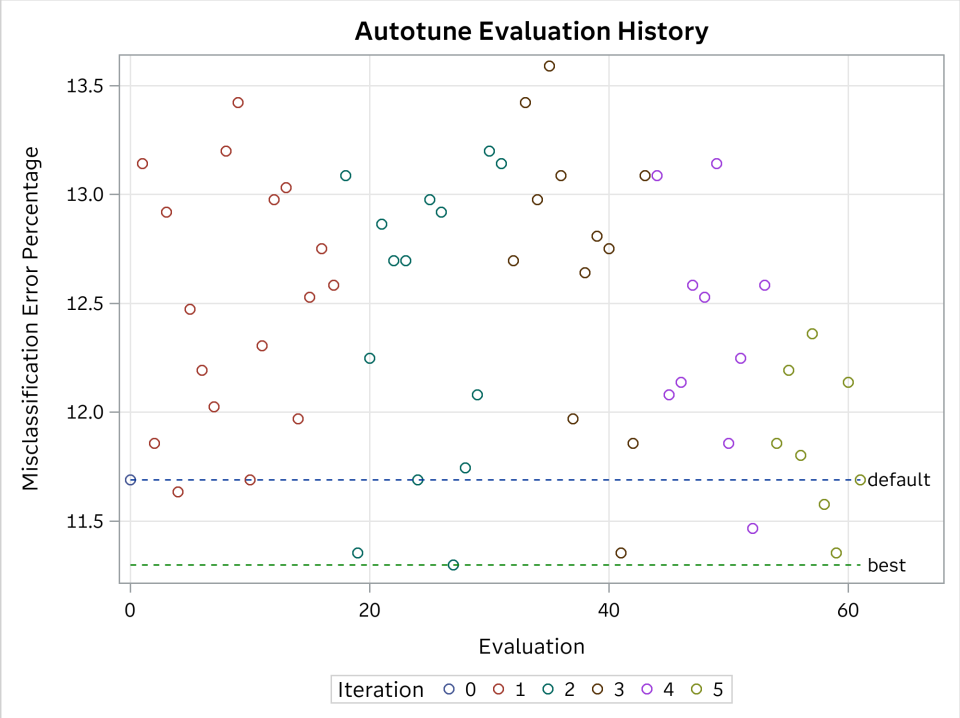
```
ods graphics on;

proc treesplit data=mylib.hmeq;
   class Bad Reason;
   model Bad = CLAge CLNo DebtInc Derog
```

```
            Loan MortDue Reason Value;
   prune off;
   autotune
      /* Tuning Parameters
      You do not need to specify any tuning parameters for the default
      tuning process. If you want to make adjustments to the default
      tuning process, uncomment the following block of code and change
      any of the tuning parameters' attributes.

      tuningParameters=(
         CRITERION   ( values=GAIN GINI GAINRATIO
                     CHAID CHISQUARE init=GAINRATIO  )
         NUMBIN      ( lb=20    ub=200   init=20  )
         MAXDEPTH    ( lb=1     ub=19    init=10  )
         MINLEAFSIZE ( values=1 5 10 20 40 80 160 320 init=5 EXCLUDE  )
      )
      */
   ;
   /* Remove this line to see all results */
   ods select BestConfiguration EvaluationHistoryPlot IterationHistoryPlot;
run;
```

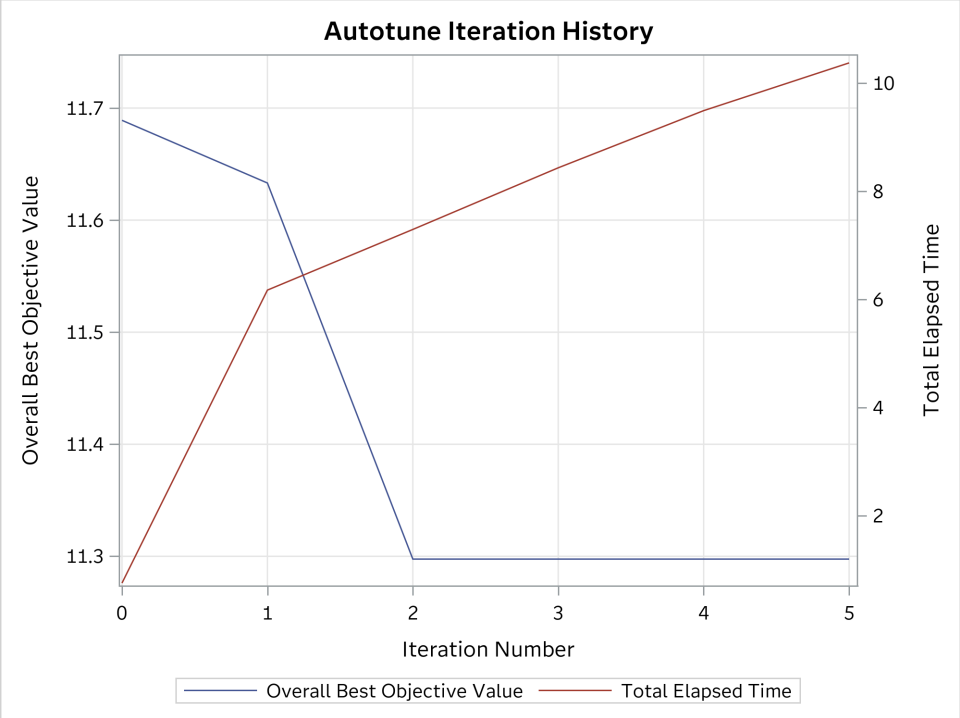
The preceding statements produce the table and the plots shown in Output 34.5.1 through Output 34.5.3. The table in Output 34.5.1 displays the evaluation number, the values of the tuning parameters, and the error metric value for the best decision tree model that the tuner found. Note that the ODS SELECT statement limits the displayed results to a single table and two plots. You can remove this statement to display all tables and plots. For the full list of ODS tables that PROC TREESPLIT produces, see Table 34.5.



Output 34.5.1 Best Configuration Table

The TREESPLIT Procedure

Best Configuration	
Evaluation	3
Maximum Tree Levels	6
Maximum Bins	160
Criterion	GAIN
Misclassification Error Percentage	10.68



Output 34.5.2 displays a scatter plot of all configurations that the tuner tried. The objective values are shown on the Y axis, and the evaluation numbers are shown on the X axis.

Output 34.5.2 Evaluation History Plot

The plot in Output 34.5.3 displays how the best found objective value and the elapsed time changed with each iteration of the tuner.

Output 34.5.3 Iteration History Plot

Examples: VARIMPUTE Procedure **1884**
Example 35.1: Imputation of Missing Values for HMEQ Data Table 1884

Overview: VARIMPUTE Procedure

The VARIMPUTE procedure performs variable imputation on a data table. Imputation is a common step in data preparation.

The VARIMPUTE procedure can replace numeric missing values with a specified value, with the mean or median of the nonmissing values, or with some random value between the minimum value and the maximum value of the nonmissing values.

The VARIMPUTE procedure can replace nominal missing values with a specified value and with the nonmissing value which has the most frequent appearance for that variable.

The VARIMPUTE procedure also supports formatted values including user defined formats.

When PROC VARIMPUTE calculates the mean, median, mode, or a random value, it ignores any observation that has a value that is less than or equal to 0 for any variable that is named in the FREQ statement.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “Introduction to Shared Concepts” on page 6 in Chapter 2, “Shared Concepts.”

Getting Started: VARIMPUTE Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/varimpute_gs.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

The VARIMPUTE procedure can use any or all of six methods to impute numeric missing values. This example uses all six imputation methods to manipulate a data table. The input data table mylib.hmeq includes information about fictitious mortgages. Each observation represents an applicant for a home equity loan, and all applicants have an existing mortgage.

You can load the sampsio.hmeq data set into your CAS session in the following DATA step:

```
data mylib.hmeq;
   set sampsio.hmeq;
run;
```

The following statements perform the imputation:

```
proc varimpute data=mylib.hmeq seed=18000;
   input clage /ctech=mean;
   input delinq/ctech=median;
   input ninq/ctech=random;
   input reason/ntech=mode;
   input job/ntech=value valuescharacter=Office;
   input debtinc yoj/ctech=value cvalues=50,100;
   output out=mylib.out;
run;
```

The SEED= option specifies 18,000 as the random seed to be used in the random imputation process. The first INPUT statement (which includes the CTECH=MEAN option) requests that mean imputation be used for the variable clage. The second INPUT statement (which includes the CTECH=MEDIAN) option requests that median imputation be used for the variable delinq. The third INPUT statement (which includes the CTECH=RANDOM option) requests that random imputation be used for the variable ninq. The fourth INPUT statement (which includes the NTECH=MODE option) requests that mode imputation be used for the variable reason. The fifth INPUT statement (which includes the NTECH=VALUE option) requests that Office be imputed as the value of the variable job. The sixth INPUT statement (which includes the CTECH=VALUE) option requests that 50 be imputed as the value of variable debtinc and 100 be imputed as the value of variable yoj. The OUTPUT statement creates a new data table to contain the imputed values; it is shown in Output 35.1 and Output 35.2. The Variable column shows the original variable names from the input data table. The Imputation Method column shows the types of imputation methods: value (for character or numeric variables), median, random (between the minimum value and the maximum value of the nonmissing values), mean, and mode. For random imputation, the last column does not show any number, because the imputation is done by using a random seed. For other imputation methods, the last column shows the imputation values that are used to replace missing values. The Result Variable column shows the new variable names in the output data table.

Figure 35.1 Imputed Values for Interval Variables

The VARIMPUTE Procedure

Imputed Values for Interval Variables

Variable	Imputation Method	Result Variable	N	Number of Missing	Imputed Value
CLAGE	Mean	IM_CLAGE	5652	308	179.766
DELINQ	Median	IM_DELINQ	5380	580	0
NINQ	Random	IM_NINQ	5450	510	
DEBTINC	Value	IM_DEBTINC	4693	1267	50
YOJ	Value	IM_YOJ	5445	515	100

Figure 35.2 Imputed Values for Nominal Variables

Imputed Values for Nominal Variables

Variable	Imputation Method	Result Variable	N	Number of Missing	Imputed Value
REASON	Mode	IM_REASON	5708	252	DebtCon
JOB	Value	IM_JOB	5681	279	OFFICE

Syntax: VARIMPUTE Procedure

The following statements are available in the VARIMPUTE procedure:

PROC VARIMPUTE DATA=*libref.data-table* < *options* > **;**
CODE FILE=*filename* **;**
FREQ *variable* **;**
INPUT *variables* < */options* > **;**
OUTPUT OUT=*libref.data-table* < *option* > **;**
WEIGHT *variable* **;**

The PROC VARIMPUTE and INPUT statements are required. The INPUT statement can appear multiple times. If the same variable is specified in more than one INPUT statement, the imputation method specified in the first INPUT statement (or the default imputation method if the first statement does not specify a method) is applied.

PROC VARIMPUTE Statement

PROC VARIMPUTE DATA=*libref.data-table* < *options* > **;**

The PROC VARIMPUTE statement invokes the procedure.

You can specify the following *options*:

DATA=*libref.data-table*
names the input data table for PROC VARIMPUTE to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1876.

data-table specifies the name of the input data table.

NTHREADS=*number-of-threads*
specifies the number of threads to be used. The default is the CPU count on each node.

SEED=*random-seed*
specifies an integer that is used to start the pseudorandom number generator. If you do not specify a seed or you specify a value less than or equal to 0, the seed is generated from reading the time of day from the computer's clock. If your specified seed is out of the range of an integer, the computer's clock time is used as the seed. The SEED= option enables you to reproduce the same sample output.

CODE Statement

CODE < *options* > **;**

The CODE statement writes SAS DATA step code for computing predicted values of the fitted model to a file or to a table. To score new data, you can then include the file in a DATA step, or you can specify the table in the **`runCodeTable`** action in the **`dataStep`** action set (for more information, see *SAS Viya: System Programming Guide*).

Table 35.1 summarizes the *options* available in the CODE statement.

Table 35.1 CODE Statement Options

Option	Description
COMMENT	Adds comments to the generated code
FILE=	Names the file in which to save the generated code
FORMATWIDTH=	Specifies the numeric format width for the regression coefficients
INDENTSIZE=	Specifies the number of spaces to indent the generated code
LABELID=	Specifies a number used to construct names and labels
LINESIZE=	Specifies the line size for the generated code
NOTRIM	Compares formatted values, including blank padding
OUT=	Names an output table in which to save the generated code

For more information about the syntax of the CODE statement, see the section "CODE Statement" on page 13 in Chapter 2, "Shared Concepts."

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC VARIMPUTE treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1.

INPUT Statement

INPUT *variables* < */options* > **;**

The INPUT statement names one or more input *variables* and specifies the method that is used to impute missing values.

You can specify the following *options*:

CONTINUOUSTECH=*imputation-method*

CTECH=*imputation-method*

specifies the imputation method for interval variables.

You can choose from the following methods:

MEAN specifies that missing values of each variable are replaced by the algebraic mean of the nonmissing values of that variable.

MEDIAN specifies that missing values of each variable are replaced by the algebraic median of the nonmissing values of that variable.

RANDOM specifies that missing values of each variable are replaced by a random value that is drawn between the minimum value and the maximum values of the nonmissing values of that variable.

VALUE CVALUES=*value-list* specifies that missing values for each numeric input variable are replaced by the corresponding numeric value in the value-list.

By default, CONTINUOUSTECH=MEAN.

NOMINALTECH=*imputation-method*

NTECH=*imputation-method*

specifies the imputation method for nominal variables.

You can choose from the following *imputation-methods*:

MODE replaces missing values of each variable by the nonmissing value that appears most frequently for that variable.

VALUE VALUESNUMERIC=*value-list* replaces missing values for each numeric input variable by the corresponding numeric value in the *value-list*.

VALUE VALUESCHARACTER=*value-list* replaces missing values for each character input variable by the corresponding character value in the *value-list*.

By default, NOMINALTECH=MODE.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *option* > **;**

The OUTPUT statement creates an output data table to contain the results of PROC VARIMPUTE.

You must specify the following option:

OUT=*libref.data-table*

names the output data table for PROC VARIMPUTE to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1876.

data-table specifies the name of the output data table.

The output data table contains the scored data.

You can also specify the following *option*:

COPYVAR=*variable*

COPYVARS=(*variables***)**

lists one or more variables from the input data table to be transferred to the output data table.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

Details: VARIMPUTE Procedure

Obtaining the Statistics for Imputation

PROC VARIMPUTE first computes the imputation value and then imputes with that value. The statistics mean, median, mode, minimum, and maximum are computed precisely. To compute the median, PROC VARIMPUTE uses the empirical distribution function. Let n be the number of nonmissing values for a variable, and let $x_1, x_2, \ldots, x_n$ represent the ordered values of the variable. Let the 50th percentile be y, $p = 0.5$, and $np = j + g$ where j is the integer part of np and g is the fractional part of np. Then, the median y is

$$\begin{aligned} y &= x_j \quad \text{if} \quad g = 0 \\ y &= x_{j+1} \quad \text{if} \quad g > 0 \end{aligned}$$

Random Imputation

If you specify CONTINUOUSTECH=RANDOM in the INPUT statement, PROC VARIMPUTE replaces missing values with a random value that is drawn between the minimum and maximum of the variable. For variable x, assume that the input data table is $\{x_i\}$, where $i = 1, 2, \ldots, n$. Let $\min(x) = \min_{i \in \{1 \ldots n\}} \{x_i\}$, and let $\max(x) = \max_{i \in \{1 \ldots n\}} \{x_i\}$. The random value is calculated as $R = \min(x) + (\max(x) - \min(x)) \times \text{rand}('\text{uniform}')$, where $\text{rand}('\text{uniform}')$ is a function that takes a seed as input and returns a random value from a uniform distribution between 0 and 1. You can specify the seed as a nonnegative integer in the SEED= option in the PROC VARIMPUTE statement. If you do not specify the SEED= option, the seed is generated from reading the time of day from the computer's clock.

Displayed Output

The following sections describe the output that PROC VARIMPUTE produces. The output is organized into various tables, which are discussed in their order of appearance.

Imputation Requests

The first table displayed lists the imputation method, the number of variables that are imputed, and the seed value for the random imputation.

Imputed Values for Interval Variables

The "Imputed Values for Interval Variables" table lists the names of the interval variables, the imputation method, the numbers of nonmissing and missing values for each variable, and the imputation values that replace missing values for interval variables.

Imputed Values for Nominal Variables

The "Imputed Values for Nominal Variables" table lists the names of the nominal variables, the imputation method, the numbers of nonmissing and missing values for each variable, and the imputation values that replace missing values for nominal variables.

ODS Table Names

Each table that the VARIMPUTE procedure creates has a name associated with it. You must use this name to refer to the table when you use ODS statements. The name of each table and a short description of the contents are listed in Table 35.2.

Table 35.2 ODS Tables Produced by PROC VARIMPUTE

Table Name	Description	Statement	Option
ImputeInfo	Imputation method, number of variables that are imputed, and seed for the pseudorandom number generator	PROC VARIMPUTE	Default
VarImputeInfo (Interval Variables)	Variables, imputation method, number of nonmissing values, number of missing values, and imputation values	PROC VARIMPUTE	Default
VarImputeInfo (Nominal Variables)	Variables, imputation method, number of nonmissing values, number of missing values, and imputation values	PROC VARIMPUTE	Default

Examples: VARIMPUTE Procedure

The examples in this chapter are available in the GitHub repository located at https://github.com/sascommunities/doc-supplement-casstat.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 35.1: Imputation of Missing Values for HMEQ Data Table

(View the complete code for this example (varimpute_ex1.sas) in the example repository.)

This example demonstrates how to use PROC VARIMPUTE to perform imputation; it uses the same data table as in the section "Getting Started: VARIMPUTE Procedure" on page 1877.

Using DATA step, you can load the sampsio.hmeq data into the mylib.hmeq table:

```
data mylib.hmeq;
   set sampsio.hmeq;
   id = _N_;
run;
```

The following statements perform the imputation:

```
proc varimpute data=mylib.hmeq seed=12345;
   input derog clno/ctech=value cvalues=5,20;
   input value /ctech=mean;
   input job/ntech=mode;
   input mortdue /ctech=median;
   input ninq /ctech=random;
   input reason/ntech=value valuescharacter=unknown;
   output out=mylib.out1 copyvar=(id);
run;

data out2; set mylib.out1; run;
proc sort data=out2; by id; run;
proc print data=out2(firstobs=110 obs=124);
run;
```

Output 35.1.1 shows the number of variables for which the missing observations are imputed and the random seed value for the random imputation method.

Output 35.1.1 Imputation Requests

The VARIMPUTE Procedure

Imputation Method	Number of Variables	Seed
Mean	1	
Random	1	12345
Median	1	
Numeric Value	2	
Mode	1	
Character Value	1	

Output 35.1.2 shows the imputation results for interval variables.

Output 35.1.2 Imputed Values for Interval Variables

Imputed Values for Interval Variables

Variable	Imputation Method	Result Variable	N	Number of Missing	Imputed Value
VALUE	Mean	IM_VALUE	5848	112	101776
MORTDUE	Median	IM_MORTDUE	5442	518	65017
NINQ	Random	IM_NINQ	5450	510	
DEROG	Value	IM_DEROG	5252	708	5
CLNO	Value	IM_CLNO	5738	222	20

Output 35.1.3 shows the imputation results for nominal variables.

Output 35.1.3 Imputed Values for Nominal Variables

Imputed Values for Nominal Variables

Variable	Imputation Method	Result Variable	N	Number of Missing	Imputed Value
JOB	Mode	IM_JOB	5681	279	Other
REASON	Value	IM_REASON	5708	252	UNKNOWN

Output 35.1.4 shows 15 output observations with the new imputed values for those input variable values that were missing.

Output 35.1.4 Output Data Table

Overview: VARREDUCE Procedure

The VARREDUCE procedure performs both supervised and unsupervised variable selection in SAS Viya. You can use this procedure to read data in distributed form and perform variable selection in parallel.

The VARREDUCE procedure performs unsupervised variable selection by identifying a set of variables that jointly explain the maximum amount of data variance. Unlike principal component analysis (PCA), which reduces dimensionality by generating a set of new variables (variable extraction), PROC VARREDUCE reduces dimensionality by selecting a subset of the original variables (variable selection). Thus, this technique preserves model interpretation.

PROC VARREDUCE performs supervised variable selection by identifying a set of variables that jointly explain the maximum amount of variance contained in the response variables. It supports variable selection in both the regression setting and the classification (categorization) setting.

PROC VARREDUCE Features

The VARREDUCE procedure analyzes variance and reduces dimensionality by selecting the variables that contribute the most to the overall variance of the data in unsupervised variable selection (or to the overall variance of the response variables in supervised variable selection). The following list summarizes the basic features of this procedure:

- Variable selection is based on covariance analysis.
- Input data can be read in parallel.
- Computation of the Pearson correlation, covariance, or sums of squares and crossproducts matrix is distributed.
- Computation of the variable selection steps is distributed.
- All phases of analytic execution use of high degree of multithreading.
- Both supervised and unsupervised variable selection are supported.
- Multiple response variables are supported in variable selection for regression.
- The CLASS statement supports categorical inputs.
- The REDUCE statement supports main and interaction effects.

- The OUTCP option supports outputting a CORR, COV, or SSCP matrix.

PROC VARREDUCE Compared to Other SAS Procedures

This section compares the VARREDUCE procedure with the PCA and GENSELECT procedures in SAS Visual Statistics and with the FACTOR, PRINCOMP, GLMSELECT, and DISCRIM procedures in SAS/STAT software.

When PROC VARREDUCE performs unsupervised variable selection, it analyzes variance and reduces dimensionality by forward selection of the variables that contribute the most to the overall data variance. The output lists the variables in order of their contribution to data variance; the output can be used directly for reporting or for selecting variables for procedures that build models. In contrast, principal component analysis analyzes the variance and then projects the data space onto an orthogonal set of axes by a linear combination of the original variables. These new principal components best explain the data variance and can be used as input to procedures that build models. Principal component analysis can be done through the FACTOR, PRINCOMP, and PCA procedures, which reduce the number of inputs from the original set. The primary difference between principal component analysis (PCA) and PROC VARREDUCE is that PCA generates new variables, whereas PROC VARREDUCE reduces data dimensionality by selecting a subset of the original variables. This feature of PROC VARREDUCE is beneficial in applications where retaining the original variables is important for model exploration and interpretation.

When PROC VARREDUCE performs supervised variable selection, it analyzes the variance and reduces dimensionality by forward selection of the variables that contribute the most to explaining the overall variance of the response variables (targets). The output lists the variables in order of their contribution to explaining the response variance. The output can be used directly for reporting or for selecting variables for procedures that build models. When PROC VARREDUCE is used to perform supervised variable selection, it most resembles the GLMSELECT and GENSELECT procedures. However, PROC VARREDUCE allows multiple response variables, whereas PROC GLMSELECT and PROC GENSELECT do not. When the response variable is a classification variable and its levelization is done in a special format, PROC VARREDUCE analyzes the variance in the same way that linear discriminant analysis (LDA) does. LDA can be done through the DISCRIM procedure in SAS/STAT. Like principal component analysis, LDA generates new variables by linearly combining all original variables, whereas PROC VARREDUCE reduces data dimensionality by selecting a subset of the original variables.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section "Introduction to Shared Concepts" on page 6 in Chapter 2, "Shared Concepts."

Getting Started: VARREDUCE Procedure

(View the complete code for this example at https://github.com/sascommunities/doc-supplement-casstat/tree/main/Examples/varreduce_gs.sas.)

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

This example uses a data table which contains 100 observations that contain one character variable (C), one classification variable (y), and 10 continuous variables (x1–x10). This data table is used for both of the getting-started examples in the following sections.

The following DATA step stores the variables in the mylib.getStarted data table and loads the table into your CAS session:

```
data mylib.getStarted;
   input C$ y x1-x10;
   datalines;
D  0  10.2  6  1.6  38  15  2.4  20  0.8  8.5  3.9
F  1  12.2  6  2.6  42  61  1.5  10  0.6  8.5  0.7

;
```

These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

Unsupervised Variable Selection

The following statements use PROC VARREDUCE for unsupervised variable selection:

```
proc varreduce data=mylib.getStarted technique=VarianceAnalysis;
   class C;
   reduce unsupervised C x1-x10 / maxeffects=5 varexp=0.99;
run;
```

The TECHNIQUE= option in the PROC VARREDUCE statement specifies variance analysis as the technique to be used for variable selection. In the REDUCE statement, the MAXEFFECTS= option specifies 5 as the maximum number of variables to select, and the VAREXP= option specifies 99% as the maximum percentage of the total variance to explain. The procedure stops when either of these two conditions is satisfied.

The output from this analysis is presented in Figure 36.1 through Figure 36.3.

Figure 36.1 displays the "Number of Observations" tables. This table shows that all 100 observations in the data table are used in the analysis.

Figure 36.1 Number of Observations

The VARREDUCE Procedure

Number of Observations Read	100
Number of Observations Used	100

Figure 36.2 and Figure 36.3 show the "Selection Summary" and "Selected Effects" tables. The "Selection Summary" table shows which variable (or level for CLASS variables) is selected in each step, in addition to showing the total variance that is explained by the variables selected so far. The "Selected Effects" table presents all the selected variables and their corresponding variable types.

Supervised Variable Selection

The following statements use PROC VARREDUCE for supervised variable selection. The CLASS statement specifies that y is a categorical response variable. The TECHNIQUE= option specifies discriminant analysis as the technique to be used for variable selection. The MAXEFFECTS= option in the REDUCE statement specifies 5 as the maximum number of variables to select.

```
proc varreduce data=mylib.getStarted technique=DiscriminantAnalysis;
   class C y;
   reduce supervised y = C x1-x10 / maxeffects=5;
run;
```

The output from this analysis is presented in Figure 36.4 through Figure 36.6.

Figure 36.4 shows that all 100 observations in the data table are used in the analysis.

Syntax: VARREDUCE Procedure

The following statements are available in the VARREDUCE procedure:

PROC VARREDUCE < *options* > **;**
CLASS *variable* < *(options)* >. . .< *variable* < *(options)* > > < */ global-options* > **;**
DISPLAY < *table-list* > < */options* > **;**
DISPLAYOUT *table-spec-list* < */options* > **;**
FREQ *variable* **;**
REDUCE UNSUPERVISED *effects* < */ reduce-options* > **;**
REDUCE SUPERVISED *response* . . .< *response* > **=** *effects* < */ reduce-options* > **;**
WEIGHT *variable* **;**

The PROC VARREDUCE statement and one REDUCE statement are required. The CLASS statement can appear multiple times. If a CLASS statement is specified, it must precede the REDUCE statement.

PROC VARREDUCE Statement

PROC VARREDUCE < *options* > **;**

The PROC VARREDUCE statement invokes the procedure. Table 36.1 summarizes the important options in the PROC VARREDUCE statement by function. The options are then described fully in alphabetical order.

Table 36.1 PROC VARREDUCE Statement Options

Option	Description
Basic Options	
DATA=	Specifies the input data table
Options Related to Variable Selection	
NOPRINT	Suppresses ODS output
MATRIX=	Specifies the matrix to use to select variables
TECHNIQUE=	Selects the variable selection technique
OUTCP=	Outputs the CORR, COV, or SSCP matrix, which is specified in the MATRIX= option

You can specify the following *options*:

DATA=*libref.data-table*
names the input data table for PROC VARREDUCE to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section "Using CAS Sessions and CAS Engine Librefs" on page 1889.

data-table specifies the name of the input data table.

MATRIX=CORR | COV | SSCP
specifies which matrix to use to select variables.

You can specify the following values:

CORR selects variables based on the Pearson correlation matrix. Assuming that X and Y are two variables, the correlation between X and Y is computed by

$$\mathrm{Corr}(X,Y) = \frac{E\left((X - E\left(X\right))\left(Y - E\left(Y\right)\right)\right)}{\sqrt{E\left(X - E\left(X\right)\right)^2 E\left(Y - E\left(Y\right)\right)^2}}$$

COV selects variables based on the covariance matrix. Assuming that X and Y are two variables, the covariance between X and Y is computed by

$$\mathrm{Cov}(X,Y) = E\left(\left(X - E\left(X\right)\right)\left(Y - E\left(Y\right)\right)\right)$$

SSCP selects variables based on the sums of squares and crossproducts matrix. Assuming that X and Y are two variables and that $\mathbf{x}$ and $\mathbf{y}$ are their corresponding variable vectors, the SSCP between X and Y is computed by

$$\mathrm{SSCP}(X,Y) = \mathbf{x}^{\top}\mathbf{y}$$

By default, MATRIX=CORR.

NOPRINT
suppresses the generation of ODS output.

OUTCP=*libref.data-table* **< / LIST < EPS =** *number* **> >**
creates a data table that contains a symmetric matrix that depicts the relationships among variables and also creates a set of statistics about the input data table and variables. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section "Using CAS Sessions and CAS Engine Librefs" on page 1889. Depending on the value of the MATRIX= option, the symmetric matrix can be a correlation (CORR) matrix, a covariance (COV) matrix, or a sums of squares and crossproducts (SSCP) matrix.

When you specify the LIST option, the symmetric matrix is output in the list-of-list (LIL) format. In this format, the matrix is represented as a set of tuples $(i,\ j,\ x)$, where x is an entry in the matrix and i and j denote its row and column indices, respectively. LIL format can be used when the output contains too many columns to fit in a data table. For example, in most database systems, the maximum number of columns in a table is usually limited to several thousand. If an output matrix contains more columns than the limit, you must use the LIST option to avoid errors that would arise from writing too many columns to the table. When LIL format is used, all 0 entries in the matrix are ignored in the output.

When you specify EPS= *number* in the LIST suboption, matrix entries whose absolute value is smaller than *number* are ignored in the output. This feature helps omit unreliable estimations and generate a compact representation of the matrix. When you do not specify the EPS= option, only the 0 entries in the matrix are ignored in the output.

TECHNIQUE=*keyword*

TECH=*keyword*

specifies the variable selection technique.

You can specify the following *keyword*s:

VARIANCEANALYSIS | VAR performs variance analysis for variable selection.

DISCRIMINANTANALYSIS | DSC performs discriminant analysis for variable selection.

By default, TECHNIQUE=VAR.

You can use variance analysis for both supervised and unsupervised variable selection. You can use discriminant analysis only for supervised variable selection that uses one classification variable as the response. For more information, see the section "Variable Selection for Classification" on page 1904.

CLASS Statement

CLASS *variable* < *(options)* >. . . < *variable* < *(options)* > > < / *global-options* > **;**

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. The CLASS statement must precede the REDUCE statement.

The VARREDUCE procedure supports the GLM method of CLASS variable parameterization; for more information, see the section "GLM Parameterization of Classification Variables and Effects" on page 1907.

You can specify options either as individual variable *options*, by enclosing the options in parentheses after the variable name, or as *global-options*, by placing them after a slash (/). *Global-options* are applied to all variables that are specified in the CLASS statement. If you specify more than one CLASS statement, the *global-options* that are specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the *global-options*.

Table 36.2 summarizes the values you can use for either an *option* or a *global-option*. The options are described in detail in the list that follows Table 36.2.

Table 36.2 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels

DESCENDING

DESC

reverses the sort order of the classification variable.

MISSING

treats missing values (“.”, “.A”, . . . , “.Z” for numeric variables and blanks for character variables) as valid values for the CLASS variable.

If you do not specify the MISSING option, observations that have missing values for CLASS variables are removed from the analysis.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > **;**

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section “ODS Table Names” on page 1912. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying “/tions/” selects all pathnames that contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected.

Specifying "!/tions/" selects all pathnames that do not contain the substring "tions"; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE
performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE
displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL
suppresses display of all tables. This option takes precedence over the other options.

TRACE
displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > **;**

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key*=*value* format or a *key* format:

key=*value*	specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.
key	specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section "ODS Table Names" on page 1912. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the DISPLAY statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL
creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE
does not replace any existing output table of the same name.

REPEATED
replicates all output tables on all nodes.

FREQ Statement

FREQ *variable* **;**

The *variable* in the FREQ statement identifies a numeric variable in the input data table that contains the frequency of occurrence of each observation. PROC VARREDUCE treats each observation as if it appears f times, where f is the value of the FREQ *variable* for the observation. If f is not an integer, it is truncated to an integer. If f is less than 1 or missing, the observation is not used in the analysis. When you omit the FREQ statement, each observation is assigned a frequency of 1.

REDUCE Statement

REDUCE UNSUPERVISED *effects* < / *reduce-options* > **;**

REDUCE SUPERVISED *response-variable* < *response-variable* > . . . = *effects* < / *reduce-options* > **;**

PROC VARREDUCE can be used for either of the following types of variable selection:

- For unsupervised variable selection, you specify the *effects* to be considered in the variable selection process. An *effect* can be an original variable in the input data table or a variable that is constructed from the original variables.
- For supervised variable selection, you specify both the *effects* and one or more *response-variables*. A *response-variable* can be an original variable in the input data table or a variable that is constructed from the original variables. PROC VARREDUCE supports variable selection both in a classification (categorization) context, in which you specify one *response-variable*, and in a regression context, in which you can specify more than one *response-variable*.

Table 36.3 summarizes the *reduce-options*, which control the number of variables to be selected.

Table 36.3 *reduce-options*

Option	Description
AIC	Uses Akaike's information criterion to perform model selection
AICC	Uses the corrected Akaike's information criterion to perform model selection
BIC	Uses Schwarz Bayesian information criterion to perform model selection

Table 36.3 *continued*

Option	Description
MAXITER= | MAXSTEPS=	Specifies the maximum number of steps to take; the number must be greater than or equal to 1
MAXEFFECTS=	Specifies the number of effects to select; the number must be greater than or equal to 1.
VARIANCEEXPLAINED= | VAREXP=	Specifies the fraction of the total variance to be explained; the value must be between 0 and 1.
MINVARIANCEINCREMENT= | VARINC=	Specifies the minimum increment of explained variance (in a fraction of the total variance); the value must be between 0 and 1.

The *reduce-options* determine the number of variables to be selected. You can specify the following *reduce-options* as stopping criteria for the VARREDUCE procedure. When you specify more than one option, PROC VARREDUCE stops whenever one of the specified options is satisfied, or when the explained variance equals the total variance. In the latter case, the procedure prints the following message in the log: "Early stop: the proportion of the explained variance to the total variance equals 1."

You can specify the following *reduce-options* only for supervised variable selection:

AIC
stops PROC VARREDUCE if the Akaike's information criterion (AIC) value fails to decrease in three contiguous steps.

AICC
stops PROC VARREDUCE if the corrected Akaike's information (AICC) value fails to decrease in three contiguous steps.

BIC
stops PROC VARREDUCE if the Schwarz Bayesian information criterion (BIC) value fails to decrease in three contiguous steps.

You can specify the following *reduce-options* for both supervised and unsupervised variable selection:

MAXITER=*n*

MAXSTEPS=*n*
stops PROC VARREDUCE after it runs *n* steps.

By default, *n* is the number of input variables.

MAXEFFECTS=*n*
stops PROC VARREDUCE after *n* effects have been selected. Because individual levels of one classification variable can be selected in different steps of the variable selection process, selecting *n* effects might require more steps than are specified by the value of the MAXITER= option.

By default, MAXEFFECTS=200.

VARIANCEEXPLAINED=*fraction*

VAREXP=*fraction*

stops PROC VARREDUCE when the *fraction* of the total variance can be explained by the selected variables.

By default, VARIANCEEXPLAINED=0.9.

MINVARIANCEINCREMENT=*fraction*

VARINC=*fraction*

stops PROC VARREDUCE when the minimum increment of the explained variance is less than *fraction* of the total variance.

By default, MINVARIANCEINCREMENT=0.

WEIGHT Statement

WEIGHT *variable* **;**

The *variable* in the WEIGHT statement is used as a weight to perform a weighted analysis of the data. Observations that have nonpositive or missing weights are not included in the analysis. The values of the WEIGHT variable can be nonintegral and are not truncated. When you omit the WEIGHT statement, all observations that are used in the analysis are assigned a weight of 1.

Details: VARREDUCE Procedure

The performance of a learning model usually decreases in terms of accuracy and efficiency when the dimensionality of the input data is high. The problem is known as the "curse of dimensionality." Variable selection techniques can reduce the dimensionality of data by removing irrelevant and redundant variables (Liu and Motoda 1998).

The VARREDUCE procedure performs both supervised and unsupervised variable selection. It selects variables by identifying a set of variables that can jointly explain the maximum amount of data variance.

Missing Values

Any observation that has missing values for the responses, frequency, or effects is excluded from the analysis; however, missing values are valid for responses and effects if the MISSING option is specified in the CLASS statement. Observations that have a frequency less than 1 are also excluded.

Unsupervised Variable Selection

When no response variable is specified, PROC VARREDUCE conducts unsupervised variable selection. Assume that k variables need to be selected. Let $\mathbf{X} \in \mathbb{R}^{n \times m}$ be a data table that contains n samples and m variables; let $\mathbf{X} = (\mathbf{X}_1, \mathbf{X}_2)$, where $\mathbf{X}_1 \in \mathbb{R}^{n \times k}$ contains the k selected variables and $\mathbf{X}_2 \in \mathbb{R}^{n \times (m-k)}$ contains the remaining $m - k$ variables. PROC VARREDUCE selects the variables by minimizing the following equation:

$$\min \text{Trace}\left(\mathbf{X}_2^\top \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1\right)^{-1} \mathbf{X}_1^\top\right) \mathbf{X}_2\right)$$

$\left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1\right)^{-1} \mathbf{X}_1^\top\right)^{\frac{1}{2}} \mathbf{X}_2$ projects $\mathbf{X}_2$ to the null space of $\mathbf{X}_1$. Therefore, the preceding equation measures the data variance that resides in the null space of $\mathbf{X}_1$, which is the data variance that cannot be explained by the variables in $\mathbf{X}_1$. Minimizing this equation leads to the selection of the variables that jointly explain the maximum amount of the variance in the original data.

Let $\mathbf{C}_{11} = \mathbf{X}_1^\top \mathbf{X}_1$, $\mathbf{C}_{12} = \mathbf{X}_1^\top \mathbf{X}_2$, and $\mathbf{C}_{21} = \mathbf{X}_2^\top \mathbf{X}_1$. The following equations hold:

$$\mathbf{C} = \mathbf{X}^\top \mathbf{X} = \begin{pmatrix} \mathbf{C}_{11} & \mathbf{C}_{12} \\ \mathbf{C}_{21} & \mathbf{C}_{22} \end{pmatrix}$$

$$\mathbf{X}_2^\top \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1\right)^{-1} \mathbf{X}_1^\top\right) \mathbf{X}_2 = \mathbf{C}_{22} - \mathbf{C}_{21}\mathbf{C}_{11}^{-1}\mathbf{C}_{12}$$

When all the variables are centralized to have a zero mean, $\mathbf{C}$ is the covariance matrix. This corresponds to specifying MATRIX=COV in the PROC VARREDUCE statement, which requests that the covariance matrix be used for variable selection. Similarly, if variables need to be both centralized and normalized to have unit length, you should specify MATRIX=CORR in the PROC VARREDUCE statement, which requests that the correlation matrix be used for variable selection. If neither centralization nor normalization should be applied, specify MATRIX=SSCP in the PROC VARREDUCE statement.

Principal component analysis (PCA) (Jolliffe 2002) also reduces dimensionality by preserving data variance. The key difference between PCA and PROC VARREDUCE is that PCA generates a small set of new variables (variable extraction) by linearly combining the original variables, whereas PROC VARREDUCE selects a small set of the original variables (variable selection). The variables returned by PROC VARREDUCE are the original variables. This feature is very important in applications where retaining the original variables is important for model exploration or interpretation (for example, genetic analysis and text mining).

Supervised Variable Selection

When response variables are specified in a REDUCE statement, PROC VARREDUCE conducts supervised variable selection, either in a regression context or in a classification (categorization) context.

Variable Selection for Regression

In a regression context, all response variables should be numerical. When the response is a classification variable, it needs to be levelized to multiple dummy variables, where each dummy variable corresponds to a level of the classification variable. You can achieve this levelization by adding this variable to the variable list in the CLASS statement.

Let $\mathbf{Y} \in \mathbb{R}^{n \times t}$ be the response data that contain t response variables. Assume that k variables need to be selected. Let $\mathbf{X} \in \mathbb{R}^{n \times m}$ be a data table that contains n samples and m variables; let $\mathbf{X} = (\mathbf{X}_1, \mathbf{X}_2)$, where $\mathbf{X}_1 \in \mathbb{R}^{n \times k}$ contains the k selected variables and $\mathbf{X}_2 \in \mathbb{R}^{n \times (m-k)}$ contains the remaining $m - k$ variables. PROC VARREDUCE selects the variables by minimizing the following equation:

$$\min \text{Trace}\left(\mathbf{Y}^\top \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1\right)^{-1} \mathbf{X}_1^\top\right) \mathbf{Y}\right)$$

$\left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1\right)^{-1} \mathbf{X}_1^\top\right)^{\frac{1}{2}} \mathbf{Y}$ projects $\mathbf{Y}$ onto the null space of $\mathbf{X}_1$. Therefore, the equation measures the response variance that resides in the null space of $\mathbf{X}_1$, which is the variance of the response variables that cannot be explained by the variables in $\mathbf{X}_1$. Minimizing the equation leads to the selection of the variables that jointly explain the maximum amount of the variance of the response variables.

Variable Selection for Classification

In a classification context, one classification variable is specified as the response, and each of its levels corresponds to a category of the classification problem. Let the classification variable be $\mathbf{y}$ with c levels $\{1, \ldots, c\}$. Then $\mathbf{y}$ can be levelized in a special way to generate response data $\mathbf{Y} \in \mathbb{R}^{n \times c}$ as:

$$\mathbf{Y}_{i,j} = \begin{cases} \frac{1}{\sqrt{n}} \left(\sqrt{\frac{n}{n_j}} - \sqrt{\frac{n_j}{n}}\right), & \mathbf{y}_i = j \\ -\frac{1}{\sqrt{n}} \sqrt{\frac{n_j}{n}}, & \mathbf{y}_i \neq j \end{cases}$$

By using this $\mathbf{Y}$ in the variance analysis, PROC VARREDUCE selects variables by using the discriminant criterion that is specified in linear discriminant analysis (LDA) (Fisher 1936; Cooley and Lohnes 1971). LDA also reduces dimensionality. The key difference between LDA and PROC VARREDUCE is that LDA generates a small set of new variables (variable extraction) by linearly combining the original variables, whereas PROC VARREDUCE selects a small set of the original variables (variable selection).

Criteria Used in Model Selection

The VARREDUCE procedure supports the following three fit statistics that you can specify as stopping criteria in the REDUCE statement. These statistics are produced only for the supervised variable selection.

AIC	Akaike's information criterion (Akaike 1969; Judge et al. 1985)
AICC	Corrected Akaike's information criterion (Hurvich and Tsai 1989)
BIC	Schwarz Bayesian information criterion (Schwarz 1978; Judge et al. 1985)

The VARREDUCE procedure supports multiple response variables; therefore, it computes the AIC, AICC, and BIC that are defined for multivariate regression. Besides the three criteria, it also computes the error sum of squares (SSE) and residual mean square error (MSE).

Table 36.4 provides formulas and definitions for these fit statistics.

Table 36.4 Formulas and Definitions for Model Fit Summary Statistics

Statistic	Definition or Formula
n	Number of observations
p	Number of parameters
t	Number of response variables in supervised selection; number of unselected variables in unsupervised selection
SSE	Error sum of squares
MSE	$\frac{\text{SSE}}{n-p}$
AIC	$\ln(\text{SSE}) + \frac{2pt + t(t+1)}{n}$
AICC	$\ln(\text{SSE}) + \frac{(n+p)t}{n-p-t-1}$
BIC	$\ln(\text{SSE}) + \frac{p\ln(n)}{n}$

Computational Method

Given m variables, finding the k variables that minimize the proposed equations is a combinatorial problem, which is NP-hard (nondeterministic polynomial-time hard). To select k variables, PROC VARREDUCE applies k steps of a greedy search to generate a suboptimal solution for the problem.

Assume that q features have been selected, that $\mathbf{X}_1$ contains the q selected variables, and that $\mathbf{X}_2$ contains the remaining variables. PROC VARREDUCE selects the $q+1$ variable, F, by minimizing the equation

$$\arg\min_{F} \text{Trace}\left(\hat{\mathbf{X}}_2^{\top}\left(\mathbf{I} - \hat{\mathbf{X}}_1\left(\hat{\mathbf{X}}_1^{\top}\hat{\mathbf{X}}_1\right)^{-1}\hat{\mathbf{X}}_1^{\top}\right)\hat{\mathbf{X}}_2\right)$$

where $\hat{\mathbf{X}}_1$ is the data table that contains the feature F and the q selected variables, and $\hat{\mathbf{X}}_2$ is the data table that contains the remaining variables. Minimizing the preceding problem is equivalent to maximizing the following problem:

$$\frac{\left\| \mathbf{X}_2^\top \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1 \right)^{-1} \mathbf{X}_1^\top \right) \mathbf{f} \right\|_2^2}{\left\| \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1 \right)^{-1} \mathbf{X}_1^\top \right)^{\frac{1}{2}} \mathbf{f} \right\|_2^2}$$

In the preceding equation, $\left\| \mathbf{X}_2^\top \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1 \right)^{-1} \mathbf{X}_1^\top \right) \mathbf{f} \right\|_2^2$ is the summation of the squares of the covariance between the variable $\mathbf{f}$ and all the unselected variables in the null space of $\mathbf{X}_1$. And $\left\| \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1 \right)^{-1} \mathbf{X}_1^\top \right)^{\frac{1}{2}} \mathbf{f} \right\|_2^2$ is the square of the variance of $\mathbf{f}$ in the null space of $\mathbf{X}_1$, which is used as a normalization factor.

This problem can be solved efficiently. Assuming that $m \gg k$, the time complexity for solving it is

$$O\left(m^2 \left(n + k^2\right)\right)$$

where m is the number of variables, n is the number of samples, and k is the number of selected variables. In the equation, $m^2 n$ corresponds to the time for computing the covariance (or correlation or SSCP) matrix. And $m^2 k^2$ corresponds to the time for selecting k variables out of m.

Similar analysis also applies to supervised variable selection with PROC VARREDUCE. The following problem is maximized for supervised variable selection:

$$\frac{\left\| \mathbf{Y}^\top \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1 \right)^{-1} \mathbf{X}_1^\top \right) \mathbf{f} \right\|_2^2}{\left\| \left(\mathbf{I} - \mathbf{X}_1 \left(\mathbf{X}_1^\top \mathbf{X}_1 \right)^{-1} \mathbf{X}_1^\top \right)^{\frac{1}{2}} \mathbf{f} \right\|_2^2}$$

Here, $\mathbf{Y}$ is the response data table. Let c be the number of columns in $\mathbf{Y}$. The time complexity for selecting k variables by solving the preceding problem is

$$O\left(k^2 \left(c + k\right) m + m^2 n\right)$$

Note that for most data of very high dimensionality, $c + k \ll m$.

PROC VARREDUCE is fully threaded and distributed. When there are p machines used for computing, the time complexity for unsupervised variable selection is

$$\mathrm{CPU}\left(\frac{m^2 \left(n + k^2\right)}{p} + m^2 \log p\right) + \mathrm{NET}\left(m^2 \log p\right)$$

and the time complexity for supervised variable selection is

$$\mathrm{CPU}\left(\frac{k^2 \left(c + k\right) m + m^2 n}{p} + m^2 \log p\right) + \mathrm{NET}\left(m^2 \log p\right)$$

where CPU corresponds to the time used for computing and NET corresponds to the time used for communication among computers.

GLM Parameterization of Classification Variables and Effects

Table 36.5 shows the types of effects that are available in the VARREDUCE procedure; they are discussed in more detail in the following subsections. Let A, B, and C represent classification variables, and let X and Z represent continuous variables.

Table 36.5 Available Types of Effects

Effect	Example	Description
Intercept	Default	Intercept (unless the NOINT option is specified)
Regression	X Z	Continuous variables
Polynomial	X*Z	Interaction of continuous variables
Main	A B	CLASS variables
Interaction	A*B	Crossing of CLASS variables
Nested	A(B)	Main effect A nested within CLASS effect B
Continuous-by-class	X*A	Crossing of continuous and CLASS variables
Continuous-nesting-class	X(A)	Continuous variable X1 nested within CLASS variable A
General	X*Z*A(B)	Combinations of different types of effects

Table 36.6 shows some examples of MODEL statements that use various types of effects.

Table 36.6 Model Statement Effect Examples

Specification	Type of Model
`model Y=X;`	Simple regression
`model Y=X Z;`	Multiple regression
`model Y=X X*X;`	Polynomial regression
`model Y=A;`	One-way analysis of variance (ANOVA)
`model Y=A B C;`	Main-effects ANOVA
`model Y=A B A*B;`	Factorial ANOVA with interaction
`model y=A B(A) C(B A);`	Nested ANOVA
`model Y=A X;`	Analysis of covariance (ANCOVA)
`model Y=A X(A);`	Separate-slopes regression
`model Y=A X X*A;`	Homogeneity-of-slopes regression

Intercept

By default, linear models that are created by the VARREDUCE procedure automatically include a column of 1s in **X**. This column corresponds to an intercept parameter. In many procedures, you can use the NOINT option in the MODEL statement to suppress this intercept. For example, the NOINT option is useful when the MODEL statement contains a classification effect and you want the parameter estimates to be in terms of the mean response for each level of that effect.

Regression Effects

Numeric variables or polynomial terms that involve them can be included in the model as regression effects (covariates). The actual values of such terms are included as columns of the relevant model matrices. You can use the bar operator along with a regression effect to generate polynomial effects. For example, X | X | X expands to X X*X X*X*X, which is a cubic model.

Main Effects

If a classification variable has *m* levels, the GLM parameterization generates *m* columns for its main effect in the model matrix. Each column is an indicator variable for a particular level. The order of the columns is the sort order of the values of their levels and can be controlled by the ORDER= option in the CLASS statement.

Table 36.7 is an example where β_0 denotes the intercept and A and B are classification variables that have two and three levels, respectively.

Table 36.7 Example of Main Effects

Data		I	A		B		
A	B	β_0	A1	A2	B1	B2	B3
1	1	1	1	0	1	0	0
1	2	1	1	0	0	1	0
1	3	1	1	0	0	0	1
2	1	1	0	1	1	0	0
2	2	1	0	1	0	1	0
2	3	1	0	1	0	0	1

There are usually more columns for these effects than there are degrees of freedom to estimate them. In other words, the GLM parameterization of main effects is *singular*.

Interaction Effects

Often a model includes interaction (crossed) effects to account for how the effect of a variable changes along with the values of other variables. With an interaction, the terms are first reordered to correspond to the order of the variables in the CLASS statement. Thus, B*A becomes A*B if A precedes B in the CLASS statement. Then, the GLM parameterization generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the interaction change faster than the leftmost variables (Table 36.8).

Table 36.8 Example of Interaction Effects

Data		I	A		B			A*B					
A	B	β_0	A1	A2	B1	B2	B3	A1B1	A1B2	A1B3	A2B1	A2B2	A2B3
1	1	1	1	0	1	0	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	1	0	0	0
2	1	1	0	1	1	0	0	0	0	0	1	0	0
2	2	1	0	1	0	1	0	0	0	0	0	1	0
2	3	1	0	1	0	0	1	0	0	0	0	0	1

In the preceding matrix, main-effects columns are not linearly independent of crossed-effects columns. In fact, the column space for the crossed effects contains the space of the main effect.

When your model contains many interaction effects, you might be able to code them more parsimoniously by using the bar operator (|). The bar operator generates all possible interaction effects. For example, A | B | C expands to A B A*B C A*C B*C A*B*C. To eliminate higher-order interaction effects, use the at sign (@) in conjunction with the bar operator. For example, A | B | C | D@2 expands to A B A*B C A*C B*C D A*D B*D C*D.

Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns that are generated by the following two statements are the same (but the ordering of the columns is different):

```
model Y=A B(A);

model Y=A A*B;
```

The nesting operator in the VARREDUCE procedure is more of a notational convenience than an operation that is distinct from crossing. Nested effects are typically characterized by the property that the nested variables do not appear as main effects. The order of the variables within nesting parentheses is made to correspond to the order of these variables in the CLASS statement. The order of the columns is such that variables outside the parentheses index faster than those inside the parentheses, and the rightmost nested variables index faster than the leftmost variables (Table 36.9).

Table 36.9 Example of Nested Effects

Data		I	A		B(A)					
A	B	β_0	A1	A2	B1A1	B2A1	B3A1	B1A2	B2A2	B3A2
1	1	1	1	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	0
2	1	1	0	1	0	0	0	1	0	0
2	2	1	0	1	0	0	0	0	1	0
2	3	1	0	1	0	0	0	0	0	1

Continuous-Nesting-Class Effects

When a continuous variable nests or crosses with a classification variable, the design columns are constructed by multiplying the continuous values into the design columns for the classification effect (Table 36.10).

Table 36.10 Example of Continuous-Nesting-Class Effects

Data		I	A		X(A)	
X	A	β_0	A1	A2	X(A1)	X(A2)
21	1	1	1	0	21	0
24	1	1	1	0	24	0

Table 36.10 *continued*

Data		I	A		X(A)	
22	1	1	1	0	22	0
28	2	1	0	1	0	28
19	2	1	0	1	0	19
23	2	1	0	1	0	23

This model estimates a separate intercept and a separate slope for X within each level of A.

Continuous-by-Class Effects

Continuous-by-class effects generate the same design columns as continuous-nesting-class effects. Table 36.11 shows the construction of the X*A effect. The two columns for this effect are the same as the columns for the X(A) effect in Table 36.10.

Table 36.11 Example of Continuous-by-Class Effects

Data		I	X	A		X*A	
X	A	β_0	X	A1	A2	X*A1	X*A2
21	1	1	21	1	0	21	0
24	1	1	24	1	0	24	0
22	1	1	22	1	0	22	0
28	2	1	28	0	1	0	28
19	2	1	19	0	1	0	19
23	2	1	23	0	1	0	23

You can use continuous-by-class effects together with pure continuous effects to test for homogeneity of slopes.

General Effects

An example that combines all the effects is X1*X2*A*B*C(D E). The continuous list comes first, followed by the crossed list, followed by the nested list in parentheses.

Effects might be renamed by the procedure to correspond to ordering rules. For example, B*A(E D) might be renamed A*B(D E) to satisfy the following:

- Classification variables that occur outside parentheses (crossed effects) are sorted in the order in which they appear in the CLASS statement.
- Variables within parentheses (nested effects) are sorted in the order in which they appear in the CLASS statement.

The sequencing of the parameters that are generated by an effect is determined by the variables whose levels are indexed faster:

- Variables in the crossed list index faster than variables in the nested list.
- Within a crossed or nested list, variables to the right index faster than variables to the left.

For example, suppose that a model includes four effects—A, B, C, and D—each having two levels, 1 and 2, and that the CLASS statement is as follows:

```
class A B C D;
```

Then the order of the parameters for the effect B*A(C D), which is renamed A*B(C D), is as follows:

$$\begin{array}{llll} A_1B_1C_1D_1 \rightarrow & A_1B_2C_1D_1 \rightarrow & A_2B_1C_1D_1 \rightarrow & A_2B_2C_1D_1 \rightarrow \\ A_1B_1C_1D_2 \rightarrow & A_1B_2C_1D_2 \rightarrow & A_2B_1C_1D_2 \rightarrow & A_2B_2C_1D_2 \rightarrow \\ A_1B_1C_2D_1 \rightarrow & A_1B_2C_2D_1 \rightarrow & A_2B_1C_2D_1 \rightarrow & A_2B_2C_2D_1 \rightarrow \\ A_1B_1C_2D_2 \rightarrow & A_1B_2C_2D_2 \rightarrow & A_2B_1C_2D_2 \rightarrow & A_2B_2C_2D_2 \end{array}$$

Note that first the crossed effects B and A are sorted in the order in which they appear in the CLASS statement so that A precedes B in the parameter list. Then, for each combination of the nested effects in turn, combinations of A and B appear. The B effect changes fastest because it is rightmost in the cross list. Then A changes next fastest, and D changes next fastest. The C effect changes most slowly because it is leftmost in the nested list.

Displayed Output

The following sections describe the output that PROC VARREDUCE produces by default. The output is organized into various tables, which are discussed in the order of appearance.

Number of Observations

The "Number of Observations" table displays the number of observations read from the input data table and the number of observations used in the analysis.

Selection Summary

The "Selection Summary" table displays for each iteration the name of the selected effect, the name of the selected level, and the total variance explained after the iteration.

Selected Variables

The "Selected Variables" table summarizes which variables were selected in the selection process. It also provides information about the variable type of each selected variable.

ODS Table Names

Each table that the VARREDUCE procedure creates has a name associated with it. You must use this name to refer to the table when you use ODS statements. The name of each table and a short description of the contents are listed in Table 36.12.

Table 36.12 ODS Tables Produced by PROC VARREDUCE

Table Name	Description	Statement	Option
NObs	Number of observations read and used; number of events and trials, if applicable	PROC VARREDUCE	Default
SelectedEffects	Summary of selected variables	PROC VARREDUCE	Default
SelectionSummary	Selection summary	PROC VARREDUCE	Default

Examples: VARREDUCE Procedure

The examples in this chapter are available in the GitHub repository located at `https://github.com/sascommunities/doc-supplement-casstat`.

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections "Using CAS Sessions and CAS Engine Librefs" on page 7 and "Loading a SAS Data Set onto a CAS Server" on page 7 in Chapter 2, "Shared Concepts."

Example 36.1: Analyzing Framingham Heart Study Data

(View the complete code for this example (varreduce_ex1.sas) in the example repository.)

This example analyzes the data from the Framingham Heart Study for feature selection, which are available in a data set named Heart in the Sashelp library.

You can load the Sashelp.Heart data set into your CAS session by specifying your CAS engine libref in the first statement in the following DATA step:

```
data mylib.heart;
   set sashelp.heart;
run;
```

These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

The following statements invoke the VARREDUCE procedure:

```
proc varreduce data=mylib.heart matrix=COV tech=DSC;
   ods output SelectionSummary=Summary;
   class Status Sex Chol_Status BP_Status Weight_Status Smoking_Status;
   reduce supervised Status = Sex AgeAtStart Height Weight Diastolic Systolic MRW
                              Smoking Cholesterol Chol_Status BP_Status Weight_Status
                              Smoking_Status/ maxiter=15 BIC;
   display 'SelectionSummary' 'SelectedEffects';
run;

proc sgplot data=Summary;
   series x=Iteration  y=BIC;
run;
```

The TECH=DSC option in the PROC VARREDUCE statement requests a discriminant analysis of the Heart data table for feature selection. The ODS OUTPUT statement stores the "Selection Summary" table as a local file named *Summary*. The MATRIX=COV option in the PROC VARREDUCE statement requests that selections be done based on the covariance matrix. The BIC option specifies the stop criterion, and the MAXITER= option specifies 15 as the maximum number of iterations. The selection process terminates when the BIC statistic increases in the last three consecutive steps.

Output 36.1.1 and Output 36.1.2 display the selection summary from each iteration and the selected effects.

Output 36.1.1 Selection Summary

The VARREDUCE Procedure

Selection Summary

Iteration	Parameter	Proportion of Variance Explained	SSE	MSE	AIC	AICC	BIC
1	AgeAtStart	0.191310	0.808690	0.00016052	-0.210355	1.789647	-0.210648
2	Smoking	0.220923	0.779077	0.00015467	-0.246867	1.753136	-0.246262

Example 36.2: Output a Correlation Matrix to a SAS Data File

(View the complete code for this example (varreduce_ex2.sas) in the example repository.)

This example shows how to output a correlation matrix to a SAS data file. The OUTCP= option creates an output data table named mylib.corr.

The following DATA step generates a data table that has 2,000 observations and contains both interval variables (x1–x2) and CLASS variables (a, c1, and c2):

```
data mylib.data1;
   array x{2};
   array c{2};
   do i=1 to 2000;
      a=int(ranuni(1)*2);
      do j=1 to 2;
         x{j}=ranuni(1);
         c{j}=int(ranuni(1)*2);
      end;
      output;
   end;
run;
```

These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

The following statements invoke the VARREDUCE procedure:

```
title  "Output the Correlation Matrix";

proc varreduce data=mylib.data1 matrix=corr outcp=mylib.corr;
   class a;
   reduce unsupervised a x1-x2 /maxsteps=4;
```

```
run;

proc print data=mylib.corr;
run;
```

Output 36.2.1 shows the content of the data file that PROC VARREDUCE generates.

Output 36.2.1 Output the Correlation Matrix

Output the Correlation Matrix

Obs	_ID_	_TYPE_	_VAR_	_vID_	v1	v2	v3	v4
1	1	MEAN/FREQ			1015.00	985.00	0.50	0.50
2	2	N			2000.00	2000.00	2000.00	2000.00
3	3	CORR	a 0	v1	1.00	-1.00	-0.00	-0.02
4	4	CORR	a 1	v2	-1.00	1.00	0.00	0.02
5	5	CORR	x1	v3	-0.00	0.00	1.00	-0.01
6	6	CORR	x2	v4	-0.02	0.02	-0.01	1.00

The _VAR_ column displays the names of all variables and the levels of the CLASS variables. Assuming that you have *n* effects (the total number of interval variables and the levels of CLASS variables), the _vID_ column contains *n* markers, v1 to v*n*, where v*i* denotes the *i*th effect. The column _TYPE_ defines the role of each row. When the _TYPE_ column displays MEAN/FREQ, the corresponding row contains either the mean for an interval variable or the frequency for a level of a CLASS variable. When the _TYPE_ column displays N, the corresponding row contains the number of samples. And when the _TYPE_ column displays CORR, COV, or SSCP, the corresponding row contains a row of the CORR, COV, or SSCP matrix. In this example, the CORR matrix is 4×4, and it resides in the table in rows 3–6 and columns 7–10.

Example 36.3: Output the Correlation Matrix in LIL Format

(View the complete code for this example (varreduce_ex3.sas) in the example repository.)

This example shows how to output a correlation matrix in list-of-list (LIL) format. The OUTCP= option creates an output data table named mylib.corr_lil.

The following DATA step generates a data table that has 2,000 observations and contains both interval variables (x1–x2) and a CLASS variable (a):

```
data mylib.data2;
   array x{2};
   do i=1 to 2000;
      a=int(ranuni(1)*2);
      do j=1 to 2;
         x{j}=ranuni(1);
      end;
      output;
   end;
run;
```

These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

The following statements invoke the VARREDUCE procedure:

```
title  "Output the Correlation Matrix in LIL Format";

proc varreduce data=mylib.data2 matrix=corr outcp=mylib.corr_lil/list eps=0.01;
   class a;
   reduce unsupervised a x1-x2 /maxsteps=4;
run;

proc print data=mylib.corr_lil;
run;
```

Output 36.3.1 shows the correlation matrix in LIL format.

Output 36.3.1 Output the Correlation Matrix in LIL Format

Output the Correlation Matrix in LIL Format

Obs	_TYPE_	_ID_	_NAME1_	_NAME2_	_VAL_
1	S	1	samples		2000.00
2	S	2	nVar		3.00
3	S	3	nEff		4.00
4	F	1	a 0		979.00
5	F	2	a 1		1021.00
6	M	3	x1		0.49
7	M	4	x2		0.50
8	R	1	1	1	1.00
9	R	2	2	1	-1.00
10	R	3	2	2	1.00
11	R	4	3	1	0.03
12	R	5	3	2	-0.03
13	R	6	3	3	1.00
14	R	10	4	4	1.00

The column _TYPE_ defines the type of each row:

- When the _TYPE_ column displays S, the corresponding row contains the statistics of the data table. More specifically, when the _TYPE_ column displays S and the _NAME1_ column displays samples, the _VAL_ column in the corresponding row contains the number of samples in the data table. Similarly, when the _TYPE_ column displays S and the _NAME1_ column displays nVar, the _VAL_ column contains the number of variables. And when the _TYPE_ column displays S and the _NAME1_ column displays nEff, the _VAL_ column in the corresponding row contains the number of effects.
- When the _TYPE_ column displays F, the row contains the frequency of a level of a CLASS variable. In this case, the _NAME1_ column contains the name and level of the CLASS variable.
- When the _TYPE_ column displays M, the row contains the mean of an interval variable. In this case, the _NAME1_ column contains the name of the variable and the _NAME2_ column is empty.
- When the _TYPE_ column displays R, the row contains an entry in the correlation matrix. In this case, the _NAME1_ column contains the row ID, the _NAME2_ column contains the column ID, and the _VAL_ column contains the value.

- When the _TYPE_ column displays V or P, the corresponding row contains an entry of a COV matrix or an SSCP matrix, respectively.

Only entries in the lower triangle of the correlation matrix are written to the file, because the correlation matrix is symmetric. Also, any entry of the matrix whose value is smaller than 0.01 is ignored in the output (EPS = 0.01); this saves storage space.
